As discussed in the preceding section, RDS Proxy supports a range of parameters to help you align the proxy behavior with your application needs. However, choosing the right configuration values is a task that cuts across all layers of the stack: the application, the proxy, and the database itself. The settings of all those components must be aligned with the following goals in mind:

1. Provide the expected level of performance and scalability during normal operations.
2. Promote clarity and ease of troubleshooting during workload issues.
3. Help the stack deal with unexpected events (such as workload surges) with minimal impact to the application.

When choosing and tuning settings in a multi-layered environment, try to align configuration values such that the limits and timeouts at a lower layer are equal to or higher than the corresponding limits and timeouts at a higher layer. In other words, treat settings from one layer as an envelope that fits into the next configuration envelope further down the stack.

For example, assume that your application is the top layer, the proxy is a middle layer, and the database is the lower layer. If the timeouts and limits at the proxy level are lower than the limits at

the application level, proxy limits preempt application limits. The application is unable to exercise its settings and it experiences behaviors that can't be explained by its own configuration.

Consider the `IdleClientTimeout` proxy setting as an example. If your application drivers or client pools enforce their own idle timeouts, the proxy's idle timeout is a safety net on top of the application settings. This means the `IdleClientTimeout` must be at least equal to any application-level idle timeouts to prevent confusion:

- When the application idle timeout is lower than the proxy timeout, you expect the application to close its connections as configured. If the application fails to close idle connections in a timely manner, the proxy acts as a backstop.
- When the application idle timeout is longer than the proxy timeout, the application might experience connection closures that are considered premature. This can lead to confusion on the application side.

The same logic applies to other settings such as connection limits: each layer's settings should fit inside of the envelope defined by the next layer's configuration.

For best results, configuration settings should include some padding between one layer and the next. For example, you can make the proxy timeout a few seconds longer than the application timeout to avoid sporadic errors due to client/server clock drift, or in case the client needs additional time to gracefully close the connection.

In other words, align your settings like this:

```
client timeout < proxy timeout < database timeout
```

Instead of doing this:

```
client timeout = proxy timeout = database timeout
```

And avoid this:

```
client timeout > proxy timeout > database timeout
```

Database configuration

Connection limits

RDS Proxy uses the `MaxConnectionsPercent` setting to determine the maximum size of its connection pool, which means the proxy's connection pool size is relative to the database's

connection limit. When you change the database's connection limit, the proxy's pool size follows automatically. If you want the database to reserve a portion of connection limit for non-proxy users, you should do that by lowering the `MaxConnectionsPercent` setting in the proxy rather than by increasing the database limit.

RDS Proxy doesn't eliminate the need for proper configuration of database connection limits. A single proxy connection isn't inherently lighter than a single direct client connection, so don't increase database limits solely because you're using a proxy. A proxy doesn't reduce the amount of work the database must perform to handle queries, but it helps the database handle the same workload using fewer connections.

Idle timeouts

Databases can enforce their own idle timeouts, for example, using the `wait_timeout` and `interactive_timeout` settings in MySQL or the `transaction_timeout` and `idle_in_transaction_session_timeout` settings in PostgreSQL. Default values for those settings are unlikely to interfere with proxy configuration, but if you use custom database-level timeouts, make sure they're at least as long as the corresponding proxy timeouts or otherwise the proxy experiences connection errors due to premature timeouts.

The same logic applies to database environments using connection killers, which are scripts or processes that monitor session state and actively terminate connections based on certain criteria. If your environment uses such techniques, ensure that the connection termination logic aligns with proxy settings.

Databases that handle all their workload through the proxy can typically depend on the proxy configuration for idle timeouts, and leave the database-level settings at their default values.

Application configuration

Managing session state

Many database drivers, application frameworks, and object-relational mapping (ORM) tools use session variables or SET statements to set up connections before sending query traffic. The use of connection and transaction initialization statements might not be obvious when looking at the application code alone, and there can be several layers of abstraction between the database itself and the SQL statements and application logic. You can use the RDS Proxy enhanced logging feature to record reasons for connection pinning, and database query logs can provide further information about all statements sent over your database connections.

Consider the following best practices:

1. Set connection parameters only when they're different from database defaults and the client session must deviate from those defaults. Removing unnecessary initialization statements not only helps with multiplexing, but it also reduces the number of client-server round trips for each new database connection.
2. Set variables and configuration settings consistently across all connections.
3. Avoid session configuration that can also be applied at query runtime. For example, if different clients need to see data in different time zones, consider using time zone conversion functions at the query level instead of setting the time zone at the session level.
4. If possible, move session configuration statements to the proxy layer using the initialization query feature. For more details, see Initialization queries and pinning filters.

Liveness checks

If your application uses connection pooling or advanced drivers, look for configuration related to liveness checks such as protocol pings, health check statements, or keep-alive queries. RDS Proxy treats all client requests equally, so even though a `SELECT 1;` query or a `COM_PING` request is a no-op from the application perspective, it prevents the proxy from enforcing idle client timeouts and managing the connection pool size according to `MaxIdleConnectionsPercent`.

> **Note**
>
> RDS Proxy enforces a maximum connection lifetime of 24 hours regardless of the activity on the connection.

In most cases, it might be appropriate to disable client-side liveness checks to reduce protocol noise and help RDS Proxy manage idle connections. There are edge cases when you might want to run those health checks regardless:

- You deliberately want to prevent certain connections from timing out in the proxy layer.
- You want to allow the application driver or pool to proactively detect when a connection is dropped by the proxy. For example, pinned back-end connections might be closed due to a database restart and client connections might exceed the 24 hour maximum lifetime.

Consider disabling liveness checks on the application side, or only perform them for the specific connections that you want to keep from timing out.

Session state tracking

Some MySQL database drivers, such as the MariaDB driver, use `session_track_*` variables to enable tracking of session state. With this feature enabled, whenever the client makes a session state change that the server can track, the server includes the state change information in its response packets. This allows the driver to be advised about session state by the server.

This manner of session state tracking can be meaningful when the client interacts with the server directly and implements its own session management features, such as session migration in multi-server environments. RDS Proxy implements its own state tracking mechanisms and doesn't use the information enabled by `session_track_*` variables, however setting those variables causes session pinning.

If your database driver sets those variables, you can look for ways to disable the tracking functionality in the driver, switch to a different driver, or use session pinning filters to ignore the statements if it's safe to do so. For more details, see Initialization queries and pinning filters.

Amazon Aurora On-Demand Capacity Reservations

On-Demand Capacity Reservations for Amazon Aurora let you reserve compute capacity for your Aurora DB instances in one or more Availability Zones in an Amazon Region. By creating a Capacity Reservation, you help make sure that you have access to Aurora compute capacity when you need it, for as long as you need it. Then DB instance create and compute scaling operations don't fail because of insufficient capacity.

You can reserve capacity for immediate use, or schedule a reservation to begin on a future date so that capacity is reserved ahead of a planned event such as a migration, a product launch, or a seasonal peak.

Immediately active reservations require no commitment, and you can cancel them at any time. Future-dated reservations require a minimum commitment duration.

A Capacity Reservation applies to individual DB instances, not to a DB cluster. You specify the reservation for each DB instance that you want to place in reserved capacity.

Topics

- Getting started with On-Demand Capacity Reservations
- Capacity Reservation pricing and billing
- Creating a Capacity Reservation
- Viewing and modifying your Capacity Reservations
- Canceling a Capacity Reservation
- Using a Capacity Reservation with an Aurora DB instance
- Stopping and starting a DB cluster in a reservation

Getting started with On-Demand Capacity Reservations

An Aurora Capacity Reservation holds compute capacity for a specific combination of DB instance class, database engine, and Availability Zones, and reports a state that reflects where it is in its lifecycle. Before you create a reservation, review what it holds, how it's identified, when to use one, and the states it can report.

A reservation holds compute capacity for a specific combination of:

- **DB instance class** (for example, db.r7g.large)
- **Database engine** (for example, Aurora PostgreSQL or Aurora MySQL)
- **One or more Availability Zones** in a single Amazon Region
- **Reserved capacity per Availability Zone** – the number of DB instances to reserve in each zone

A reservation holds the same capacity in every Availability Zone you specify. Because each DB instance references its own reservation, the DB instances of one DB cluster don't have to share a reservation. For example, the writer can use a reservation in one Availability Zone, and an Aurora Replica can use a different reservation in another Availability Zone.

To use reserved capacity, you explicitly reference the reservation by either the name you gave it or the ID that Amazon RDS assigns to it when you create or modify an Aurora DB instance (see Using a Capacity Reservation with an Aurora DB instance). Amazon RDS Capacity Reservations are targeted – a DB instance draws from a reservation only when you specify that reservation's identifier or name. Creating a reservation on its own does not change how other DB instances in your account are placed.

A Capacity Reservation is identified by an ID with the prefix `dbcr-` (for example, `dbcr-abc123example`) and by a name that you assign when you create it.

Use a Capacity Reservation in the following cases:

- Reserving capacity for a planned migration into Amazon Aurora.
- Reserving capacity ahead of a launch or a seasonal peak (for example, a fourth-quarter sales event).
- Reserving capacity for a specific future date so it's in place before you need it.

- Differences between Capacity Reservations, reserved DB instances, and Savings Plans
- Quotas for Capacity Reservations
- Considerations and limitations
- Capacity Reservation states

Differences between Capacity Reservations, reserved DB instances, and Savings Plans

The following table shows the key differences between Capacity Reservations, reserved DB instances, and Database Savings Plans.

Feature	Capacity Reservations	Reserved DB instances	Database Savings Plans
Term	No commitment required for immediate-use Capacity Reservations. You can create, modify, and cancel them as needed. With future-dated Capacity Reservati ons, you specify a commitment duration for which you commit to keeping the capacity in your account.	Requires a fixed one-year or three-year commitment.	Requires a fixed one-year commitment.
Capacity benefit	Capacity reserved in a specific Availability Zone.	No capacity reserved.	No capacity reserved.
Billing discount	No billing discount. You can combine Capacity Reservations with Database Savings Plans or Reserved DB instances to receive a discount.	Provides a billing discount.	Provides a billing discount.
Instance limits	Your On-Demand DB instance quota for each Region applies.	Asia Pacific (Mumbai) (ap-south-1): 20. Each of the other supported Regions: 40.	No limit.

For more information, see Reserved DB instances for Amazon Aurora and Database Savings Plans.

Quotas for Capacity Reservations

The number of DB instances that you can reserve capacity for is based on your account's On-Demand DB instance quota. The quota covers your existing DB instances plus any unused reserved capacity. The capacity you can newly reserve is your quota, minus the DB instances you already have, minus the unused capacity in your other reservations. Reserved capacity is counted as the capacity per Availability Zone multiplied by the number of Availability Zones, so reserving 3 DB instances across 3 Availability Zones uses 9 of your quota.

Considerations and limitations

Keep in mind the following limitations:

- Capacity Reservations aren't supported with Amazon RDS Blue/Green Deployments. You can't specify a Capacity Reservation when you create a blue/green deployment, and the DB instances in the green environment don't draw from a reservation.
- Capacity Reservations are scoped to a single Amazon Region, and within that Region to the specific Availability Zones you specify. Reserved capacity can be used only in those Availability Zones – a DB instance in any other zone can't draw on the reservation, even in the same Region. Create separate reservations in each Region and Availability Zone where you need reserved capacity.
- A reservation covers one DB instance class and one engine (`aurora-mysql` or `aurora-postgresql`), across one or more Availability Zones. To reserve different combinations, create multiple reservations.
- A reservation reserves the same capacity in each Availability Zone you specify, up to the number of Availability Zones in the Region. Each Aurora DB instance uses one unit of capacity in one Availability Zone. To place the writer and Aurora Replicas of a DB cluster in different Availability Zones, you can use one reservation that includes those Availability Zones, or a separate reservation for each DB instance or Availability Zone.
- You specify a Capacity Reservation for each DB instance, not for a DB cluster. DB instances in the same DB cluster can use different reservations, and some can use On-Demand capacity.
- Reserved capacity applies to matching DB instances in the same account.
- Capacity Reservations don't support Aurora Serverless v2 DB instances (the `db.serverless` DB instance class).
- Future-dated reservations:

- Can be scheduled between 5 and 120 days ahead of the current date.
- Require a minimum commitment duration of 14 days. For the X family, the minimum commitment duration is 12 weeks.
- Support only DB instance classes in the C, M, R, T, and X families.
- Require M and R DB instance classes of generation 7 or later. For example, you can use db.m7g and db.r7g, but not db.m6g or db.r6i.
- Require at least 32 vCPUs in each Availability Zone of the reservation. For example, a db.r7g.large reservation (2 vCPUs for each unit) must reserve at least 16 units of DB capacity in each Availability Zone.

- Capacity Reservations don't reserve storage, I/O, or any resource other than compute capacity for the specified DB instance class.

Capacity Reservation states

A Capacity Reservation reports a state that reflects where it is in its lifecycle.

State	Description
`pending`	Amazon RDS is provisioning the reserved capacity.
`active`	Capacity is reserved and available for your DB instances. Billing is in effect.
`expired`	The reservation reached its end date and capacity has been released.
`cancelled`	You canceled the reservation and capacity has been released.
`failed`	The reservation couldn't be provisioned.

For future-dated reservations, the following additional states apply while the reservation is scheduled ahead of its start date.

State	Description
`assessing`	Amazon RDS is evaluating whether the requested future capacity can be delivered.

State	Description
`scheduled`	The request was accepted. Amazon RDS delivers the capacity on the start date. No charges apply yet.
`delayed`	Amazon RDS couldn't deliver capacity on the requested start date and is still working to fulfill it. Amazon RDS doesn't provide a revised delivery date. The reservation reports `CommitmentEndDate` equal to `StartDate` . The commitment is partly waived. You can cancel the reservation immediately, while it is in the `delayed` state, and you can set an end date earlier than the original commitment end date. But until the original commitment end date, you can't reduce the capacity below the committed capacity.
`unsupported`	The requested configuration can't be scheduled for the future date.

A future-dated reservation moves from `assessing` to `scheduled`, and then to `active` on the start date.

Capacity Reservation pricing and billing

The following topics give an overview of pricing and billing for Capacity Reservations.

Topics

- Pricing
- Billing
- Billing discounts
- Viewing your bill

Pricing

Capacity Reservations are charged at the equivalent On-Demand rate whether you run instances in reserved capacity or not. When you run a matching DB instance that matches the attributes of a reservation, you just pay for the DB instance and the capacity that it uses has no separate charge. Reserved capacity that has no DB instance usage appears as unused reservation on your bill. There are no upfront charges.

For example, you create a Capacity Reservation for 20 db.r7g.large DB instances in one Availability Zone, and you run 15 matching DB instances in that Availability Zone. You will be charged for the 15 DB instances and for 5 units of unused reserved capacity.

A Capacity Reservation reserves only compute capacity. Storage, I/O, backup storage, and other resources of your DB instances are billed as usual.

For more information, see Aurora pricing.

Billing

Billing for a Capacity Reservation starts as soon as the Capacity Reservation is provisioned in your account, and it continues while the Capacity Reservation remains provisioned in your account. For future-dated Capacity Reservations, this means that billing starts only after the Capacity Reservation is provisioned in your account at the requested future date.

Capacity Reservations are billed at per-second granularity, with a minimum of 60 seconds. This means that you are charged for partial hours. For example, if a Capacity Reservation remains provisioned in your account for 24 hours and 15 minutes, you are billed for 24.25 reservation hours.

The following example shows how a Capacity Reservation is billed. The Capacity Reservation is created for one db.r7g.large Aurora PostgreSQL DB instance in the US East (Ohio) Region. For this example, assume that the On-Demand rate of the db.r7g.large DB instance class is USD $0.276 per usage hour. In this example, the Capacity Reservation is provisioned in the account for five hours. The Capacity Reservation is unused for the first hour, so it is billed for one unused hour at the standard On-Demand rate of the db.r7g.large DB instance class. In hours two through five, the Capacity Reservation is occupied by a db.r7g.large Aurora PostgreSQL DB instance. During this time, the Capacity Reservation accrues no charges, and the account is instead billed for the db.r7g.large DB instance that occupies it. In the sixth hour, the Capacity Reservation is canceled and the db.r7g.large DB instance runs normally outside of the reserved capacity. For that hour, it is charged at the On-Demand rate of the db.r7g.large DB instance class.

Hour	Capacity Reservation	DB instance	Charge in this example
1	Active, unused	None	USD $0.276 for one hour of unused reserved capacity

Hour	Capacity Reservation	DB instance	Charge in this example
2–5	Active, used by one db.r7g.large DB instance	Runs in the reserved capacity	USD $0.276 per hour for the DB instance. No charge for the Capacity Reservation.
6	Canceled	Runs outside the reserved capacity	USD $0.276 for the On-Demand DB instance

In this example, the total charge for the six hours would be 6 × USD $0.276 = USD $1.656. The Capacity Reservation adds no charge for the hours that a DB instance uses it.

The following also applies to billing:

- Billing stops when you cancel the Capacity Reservation, or when it reaches its end date.
- When you increase the reserved capacity or set a later end date, the additional charges apply immediately. When you decrease the reserved capacity or set an earlier end date, you don't get a refund for time that has already passed.
- Stopping a DB cluster doesn't change the cost of the reservations that its DB instances use. The capacity that the stopped DB instances used appears as unused reservation.

Billing discounts

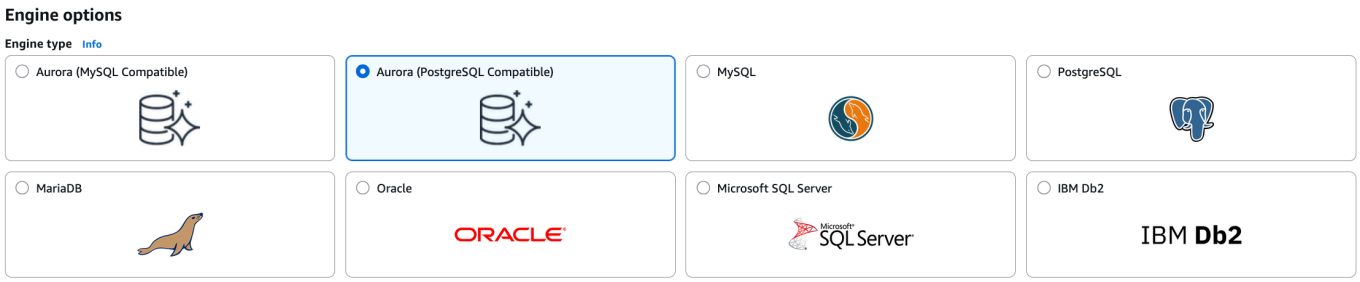
A Capacity Reservation doesn't give a billing discount. To get a discount, use Capacity Reservations together with reserved DB instances or Database Savings Plans. Amazon applies these discounts automatically to matching usage. When a DB instance uses the reserved capacity, the discount applies to the DB instance.

For more information, see Reserved DB instances for Amazon Aurora and Database Savings Plans.

Viewing your bill

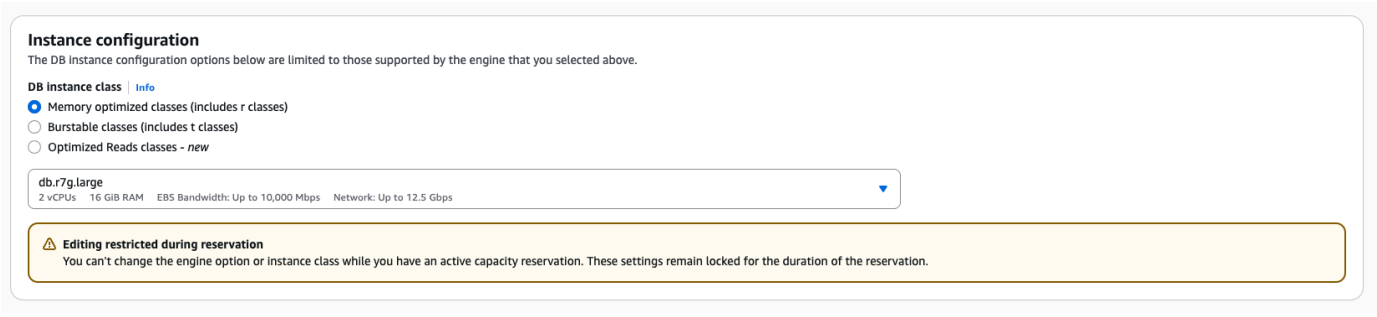
You can review the charges for your Capacity Reservations on the Amazon Billing and Cost Management console. On the **Bills** page, under **Details**, expand the **Relational Database Service** section and the Region.

Creating a Capacity Reservation



When you create a Capacity Reservation, you specify a DB instance class, database engine, and one or more Availability Zones in a single Amazon Region, along with the amount of capacity to reserve in each Availability Zone. You can create the reservation for immediate use, or schedule it to begin on a future date ahead of a planned event. After the reservation becomes active, you reference it by name or by identifier to place DB instances into the reserved capacity.

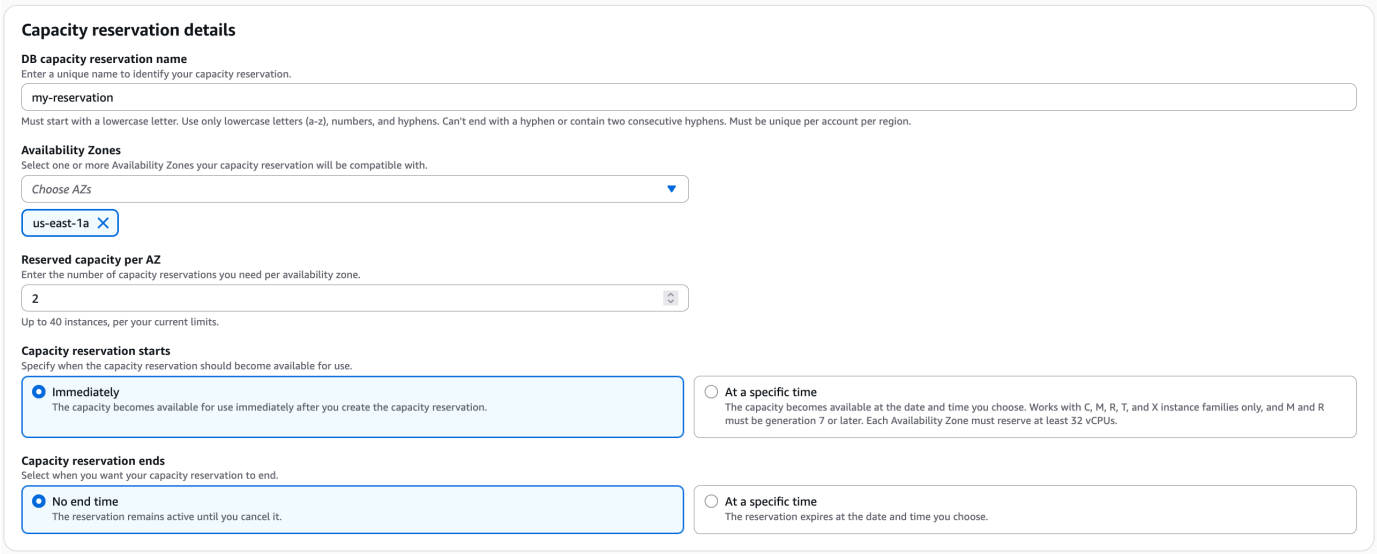
Creating a reservation without a start date makes it immediately active. Capacity is reserved and billing begins immediately.



Console

To create a Capacity Reservation

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Capacity reservations**.
3. Choose **Create capacity reservation**.
4. Under **Engine options**, choose **Aurora (MySQL Compatible)** or **Aurora (PostgreSQL Compatible)**.



5. Under **Instance configuration**, choose the DB instance configuration.

6. Under **Capacity reservation details**, do the following:

- For **DB capacity reservation name**, enter a name for the reservation. The name must start with a lowercase letter and can contain lowercase letters, digits, and hyphens, up to 63 characters. It can't end with a hyphen or contain two consecutive hyphens.
- Under **Availability Zones**, select one or more Availability Zones in the current Region. Select the Availability Zones where you plan to place the DB instances that use this reservation.
- For **Reserved capacity per AZ**, enter the number of DB instances to reserve in each Availability Zone.
- Under **Capacity reservation starts**, choose **Immediately**.
- (Optional) Under **Capacity reservation ends**, choose **No end time** to keep the reservation until you cancel it, or **At a specific time** to set an end date.

7. (Optional) Add tags.
8. Choose **Create capacity reservation**.

The reservation appears in the list. When its state becomes `active`, capacity is reserved and you can launch DB instances into it by referencing the reservation by name or by identifier. Creating a reservation does not change the placement of DB instances that don't target it.

Billing for an immediately active reservation starts when you create it. To stop the charges, cancel the reservation when you no longer need it. For more information, see Canceling a Capacity Reservation.

Amazon CLI

Create an immediately active reservation with the create-db-capacity-reservation command.

To reserve capacity in more than one Availability Zone with one reservation, list two or more Availability Zones. You can also create a separate reservation for each Availability Zone, and specify a different reservation for each DB instance in the DB cluster.

```
aws rds create-db-capacity-reservation \
    --db-capacity-reservation-name my-cluster-reservation \
    --engine aurora-postgresql \
    --db-instance-class db.r7g.large \
    --availability-zones us-east-1a us-east-1b \
    --capacity-per-availability-zone 2
```

Example response:

```
{
    "DBCapacityReservation": {
        "DBCapacityReservationName": "my-cluster-reservation",
        "DBInstanceClass": "db.r7g.large",
        "Engine": "aurora-postgresql",
        "ReservedCapacityPerAvailabilityZone": 2,
        "AvailableCapacityPerAvailabilityZoneList": [
            {
                "AvailabilityZone": "us-east-1a",
                "AvailableCapacity": 2
            },
            {
                "AvailabilityZone": "us-east-1b",
                "AvailableCapacity": 2
            }
        ],
        "CreateDate": "2026-09-21T21:44:50.147000+00:00",
        "State": "active",
        "DBCapacityReservationArn": "arn:aws:rds:us-east-1:123456789012:db-capacity-
reservation:dbcr-abc123example",
        "DBCapacityReservationIdentifier": "dbcr-abc123example",
        "TagList": []
    }
}
```

RDS API

To create a Capacity Reservation by using the Amazon RDS API, call the CreateDBCapacityReservation operation with the following parameters:

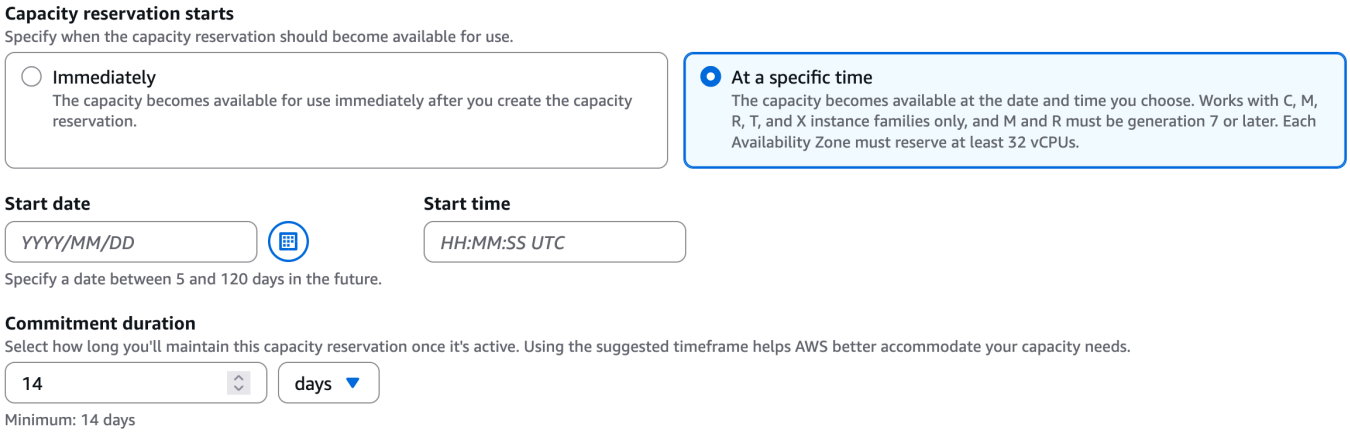
- `DBCapacityReservationName` – A name for the reservation. The name must start with a lowercase letter and can contain lowercase letters, digits, and hyphens, up to 63 characters. It can't end with a hyphen, contain two consecutive hyphens, or start with `dbcr-`.
- `Engine` – The database engine to reserve capacity for: `aurora-mysql` or `aurora-postgresql`.
- `DBInstanceClass` – The DB instance class to reserve capacity for, for example `db.r7g.large`.
- `AvailabilityZones` – One or more Availability Zones in the current Amazon Region.
- `CapacityPerAvailabilityZone` – The number of DB instances to reserve in each Availability Zone.

You can also specify the following optional parameters:

- `EndDate` – The date and time when the reservation expires, in UTC. If you don't specify it, the reservation doesn't expire.
- `Tags` – Tags to assign to the Capacity Reservation.

Creating a future-dated Capacity Reservation

To schedule a reservation to begin on a future date, provide a start date and a commitment duration. Amazon RDS assesses the request, and if it can deliver the capacity, moves the reservation to the `scheduled` state. No charges apply until the start date, when Amazon RDS activates the reservation.



While assessing a request, Amazon RDS might determine that it can support a shorter commitment duration. In that case, Amazon RDS schedules the reservation with the shorter commitment duration, and you are committed to keeping the reservation for a shorter period than you requested. To see the commitment that applies, check `CommitmentInfo.CommitmentEndDate` in the output of `describe-db-capacity-reservations`.

Console

Follow the steps in Creating a Capacity Reservation. Under **Capacity reservation starts**, do the following:

To create a future-dated Capacity Reservation

1. Choose **At a specific time**.
2. Set the **Start date** and **Start time** (must be at least 5 days in the future).
3. Set the **Commitment duration** (minimum 14 days). This is the period you commit to keep the reservation after it becomes active.

Complete the remaining steps and choose **Create capacity reservation**. The reservation is created in the `assessing` state and moves to `scheduled` after Amazon RDS accepts the request.

Amazon CLI

Add `--start-date` and `--commitment-duration` to the `create-db-capacity-reservation` command. `--commitment-duration` is specified in seconds (for example, `1209600` for 14 days).

```
aws rds create-db-capacity-reservation \
    --db-capacity-reservation-name peak-reservation \
    --engine aurora-postgresql \
    --db-instance-class db.r7g.large \
    --availability-zones us-east-1a \
    --capacity-per-availability-zone 16 \
    --start-date 2026-11-01T00:00:00Z \
    --commitment-duration 1209600
```

Example response:

```
{
    "DBCapacityReservation": {
        "DBCapacityReservationName": "peak-reservation",
        "DBInstanceClass": "db.r7g.large",
        "Engine": "aurora-postgresql",
        "ReservedCapacityPerAvailabilityZone": 16,
        "StartDate": "2026-11-01T00:00:00Z",
        "CommitmentInfo": {
            "CommittedCapacityPerAvailabilityZone": 16,
            "CommitmentEndDate": "2026-11-15T00:00:00Z"
        },
        "CreateDate": "2026-09-21T21:44:50.147000+00:00",
        "State": "assessing",
        "DBCapacityReservationArn": "arn:aws:rds:us-east-1:123456789012:db-capacity-
reservation:dbcr-def456example",
        "DBCapacityReservationIdentifier": "dbcr-def456example",
        "TagList": []
    }
}
```

Note

Omitting `--start-date` and `--commitment-duration` creates an immediately active reservation. The two future-dated parameters are used together.

RDS API

To create a future-dated Capacity Reservation by using the Amazon RDS API, call the CreateDBCapacityReservation operation with the parameters for an immediately active reservation, and with the following parameters:

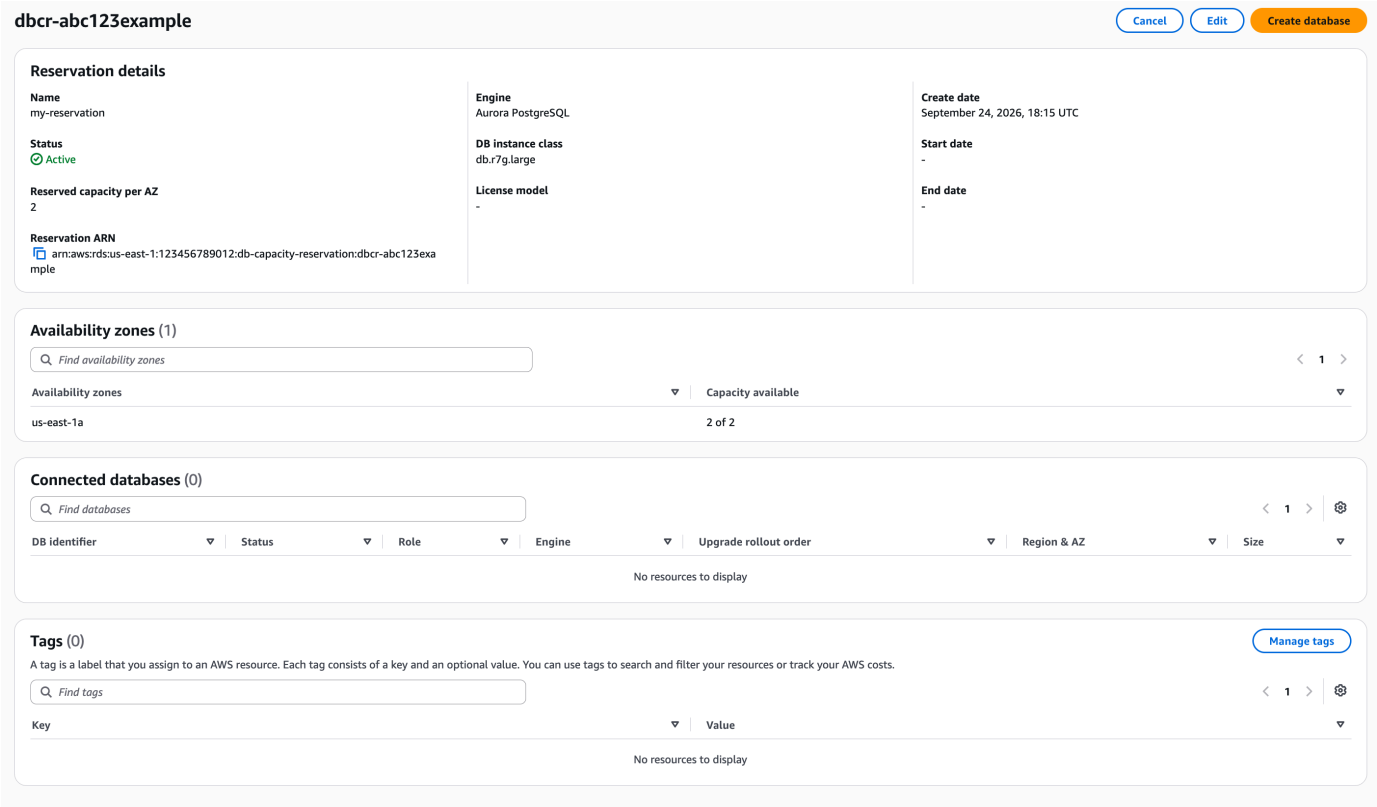
- `StartDate` – The date and time when the reservation starts, in UTC. It must be 5–120 days in the future.
- `CommitmentDuration` – The length of the commitment, in seconds. The minimum is `1209600` (14 days). For the X family, the minimum is `7257600` (12 weeks).

Viewing and modifying your Capacity Reservations

After you create a Capacity Reservation, you can view its state and capacity usage at any time, and change the amount of capacity it reserves as your needs change. Viewing a reservation shows the capacity reserved and still available in each Availability Zone, along with its start and end dates, commitment information, and lifecycle state. Modifying a reservation changes the number of DB instances reserved in each Availability Zone while the reservation is active.

Topics

- Viewing Capacity Reservations
- Modifying a Capacity Reservation



Viewing Capacity Reservations

You can view Amazon Aurora Capacity Reservations using the Amazon Web Services Management Console, the Amazon CLI, or the Amazon RDS API.

Console

To view Capacity Reservations

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Capacity reservations**.
3. Select a reservation to see its state, reserved capacity, available capacity in each Availability Zone, start and end dates, and commitment information.

Amazon CLI

Use the [describe-db-capacity-reservations] command.

List all reservations in the Region:

```
aws rds describe-db-capacity-reservations
```

Describe a specific reservation, by name or by ID:

```
aws rds describe-db-capacity-reservations \
    --db-capacity-reservation-identifier my-reservation
```

The response includes `ReservedCapacityPerAvailabilityZone` (capacity reserved in each Availability Zone) and `AvailableCapacityPerAvailabilityZoneList` (capacity not yet in use, broken out by Availability Zone), which you can use to monitor utilization and find which Availability Zone has little available capacity.

RDS API

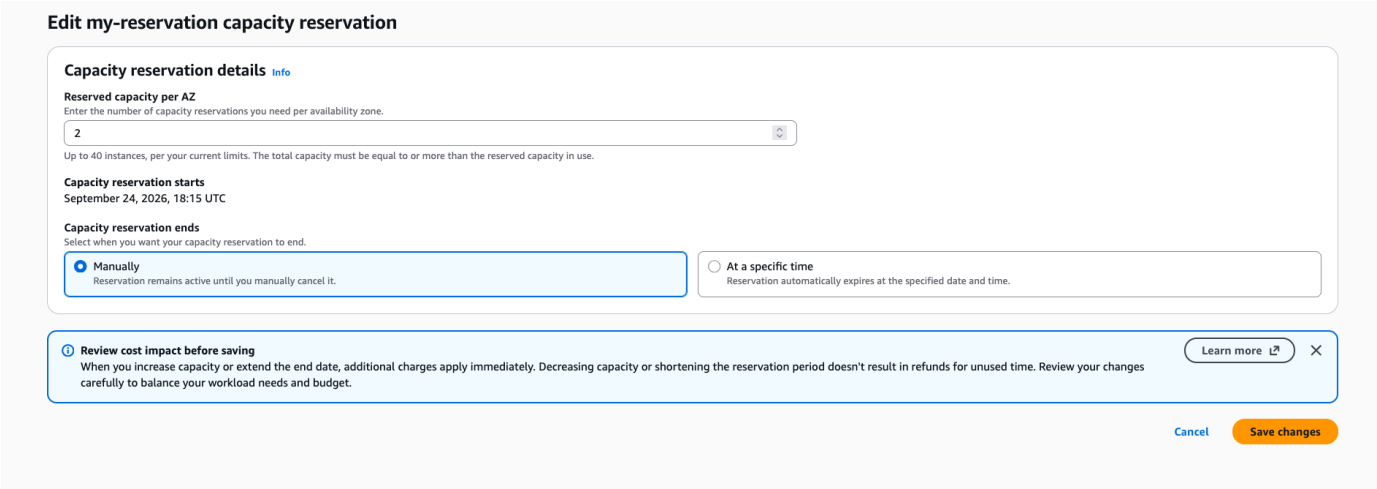
To view Capacity Reservations by using the Amazon RDS API, call the DescribeDBCapacityReservations operation. You can specify the following optional parameters:

- `DBCapacityReservationIdentifier` – The name or the `dbcr-` ID of the Capacity Reservation. If you don't specify it, the operation returns all the Capacity Reservations in the Region.
- `Filters` – Filters that limit the result. The supported filters are `db-capacity-reservation-name`, `state`, `engine`, `db-instance-class`, and `availability-zone`.
- `MaxRecords` – The maximum number of records to return, from 20 to 100. The default is 100.
- `Marker` – The pagination token from a previous request.

Modifying a Capacity Reservation

You can change the reserved capacity of a reservation, that is, the number of DB instances reserved in each Availability Zone. You can also change its end date.

You can modify a reservation only while it is `active` and has not reached its end date. A future-dated reservation can't be modified while it is in the `assessing`, `scheduled`, or `delayed` state – wait until it becomes active on its start date. Reservations in the `pending`, `expired`, `cancelled`, `failed`, or `unsupported` state can't be modified.



The following limits apply to a change in reserved capacity:

- You can't reduce the capacity below the capacity already in use. The new value must fit the Availability Zone that holds the most DB instances.
- Increasing the capacity depends on capacity being available, and on your account's Capacity Reservation quota.
- While a reservation is still within its commitment duration, you can't reduce its capacity below the committed capacity, and you can't set an end date earlier than the commitment end date. For a reservation that was `delayed`, the capacity limit applies until the original commitment end date, but the end date limit doesn't apply.

Console

To modify a Capacity Reservation

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Capacity reservations**.
3. In the list of reservations, select the reservation.
4. For **Actions**, choose **Edit**.
5. Under **Capacity reservation details**, do the following:
   - For **Reserved capacity per AZ**, enter the new number of DB instances to reserve in each Availability Zone.
   - (Optional) For **Capacity reservation ends**, choose **Manually** to keep the reservation until you cancel it, or **At a specific time** to set an end date.

6. Review the cost impact, and then choose **Save changes**. An increase in capacity or a later end date adds charges immediately. A decrease in capacity or an earlier end date doesn't refund charges for the time that has already passed.

Amazon CLI

Use the modify-db-capacity-reservation command.

```
aws rds modify-db-capacity-reservation \
    --db-capacity-reservation-identifier my-reservation \
```

```
    --capacity-per-availability-zone 4
```

The new capacity applies to each Availability Zone in the reservation. Increasing it is subject to capacity being available in all of them. Decreasing it releases the difference and reduces charges.

RDS API

To modify a Capacity Reservation by using the Amazon RDS API, call the ModifyDBCapacityReservation operation with the following parameter:

- `DBCapacityReservationIdentifier` – The name or the `dbcr-` ID of the Capacity Reservation.

Also specify at least one of the following parameters:

- `CapacityPerAvailabilityZone` – The new number of DB instances to reserve in each Availability Zone.
- `EndDateType` – `limited` to set an end date, or `unlimited` to keep the reservation until you cancel it.
- `EndDate` – The new end date, in UTC. Required when `EndDateType` is `limited`.

Canceling a Capacity Reservation

Canceling a reservation releases the reserved capacity and stops the associated charges. Any DB instances currently running in the reservation continue to run as normal On-Demand instances.

You can cancel a reservation that is in the `active`, `assessing`, or `delayed` state:

- `active` – cancel at any time, unless the reservation is still within a commitment duration. A future-dated reservation that has become active can't be canceled until its commitment ends.
- `assessing` – a future-dated reservation can be canceled while Amazon RDS is still evaluating whether it can deliver the capacity, because no commitment has begun.
- `delayed` – if Amazon RDS couldn't deliver the capacity on the requested start date, the commitment is waived and you can cancel the reservation immediately.

A reservation in the `scheduled` state can't be canceled. After Amazon RDS accepts a future-dated request and schedules the capacity, the reservation stays in place until its start date, becomes

active, and can then be canceled only after its commitment duration ends. Take that into account when you choose a start date and a commitment duration.

Reservations in the `pending`, `expired`, `cancelled`, `failed`, or `unsupported` state can't be canceled. An expired or canceled reservation has already released its capacity.

Console

To cancel a Capacity Reservation

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Capacity reservations**.
3. Select the reservation.
4. Choose **Cancel reservation**, and then confirm the cancellation.

Amazon CLI

Use the cancel-db-capacity-reservation command.

```
aws rds cancel-db-capacity-reservation \
    --db-capacity-reservation-identifier my-reservation
```

RDS API

To cancel a Capacity Reservation by using the Amazon RDS API, call the CancelDBCapacityReservation operation with the following parameter:

- `DBCapacityReservationIdentifier` – The name or the `dbcr-` ID of the Capacity Reservation.

Using a Capacity Reservation with an Aurora DB instance

Reserved capacity is used only when you explicitly target the reservation. You reference the reservation by its identifier (`dbcr-`) or its name when you perform any of the following operations:

- Create a DB instance in a DB cluster (`CreateDBInstance`) – for the writer and for each Aurora Replica

- Modify a DB instance to move it into a reservation (`ModifyDBInstance`)

The DB instance's engine, DB instance class, and Availability Zone must match the reservation, and the reservation must have available capacity in that Availability Zone (the matching entry in `AvailableCapacityPerAvailabilityZoneList` has an `AvailableCapacity` greater than 0). If they don't match or no capacity is available, the operation fails with an error that says the Availability Zone doesn't have enough capacity.

> **Note**
>
> Blue/Green Deployments don't support Capacity Reservations.

Console

When you add a DB instance to an Aurora DB cluster in the Amazon RDS console, in the **Capacity reservation** section, choose the reservation to launch into.

Amazon CLI

Add the `--db-capacity-reservation-identifier` parameter to the create or modify command. For example, to create a DB instance that uses a reservation:

```
aws rds create-db-instance \
    --db-instance-identifier my-db-instance \
    --db-cluster-identifier my-aurora-cluster \
    --engine aurora-postgresql \
    --db-instance-class db.r7g.large \
    --availability-zone us-east-1a \
    --db-capacity-reservation-identifier my-reservation
```

The `--db-capacity-reservation-identifier` parameter accepts either the reservation name or its `dbcr-` ID.

To restore into a reservation, restore the DB cluster first, and then add its DB instances with the reservation. A DB cluster restore (`restore-db-cluster-from-snapshot` or `restore-db-cluster-to-point-in-time`) creates the DB cluster without DB instances and doesn't take a Capacity Reservation.

```
aws rds restore-db-cluster-from-snapshot \
```

```
    --db-cluster-identifier my-restored-cluster \
    --snapshot-identifier my-cluster-snapshot \
    --engine aurora-postgresql

aws rds create-db-instance \
    --db-instance-identifier my-restored-instance \
    --db-cluster-identifier my-restored-cluster \
    --engine aurora-postgresql \
    --db-instance-class db.r7g.large \
    --db-capacity-reservation-identifier my-reservation
```

To move an existing DB instance into a reservation, specify the reservation in a modify request that also changes the DB instance class. The reservation must match the configuration that the DB instance has after the change. For example, to scale a DB instance to db.r7g.large and place it in a db.r7g.large reservation:

```
aws rds modify-db-instance \
    --db-instance-identifier my-db-instance \
    --db-instance-class db.r7g.large \
    --db-capacity-reservation-identifier my-reservation \
    --apply-immediately
```

A modify request that specifies a reservation without a DB instance class change fails.

When DB instances are placed into the reservation, the `AvailableCapacity` for the affected Availability Zone decreases. You can track this with `describe-db-capacity-reservations`.

RDS API

Specify the `DBCapacityReservationIdentifier` parameter in the CreateDBInstance or ModifyDBInstance operation.

Stopping and starting a DB cluster in a reservation

You stop and start Aurora DB instances at the DB cluster level. The `stop-db-cluster` and `start-db-cluster` commands don't take the `--db-capacity-reservation-identifier` or `--detach-from-db-capacity-reservation` parameter, so you can't attach a DB instance to a reservation, or detach it, when you stop or start a DB cluster.

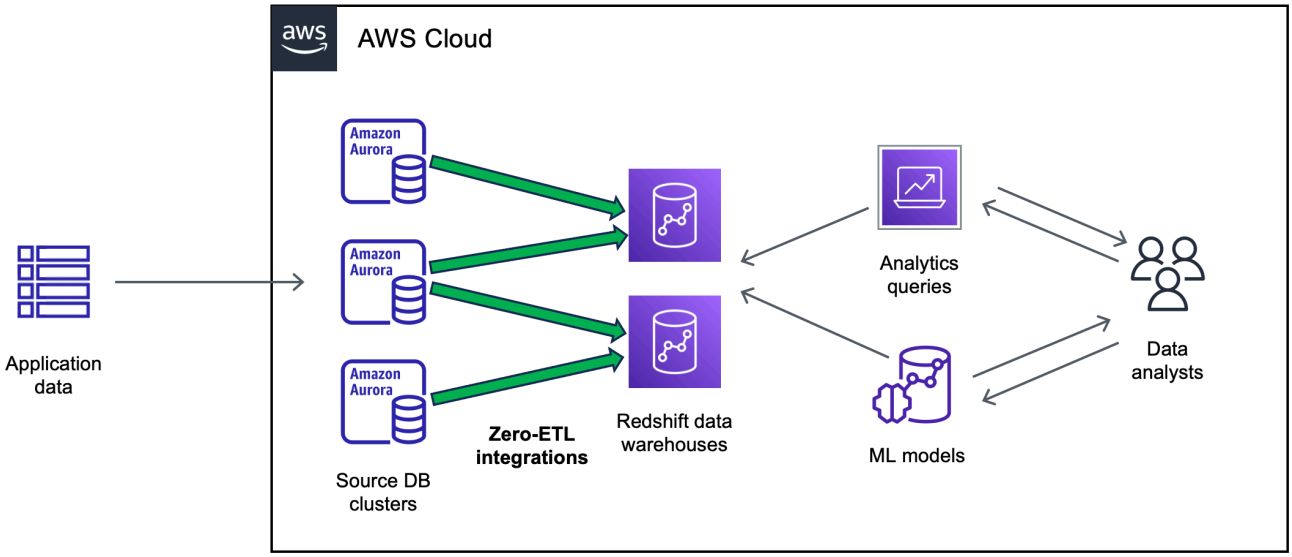
When you stop a DB cluster, each DB instance that uses reserved capacity stays associated with its reservation, but the capacity it was using is released back to the reservation.

Because the association persists, starting the DB cluster returns each DB instance to the same reservation. Amazon RDS places it back into the reservation using whatever capacity is available at that point.

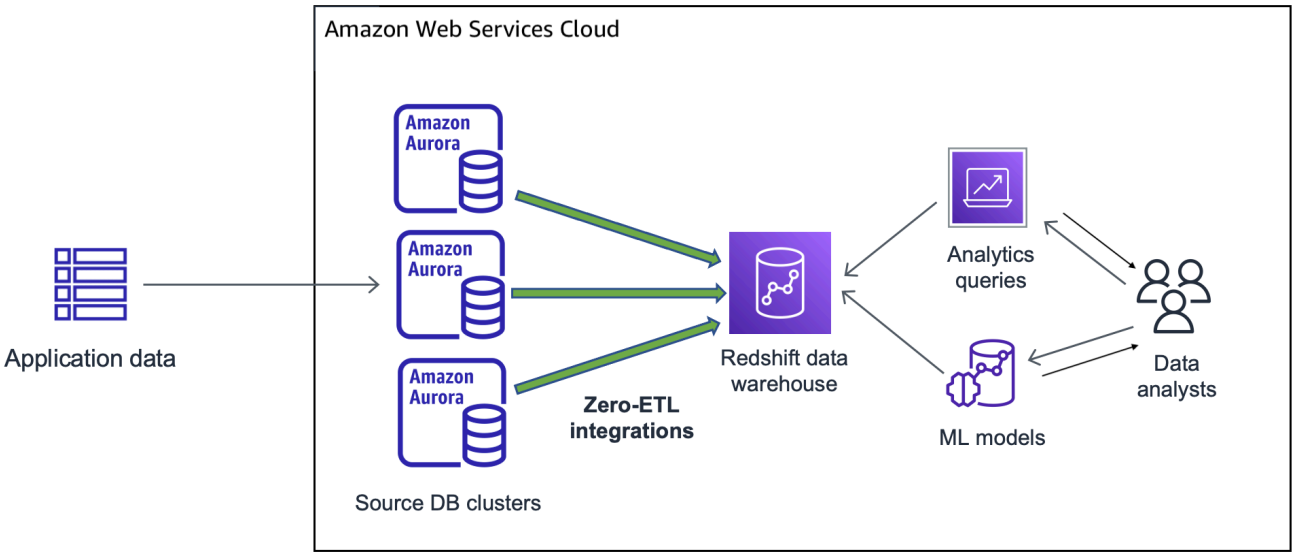
> **Important**
>
> Because stopping the DB cluster releases the capacity, another DB instance can take it while the DB cluster is stopped.

The DB instances of a DB cluster can use different reservations. If any of those reservations has no available capacity in its DB instance's Availability Zone, the start fails with an error, and the DB cluster stays stopped. No DB instance in the DB cluster starts, even if the other reservations have capacity. Amazon RDS doesn't fall back to On-Demand capacity, so that each DB instance keeps its reservation. If a DB instance's reservation was canceled or has expired, that DB instance starts with On-Demand capacity and is no longer associated with the reservation.

If Aurora automatically starts a DB cluster after it has been stopped for 7 days, and the reservation has no available capacity, the automatic start is postponed until capacity is available.

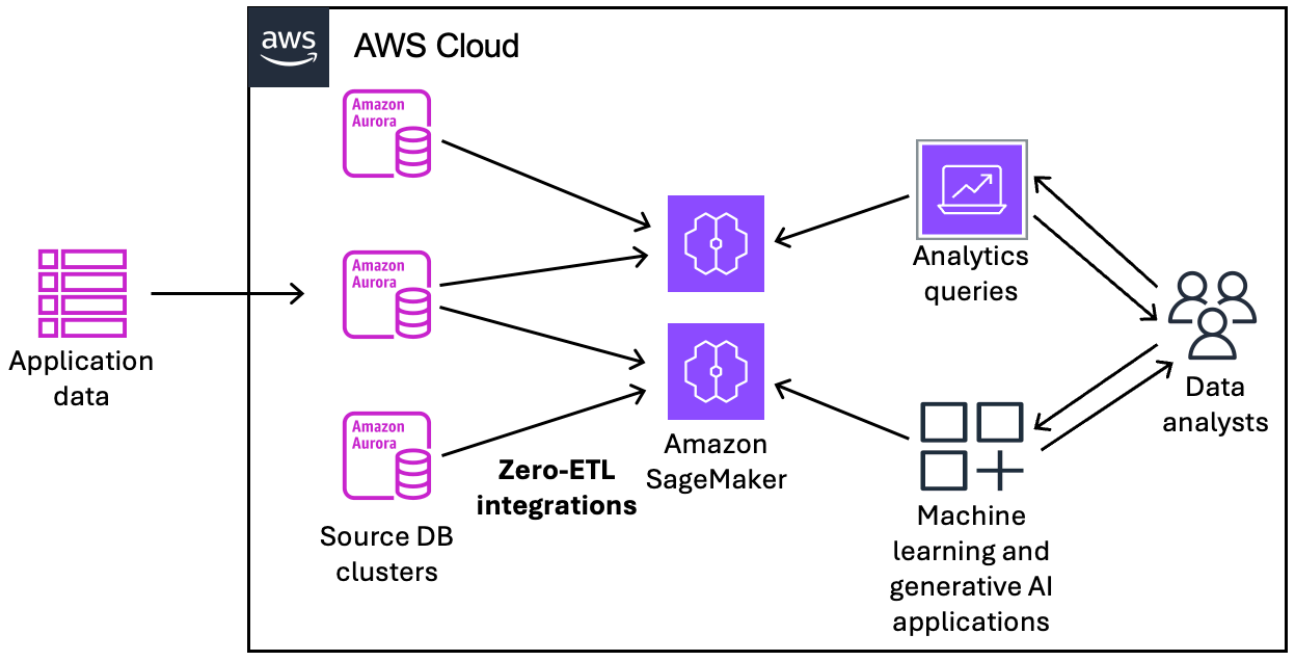


Aurora zero-ETL integrations



An Aurora zero-ETL integration with Amazon Redshift and Amazon SageMaker AI enables near real-time analytics and machine learning (ML) using data from Aurora. It's a fully managed solution for making transactional data available in your analytics destination after it is written to an Aurora DB cluster. *Extract, transform,* and *load* (ETL) is the process of combining data from multiple sources into a large, central data warehouse.

A zero-ETL integration makes the data in your Aurora DB cluster available in Amazon Redshift or an Amazon SageMaker AI lakehouse in near real-time. Once that data is in the target data warehouse or data lake, you can power your analytics, ML, and AI workloads using the built-in capabilities, such as machine learning, materialized views, data sharing, federated access to multiple data stores and data lakes, and integrations with Amazon SageMaker AI, Quick, and other Amazon Web Services services.



To create a zero-ETL integration, you specify an Aurora DB cluster as the *source*, and a supported data warehouse or lakehouse as the *target*. The integration replicates data from the source database into the target data warehouse or lakehouse.

The following diagram illustrates this functionality for zero-ETL integration with Amazon Redshift:

The following diagram illustrates this functionality for zero-ETL integration with an Amazon SageMaker AI lakehouse:

The integration monitors the health of the data pipeline and recovers from issues when possible. You can create integrations from multiple Aurora DB clusters into a single target data warehouse or lakehouse enabling you to derive insights across multiple applications.

For information about pricing for zero-ETL integrations, see Amazon Aurora pricing and Amazon Redshift pricing.

Topics

- Benefits

- Creating Aurora zero-ETL integrations with Amazon Redshift
- Creating Aurora zero-ETL integrations with an Amazon SageMaker lakehouse
- Data filtering for Aurora zero-ETL integrations
- Adding data to a source Aurora DB cluster and querying it
- Viewing and monitoring Aurora zero-ETL integrations
- Modifying Aurora zero-ETL integrations
- Deleting Aurora zero-ETL integrations
- Troubleshooting Aurora zero-ETL integrations

Benefits

Aurora zero-ETL integrations have the following benefits:

- Help you derive holistic insights from multiple data sources.
- Eliminate the need to build and maintain complex data pipelines that perform extract, transform, and load (ETL) operations. Zero-ETL integrations remove the challenges that come with building and managing pipelines by provisioning and managing them for you.
- Reduce operational burden and cost, and let you focus on improving your applications.
- Let you leverage the target destination's analytics and ML capabilities to derive insights from transactional and other data, to respond effectively to critical, time-sensitive events.

Key concepts

As you get started with zero-ETL integrations, consider the following concepts:

Integration

A fully managed data pipeline that automatically replicates transactional data and schemas from an Aurora DB cluster to a data warehouse or catalog.

Source DB cluster

The Aurora DB cluster where data is replicated from. You can specify a DB cluster that uses provisioned DB instances or Aurora serverless DB instances as the source.

Target

The data warehouse or lakehouse where the data is replicated to. There are two types of data warehouse: a provisioned cluster data warehouse and a serverless data warehouse. A provisioned cluster data warehouse is a collection of computing resources called nodes, which are organized into a group called a *cluster*. A serverless data warehouse is comprised of a workgroup that stores compute resources, and a namespace that houses the database objects and users. Both data warehouses run an analytics engine and contain one or more databases.

A target lakehouse consists of catalogs, databases, tables, and views. For more information about lakehouse architecture, see SageMaker Lakehouse components in the *Amazon SageMaker AI Unified Studio User Guide*.

Multiple source DB clusters can write to the same target.

For more information, see Data warehouse system architecture in the *Amazon Redshift Developer Guide*.

Limitations

The following limitations apply to Aurora zero-ETL integrations.

Topics

- General limitations
- Aurora MySQL limitations
- Aurora PostgreSQL limitations
- Amazon Redshift limitations
- Amazon SageMaker AI lakehouse limitations

General limitations

- The source DB cluster must be in the same Region as the target.
- You can't rename a DB cluster or any of its instances if it has existing integrations.
- You can't create multiple integrations between the same source and target databases.
- You can't delete a DB cluster that has existing integrations. You must delete all associated integrations first.
- If you stop the source DB cluster, the last few transactions might not be replicated to the target until you resume the cluster.
- If your cluster is the source of a blue/green deployment, the blue and green environments can't have existing zero-ETL integrations during switchover. You must delete the integration first and switch over, then recreate it.
- A DB cluster must contain at least one DB instance in order to be the source of an integration.
- You can't create an integration for a source DB cluster that is a cross-account clone, such as those shared using Amazon Resource Access Manager (Amazon RAM).
- If your source cluster is the primary DB cluster in an Aurora global database and it fails over to one of its secondary clusters, the integration becomes inactive. You must delete and recreate the integration.
- You can't create an integration for a source database that has another integration being actively created.
- When you initially create an integration, or when a table is being resynchronized, data seeding from the source to the target can take 20-25 minutes or more depending on the size of the source database. This delay can lead to increased replica lag.
- Some data types aren't supported. For more information, see the section called “Data type differences”.
- System tables, temporary tables, and views aren't replicated to target warehouses.
- Performing DDL commands (for example `ALTER TABLE`) on a source table can trigger a table resynchronization, making the table unavailable for querying while it's resynchronizing. For more information, see the section called “One or more of my Amazon Redshift tables requires a resync”.

Aurora MySQL limitations

- Your source DB cluster must be running a supported version of Aurora MySQL. For a list of supported versions, see the section called "Zero-ETL integrations ".
- Zero-ETL integrations rely on MySQL binary logging (binlog) to capture ongoing data changes. Don't use binlog-based data filtering, as it can cause data inconsistencies between the source and target databases.
- Zero-ETL integrations are supported only for databases configured to use the InnoDB storage engine.
- Foreign key references with predefined table updates aren't supported. Specifically, `ON DELETE` and `ON UPDATE` rules aren't supported with `CASCADE`, `SET NULL`, and `SET DEFAULT` actions. Attempting to create or update a table with such references to another table will put the table into a failed state.
- XA transactions performed on the source DB cluster cause the integration to enter a state of `Syncing`.

Aurora PostgreSQL limitations

- Your source DB cluster must be running a supported version of Aurora PostgreSQL. For a list of supported versions, see the section called "Zero-ETL integrations ".
- If you select an Aurora PostgreSQL source DB cluster, you must specify at least one data filter pattern. At minimum, the pattern must include a single database (*`database-name`*`.*.*`) for replication to the target warehouse. For more information, see the section called "Data filtering for zero-ETL integrations".
- All databases created within the source Aurora PostgreSQL DB cluster must use UTF-8 encoding.
- When using declarative partitioning, the table partitions will be replicated to Amazon Redshift. However, the partitioned table itself isn't replicated to Amazon Redshift.
- Two-phase transactions aren't supported.
- If you delete all DB instances from a DB cluster that is the source of an integration and then re-add a DB instance, replication breaks between the source and the target clusters.
- The source DB cluster can't use Aurora Limitless Database.
- Primary keys are required on all tables present in the data filter. Any tables without a primary key will be put into the failed state.

Amazon Redshift limitations

For a list of Amazon Redshift limitations related to zero-ETL integrations, see Considerations when using zero-ETL integrations with Amazon Redshift in the *Amazon Redshift Management Guide*.

Amazon SageMaker AI lakehouse limitations

Following is a limitation for Amazon SageMaker AI lakehouse zero-ETL integrations.

- Catalog names are limited to 19 characters in length.

Quotas

Your account has the following quotas related to Aurora zero-ETL integrations. Each quota is per-Region unless otherwise specified.

Name	Default	Description
Integrations	100	The total number of integrations within an Amazon Web Services account.
Integrations per target	50	The number of integrations sending data to a single target data warehouse or lakehouse.
Integrations per source cluster	5	The number of integrations sending data from a single source DB cluster.

In addition, the target warehouse places certain limits on the number of tables allowed in each DB instance or cluster node. For more information about Amazon Redshift quotas and limits, see Quotas and limits in Amazon Redshift in the *Amazon Redshift Management Guide*.

Supported Regions

Aurora zero-ETL integrations are available in a subset of Amazon Web Services Regions. For a list of supported Regions, see the section called “Zero-ETL integrations ”.

Getting started with Aurora zero-ETL integrations

Before you create a zero-ETL integration, configure your Aurora DB cluster and your data warehouse with the required parameters and permissions. During setup, you'll complete the following steps:

1. Create a custom DB cluster parameter group.
2. Create a source DB cluster.
3. Create a target data warehouse for Amazon Redshift or Create a target Amazon SageMaker Lakehouse.

After you complete these tasks, continue to the section called "Creating zero-ETL integrations with Amazon Redshift" or the section called "Creating zero-ETL integrations with an Amazon SageMaker lakehouse".

You can use the Amazon SDKs to automate the setup process for you. For more information, see the section called "Set up an integration using the Amazon SDKs".

> **Tip**
>
> You can have RDS complete these setup steps for you while you're creating the integration, rather than performing them manually. To immediately start creating an integration, see the section called "Creating zero-ETL integrations with Amazon Redshift".

For Step 3, you can choose to create either a target data warehouse (Step 3a) or a target lakehouse (Step 3b) depending on your needs:

- Choose a data warehouse if you need traditional data warehousing capabilities with SQL-based analytics.
- Choose an Amazon SageMaker Lakehouse if you need machine learning capabilities and want to use lakehouse features for data science and ML workflows.

Step 1: Create a custom DB cluster parameter group

Aurora zero-ETL integrations require specific values for the DB cluster parameters that control replication. Specifically, Aurora MySQL requires *enhanced binlog*

(aurora_enhanced_binlog), and Aurora PostgreSQL requires *enhanced logical replication* (aurora.enhanced_logical_replication).

To configure binary logging or logical replication, you must first create a custom DB cluster parameter group, and then associate it with the source DB cluster.

Aurora MySQL (aurora-mysql8.0 family):

- aurora_enhanced_binlog=1
- binlog_backup=0
- binlog_format=ROW
- binlog_replication_globaldb=0
- binlog_row_image=full
- binlog_row_metadata=full

In addition, make sure that the binlog_transaction_compression parameter is *not* set to ON, and that the binlog_row_value_options parameter is *not* set to PARTIAL_JSON.

For more information about Aurora MySQL enhanced binlog, see the section called "Setting up enhanced binlog".

Aurora PostgreSQL (aurora-postgresql16 family):

- rds.logical_replication=1
- aurora.enhanced_logical_replication=1
- aurora.logical_replication_backup=0
- aurora.logical_replication_globaldb=0

Enabling enhanced logical replication (aurora.enhanced_logical_replication) will always write all column values to the write ahead log (WAL) even if REPLICA IDENTITY FULL isn't enabled. This might increase the IOPS for your source DB cluster.

> **Important**
>
> If you enable or disable the aurora.enhanced_logical_replication DB cluster parameter, the primary DB instance invalidates all logical replication slots. This stops

replication from the source to the target, and you must recreate replication slots on the primary DB instance. To prevent interruptions, keep the parameter state consistent during replication.

Step 2: Select or create a source DB cluster

After you create a custom DB cluster parameter group, choose or create an Aurora DB cluster. This cluster will be the source of data replication to the target data warehouse. You can specify a DB cluster that uses provisioned DB instances or Aurora serverless DB instances as the source. For instructions to create a DB cluster, see the section called "Creating a DB cluster" or the section called "Creating an Aurora serverless DB cluster".

The database must be running a supported DB engine version. For a list of supported versions, see the section called "Zero-ETL integrations ".

When you create the database, under **Additional configuration**, change the default **DB cluster parameter group** to the custom parameter group that you created in the previous step.

Note

If you associate the parameter group with the DB cluster *after* the cluster is already created, you must reboot the primary DB instance in the cluster to apply the changes before you can create a zero-ETL integration. For instructions, see the section called "Rebooting an Aurora DB cluster or instance".

Step 3a: Create a target data warehouse

After you create your source DB cluster, you must create and configure a target data warehouse. The data warehouse must meet the following requirements:

- Using an RA3 node type with at least two nodes, or Redshift Serverless.
- Encrypted (if using a provisioned cluster). For more information, see Amazon Redshift database encryption.

For instructions to create a data warehouse, see Creating a cluster for provisioned clusters, or Creating a workgroup with a namespace for Redshift Serverless.

Enable case sensitivity on the data warehouse

For the integration to be successful, the case sensitivity parameter (`enable_case_sensitive_identifier`) must be enabled for the data warehouse. By default, case sensitivity is disabled on all provisioned clusters and Redshift Serverless workgroups.

To enable case sensitivity, perform the following steps depending on your data warehouse type:

- **Provisioned cluster** – To enable case sensitivity on a provisioned cluster, create a custom parameter group with the `enable_case_sensitive_identifier` parameter enabled. Then, associate the parameter group with the cluster. For instructions, see Managing parameter groups using the console or Configuring parameter values using the Amazon CLI.

  > **Note**
  >
  > Remember to reboot the cluster after you associate the custom parameter group with it.

- **Serverless workgroup** – To enable case sensitivity on a Redshift Serverless workgroup, you must use the Amazon CLI. The Amazon Redshift console doesn't currently support modifying Redshift Serverless parameter values. Send the following update-workgroup request:

  ```
  aws redshift-serverless update-workgroup \
    --workgroup-name target-workgroup \
    --config-parameters
   parameterKey=enable_case_sensitive_identifier,parameterValue=true
  ```

  You don't need to reboot a workgroup after you modify its parameter values.

Configure authorization for the data warehouse

After you create a data warehouse, you must configure the source Aurora DB cluster as an authorized integration source. For instructions, see Configure authorization for your Amazon Redshift data warehouse.

Set up an integration using the Amazon SDKs

Rather than setting up each resource manually, you can run the following Python script to automatically set up the required resources for you. The code example uses the Amazon SDK for Python (Boto3) to create a source Amazon Aurora DB cluster and target data warehouse, each with

the required parameter values. It then waits for the databases to be available before creating a zero-ETL integration between them. You can comment out different functions depending on which resources you need to set up.

To install the required dependencies, run the following commands:

```
pip install boto3
pip install time
```

Within the script, optionally modify the names of the source, target, and parameter groups. The final function creates an integration named `my-integration` after the resources are set up.

Python code example

Aurora MySQL

```
import boto3
import time

# Build the client using the default credential configuration.
# You can use the CLI and run 'aws configure' to set access key, secret
# key, and default Region.

rds = boto3.client('rds')
redshift = boto3.client('redshift')
sts = boto3.client('sts')

source_cluster_name = 'my-source-cluster' # A name for the source cluster
source_param_group_name = 'my-source-param-group' # A name for the source parameter
 group
target_cluster_name = 'my-target-cluster' # A name for the target cluster
target_param_group_name = 'my-target-param-group' # A name for the target parameter
 group

def create_source_cluster(*args):
    """Creates a source Aurora MySQL DB cluster"""

    response = rds.create_db_cluster_parameter_group(
        DBClusterParameterGroupName=source_param_group_name,
        DBParameterGroupFamily='aurora-mysql8.0',
        Description='For Aurora MySQL binary logging'
    )
```

```
    print('Created source parameter group: ' + response['DBClusterParameterGroup']
['DBClusterParameterGroupName'])

    response = rds.modify_db_cluster_parameter_group(
        DBClusterParameterGroupName=source_param_group_name,
        Parameters=[
            {
                'ParameterName': 'aurora_enhanced_binlog',
                'ParameterValue': '1',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_backup',
                'ParameterValue': '0',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_format',
                'ParameterValue': 'ROW',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_replication_globaldb',
                'ParameterValue': '0',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_row_image',
                'ParameterValue': 'full',
                'ApplyMethod': 'pending-reboot'
            },
            {
                'ParameterName': 'binlog_row_metadata',
                'ParameterValue': 'full',
                'ApplyMethod': 'pending-reboot'
            }
        ]
    )
    print('Modified source parameter group: ' +
 response['DBClusterParameterGroupName'])

    response = rds.create_db_cluster(
        DBClusterIdentifier=source_cluster_name,
        DBClusterParameterGroupName=source_param_group_name,
```

```
        Engine='aurora-mysql',
        EngineVersion='8.0.mysql_aurora.3.05.2',
        DatabaseName='myauroradb',
        MasterUsername='username',
        MasterUserPassword='Password01**'
    )
    print('Creating source cluster: ' + response['DBCluster']
['DBClusterIdentifier'])
    source_arn = (response['DBCluster']['DBClusterArn'])
    create_target_cluster(target_cluster_name, source_arn, target_param_group_name)

    response = rds.create_db_instance(
        DBInstanceClass='db.r6g.2xlarge',
        DBClusterIdentifier=source_cluster_name,
        DBInstanceIdentifier=source_cluster_name + '-instance',
        Engine='aurora-mysql'
    )
    return(response)

def create_target_cluster(target_cluster_name, source_arn, target_param_group_name):

Step 3b: Create an Amazon Glue catalog for Amazon SageMaker Lakehouse zero-ETL integration

When creating a zero-ETL integration with an Amazon SageMaker Lakehouse, you must create an Amazon Glue managed catalog in Amazon Lake Formation. The target catalog must be an Amazon Redshift managed catalog. To create an Amazon Redshift managed catalog, first create

the `AWSServiceRoleForRedshift` service-linked role. In the Lake Formation console, add the `AWSServiceRoleForRedshift` as a read-only administrator.

For more information about the previous tasks, see the following topics.

- For information about creating an Amazon Redshift managed catalog, see Creating an Amazon Redshift managed catalog in the Amazon Glue Data Catalog in the *Amazon Lake Formation Developer Guide*.
- For information about the service-linked role for Amazon Redshift, see Using service-linked roles for Amazon Redshift in the *Amazon Redshift Management Guide*.
- For information about read-only administrator permissions for Lake Formation, see Lake Formation personas and IAM permissions reference in the *Amazon Lake Formation Developer Guide*.

Configure permissions for the target Amazon Glue catalog

Before creating a target catalog for zero-ETL integration, you must create the Lake Formation target creation role and the Amazon Glue data transfer role. Use the Lake Formation target creation role to create the target catalog. When creating the target catalog, enter the Glue data transfer role in the **IAM role** field in the **Access from engines section**.

Lake Formation target creation role

The target creation role must be a Lake Formation administrator and requires the following permissions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "lakeformation:RegisterResource",
            "Resource": "*"
        },
        {
            "Sid": "VisualEditor1",
```

```
            "Effect": "Allow",
            "Action": [
                "s3:PutEncryptionConfiguration",
                "iam:PassRole",
                "glue:CreateCatalog",
                "glue:GetCatalog",
                "s3:PutBucketTagging",
                "s3:PutLifecycleConfiguration",
                "s3:PutBucketPolicy",
                "s3:CreateBucket",
                "redshift-serverless:CreateNamespace",
                "s3:DeleteBucket",
                "s3:PutBucketVersioning",
                "redshift-serverless:CreateWorkgroup"
            ],
            "Resource": [
                "arn:aws-cn:glue:*:111122223333:catalog",
                "arn:aws-cn:glue:*:111122223333:catalog/*",
                "arn:aws-cn:s3:::*",
                "arn:aws-cn:redshift-serverless:*:111122223333:workgroup/*",
                "arn:aws-cn:redshift-serverless:*:111122223333:namespace/*",
                "arn:aws-cn:iam::111122223333:role/
GlueDataCatalogDataTransferRole"
            ]
        }
    ]
}
```

The target creation role must have the following trust relationship.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "glue.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        },
```

```
        {
          "Effect": "Allow",
          "Principal": {
            "AWS": "arn:aws-cn:iam::111122223333:user/Username"
          },
          "Action": "sts:AssumeRole"
        }
    ]
}
```

Glue data transfer role

The Glue data transfer role is required for MySQL catalog operations and must have the following permissions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "DataTransferRolePolicy",
            "Effect": "Allow",
            "Action": [
                "kms:GenerateDataKey",
                "kms:Decrypt",
                "glue:GetCatalog",
                "glue:GetDatabase"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

The Glue data transfer role must have the following trust relationship.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "glue.amazonaws.com",
                    "redshift.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Next steps

With a source Aurora DB cluster and either an Amazon Redshift target data warehouse or Amazon SageMaker Lakehouse, you can create a zero-ETL integration and replicate data. For instructions, see the section called “Creating zero-ETL integrations with Amazon Redshift”.

Creating Aurora zero-ETL integrations with Amazon Redshift

When you create an Aurora zero-ETL integration, you specify the source Aurora DB cluster and the target Amazon Redshift data warehouse. You can also customize encryption settings and add tags. Aurora creates an integration between the source DB cluster and its target. Once the integration is active, any data that you insert into the source DB cluster will be replicated into the configured Amazon Redshift target.

Prerequisites

Before you create a zero-ETL integration, you must create a source DB cluster and a target Amazon Redshift data warehouse. You also must allow replication into the data warehouse by adding the DB cluster as an authorized integration source.

For instructions to complete each of these steps, see the section called "Getting started with zero-ETL integrations".

Required permissions

Certain IAM permissions are required to create a zero-ETL integration. At minimum, you need permissions to perform the following actions:

- Create zero-ETL integrations for the source Aurora DB cluster.
- View and delete all zero-ETL integrations.
- Create inbound integrations into the target data warehouse.

The following sample policies demonstrate the least privilege permissions required to create and manage integrations. You might not need these exact permissions if your user or role has broader permissions, such as an `AdministratorAccess` managed policy.

> **Note**
>
> Redshift Amazon Resource Names (ARNs) have the following format. Note the use of a forward slash (`/`) rather than a colon (`:`) before the serverless namespace UUID.
>
> - Provisioned cluster – `arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid`
> - Serverless – `arn:aws:redshift-serverless:{region}:{account-id}:namespace/namespace-uuid`

Sample policy for Redshift target

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "CreateIntegration",
      "Effect": "Allow",
```

```
      "Action": [
        "rds:CreateIntegration"
      ],
      "Resource": [
        "arn:aws-cn:rds:us-east-1:123456789012:db:source-db",
        "arn:aws-cn:rds:us-east-1:123456789012:integration:*"
      ]
    },
    {
      "Sid": "DescribeIntegrationDetails",
      "Effect": "Allow",
      "Action": [
        "rds:DescribeIntegrations"
      ],
      "Resource": [
      "arn:aws-cn:rds:us-east-1:123456789012:integration:*"
  ]
    },
    {
      "Sid": "ChangeIntegrationDetails",
      "Effect": "Allow",
      "Action": [
        "rds:DeleteIntegration",
        "rds:ModifyIntegration"
      ],
      "Resource": [
        "arn:aws-cn:rds:us-east-1:123456789012:integration:*"
      ]
    },
    {
      "Sid": "AllowRedShiftIntegration",
      "Effect": "Allow",
      "Action": [
        "redshift:CreateInboundIntegration"
      ],
      "Resource": [
        "arn:aws-cn:redshift:us-east-1:123456789012:namespace:namespace-uuid"
      ]
    }
  ]
}
```

Choosing a target data warehouse in a different account

If you plan to specify a target Amazon Redshift data warehouse that's in another Amazon Web Services account, you must create a role that allows users in the current account to access resources in the target account. For more information, see Providing access to an IAM user in another Amazon Web Services account that you own.

The role must have the following permissions, which allow the user to view available Amazon Redshift provisioned clusters and Redshift Serverless namespaces in the target account.

Required permissions and trust policy

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "redshift:DescribeClusters",
            "redshift-serverless:ListNamespaces"
         ],
         "Resource":[
            "*"
         ]
      }
   ]
}
```

The role must have the following trust policy, which specifies the target account ID.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
```

```
                "AWS": "arn:aws-cn:iam::111122223333:root"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

For instructions to create the role, see Creating a role using custom trust policies.

Creating zero-ETL integrations

You can create a zero-ETL integration using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

> **Important**
>
> zero-ETL integrations do not support refresh or resync operations. If you encounter issues with an integration after creation, you must delete the integration and create a new one.

RDS console

To create a zero-ETL integration

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the left navigation pane, choose **Zero-ETL integrations**.
3. Choose **Create zero-ETL integration**.
4. For **Integration identifier**, enter a name for the integration. The name can have up to 63 alphanumeric characters and can include hyphens.

   > **Important**
   >
   > Catalog names are limited to 19 characters in length. Ensure your integration identifier meets this requirement if it will be used as a catalog name.

5. Choose **Next**.
6. For **Source**, select the Aurora DB cluster where the data will originate from.

> **Note**
>
> RDS notifies you if the DB cluster parameters aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see the section called "Step 1: Create a custom DB cluster parameter group".
> Modifying DB cluster parameters requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter values must be successfully applied to the cluster.

7. (Optional) Select **Customize data filtering options** and add data filters to your integration. You can use data filters to define the scope of replication to the target data warehouse. For more information, see the section called "Data filtering for zero-ETL integrations".
8. Once your source DB cluster is successfully configured, choose **Next**.
9. For **Target**, do the following:

    1. (Optional) To use a different Amazon Web Services account for the Amazon Redshift target, choose **Specify a different account**. Then, enter the ARN of an IAM role with permissions to display your data warehouses. For instructions to create the IAM role, see the section called "Choosing a target data warehouse in a different account".
    2. For **Amazon Redshift data warehouse**, select the target for replicated data from the source DB cluster. You can choose a provisioned Amazon Redshift *cluster* or a Redshift Serverless *namespace* as the target.

> **Note**
>
> RDS notifies you if the resource policy or case sensitivity settings for the specified data warehouse aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see Turn on case sensitivity for your data warehouse and Configure authorization for your data warehouse in the *Amazon Redshift Management Guide*.
> Modifying case sensitivity for a *provisioned* Redshift cluster requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter value must be successfully applied to the cluster.

If your selected source and target are in different Amazon Web Services accounts, then Amazon RDS cannot fix these settings for you. You must navigate to the other account and fix them manually in Amazon Redshift.

10. Once your target data warehouse is configured correctly, choose **Next**.
11. (Optional) For **Tags**, add one or more tags to the integration. For more information, see the section called "Tagging Aurora and RDS resources".
12. For **Encryption**, specify how you want your integration to be encrypted. By default, RDS encrypts all integrations with an Amazon owned key. To choose a customer managed key instead, enable **Customize encryption settings** and choose a KMS key to use for encryption. For more information, see the section called "Encrypting Amazon Aurora resources".

    Optionally, add an encryption context. For more information, see Encryption context in the *Amazon Key Management Service Developer Guide*.

    Note

    Amazon RDS adds the following encryption context pairs in addition to any that you add:

    - `aws:redshift:integration:arn` - `IntegrationArn`
    - `aws:servicename:id` - `Redshift`

    This reduces the overall number of pairs that you can add from 8 to 6, and contributes to the overall character limit of the grant constraint. For more information, see Using grant constraints in the *Amazon Key Management Service Developer Guide*.
13. Choose **Next**.
14. Review your integration settings and choose **Create zero-ETL integration**.

    If creation fails, see the section called "I can't create a zero-ETL integration" for troubleshooting steps.

The integration has a status of `Creating` while it's being created, and the target Amazon Redshift data warehouse has a status of `Modifying`. During this time, you can't query the data warehouse or make any configuration changes on it.

When the integration is successfully created, the status of the integration and the target Amazon Redshift data warehouse both change to `Active`.

Amazon CLI

To create a zero-ETL integration using the Amazon CLI, use the create-integration command with the following options:

> **Note**
>
> Remember that catalog names are limited to 19 characters. Choose your integration name accordingly if it will be used as a catalog name.

- `--integration-name` – Specify a name for the integration.
- `--source-arn` – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- `--target-arn` – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

Example

For Linux, macOS, or Unix:

```
aws rds create-integration \
    --integration-name my-integration \
    --source-arn arn:aws:rds:{region}:{account-id}:my-db \
    --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

For Windows:

```
aws rds create-integration ^
    --integration-name my-integration ^
    --source-arn arn:aws:rds:{region}:{account-id}:my-db ^
    --target-arn arn:aws:redshift:{region}:{account-id}:namespace:namespace-uuid
```

RDS API

To create a zero-ETL integration by using the Amazon RDS API, use the `CreateIntegration` operation with the following parameters:

> **Note**
>
> Catalog names are limited to 19 characters. Ensure your IntegrationName parameter meets this requirement if it will be used as a catalog name.

- `IntegrationName` – Specify a name for the integration.
- `SourceArn` – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- `TargetArn` – Specify the ARN of the Amazon Redshift data warehouse that will be the target for the integration.

Encrypting integrations with a customer managed key

If you specify a custom KMS key rather than an Amazon owned key when you create an integration, the key policy must provide the Amazon Redshift service principal access to the `CreateGrant` action. In addition, it must allow the current user to perform to the `DescribeKey` and `CreateGrant` actions.

The following sample policy demonstrates how to provide the required permissions in the key policy. It includes context keys to further reduce the scope of permissions.

Sample key policy

JSON

```
{
    "Version":"2012-10-17",
    "Id": "Key policy",
    "Statement": [
        {
            "Sid": "Enables IAM user permissions",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:root"
            },
            "Action": "kms:*",
            "Resource": "*"
        },
```

```
        {
            "Sid": "Allows the Redshift service principal to add a grant to a KMS
key",
            "Effect": "Allow",
            "Principal": {
                "Service": "redshift.amazonaws.com"
            },
            "Action": "kms:CreateGrant",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "kms:EncryptionContext:{context-key}": "{context-value}"
                },
                "ForAllValues:StringEquals": {
                    "kms:GrantOperations": [
                        "Decrypt",
                        "GenerateDataKey",
                        "CreateGrant"
                    ]
                }
            }
        },
        {
            "Sid": "Allows the current user or role to add a grant to a KMS key",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:role/{role-name}"
            },
            "Action": "kms:CreateGrant",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "kms:EncryptionContext:{context-key}": "{context-value}",
                    "kms:ViaService": "rds.us-east-1.amazonaws.com"
                },
                "ForAllValues:StringEquals": {
                    "kms:GrantOperations": [
                        "Decrypt",
                        "GenerateDataKey",
                        "CreateGrant"
                    ]
                }
            }
        },
```

```
        {
            "Sid": "Allows the current uer or role to retrieve information about
 a KMS key",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:role/{role-name}"
            },
            "Action": "kms:DescribeKey",
            "Resource": "*"
        }
    ]
}
```

For more information, see Creating a key policy in the *Amazon Key Management Service Developer Guide*.

Next steps

After you successfully create a zero-ETL integration, you must create a destination database within your target Amazon Redshift cluster or workgroup. Then, you can start adding data to the source Aurora DB cluster and querying it in Amazon Redshift. For instructions, see Creating destination databases in Amazon Redshift.

Creating Aurora zero-ETL integrations with an Amazon SageMaker lakehouse

When you create an Aurora zero-ETL integration with an Amazon SageMaker lakehouse, you specify the source Aurora DB cluster and the target Amazon Glue managed catalog. You can also customize encryption settings and add tags. Aurora creates an integration between the source DB cluster and its target. Once the integration is active, any data that you insert into the source DB cluster will be replicated into the configured target.

Prerequisites

Before you create a zero-ETL integration with an Amazon SageMaker lakehouse, you must create a source DB cluster and a target Amazon Glue managed catalog. You also must allow replication into the catalog by adding the DB cluster as an authorized integration source.

For instructions to complete each of these steps, see the section called "Getting started with zero-ETL integrations".

Required permissions

Certain IAM permissions are required to create a zero-ETL integration with an Amazon SageMaker lakehouse. At minimum, you need permissions to perform the following actions:

- Create zero-ETL integrations for the source Aurora DB cluster.
- View and delete all zero-ETL integrations.
- Create inbound integrations into the target Amazon Glue managed catalog.
- Access Amazon S3 buckets used by the Amazon Glue managed catalog.
- Use Amazon KMS keys for encryption if custom encryption is configured.
- Register resources with Lake Formation.
- Put resource policy on the Amazon Glue managed catalog to authorize inbound integrations.

The following sample policy demonstrates the least privilege permissions required to create and manage integrations with an Amazon SageMaker lakehouse. You might not need these exact permissions if your user or role has broader permissions, such as an `AdministratorAccess` managed policy.

Additionally, you must configure a resource policy on the target Amazon Glue managed catalog to authorize inbound integrations. Use the following Amazon CLI command to apply the resource policy.

Sample Amazon CLI command to authorize inbound integrations on the target catalog

```
aws glue put-resource-policy \
      --policy-in-json  '{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Principal": {
            "Service": "glue.amazonaws.com"
        },
        "Action": [
            "glue:AuthorizeInboundIntegration"
        ],
```

```
        "Resource": ["arn:aws:glue:region:account_id:catalog/catalog_name"],
        "Condition": {
            "StringEquals": {
                "aws:SourceArn": "arn:aws:rds:region:account_id:db:source_name"
            }
        }
    },
    {
        "Effect": "Allow",
        "Principal": {
            "AWS": "account_id"
        },
        "Action": ["glue:CreateInboundIntegration"],
        "Resource": ["arn:aws:glue:region:account_id:catalog/catalog_name"]
    }
    ]
}' \
      --region region
```

Note

Glue catalog Amazon Resource Names (ARNs) have the following format:

- Glue catalog – `arn:aws:glue:{region}:{account-id}:catalog/catalog-name`

Choosing a target Amazon Glue managed catalog in a different account

If you plan to specify a target Amazon Glue managed catalog that's in another Amazon Web Services account, you must create a role that allows users in the current account to access resources in the target account. For more information, see Providing access to an IAM user in another Amazon Web Services account that you own.

The role must have the following permissions, which allow the user to view available Amazon Glue catalogs in the target account.

Required permissions and trust policy

JSON

```
{
```

```
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "glue:GetCatalog"
         ],
         "Resource":[
            "*"
         ]
      }
   ]
}
```

The role must have the following trust policy, which specifies the target account ID.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "AWS": "arn:aws-cn:iam::111122223333:root"
         },
         "Action":"sts:AssumeRole"
      }
   ]
}
```

For instructions to create the role, see Creating a role using custom trust policies.

Creating zero-ETL integrations with an Amazon SageMaker lakehouse

You can create a zero-ETL integration with an Amazon SageMaker lakehouse using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

> **Important**
>
> Zero-ETL integrations with an Amazon SageMaker lakehouse do not support refresh or resync operations. If you encounter issues with an integration after creation, you must delete the integration and create a new one.

RDS console

To create a zero-ETL integration with an Amazon SageMaker lakehouse

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the left navigation pane, choose **Zero-ETL integrations**.
3. Choose **Create zero-ETL integration**.
4. For **Integration identifier**, enter a name for the integration. The name can have up to 63 alphanumeric characters and can include hyphens.
5. Choose **Next**.
6. For **Source**, select the Aurora DB cluster where the data will originate from.

   > **Note**
   >
   > RDS notifies you if the DB cluster parameters aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually. For instructions to fix them manually, see the section called "Step 1: Create a custom DB cluster parameter group".
   > Modifying DB cluster parameters requires a reboot. Before you can create the integration, the reboot must be complete and the new parameter values must be successfully applied to the cluster.

7. (Optional) Select **Customize data filtering options** and add data filters to your integration. You can use data filters to define the scope of replication to the target Amazon SageMaker lakehouse. For more information, see the section called "Data filtering for zero-ETL integrations".
8. Once your source DB cluster is successfully configured, choose **Next**.
9. For **Target**, do the following:

1. (Optional) To use a different Amazon Web Services account for the Amazon SageMaker lakehouse target, choose **Specify a different account**. Then, enter the ARN of an IAM role with permissions to display your Amazon Glue catalogs. For instructions to create the IAM role, see the section called “Choosing a target Amazon Glue managed catalog in a different account”.
2. For **Amazon Glue catalog**, select the target for replicated data from the source DB cluster. You can choose an existing Amazon Glue managed catalog as the target.
3. The target IAM role needs describe permissions on the target catalog and must have the following permissions:

   JSON

   ```
   {
       "Version":"2012-10-17",
       "Statement": [
           {
               "Sid": "VisualEditor0",
               "Effect": "Allow",
               "Action": "glue:GetCatalog",
               "Resource": [
                   "arn:aws-cn:glue:us-east-1:111122223333:catalog/*",
                   "arn:aws-cn:glue:us-east-1:111122223333:catalog"
               ]
           }
       ]
   }
   ```

   The target IAM role must have the following trust relationship:

   JSON

   ```
   {
       "Version":"2012-10-17",
       "Statement": [
           {
               "Effect": "Allow",
               "Principal": {
                   "Service": "glue.amazonaws.com"
               },
               "Action": "sts:AssumeRole"
   ```

```
        }
    ]
}
```

4. You must grant the target IAM role describe permissions for the target Amazon Glue managed catalog with the Lake Formation administrator role created in Step 3b: Create an Amazon Glue catalog for Amazon SageMaker Lakehouse zero-ETL integration.

> **Note**
>
> RDS notifies you if the resource policy or configuration settings for the specified Amazon Glue managed catalog aren't configured correctly. If you receive this message, you can either choose **Fix it for me**, or configure them manually.
> If your selected source and target are in different Amazon Web Services accounts, then Amazon RDS cannot fix these settings for you. You must navigate to the other account and fix them manually in SageMaker Unified Studio.

10. Once your target Amazon Glue managed catalog is configured correctly, choose **Next**.
11. (Optional) For **Tags**, add one or more tags to the integration. For more information, see the section called "Tagging Aurora and RDS resources".
12. For **Encryption**, specify how you want your integration to be encrypted. By default, RDS encrypts all integrations with an Amazon owned key. To choose a customer managed key instead, enable **Customize encryption settings** and choose a KMS key to use for encryption. For more information, see the section called "Encrypting Amazon Aurora resources".

    Optionally, add an encryption context. For more information, see Encryption context in the *Amazon Key Management Service Developer Guide*.

> **Note**
>
> Amazon RDS adds the following encryption context pairs in addition to any that you add:
>
> - `aws:glue:integration:arn` - `IntegrationArn`
> - `aws:servicename:id` - `glue`

This reduces the overall number of pairs that you can add from 8 to 6, and contributes to the overall character limit of the grant constraint. For more information, see Using grant constraints in the *Amazon Key Management Service Developer Guide*.

13. Choose **Next**.
14. Review your integration settings and choose **Create zero-ETL integration**.

    If creation fails, see the section called "Troubleshooting zero-ETL integrations" for troubleshooting steps.

The integration has a status of `Creating` while it's being created, and the target Amazon SageMaker lakehouse has a status of `Modifying`. During this time, you can't query the catalog or make any configuration changes on it.

When the integration is successfully created, the status of the integration and the target Amazon SageMaker lakehouse both change to `Active`.

Amazon CLI

To prepare a target Amazon Glue managed catalog for zero-ETL integration using the Amazon CLI, you must first use the create-integration-resource-property command with the following options:

- `--resource-arn` – Specify the ARN of the Amazon Glue managed catalog that will be the target for the integration.
- `--target-processing-properties` – Specify the ARN of the IAM role to access the target Amazon Glue managed catalog

```
aws glue create-integration-resource-property --region us-east-1
 --resource-arn arn:aws:glue:region:account_id:catalog/catalog_name \
 --target-processing-properties '{"RoleArn" : "arn:aws:iam::account_id:role/
TargetIamRole"}'
```

To create a zero-ETL integration with an Amazon SageMaker lakehouse using the Amazon CLI, use the create-integration command with the following options:

- `--integration-name` – Specify a name for the integration.

- `--source-arn` – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- `--target-arn` – Specify the ARN of the Amazon Glue managed catalog that will be the target for the integration.

Example

For Linux, macOS, or Unix:

```
aws rds create-integration \
    --integration-name my-sagemaker-integration \
    --source-arn arn:aws:rds:{region}:{account-id}:cluster:my-db \
    --target-arn arn:aws:glue:{region}:{account-id}:catalog/catalog-name
```

For Windows:

```
aws rds create-integration ^
    --integration-name my-sagemaker-integration ^
    --source-arn arn:aws:rds:{region}:{account-id}:cluster:my-db ^
    --target-arn arn:aws:glue:{region}:{account-id}:catalog/catalog-name
```

RDS API

To create a zero-ETL integration with Amazon SageMaker by using the Amazon RDS API, use the `CreateIntegration` operation with the following parameters:

> **Note**
>
> Catalog names are limited to 19 characters. Ensure your IntegrationName parameter meets this requirement if it will be used as a catalog name.

- `IntegrationName` – Specify a name for the integration.
- `SourceArn` – Specify the ARN of the Aurora DB cluster that will be the source for the integration.
- `TargetArn` – Specify the ARN of the Amazon Glue managed catalog that will be the target for the integration.

Encrypting integrations with a customer managed key

If you specify a custom KMS key rather than an Amazon owned key when you create an integration with Amazon SageMaker, the key policy must provide the SageMaker Unified Studio service principal access to the `CreateGrant` action. In addition, it must allow the current user to perform to the `DescribeKey` and `CreateGrant` actions.

The following sample policy demonstrates how to provide the required permissions in the key policy. It includes context keys to further reduce the scope of permissions.

Sample key policy

JSON

```
{
    "Version":"2012-10-17",
    "Id": "Key policy",
    "Statement": [
        {
            "Sid": "EnablesIAMUserPermissions",
            "Effect": "Allow",
            "Principal": {
            "AWS": "arn:aws-cn:iam::111122223333:root"
            },
            "Action": "kms:*",
            "Resource": "*"
        },
        {
            "Sid": "GlueServicePrincipalAddGrant",
            "Effect": "Allow",
            "Principal": {
                "Service": "glue.amazonaws.com"
            },
            "Action": "kms:CreateGrant",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "kms:EncryptionContext:{context-key}":"{context-value}"
                },
                "ForAllValues:StringEquals": {
                    "kms:GrantOperations": [
                        "Decrypt",
```

```
                    "GenerateDataKey",
                    "CreateGrant"
                ]
            }
        }
    },
    {
        "Sid": "AllowsCurrentUserRoleAddGrantKMSKey",
        "Effect": "Allow",
        "Principal": {
        "AWS": "arn:aws-cn:iam::111122223333:role/{role-name}"
        },
        "Action": "kms:CreateGrant",
        "Resource": "*",
        "Condition": {
            "StringEquals": {
                "kms:EncryptionContext:{context-key}":"{context-value}",
                "kms:ViaService": "rds.us-east-1.amazonaws.com"
            },
            "ForAllValues:StringEquals": {
                "kms:GrantOperations": [
                    "Decrypt",
                    "GenerateDataKey",
                    "CreateGrant"
                ]
            }
        }
    },
    {
        "Sid": "AllowsCurrentUserRoleRetrieveKMSKeyInformation",
        "Effect": "Allow",
        "Principal": {
        "AWS": "arn:aws-cn:iam::111122223333:role/{role-name}"
        },
        "Action": "kms:DescribeKey",
        "Resource": "*"
    }
  ]
}
```

For more information, see Creating a key policy in the *Amazon Key Management Service Developer Guide*.

Next steps

After you successfully create a zero-ETL integration with Amazon SageMaker, you can start adding data to the source Aurora DB cluster and querying it in your Amazon SageMaker lakehouse. The data will be automatically replicated and made available for analytics and machine learning workloads.

Data filtering for Aurora zero-ETL integrations

Aurora zero-ETL integrations support data filtering, which lets you control which data is replicated from your source Aurora DB cluster to your target data warehouse. Instead of replicating the entire database, you can apply one or more filters to selectively include or exclude specific tables. This helps you optimize storage and query performance by ensuring that only relevant data is transferred. Currently, filtering is limited to the database and table levels. Column- and row-level filtering are not supported.

Data filtering can be useful when you want to:

- Join certain tables from two or more different source clusters, and you don't need complete data from either cluster.
- Save costs by performing analytics using only a subset of tables rather than an entire fleet of databases.
- Filter out sensitive information—such as phone numbers, addresses, or credit card details—from certain tables.

You can add data filters to a zero-ETL integration using the Amazon Web Services Management Console, the Amazon Command Line Interface (Amazon CLI), or the Amazon RDS API.

If the integration has a provisioned cluster as its target, the cluster must be on patch 180 or higher to use data filtering.

Topics

- Format of a data filter

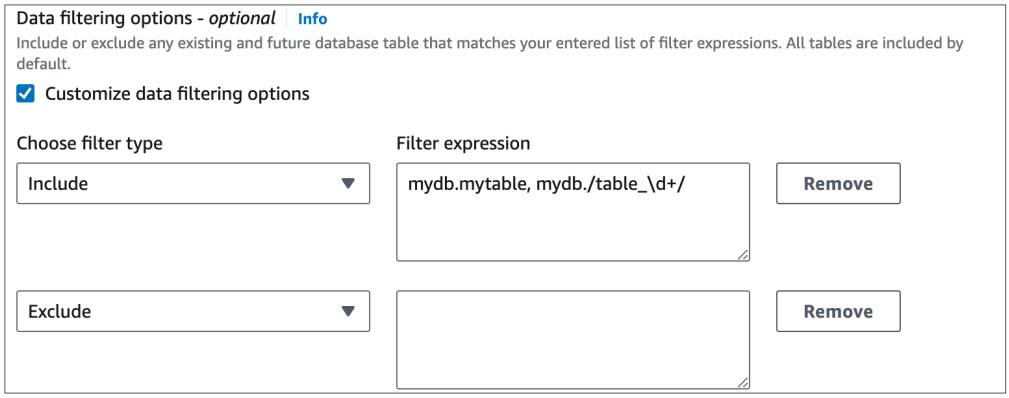
- Aurora PostgreSQL examples

- Adding data filters to an integration
- Removing data filters from an integration

Format of a data filter

You can define multiple filters for a single integration. Each filter either includes or excludes any existing and future database tables that match one of the patterns in the filter expression. Aurora zero-ETL integrations use Maxwell filter syntax for data filtering.

Each filter has the following elements:



Element	Description
Filter type	An `Include` filter type *includes* all tables that match one of the patterns in the filter expression. An `Exclude` filter type *excludes* all tables that match one of the patterns.
Filter expression	A comma-separated list of patterns. Expressions must use Maxwell filter syntax.
Pattern	A filter pattern in the format *`database`*`.`*`table`* for Aurora MySQL, or *`database`*`.`*`schema`*`.`*`table`* for Aurora PostgreSQL. You can specify literal names, or define regular expressions. **Note** For Aurora MySQL, regular expressio ns are supported in both the database and table name. For Aurora PostgreSQL, regular expressions are supported only in the schema and table name, not in the database name.

Element	Description
	You can't include column-level filters or denylists. A single integration can have a maximum of 99 total patterns. In the console, you can enter patterns within a single filter expressio n, or spread them out among multiple expressions. A single pattern can't exceed 256 characters in length.

Important

If you select an Aurora PostgreSQL source DB cluster, you must specify at least one data filter pattern. At minimum, the pattern must include a single database (*database-name*`.*.*`) for replication to the target data warehouse.

The following image shows the structure of Aurora MySQL data filters in the console:

Important

Do not include personally identifying, confidential, or sensitive information in your filter patterns.

Data filters in the Amazon CLI

When using the Amazon CLI to add a data filter, the syntax differs slightly from the console. You must assign a filter type (`Include` or `Exclude`) to each pattern individually, so you can't group multiple patterns under one filter type.

For example, in the console you can group the following comma-separated patterns under a single `Include` statement:

Aurora MySQL

```
mydb.mytable, mydb./table_\d+/
```

Aurora PostgreSQL

```
mydb.myschema.mytable, mydb.myschema./table_\d+/
```

However, when using the Amazon CLI, the same data filter must be in the following format:

Aurora MySQL

```
'include: mydb.mytable, include: mydb./table_\d+/'
```

Aurora PostgreSQL

```
'include: mydb.myschema.mytable, include: mydb.myschema./table_\d+/'
```

Filter logic

If you don't specify any data filters in your integration, Aurora assumes a default filter of `include:*.*`, which replicates all tables to the target data warehouse. However, if you add at least one filter, the default logic switches to `exclude:*.*`, which excludes all tables by default. This lets you explicitly define which databases and tables to include in replication.

For example, if you define the following filter:

```
'include: db.table1, include: db.table2'
```

Aurora evaluates the filter as follows:

```
'exclude:*.*, include: db.table1, include: db.table2'
```

Therefore, Aurora only replicates `table1` and `table2` from the database named db to the target data warehouse.

Filter precedence

Aurora evaluates data filters in the order you specify. In the Amazon Web Services Management Console, it processes filter expressions from left to right and top to bottom. A second filter or an individual pattern that follows the first can override it.

For example, if the first filter is `Include books.stephenking`, it includes only the `stephenking` table from the `books` database. However, if you add a second filter, `Exclude books.*`, it overrides the first filter. This prevents any tables from the `books` index from being replicated to the target data warehouse.

When you specify at least one filter, the logic starts by assuming `exclude:*.*` by default, which automatically *excludes* all tables from replication. As a best practice, define filters from broadest to most specific. Start with one or more `Include` statements to specify the data to replicate, then add `Exclude` filters to selectively remove certain tables.

The same principle applies to filters that you define using the Amazon CLI. Aurora evaluates these filter patterns in the order that you specify them, so a pattern might override one that you specify before it.

Aurora MySQL examples

The following examples demonstrate how data filtering works for Aurora MySQL examples zero-ETL integrations:

- Include all databases and all tables:

  ```
  'include: *.*'
  ```

- Include all tables within the `books` database:

  ```
  'include: books.*'
  ```

- Exclude any tables named `mystery`:

```
'include: *.*, exclude: *.mystery'
```

- Include two specific tables within the `books` database:

```
'include: books.stephen_king, include: books.carolyn_keene'
```

- Include all tables in the `books` database, except for those containing the substring `mystery`:

```
'include: books.*, exclude: books./.*mystery.*/'
```

- Include all tables in the `books` database, except those starting with `mystery`:

```
'include: books.*, exclude: books./mystery.*/'
```

- Include all tables in the `books` database, except those ending with `mystery`:

```
'include: books.*, exclude: books./.*mystery/'
```

- Include all tables in the `books` database that start with `table_`, except for the one named `table_stephen_king`. For example, `table_movies` or `table_books` would be replicated, but not `table_stephen_king`.

```
'include: books./table_.*/, exclude: books.table_stephen_king'
```

Aurora PostgreSQL examples

The following examples demonstrate how data filtering works for Aurora PostgreSQL zero-ETL integrations:

- Include all tables within the `books` database:

```
'include: books.*.*'
```

- Exclude any tables named `mystery` in the `books` database:

```
'include: books.*.*, exclude: books.*.mystery'
```

- Include one table within the `books` database in the `mystery` schema, and one table within `employee` database in the `finance` schema:

```
'include: books.mystery.stephen_king, include: employee.finance.benefits'
```

- Include all tables in the `books` database and `science_fiction` schema, except for those containing the substring `king`:

```
'include: books.science_fiction.*, exclude: books.*./.*king.*/
```

- Include all tables in the `books` database, except those with a schema name starting with `sci`:

```
'include: books.*.*, exclude: books./sci.*/.*'
```

- Include all tables in the `books` database, except those in the `mystery` schema ending with `king`:

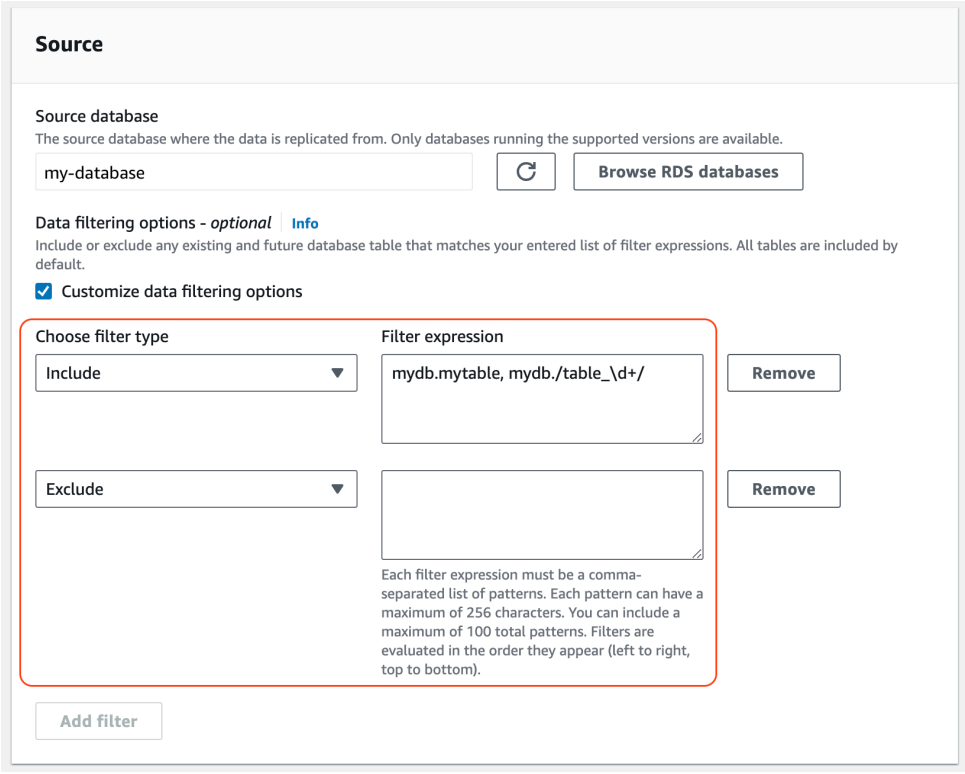
```
'include: books.*.*, exclude: books.mystery./.*king/'
```

- Include all tables in the `books` database that start with `table_`, except for the one named `table_stephen_king`. For example, `table_movies` in the `fiction` schema and `table_books` in the `mystery` schema are replicated, but not `table_stephen_king` in either schema:

```
'include: books.*./table_.*/, exclude: books.*.table_stephen_king'
```

Adding data filters to an integration

You can configure data filtering using the Amazon Web Services Management Console, the Amazon CLI, or the Amazon RDS API.



> **Important**
>
> If you add a filter after you create an integration, Aurora treats it as if it always existed. It removes any data in the target data warehouse that doesn't match the new filtering criteria and resynchronizes all affected tables.

RDS console

To add data filters to a zero-ETL integration

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Zero-ETL integrations**. Select the integration that you want to add data filters to, and then choose **Modify**.
3. Under **Source**, add one or more `Include` and `Exclude` statements.

   The following image shows an example of data filters for a MySQL integration:

4. When you're satisfied with the changes, choose **Continue** and **Save changes**.

Amazon CLI

To add data filters to a zero-ETL integration using the Amazon CLI, call the modify-integration command. In addition to the integration identifier, specify the `--data-filter` parameter with a comma-separated list of `Include` and `Exclude` Maxwell filters.

Example

The following example adds filter patterns to `my-integration`.

For Linux, macOS, or Unix:

```
aws rds modify-integration \
    --integration-identifier my-integration \
    --data-filter 'include: foodb.*, exclude: foodb.tbl, exclude: foodb./table_\d+/'
```

For Windows:

```
aws rds modify-integration ^
    --integration-identifier my-integration ^
    --data-filter 'include: foodb.*, exclude: foodb.tbl, exclude: foodb./table_\d+/'
```

RDS API

To modify a zero-ETL integration using the RDS API, call the ModifyIntegration operation. Specify the integration identifier and provide a comma-separated list of filter patterns.

Removing data filters from an integration

When you remove a data filter from an integration, Aurora reevaluates the remaining filters as if the removed filter never existed. It then replicates any previously excluded data that now meets the criteria into the target data warehouse. This triggers a resynchronization of all affected tables.

Adding data to a source Aurora DB cluster and querying it

To finish creating a zero-ETL integration that replicates data from Amazon Aurora into Amazon Redshift, you must create a database in the target destination.

For connections with Amazon Redshift, connect to your Amazon Redshift cluster or workgroup and create a database with a reference to your integration identifier. Then, you can add data to your source Aurora DB cluster and see it replicated in Amazon Redshift or Amazon SageMaker.

Topics

- Creating a target database
- Adding data to the source DB cluster
- Querying your Aurora data in Amazon Redshift

- Data type differences between Aurora and Amazon Redshift databases
- DDL operations for Aurora PostgreSQL

Creating a target database

Before you can start replicating data into Amazon Redshift, after you create an integration, you must create a database in your target data warehouse. This database must include a reference to the integration identifier. You can use the Amazon Redshift console or the Query editor v2 to create the database.

For instructions to create a destination database, see Create a destination database in Amazon Redshift.

Adding data to the source DB cluster

After you configure your integration, you can populate the source Aurora DB cluster with data that you want to replicate into your data warehouse.

> **Note**
>
> There are differences between data types in Amazon Aurora and the target analytics warehouse. For a table of data type mappings, see the section called “Data type differences”.

First, connect to the source DB cluster using the MySQL or PostgreSQL client of your choice. For instructions, see the section called “Connecting to a DB cluster”.

Then, create a table and insert a row of sample data.

> **Important**
>
> Make sure that the table has a primary key. Otherwise, it can't be replicated to the target data warehouse.

The pg_dump and pg_restore PostgreSQL utilities initially create tables without a primary key and then add it afterwards. If you're using one of these utilities, we recommend first creating a schema and then loading data in a separate command.

MySQL

The following example uses the MySQL Workbench utility.

```
CREATE DATABASE my_db;

USE my_db;

CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL, Author
 VARCHAR(50) NOT NULL,
Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));

INSERT INTO books_table VALUES (1, 'The Shining', 'Stephen King', 1977, 'Supernatural
 fiction');
```

PostgreSQL

The following example uses the psql PostgreSQL interactive terminal. When connecting to the cluster, include the named database that you specified when creating the integration.

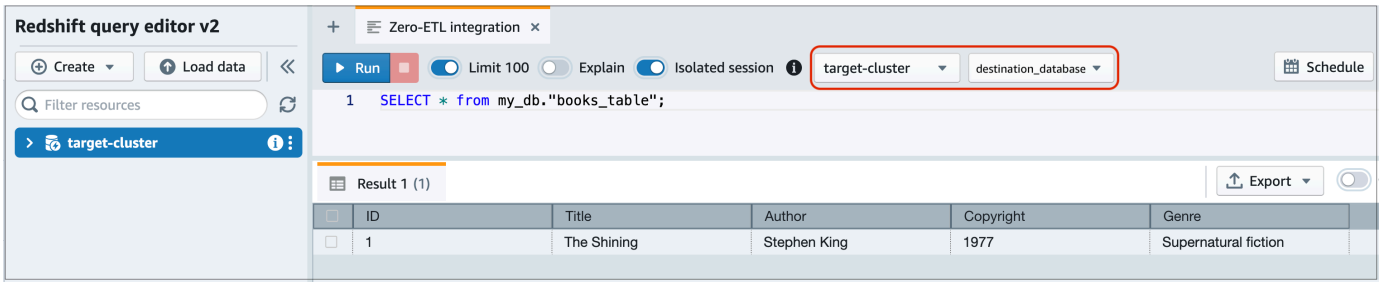
```
psql -h mycluster.cluster-123456789012.us-east-2.rds.amazonaws.com -p 5432 -U username
 -d named_db;

named_db=> CREATE TABLE books_table (ID int NOT NULL, Title VARCHAR(50) NOT NULL,
 Author VARCHAR(50) NOT NULL,
Copyright INT NOT NULL, Genre VARCHAR(50) NOT NULL, PRIMARY KEY (ID));

named_db=> INSERT INTO books_table VALUES (1, 'The Shining', 'Stephen King', 1977,
 'Supernatural fiction');
```

Querying your Aurora data in Amazon Redshift

After you add data to the Aurora DB cluster, it's replicated into the destination database and is ready to be queried.



To query the replicated data

1. Navigate to the Amazon Redshift console and choose **Query editor v2** from the left navigation pane.
2. Connect to your cluster or workgroup and choose your destination database (which you created from the integration) from the dropdown menu (**destination_database** in this

example). For instructions to create a destination database, see Create a destination database in Amazon Redshift.

3. Use a SELECT statement to query your data. In this example, you can run the following command to select all data from the table that you created in the source Aurora DB cluster:

```
SELECT * from my_db."books_table";
```

- *my_db* is the Aurora database schema name. This option is only needed for MySQL databases.
- *books_table* is the Aurora table name.

You can also query the data using the a command line client. For example:

```
destination_database=# select * from my_db."books_table";

 ID |       Title |        Author |   Copyright |                  Genre |  txn_seq |
 txn_id
----+-------------+---------------+-------------+------------------------+----------
+--------+
  1 | The Shining |  Stephen King |        1977 |   Supernatural fiction |        2 |
 12192
```

> **Note**
>
> For case-sensitivity, use double quotes (" ") for schema, table, and column names. For more information, see enable_case_sensitive_identifier.

Data type differences between Aurora and Amazon Redshift databases

The following tables show the mappings of Aurora MySQL and Aurora PostgreSQL data types to corresponding destination data types. *Amazon Aurora currently supports only these data types for zero-ETL integrations.*

If a table in your source DB cluster includes an unsupported data type, the table goes out of sync and isn't consumable by the destination target. Streaming from the source to the target continues, but the table with the unsupported data type isn't available. To fix the table and make it available in the target destination, you must manually revert the breaking change and then refresh the integration by running `ALTER DATABASE...INTEGRATION REFRESH`.

> **Note**
>
> You can't refresh zero-ETL integrations with an Amazon SageMaker lakehouse. Instead, delete and try to create the integration again.

Aurora PostgreSQL

Zero-ETL integrations for Aurora PostgreSQL don't support custom data types or data types created by extensions. This includes enum types that you create with `CREATE TYPE ... AS ENUM`, and arrays of such types. If a table contains a column with an unsupported data type, Amazon Redshift doesn't replicate the table, and the table state is `Failed`. To replicate the rest of your data, exclude the table by using a data filter. For more information, see Data filtering for Aurora zero-ETL integrations.

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
array	SUPER	Semistructured data or documents as values	Arrays of unsupported data types, such as enum types, aren't supported
bigint	BIGINT	Signed eight-byte integer	None
bigserial	BIGINT	Signed eight-byte integer	None
bit varying(n)	VARBYTE(n)	Variable-length binary value up to 16,777,216 bytes	None

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
bit(n)	VARBYTE(n)	Variable-length binary value up to 16,777,216 bytes	None
bit, bit varying	VARBYTE(16777216)	Variable-length binary value up to 16,777,216 bytes	None
boolean	BOOLEAN	Logical boolean (true/false)	None
bytea	VARBYTE(16777216)	Variable-length binary value up to 16,777,216 bytes	None
char(n)	CHAR(n)	Fixed-length character string value up to 65,535 bytes	None
char varying(n)	VARCHAR(65535)	Variable-length character string value up to 65,535 characters	None
cid	BIGINT	Signed eight-byte integer	None
cidr	VARCHAR(19)	Variable-length string value up to 19 characters	None

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
date	DATE	Calendar date (year, month, day)	Values greater than 294,276 A.D. not supported
double precision	DOUBLE PRECISION	Double precision floating-point numbers	Subnormal values not fully supported

xid	BIGINT	Signed eight-byte integer	None

Aurora PostgreSQL data type	Amazon Redshift data type	Description	Limitations
xid8	DECIMAL(20, 0)	Fixed precision decimal	None
xml	VARCHAR(65535)	Variable-length string value up to 65,535 characters	None

DDL operations for Aurora PostgreSQL

Amazon Redshift is derived from PostgreSQL, so it shares several features with Aurora PostgreSQL due to their common PostgreSQL architecture. Zero-ETL integrations leverage these similarities to streamline data replication from Aurora PostgreSQL to Amazon Redshift, mapping databases by name and utilizing the shared database, schema, and table structure.

Consider the following points when managing Aurora PostgreSQL zero-ETL integrations:

- Isolation is managed at the database level.
- Replication occurs at the database level.
- Aurora PostgreSQL databases are mapped to Amazon Redshift databases by name, with data flowing to the corresponding renamed Redshift database if the original is renamed.

Despite their similarities, Amazon Redshift and Aurora PostgreSQL have important differences. The following sections outline Amazon Redshift system responses for common DDL operations.

Topics

- Database operations
- Schema operations
- Table operations

Database operations

The following table shows the system responses for database DDL operations.

DDL operation	Redshift system response
`CREATE DATABASE`	No operation
`DROP DATABASE`	Amazon Redshift drops all the data in the target Redshift database.
`RENAME DATABASE`	Amazon Redshift drops all the data in the original target database and resynchro nize the data in the new target database. If the new database doesn't exist, you must manually create it. For instructions, see Create a destination database in Amazon Redshift.

Schema operations

The following table shows the system responses for schema DDL operations.

DDL operation	Redshift system response
`CREATE SCHEMA`	No operation
`DROP SCHEMA`	Amazon Redshift drops the original schema.
`RENAME SCHEMA`	Amazon Redshift drops the original schema then resynchronizes the data in the new schema.

Table operations

The following table shows the system responses for table DDL operations.

DDL operation	Redshift system response
`CREATE TABLE`	Amazon Redshift creates the table.

DDL operation	Redshift system response
	Some operations cause table creation to fail, such as creating a table without a primary key or performing declarative partitioning. For more information, see the section called "Limitations" and the section called "Troubleshooting zero-ETL integrations".
`DROP TABLE`	Amazon Redshift drops the table.
`TRUNCATE TABLE`	Amazon Redshift truncates the table.
`ALTER TABLE (RENAME... )`	Amazon Redshift renames the table or column.
`ALTER TABLE (SET SCHEMA)`	Amazon Redshift drops the table in the original schema and resynchronizes the table in the new schema.
`ALTER TABLE (ADD PRIMARY KEY)`	Amazon Redshift adds a primary key and resynchronizes the table.
`ALTER TABLE (ADD COLUMN)`	Amazon Redshift adds a column to the table.
`ALTER TABLE (DROP COLUMN)`	Amazon Redshift drops the column if it's not a primary key column. Otherwise, it resynchronizes the table.
`ALTER TABLE (SET LOGGED/UNLOGGED )`	If you change the table to logged, Amazon Redshift resynchronizes the table. If you change the table to unlogged, Amazon Redshift drops the table.

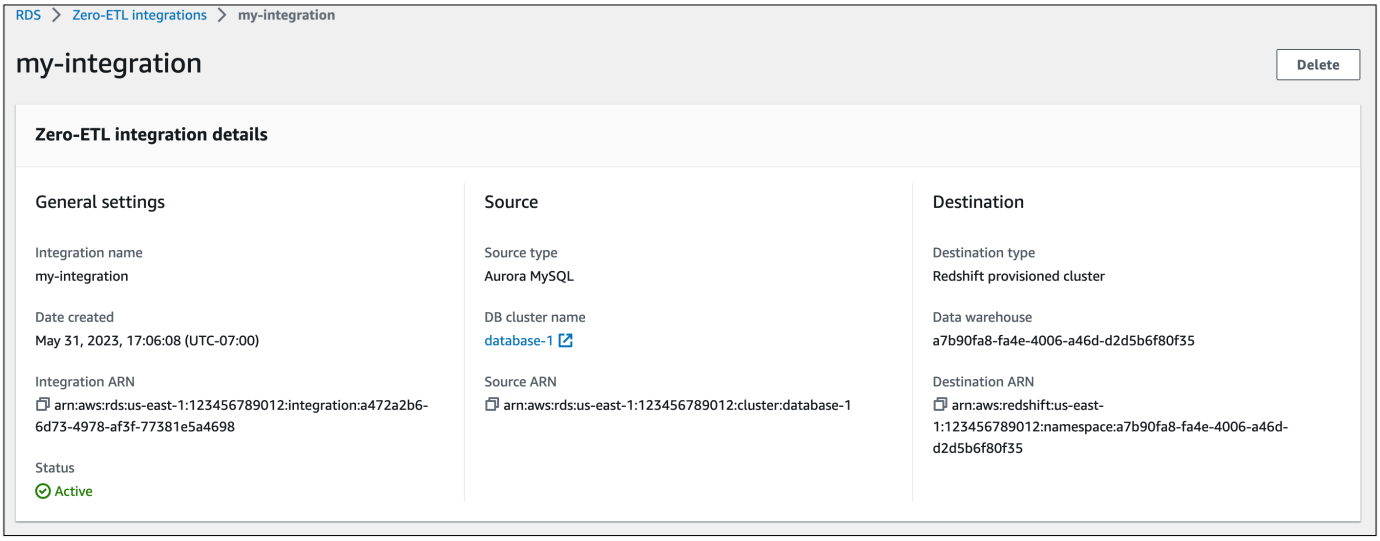
Viewing and monitoring Aurora zero-ETL integrations

You can view the details of an Amazon Aurora zero-ETL integration to see its configuration information and current status. You can also monitor the status of your integration by querying specific system views in Amazon Redshift. In addition, Amazon Redshift publishes certain

integration-related metrics to Amazon CloudWatch, which you can view within the Amazon Redshift console.

Topics

- Viewing integrations
- Monitoring integrations using system tables for Amazon Redshift
- Monitoring integrations with Amazon EventBridge for Amazon Redshift



Viewing integrations

You can view Aurora zero-ETL integrations using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

Console

To view the details of a zero-ETL integration

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. From the left navigation pane, choose **Zero-ETL integrations**.
3. Select an integration to view more details about it, such as its source DB cluster and target data warehouse.

An integration can have the following statuses:

- `Creating` – The integration is being created.
- `Active` – The integration is sending transactional data to the target data warehouse.
- `Syncing` – The integration has encountered a recoverable error and is reseeding data. Affected tables aren't available for querying until they finish resyncing.
- `Needs attention` – The integration encountered an event or error that requires manual intervention to resolve it. To fix the issue, follow the instructions in the error message on the integration details page.
- `Failed` – The integration encountered an unrecoverable event or error that can't be fixed. You must delete and recreate the integration.
- `Deleting` – The integration is being deleted.

Amazon CLI

To view all zero-ETL integrations in the current account using the Amazon CLI, use the describe-integrations command and specify the `--integration-identifier` option.

Example

For Linux, macOS, or Unix:

```
aws rds describe-integrations \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```
aws rds describe-integrations ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

RDS API

To view zero-ETL integration using the Amazon RDS API, use the `DescribeIntegrations` operation with the `IntegrationIdentifier` parameter.

Monitoring integrations using system tables for Amazon Redshift

Amazon Redshift has system tables and views that contain information about how the system is functioning. You can query these system tables and views the same way that you would query any

other database table. For more information about system tables and views in Amazon Redshift, see System tables and views reference in the *Amazon Redshift Database Developer Guide*.

You can query the following system views and tables to get information about your Aurora zero-ETL integrations:

- SVV_INTEGRATION – Provides configuration details for your integrations.
- SVV_INTEGRATION_TABLE_STATE – Describes the state of each table within an integration.
- SYS_INTEGRATION_TABLE_STATE_CHANGE – Displays table state change logs for an integration.
- SYS_INTEGRATION_ACTIVITY – Provides information about completed integration runs.

All integration-related Amazon CloudWatch metrics originate from Amazon Redshift. For more information, see Metrics for zero-ETL integrations in the *Amazon Redshift Management Guide*. Currently, Amazon Aurora doesn't publish any integration metrics to CloudWatch.

Monitoring integrations with Amazon EventBridge for Amazon Redshift

Amazon Redshift send integration-related events to Amazon EventBridge. For a list of events and their corresponding event IDs, see Zero-ETL integration event notifications with Amazon EventBridge in the *Amazon Redshift Management Guide*.

Modifying Aurora zero-ETL integrations

You can modify only the name, description, and data filtering options for a zero-ETL integration in a supported data warehouse. You can't modify the Amazon KMS key used to encrypt the integration, or the source or target databases.

If you add a data filter to an existing integration, Aurora reevaluates the filter as if it always existed. It removes any data that is currently in the target data warehouse that doesn't match the new filtering criteria. If you *remove* a data filter from an integration, it replicates any data that previously didn't match the filtering criteria (but now does) into the target data warehouse. For more information, see the section called “Data filtering for zero-ETL integrations”.

You can modify a zero-ETL integration using the Amazon Web Services Management Console, the Amazon CLI, or the Amazon RDS API.

RDS console

To modify a zero-ETL integration

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Zero-ETL integrations**, and then choose the integration that you want to modify.
3. Choose **Modify** and make modifications to any available settings.
4. When all the changes are as you want them, choose **Modify**.

Amazon CLI

To modify a zero-ETL integration using the Amazon CLI, call the modify-integration command. Along with the `--integration-identifier`, specify any of the following options:

- `--integration-name` – Specify a new name for the integration.
- `--description` – Specify a new description for the integration.
- `--data-filter` – Specify data filtering options for the integration. For more information, see the section called "Data filtering for zero-ETL integrations".

Example

The following request modifies an existing integration.

For Linux, macOS, or Unix:

```
aws rds modify-integration \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374 \
    --integration-name my-renamed-integration
```

For Windows:

```
aws rds modify-integration ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374 ^
    --integration-name my-renamed-integration
```

RDS API

To modify a zero-ETL integration using the RDS API, call the ModifyIntegration operation. Specify the integration identifier, and the parameters that you want to modify.

Deleting Aurora zero-ETL integrations

When you delete a zero-ETL integration, Amazon Aurora removes it from the source Aurora DB cluster. Your transactional data isn't deleted from Amazon Aurora or the analytics destination, but Aurora doesn't send new data to Amazon Redshift or Amazon SageMaker.

You can only delete an integration when it has a status of `Active`, `Failed`, `Syncing`, or `Needs attention`.

You can delete zero-ETL integrations using the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

Console

To delete a zero-ETL integration

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. From the left navigation pane, choose **Zero-ETL integrations**.
3. Select the zero-ETL integration that you want to delete.
4. Choose **Actions**, **Delete**, and confirm deletion.

Amazon CLI

To delete a zero-ETL integration, use the delete-integration command and specify the `--integration-identifier` option.

Example

For Linux, macOS, or Unix:

```
aws rds delete-integration \
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

For Windows:

```
aws rds delete-integration ^
    --integration-identifier ee605691-6c47-48e8-8622-83f99b1af374
```

RDS API

To delete a zero-ETL integration using the Amazon RDS API, use the `DeleteIntegration` operation with the `IntegrationIdentifier` parameter.

Troubleshooting Aurora zero-ETL integrations

You can check the state of a zero-ETL integration by querying the SVV_INTEGRATION system table in the analytics destination. If the `state` column has a value of `ErrorState`, it means something's wrong. For more information, see the section called “Monitoring using system tables”.

Use the following information to troubleshoot common issues with Aurora zero-ETL integrations.

> **Important**
>
> Resync and refresh operations are not available for zero-ETL integrations with an Amazon SageMaker AI lakehouse. If there are issues with an integration, you must delete the integration and create a new integration. You can't refresh or resync an existing integration.

Topics

- I can't create a zero-ETL integration
- My integration is stuck in a state of Syncing
- My tables aren't replicating to Amazon Redshift
- One or more of my Amazon Redshift tables requires a resync
- Integration failed issues for Amazon SageMaker AI lakehouse zero-ETL integrations
- DDL changes are in Amazon Redshift before the DDL transaction is complete for Aurora PostgreSQL

I can't create a zero-ETL integration

If you can't create a zero-ETL integration, make sure that the following are correct for your source database:

- Your source database must be running a supported DB engine version. For a list of supported versions, see the section called “Zero-ETL integrations ”.
- You correctly configured DB parameters. If the required parameters are set incorrectly or not associated with the database, creation fails. See the section called “Step 1: Create a custom DB cluster parameter group”.

In addition, make sure the following are correct for your target data warehouse:

- Case sensitivity is enabled. See Turn on case sensitivity for your data warehouse.
- You added the correct authorized principal and integration source. See Configure authorization for your Amazon Redshift data warehouse.
- The data warehouse is encrypted (if it's a provisioned cluster). See Amazon Redshift database encryption.

My integration is stuck in a state of `Syncing`

Your integration might consistently show a status of `Syncing` if you change the value of one of the required DB parameters.

To fix this issue, check the values of the parameters in the parameter group associated with the source DB cluster, and make sure that they match the required values. For more information, see the section called “Step 1: Create a custom DB cluster parameter group”.

If you modify any parameters, make sure to reboot the DB cluster to apply the changes.

My tables aren't replicating to Amazon Redshift

If you don't see one or more tables reflected in Amazon Redshift, you can run the following command to resynchronize them:

```
ALTER DATABASE dbname INTEGRATION REFRESH TABLES table1, table2;
```

For more information, see ALTER DATABASE in the Amazon Redshift SQL reference.

Your data might not be replicating because one or more of your source tables doesn't have a primary key. The monitoring dashboard in Amazon Redshift displays the status of these tables as `Failed`, and the status of the overall zero-ETL integration changes to `Needs attention`. To

resolve this issue, you can identify an existing key in your table that can become a primary key, or you can add a synthetic primary key. For detailed solutions, see the following resources:

- Handle tables without primary keys while creating Amazon Aurora MySQL or Amazon RDS for MySQL zero-ETL integrations with Amazon Redshift
- Handle tables without primary keys while creating Amazon Aurora PostgreSQL zero-ETL integrations with Amazon Redshift

One or more of my Amazon Redshift tables requires a resync

Running certain commands on your source database might require your tables to be resynchronized. In these cases, the SVV_INTEGRATION_TABLE_STATE system view shows a `table_state` of `ResyncRequired`, which means that the integration must completely reload data for that specific table from MySQL to Amazon Redshift.

When the table starts to resynchronize, it enters a state of `Syncing`. You don't need to take any manual action to resynchronize a table. While table data is resynchronizing, you can't access it in Amazon Redshift.

The following are some example operations that can put a table into a `ResyncRequired` state, and possible alternatives to consider.

Operation	Example	Alternative
Adding a column into a specific position	`ALTER TABLE table_name ADD COLUMN column_name INTEGER NOT NULL first;`	Amazon Redshift doesn't support adding columns into specific positions using `first` or `after` keywords. If the order of columns

Operation	Example	Alternative
		in the target table isn't critical, add the column to the end of the table using a simpler command: `ALTER TABLE table_name ADD COLUMN column_name column_type ;`

Operation	Example	Alternative
Adding a timestamp column with the default CURRENT_TIMESTAMP	`ALTER TABLE table_name ADD COLUMN column_name TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP;`	The CURRENT_TIMESTAMP value for existing table rows is calculated by Aurora MySQL and can't be simulated in Amazon Redshift without full table data resynchronization. If possible, switch the default value to a literal constant like 2023-01-01 00:00:15 to avoid latency in table availability.

Operation	Example	Alternative
Performing multiple column operations within a single command	`ALTER TABLE table_name ADD COLUMN column_1, RENAME COLUMN column_2 TO column_3;`	Consider splitting the command into two separate operations, ADD and RENAME, which won't require resynchronization.

Integration failed issues for Amazon SageMaker AI lakehouse zero-ETL integrations

If you encounter issues with an existing zero-ETL integration with an Amazon SageMaker AI lakehouse, the only resolution is to delete the integration and create a new one. Unlike other Amazon services, zero-ETL integrations do not support refresh or resync operations.

To resolve integration issues:

1. Delete the problematic zero-ETL integration using the console, CLI, or API.
2. Verify that the source database and target data warehouse configurations are correct.
3. Create a new zero-ETL integration with the same or updated configuration.

This process will result in a complete re-initialization of the data pipeline, which may take time depending on the size of your source database.

DDL changes are in Amazon Redshift before the DDL transaction is complete for Aurora PostgreSQL

DDL changes can appear in Amazon Redshift before a DDL operation finishes in Aurora PostgreSQL zero-ETL integrations. For more information, see DDL operations for Aurora PostgreSQL.

Using Aurora serverless

Aurora serverless is an on-demand, autoscaling configuration for Amazon Aurora. Aurora serverless helps to automate the processes of monitoring the workload and adjusting the capacity for your databases. Capacity is adjusted automatically based on application demand. You're charged only for the resources that your DB clusters consume. Thus, Aurora serverless can help you to stay within budget and avoid paying for computer resources that you don't use.

This type of automation is especially valuable for multitenant databases, distributed databases, development and test systems, and other environments with highly variable and unpredictable workloads.

Topics

- Aurora serverless use cases
- Advantages of Aurora serverless
- How Aurora serverless works
- Requirements and limitations for Aurora serverless
- Creating a DB cluster that uses Aurora serverless
- Managing Aurora serverless DB clusters
- Performance and scaling for Aurora serverless
- Scaling to Zero ACUs with automatic pause and resume for Aurora serverless

Aurora serverless use cases

Aurora serverless supports many types of database workloads. These range from development and testing environments, to websites and applications that have unpredictable workloads, to the most demanding, business-critical applications that require high scale and availability.

Aurora serverless is especially useful for the following use cases:

- **Variable workloads** – You're running workloads that have sudden and unpredictable increases in activity. An example is a traffic site that sees a surge of activity when it starts raining. Another is an e-commerce site with increased traffic when you offer sales or special promotions. With Aurora serverless, your database automatically scales capacity to meet the needs of the

application's peak load and scales back down when the surge of activity is over. With Aurora serverless, you no longer need to provision for peak or average capacity. You can specify an upper capacity limit to handle the worst-case situation, and that capacity isn't used unless it's needed.

The granularity of scaling in Aurora serverless helps you to match capacity closely to your database's needs. For a provisioned cluster, scaling up requires adding a whole new DB instance. Aurora serverless can add half an ACU when only a little more capacity is needed. It can add 0.5, 1, 1.5, 2, or additional half-ACUs based on the additional capacity needed to handle an increase in workload. And it can remove 0.5, 1, 1.5, 2, or additional half-ACUs when the workload decreases and that capacity is no longer needed.

- **Multi-tenant applications** – With Aurora serverless, you don't have to individually manage database capacity for each application in your fleet. Aurora serverless manages individual database capacity for you.

  You can create a cluster for each tenant. That way, you can use features such as cloning, snapshot restore, and Aurora global databases to enhance high availability and disaster recovery as appropriate for each tenant.

  Each tenant might have specific busy and idle periods depending on the time of day, time of year, promotional events, and so on. Each cluster can have a wide capacity range. That way, clusters with low activity incur minimal DB instance charges. Any cluster can quickly scale up to handle periods of high activity.
- **New applications** – You're deploying a new application and you're unsure about the DB instance size you need. By using Aurora serverless, you can set up a cluster with one or many DB instances and have the database autoscale to the capacity requirements of your application.
- **Mixed-use applications** – Suppose that you have an online transaction processing (OLTP) application, but you periodically experience spikes in query traffic. By specifying promotion tiers for the Aurora serverless DB instances in a cluster, you can configure your cluster so that the reader DB instances can scale independently of the writer DB instance to handle the additional load. When the usage spike subsides, the reader DB instances scale back down to match the capacity of the writer DB instance.
- **Capacity planning** – Suppose that you usually adjust your database capacity, or verify the optimal database capacity for your workload, by modifying the DB instance classes of all the DB instances in a cluster. With Aurora serverless, you can avoid this administrative overhead. You can determine the appropriate minimum and maximum capacity by running the workload and checking how much the DB instances actually scale.

You can modify existing DB instances from provisioned to Aurora serverless or from Aurora serverless to provisioned. You don't need to create a new cluster or a new DB instance in such cases.

With an Aurora global database, you might not need as much capacity for the secondary clusters as in the primary cluster. You can use Aurora serverless DB instances in the secondary clusters. That way, the cluster capacity can scale up if a secondary region is promoted and takes over your application's workload.

- **Development and testing** – In addition to running your most demanding applications, you can also use Aurora serverless for development and testing environments. With Aurora serverless, you can create DB instances with a low minimum capacity instead of using burstable db.t* DB instance classes. You can set the maximum capacity high enough that those DB instances can still run substantial workloads without running low on memory. When the database isn't in use, all of the DB instances scale down to avoid unnecessary charges.

  Tip

  To make it convenient to use Aurora serverless in development and test environments, the Amazon Web Services Management Console provides the **Easy create** shortcut when you create a new cluster. If you choose the **Dev/Test** option, Aurora creates a cluster with an Aurora serverless DB instance and a capacity range that's typical for a development and test system.

Using Aurora serverless for existing provisioned workloads

Suppose that you already have an Aurora application running on a provisioned cluster. You can check how the application would work with Aurora serverless by adding one or more Aurora serverless DB instances to the existing cluster as reader DB instances. You can check how often the reader DB instances scale up and down. You can use the Aurora failover mechanism to promote an Aurora serverless DB instance to be the writer and check how it handles the read/write workload. That way, you can switch over with minimal downtime and without changing the endpoint that your client applications use. For details on the procedure to convert existing clusters to Aurora serverless, see Converting a provisioned writer or reader to Aurora serverless.

Advantages of Aurora serverless

Aurora serverless is intended for variable or "spiky" workloads. With such unpredictable workloads, you might have difficulty planning when to change your database capacity. You might also have trouble making capacity changes quickly enough using the familiar mechanisms such as adding DB instances or changing DB instance classes. Aurora serverless provides the following advantages to help with such use cases:

- **Simpler capacity management than provisioned** – Aurora serverless reduces the effort for planning DB instance sizes and resizing DB instances as the workload changes. It also reduces the effort for maintaining consistent capacity for all the DB instances in a cluster.
- **Faster and easier scaling during periods of high activity** – Aurora serverless scales compute and memory capacity as needed, with no disruption to client transactions or your overall workload. The ability to use reader DB instances with Aurora serverless helps you to take advantage of horizontal scaling in addition to vertical scaling. The ability to use Aurora global databases means that you can spread your Aurora serverless read workload across multiple Amazon Web Services Regions. This capability is more convenient than the scaling mechanisms for provisioned clusters.
- **Cost-effective during periods of low activity** – Aurora serverless helps you to avoid overprovisioning your DB instances. Aurora serverless adds resources in granular increments when DB instances scale up. You pay only for the database resources that you consume. Aurora serverless resource usage is measured on a per-second basis. That way, when a DB instance scales down, the reduced resource usage is registered right away.
- **Greater feature parity with provisioned** – You can use many Aurora features with Aurora serverless oFor example, with Aurora serverless you can use reader DB instances, global databases, Amazon Identity and Access Management (IAM) database authentication, and Performance Insights.

  In particular, with Aurora serverless you can take advantage of the following features from provisioned clusters:

  - **Reader DB instances** – Aurora serverless can take advantage of reader DB instances to scale horizontally. When a cluster contains one or more reader DB instances, the cluster can fail over immediately in case of problems with the writer DB instance.
  - **Multi-AZ clusters** – You can distribute the Aurora serverless DB instances of a cluster across multiple Availability Zones (AZs). Setting up a Multi-AZ cluster helps to ensure business continuity even in the rare case of issues that affect an entire AZ.

- **Global databases** – You can use Aurora serverless in combination with Aurora global databases to create additional read-only copies of your cluster in other Amazon Web Services Regions for disaster recovery purposes.
- **RDS Proxy** – You can use Amazon RDS Proxy to allow your applications to pool and share database connections to improve their ability to scale.

- **Faster, more granular, less disruptive scaling** – Aurora serverless can scale up and down faster. Scaling can change capacity by as little as 0.5 ACUs, instead of doubling or halving the number of ACUs. Scaling typically happens with no pause in processing at all. Scaling doesn't involve an event that you have to be aware of. Scaling can happen while SQL statements are running and transactions are open, without the need to wait for a quiet point.

How Aurora serverless works

The following overview describes how Aurora serverless works.

Topics

- Aurora serverless overview
- Configurations for Aurora DB clusters
- Aurora serverless capacity
- Aurora serverless scaling
- Aurora serverless and high availability
- Aurora serverless and storage
- Configuration parameters for Aurora clusters

Aurora serverless overview

Amazon Aurora serverless is suitable for the most demanding, highly variable workloads. For example, your database usage might be heavy for a short period of time, followed by long periods of light activity or no activity at all. Some examples are retail, gaming, or sports websites with periodic promotional events, and databases that produce reports when needed. Others are development and testing environments, and new applications where usage might ramp up quickly. For cases such as these and many others, configuring capacity correctly in advance isn't always possible with the provisioned model. It can also result in higher costs if you overprovision and have capacity that you don't use.

In contrast, *Aurora provisioned clusters* are suitable for steady workloads. With provisioned clusters, you choose a DB instance class that has a predefined amount of memory, CPU power, I/O bandwidth, and so on. If your workload changes, you manually modify the instance class of your writer and readers. The provisioned model works well when you can adjust capacity in advance of expected consumption patterns and it's acceptable to have brief outages while you change the instance class of the writer and readers in your cluster.

Aurora serverless is architected from the ground up to support serverless DB clusters that are instantly scalable. Aurora serverless is engineered to provide the same degree of security and isolation as with provisioned writers and readers. These aspects are crucial in multitenant serverless cloud environments. The dynamic scaling mechanism has very little overhead so that it can respond quickly to changes in the database workload. It's also powerful enough to meet dramatic increases in processing demand.

By using Aurora serverless, you can create an Aurora DB cluster without being locked into a specific database capacity for each writer and reader. You specify the minimum and maximum capacity range. Aurora scales each Aurora serverless writer or reader in the cluster within that capacity range. By using a Multi-AZ cluster where each writer or reader can scale dynamically, you can take advantage of dynamic scaling and high availability.

Aurora serverless scales the database resources automatically based on your minimum and maximum capacity specifications. Scaling is fast because most scaling events operations keep the writer or reader on the same host. In the rare cases that an Aurora serverless writer or reader is moved from one host to another, Aurora serverless manages the connections automatically. You don't need to change your database client application code or your database connection strings.

With Aurora serverless, as with provisioned clusters, storage capacity and compute capacity are separate. When we refer to Aurora serverless capacity and scaling, it's always compute capacity that's increasing or decreasing. Thus, your cluster can contain many terabytes of data even when the CPU and memory capacity scale down to low levels.

Instead of provisioning and managing database servers, you specify database capacity. For details about Aurora serverless capacity, see Aurora serverless capacity. The actual capacity of each Aurora serverless writer or reader varies over time, depending on your workload. For details about that mechanism, see Aurora serverless scaling.

Important

With Aurora serverless, your cluster can contain readers in addition to the writer. Each Aurora serverless writer and reader can scale between the minimum and maximum capacity values. Thus, the total capacity of your Aurora serverless cluster depends on both the capacity range that you define for your DB cluster and the number of writers and readers in the cluster. At any specific time, you are only charged for the Aurora serverless capacity that is being actively used in your Aurora DB cluster.

Configurations for Aurora DB clusters

For each of your Aurora DB clusters, you can choose any combination of Aurora serverless capacity, provisioned capacity, or both.

You can set up a cluster that contains both Aurora serverless and provisioned capacity, called a *mixed-configuration cluster*. For example, suppose that you need more read/write capacity than is available for an Aurora serverless writer. In this case, you can set up the cluster with a very large provisioned writer. In that case, you can still use Aurora serverless for the readers. Or suppose that the write workload for your cluster varies but the read workload is steady. In this case, you can set up your cluster with an Aurora serverless writer and one or more provisioned readers.

You can also set up a DB cluster where all the capacity is managed by Aurora serverless. To do this, you can create a new cluster and use Aurora serverless from the start. Or you can replace all the provisioned capacity in an existing cluster with Aurora serverless. For example, some of the upgrade paths from older engine versions require starting with a provisioned writer and replacing it with a Aurora serverless writer. For the procedures to create a new DB cluster with Aurora serverless or to switch an existing DB cluster to Aurora serverless, see Creating an Aurora serverless DB cluster and Converting a provisioned writer or reader to Aurora serverless.

If you don't use Aurora serverless at all in a DB cluster, all the writers and readers in the DB cluster are *provisioned*. This is the oldest and most common kind of DB cluster that most users are familiar with. In fact, before Aurora Serverless, there wasn't a special name for this kind of Aurora DB cluster. Provisioned capacity is constant. The charges are relatively easy to forecast. However, you have to predict in advance how much capacity you need. In some cases, your predictions might be inaccurate or your capacity needs might change. In these cases, your DB cluster can become underprovisioned (slower than you want) or overprovisioned (more expensive than you want).

Aurora serverless capacity

The unit of measure for Aurora serverless is the *Aurora capacity unit (ACU)*. Aurora serverless capacity isn't tied to the DB instance classes that you use for provisioned clusters.

Each ACU is a combination of approximately 2 gibibytes (GiB) of memory, corresponding CPU, and networking. You specify the database capacity range (minimum and maximum) using this unit of measure. Aurora serverless offers capacity from 0 ACUs to 256 ACUs for Aurora MySQL and to 384 ACUs for Aurora PostgreSQL. With the minimum capacity of 0 ACUs, the cluster will scale to 0 when there is no workload running.The `ServerlessDatabaseCapacity` and `ACUUtilization` metrics help you to determine how much capacity your database is actually using and where that capacity falls within the specified range.

At any moment in time, each Aurora serverless DB writer or reader has a *capacity*. The capacity is represented as a floating-point number representing ACUs. The capacity increases or decreases whenever the writer or reader scales. This value is measured every second. For each DB cluster where you intend to use Aurora serverless, you define a *capacity range*: the minimum and maximum capacity values that each Aurora serverless writer or reader can scale between. The capacity range is the same for each Aurora serverless writer or reader in a DB cluster. Each Aurora serverless writer or reader has its own capacity, falling somewhere in that range.

The following table shows the Aurora serverless capacity ranges and engine version support for Aurora MySQL and Aurora PostgreSQL.

Capacity range (ACUs)	Aurora MySQL supported versions	Aurora PostgreSQL supported versions
0.5–128	3.02.0 and higher	13.6 and higher, 14.3 and higher, 15.2 and higher, 16.1 and higher
0.5–256	3.06.0 and higher	13.13 and higher, 14.10 and higher, 15.5 and higher, 16.1 and higher
0–256	3.08.0 and higher	13.15 and higher, 14.12 and higher, 15.7 and higher, 16.3 and higher, 17.4 and higher, 18.3 and higher

Capacity range (ACUs)	Aurora MySQL supported versions	Aurora PostgreSQL supported versions
0–384		14.23 and higher, 15.18 and higher, 16.14 and higher, 17.10 and higher, 18.4 and higher

Platform versions in Aurora serverless represent improvements in performance, scaling capabilities or features. Amazon Aurora automatically manages platform version assignments at the cluster level. All new clusters, database restores, and new clones launch with the latest platform version available in your Amazon Web Services Region. When a new platform version becomes available, existing clusters on previous platform versions can be upgraded directly to the latest platform version by applying the pending maintenance, stopping and restarting the cluster, or by using blue/green deployments. Amazon Aurora recommends upgrading to the latest platform version to benefit from all the latest improvements.

The following table shows the Aurora serverless platform versions with their ACU ranges and performance characteristics.

Aurora serverless platform version	ACU range	Performance
1	0–128	Baseline performance
2	0–256	Baseline performance
3	0–256	Up to 30% improved performance compared to platform version 2
4	0-256 (Aurora MySQL),0-384 (Aurora PostgreSQL)	Up to 30% improved performance compared to platform version 3

Note

The available scaling range for a given cluster is determined by both engine version and platform version. It is possible to have a more capable engine version running on a less

capable platform version and vice-versa. The scaling range is determined by the lowest capable engine or platform version. Platform versions should not be confused with Aurora Serverless v1, which is a deprecated product with a different architecture.

Platform version 1, 2, and 3 are available in all regions where Aurora serverless is supported. Platform Version 4 is available in the following regions: US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon), Asia Pacific (Hong Kong), Asia Pacific (Hyderabad), Asia Pacific (Jakarta), Asia Pacific (Malaysia), Asia Pacific (Melbourne), Asia Pacific (Mumbai), Asia Pacific (Osaka), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Canada (Central), Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris), Europe (Spain), Europe (Stockholm), Europe (Zurich), South America (São Paulo), Amazon GovCloud (US-East), and Amazon GovCloud (US-West).

You can determine what platform version your cluster is running on in the Instance Configuration section of the Amazon Web Services Management Console or through the API by viewing the `ServerlessV2PlatformVersion` for a DBCluster.

The smallest Aurora serverless capacity that you can define is 0 ACUs, for Aurora serverless versions that support the auto-pause feature. You can specify a higher number if it's less than or equal to the maximum capacity value. Setting the minimum capacity to a small number lets lightly loaded DB clusters consume minimal compute resources. At the same time, they stay ready to accept connections immediately and scale up when they become busy.

We recommend setting the minimum to a value that allows each DB writer or reader to hold the working set of the application in the buffer pool. That way, the contents of the buffer pool aren't discarded during idle periods. For all the considerations when choosing the minimum capacity value, see Choosing the minimum Aurora serverless capacity setting for a cluster. For all the considerations when choosing the maximum capacity value, see Choosing the maximum Aurora serverless capacity setting for a cluster.

Depending on how you configure the readers in a Multi-AZ deployment, their capacities can be tied to the capacity of the writer or independently. For details about how to do that, see Aurora serverless scaling.

Monitoring Aurora serverless involves measuring the capacity values for the writer and readers in your DB cluster over time. If your database doesn't scale down to the minimum capacity, you can take actions such as adjusting the minimum and optimizing your database application. If your

database consistently reaches its maximum capacity, you can take actions such as increasing the maximum. You can also optimize your database application and spread the query load across more readers.

The charges for Aurora serverless capacity are measured in terms of ACU-hours. For information about how Aurora serverless charges are calculated, see the Aurora pricing page.

Suppose that the total number of writers and readers in your cluster is *n*. In that case, the cluster consumes approximately *n* x *minimum ACUs* when you aren't running any database operations. Aurora itself might run monitoring or maintenance operations that cause some small amount of load. That cluster consumes no more than *n* x *maximum ACUs* when the database is running at full capacity.

For more details about choosing appropriate minimum and maximum ACU values, see Choosing the Aurora serverless capacity range for an Aurora cluster. The minimum and maximum ACU values that you specify also affect the way some of the Aurora configuration parameters work for Aurora serverless. For details about the interaction between the capacity range and configuration parameters, see Working with parameter groups for Aurora serverless.

Aurora serverless scaling

For each Aurora serverless writer or reader, Aurora continuously tracks utilization of resources such as CPU, memory, and network. These measurements collectively are called the *load*. The load includes the database operations performed by your application. It also includes background processing for the database server and Aurora administrative tasks. When capacity is constrained by any of these, Aurora serverless scales up. Aurora serverless also scales up when it detects performance issues that it can resolve by doing so. You can monitor resource utilization and how it affects Aurora serverless scaling by using the procedures in Important Amazon CloudWatch metrics for Aurora serverless and Monitoring Aurora serverless performance with Performance Insights.

The load can vary across the writer and readers in your DB cluster. The writer handles all data definition language (DDL) statements, such as `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE`. The writer also handles all data manipulation language (DML) statements, such as `INSERT` and `UPDATE`. Readers can process read-only statements, such as `SELECT` queries.

Scaling is the operation that increases or decreases Aurora serverless capacity for your database. With Aurora serverless, each writer and reader has its own current capacity value, measured in ACUs. Aurora serverless scales a writer or reader up to a higher capacity when its current capacity is

too low to handle the load. It scales the writer or reader down to a lower capacity when its current capacity is higher than needed.

Aurora serverless can increase capacity incrementally. When your workload demand begins to reach the current database capacity of a writer or reader, Aurora serverless increases the number of ACUs for that writer or reader. Aurora serverless scales capacity in the increments required to provide the best performance for the resources consumed. Scaling happens in increments as small as 0.5 ACUs. The larger the current capacity, the larger the scaling increment and thus the faster scaling can happen.

Because Aurora serverless scaling is so frequent, granular, and nondisruptive, it doesn't cause discrete events in the Amazon Web Services Management Console. Instead, you can measure the Amazon CloudWatch metrics such as `ServerlessDatabaseCapacity` and `ACUUtilization` and track their minimum, maximum, and average values over time. To learn more about Aurora metrics, see Monitoring metrics in an Amazon Aurora cluster. For tips about monitoring Aurora serverless, see Important Amazon CloudWatch metrics for Aurora serverless.

You can choose to make a reader follow the capacity of the associated writer, or scale independently from the writer. You do so by specifying the promotion tier for that reader.

- For readers in promotion tiers 0 and 1, the minimum capacity is defined by the current writer capacity and the maximum capacity is the maximum ACU value specified for the cluster. That scaling behavior makes readers in priority tiers 0 and 1 ideal for availability. That's because they are at least as large as the writer, so they can take over the workload from the writer in case of a failover. If the writer is a provisioned instance, the serverless reader's minimum capacity is the ACU equivalent of the writer's memory size.
- Readers in promotion tiers 2–15 scale independently from the writer. Each reader remains within the minimum and maximum ACU values that you specified for your cluster. When a reader scales independently of the associated writer DB, it can become idle and scale down while the writer continues to process a high volume of transactions. It's still available as a failover target, if no other readers are available in lower promotion tiers. However, if it's promoted to be the writer, it might need to scale up to handle the full workload of the writer.

For details about promotion tiers, see Choosing the promotion tier for an Aurora serverless reader.

Aurora serverless scaling can happen while database connections are open, while SQL transactions are in process, while tables are locked, and while temporary tables are in use. Aurora serverless

doesn't wait for a quiet point to begin scaling. Scaling doesn't disrupt any database operations that are underway.

If your workload requires more read capacity than is available with a single writer and a single reader, you can add multiple Aurora serverless readers to the cluster. Each Aurora serverless reader can scale within the range of minimum and maximum capacity values that you specified for your DB cluster. You can use the cluster's reader endpoint to direct read-only sessions to the readers and reduce the load on the writer.

Whether Aurora serverless performs scaling, and how fast scaling occurs once it starts, also depends on the minimum and maximum ACU settings for the cluster. In addition, it depends on whether a reader is configured to scale along with the writer or independently from it. For details about the factors that affect Aurora serverless scaling, see Performance and scaling for Aurora serverless.

Scaling to Zero

In recent Aurora MySQL and Aurora PostgreSQL versions, Aurora serverless writers and readers can scale all the way down to zero ACUs. We refer to this capability as automatic pause and resume, or auto-pause. You can choose whether to allow this behavior by specifying a zero or nonzero value for the minimum capacity. You can also choose how long to wait before an Aurora serverless instance pauses. For information about which versions have this capability, see Aurora serverless capacity. For information about how to use it effectively, see Scaling to Zero ACUs with automatic pause and resume for Aurora serverless.

In older Aurora MySQL and Aurora PostgreSQL versions, idle Aurora serverless writers and readers can scale down to the minimum ACU value that you specified for the cluster, but not all the way to zero ACUs. In that case, zero ACUs isn't available as a choice when you set the capacity range.

When your DB cluster with Aurora serverless capacity isn't needed for some time, you can also stop and start the entire cluster, the same as with provisioned DB clusters. This technique is most appropriate for development and test systems, where they might not be needed for many hours at a time, and the speed of resuming the cluster isn't crucial. The stop/start cluster feature is available for all Aurora serverless versions. For more information about that feature, see Stopping and starting an Amazon Aurora DB cluster.

Aurora serverless and high availability

The way to establish high availability for an Aurora DB cluster is to make it a Multi-AZ DB cluster. A *Multi-AZ Aurora DB cluster* has compute capacity available at all times in more than one Availability

Zone (AZ). That configuration keeps your database up and running even in case of a significant outage. Aurora performs an automatic failover in case of an issue that affects the writer or even the entire AZ. With Aurora serverless, you can choose for the standby compute capacity to scale up and down along with the capacity of the writer. That way, the compute capacity in the second AZ is ready to take over the current workload at any time. At the same time, the compute capacity in all AZs can scale down when the database is idle. For details about how Aurora works with Amazon Web Services Regions and Availability Zones, see High availability for Aurora DB instances.

The Aurora serverless Multi-AZ capability uses *readers* in addition to the writer. Support for readers is new for Aurora serverless. You can add up to 15 Aurora serverless readers spread across 3 AZs to an Aurora DB cluster.

For business-critical applications that must remain available even in case of an issue that affects your entire cluster or the whole Amazon Region, you can set up an Aurora global database. You can use Aurora serverless capacity in the secondary clusters so they're ready to take over during disaster recovery. They can also scale down when the database isn't busy. For details about Aurora global databases, see Using Amazon Aurora Global Database.

Aurora serverless works like provisioned for failover and other high availability features. For more information, see High availability for Amazon Aurora.

Suppose that you want to ensure maximum availability for your Aurora serverless cluster. You can create a reader in addition to the writer. If you assign the reader to promotion tier 0 or 1, the reader's minimum capacity will match the current writer capacity (or writer's memory size, for provisioned writers). That way, a reader is always ready to take over for the writer in case of a failover.

Suppose that you want to run quarterly reports for your business at the same time as your cluster continues to process transactions. If you add an Aurora serverless reader to the cluster and assign it to a promotion tier from 2 through 15, you can connect directly to that reader to run the reports. Depending on how memory-intensive and CPU-intensive the reporting queries are, that reader can scale up to accommodate the workload. It can then scale down again when the reports are finished.

Aurora serverless and storage

The storage for each Aurora DB cluster consists of six copies of all your data, spread across three AZs. This built-in data replication applies regardless of whether your DB cluster includes any readers in addition to the writer. That way, your data is safe, even from issues that affect the compute capacity of the cluster.

Aurora serverless storage has the same reliability and durability characteristics as described in Amazon Aurora storage. That's because the storage for Aurora DB clusters works the same whether the compute capacity uses Aurora serverless or provisioned.

Configuration parameters for Aurora clusters

You can adjust all the same cluster and database configuration parameters for clusters with Aurora serverless capacity as for provisioned DB clusters. However, some capacity-related parameters are handled differently for Aurora serverless. In a mixed-configuration cluster, the parameter values that you specify for those capacity-related parameters still apply to any provisioned writers and readers.

Almost all of the parameters work the same way for Aurora serverless writers and readers as for provisioned ones. The exceptions are some parameters that Aurora automatically adjusts during scaling, and some parameters that Aurora keeps at fixed values that depend on the maximum capacity setting.

For example, the amount of memory reserved for the buffer cache increases as a writer or reader scales up, and decreases as it scales down. That way, memory can be released when your database isn't busy. Conversely, Aurora automatically sets the maximum number of connections to a value that's appropriate based on the maximum capacity setting. That way, active connections aren't dropped if the load drops and Aurora serverless scales down. For information about how Aurora serverless handles specific parameters, see Working with parameter groups for Aurora serverless.

Requirements and limitations for Aurora serverless

When you create a cluster where you intend to use Aurora serverless DB instances, pay attention to the following requirements and limitations.

Topics

- Region and version availability
- Clusters that use Aurora serverless must have a capacity range specified
- Incompatible scaling configuration
- Some provisioned features aren't supported in Aurora serverless

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across Amazon Web Services Regions. For more information on version and Region availability with Aurora and Aurora serverless, see Supported Regions and Aurora DB engines for Aurora serverless.

The following example shows the Amazon CLI commands to confirm the exact DB engine values you can use with Aurora serverless for a specific Amazon Web Services Region. The `--db-instance-class` parameter for Aurora serverless is always `db.serverless`. The `--engine` parameter can be `aurora-mysql` or `aurora-postgresql`. Substitute the appropriate `--region` and `--engine` values to confirm the `--engine-version` values that you can use. If the command doesn't produce any output, Aurora serverless isn't available for that combination of Amazon Web Services Region and DB engine.

```
aws rds describe-orderable-db-instance-options --engine aurora-mysql --db-instance-
class db.serverless \
  --region my_region --query 'OrderableDBInstanceOptions[].[EngineVersion]' --output
 text

aws rds describe-orderable-db-instance-options --engine aurora-postgresql --db-
instance-class db.serverless \
  --region my_region --query 'OrderableDBInstanceOptions[].[EngineVersion]' --output
 text
```

Clusters that use Aurora serverless must have a capacity range specified

An Aurora cluster must have a `ServerlessV2ScalingConfiguration` attribute before you can add any DB instances that use the `db.serverless` DB instance class. This attribute specifies the capacity range. Aurora serverless capacity ranges from a minimum of 0 Aurora capacity units (ACU) to a maximum of 256 ACUs for Aurora MySQL and to 384 ACUs for Aurora PostgreSQL, in increments of 0.5 ACU. The allowed minimum value depends on the Aurora version. Each ACU provides the equivalent of approximately 2 gibibytes (GiB) of RAM and associated CPU and networking. For details about how Aurora serverless uses the capacity range settings, see How Aurora serverless works.

For the allowed capacity ranges for various DB engine versions and platform versions, see Aurora serverless capacity. The available scaling range for a given cluster is influenced by both engine version and hardware (platform version).

You can specify the minimum and maximum ACU values in the Amazon Web Services Management Console when you create a cluster and associated Aurora serverless DB instance. You can also specify the `--serverless-v2-scaling-configuration` option in the Amazon CLI. Or you can specify the `ServerlessV2ScalingConfiguration` parameter with the Amazon RDS API. You can specify this attribute when you create a cluster or modify an existing cluster. For the procedures to set the capacity range, see Setting the Aurora serverless capacity range for a cluster. For a detailed discussion of how to pick minimum and maximum capacity values and how those settings affect some database parameters, see Choosing the Aurora serverless capacity range for an Aurora cluster.

Incompatible scaling configuration

When you modify your Aurora PostgreSQL cluster with a lower maximum capacity, each instance will be scaled down to match the new configuration. If Aurora detects that any of your instances are having trouble scaling down, it may cancel and roll back the scaling configuration update. As a result, the instances will scale back up to their previous configuration. This issue may occur if the new maximum capacity is insufficient to handle the current workload or if the custom parameters applied to the cluster's or instances' database parameter group are set too high.

When the rollback starts, you will be notified via an Amazon RDS event containing information about instances that could not apply your desired scaling configuration. After the rollback completes, the scaling configuration's maximum capacity will return to its original higher value. Due to the roll back, you may observe that the Aurora Serverless database capacity across all of your cluster's instances may also increase, leading to higher costs.

For example, you have an Aurora PostgreSQL Aurora Serverless cluster with a single instance and the scaling configuration is set to `minCapacity=0.5`, `maxCapacity=128`, and `secondsUntilAutopause=null`. In addition, the database parameter `track_activity_query_size` is set to a custom value of 40960. If you then modify the cluster's scaling configuration to have a maximum capacity of 1 ACU, you may notice that after a couple of hours, the modification has not completed. The high value of the `track_activity_query_size` parameter requires more resources than the new maximum capacity can provide. As a result, even with no workload, the instance's `ServerlessDatabaseCapacity` cannot scale down to match the new maximum capacity of 1 ACU. Aurora serverless will then cancel the scaling configuration modification and will reapply the previous scaling configuration of `minCapacity=0.5`, `maxCapacity=128`, `secondsUntilAutopause=null`. The instance will then scale up to match the previous scaling configuration, ending the cluster's modification. An Amazon RDS event is

published notifying you that an incompatible scaling configuration update was detected, canceled, and rolled back to the previous configuration.

Issues and Remediations

New scaling configuration is incompatible with workload

The new Aurora serverless scaling configuration's maximum capacity is too low to handle the current workload.

Recommendations:

- Reduce your workload before reapplying the lower maximum capacity.
- If reducing the workload is not an option, reevaluate the desired maximum capacity. To pick an appropriate maximum capacity, check the maximum `ServerlessDatabaseCapacity` CloudWatch metric for your Aurora PostgreSQL cluster before the scaling configuration update was cancelled and rolled back. Then set your new scaling configuration's maximum capacity to be at least the observed ServerlessDatabaseCapacity value. For more guidance on choosing a maximum capacity, see Choosing the Aurora serverless capacity range for an Aurora cluster.

New scaling configuration is incompatible with custom database parameters

Your cluster's or instances' custom database parameter groups require additional resources that exceed the new scaling configuration's maximum capacity.

Potential incompatible Aurora PostgreSQL database parameters:

- max_connections
- track_activity_query_size
- min_dynamic_shared_memory

Recommendations:

- To pick an appropriate database parameter value, check the default parameter values for each of the parameters listed above. If your configured value exceeds the default values, reduce the parameters to their default values before modifying the scaling configuration with the same reduced maximum capacity.
- If reducing the database parameters is not an option, follow the same steps to pick an appropriate maximum capacity outlined above in: New scaling configuration is incompatible with workload.

Some provisioned features aren't supported in Aurora serverless

The following features from Aurora provisioned DB instances currently aren't available for Amazon Aurora serverless:

- Database activity streams (DAS).
- Cluster cache management for Aurora PostgreSQL. The `apg_ccm_enabled` configuration parameter doesn't apply to Aurora serverless DB instances.

Some Aurora features work with Aurora serverless, but might cause issues if your capacity range is lower than needed for the memory requirements for those features with your specific workload. In that case, your database might not perform as well as usual, or might encounter out-of-memory errors. For recommendations about setting the appropriate capacity range, see Choosing the Aurora serverless capacity range for an Aurora cluster. For troubleshooting information if your database encounters out-of-memory errors due to a misconfigured capacity range, see Avoiding out-of-memory errors and CPU saturation.

Aurora Auto Scaling isn't supported. This type of scaling adds new readers to handle additional read-intensive workload, based on CPU usage. However, scaling based on CPU usage isn't meaningful for Aurora serverless. As an alternative, you can create Aurora serverless reader DB instances in advance and leave them scaled down to low capacity. That's a faster and less disruptive way to scale a cluster's read capacity than adding new DB instances dynamically.

Creating a DB cluster that uses Aurora serverless

To create an Aurora cluster where you can add Aurora serverless DB instances, you follow the same procedure as in Creating an Amazon Aurora DB cluster. With Aurora serverless, your clusters are interchangeable with provisioned clusters. You can have clusters where some DB instances use Aurora serverless and some DB instances are provisioned.

Topics

- Settings for Aurora serverless DB clusters
- Creating an Aurora serverless DB cluster
- Creating an Aurora serverless writer DB instance

Settings for Aurora serverless DB clusters

Make sure that the cluster's initial settings meet the requirements listed in Requirements and limitations for Aurora serverless. Specify the following settings to make sure that you can add Aurora serverless DB instances to the cluster:

Amazon Web Services Region

Create the cluster in an Amazon Web Services Region where Aurora serverless DB instances are available. For details about available Regions, see Supported Regions and Aurora DB engines for Aurora serverless.

DB engine version

Choose an engine version that's compatible with Aurora serverless. For information about the Aurora serverless version requirements, see Requirements and limitations for Aurora serverless.

DB instance class

If you create a cluster using the Amazon Web Services Management Console, you choose the DB instance class for the writer DB instance at the same time. Choose the **Serverless** DB instance class. When you choose that DB instance class, you also specify the capacity range for the writer DB instance. That same capacity range applies to all other Aurora serverless DB instances that you add to that cluster.

If you don't see the **Serverless** choice for the DB instance class, make sure that you chose a DB engine version that's supported for Supported Regions and Aurora DB engines for Aurora serverless.

When you use the Amazon CLI or the Amazon RDS API, the parameter that you specify for the DB instance class is `db.serverless`.

Capacity range

Fill in the minimum and maximum Aurora capacity unit (ACU) values that apply to all the DB instances in the cluster. This option is available on both the **Create cluster** and **Add reader** console pages when you choose **Serverless** for the DB instance class.

For the allowed capacity ranges for various DB engine versions, see Aurora serverless capacity.

If you don't see the minimum and maximum ACU fields, make sure that you chose the **Serverless** DB instance class for the writer DB instance.

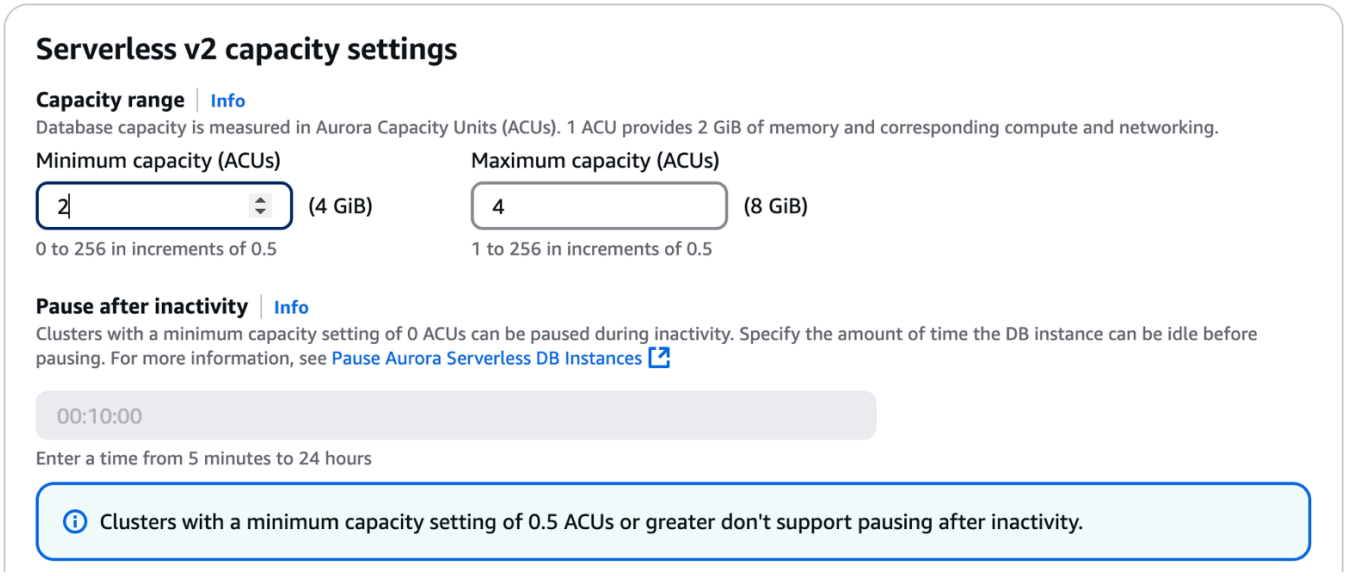
If you initially create the cluster with a provisioned DB instance, you don't specify the minimum and maximum ACUs. In that case you can modify the cluster afterward to add that setting. You can also add an Aurora serverless reader DB instance to the cluster. You specify the capacity range as part of that process.

Until you specify the capacity range for your cluster, you can't add any Aurora serverless DB instances to the cluster using the Amazon CLI or RDS API. If you try to add a Aurora serverless DB instance, you get an error. In the Amazon CLI or the RDS API procedures, the capacity range is represented by the `ServerlessV2ScalingConfiguration` attribute.

For clusters containing more than one reader DB instance, the failover priority of each Aurora serverless reader DB instance plays an important part in how that DB instance scales up and down. You can't specify the priority when you initially create the cluster. Keep this property in mind when you add a second or later reader DB instance to your cluster. For more information, see Choosing the promotion tier for an Aurora serverless reader.

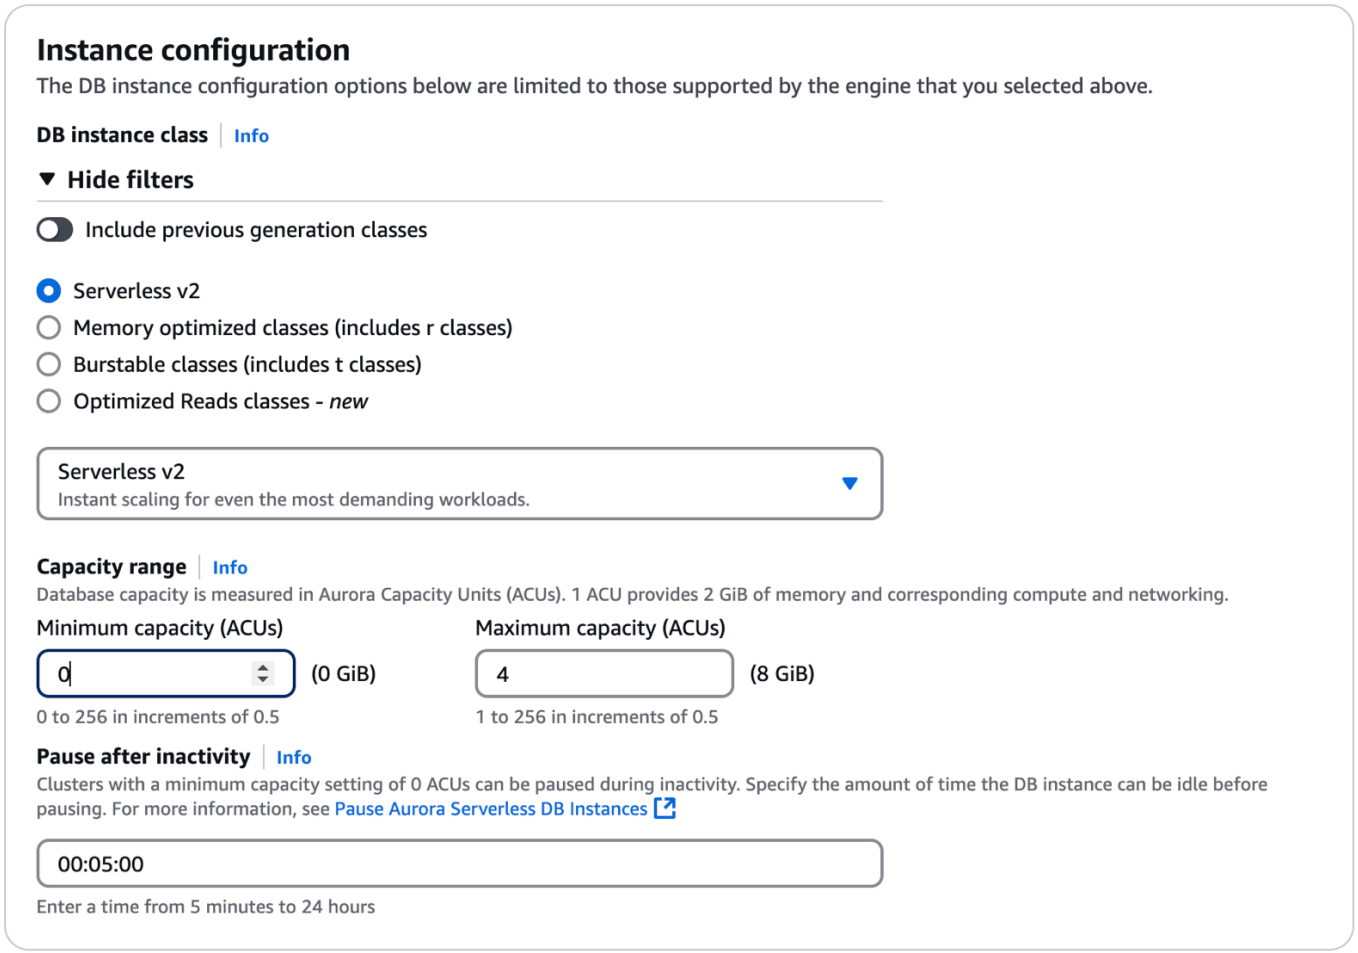
Creating an Aurora serverless DB cluster

You can use the Amazon Web Services Management Console, Amazon CLI, or RDS API to create an Aurora serverless DB cluster.



Console

To create a cluster with an Aurora serverless writer



1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose **Create database**. On the page that appears, choose the following options:
   - For **Engine type**, choose **Aurora (MySQL Compatible)** or **Aurora (PostgreSQL Compatible)**.
   - For **Version**, choose one of the supported versions for Supported Regions and Aurora DB engines for Aurora serverless.
4. For **DB instance class**, select **Serverless v2**.
5. For **Capacity range**, you can accept the default range. Or you can choose other values for minimum and maximum capacity units. You can choose from 0 ACUs through 256 ACUs for Aurora MySQL and to 384 ACUs for Aurora PostgreSQL, in increments of 0.5 ACU.

For more information about Aurora serverless capacity units, see Aurora serverless capacity and Performance and scaling for Aurora serverless.

Depending on the engine and version that you choose, the upper limit might be 128 ACUs, the lower limit might be 0.5 ACUs, or both. For details about the limit for each combination of Aurora engine and version, see Aurora serverless capacity.

Choosing a minimum capacity of 0 ACUs enables the Aurora serverless automatic pause and resume capability. In that case, you can make an additional choice of how long the Aurora serverless DB instances wait with no database connections before automatically pausing. For information about the automatic pause and resume capability, see Scaling to Zero ACUs with automatic pause and resume for Aurora serverless.

6. Choose any other DB cluster settings, as described in Settings for Aurora DB clusters.
7. Choose **Create database** to create your Aurora DB cluster with an Aurora serverless DB instance as the writer instance, also known as the primary DB instance.

CLI

To create a DB cluster that's compatible with Aurora serverless DB instances using the Amazon CLI, you follow the CLI procedure in Creating an Amazon Aurora DB cluster. Include the following parameters in your `create-db-cluster` command:

- --region *AWS_Region_where_Aurora serverless_instances_are_available*
- --engine-version *serverless_v2_compatible_engine_version*
- --serverless-v2-scaling-configuration MinCapacity=*minimum_capacity*,MaxCapacity=*maximum_capacity*

The following example shows the creation of an Aurora serverless DB cluster.

```
aws rds create-db-cluster \
    --db-cluster-identifier my-serverless-v2-cluster \
    --region eu-central-1 \
    --engine aurora-mysql \
    --engine-version 8.0.mysql_aurora.3.04.1 \
    --serverless-v2-scaling-configuration MinCapacity=1,MaxCapacity=4 \
    --master-username myuser \
    --manage-master-user-password
```

Note

When you create an Aurora serverless DB cluster using the Amazon CLI, the engine mode appears in the output as `provisioned` rather than `serverless`.

This example specifies the `--manage-master-user-password` option to generate the administrative password and manage it in Secrets Manager. For more information, see Password management with Amazon Aurora and Amazon Secrets Manager. Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

For information about the Aurora serverless version requirements, see Requirements and limitations for Aurora serverless. For information about the allowed numbers for the capacity range and what those numbers represent, see Aurora serverless capacity and Performance and scaling for Aurora serverless.

To verify whether an existing cluster has the capacity settings specified, check the output of the `describe-db-clusters` command for the `ServerlessV2ScalingConfiguration` attribute. That attribute looks similar to the following.

```
"ServerlessV2ScalingConfiguration": {
    "MinCapacity": 1.5,
    "MaxCapacity": 24.0
}
```

Tip

If you don't specify the minimum and maximum ACUs when you create the cluster, you can use the `modify-db-cluster` command afterward to add that setting. Until you

do, you can't add any Aurora serverless DB instances to the cluster. If you try to add a `db.serverless` DB instance, you get an error.

API

To create a DB cluster that's compatible with Aurora serverless DB instances using the RDS API, you follow the API procedure in Creating an Amazon Aurora DB cluster. Choose the following settings. Make sure that your `CreateDBCluster` operation includes the following parameters:

```
EngineVersion serverless_v2_compatible_engine_version
ServerlessV2ScalingConfiguration with MinCapacity=minimum_capacity and
 MaxCapacity=maximum_capacity
```

For information about the Aurora serverless version requirements, see Requirements and limitations for Aurora serverless. For information about the allowed numbers for the capacity range and what those numbers represent, see Aurora serverless capacity and Performance and scaling for Aurora serverless.

To check if an existing cluster has the capacity settings specified, check the output of the `DescribeDBClusters` operation for the `ServerlessV2ScalingConfiguration` attribute. That attribute looks similar to the following.

```
"ServerlessV2ScalingConfiguration": {
    "MinCapacity": 1.5,
    "MaxCapacity": 24.0
}
```

Tip

If you don't specify the minimum and maximum ACUs when you create the cluster, you can use the `ModifyDBCluster` operation afterward to add that setting. Until you do, you can't add any Aurora serverless DB instances to the cluster. If you try to add a `db.serverless` DB instance, you get an error.

Creating an Aurora serverless writer DB instance

Although you specify the Aurora serverless capacity range when you create an Aurora cluster, you can choose whether to use Aurora serverless or provisioned for each DB instance in the cluster. To begin using Aurora serverless immediately in your DB cluster, add a writer DB instance that uses the db.serverless instance class. In the console, you typically make this choice as part of the workflow to create the DB cluster. Therefore, this procedure applies mostly when you do the setup through the CLI.

Console

When you create a DB cluster using the Amazon Web Services Management Console, you specify the properties of the writer DB instance at the same time. To make the writer DB instance use Aurora serverless, choose the **Serverless** DB instance class.

Then you set the capacity range for the cluster by specifying the minimum and maximum Aurora capacity unit (ACU) values. These minimum and maximum values apply to each Aurora serverless DB instance in the cluster. For that procedure and the significance of the minimum and maximum capacity settings, see Creating an Aurora serverless DB cluster.

If you don't create an Aurora serverless DB instance when you first create the cluster, you can add one or more Aurora serverless DB instances later. To do so, follow the procedures in Adding an Aurora serverless reader and Converting a provisioned writer or reader to Aurora serverless. You specify the capacity range at the time that you add the first Aurora serverless DB instance to the cluster. You can change the capacity range later by following the procedure in Setting the Aurora serverless capacity range for a cluster.

CLI

When you create a Aurora serverless DB cluster using the Amazon CLI, you explicitly add the writer DB instance using the create-db-instance command. Include the following parameter:

- `--db-instance-class db.serverless`

The following example shows the creation of an Aurora serverless writer DB instance.

```
aws rds create-db-instance \
    --db-cluster-identifier my-serverless-v2-cluster \
    --db-instance-identifier my-serverless-v2-instance \
```

```
    --db-instance-class db.serverless \
    --engine aurora-mysql
```

Managing Aurora serverless DB clusters

With Aurora serverless, your clusters are interchangeable with provisioned clusters. The Aurora serverless properties apply to one or more DB instances within a DB cluster. Thus, the procedures for creating clusters, modifying clusters, creating and restoring snapshots, and so on, are basically the same as for other kinds of Aurora clusters. For general procedures for managing Aurora clusters and DB instances, see Managing an Amazon Aurora DB cluster.

In the following topics, you can learn about management considerations for clusters that contain Aurora serverless DB instances.

Topics

- Setting the Aurora serverless capacity range for a cluster
- Checking the capacity range for Aurora serverless
- Checking the platform version for an existing Aurora serverless cluster
- Adding an Aurora serverless reader
- Converting a provisioned writer or reader to Aurora serverless
- Converting an Aurora serverless writer or reader to provisioned
- Pausing Aurora serverless DB instances
- Choosing the promotion tier for an Aurora serverless reader
- Using TLS/SSL with Aurora serverless
- Viewing Aurora serverless writers and readers
- Logging for Aurora serverless

Setting the Aurora serverless capacity range for a cluster

To modify configuration parameters or other settings for clusters containing Aurora serverless DB instances, or the DB instances themselves, follow the same general procedures as for provisioned clusters. For details, see Modifying an Amazon Aurora DB cluster.

The most important setting that's unique to Aurora serverless is the capacity range. After you set the minimum and maximum Aurora capacity unit (ACU) values for an Aurora cluster, you don't need

to actively adjust the capacity of the Aurora serverless DB instances in the cluster. Aurora does that for you. This setting is managed at the cluster level. The same minimum and maximum ACU values apply to each Aurora serverless DB instance in the cluster.

You can set the following specific values:

- **Minimum ACUs** – The Aurora serverless DB instance can reduce capacity down to this number of ACUs.
- **Maximum ACUs** – The Aurora serverless DB instance can increase capacity up to this number of ACUs.

The available capacity range for Aurora serverless is a function of both the DB engine version and the platform version. Newer DB engine versions allow a maximum capacity of 256 ACUs for Aurora MySQL and to 384 ACUs for Aurora PostgreSQL, a minimum capacity of 0 ACUs, or both. For the capacity ranges for various DB engine versions, see Aurora serverless capacity.

For the auto-pause and resume capability that's enabled by setting the minimum capacity to 0 ACUs, see Scaling to Zero ACUs with automatic pause and resume for Aurora serverless.

For more information on making sure that your Aurora serverless DB clusters can scale up to 256 ACUs for Aurora MySQL and to 384 ACUs for Aurora PostgreSQL, see Upgrading your Aurora serverless DB cluster to allow scaling to maximum ACUs.

> **Note**
>
> When you modify the capacity range for an Aurora serverless DB cluster, the change takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

In Aurora serverless, you can't directly set the current capacity without modifying the capacity range, as capacity dynamically adjusts based on the workload within the specified range. However, you can influence the capacity indirectly in the following ways:

- **Adjust the minimum capacity** – Temporarily lower the minimum capacity to reduce the baseline capacity when workloads are light.
- **Pause scaling temporarily** – To fix the capacity at a specific value, set the minimum and maximum capacity to the same level.

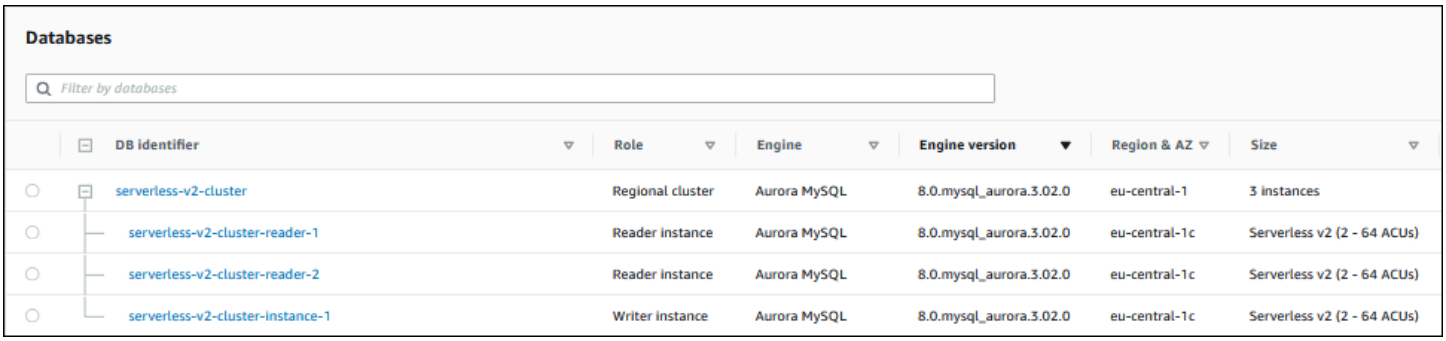
- **Scale proactive for bursting usage** – If you anticipate bursting workloads, increase the minimum capacity beforehand to maintain a higher baseline during periods of high activity.

For details about the effects of the capacity range and how to monitor and fine-tune it, see Important Amazon CloudWatch metrics for Aurora serverless and Performance and scaling for Aurora serverless. Your goal is to make sure that the maximum capacity for the cluster is high enough to handle spikes in workload, and the minimum is low enough to minimize costs when the cluster isn't busy.

Suppose that you determine based on your monitoring that the ACU range for the cluster should be higher, lower, wider, or narrower. You can set the capacity of an Aurora cluster to a specific range of ACUs with the Amazon Web Services Management Console, the Amazon CLI, or the Amazon RDS API. This capacity range applies to every Aurora serverless DB instance in the cluster.

For example, suppose that your cluster has a capacity range of 1–16 ACUs and contains two Aurora serverless DB instances. Then the cluster as a whole consumes somewhere between 2 ACUs (when idle) and 32 ACUs (when fully utilized). If you change the capacity range from 8 to 40.5 ACUs, now the entire cluster consumes 16 ACUs when idle, and up to 81 ACUs when fully utilized.

Aurora automatically sets certain parameters for Aurora serverless DB instances to values that depend on the maximum ACU value in the capacity range. For the list of such parameters, see Maximum connections for Aurora serverless. For static parameters that rely on this type of calculation, the value is evaluated again when you reboot the DB instance. Thus, you can update the value of such parameters by rebooting the DB instance after changing the capacity range. To check whether you need to reboot your DB instance to pick up such parameter changes, check the `ParameterApplyStatus` attribute of the DB instance. A value of `pending-reboot` indicates that rebooting will apply changes to some parameter values.



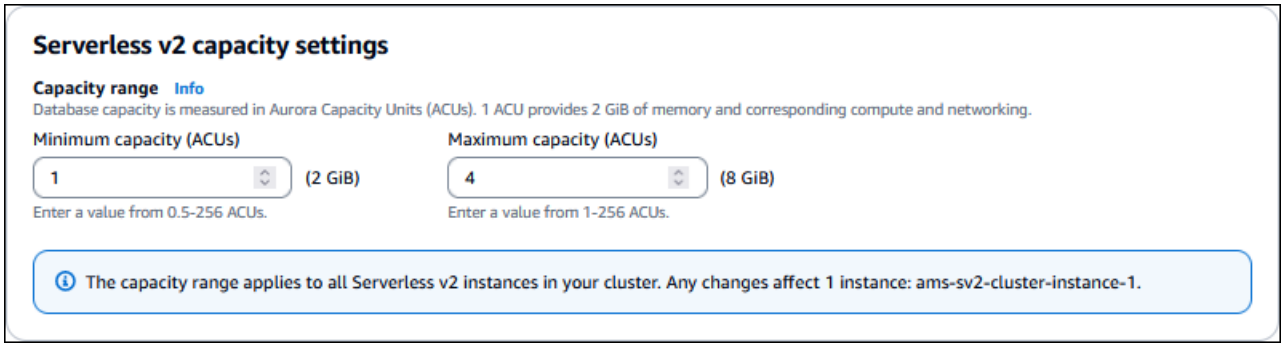
Console

You can set the capacity range of a cluster that contains Aurora serverless DB instances with the Amazon Web Services Management Console.

When you use the console, you set the capacity range for the cluster at the time that you add the first Aurora serverless DB instance to that cluster. You might do so when you choose the **Serverless v2** DB instance class for the writer DB instance when you create the cluster. Or you might do so when you choose the **Serverless** DB instance class when you add an Aurora serverless reader DB instance to the cluster. Or you might do so when you convert an existing provisioned DB

instance in the cluster to the **Serverless** DB instance class. For the full versions of those procedures, see Creating an Aurora serverless writer DB instance, Adding an Aurora serverless reader, and Converting a provisioned writer or reader to Aurora serverless.

Whatever capacity range that you set at the cluster level applies to all Aurora serverless DB instances in your cluster. The following image shows a cluster with multiple Aurora serverless reader DB instances. Each has an identical capacity range of 2–64 ACUs.



To modify the capacity range of an Aurora serverless cluster

1. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the cluster containing your Aurora serverless DB instances from the list. The cluster must already contain at least one Aurora serverless DB instance. Otherwise, Aurora doesn't show the **Capacity range** section.
4. For **Actions**, choose **Modify**.
5. In the **Capacity range** section, choose the following:

    a. Enter a value for **Minimum ACUs**. The console shows the allowed range of values. You can choose a minimum capacity from 0 to 384 ACUs. You can choose a maximum capacity from 1 to 384 ACUs. You can adjust the capacity values in increments of 0.5 ACU. The available capacity range depends on both your DB engine version and the platform version.

    b. Enter a value for **Maximum ACUs**. This value must be greater than or equal to **Minimum ACUs**. The console shows the allowed range of values. The following figure shows that choice.

6. Choose **Continue**. The **Summary of modifications** page appears.
7. Choose **Apply immediately**.

   The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.
8. Choose **Modify cluster** to accept the summary of modifications. You can also choose **Back** to modify your changes or **Cancel** to discard your changes.

Amazon CLI

To set the capacity of a cluster where you intend to use Aurora serverless DB instances using the Amazon CLI, run the modify-db-cluster Amazon CLI command. Specify the `--serverless-v2-scaling-configuration` option. The cluster might already contain one or more Aurora serverless DB instances, or you can add the DB instances later. Valid values for the `MinCapacity` and `MaxCapacity` fields include the following:

- `0`, `0.5`, 1, `1.5`, 2, and so on, in steps of 0.5, up to a maximum of 256 for Aurora MySQL and to 384 ACUs for Aurora PostgreSQL. The minimum ACU value of 0 is only available for the Aurora versions that support the auto-pause feature.

The maximum available capacity depends on both your DB engine version and the platform version.

In this example, you set the ACU range of an Aurora DB cluster named `sample-cluster` to a minimum of `48.5` and a maximum of 64.

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster \
  --serverless-v2-scaling-configuration MinCapacity=48.5,MaxCapacity=64
```

The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

After doing so, you can add Aurora serverless DB instances to the cluster and each new DB instance can scale between 48.5 and 64 ACUs. The new capacity range also applies to any Aurora serverless DB instances that were already in the cluster. The DB instances scale up or down if necessary to fall within the new capacity range.

For additional examples of setting the capacity range using the CLI, see Choosing the Aurora serverless capacity range for an Aurora cluster.

To modify the scaling configuration of an Aurora Serverless DB cluster using the Amazon CLI, run the modify-db-cluster Amazon CLI command. Specify the `--serverless-v2-scaling-configuration` option to configure the minimum capacity and maximum capacity. Valid capacity values include the following:

- Aurora MySQL: `0`, `0.5`, 1, `1.5`, 2, and so on, in increments of 0.5 ACUs up to a maximum of 256.
- Aurora PostgreSQL: `0`, `0.5`, 1, `1.5`, 2, and so on, in increments of 0.5 ACUs up to a maximum of 384.
- The minimum ACU value of 0 is only available for the Aurora versions that support the auto-pause feature.

In the following example, you modify the scaling configuration of an Aurora serverless DB instance named `sample-instance` that's part of a cluster named `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster \
--serverless-v2-scaling-configuration MinCapacity=8,MaxCapacity=64
```

For Windows:

```
aws rds modify-db-cluster --db-cluster-identifier sample-cluster ^
--serverless-v2-scaling-configuration MinCapacity=8,MaxCapacity=64
```

RDS API

You can set the capacity of an Aurora DB instance with the ModifyDBCluster API operation. Specify the `ServerlessV2ScalingConfiguration` parameter. Valid values for the `MinCapacity` and `MaxCapacity` fields include the following:

- `0`, `0.5`, 1, `1.5`, 2, and so on, in steps of 0.5, up to a maximum of 256 for Aurora MySQL and to 384 ACUs for Aurora PostgreSQL. The minimum ACU value of 0 is only available for the Aurora versions that support the auto-pause feature.

You can modify the scaling configuration of a cluster containing Aurora serverless DB instances with the ModifyDBCluster API operation. Specify the `ServerlessV2ScalingConfiguration` parameter to configure the minimum capacity and the maximum capacity. Valid capacity values include the following:

- Aurora MySQL: `0`, `0.5`, 1, `1.5`, 2, and so on, in increments of 0.5 ACUs up to a maximum of 256.
- Aurora PostgreSQL: `0`, `0.5`, 1, `1.5`, 2, and so on, in increments of 0.5 ACUs up to a maximum of 384.
- The minimum ACU value of 0 is only available for the Aurora versions that support the auto-pause feature.

The maximum available capacity depends on both your DB engine version and the platform version.

The capacity modification takes place immediately, regardless of whether you choose to apply it immediately or during the next scheduled maintenance window.

Upgrading your Aurora serverless DB cluster to allow scaling to maximum ACUs

In some cases, when you try to scale your Aurora serverless DB cluster to capacities greater than 128 ACUs, you receive an error message. The error message tells you which instances are incompatible with the new scaling range. This highlights the important relationship between your capacity range, DB engine version, and platform version.

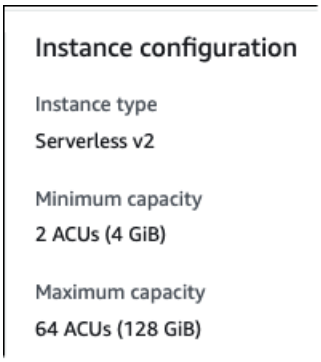
The inability to scale greater than 128 ACUs can happen for one of two reasons:

- Older DB engine version – Upgrade the DB engine version to one that supports 256 ACUs for Aurora MySQL and to 384 ACUs for Aurora PostgreSQL. For more information, see Aurora serverless capacity.
- Older platform version – Upgrade the platform for your Aurora serverless DB cluster. You can do this in one of the following ways:
  - Stop and restart the DB cluster. When the cluster restarts, it will be on the latest platform version capable which may be capable of a higher ACU maximum.

    However, stopping and starting a DB cluster incurs some downtime, usually several minutes. For more information, see Stopping and starting an Amazon Aurora DB cluster.
  - Use a blue/green deployment. For more information, see Overview of Amazon Aurora Blue/Green Deployments.
    1. Create a blue/green deployment. For more information, see Creating a blue/green deployment in Amazon Aurora.
    2. Confirm that you can set the maximum capacity for the staging (green) environment to 256 ACUs for Aurora MySQL and to 384 ACUs for Aurora PostgreSQL.
    3. Switch over to the green environment. For more information, see Switching a blue/green deployment in Amazon Aurora.
    4. Delete the original DB cluster.

    Note

    - If you maintain your database credentials in Amazon Secrets Manager, you can't use blue/green deployments.
    - Aurora Global Database doesn't support blue/green deployments.
    - **Important:** Once you upgrade to a newer platform version, you cannot downgrade to a previous version.



Checking the capacity range for Aurora serverless

The procedure to check the capacity range for your Aurora serverless cluster requires that you first set a capacity range. If you haven't done so, follow the procedure in Setting the Aurora serverless capacity range for a cluster.

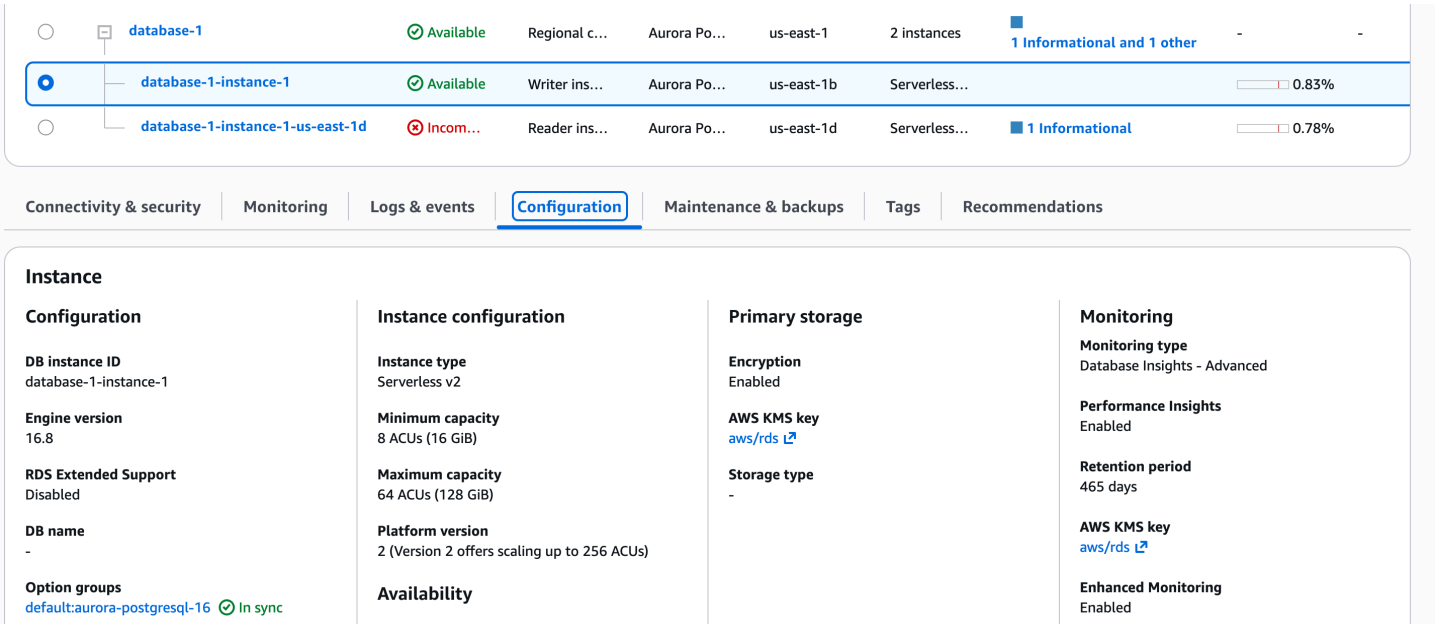
Whatever capacity range you set at the cluster level applies to all Aurora serverless DB instances in your cluster. The following image shows a cluster with multiple Aurora serverless DB instances. Each has an identical capacity range.

You can also view the details page for any Aurora serverless DB instance in the cluster. DB instances' capacity range appears on the **Configuration** tab.

You can also see the current capacity range for the cluster on the **Modify** page for the cluster. At that point, you can change the capacity range. For all the ways that you can set or change the capacity range, see Setting the Aurora serverless capacity range for a cluster.

Checking the current capacity range for an Aurora cluster

You can check the capacity range that's configured for Aurora serverless DB instances in a cluster by examining the `ServerlessV2ScalingConfiguration` attribute for the cluster. The following Amazon CLI example shows a cluster with a minimum capacity of 0.5 Aurora capacity units (ACUs) and a maximum capacity of 16 ACUs.



```
$ aws rds describe-db-clusters --db-cluster-identifier serverless-v2-64-acu-cluster \
  --query 'DBClusters[*].[ServerlessV2ScalingConfiguration]'
[
    [
        {
```

```
            "MinCapacity": 0.5,
            "MaxCapacity": 16.0
        }
    ]
]
```

Checking the platform version for an existing Aurora serverless cluster

Console

The platform version is displayed in the Instance Configuration section of the instance.

Amazon CLI

You can use the `describe-db-clusters` command to check the platform version for existing cluster(s).

Example

```
aws rds describe-db-clusters \
    --db-cluster-identifier mydbcluster
```

Checking the default platform version

Amazon CLI

You can use the `describe-serverless-v2-platform-versions` command to check the details of a platform version or to check the default platform version that you will get when you create a new cluster.

Example

```
$ aws rds describe-serverless-v2-platform-versions
{
    "ServerlessV2PlatformVersions": [
        {
            "Engine": "aurora-postgresql",
            "ServerlessV2PlatformVersion": "3",
            "ServerlessV2PlatformVersionDescription": "Version 3 powered by Graviton
 3 processors offering scaling up to 256 ACUs, and performance improvement up to 30%
 compared to version 2"
            "ServerlessV2FeatureSupport": {
                "MinCapacity": 0
                "MaxCapacity": 256
            },
            "Status": "available",
            "IsDefault": True
        },
        ...
    ]
}

# describing the default platform version for an engine
$ aws rds describe-serverless-v2-platform-versions --engine aurora-postgresql --
default-only
{
    "ServerlessV2PlatformVersions": [
        {
            "Engine": "aurora-postgresql",
            "ServerlessV2PlatformVersion": "3",
            "ServerlessV2PlatformVersionDescription": "Version 3 powered by Graviton
 3 processors offering scaling up to 256 ACUs, and performance improvement up to 30%
 compared to version 2"
            "ServerlessV2FeatureSupport": {
                "MinCapacity": 0
```

```
                "MaxCapacity": 256
            },
            "Status": "available",
            "IsDefault": True
        }
    ]
}
```

Checking for pending platform version upgrades

You can use the `describe-pending-maintenance-actions` command to check whether there are any pending platform version upgrades for your Aurora serverless DB clusters.

To check for pending upgrades on a specific cluster, use the `--resource-identifier` parameter to specify the Amazon Resource Name (ARN) of your DB cluster:

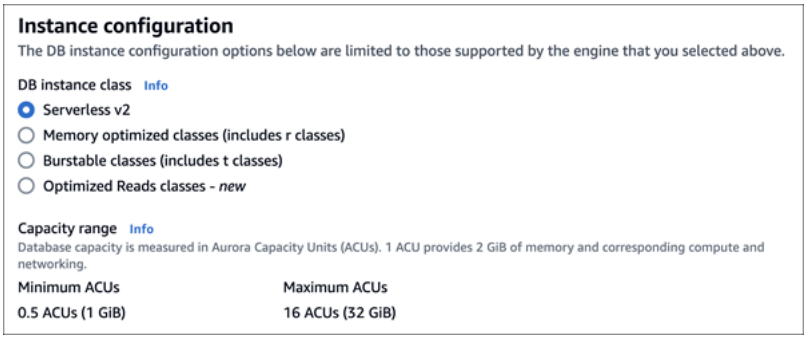
Example

```
aws rds describe-pending-maintenance-actions \
    --resource-identifier arn:aws:rds:us-east-1:123456789012
    :cluster:my-serverless-cluster
```

Scheduling a platform version upgrade

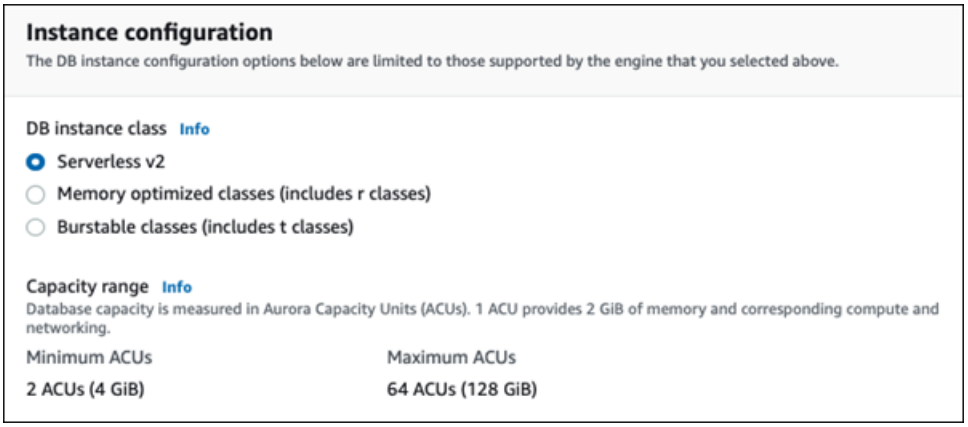
After you identify a pending platform version upgrade, you can use the `apply-pending-maintenance-action` command to schedule when the upgrade occurs.

To schedule a platform version upgrade, specify the following parameters:



- `--resource-identifier` – The ARN of your Aurora serverless DB cluster
- `--apply-action` – Use `serverless-platform-version-update` to specify a platform version upgrade
- `--opt-in-type` – Choose when to apply the upgrade:
  - `immediate` – Apply the upgrade immediately
  - `next-maintenance` – Apply the upgrade during your next schedule

Adding an Aurora serverless reader



To add an Aurora serverless reader DB instance to your cluster, you follow the same general procedure as in Adding Aurora Replicas to a DB cluster. Choose the **Serverless v2** instance class for the new DB instance.

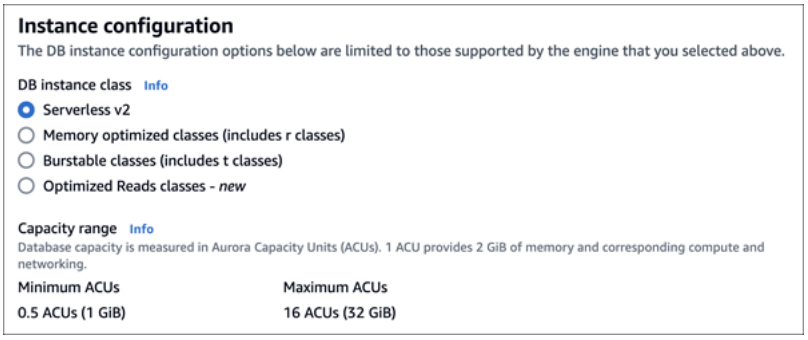
If the reader DB instance is the first Aurora serverless DB instance in the cluster, you also choose the capacity range. This setting applies to this reader DB instance and to any other Aurora serverless DB instances that you add to the cluster. Each Aurora serverless DB instance can scale between the minimum and maximum ACU values.

If any other Aurora serverless instances already exist in the cluster, the **Add reader** dialog shows the current capacity range for the cluster. In that case, you can't change the capacity. The following image shows the report of the current cluster capacity.

If you already added any Aurora serverless DB instances to the cluster, adding another Aurora serverless reader DB instance shows you the current capacity range. The following image shows those read-only controls.

If you want to change the capacity range for the cluster, follow the procedure in Setting the Aurora serverless capacity range for a cluster.

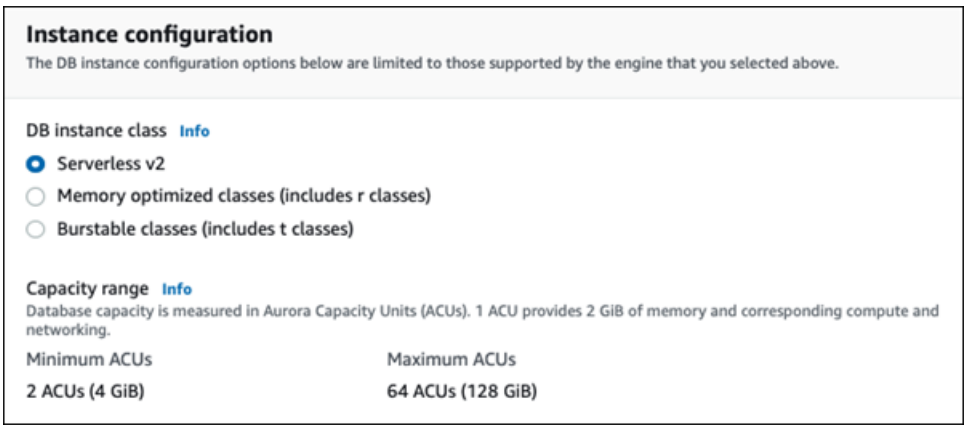
For clusters containing more than one reader DB instance, the failover priority of each Aurora serverless reader DB instance plays an important part in how that DB instance scales up and down. You can't specify the priority when you initially create the cluster. Keep this property in mind when you add a second reader or later DB instance to your cluster. For more information, see Choosing the promotion tier for an Aurora serverless reader.



For other ways that you can see the current capacity range for a cluster, see Checking the capacity range for Aurora serverless.

Converting a provisioned writer or reader to Aurora serverless

You can convert a provisioned DB instance to use Aurora serverless. To do so, you follow the procedure in Modifying a DB instance in a DB cluster. The cluster must meet the requirements in Requirements and limitations for Aurora serverless. For example, Aurora serverless DB instances require that the cluster be running certain minimum engine versions.



Suppose that you are converting a running provisioned cluster to take advantage of Aurora serverless. In that case, you can minimize downtime by converting a DB instance to Aurora serverless as the first step in the switchover process. For the full procedure, see Converting a provisioned writer or reader to Aurora serverless.

If the DB instance that you convert is the first Aurora serverless DB instance in the cluster, you choose the capacity range for the cluster as part of the **Modify** operation. This capacity range applies to each Aurora serverless DB instance that you add to the cluster. The following image shows the page where you specify the minimum and maximum Aurora capacity units (ACUs).

For details about the significance of the capacity range, see Aurora serverless capacity.

If the cluster already contains one or more Aurora serverless DB instances, you see the existing capacity range during the **Modify** operation. The following image shows an example of that information panel.

If you want to change the capacity range for the cluster after you add more Aurora serverless DB instances, follow the procedure in Setting the Aurora serverless capacity range for a cluster.

Converting an Aurora serverless writer or reader to provisioned

You can convert an Aurora serverless DB instance to a provisioned DB instance. To do so, you follow the procedure in Modifying a DB instance in a DB cluster. Choose a DB instance class other than **Serverless**.

You might convert an Aurora serverless DB instance to provisioned if it needs a larger capacity than is available with the maximum Aurora capacity units (ACUs) of an Aurora serverless DB instance. For example, the largest db.r5 and db.r6g DB instance classes have a larger memory capacity than an Aurora serverless DB instance can scale to.

> **Tip**
>
> Some of the older DB instance classes such as db.r3 and db.t2 aren't available for the Aurora versions that you use with Aurora serverless. To see which DB instance classes you can use when converting an Aurora serverless DB instance to a provisioned one, see Supported DB engines for DB instance classes.

If you are converting the writer DB instance of your cluster from Aurora serverless to provisioned, you can follow the procedure in Converting a provisioned writer or reader to Aurora serverless but in reverse. Switch one of the reader DB instances in the cluster from Aurora serverless to provisioned. Then perform a failover to make that provisioned DB instance into the writer.

Any capacity range that you previously specified for the cluster remains in place, even if all Aurora serverless DB instances are removed from the cluster. If you want to change the capacity range, you can modify the cluster, as explained in Setting the Aurora serverless capacity range for a cluster.

Pausing Aurora serverless DB instances

You can configure Aurora clusters to automatically pause and resume their Aurora serverless DB instances. For more information, see Scaling to Zero ACUs with automatic pause and resume for Aurora serverless.

Choosing the promotion tier for an Aurora serverless reader

For clusters containing multiple Aurora serverless DB instances or a mixture of provisioned and Aurora serverless DB instances, pay attention to the promotion tier setting for each Aurora serverless DB instance. This setting controls more behavior for Aurora serverless DB instances than for provisioned DB instances.

In the Amazon Web Services Management Console, you specify this setting using the **Failover priority** choice under **Additional configuration** for the **Create database**, **Modify instance**, and **Add reader** pages. You see this property for existing DB instances in the optional **Priority tier** column on the **Databases** page. You can also see this property on the details page for a DB cluster or DB instance.

For provisioned DB instances, the choice of tier 0–15 determines only the order in which Aurora chooses which reader DB instance to promote to the writer during a failover operation. For Aurora serverless reader DB instances, the tier number also determines whether the DB instance scales up to match the capacity of the writer DB instance or scales independently based on its own workload. Aurora serverless reader DB instances in tier 0 or 1 are kept at a minimum capacity at least as high as the writer DB instance. That way, they are ready to take over from the writer DB instance in case of a failover. If the writer DB instance is a provisioned DB instance, Aurora estimates the equivalent Aurora serverless capacity. It uses that estimate as the minimum capacity for the Aurora serverless reader DB instance.

Aurora serverless reader DB instances in tiers 2–15 don't have the same constraint on their minimum capacity. When they are idle, they can scale down to the minimum Aurora capacity unit (ACU) value specified in the cluster's capacity range.

The following Linux Amazon CLI example shows how to examine the promotion tiers of all the DB instances in your cluster. The final field includes a value of `True` for the writer DB instance and `False` for all the reader DB instances.

```
$ aws rds describe-db-clusters --db-cluster-identifier promotion-tier-demo \
  --query 'DBClusters[*].DBClusterMembers[*].
[PromotionTier,DBInstanceIdentifier,IsClusterWriter]' \
  --output text

1   instance-192  True
1   tier-01-4840  False
10  tier-10-7425  False
15  tier-15-6694  False
```

The following Linux Amazon CLI example shows how to change the promotion tier of a specific DB instance in your cluster. The commands first modify the DB instance with a new promotion tier. Then they wait for the DB instance to become available again and confirm the new promotion tier for the DB instance.

```
$ aws rds modify-db-instance --db-instance-identifier instance-192 --promotion-tier 0
$ aws rds wait db-instance-available --db-instance-identifier instance-192
$ aws rds describe-db-instances --db-instance-identifier instance-192 \
  --query '*[].[PromotionTier]' --output text
0
```

For more guidance about specifying promotion tiers for different use cases, see Aurora serverless scaling.

Using TLS/SSL with Aurora serverless

Aurora serverless can use the Transport Layer Security/Secure Sockets Layer (TLS/SSL) protocol to encrypt communications between clients and your Aurora serverless DB instances. It supports TLS/SSL versions 1.0, 1.1, and 1.2. For general information about using TLS/SSL with Aurora, see TLS connections to Aurora MySQL DB clusters.

To learn more about connecting to Aurora MySQL database with the MySQL client, see Connecting to a DB instance running the MySQL database engine.

Aurora serverless supports all TLS/SSL modes available to the MySQL client (`mysql`) and PostgreSQL client (`psql`), including those listed in the following table.

Description of TLS/SSL mode	mysql	psql
Connect without using TLS/SSL.	DISABLED	disable
Try the connection using TLS/SSL first, but fall back to non-SSL if necessary.	PREFERRED	prefer (default)
Enforce using TLS/SSL.	REQUIRED	require
Enforce TLS/SSL and verify the certificate authority (CA).	VERIFY_CA	verify-ca
Enforce TLS/SSL, verify the CA, and verify the CA hostname.	VERIFY_IDENTITY	verify-full

Aurora serverless uses wildcard certificates. If you specify the "verify CA" or the "verify CA and CA hostname" option when using TLS/SSL, first download the Amazon root CA 1 trust store from Amazon Trust Services. After doing so, you can identify this PEM-formatted file in your client command. To do so using the PostgreSQL client, do the following.

For Linux, macOS, or Unix:

```
psql 'host=endpoint user=user sslmode=require sslrootcert=amazon-root-CA-1.pem
 dbname=db-name'
```

To learn more about working with the Aurora PostgreSQL database using the Postgres client, see Connecting to a DB instance running the PostgreSQL database engine.

For more information about connecting to Aurora DB clusters in general, see Connecting to an Amazon Aurora DB cluster.

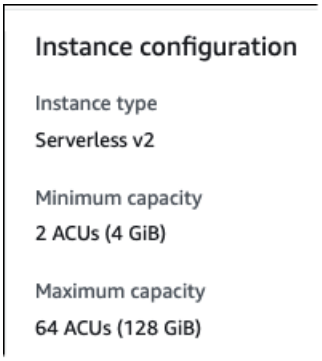
Supported cipher suites for connections to Aurora serverless DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client TLS/

SSL connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this prevents the use of ciphers that aren't secure or that are no longer used.

Aurora serverless DB clusters that are based on Aurora MySQL support the same cipher suites as Aurora MySQL provisioned DB clusters. For information about these cipher suites, see Configuring cipher suites for connections to Aurora MySQL DB clusters.

Aurora serverless DB clusters that are based on Aurora PostgreSQL support the same cipher suites as Aurora PostgreSQL provisioned DB clusters. For information about these cipher suites, see Configuring cipher suites for connections to Aurora PostgreSQL DB clusters.



Viewing Aurora serverless writers and readers

You can view the details of Aurora serverless DB instances in the same way that you do for provisioned DB instances. To do so, follow the general procedure from Viewing an Amazon Aurora DB cluster. A cluster might contain all Aurora serverless DB instances, all provisioned DB instances, or some of each.

After you create one or more Aurora serverless DB instances, you can view which DB instances are type **Serverless** and which are type **Instance**. You can also view the minimum and maximum Aurora capacity units (ACUs) that the Aurora serverless DB instance can use. Each ACU is a combination of processing (CPU) and memory (RAM) capacity. This capacity range applies to each Aurora serverless DB instance in the cluster. For the procedure to check the capacity range of a cluster or any Aurora serverless DB instance in the cluster, see Checking the capacity range for Aurora serverless.

In the Amazon Web Services Management Console, Aurora serverless DB instances are marked under the **Size** column in the **Databases** page. Provisioned DB instances show the name of a DB instance class such as r6g.xlarge. The Aurora Serverless DB instances show **Serverless** for the DB instance class, along with the DB instance's minimum and maximum capacity. For example, you might see **Serverless v2 (4–64 ACUs)** or **Serverless v2 (1–40 ACUs)**.

You can find the same information on the **Configuration** tab for each Aurora serverless DB instance in the console. For example, you might see an **Instance type** section such as the following. Here, the **Instance type** value is **Serverless v2**, the **Minimum capacity** value is **2 ACUs (4 GiB)**, and the **Maximum capacity** value is **64 ACUs (128 GiB)**.

You can monitor the capacity of each Aurora serverless DB instance over time. That way, you can check the minimum, maximum, and average ACUs consumed by each DB instance. You can also check how close the DB instance came to its minimum or maximum capacity. To see such details in the Amazon Web Services Management Console, examine the graphs of Amazon CloudWatch metrics on the **Monitoring** tab for the DB instance. For information about the metrics to watch and how to interpret them, see Important Amazon CloudWatch metrics for Aurora serverless.

Logging for Aurora serverless

To turn on database logging, you specify the logs to enable using configuration parameters in your custom parameter group.

For Aurora MySQL, you can enable the following logs.

Aurora MySQL	Description
`general_log`	Creates the general log. Set to 1 to turn on. Default is off (0).
`log_queries_not_using_indexes`	Logs any queries to the slow query log that don't use an index. Default is off (0). Set to 1 to turn on this log.
`long_query_time`	Prevents fast-running queries from being logged in the slow query log. Can be set to a float between 0 and 31536000. Default is 0 (not active).
`server_audit_events`	The list of events to capture in the logs. Supported values are `CONNECT`, `QUERY`,

Aurora MySQL	Description
	QUERY_DCL , QUERY_DDL , QUERY_DML , and TABLE.
server_audit_logging	Set to 1 to turn on server audit logging. If you turn this on, you can specify the audit events to send to CloudWatch by listing them in the server_audit_events parameter.
slow_query_log	Creates a slow query log. Set to 1 to turn on the slow query log. Default is off (0).

For more information, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster.

For Aurora PostgreSQL, you can enable the following logs on your Aurora serverless DB instances.

Aurora PostgreSQL	Description
log_connections	Logs each successful connection.
log_disconnections	Logs end of a session including duration.
log_lock_waits	Default is 0 (off). Set to 1 to log lock waits.
log_min_duration_statement	The minimum duration (in milliseconds) for a statement to run before it's logged.
log_min_messages	Sets the message levels that are logged. Supported values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic. To log performance data to the postgres log, set the value to debug1.
log_temp_files	Logs the use of temporary files that are above the specified kilobytes (kB).

Aurora PostgreSQL	Description
`log_statement`	Controls the specific SQL statements that get logged. Supported values are none, `ddl`, mod, and `all`. Default is none.

Topics

- Logging with Amazon CloudWatch
- Viewing Aurora serverless logs in Amazon CloudWatch
- Monitoring capacity with Amazon CloudWatch
- Monitoring Aurora serverless pause and resume activity

Logging with Amazon CloudWatch

After you use the procedure in Logging for Aurora serverless to choose which database logs to turn on, you can choose which logs to upload ("publish") to Amazon CloudWatch.

You can use Amazon CloudWatch to analyze log data, create alarms, and view metrics. By default, error logs for Aurora serverless are enabled and automatically uploaded to CloudWatch. You can also upload other logs from Aurora serverless DB instances to CloudWatch.

Then you choose which of those logs to upload to CloudWatch, by using the **Log exports** settings in the Amazon Web Services Management Console or the `--enable-cloudwatch-logs-exports` option in the Amazon CLI.

You can choose which of your Aurora serverless logs to upload to CloudWatch. For more information, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster.

As with any type of Aurora DB cluster, you can't modify the default DB cluster parameter group. Instead, create your own DB cluster parameter group based on a default parameter for your DB cluster and engine type. We recommend that you create your custom DB cluster parameter group before creating your Aurora serverless DB cluster, so that it's available to choose when you create a database on the console.

> **Note**
>
> For Aurora serverless, you can create both DB cluster and DB parameter groups.

Viewing Aurora serverless logs in Amazon CloudWatch

After you use the procedure in Logging with Amazon CloudWatch to choose which database logs to turn on, you can view the contents of the logs.

For more information on using CloudWatch with Aurora MySQL and Aurora PostgreSQL logs, see Monitoring log events in Amazon CloudWatch and Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs.

To view logs for your Aurora serverless DB cluster

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose your Amazon Web Services Region.
3. Choose **Log groups**.
4. Choose your Aurora serverless DB cluster log from the list. The log naming pattern is as follows.

```
/aws/rds/cluster/cluster-name/log_type
```

> **Note**
>
> For Aurora MySQL–compatible Aurora serverless DB clusters, the error log includes buffer pool scaling events even when there are no errors.

Monitoring capacity with Amazon CloudWatch

With Aurora serverless, you can use CloudWatch to to monitor the capacity and utilization of all the Aurora serverless DB instances in your cluster. You can view instance-level metrics to check the capacity of each Aurora serverless DB instance as it scales up and down. You can also compare the capacity-related metrics to other metrics to see how changes in workloads affect resource consumption. For example, you can compare `ServerlessDatabaseCapacity` to `DatabaseUsedMemory`, `DatabaseConnections`, and `DMLThroughput` to assess how your DB cluster is responding during operations. For details about the capacity-related metrics that apply to Aurora serverless, see Important Amazon CloudWatch metrics for Aurora serverless.

To monitor your Aurora serverless DB cluster's capacity

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Metrics**. All available metrics appear as cards in the console, grouped by service name.
3. Choose **RDS**.
4. (Optional) Use the **Search** box to find the metrics that are especially important for Aurora serverless: `ServerlessDatabaseCapacity`, `ACUUtilization`, `CPUUtilization`, and `FreeableMemory`.

We recommend that you set up a CloudWatch dashboard to monitor your Aurora serverless DB cluster capacity using the capacity-related metrics. To learn how, see Building dashboards with CloudWatch.

To learn more about using Amazon CloudWatch with Amazon Aurora, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs.

Monitoring Aurora serverless pause and resume activity

Aurora writes a separate log file for Aurora serverless DB instances with auto-pause enabled. Aurora writes to the log for each 10-minute interval that the instance isn't paused. Aurora retains up to seven of these logs, rotated daily. The current log file is named `instance.log`, and older logs are named using the pattern `instance.`*`YYYY-MM-DD`*`.`*`N`*`.log`.

This log is enabled by default for Aurora serverless DB instances with auto-pause enabled. You can view the contents of this log in the Amazon Web Services Management Console or by using the Amazon CLI or RDSP API. Currently, you can't upload this log to CloudWatch.

The events listed in DB instance events provide a high-level overview of pause and resume activity, such as the following:

- When the instance begins to pause, and when it finishes pausing.
- When the instance begins to resume, and when it finishes resuming.
- Cases where the instance attempted to pause, but some condition prevented it from pausing.

The `instance.log` provides more granular detail about the reasons why an Aurora serverless instance might or might not be able to pause.

The log might indicate that an instance resumed for different reasons:

- **user activity**: A database connection request. This could be from an interactive client session, an RDS Data API call, or a request to download logs from the instance.
- **background activity**: A broad category that includes all the reasons why Aurora resumes an instance. For example, when a connection request to a reader instance causes the writer instance to resume, the log for the reader indicates user activity, while the log for the writer classifies that resume request as background activity. For the reasons why Aurora might resume an instance other than a user connection request, see Resuming an auto-paused Aurora serverless instance.

When Aurora isn't aware of any conditions that would prevent the instance from pausing when the auto-pause interval expires, it periodically writes an informational message to the log. For clusters with only a single DB instance, the log contains this message:

```
[INFO] No auto-pause blockers registered since time
```

For clusters with multiple DB instances, the message is slightly different. That's because a writer might be unable to pause due to activity on any of the reader instances. If the activity on the reader finishes before the auto-pause interval expires on the writer, the writer is able to pause at the expected time.

```
[INFO] No auto-pause blockers registered since time.
Database might be required to maintain compute capacity for high availability.
```

If a pause operation starts, but a new database connection request arrives before the instance finishes pausing, the log contains this message:

```
[INFO] Unable to pause database due to a new database activity
```

If Aurora becomes aware of any conditions that definitely prevent the instance from pausing, the log contains this message that lists all such conditions:

```
[INFO] Auto-pause blockers registered since time: list_of_conditions
```

That way, Aurora doesn't prevent you from turning on replication, zero-ETL integration, Aurora Global Database, and so on in combination with the auto-pause feature. The log informs you when the use of such features might prevent auto-pause from taking effect.

The following are reasons why an Aurora serverless instance might exceed the auto-pause timeout interval, but be prevented from pausing:

- **database activity before auto-pause timeout**: The DB instance received a connection request before the timeout interval expired.
- **member of global database**: If the DB cluster is part of an Aurora global database, the Aurora serverless instances in the cluster don't pause. A cluster can change from a standalone cluster to a global database cluster. Thus, instances that formerly auto-paused might stop pausing, and report this reason in the log. Once a cluster becomes a member of a global database, it doesn't revert to a standalone cluster until you explicitly detach it. The primary cluster is still considered part of the global database even if you detach all of the secondary clusters.
- **replication capability configured**: The writer DB instance has engine-specific replication enabled, either binlog replication for MySQL or logical replication for PostgreSQL. This condition could also be caused by using another Aurora feature that requires turning on replication, such as zero-ETL integrations or Database Activity Streams (DAS).
- **continuous backup lag**: If the Aurora storage system hasn't finished applying the storage changes up to the current point in time, the writer instance doesn't pause until it catches up. This condition only affects the writer instance, and is expected to be relatively brief.
- **service or customer maintenance action**: If a maintenance operation starts, the DB instance won't pause again until that operation finishes. This condition includes a wide variety of operations that might be started by you or by Aurora, such as upgrades, cloning, changing configuration settings, upgrades, downloading log files, and so on. This event also happens when you request to delete an instance, and Aurora briefly resumes the instance as part of the deletion mechanism.
- **transient communication issue**: If Aurora can't determine whether the scaling configuration currently has a minimum capacity setting of zero ACUs, it doesn't pause the instance. This is expected to be a very rare occurrence.

Performance and scaling for Aurora serverless

The following procedures and examples show how you can set the capacity range for Aurora serverless clusters and their associated DB instances. You can also use procedures following to monitor how busy your DB instances are. Then you can use your findings to determine if you need to adjust the capacity range upward or downward.

Before you use these procedures, make sure that you are familiar with how Aurora serverless scaling works. For details, see Aurora serverless scaling.

Choosing the Aurora serverless capacity range for an Aurora cluster

With Aurora serverless DB instances, you set the capacity range that applies to all the DB instances in your DB cluster at the same time that you add the first Aurora serverless DB instance to the DB cluster. For the procedure to do so, see Setting the Aurora serverless capacity range for a cluster.

You can also change the capacity range for an existing cluster. The following sections discuss in more detail how to choose appropriate minimum and maximum values and what happens when you make a change to the capacity range. For example, changing the capacity range can modify the default values of some configuration parameters. Applying all the parameter changes can require rebooting each Aurora serverless DB instance.

Topics

- Example: Change the Aurora serverless capacity range of an Aurora MySQL cluster

- Example: Change the Aurora serverless capacity range of an Aurora PostgreSQL cluster

Choosing the minimum Aurora serverless capacity setting for a cluster

It's tempting to always choose 0.5 for the minimum Aurora serverless capacity setting. That value allows the DB instance to scale down to the smallest capacity when it's completely idle, while remaining active. You can also enable automatic pause behavior by specifying a minimum capacity of 0 ACUs, as explained in Scaling to Zero ACUs with automatic pause and resume for Aurora serverless. However, depending on how you use that cluster and the other settings that you configure, a different minimum capacity might be the most effective. Consider the following factors when choosing the minimum capacity setting:

- The scaling rate for an Aurora serverless DB instance depends on its current capacity. The higher the current capacity, the faster it can scale up. If you need the DB instance to quickly scale up to a very high capacity, consider setting the minimum capacity to a value where the scaling rate meets your requirement.
- If you typically modify the DB instance class of your DB instances in anticipation of especially high or low workload, you can use that experience to make a rough estimate of the equivalent Aurora serverless capacity range. To determine the memory size to use in times of low traffic, consult Hardware specifications for DB instance classes for Aurora.

  For example, suppose that you use the db.r6g.xlarge DB instance class when your cluster has a low workload. That DB instance class has 32 GiB of memory. Thus, you can specify a minimum Aurora capacity unit (ACU) setting of 16 to set up an Aurora serverless DB instance that can scale down to approximately that same capacity. That's because each ACU corresponds to approximately 2 GiB of memory. You might specify a somewhat lower value to let the DB instance scale down further in case your db.r6g.xlarge DB instance was sometimes underutilized.
- If your application works most efficiently when the DB instances have a certain amount of data in the buffer cache, consider specifying a minimum ACU setting where the memory is large enough to hold the frequently accessed data. Otherwise, some data is evicted from the buffer cache when the Aurora serverless DB instances scale down to a lower memory size. Then when the DB instances scale back up, the information is read back into the buffer cache over time. If the amount of I/O to bring the data back into the buffer cache is substantial, it might be more effective to choose a higher minimum ACU value.
- If your Aurora serverless DB instances run most of the time at a particular capacity, consider specifying a minimum capacity setting that's lower than that baseline, but not too much lower.

Aurora serverless DB instances can most effectively estimate how much and how fast to scale up when the current capacity isn't drastically lower than the required capacity.

- If your provisioned workload has memory requirements that are too high for small DB instance classes such as T3 or T4g, choose a minimum ACU setting that provides memory comparable to an R5 or R6g DB instance.

  In particular, we recommend the following minimum capacity for use with the specified features (these recommendations are subject to change):

  - Performance Insights – 2 ACUs
  - Aurora global databases – 8 ACUs (applies only to the primary Amazon Web Services Region)
- In Aurora, replication occurs at the storage layer, so reader capacity doesn't directly affect replication. However, for Aurora serverless reader DB instances that scale independently, make sure that the minimum capacity is sufficient to handle workloads during write-intensive periods to avoid query latency. If reader DB instances in promotion tiers 2–15 experience performance issues, consider increasing the cluster's minimum capacity. For details on choosing whether reader DB instances scale along with the writer or independently, see Choosing the promotion tier for an Aurora serverless reader.
- If you have a DB cluster with Aurora serverless reader DB instances, the readers don't scale along with the writer DB instance when the promotion tier of the readers isn't 0 or 1. In that case, setting a low minimum capacity can result in excessive replication lag. That's because the readers might not have enough capacity to apply changes from the writer when the database is busy. We recommend that you set the minimum capacity to a value that represents a comparable amount of memory and CPU to the writer DB instance.
- The value of the `max_connections` parameter for Aurora serverlessDB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0 or 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

  If you intend to use the Aurora PostgreSQL cluster for a high-connection workload, consider using a minimum ACU setting of 1 or higher. For details about how Aurora serverless handles the `max_connections` configuration parameter, see Maximum connections for Aurora serverless.
- The time it takes for an Aurora serverless DB instance to scale from its minimum capacity to its maximum capacity depends on the difference between its minimum and maximum ACU values. When the current capacity of the DB instance is large, Aurora serverless scales up in larger increments than when the DB instance starts from a small capacity. Thus, if you specify a relatively large maximum capacity and the DB instance spends most of its time near that

capacity, consider increasing the minimum ACU setting. That way, an idle DB instance can scale back up to maximum capacity more quickly.

Choosing the maximum Aurora serverless capacity setting for a cluster

It's tempting to always choose some high value for the maximum Aurora serverless capacity setting. A large maximum capacity allows the DB instance to scale up the most when it's running an intensive workload. A low value avoids the possibility of unexpected charges. Depending on how you use that cluster and the other settings that you configure, the most effective value might be higher or lower than you originally thought. Consider the following factors when choosing the maximum capacity setting:

- The maximum capacity must be at least as high as the minimum capacity. You can set the minimum and maximum capacity to be identical. However, in that case the capacity never scales up or down. Thus, using identical values for minimum and maximum capacity isn't appropriate outside of testing situations.
- The maximum capacity must be higher than 0.5 ACUs. You can set the minimum and maximum capacity to be the same in most cases. However, you can't specify 0.5 for both the minimum and maximum. Use a value of 1 or higher for the maximum capacity.
- If you typically modify the DB instance class of your DB instances in anticipation of especially high or low workload, you can use that experience to estimate the equivalent Aurora serverless capacity range. To determine the memory size to use in times of high traffic, consult Hardware specifications for DB instance classes for Aurora.

  For example, suppose that you use the db.r6g.4xlarge DB instance class when your cluster has a high workload. That DB instance class has 128 GiB of memory. Thus, you can specify a maximum ACU setting of 64 to set up an Aurora serverless DB instance that can scale up to approximately that same capacity. That's because each ACU corresponds to approximately 2 GiB of memory. You might specify a somewhat higher value to let the DB instance scale up farther in case your db.r6g.4xlarge DB instance sometimes doesn't have enough capacity to handle the workload effectively.
- If you have a budgetary cap on your database usage, choose a value that stays within that cap even if all your Aurora serverless DB instances run at maximum capacity all the time. Remember that when you have *n* Aurora serverless DB instances in your cluster, the theoretical maximum Aurora serverless capacity that the cluster can consume at any moment is *n* times the maximum ACU setting for the cluster. (The actual amount consumed might be less, for example if some readers scale independently from the writer.)

- If you make use of Aurora serverless reader DB instances to offload some of the read-only workload from the writer DB instance, you might be able to choose a lower maximum capacity setting. You do this to reflect that each reader DB instance doesn't need to scale as high as if the cluster contains only a single DB instance.
- Suppose that you want to protect against excessive usage due to misconfigured database parameters or inefficient queries in your application. In that case, you might avoid accidental overuse by choosing a maximum capacity setting that's lower than the absolute highest that you could set.
- If spikes due to real user activity are rare but do happen, you can take those occasions into account when choosing the maximum capacity setting. If the priority is for the application to keep running with full performance and scalability, you can specify a maximum capacity setting that's higher than you observe in normal usage. If it's OK for the application to run with reduced throughput during very extreme spikes in activity, you can choose a slightly lower maximum capacity setting. Make sure that you choose a setting that still has enough memory and CPU resources to keep the application running.
- If you turn on settings in your cluster that increase the memory usage for each DB instance, take that memory into account when deciding on the maximum ACU value. Such settings include those for Performance Insights, Aurora MySQL parallel queries, Aurora MySQL performance schema, and Aurora MySQL binary log replication. Make sure that the maximum ACU value allows the Aurora serverless DB instances to scale up enough to handle the workload when those feature are being used. For information about troubleshooting problems caused by the combination of a low maximum ACU setting and Aurora features that impose memory overhead, see Avoiding out-of-memory errors and CPU saturation.

Example: Change the Aurora serverless capacity range of an Aurora MySQL cluster

The following Amazon CLI example shows how to update the ACU range for Aurora serverless DB instances in an existing Aurora MySQL cluster. Initially, the capacity range for the cluster is 8–32 ACUs.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 8.0,
    "MaxCapacity": 32.0
```

```
}
```

The DB instance is idle and scaled down to 8 ACUs. The following capacity-related settings apply to the DB instance at this point. To represent the size of the buffer pool in easily readable units, we divide it by 2 to the power of 30, yielding a measurement in gibibytes (GiB). That's because memory-related measurements for Aurora use units based on powers of 2, not powers of 10.

```
mysql> select @@max_connections;
+-------------------+
| @@max_connections |
+-------------------+
|              3000 |
+-------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|                9294577664 |
+---------------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----------+
| gibibytes |
+-----------+
|   8.65625 |
+-----------+
1 row in set (0.00 sec)
```

Next, we change the capacity range for the cluster. After the `modify-db-cluster` command finishes, the ACU range for the cluster is 12.5–80.

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
  --serverless-v2-scaling-configuration MinCapacity=12.5,MaxCapacity=80

aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 12.5,
    "MaxCapacity": 80.0
```

```
}
```

Changing the capacity range caused changes to the default values of some configuration parameters. Aurora can apply some of those new defaults immediately. However, some of the parameter changes take effect only after a reboot. The `pending-reboot` status indicates that a reboot is needed to apply some parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].{DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGrou
[0]'
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "pending-reboot"
        }
    ]
}
```

At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 12.5 ACUs. The `innodb_buffer_pool_size` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` parameter still reflects the value from the former maximum capacity. Resetting that value requires rebooting the DB instance.

> **Note**
>
> If you set the `max_connections` parameter directly in a custom DB parameter group, no reboot is required.

```
mysql> select @@max_connections;
+-------------------+
| @@max_connections |
+-------------------+
|              3000 |
+-------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size;
```

```
+----------------------------+
| @@innodb_buffer_pool_size |
+----------------------------+
|               15572402176 |
+----------------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+---------------+
| gibibytes     |
+---------------+
| 14.5029296875 |
+---------------+
1 row in set (0.00 sec)
```

Now we reboot the DB instance and wait for it to become available again.

```
aws rds reboot-db-instance --db-instance-identifier serverless-v2-instance-1
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBInstanceStatus": "rebooting"
}

aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
```

The `pending-reboot` status is cleared. The value `in-sync` confirms that Aurora has applied all the pending parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].{DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGrou
[0]'
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "in-sync"
        }
    ]
}
```

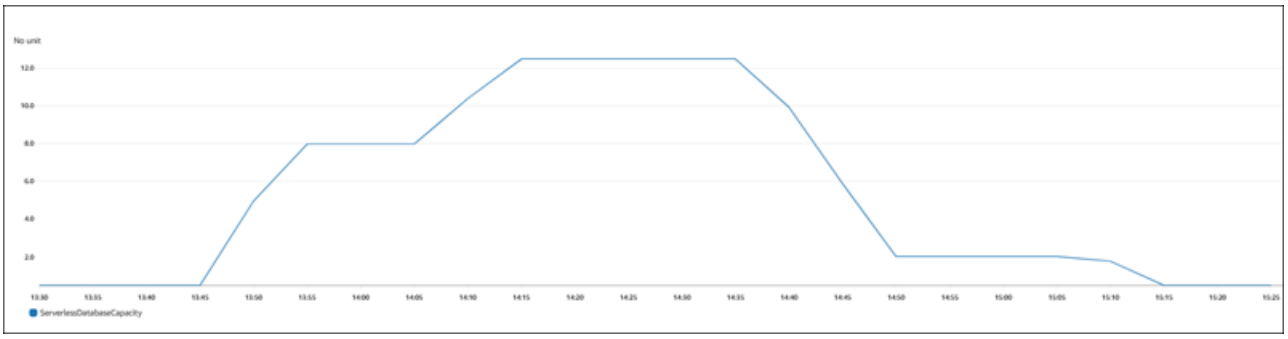
The innodb_buffer_pool_size parameter has increased to its final size for an idle DB instance. The max_connections parameter has increased to reflect a value derived from the maximum ACU value. The formula that Aurora uses for max_connections causes an increase of 1,000 when the memory size doubles.

```
mysql> select @@innodb_buffer_pool_size;
+---------------------------+
| @@innodb_buffer_pool_size |
+---------------------------+
|               16139681792 |
+---------------------------+
1 row in set (0.00 sec)

mysql> select @@innodb_buffer_pool_size / pow(2,30) as gibibytes;
+-----------+
| gibibytes |
+-----------+
|  15.03125 |
+-----------+
1 row in set (0.00 sec)

mysql> select @@max_connections;
+-------------------+
| @@max_connections |
+-------------------+
|              4000 |
+-------------------+
1 row in set (0.00 sec)
```

We set the capacity range to 0.5–128 ACUs, and reboot the DB instance. Now the idle DB instance has a buffer cache size that's less than 1 GiB, so we measure it in mebibytes (MiB). The max_connections value of 5000 is derived from the memory size of the maximum capacity setting.



```
mysql> select @@innodb_buffer_pool_size / pow(2,20) as mebibytes, @@max_connections;
+-----------+-------------------+
| mebibytes | @@max_connections |
+-----------+-------------------+
|       672 |              5000 |
+-----------+-------------------+
1 row in set (0.00 sec)
```

Example: Change the Aurora serverless capacity range of an Aurora PostgreSQL cluster

The following CLI examples show how to update the ACU range for Aurora serverless DB instances in an existing Aurora PostgreSQL cluster.

1. The capacity range for the cluster starts at 0.5–1 ACU.
2. Change the capacity range to 8–32 ACUs.
3. Change the capacity range to 12.5–80 ACUs.
4. Change the capacity range to 0.5–128 ACUs.
5. Return the capacity to its initial range of 0.5–1 ACU.

The following figure shows the capacity changes in Amazon CloudWatch.

The DB instance is idle and scaled down to 0.5 ACUs. The following capacity-related settings apply to the DB instance at this point.

```
postgres=> show max_connections;
 max_connections
-----------------
 189
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 16384
(1 row)
```

Next, we change the capacity range for the cluster. After the `modify-db-cluster` command finishes, the ACU range for the cluster is 8.0–32.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 8.0,
    "MaxCapacity": 32.0
}
```

Changing the capacity range causes changes to the default values of some configuration parameters. Aurora can apply some of those new defaults immediately. However, some of the parameter changes take effect only after a reboot. The `pending-reboot` status indicates that you need a reboot to apply some parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].{DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGrou
[0]'
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "pending-reboot"
        }
    ]
}
```

At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 8.0 ACUs. The `shared_buffers` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` parameter still reflects the value from the former maximum capacity. Resetting that value requires rebooting the DB instance.

> **Note**
>
> If you set the `max_connections` parameter directly in a custom DB parameter group, no reboot is required.

```
postgres=> show max_connections;
 max_connections
-----------------
```

```
 189
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 1425408
(1 row)
```

We reboot the DB instance and wait for it to become available again.

```
aws rds reboot-db-instance --db-instance-identifier serverless-v2-instance-1
{
  "DBInstanceIdentifier": "serverless-v2-instance-1",
  "DBInstanceStatus": "rebooting"
}

aws rds wait db-instance-available --db-instance-identifier serverless-v2-instance-1
```

Now that the DB instance is rebooted, the `pending-reboot` status is cleared. The value `in-sync` confirms that Aurora has applied all the pending parameter changes.

```
aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query '*[].{DBClusterMembers:DBClusterMembers[*].
{DBInstanceIdentifier:DBInstanceIdentifier,DBClusterParameterGroupStatus:DBClusterParameterGrou
[0]'
{
    "DBClusterMembers": [
        {
            "DBInstanceIdentifier": "serverless-v2-instance-1",
            "DBClusterParameterGroupStatus": "in-sync"
        }
    ]
}
```

After rebooting, `max_connections` shows the value from the new maximum capacity.

```
postgres=> show max_connections;
 max_connections
-----------------
 5000
(1 row)
```

```
postgres=> show shared_buffers;
 shared_buffers
----------------
 1425408
(1 row)
```

Next, we change the capacity range for the cluster to 12.5–80 ACUs.

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
  --serverless-v2-scaling-configuration MinCapacity=12.5,MaxCapacity=80

aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 12.5,
    "MaxCapacity": 80.0
}
```

At this point, the cluster is idle and the DB instance `serverless-v2-instance-1` is consuming 12.5 ACUs. The `shared_buffers` parameter is already adjusted based on the current capacity of the DB instance. The `max_connections` value is still 5000.

```
postgres=> show max_connections;
 max_connections
-----------------
 5000
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 2211840
(1 row)
```

We reboot again, but the parameter values stay the same. This is because `max_connections` has a maximum value of 5000 for an Aurora serverless DB cluster running Aurora PostgreSQL.

```
postgres=> show max_connections;
 max_connections
-----------------
```

```
 5000
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 2211840
(1 row)
```

Now we set the capacity range from 0.5 to 128 ACUs. The DB cluster scales down to 10 ACUs, then to 2. We reboot the DB instance.

```
postgres=> show max_connections;
 max_connections
-----------------
 2000
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 16384
(1 row)
```

The `max_connections` value for Aurora serverless DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0 or 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

Now we return the capacity to its initial range of 0.5–1 ACU and reboot the DB instance. The `max_connections` parameter has returned to its original value.

```
postgres=> show max_connections;
 max_connections
-----------------
 189
(1 row)

postgres=> show shared_buffers;
 shared_buffers
----------------
 16384
```

```
(1 row)
```

Working with parameter groups for Aurora serverless

When you create your Aurora serverless DB cluster, you choose a specific Aurora DB engine and an associated DB cluster parameter group. If you aren't familiar with how Aurora uses parameter groups to apply configuration settings consistently across clusters, see Parameter groups for Amazon Aurora. All of those procedures for creating, modifying, applying, and other actions for parameter groups apply to Aurora serverless.

The parameter group feature works generally the same between provisioned clusters and clusters containing Aurora serverless DB instances:

- The default parameter values for all DB instances in the cluster are defined by the cluster parameter group.
- You can override some parameters for specific DB instances by specifying a custom DB parameter group for those DB instances. You might do so during debugging or performance tuning for specific DB instances. For example, suppose that you have a cluster containing some Aurora serverless DB instances and some provisioned DB instances. In this case, you might specify some different parameters for the provisioned DB instances by using a custom DB parameter group.
- For Aurora serverless, you can use all the parameters that have the value `provisioned` in the `SupportedEngineModes` attribute in the parameter group.

Topics

- Default parameter values
- Maximum connections for Aurora serverless
- Parameters that Aurora adjusts as Aurora serverless scales up and down
- Parameters that Aurora computes based on Aurora serverless maximum capacity

Default parameter values

The crucial difference between provisioned DB instances and Aurora serverless DB instances is that Aurora overrides any custom parameter values for certain parameters that are related to DB instance capacity. The custom parameter values still apply to any provisioned DB instances in your cluster. For more details about how Aurora serverless DB instances interpret the parameters from Aurora parameter groups, see Configuration parameters for Aurora clusters. For the specific

parameters that Aurora serverless overrides, see Parameters that Aurora adjusts as Aurora serverless scales up and down and Parameters that Aurora computes based on Aurora serverless maximum capacity.

You can get a list of default values for the default parameter groups for the various Aurora DB engines by using the describe-db-cluster-parameters CLI command and querying the Amazon Web Services Region. The following are values that you can use for the `--db-parameter-group-family` and `-db-parameter-group-name` options for engine versions that are compatible with Aurora serverless.

Database engine and version	Parameter group family	Default parameter group name
Aurora MySQL version 3	`aurora-mysql8.0`	`default.aurora-mysql8.0`
Aurora PostgreSQL version 13.x	`aurora-postgresql13`	`default.aurora-postgresql13`
Aurora PostgreSQL version 14.x	`aurora-postgresql14`	`default.aurora-postgresql14`
Aurora PostgreSQL version 15.x	`aurora-postgresql15`	`default.aurora-postgresql15`
Aurora PostgreSQL version 16.x	`aurora-postgresql16`	`default.aurora-postgresql16`
Aurora PostgreSQL version 17.x	`aurora-postgresql17`	`default.aurora-postgresql17`

The following example gets a list of parameters from the default DB cluster group for Aurora MySQL version 3 and Aurora PostgreSQL 13. Those are the Aurora MySQL and Aurora PostgreSQL versions that you use with Aurora serverless.

For Linux, macOS, or Unix:

```
aws rds describe-db-cluster-parameters \
  --db-cluster-parameter-group-name default.aurora-mysql8.0 \
```

```
  --query 'Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |
    [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' \
  --output text

aws rds describe-db-cluster-parameters \
  --db-cluster-parameter-group-name default.aurora-postgresql13 \
  --query 'Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |
    [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' \
  --output text
```

For Windows:

```
aws rds describe-db-cluster-parameters ^
  --db-cluster-parameter-group-name default.aurora-mysql8.0 ^
  --query 'Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |
    [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' ^
  --output text

aws rds describe-db-cluster-parameters ^
  --db-cluster-parameter-group-name default.aurora-postgresql13 ^
  --query 'Parameters[*].
{ParameterName:ParameterName,SupportedEngineModes:SupportedEngineModes} |
    [?contains(SupportedEngineModes, `provisioned`) == `true`] | [*].[ParameterName]' ^
  --output text
```

Maximum connections for Aurora serverless

For both Aurora MySQL and Aurora PostgreSQL, Aurora serverless DB instances hold the `max_connections` parameter constant so that connections aren't dropped when the DB instance scales down. The default value for this parameter is derived from a formula based on the memory size of the DB instance. For details about the formula and the default values for provisioned DB instance classes, see Maximum connections to an Aurora MySQL DB instance and Maximum connections to an Aurora PostgreSQL DB instance.

When Aurora serverless evaluates the formula, it uses the memory size based on the maximum Aurora capacity units (ACUs) for the DB instance, not the current ACU value. If you change the default value, we recommend using a variation of the formula instead of specifying a constant value. That way, Aurora serverless can use an appropriate setting based on the maximum capacity.

When you change the maximum capacity of an Aurora serverless DB cluster, you have to reboot the Aurora serverless DB instances to update the `max_connections` value. This is because `max_connections` is a static parameter for Aurora serverless.

The default `max_connections` values for Aurora serverless correspond to the maximum ACU value and differ between Aurora MySQL and Aurora PostgreSQL.

The following table shows the default `max_connections` values for Aurora MySQL.

Maximum ACUs	Default maximum connections on Aurora MySQL
1	90
4	135
8	1,000
16	2,000
32	3,000
64	4,000
128	5,000
192	6,000
256	6,000

Note

These Aurora MySQL values are the same across all Aurora serverless platform versions.

The following table shows the default `max_connections` values for Aurora PostgreSQL, which vary by Aurora serverless platform version.

Maximum ACUs	Platform version 1 and 2	Platform version 3	Platform version 4
1	189	193	194
4	823	840	844
8	1,669	1,703	1,710
16	3,360	3,429	3,443
32	5,000	5,000	5,000
64	5,000	5,000	5,000
128	5,000	5,000	5,000
192	5,000	5,000	5,000
256	5,000	5,000	5,000
384			5,000

For Aurora PostgreSQL, the default value depends on the Aurora serverless platform version of your DB cluster.

Note

The `max_connections` value for Aurora serverless DB instances is based on the memory size derived from the maximum ACUs. However, when you specify a minimum capacity of 0 or 0.5 ACUs on PostgreSQL-compatible DB instances, the maximum value of `max_connections` is capped at 2,000.

For specific examples showing how `max_connections` changes with the maximum ACU value, see Example: Change the Aurora serverless capacity range of an Aurora MySQL cluster and Example: Change the Aurora serverless capacity range of an Aurora PostgreSQL cluster.

Parameters that Aurora adjusts as Aurora serverless scales up and down

During autoscaling, Aurora serverless needs to be able to change parameters for each DB instance to work best for the increased or decreased capacity. Thus, you can't override some parameters related to capacity. For some parameters that you can override, avoid hardcoding fixed values. The following considerations apply to these settings that are related to capacity.

For Aurora MySQL, Aurora serverless resizes some parameters dynamically during scaling. For the following parameters, Aurora serverless doesn't use any custom parameter values that you specify:

- `innodb_buffer_pool_size`
- `innodb_purge_threads`
- `table_definition_cache`
- `table_open_cache`

For Aurora PostgreSQL, Aurora serverless resizes the following parameter dynamically during scaling. For the following parameters, Aurora serverless doesn't use any custom parameter values that you specify:

- `shared_buffers`

For all parameters other than those listed here, Aurora serverless DB instances work the same as provisioned DB instances. The default parameter value is inherited from the cluster parameter group. You can modify the default for the whole cluster by using a custom cluster parameter group. Or you can modify the default for certain DB instances by using a custom DB parameter group. Dynamic parameters are updated immediately. Changes to static parameters only take effect after you reboot the DB instance.

Parameters that Aurora computes based on Aurora serverless maximum capacity

For the following parameters, Aurora PostgreSQL uses default values that are derived from the memory size based on the maximum ACU setting, the same as with `max_connections`:

- `autovacuum_max_workers`
- `autovacuum_vacuum_cost_limit`
- `autovacuum_work_mem`
- `effective_cache_size`

- `maintenance_work_mem`

Avoiding out-of-memory errors and CPU saturation

If one of your Aurora serverless DB instances consistently reaches the limit of its maximum capacity, Aurora indicates this condition by setting the DB instance to a status of `incompatible-parameters`. While the DB instance has the `incompatible-parameters` status, some operations are blocked. For example, you can't upgrade the engine version. However, you can still modify the capacity range for the DB cluster.

Typically, your DB instance goes into this status when it restarts frequently because the workload requires more memory or CPU than the maximum capacity allows. Aurora records an event when this type of restart happens. The event identifies whether the cause was memory pressure, CPU pressure, or both. You can view the event by following the procedure in Viewing Amazon RDS events. Unusually high memory usage can happen because of overhead from turning on settings such as Performance Insights and IAM authentication. It can also come from a heavy workload on your DB instance or from managing the metadata associated with a large number of schema objects. High CPU usage can result from a heavy or inefficient workload, or from a large number of concurrent connections.

If the memory or CPU pressure becomes lower so that the DB instance doesn't reach its maximum capacity very often, Aurora automatically changes the DB instance status back to `available`. Repeated events indicate that your workload still requires more memory or CPU than the maximum capacity allows.

To recover from this condition, you can take some or all of the following actions:

- Increase the lower limit on capacity for Aurora serverless DB instances by changing the minimum Aurora capacity unit (ACU) value for the cluster. Doing so avoids issues where an idle database scales down to a capacity with less memory than is needed for the features that are turned on in your cluster. After changing the ACU settings for the cluster, reboot the Aurora serverless DB instance. Doing so evaluates whether Aurora can reset the status back to `available`.
- Increase the upper limit on capacity for Aurora serverless DB instances by changing the maximum ACU value for the cluster. Doing so avoids issues where a busy database can't scale up to a capacity with enough memory and CPU for the database workload and the features that are turned on in your cluster. After changing the ACU settings for the cluster, reboot the Aurora serverless DB instance. Doing so evaluates whether Aurora can reset the status back to `available`.

- Turn off configuration settings that require memory overhead. For example, suppose that you have features such as Amazon Identity and Access Management (IAM), Performance Insights, or Aurora MySQL binary log replication turned on but don't use them. If so, you can turn them off. Or you can adjust the minimum and maximum capacity values for the cluster higher to account for the memory used by those features. For guidelines about choosing minimum and maximum capacity settings, see Choosing the Aurora serverless capacity range for an Aurora cluster.
- Reduce the workload on the DB instance. For example, you can add reader DB instances to the cluster to spread the load from read-only queries across more DB instances.
- Tune the SQL code used by your application to use fewer resources. For example, you can examine your query plans, check the slow query log, or adjust the indexes on your tables. You can also perform other traditional kinds of SQL tuning.

Important Amazon CloudWatch metrics for Aurora serverless

To get started with Amazon CloudWatch for your Aurora serverless DB instance, see Viewing Aurora serverless logs in Amazon CloudWatch. To learn more about how to monitor Aurora DB clusters through CloudWatch, see Monitoring log events in Amazon CloudWatch.

You can view your Aurora serverless DB instances in CloudWatch to monitor the capacity consumed by each DB instance with the `ServerlessDatabaseCapacity` metric. You can also monitor all of the standard Aurora CloudWatch metrics, such as `DatabaseConnections` and `Queries`. For the full list of CloudWatch metrics that you can monitor for Aurora, see Amazon CloudWatch metrics for Amazon Aurora. The metrics are divided into cluster-level and instance-level metrics, in Cluster-level metrics for Amazon Aurora and Instance-level metrics for Amazon Aurora.

The following CloudWatch instance-level metrics are important to monitor for you to understand how your Aurora serverless DB instances are scaling up and down. All of these metrics are calculated every second. That way, you can monitor the current status of your Aurora serverless DB instances. You can set alarms to notify you if any Aurora serverless DB instance approaches a threshold for metrics related to capacity. You can determine if the minimum and maximum capacity settings are appropriate, or if you need to adjust them. You can determine where to focus your efforts for optimizing the efficiency of your database.

- `ServerlessDatabaseCapacity`. As an instance-level metric, it reports the number of ACUs represented by the current DB instance capacity. As a cluster-level metric, it represents the average of the `ServerlessDatabaseCapacity` values of all the Aurora serverless DB instances in the cluster. It's available at the DB instance level and at the cluster level.

- `ACUUtilization`. This metric is new in Aurora serverless. This value is represented as a percentage. It's calculated as the value of the `ServerlessDatabaseCapacity` metric divided by the maximum ACU value of the DB cluster. Consider the following guidelines to interpret this metric and take action:
  - If this metric approaches a value of `100.0`, the DB instance has scaled up as high as it can. Consider increasing the maximum ACU setting for the cluster. That way, both writer and reader DB instances can scale to a higher capacity.
  - Suppose that a read-only workload causes a reader DB instance to approach an `ACUUtilization` of `100.0`, while the writer DB instance isn't close to its maximum capacity. In that case, consider adding additional reader DB instances to the cluster. That way, you can spread the read-only part of the workload spread across more DB instances, reducing the load on each reader DB instance.
  - Suppose that you are running a production application, where performance and scalability are the primary considerations. In that case, you can set the maximum ACU value for the cluster to a high number. Your goal is for the `ACUUtilization` metric to always be below `100.0`. With a high maximum ACU value, you can be confident that there's enough room in case there are unexpected spikes in database activity. You are only charged for the database capacity that's actually consumed.
- `CPUUtilization`. This metric is interpreted differently in Aurora serverless than in provisioned DB instances. For Aurora serverless, this value is a percentage that's calculated as the amount of CPU currently being used divided by the CPU capacity that's available under the maximum ACU value of the DB cluster. Aurora monitors this value automatically and scales up your Aurora serverless DB instance when the DB instance consistently uses a high proportion of its CPU capacity.

  If this metric approaches a value of `100.0`, the DB instance has reached its maximum CPU capacity. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of `100.0` on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, you can spread the read-only part of the workload spread across more DB instances, reducing the load on each reader DB instance.
- `FreeableMemory`. This value represents the amount of unused memory that is available when the Aurora serverless DB instance is scaled to its maximum capacity. For every ACU that the current capacity is below the maximum capacity, this value increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB instance is scaled up as high as it can.

If this metric approaches a value of `0`, the DB instance has scaled up as much as it can and is nearing the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of `0` on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, the read-only part of the workload can be spread across more DB instances, reducing the memory usage on each reader DB instance.

- `TempStorageIOPS`. The number of IOPS done on local storage attached to the DB instance. It includes the IOPS for both reads and writes. This metric represents a count and is measured once per second. This is a new metric for Aurora serverless. For details, see Instance-level metrics for Amazon Aurora.
- `TempStorageThroughput`. The amount of data transferred to and from local storage associated with the DB instance. This metric represents bytes and is measured once per second. This is a new metric for Aurora serverless. For details, see Instance-level metrics for Amazon Aurora.

Typically, most scaling up for Aurora serverless DB instances is caused by memory usage and CPU activity. The `TempStorageIOPS` and `TempStorageThroughput` metrics can help you to diagnose the rare cases where network activity for transfers between your DB instance and local storage devices is responsible for unexpected capacity increases. To monitor other network activity, you can use these existing metrics:

- `NetworkReceiveThroughput`
- `NetworkThroughput`
- `NetworkTransmitThroughput`
- `StorageNetworkReceiveThroughput`
- `StorageNetworkThroughput`
- `StorageNetworkTransmitThroughput`

You can have Aurora publish some or all database logs to Amazon CloudWatch Logs. For instructions, see the following depending on your database engine:

- the section called “Publishing Aurora PostgreSQL logs to CloudWatch Logs”
- the section called “Publishing Aurora MySQL logs to CloudWatch Logs”

How Aurora serverless metrics apply to your Amazon bill

The Aurora serverless charges on your Amazon bill are calculated based on the same `ServerlessDatabaseCapacity` metric that you can monitor. The billing mechanism can differ from the computed CloudWatch average for this metric in cases where you use Aurora serverless capacity for only part of an hour. It can also differ if system issues make the CloudWatch metric unavailable for brief periods. Thus, you might see a slightly different value of ACU-hours on your bill than if you compute the number yourself from the `ServerlessDatabaseCapacity` average value.

Examples of CloudWatch commands for Aurora serverless metrics

The following Amazon CLI examples demonstrate how you can monitor the most important CloudWatch metrics related to Aurora serverless. In each case, replace the `Value=` string for the `--dimensions` parameter with the identifier of your own Aurora serverless DB instance.

The following Linux example displays the minimum, maximum, and average capacity values for a DB instance, measured every 10 minutes over one hour. The Linux `date` command specifies the start and end times relative to the current date and time. The `sort_by` function in the `--query` parameter sorts the results chronologically based on the `Timestamp` field.

```
aws cloudwatch get-metric-statistics --metric-name "ServerlessDatabaseCapacity" \
  --start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \
  --dimensions Name=DBInstanceIdentifier,Value=my_instance \
  --query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

The following Linux examples demonstrate monitoring the capacity of each DB instance in a cluster. They measure the minimum, maximum, and average capacity utilization of each DB instance. The measurements are taken once each hour over a three-hour period. These examples use the `ACUUtilization` metric representing a percentage of the upper limit on ACUs, instead of `ServerlessDatabaseCapacity` representing a fixed number of ACUs. That way, you don't need to know the actual numbers for the minimum and maximum ACU values in the capacity range. You can see percentages ranging from 0 to 100.

```
aws cloudwatch get-metric-statistics --metric-name "ACUUtilization" \
  --start-time "$(date -d '3 hours ago')" --end-time "$(date -d 'now')" --period 3600 \
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \
  --dimensions Name=DBInstanceIdentifier,Value=my_writer_instance \
```

```
  --query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table

aws cloudwatch get-metric-statistics --metric-name "ACUUtilization" \
  --start-time "$(date -d '3 hours ago')" --end-time "$(date -d 'now')" --period 3600 \
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \
  --dimensions Name=DBInstanceIdentifier,Value=my_reader_instance \
  --query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

The following Linux example does similar measurements as the previous ones. In this case, the measurements are for the `CPUUtilization` metric. The measurements are taken every 10 minutes over a 1-hour period. The numbers represent the percentage of available CPU used, based on the CPU resources available to the maximum capacity setting for the DB instance.

```
aws cloudwatch get-metric-statistics --metric-name "CPUUtilization" \
  --start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \
  --dimensions Name=DBInstanceIdentifier,Value=my_instance \
  --query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

The following Linux example does similar measurements as the previous ones. In this case, the measurements are for the `FreeableMemory` metric. The measurements are taken every 10 minutes over a 1-hour period.

```
aws cloudwatch get-metric-statistics --metric-name "FreeableMemory" \
  --start-time "$(date -d '1 hour ago')" --end-time "$(date -d 'now')" --period 600 \
  --namespace "AWS/RDS" --statistics Minimum Maximum Average \
  --dimensions Name=DBInstanceIdentifier,Value=my_instance \
  --query 'sort_by(Datapoints[*].
{min:Minimum,max:Maximum,avg:Average,ts:Timestamp},&ts)' --output table
```

Monitoring Aurora serverless performance with Performance Insights

You can use Performance Insights to monitor the performance of Aurora serverless DB instances. For Performance Insights procedures, see Monitoring DB load with Amazon CloudWatch Database Insights on Amazon Aurora.

The following new detailed per-query and database counter metrics, exposed through the Performance Insights API, apply to Aurora serverless DB instances:

- `os.general.serverlessDatabaseCapacity` – The current capacity of the DB instance in ACUs. The value corresponds to the `ServerlessDatabaseCapacity` CloudWatch metric for the DB instance.
- `os.general.acuUtilization` – The percentage of current capacity out of the maximum configured capacity. The value corresponds to the `ACUUtilization` CloudWatch metric for the DB instance.
- `os.general.maxConfiguredAcu` – The maximum capacity that you configured for this Aurora serverless DB instance. It's measured in ACUs.
- `os.general.minConfiguredAcu` – The minimum capacity that you configured for this Aurora serverless DB instance. It's measured in ACUs

For the full list of detailed per-query and database counter metrics, see Detailed Database Metrics.

When vCPU values are shown for an Aurora serverless DB instance in Performance Insights, those values represent estimates based on the ACU value for the DB instance. At the default interval of one minute, any fractional vCPU values are rounded up to the nearest whole number. For longer intervals, the vCPU value shown is the average of the integer vCPU values for each minute.

Troubleshooting Aurora serverless capacity issues

In some cases, Aurora serverless doesn't scale down to the minimum capacity, even with no load on the database. This can happen for the following reasons:

- Certain features can increase resource usage and prevent the database from scaling down to minimum capacity. These features include the following:
  - Aurora global databases
  - Exporting CloudWatch Logs
  - Enabling `pg_audit` on Aurora PostgreSQL–compatible DB clusters
  - Enhanced Monitoring
  - Performance Insights

  For more information, see Choosing the minimum Aurora serverless capacity setting for a cluster.
- If a reader instance isn't scaling down to the minimum and stays at the same or higher capacity than the writer instance, then check the priority tier of the reader instance. Aurora serverless reader DB instances in tier 0 or 1 are kept at a minimum capacity at least as high as the writer DB instance. Change the priority tier of the reader to 2 or higher so that it scales up and down

independently of the writer. For more information, see Choosing the promotion tier for an Aurora serverless reader.

- Set any database parameters that impact the size of shared memory to their default values. Setting a value higher than the default increases the shared memory requirement and prevents the database from scaling down to the minimum capacity. Examples are `max_connections` and `max_locks_per_transaction`.

  > **Note**
  >
  > Updating shared memory parameters requires a database restart for the changes to take effect.

- Heavy database workloads can increase resource usage.
- Large database volumes can increase resource usage.

  Amazon Aurora uses memory and CPU resources for DB cluster management. Aurora requires more CPU and memory to manage DB clusters with larger database volumes. If your cluster's minimum capacity is less than the minimum required for cluster management, your cluster won't scale down to the minimum capacity.
- Background processes, such as purge, can also increase resource usage.
- Platform version limitations can affect scaling capabilities. The available scaling range for a given cluster is influenced by both engine version and hardware (platform version). It is possible to have a more capable engine version running on a less capable platform version and vice-versa.

If the database still doesn't scale down to the minimum capacity configured, then stop and restart the database to reclaim any memory fragments that might have built up over time. Stopping and starting a database results in downtime, so we recommend doing this sparingly.

Scaling to Zero ACUs with automatic pause and resume for Aurora serverless

You can specify that Aurora serverless DB instances scale down to zero ACUs and automatically pause, if they don't have any connections initiated by user activity within a specified time period. You do so by specifying a minimum ACU value of zero for your DB cluster. You aren't charged for instance capacity while an instance is in the paused state. Enabling the automatic pause and resume feature (auto-pause) for Aurora clusters that are lightly used or have extended periods of inactivity can help you to manage costs for your database fleet.

> **Note**
>
> The auto-pause feature is available for Aurora serverless with both Aurora PostgreSQL and Aurora MySQL. You might need to upgrade your Aurora database engine version to take advantage of this feature. For the engine versions where a minimum capacity of 0 ACUs is available, see Aurora serverless capacity.

Topics

- Overview of the Aurora serverless auto-pause feature
- Prerequisites and Limitations for the Aurora serverless auto-pause feature
- Turning the auto-pause feature on and off
- How the Aurora serverless auto-pause feature works
- How Aurora serverless auto-pause works for different types of Aurora clusters
- Monitoring Aurora clusters that use auto-pause
- Troubleshooting for Aurora serverless auto-pause
- Application design considerations for the Aurora serverless auto-pause feature

Overview of the Aurora serverless auto-pause feature

Aurora serverless DB instances can automatically pause after a period with no user connections, and automatically resume when a connection request arrives. The Aurora serverless automatic pause/resume feature helps to manage costs for systems that don't have a stringent service level objective (SLO). For example, you might enable this feature for clusters used for development and

testing, or for internal applications where a brief pause is acceptable while the database resumes. If your workload has periods of inactivity and can tolerate slight delays in connecting while the instance resumes, consider using auto-pause with your Aurora serverless instances to reduce costs.

You control this behavior by specifying whether the Aurora serverless DB instances in a cluster can automatically pause or not, and how long each instance must be idle before it pauses. To enable the auto-pause behavior for all the Aurora serverless DB instances in an Aurora cluster, you set the minimum capacity value for the cluster to zero ACUs.

The cost-savings benefits of the auto-pause feature are similar to using the stop/start cluster feature. Auto-pause for Aurora serverless has the additional benefits of a faster resume than starting a stopped cluster, and automating the process of determining when to pause and resume each DB instance.

The auto-pause feature also provides additional granularity in controlling costs for compute resources within your cluster. You can enable some reader instances to pause even while the writer instance and other readers in the cluster remain active at all times. You do so by assigning the reader instances that can pause independently of other instances a failover priority in the range 2-15.

The writer instances and all reader instances with failover priority 0 and 1 always pause and resume at the same time. Thus, the instances in this group pause after none of them have any connections for the specified time interval.

Aurora DB clusters can contain a combination of writer and reader DB instances and provisioned and Aurora serverless DB instances. Therefore, to use this feature effectively, it's helpful to understand the following aspects of the auto-pause mechanism:

- The circumstances when a DB instance might automatically pause.
- When a DB instance might be prevented from pausing. For example, enabling some Aurora features or performing certain kinds of operations on the cluster might prevent instances from pausing, even without any connections to those instances.
- The consequences for monitoring and billing while an instance is paused.
- What actions cause a DB instance to resume processing.
- How the capacity of a DB instance changes around the time of the pause and resume events.
- How to control the idle interval before a DB instance pauses.
- How to code application logic to handle the period while a DB instance is resuming processing.

Prerequisites and Limitations for the Aurora serverless auto-pause feature

Before using the auto-pause feature, check which engine versions to use. Also, check whether auto-pause works in combination with the other Aurora features you intend to use. You can't turn on auto-pause if you're using an engine version that doesn't support it. For incompatible features, you won't get any error if you use them in combination with auto-pause. If the cluster is using any incompatible features or settings, the Aurora serverless instances won't automatically pause.

- If you're using Aurora PostgreSQL, the database engine must be running at least version 16.3, 15.7, 14.12, or 13.15.
- If you're using Aurora MySQL, the database engine must be running version 3.08.0 or higher.
- For the full list of engine versions and Amazon Regions where this feature is available, see Supported Regions and Aurora DB engines for Aurora serverless.
- When an Aurora serverless instance resumes, its capacity might be lower than it was when the instance was paused.

Certain conditions or settings prevent Aurora serverless instances from automatically pausing. For more information, see Situations where Aurora serverless doesn't auto-pause.

Turning the auto-pause feature on and off

You can turn the auto-pause feature on and off at the cluster level. To do so, you use the same procedures as when you adjust the minimum and maximum capacity for the cluster. The auto-pause feature is represented by a minimum capacity of 0 ACUs.

Topics

- Turning on auto-pause for Aurora serverless instances in a cluster
- Configurable Aurora serverless auto-pause timeout interval
- Resuming an auto-paused Aurora serverless instance
- Turning off auto-pause for Aurora serverless instances in a cluster

Turning on auto-pause for Aurora serverless instances in a cluster

Follow the procedure in Setting the Aurora serverless capacity range for a cluster. For the minimum capacity, choose 0 ACUs. When you choose a minimum capacity of 0 ACUs, you can also specify the length of time for the instance to be idle before it's automatically paused.

The following CLI example shows how you might create an Aurora cluster with the auto-pause feature enabled and the auto-pause interval set to ten minutes (600 seconds).

```
aws rds create-db-cluster \
    --db-cluster-identifier my-serverless-v2-cluster \
    --region eu-central-1 \
    --engine aurora-mysql \
    --engine-version 8.0 \
    --serverless-v2-scaling-configuration
 MinCapacity=0,MaxCapacity=4,SecondsUntilAutoPause=600 \
    --master-username myuser \
    --manage-master-user-password
```

The following CLI example shows how you might turn on the auto-pause feature for an existing Aurora cluster. This example sets the auto-pause interval to one hour (3600 seconds).

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
  --serverless-v2-scaling-configuration
 MinCapacity=0,MaxCapacity=80,SecondsUntilAutoPause=3600

aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 0,
    "MaxCapacity": 80.0,
    "SecondsUntilAutoPause": 3600
}
```

Configurable Aurora serverless auto-pause timeout interval

The timeout interval is represented in the `ServerlessV2ScalingConfiguration` attribute of your Aurora cluster. You can specify this interval in the Amazon Web Services Management Console when creating or modifying an Aurora cluster, if the minimum capacity is set to zero ACUs. You can specify it in the Amazon CLI by using the `--serverless-v2-scaling-configuration`

parameter when creating or modifying an Aurora cluster. You can specify it in the RDS API by using the `ServerlessV2ScalingConfiguration` parameter when creating or modifying an Aurora cluster.

The minimum interval that you can set is 300 seconds (five minutes). That's the default if you don't specify an interval. The maximum interval that you can set is 86,400 seconds (one day).

Suppose that you turn off the auto-pause feature for a cluster by changing the cluster's minimum capacity to a nonzero value. In that case, the interval property is removed from the `ServerlessV2ScalingConfiguration` attribute. The absence of that property provides an extra confirmation that the auto-pause feature is turned off for that cluster. If you later turn auto-pause back on, you can specify any custom interval again at that time.

Resuming an auto-paused Aurora serverless instance

- When you connect to a paused Aurora serverless instance, it automatically resumes and accepts the connection.
- A connection attempt that doesn't include valid credentials still causes the DB instance to resume.
- If you connect through the writer endpoint, Aurora resumes the writer DB instance if it's auto-paused. At the same time, Aurora resumes any auto-paused reader instances that have failover priority 0 or 1, meaning their capacity is tied to the capacity of the writer instance.
- If you connect through the reader endpoint, Aurora chooses a reader instance randomly. If that reader instance is paused, Aurora resumes it. Aurora also resumes the writer instance first, because the writer instance must always be active if any reader instances are active. When Aurora resumes that writer instance, that also causes any reader instances in failover promotion tiers zero and one to resume.
- If you send a request to your cluster through the RDS Data API, Aurora resumes the writer instance if it's paused. Then Aurora processes the Data API request.
- When you change the value of a configuration parameter in a DB cluster parameter group, Aurora automatically resumes any paused Aurora serverless instances in all clusters that use that cluster parameter group. Similarly, when you change a parameter value in a DB parameter group, Aurora automatically resumes any paused Aurora serverless instances that use that DB parameter group. The same automatic resume behavior applies when you modify a cluster to assign a different cluster parameter group, or when you modify an instance to assign a different DB parameter group.

- Performing a backtrack request automatically resumes the Aurora serverless writer instance if it's paused. Aurora processes the backtrack request after the writer instance resumes. You can backtrack to a time during which an Aurora serverless instance was paused.
- Taking a cluster snapshot or deleting a snapshot doesn't cause any Aurora serverless instances to resume.
- Creating an Aurora clone causes Aurora to resume the writer instance of the cluster that's being cloned.
- If a paused instance receives a large number of connection requests before it finishes resuming, some sessions might be unable to connect. We recommend implementing retry logic for connections to Aurora clusters that have some Aurora serverless instances with auto-pause enabled. For example, you might retry any failed connection three times.
- Aurora can perform some types of minor internal maintenance without waking up an instance. However, some types of maintenance that happen during the cluster's maintenance window do require Aurora to resume the instance. When the maintenance is finished, the instance is automatically paused again if there's no more activity after the specified interval.

> **Note**
>
> Aurora doesn't automatically resume a paused instance for engine-specific scheduled jobs, such as those in the PostgreSQL `pg_cron` extension or the MySQL event scheduler. To ensure that such jobs run, initiate a connection manually to the instance before the scheduled time. Aurora doesn't queue any jobs where the scheduled time occurs while the DB instance is paused. Such jobs are skipped when the instance resumes later.

- If the Aurora cluster undergoes a failover while an Aurora serverless instance is auto-paused, Aurora might resume an instance and then promote that instance to be the writer. The same might happen if one or more DB instances are removed from the cluster while an instance is paused. In this case, the instance becomes the writer immediately when it's resumed.
- Operations that change properties of the cluster also cause any auto-paused Aurora serverless instances to resume. For example, an auto-paused instance resumes for operations such as the following:
  - Changing the scaling range of the cluster.
  - Upgrading the engine version of the cluster.

- Describing or downloading log files from a paused instance. You can examine historical log data from paused instances by enabling log uploads to CloudWatch and analyzing the logs through CloudWatch.

Turning off auto-pause for Aurora serverless instances in a cluster

Follow the procedure in Setting the Aurora serverless capacity range for a cluster. For the minimum capacity, choose a value of 0.5 or greater. When you turn off the auto-pause feature, the interval for the instance to be idle is reset. If you turn auto-pause on again, you specify a new timeout interval.

The following CLI example shows how you might turn off the auto-pause feature for an existing Aurora cluster. The `describe-db-clusters` output shows that the `SecondsUntilAutoPause` attribute is removed when the minimum capacity is set to a nonzero value.

```
aws rds modify-db-cluster --db-cluster-identifier serverless-v2-cluster \
  --serverless-v2-scaling-configuration MinCapacity=2,MaxCapacity=80

aws rds describe-db-clusters --db-cluster-identifier serverless-v2-cluster \
  --query 'DBClusters[*].ServerlessV2ScalingConfiguration|[0]'
{
    "MinCapacity": 2,
    "MaxCapacity": 80.0
}
```

How the Aurora serverless auto-pause feature works

You can use the following information to plan your usage of the auto-pause feature. Understanding the circumstances where instances pause, resume, or stay active can help you balance the tradeoffs between availability, responsiveness, and cost savings.

Topics

- What happens when Aurora serverless instances pause
- What happens when auto-paused Aurora serverless instances resume
- How instance billing works for auto-paused Aurora serverless clusters
- Situations where Aurora serverless doesn't auto-pause
- How auto-pause works with the cluster stop/start feature

- How maintenance and upgrades work for auto-paused Aurora serverless clusters

What happens when Aurora serverless instances pause

When an Aurora serverless DB instance pauses after a period with no connections:

- Aurora begins pausing the instance after the specified interval elapses with no connections to the instance, regardless of how many ACUs the instance has at the time.
- The pause mechanism isn't instantaneous. An Aurora serverless instance that's about to be auto-paused might wait briefly to catch up with all the changes to Aurora storage.
- The instance charges for that instance are put on hold. The `ServerlessV2Usage` metric has a value of 0 while the instance is paused.
- The status value for the instance doesn't change. The status is still shown as "available".
- The instance stops writing to the database log files. It stops sending metrics to CloudWatch, other than registering zero percent for `CPUUtilization` and `ACUUtilization`, and zero for `ServerlessDatabaseCapacity`.
- Aurora emits events when an Aurora serverless DB instance begins pausing, finishes pausing, and if the pause mechanism is interrupted or is unsuccessful. For details about these events, see DB instance events.

What happens when auto-paused Aurora serverless instances resume

When an Aurora serverless DB instance resumes after being automatically paused, the following conditions apply:

- Any parameter changes that are in `pending-reboot` changes are applied when the instance resumes.
- Aurora emits instance-level events when each Aurora serverless DB instance begins resuming, finishes resuming, and if the instance can't resume for some reason. For details about these events, see DB instance events.
- Any requested connections are established after the DB instance finishes resuming. Because the typical time to resume might be approximately 15 seconds, we recommend that you adjust any client timeout settings to be longer than 15 seconds. For example, in your JDBC driver settings you might adjust the values for the `connectTimeout` and `sslResponseTimeout` settings to be longer than 15 seconds.

> **Note**
>
> If an Aurora serverless instance remains paused more than 24 hours, Aurora can put the instance into a deeper sleep that takes longer to resume. In that case, the resume time can be 30 seconds or longer, roughly equivalent to doing a reboot of the instance. If your database has periods of inactivity that last longer than a day, we recommend setting connection timeouts to 30 seconds or more.

How instance billing works for auto-paused Aurora serverless clusters

While an Aurora serverless instance is auto-paused, its instance charge is zero. The `ServerlessV2Usage` metric is zero during that period. Amazon still charges for Aurora storage and other aspects of the cluster that aren't tied to that specific DB instance.

Situations where Aurora serverless doesn't auto-pause

- If the minimum capacity value for your DB cluster is higher than zero ACUs, the Aurora serverless instances in the cluster don't automatically pause. If you have existing clusters with Aurora serverless instances from before the auto-pause feature was available, the lowest minimum capacity setting was 0.5 ACUs. To use the auto-pause feature with such clusters, modify the minimum capacity setting to zero ACUs.
- If any user-initiated connections are open to an Aurora serverless instance, the instance won't pause. The instance also won't pause while activities such as patching and upgrades are in progress. Administrative connections that Aurora uses for health checks aren't counted as activity and don't prevent the instance from pausing.
- In an Aurora PostgreSQL cluster has logical replication enabled, or an Aurora MySQL cluster that has binlog replication enabled, the writer instance and any reader instances in failover promotion tiers zero and one don't automatically pause. Aurora performs a constant minimal amount of activity for checking the health of the replication connection.

  For clusters with replication enabled, you can still have Aurora reader instances in the source cluster that auto-pause. To do so, set their failover priority to a value other than zero or one. That way, they can be paused independently of the writer instance.
- If your Aurora cluster has an associated RDS Proxy, the proxy maintains an open connection to each DB instance in the cluster. Thus, any Aurora serverless instances in such a cluster won't automatically pause.

- If your cluster is the primary cluster in an Aurora global database, Aurora doesn't automatically pause the Aurora serverless writer instance. That's because a constant level of activity is needed on the writer instance to manage the other clusters in the global database. Because the writer instance remains active, any Aurora serverless reader instances with failover priority zero or one also don't auto-pause.
- Aurora serverless instances in the secondary clusters of an Aurora Global Database don't automatically pause. If a DB cluster is promoted to a standalone cluster, then the auto-pause feature becomes effective if all the other conditions are met.
- In a cluster with an associated zero-ETL integration to Redshift, the writer instance and any reader instances in failover promotion tiers zero and one don't automatically pause.
- In addition to activity on the main database port for the instance, if an Aurora PostgreSQL instance has the Babelfish feature enabled, any connections and activity on the T-SQL port prevent the instance from being auto-paused.

How auto-pause works with the cluster stop/start feature

You can stop and start an Aurora cluster when the auto-pause feature is enabled. It doesn't matter if some instances are paused. When you start the cluster again, any paused Aurora serverless instances are automatically resumed.

While an Aurora cluster is stopped, any paused Aurora serverless instances don't automatically resume based on attempts to connect. Once the cluster is started again, the usual mechanisms for pausing and resuming Aurora serverless instances apply.

How maintenance and upgrades work for auto-paused Aurora serverless clusters

- While an Aurora serverless instance is auto-paused, if you attempt to upgrade the Aurora cluster, Aurora resumes the instance and upgrades it.
- Aurora periodically resumes any auto-paused Aurora serverless instances to perform maintenance such as minor version upgrades and changes to properties such as parameter groups.
- After an Aurora serverless instance wakes up for an administrative operation such as an upgrade or applying maintenance, Aurora waits at least 20 minutes before pausing that instance again. That's to allow any background operations to finish. The twenty-minute period also avoids pausing and resuming the instance multiple times if the instance undergoes multiple administrative operations in succession.

How Aurora serverless auto-pause works for different types of Aurora clusters

The considerations for the auto-pause feature depend on how many instances are in your Aurora cluster, the failover promotion tiers of the reader instances, and whether all the instances are Aurora serverless or a combination of Aurora serverless and provisioned.

Topics

- Recommended Aurora cluster layouts when using auto-pause
- How Aurora serverless auto-pause works for the writer instance in a DB cluster
- How Aurora serverless auto-pause works for multi-AZ clusters
- How Aurora serverless auto-pause works for clusters with provisioned instances

Recommended Aurora cluster layouts when using auto-pause

When the auto-pause feature is enabled, you can arrange your Aurora cluster for the right balance of high availability, fast response, and scalability to suit your use case. You do so by choosing the combination of Aurora serverless instances, provisioned instances, and failover promotion tiers for the DB instances in your cluster.

The following types of configurations demonstrate different tradeoffs between high availability and cost optimization for your cluster:

- For a development and test system, you can set up a single-AZ DB cluster with an Aurora serverless DB instance. The single instance serves all read and write requests. When the cluster isn't used for significant intervals of time, the DB instance pauses. At that point, the DB compute costs for your cluster are also paused.
- For a system running an application where high availability is a priority, but the cluster still has periods where it's entirely idle, you can set up a multi-AZ cluster where both the writer and reader DB instances are Aurora serverless. Set the reader instance to failover priority zero or one, so that the writer and reader instance both pause and resume at the same time. Now you get the benefit of fast failover while the cluster is active. When the cluster remains idle for longer than the auto-pause threshold, the DB instance charges for both of the instances are paused. When the cluster resumes processing, the first database session takes a brief time to connect.
- Suppose your cluster is constantly active with some minimal amount of activity, and requires fast response for any connection. In that case, you can create a cluster with more than one Aurora

serverless reader instance, and decouple the capacities of some reader instances from the writer. Specify failover priority zero or one for the writer instance and one reader instance. Specify a priority greater than one for the other reader instances. That way, the reader instances in the higher priority tiers can auto-pause, even while the writer and one of the readers remain active.

In this case, you can employ some other techniques to ensure that the cluster stays continuously available while still scaling down to a low capacity during idle periods:

- You can use provisioned instances for the writer and the priority 0 or 1 reader. That way, two DB instances never auto-pause and are always available to serve database traffic and to perform failovers.
- You can set up a custom endpoint that includes the Aurora serverless instances in the higher priority tiers, but not the writer or the promotion tier 0 or 1 readers. That way, you can direct read-only sessions that aren't sensitive to latency to the readers that might be auto-paused. You can avoid using the reader endpoint for such requests, because Aurora might direct reader endpoint connections to the always-awake reader instance, or to one of the auto-paused instances. Using the custom endpoint lets you direct connections to different groups of instances based on your preference for fast response or extra scaling capacity.

How Aurora serverless auto-pause works for the writer instance in a DB cluster

When an Aurora DB cluster contains only a single DB instance, the mechanism for auto-pausing and resuming the DB instance is straightforward. It depends only on activity on the writer instance. You might have such a configuration for clusters used for development and testing, or for running applications where high availability isn't crucial. Note that in a single-instance cluster, Aurora directs connections through the reader endpoint to the writer DB instance. Thus, for a single-instance DB cluster, attempting to connect to the reader endpoint causes the auto-paused writer DB instance to resume.

The following additional factors apply to Aurora clusters with multiple DB instances:

- Within an Aurora DB cluster, the writer DB instance is typically accessed frequently. Therefore, you might find that the writer DB instance remains active even while one or more of the reader DB instances automatically pauses.
- Certain activities on the reader DB instances require that writer DB instance to be available. Therefore, the writer DB instances can't be paused until all the reader instances are also paused. Resuming any reader instance automatically resumes the writer instance, even if your application isn't accessing the writer instance directly.

- Aurora serverless reader instances in failover promotion tiers zero and one scale to keep their capacity in synch with the writer instance. Thus, when an Aurora serverless writer instance resumes, so do any Aurora serverless reader instances that are in promotion tiers zero or one.

How Aurora serverless auto-pause works for multi-AZ clusters

Within an Aurora DB cluster containing both a writer and one or more reader DB instances, some Aurora serverless DB instances might be paused while other DB instances are active. The writer instance and any reader instances with failover priority 0 and 1 always pause and resume all at the same time. Reader instances with priority other than 0 or 1 can pause and resume independently of the other instances.

When you use this feature for clusters with multiple reader instances, you can manage costs without sacrificing high availability. The writer instance and another one or two reader instances can remain active at all times, while additional reader instances can pause when they're not needed to handle high-volume read traffic.

Whether a reader instance can automatically pause depends on whether its capacity can scale independently, or whether the capacity is tied to that of the writer DB instance. That scaling property depends on the failover priority of the reader DB instance. When the priority of the reader is zero or one, the capacity of the reader tracks the capacity of the writer DB instance. Therefore, to allow reader DB instances to automatically pause in the broadest range of situations, set their priority to a value higher than one.

The time to resume a reader instance might be slightly longer than to resume a writer instance. For the fastest response if instances might be paused, connect to the cluster endpoint.

How Aurora serverless auto-pause works for clusters with provisioned instances

Any provisioned DB instances in your Aurora DB cluster won't automatically pause. Only Aurora serverless DB instances, with the `db.serverless` instance class, can use the auto-pause feature.

When your Aurora cluster contains any provisioned DB instances, any Aurora serverless writer instance doesn't automatically pause. That's because of the requirement that the writer instance remains available while any reader instances are active. The fact that the Aurora serverless writer remains active also means that any Aurora serverless reader instances with failover priority 0 and 1 won't auto-pause in a hybrid cluster containing any provisioned instances.

Monitoring Aurora clusters that use auto-pause

To monitor Aurora, you should already be familiar with the monitoring procedures in Monitoring Amazon Aurora metrics with Amazon CloudWatch and the CloudWatch metrics listed in Metrics reference for Amazon Aurora. Be aware that there are some special considerations when you monitor Aurora clusters that use the auto-pause feature:

- There can be periods of time when Aurora serverless instances aren't recording log data and most metrics because the instances are paused. The only metrics sent to CloudWatch while an instance is paused are zero percent for `CPUUtilization` and `ACUUtilization`, and zero for `ServerlessDatabaseCapacity`.
- You can check whether Aurora serverless instances are pausing more or less frequently than you expect. To do so, check how often the `ServerlessDatabaseCapacity` metric changes from a nonzero value to zero, and how long it stays zero. If the instances don't remain paused as long as you expect, you don't save as much as you could on costs. If the instances pause and resume more frequently than you intend, your cluster might have unnecessary latency when responding to connection requests. For information about the factors that affect whether and how often Aurora serverless instances can pause, see Prerequisites and Limitations for the Aurora serverless auto-pause feature, Situations where Aurora serverless doesn't auto-pause, and Troubleshooting for Aurora serverless auto-pause.
- You can also examine a log file that records automatic pause and resume operations for an Aurora serverless instance. If an instance didn't pause after the timeout interval expired, this log file also includes the reason why auto-pause didn't happen. For more information, see Monitoring Aurora serverless pause and resume activity.

Topics

- Checking if an Aurora serverless instance is paused
- Events for auto-pause and auto-resume operations
- How auto-pause works with Performance Insights and Enhanced Monitoring
- How the Aurora serverless auto-pause feature interacts with Aurora metrics

Checking if an Aurora serverless instance is paused

To determine whether an Aurora serverless instance is in the paused state, you can observe the `ACUUtilization` metric for the instance. That metric has a value of zero while the instance is paused.

While an Aurora serverless instance is paused, its status value is still listed as **Available**. The same applies while a paused Aurora serverless instance is in the process of resuming. That's because you can successfully connect to such an instance, even if the connection experiences a slight delay.

Any metrics related to the availability of Aurora instances consider the period while the instance is paused as time that the instance was available.

Events for auto-pause and auto-resume operations

Aurora emits events for Aurora serverless instances when auto-pause and auto-resume operations start, finish, or are cancelled. The events related to the auto-pause feature are `RDS-EVENT-0370` through `RDS-EVENT-0374`. For details about these events, see DB instance events.

How auto-pause works with Performance Insights and Enhanced Monitoring

While an Aurora serverless instance is paused, Aurora doesn't collect monitoring information for that instance through either Performance Insights or Enhanced Monitoring. When the instance is resumed, there might be a brief delay before Aurora resumes collecting such monitoring information.

How the Aurora serverless auto-pause feature interacts with Aurora metrics

While an Aurora serverless instance is paused, it doesn't emit most CloudWatch metrics or write any information to its database logs. The only metrics sent to CloudWatch while an instance is paused are zero percent for `CPUUtilization` and `ACUUtilization`, and zero for `ServerlessDatabaseCapacity`.

When CloudWatch is computing statistics related to instance or cluster availability and uptime, Aurora serverless instances are considered to be available during the time that they're paused.

When you initiate an Amazon CLI or RDS API action to describe or download the logs for a paused Aurora serverless instance, the instance resumes automatically to make the log information available.

Example of CloudWatch metrics

The following Amazon CLI examples show how you might observe the capacity of an instance changing over time. During the time period, the instance auto-pauses and then resumes. While it's paused, the `ServerlessDatabaseCapacity` metric reports a value of zero. To determine whether the instance was paused at any point during the time period, we check if the minimum capacity during that time period was zero.

The following Linux example represents an Aurora serverless instance that has been automatically paused for some time. We sample the `ServerlessDatabaseCapacity` each minute, over a period of three minutes. The minimum ACU value of 0.0 confirms that the instance was paused at some point during each minute.

```
$ aws cloudwatch get-metric-statistics \
  --metric-name "ServerlessDatabaseCapacity" \
  --start-time "$(date -d '3 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
  --statistics Minimum \
  --namespace "AWS/RDS" --dimensions Name=DBInstanceIdentifier,Value=my-autopause-
instance \
  --output text | sort -k 3

ServerlessDatabaseCapacity
DATAPOINTS 0.0 2024-08-02T22:11:00+00:00 None
DATAPOINTS 0.0 2024-08-02T22:12:00+00:00 None
DATAPOINTS 0.0 2024-08-02T22:13:00+00:00 None
```

Next, we attempt to make a connection to the paused Aurora serverless instance. In this example, we intentionally use an incorrect password so that the connection attempt doesn't succeed. Despite the failure, the connection attempt causes Aurora to resume the paused instance.

```
$ mysql -h my_cluster_endpoint.rds.amazonaws.com -u admin -pwrong-password

ERROR 1045 (28000): Access denied for user 'admin'@'ip_address' (using password: YES)
```

The following Linux example demonstrates that the paused instance resumed, remained idle for approximately five minutes, and then went back into its paused state. The instance resumed at a capacity of 2.0 ACUs. Then it scaled up slightly, for example to perform some internal cleanup.

Because it didn't receive any user connection attempts within the five-minute timeout period, it went from 4.0 ACUs directly into the paused state.

```
$ aws cloudwatch get-metric-statistics \
  --metric-name "ServerlessDatabaseCapacity" \
  --start-time "$(date -d '8 minutes ago')" --end-time "$(date -d 'now')" --period 60 \
  --statistics Minimum \
  --namespace "AWS/RDS" --dimensions Name=DBInstanceIdentifier,Value=my-autopause-
instance \
  --output text | sort -k 3

ServerlessDatabaseCapacity
DATAPOINTS 0.0 2024-08-02T22:13:00+00:00 None
DATAPOINTS 2.0 2024-08-02T22:14:00+00:00 None
DATAPOINTS 3.0 2024-08-02T22:15:00+00:00 None
DATAPOINTS 3.0 2024-08-02T22:16:00+00:00 None
DATAPOINTS 4.0 2024-08-02T22:17:00+00:00 None
DATAPOINTS 4.0 2024-08-02T22:18:00+00:00 None
DATAPOINTS 4.0 2024-08-02T22:19:00+00:00 None
DATAPOINTS 0.0 2024-08-02T22:20:00+00:00 None
```

If the report was intended to show how quickly the instance scaled up to handle the workload, we might specify `Maximum` for the statistic instead of `Minimum`. For capacity planning and cost estimation, we might specify a longer time period and use the `Average` statistic. That way, we could determine typical capacity values during periods of high activity, low activity, and paused state. To examine behavior during the precise times around pausing and resuming, we might specify a period of one second and examine a shorter time interval. The timestamp values in the output, such as `2024-08-02T22:13:00+00:00`, demonstrate the format to specify precise parameters for the `--start-time` and `--end-time` options.

Troubleshooting for Aurora serverless auto-pause

If you find that Aurora serverless instances aren't pausing as often as you expect, check for the following possible causes:

- Confirm that the Aurora version you're running does support a minimum capacity of zero ACUs. For the capacity ranges of different Aurora versions, see Aurora serverless capacity.
- Confirm that the minimum capacity value for the cluster is set to zero ACUs.

- Confirm that the instance in question is actually using the Aurora serverless instance class `db.serverless`, not one of the provisioned instance classes.
- Confirm that the cluster isn't using any of the incompatible features or settings from Prerequisites and Limitations for the Aurora serverless auto-pause feature.
- Examine the log file showing when Aurora serverless instances were paused, resumed, or Aurora wasn't able to pause or resume an instance for some reason. For more information, see Monitoring Aurora serverless pause and resume activity.
- Check if any clients or applications are keeping connections open for long periods of time. Conversely, check if any applications that use RDS Data API or Lambda functions are sending frequent requests so that the instance is never idle long enough to pause. You can examine the CloudWatch metrics such as `ConnectionAttempts` and `DatabaseConnections`. For more information, see Instance-level metrics for Amazon Aurora.
- If a reader instance rarely if ever pauses, check its failover priority. If the reader is used for read scaling and not as a standby in case of failover, set it to a priority in the range 2-15.
- If the writer instance rarely if ever pauses, check your usage of the reader instances. The writer can only pause if the entire cluster is idle. That's because a connection to any reader instance causes the writer to resume.
- If your application receives timeouts during connection requests while Aurora serverless instances are resuming, consider lengthening the timeout interval used by your application code or the underlying database framework. Longer connection timeouts reduce the possibility of failed connections while Aurora serverless instances are resuming. However, the longer timeouts can also make your application slower to detect availability issues in your cluster.

  Conversely, consider lengthening the auto-pause interval so that applications don't encounter paused instances as often.

  If there isn't a logical balance between the auto-pause behavior and cluster responsiveness for your application, that cluster might not be a good candidate for using the auto-pause feature.
- If you estimate how long your Aurora serverless instances will be paused, be aware that there are factors that make it impractical to make precise predictions.
  - Instances might resume periodically to perform maintenance, minor version upgrades, or apply changes to parameter groups.
  - For multi-AZ clusters, there are situations where resuming one instance causes other instances to resume also. Resuming any reader always causes the writer to resume. Resuming the writer always causes any readers with failover priority 0 and 1 to resume.

We recommend measuring the actual paused time over a period of several days, with a realistic workload. Then use those measurements to set a baseline for what proportion of time you can expect an instance to be paused.

- You might find that internal operations such as MySQL purge, MySQL event scheduler, PostgreSQL autovacuum, or PostgreSQL jobs scheduled through the `pg_cron` extension aren't running or aren't completing. The instance doesn't automatically resume to perform such operations that don't involve a user connection to the database. If such internal operations are underway when the auto-pause timeout expires, maintenance tasks such as MySQL purge and PostgreSQL autovacuum are canceled. Scheduled jobs from the MySQL event scheduler or the PostgreSQL `pg_cron` extension are also canceled if they're in progress when Aurora initiates the pause operation.

  If you need to ensure that the instance is periodically awake to perform scheduled operations, you can initiate a connection to resume the instance before the start time of the job. You can also increase the auto-pause timeout interval so that operations such as autovacuum can run for longer after user activity is finished. You can also use mechanisms such as Lambda functions to perform database operations on a schedule, in a way that automatically resumes the instance if necessary.

Application design considerations for the Aurora serverless auto-pause feature

When an Aurora serverless DB instance resumes after being automatically paused, it begins with a relatively small capacity and scales up from there. This starting capacity applies even if the DB instance had some higher capacity immediately before it was automatically paused.

Use this feature with applications that can tolerate an interval of approximately 15 seconds while establishing a connection. That accounts for the typical case where an Aurora serverless instance resumes due to one or a small number of incoming connections. If the instance is paused for longer than 24 hours, the time to resume might be longer.

If you are using Aurora serverless in combination with the Aurora stop/start cluster feature, the resumption time for auto-paused Aurora serverless instances is typically much shorter than the time to start a cluster that's stopped.

When coding connection logic in your application, retry the connection if the first attempt return an error that has a transient cause. (If the error is due to authentication failure, correct the

credentials before retrying.) An error that happens immediately after resuming might be a timeout, or some error related to database limits. Retrying can handle issues in the rarer case where an Aurora serverless instance is resumed due to a high number of simultaneous connection requests. In that case, some connections might take longer than usual to be processed, or might exceed the limit of simultaneous connections on the first attempt.

During application development and debugging, don't leave client sessions or programming tools with connections open to the database. Aurora won't pause an instance if there are any user-initiated connections open, regardless of whether the connections aren't running any SQL statements or transactions. When one Aurora serverless instance in an Aurora cluster can't pause, other instances in the cluster might also be prevented from pausing. For more information, see Situations where Aurora serverless doesn't auto-pause.

Aurora emits events when an Aurora serverless DB instance begins resuming, finishes resuming, and if the instance can't resume for some reason. For details about these events, see DB instance events.

Using the Amazon RDS Data API

By using RDS Data API (Data API), you can work with a web-services interface to your Aurora DB cluster. Data API doesn't require a persistent connection to the DB cluster. Instead, it provides a secure HTTP endpoint and integration with Amazon SDKs. You can use the endpoint to run SQL statements without managing connections.

Users don't need to pass credentials with calls to Data API, because Data API uses database credentials stored in Amazon Secrets Manager. To store credentials in Secrets Manager, users must be granted the appropriate permissions to use Secrets Manager, and also Data API. For more information about authorizing users, see Authorizing access to the Amazon RDS Data API.

You can also use Data API to integrate Amazon Aurora with other Amazon applications such as Amazon Lambda, Amazon AppSync, and Amazon Cloud9. Data API provides a more secure way to use Amazon Lambda. It enables you to access your DB cluster without your needing to configure a Lambda function to access resources in a virtual private cloud (VPC). For more information, see Amazon Lambda, Amazon AppSync, and Amazon Cloud9.

You can enable Data API when you create the Aurora DB cluster. You can also modify the configuration later. For more information, see Enabling the Amazon RDS Data API.

After you enable Data API, you can also use the query editor to run ad hoc queries without configuring a query tool to access Aurora in a VPC. For more information, see Using the Aurora query editor.

Region and version availability for the Amazon RDS Data API

For information about the Regions and engine versions available for Data API, see the following sections.

Cluster type	Region and version availability
Aurora PostgreSQL provisioned and Aurora serverless	Data API with Aurora PostgreSQL Aurora serverless and provisioned
Aurora MySQL provisioned and Aurora serverless	Data API with Aurora MySQL Aurora serverless and provisioned

If you require cryptographic modules validated by FIPS 140-2 when accessing Data API through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

Using IPv6 with Amazon RDS Data API

Amazon RDS Data API supports IPv6 connectivity through dual-stack endpoints. This allows you to connect to Data API using IPv6 addresses while maintaining backward compatibility with IPv4.

IPv6 endpoint support

Data API provides dual-stack endpoints that support both IPv4 and IPv6 connections. These endpoints use the `.aws` domain instead of the traditional `.amazonaws.com` domain.

Available endpoint types

Public dual-stack endpoints

Format: `rds-data.`*`region`*`.api.aws`

Example: `rds-data.us-east-1.api.aws`

FIPS dual-stack endpoints

Format: `rds-data-fips.region.api.aws`

Example: `rds-data-fips.us-east-1.api.aws`

PrivateLink IPv6 endpoints

Available through VPC endpoints with IPv6 support

Allows private IPv6 connectivity within your VPC

Legacy IPv4-only endpoints

The existing `.amazonaws.com` endpoints continue to support IPv4-only connections:

- `rds-data.region.amazonaws.com`
- `rds-data-fips.region.amazonaws.com`

> **Note**
>
> Legacy endpoints remain unchanged to ensure backward compatibility with existing applications.

Using IPv6 endpoints

To use IPv6 with Data API, update your application to use the new dual-stack endpoints. Your application will automatically use IPv6 if available, or fall back to IPv4.

For general guidance on setting up IPv6 in your VPC, see Migrating to IPv6 in the *Amazon VPC User Guide*.

You can configure IPv6 endpoints in two ways:

- **Using environment variable**: Set `AWS_USE_DUALSTACK_ENDPOINT=true` in your IPv6 environment. The Amazon CLI and Amazon SDKs will automatically construct the appropriate `api.aws` endpoints without requiring you to specify endpoint URLs manually.
- **Using explicit endpoint URLs**: Specify the dual-stack endpoint URL directly in your Amazon CLI commands or SDK configuration as shown in the examples below.

Amazon CLI configuration

Configure the Amazon CLI to use IPv6 endpoints by specifying the endpoint URL:

For Linux, macOS, or Unix:

```
aws rds-data execute-statement \
     --endpoint-url https://rds-data.us-east-1.api.aws \
     --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:my-cluster" \
     --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret" \
     --database "mydb" \
     --sql "SELECT * FROM users LIMIT 10"
```

For Windows:

```
aws rds-data execute-statement ^
     --endpoint-url https://rds-data.us-east-1.api.aws ^
     --resource-arn "arn:aws:rds:us-east-1:123456789012:cluster:my-cluster" ^
     --secret-arn "arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret" ^
     --database "mydb" ^
     --sql "SELECT * FROM users LIMIT 10"
```

Amazon SDK configuration

Configure Amazon SDKs to use dual-stack endpoints:

Python

```
import boto3

 # Create RDS Data API client with IPv6 dual-stack endpoint
 client = boto3.client(
     'rds-data',
     endpoint_url='https://rds-data.us-east-1.api.aws'
 )

 # Execute a SQL statement
 response = client.execute_statement(
     resourceArn='arn:aws:rds:us-east-1:123456789012:cluster:my-cluster',
     secretArn='arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret',
     database='mydb',
     sql='SELECT * FROM users LIMIT 10'
 )
```

```
print(response['records'])
```

Java

```
import software.amazon.awssdk.services.rdsdata.RdsDataClient;
 import software.amazon.awssdk.services.rdsdata.model.ExecuteStatementRequest;
 import software.amazon.awssdk.services.rdsdata.model.ExecuteStatementResponse;
 import java.net.URI;

 // Create RDS Data API client with IPv6 dual-stack endpoint
 RdsDataClient client = RdsDataClient.builder()
     .endpointOverride(URI.create("https://rds-data.us-east-1.api.aws"))
     .build();

 // Execute a SQL statement
 ExecuteStatementRequest request = ExecuteStatementRequest.builder()
     .resourceArn("arn:aws:rds:us-east-1:123456789012:cluster:my-cluster")
     .secretArn("arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret")
     .database("mydb")
     .sql("SELECT * FROM users LIMIT 10")
     .build();

 ExecuteStatementResponse response = client.executeStatement(request);
 System.out.println(response.records());
```

JavaScript

```
const { RDSDataClient, ExecuteStatementCommand } = require("@aws-sdk/client-rds-
data");

 // Create RDS Data API client with IPv6 dual-stack endpoint
 const client = new RDSDataClient({
     endpoint: "https://rds-data.us-east-1.api.aws"
 });

 // Execute a SQL statement
 const command = new ExecuteStatementCommand({
     resourceArn: "arn:aws:rds:us-east-1:123456789012:cluster:my-cluster",
     secretArn: "arn:aws:secretsmanager:us-east-1:123456789012:secret:my-secret",
     database: "mydb",
     sql: "SELECT * FROM users LIMIT 10"
 });
```

```
const response = await client.send(command);
console.log(response.records);
```

Using Amazon PrivateLink with IPv6

You can create VPC endpoints for Data API that support IPv6 connectivity within your VPC. For detailed instructions on creating VPC endpoints for Data API, see Creating an Amazon VPC endpoint for the Amazon RDS Data API (Amazon PrivateLink).

When creating a VPC endpoint for IPv6 support, ensure that:

- Your VPC and subnets are configured to support IPv6
- Security groups allow IPv6 traffic on the required ports (typically 443 for HTTPS)
- Network ACLs are configured to allow IPv6 traffic

Migration considerations

When migrating to IPv6 endpoints, consider the following:

- **Gradual migration**: You can migrate applications gradually by updating endpoint URLs one application at a time.
- **Network compatibility**: Ensure your network infrastructure supports IPv6 before migrating.
- **Security policies**: Update security group rules and network ACLs to allow IPv6 traffic if needed.
- **Monitoring**: Update monitoring and logging configurations to handle IPv6 addresses.

> **Note**
>
> **Database connection addresses**: When using IPv6 endpoints for Data API, the underlying database connections and database logs will still show IPv4 addresses. This is expected behavior and does not affect the functionality of your IPv6-enabled applications.

Troubleshooting IPv6 connectivity

If you experience issues with IPv6 connectivity, check the following:

Network configuration

Verify that your network supports IPv6 and that IPv6 routing is configured correctly.

DNS resolution

Ensure that your DNS resolver can resolve AAAA records for the dual-stack endpoints.

Security groups

Update security group rules to allow IPv6 traffic on the required ports (typically 443 for HTTPS).

Client libraries

Verify that your HTTP client libraries support IPv6 and dual-stack connectivity.

Limitations for the Amazon RDS Data API

RDS Data API has the following limitations:

- You can only execute Data API queries on writer instances in a DB cluster. However, writer instances can accept both write and read queries.
- With Aurora global databases, you can enable Data API on both the primary and secondary DB clusters. However, a secondary cluster doesn't have a writer instance until it's promoted to be the primary. Data API requires access to the writer instance for query processing, even for read queries. As a result, read and write queries sent to the secondary cluster fail while it lacks a writer instance. Once a secondary cluster is promoted and has a writer instance available, Data API queries on that DB instance succeed.
- Data API isn't supported on T DB instance classes.
- For Aurora PostgreSQL version 14 and higher databases, Data API only supports `scram-sha-256` for password encryption.
- The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.

Session management with Amazon RDS Data API

RDS Data API maintains a pool of database connections and reuses them across calls to reduce connection overhead. Before reusing a connection, RDS Data API resets session state. The reset differs by database engine: on PostgreSQL, RDS Data API runs the `DISCARD ALL` statement to

clear session state such as temporary tables, prepared statements, and session-level parameters; on MySQL, RDS Data API resets the connection (equivalent to `COM_RESET_CONNECTION`).

These resets cover session-level attributes that the engine owns, but state created by an extension is not guaranteed to be included. Extensions may not behave in the same manner as other session-level attributes when these cleanups are executed, and their state can persist on the database connection after the reset. Because RDS Data API reuses connections, state left behind by an extension is not limited to the call that created it and can still be present when a later call reuses the same connection.

`dblink` is one example of this behavior: `DISCARD ALL` does not close connections opened by the `dblink` extension, so a named `dblink` connection opened in one call can remain open when the connection is reused. Other extensions that hold resources outside the engine's session state can behave similarly.

If you use extensions with RDS Data API, do not rely on the session reset to release extension-owned state. Create and release that state within the same transaction, using the extension's own teardown function. For `dblink`, close each connection with `dblink_disconnect`.

Authorizing access to the Amazon RDS Data API

Users can invoke Amazon RDS Data API (Data API) operations only if they are authorized to do so. You can give a user permission to use Data API by attaching an Amazon Identity and Access Management (IAM) policy that defines their privileges. You can also attach the policy to a role if you're using IAM roles. An Amazon managed policy, `AmazonRDSDataFullAccess`, includes permissions for Data API.

The `AmazonRDSDataFullAccess` policy also includes permissions for the user to get the value of a secret from Amazon Secrets Manager. Users need to use Secrets Manager to store secrets that they can use in their calls to Data API. Using secrets means that users don't need to include database credentials for the resources that they target in their calls to Data API. Data API transparently calls Secrets Manager, which allows (or denies) the user's request for the secret. For information about setting up secrets to use with Data API, see Storing database credentials in Amazon Secrets Manager.

The `AmazonRDSDataFullAccess` policy provides complete access (through Data API) to resources. You can narrow the scope by defining your own policies that specify the Amazon Resource Name (ARN) of a resource.

For example, the following policy shows an example of the minimum required permissions for a user to access Data API for the DB cluster identified by its ARN. The policy includes the needed permissions to access Secrets Manager and get authorization to the DB instance for the user.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "SecretsManagerDbCredentialsAccess",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue"
            ],
            "Resource": "arn:aws-cn:secretsmanager:*:*:secret:rds-db-credentials/
*"
        },
        {
            "Sid": "RDSDataServiceAccess",
            "Effect": "Allow",
            "Action": [
                "rds-data:BatchExecuteStatement",
                "rds-data:BeginTransaction",
                "rds-data:CommitTransaction",
                "rds-data:ExecuteStatement",
                "rds-data:RollbackTransaction"
            ],
            "Resource": "arn:aws-cn:rds:us-east-2:111122223333:cluster:prod"
        }
    ]
}
```

We recommend that you use a specific ARN for the "Resources" element in your policy statements (as shown in the example) rather than a wildcard (*).

Working with tag-based authorization

RDS Data API (Data API) and Secrets Manager both support tag-based authorization. *Tags* are key-value pairs that label a resource, such as an RDS cluster, with an additional string value, for example:

- `environment:production`
- `environment:development`

You can apply tags to your resources for cost allocation, operations support, access control, and many other reasons. (If you don't already have tags on your resources and you want to apply them, you can learn more at Tagging Amazon RDS resources.) You can use the tags in your policy statements to limit access to the RDS clusters that are labeled with these tags. As an example, an Aurora DB cluster might have tags that identify its environment as either production or development.

The following example shows how you can use tags in your policy statements. This statement requires that both the cluster and the secret passed in the Data API request have an `environment:production` tag.

Here's how the policy is applied: When a user makes a call using Data API, the request is sent to the service. Data API first verifies that the cluster ARN passed in the request is tagged with `environment:production`. It then calls Secrets Manager to retrieve the value of the user's secret in the request. Secrets Manager also verifies that the user's secret is tagged with `environment:production`. If so, Data API then uses the retrieved value for the user's DB password. Finally, if that's also correct, the Data API request is invoked successfully for the user.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "SecretsManagerDbCredentialsAccess",
            "Effect": "Allow",
            "Action": [
                 "secretsmanager:GetSecretValue"
               ],
```

```
            "Resource": "arn:aws-cn:secretsmanager:*:*:secret:rds-db-credentials/
*",
            "Condition": {
                    "StringEquals": {
                        "aws:ResourceTag/environment": [
                                        "production"
                                       ]
                     }
                }
        },
        {
            "Sid": "RDSDataServiceAccess",
            "Effect": "Allow",
            "Action": [
                  "rds-data:*"
               ],
            "Resource": "arn:aws-cn:rds:us-east-2:111122223333:cluster:*",
            "Condition": {
                    "StringEquals": {
                        "aws:ResourceTag/environment": [
                                        "production"
                                       ]
                     }
                }
         }
     ]
}
```

The example shows separate actions for `rds-data` and `secretsmanager` for Data API and Secrets Manager. However, you can combine actions and define tag conditions in many different ways to support your specific use cases. For more information, see Using identity-based policies (IAM policies) for Secrets Manager.

In the "Condition" element of the policy, you can choose tag keys from among the following:

- `aws:TagKeys`
- `aws:ResourceTag/${TagKey}`

To learn more about resource tags and how to use `aws:TagKeys`, see Controlling access to Amazon resources using resource tags.

> **Note**
>
> Both Data API and Amazon Secrets Manager authorize users. If you don't have permissions for all actions defined in a policy, you get an `AccessDeniedException` error.

Storing database credentials in Amazon Secrets Manager

When you call the Amazon RDS Data API (Data API), you pass credentials for the Aurora DB cluster by using a secret in Secrets Manager. To pass credentials in this way, you specify the name of the secret or the Amazon Resource Name (ARN) of the secret.

To store DB cluster credentials in a secret

1. Use Secrets Manager to create a secret that contains credentials for the Aurora DB cluster.

   For instructions, see Create a database secret in the *Amazon Secrets Manager User Guide*.
2. Use the Secrets Manager console to view the details for the secret you created, or run the `aws secretsmanager describe-secret` Amazon CLI command.

   Note the name and ARN of the secret. You can use them in calls to Data API.

For more information about using Secrets Manager, see the Amazon Secrets Manager User Guide.

To understand how Amazon Aurora manages identity and access management, see How Amazon Aurora works with IAM.

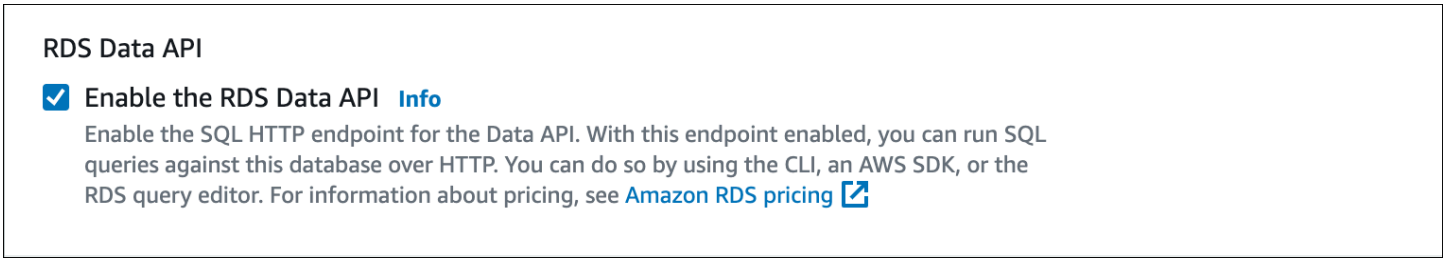
For more information about creating an IAM policy, see Creating IAM Policies in the *IAM User Guide*. For information about adding an IAM policy to a user, see Adding and Removing IAM Identity Permissions in the *IAM User Guide*.

Enabling the Amazon RDS Data API

To use the Amazon RDS Data API (Data API), enable it for your Aurora DB cluster. You can enable Data API when you create or modify the DB cluster.

> **Note**
>
> Whether Data API is available for your cluster depends on your Aurora version, database engine, and Amazon Region. For Aurora, Data API works with clusters that use both provisioned and Aurora serverless instances. To check whether your cluster can use Data API, see Supported Regions and Aurora DB engines for RDS Data API.

Topics



- Enabling RDS Data API when you create a database
- Enabling or disabling RDS Data API on an existing database

Enabling RDS Data API when you create a database

While you are creating a database that supports RDS Data API (Data API), you can enable this feature. The following procedures describe how to do so when you use the Amazon Web Services Management Console, the Amazon CLI, or the RDS API.

Console

To enable Data API when you create a DB cluster, select the **Enable the RDS Data API** checkbox in the **Connectivity** section of the **Create database** page, as in the following screenshot.

For instructions on how to create an Aurora DB cluster that can use the RDS Data API, see the following:

- For Aurora serverless and provisioned clusters – Creating an Amazon Aurora DB cluster

Amazon CLI

To enable Data API while you're creating an Aurora DB cluster, run the create-db-cluster Amazon CLI command with the `--enable-http-endpoint` option.

The following example creates an Aurora PostgreSQL DB cluster with Data API enabled.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
     --db-cluster-identifier my_pg_cluster \
     --engine aurora-postgresql \
     --enable-http-endpoint
```

For Windows:

```
aws rds create-db-cluster ^
     --db-cluster-identifier my_pg_cluster ^
     --engine aurora-postgresql ^
     --enable-http-endpoint
```

RDS API

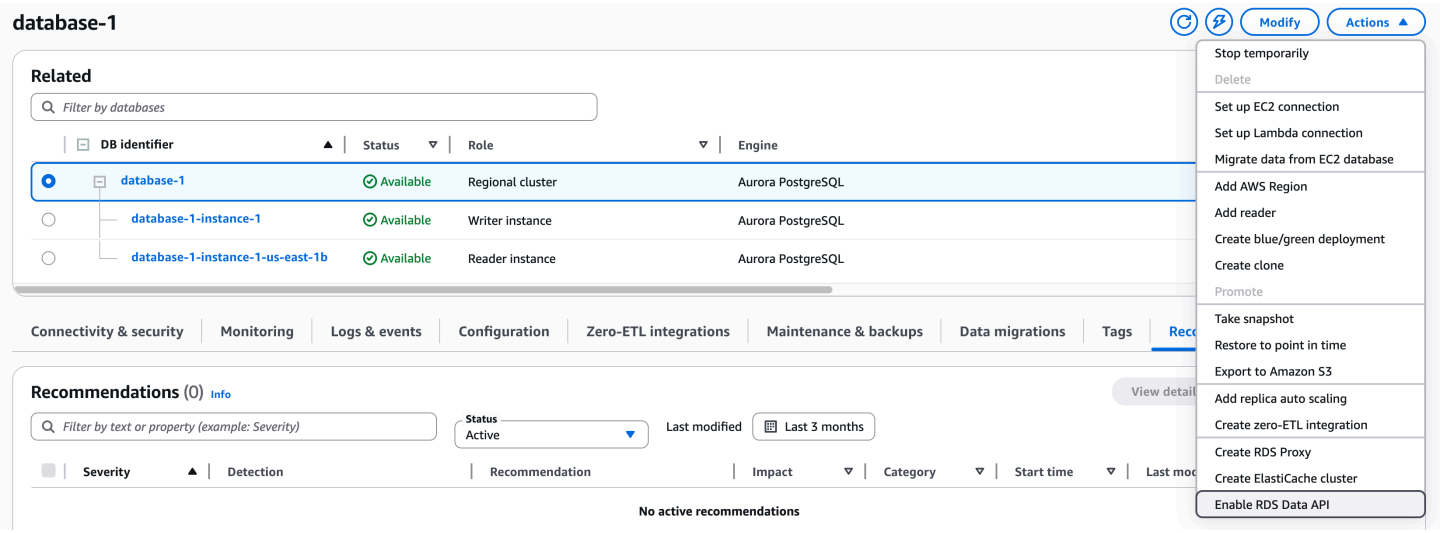
To enable Data API while you're creating an Aurora DB cluster, use the CreateDBCluster operation with the value of the `EnableHttpEndpoint` parameter set to `true`.

Enabling or disabling RDS Data API on an existing database

You can modify a DB cluster that supports RDS Data API (Data API) to enable or disable this feature.

Topics

- Enabling or disabling Data API (Aurora serverless and provisioned)



Enabling or disabling Data API (Aurora serverless and provisioned)

Use the following procedures to enable or disable Data API on Aurora serverless and provisioned databases.

Console

You can enable or disable Data API by using the RDS console for a DB cluster that supports this feature. To do so, open the cluster details page of the database on which you want to enable or disable Data API, and select **Enable RDS Data API** or **Disable RDS Data API** from the **Actions** dropdown menu. This will allow you to enable or disable the RDS Data API for your cluster.

The following screenshot shows that the **RDS Data API** isn't enabled.

Amazon CLI

To enable or disable Data API on an existing database, run the enable-http-endpoint or disable-http-endpoint Amazon CLI command, and specify the ARN of your DB cluster.

The following example enables Data API.

For Linux, macOS, or Unix:

```
aws rds enable-http-endpoint \
     --resource-arn cluster_arn
```

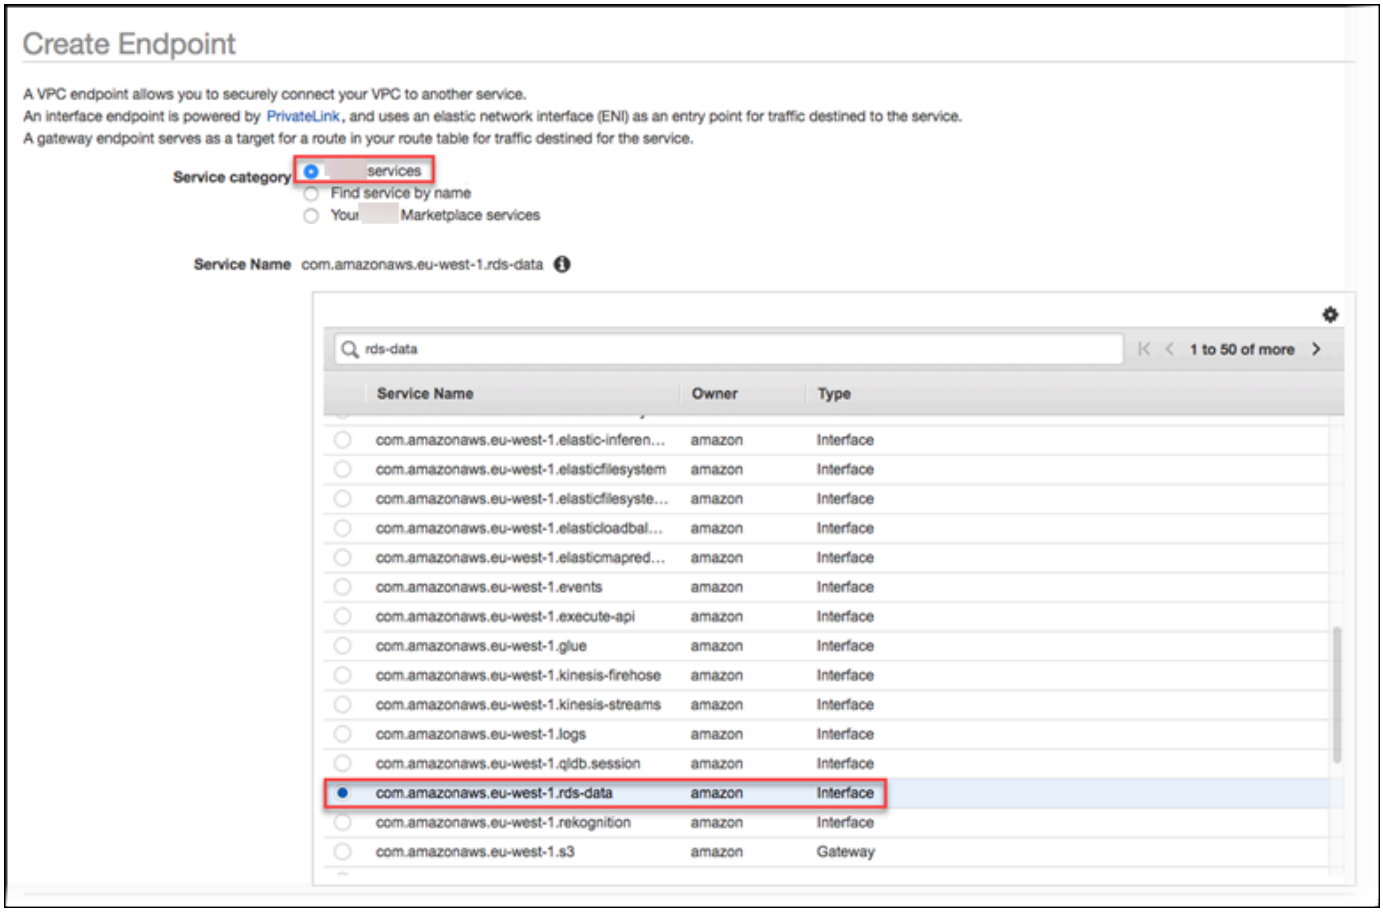
For Windows:

```
aws rds enable-http-endpoint ^
     --resource-arn cluster_arn
```

RDS API

To enable or disable Data API on an existing database, use the EnableHttpEndpoint and DisableHttpEndpoint operations.

Creating an Amazon VPC endpoint for the Amazon RDS Data API (Amazon PrivateLink)



Amazon VPC enables you to launch Amazon resources, such as Aurora DB clusters and applications, into a virtual private cloud (VPC). Amazon PrivateLink provides private connectivity between VPCs and Amazon services with high security on the Amazon network. Using Amazon PrivateLink, you can create Amazon VPC endpoints, which enable you to connect to services across different accounts and VPCs based on Amazon VPC. For more information about Amazon PrivateLink, see VPC Endpoint Services (Amazon PrivateLink) in the *Amazon Virtual Private Cloud User Guide*.

You can call RDS Data API (Data API) with Amazon VPC endpoints. Using an Amazon VPC endpoint keeps traffic between applications in your Amazon VPC and Data API in the Amazon network, without using public IP addresses. Amazon VPC endpoints can help you meet compliance and regulatory requirements related to limiting public internet connectivity. For example, if you use an Amazon VPC endpoint, you can keep traffic between an application running on an Amazon EC2 instance and Data API in the VPCs that contain them.

After you create the Amazon VPC endpoint, you can start using it without making any code or configuration changes in your application.

To create an Amazon VPC endpoint for Data API

1. Sign in to the Amazon Web Services Management Console and open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
2. Choose **Endpoints**, and then choose **Create Endpoint**.
3. On the **Create Endpoint** page, for **Service category**, choose **Amazon services**. For **Service Name**, choose **rds-data**.

4. For **VPC**, choose the VPC to create the endpoint in.

   Choose the VPC that contains the application that makes Data API calls.

5. For **Subnets**, choose the subnet for each Availability Zone (AZ) used by the Amazon service that is running your application.

To create an Amazon VPC endpoint, specify the private IP address range in which the endpoint will be accessible. To do this, choose the subnet for each Availability Zone. Doing so restricts the VPC endpoint to the private IP address range specific to each Availability Zone and also creates an Amazon VPC endpoint in each Availability Zone.

6. For **Enable DNS name**, select **Enable for this endpoint**.

   Private DNS resolves the standard Data API DNS hostname (`https://rds-data.`*`region`*`.amazonaws.com`) to the private IP addresses associated with the DNS hostname specific to your Amazon VPC endpoint. As a result, you can access the Data API VPC endpoint using the Amazon CLI or Amazon SDKs without making any code or configuration changes to update Data API's endpoint URL.

7. For **Security group**, choose a security group to associate with the Amazon VPC endpoint.

   Choose the security group that allows access to the Amazon service that is running your application. For example, if an Amazon EC2 instance is running your application, choose the security group that allows access to the Amazon EC2 instance. The security group enables you to control the traffic to the Amazon VPC endpoint from resources in your VPC.

8. For **Policy**, choose **Full Access** to allow anyone inside the Amazon VPC to access the Data API through this endpoint. Or choose **Custom** to specify a policy that limits access.

   If you choose **Custom**, enter the policy in the policy creation tool.

9. Choose **Create endpoint**.

After the endpoint is created, choose the link in the Amazon Web Services Management Console to view the endpoint details.

The endpoint **Details** tab shows the DNS hostnames that were generated while creating the Amazon VPC endpoint.

You can use the standard endpoint (`rds-data.`*`region`*`.amazonaws.com`) or one of the VPC-specific endpoints to call the Data API within the Amazon VPC. The standard Data API endpoint automatically routes to the Amazon VPC endpoint. This routing occurs because the Private DNS hostname was enabled when the Amazon VPC endpoint was created.

When you use an Amazon VPC endpoint in a Data API call, all traffic between your application and Data API remains in the Amazon VPCs that contain them. You can use an Amazon VPC endpoint for any type of Data API call. For information about calling Data API, see Calling the Amazon RDS Data API.

Calling the Amazon RDS Data API

With the Amazon RDS Data API (Data API) enabled on your Aurora DB cluster, you can run SQL statements on the Aurora DB cluster by using Data API or the Amazon CLI. Data API supports the programming languages supported by the Amazon SDKs. For more information, see Tools to build on Amazon.

Topics

- Amazon RDS Data API operations reference
- Calling the Amazon RDS Data API with the Amazon CLI
- Calling the Amazon RDS Data API from a Python application
- Calling the Amazon RDS Data API from a Java application
- Controlling Data API timeout behavior

Amazon RDS Data API operations reference

The Amazon RDS Data API provides the following operations to perform SQL statements.

Data API operation	Amazon CLI command	Description
ExecuteStatement	aws rds-data execute-statement	Runs a SQL statement on a database.
BatchExecuteStatement	aws rds-data batch-execute-statement	Runs a batch SQL statement over an array of data for bulk update and insert operations. You can run a data manipulation language (DML) statement with an array of parameter sets. A batch SQL statement can provide a significant performance improvement over individual insert and update statements.

You can use either operation to run individual SQL statements or to run transactions. For transactions, Data API provides the following operations.

Data API operation	Amazon CLI command	Description
BeginTransaction	aws rds-data begin-transaction	Starts a SQL transaction.
CommitTransaction	aws rds-data commit-transaction	Ends a SQL transaction and commits the changes.
RollbackTransaction	aws rds-data rollback-transaction	Performs a rollback of a transaction.

The operations for performing SQL statements and supporting transactions have the following common Data API parameters and Amazon CLI options. Some operations support other parameters or options.

Data API operation parameter	Amazon CLI command option	Required	Description
`resourceArn`	`--resource-arn`	Yes	The Amazon Resource Name (ARN) of the Aurora DB cluster. The cluster must be in the same Amazon Web Services account as the IAM role or user that invokes the Data API. To access a cluster in a different account, assume a role in that account.
`secretArn`	`--secret-arn`	Yes	The name or ARN of the secret that enables access to the DB cluster.

RDS Data API supports the following data types for Aurora MySQL:

- `TINYINT(1)`, `BOOLEAN`, `BOOL`
- `TINYINT`
- `SMALLINT` [`SIGNED` | `UNSIGNED`]
- `MEDIUMINT` [`SIGNED` | `UNSIGNED`]
- `INT` [`SIGNED` | `UNSIGNED`]
- `BIGINT` [`SIGNED` | `UNSIGNED`]
- `FLOAT`
- `DOUBLE`
- `VARCHAR`, `CHAR`, `TEXT`, `ENUM`
- `VARBINARY`, `BINARY`, `BLOB`
- `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`
- `DECIMAL`
- `JSON`

- BIT, BIT(N)

RDS Data API supports following Aurora PostgreSQL scalar types:

- BOOL
- BYTEA
- DATE
- CIDR
- DECIMAL, NUMERIC
- ENUM
- FLOAT8, DOUBLE PRECISION
- INET
- INT, INT4, SERIAL
- INT2, SMALLINT, SMALLSERIAL
- INT8, BIGINT, BIGSERIAL
- JSONB, JSON
- REAL, FLOAT
- TEXT, CHAR(N), VARCHAR, NAME
- TIME
- TIMESTAMP
- UUID
- VECTOR

RDS Data API supports the following Aurora PostgreSQL array types in query results. These array types apply only to values returned when you read array columns from a result set. You can't pass arrays as input parameters: Supplying an `arrayValue` in a `SqlParameter` for `ExecuteStatement` or `BatchExecuteStatement` returns `ValidationException: Array parameters are not supported`. To pass an array as input, provide a Aurora PostgreSQL array literal as a `stringValue` and cast it in SQL (for example, `:myparam::text[]`).

- BOOL[], BIT[]
- DATE[]

- DECIMAL[], NUMERIC[]
- FLOAT8[], DOUBLE PRECISION[]
- INT[], INT4[]
- INT2[]
- INT8[], BIGINT[]
- JSON[]
- REAL[], FLOAT[]
- TEXT[], CHAR(N)[], VARCHAR[], NAME[]
- TIME[]
- TIMESTAMP[]
- UUID[]

You can use parameters in Data API calls to ExecuteStatement and BatchExecuteStatement, and when you run the Amazon CLI commands execute-statement and batch-execute-statement. To use a parameter, you specify a name-value pair in the SqlParameter data type. You specify the value with the Field data type. The following table maps Java Database Connectivity (JDBC) data types to the data types that you specify in Data API calls.

JDBC data type	Data API data type
INTEGER, TINYINT, SMALLINT, BIGINT	LONG (or STRING)
FLOAT, REAL, DOUBLE	DOUBLE
DECIMAL	STRING
BOOLEAN, BIT	BOOLEAN
BLOB, BINARY, LONGVARBINARY, VARBINARY	BLOB
CLOB	STRING
Other types (including types related to date and time)	STRING

> **Note**
>
> You can specify the `LONG` or `STRING` data type in your Data API call for `LONG` values returned by the database. We recommend that you do so to avoid losing precision for extremely large numbers, which can happen when you work with JavaScript.

Certain types, such as `DECIMAL` and `TIME`, require a hint so that Data API passes `String` values to the database as the correct type. To use a hint, include values for `typeHint` in the `SqlParameter` data type. The possible values for `typeHint` are the following:

- `DATE` – The corresponding `String` parameter value is sent as an object of `DATE` type to the database. The accepted format is `YYYY-MM-DD`.
- `DECIMAL` – The corresponding `String` parameter value is sent as an object of `DECIMAL` type to the database.
- `JSON` – The corresponding `String` parameter value is sent as an object of `JSON` type to the database.
- `TIME` – The corresponding `String` parameter value is sent as an object of `TIME` type to the database. The accepted format is `HH:MM:SS[.FFF]`.
- `TIMESTAMP` – The corresponding `String` parameter value is sent as an object of `TIMESTAMP` type to the database. The accepted format is `YYYY-MM-DD HH:MM:SS[.FFF]`.
- `UUID` – The corresponding `String` parameter value is sent as an object of `UUID` type to the database.

> **Note**
>
> Currently, Data API doesn't support arrays of Universal Unique Identifiers (UUIDs).

> **Note**
>
> For Amazon Aurora PostgreSQL, Data API always returns the Aurora PostgreSQL data type `TIMESTAMPTZ` in UTC time zone.

Calling the Amazon RDS Data API with the Amazon CLI

You can call RDS Data API (Data API) using the Amazon CLI.

The following examples use the Amazon CLI for Data API. For more information, see Amazon CLI reference for the Data API.

In each example, replace the Amazon Resource Name (ARN) for the DB cluster with the ARN for your Aurora DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

> **Note**
>
> The Amazon CLI can format responses in JSON.

Topics

- Starting a SQL transaction
- Running a SQL statement
- Running a batch SQL statement over an array of data
- Committing a SQL transaction
- Rolling back a SQL transaction

Starting a SQL transaction

You can start a SQL transaction using the `aws rds-data begin-transaction` CLI command. The call returns a transaction identifier.

> **Important**
>
> Within Data API, a transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, Data API rolls it back automatically.
> MySQL data definition language (DDL) statements inside a transaction cause an implicit commit. We recommend that you run each MySQL DDL statement in a separate `execute-statement` command with the `--continue-after-timeout` option.

In addition to the common options, specify the `--database` option, which provides the name of the database.

For example, the following CLI command starts a SQL transaction.

For Linux, macOS, or Unix:

```
aws rds-data begin-transaction --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" \
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret"
```

For Windows:

```
aws rds-data begin-transaction --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret"
```

The following is an example of the response.

```
{
    "transactionId": "ABC1234567890xyz"
 }
```

Running a SQL statement

You can run a SQL statement using the `aws rds-data execute-statement` CLI command.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction using the `aws rds-data commit-transaction` CLI command.

> **Important**
>
> If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.
- `--transaction-id` (optional) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
- `--parameters` (optional) – The parameters for the SQL statement.
- `--include-result-metadata | --no-include-result-metadata` (optional) – A value that indicates whether to include metadata in the results. The default is `--no-include-result-metadata`.
- `--database` (optional) – The name of the database.

  The `--database` option might not work when you run a SQL statement after running `--sql "use database_name;"` in the previous request. We recommend that you use the `--database` option instead of running `--sql "use database_name;"` statements.
- `--continue-after-timeout | --no-continue-after-timeout` (optional) – A value that indicates whether to continue running the statement after the call exceeds the Data API timeout interval of 45 seconds. The default is `--no-continue-after-timeout`.

  For data definition language (DDL) statements, we recommend continuing to run the statement after the call times out to avoid errors and the possibility of corrupted data structures.
- `--format-records-as "JSON"|"NONE"` – An optional value that specifies whether to format the result set as a JSON string. The default is `"NONE"`. For usage information about processing JSON result sets, see Processing Amazon RDS Data API query results in JSON format.

The DB cluster returns a response for the call.

> **Note**
>
> The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.

For example, the following CLI command runs a single SQL statement and omits the metadata in the results (the default).

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" \
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret" \
 --sql "select * from mytable"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret" ^
 --sql "select * from mytable"
```

The following is an example of the response.

```
{
    "numberOfRecordsUpdated": 0,
    "records": [
        [
            {
                "longValue": 1
            },
            {
                "stringValue": "ValueOne"
            }
        ],
        [
            {
                "longValue": 2
            },
            {
                "stringValue": "ValueTwo"
            }
        ],
        [
            {
                "longValue": 3
            },
            {
                "stringValue": "ValueThree"
            }
```

```
        ]
    ]
}
```

The following CLI command runs a single SQL statement in a transaction by specifying the `--transaction-id` option.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" \
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret" \
 --sql "update mytable set quantity=5 where id=201" --transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret" ^
 --sql "update mytable set quantity=5 where id=201" --transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{
    "numberOfRecordsUpdated": 1
}
```

The following CLI command runs a single SQL statement with parameters.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" \
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret" \
 --sql "insert into mytable values (:id, :val)" --parameters "[{\"name\": \"id\",
 \"value\": {\"longValue\": 1}},{\"name\": \"val\", \"value\": {\"stringValue\":
 \"value1\"}}]"
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret" ^
 --sql "insert into mytable values (:id, :val)" --parameters "[{\"name\": \"id\",
 \"value\": {\"longValue\": 1}},{\"name\": \"val\", \"value\": {\"stringValue\":
 \"value1\"}}]"
```

The following is an example of the response.

```
{
     "numberOfRecordsUpdated": 1
 }
```

The following CLI command runs a data definition language (DDL) SQL statement. The DDL statement renames column `job` to column `role`.

> **Important**
>
> For DDL statements, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call exceeds the RDS Data API timeout interval of 45 seconds, specify the `--continue-after-timeout` option.

For Linux, macOS, or Unix:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" \
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret" \
 --sql "alter table mytable change column job role varchar(100)" --continue-after-
timeout
```

For Windows:

```
aws rds-data execute-statement --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
```

```
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret" ^
 --sql "alter table mytable change column job role varchar(100)" --continue-after-
timeout
```

The following is an example of the response.

```
{
     "generatedFields": [],
     "numberOfRecordsUpdated": 0
 }
```

> **Note**
>
> The `generatedFields` data isn't supported by Aurora PostgreSQL. To get the values of generated fields, use the `RETURNING` clause. For more information, see Returning data from modified rows in the PostgreSQL documentation.

Running a batch SQL statement over an array of data

You can run a batch SQL statement over an array of data by using the `aws rds-data batch-execute-statement` CLI command. You can use this command to perform a bulk import or update operation.

You can run the SQL statement in a transaction by specifying the transaction identifier with the `--transaction-id` option. You can start a transaction by using the `aws rds-data begin-transaction` CLI command. You can end and commit a transaction by using the `aws rds-data commit-transaction` CLI command.

> **Important**
>
> If you don't specify the `--transaction-id` option, changes that result from the call are committed automatically.

In addition to the common options, specify the following options:

- `--sql` (required) – A SQL statement to run on the DB cluster.

> **Tip**
>
> For MySQL-compatible statements, don't include a semicolon at the end of the `--sql` parameter. A trailing semicolon might cause a syntax error.

- `--transaction-id` (optional) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to include the SQL statement in.
- `--parameter-set` (optional) – The parameter sets for the batch operation.
- `--database` (optional) – The name of the database.

The DB cluster returns a response to the call.

> **Note**
>
> There isn't a fixed upper limit on the number of parameter sets. However, the maximum size of the HTTP request submitted through Data API is 4 MiB. If the request exceeds this limit, Data API returns an error and doesn't process the request. This 4 MiB limit includes the size of the HTTP headers and the JSON notation in the request. Thus, the number of parameter sets that you can include depends on a combination of factors, such as the size of the SQL statement and the size of each parameter set.
>
> The response size limit is 1 MiB. If the call returns more than 1 MiB of response data, the call is terminated.

For example, the following CLI command runs a batch SQL statement over an array of data with a parameter set.

For Linux, macOS, or Unix:

```
aws rds-data batch-execute-statement --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" \
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret" \
 --sql "insert into mytable values (:id, :val)" \
 --parameter-sets "[[{\"name\": \"id\", \"value\": {\"longValue\": 1}},{\"name\":
 \"val\", \"value\": {\"stringValue\": \"ValueOne\"}}],
```

```
 [{\"name\": \"id\", \"value\": {\"longValue\": 2}},{\"name\": \"val\", \"value\":
 {\"stringValue\": \"ValueTwo\"}}],
 [{\"name\": \"id\", \"value\": {\"longValue\": 3}},{\"name\": \"val\", \"value\":
 {\"stringValue\": \"ValueThree\"}}]]"
```

For Windows:

```
aws rds-data batch-execute-statement --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
 --database "mydb" --secret-arn "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret" ^
 --sql "insert into mytable values (:id, :val)" ^
 --parameter-sets "[[{\"name\": \"id\", \"value\": {\"longValue\": 1}},{\"name\":
 \"val\", \"value\": {\"stringValue\": \"ValueOne\"}}],
 [{\"name\": \"id\", \"value\": {\"longValue\": 2}},{\"name\": \"val\", \"value\":
 {\"stringValue\": \"ValueTwo\"}}],
 [{\"name\": \"id\", \"value\": {\"longValue\": 3}},{\"name\": \"val\", \"value\":
 {\"stringValue\": \"ValueThree\"}}]]"
```

> **Note**
>
> Don't include line breaks in the `--parameter-sets` option.

Committing a SQL transaction

Using the `aws rds-data commit-transaction` CLI command, you can end a SQL transaction that you started with `aws rds-data begin-transaction` and commit the changes.

In addition to the common options, specify the following option:

- `--transaction-id` (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to end and commit.

For example, the following CLI command ends a SQL transaction and commits the changes.

For Linux, macOS, or Unix:

```
aws rds-data commit-transaction --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" \
```

```
 --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" \
 --transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data commit-transaction --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
 --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
 --transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{
     "transactionStatus": "Transaction Committed"
 }
```

Rolling back a SQL transaction

Using the `aws rds-data rollback-transaction` CLI command, you can roll back a SQL transaction that you started with `aws rds-data begin-transaction`. Rolling back a transaction cancels its changes.

> **Important**
>
> If the transaction ID has expired, the transaction was rolled back automatically. In this case, an `aws rds-data rollback-transaction` command that specifies the expired transaction ID returns an error.

In addition to the common options, specify the following option:

- `--transaction-id` (required) – The identifier of a transaction that was started using the `begin-transaction` CLI command. Specify the transaction ID of the transaction that you want to roll back.

For example, the following Amazon CLI command rolls back a SQL transaction.

For Linux, macOS, or Unix:

```
aws rds-data rollback-transaction --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" \
 --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" \
 --transaction-id "ABC1234567890xyz"
```

For Windows:

```
aws rds-data rollback-transaction --resource-arn "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster" ^
 --secret-arn "arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret" ^
 --transaction-id "ABC1234567890xyz"
```

The following is an example of the response.

```
{
     "transactionStatus": "Rollback Complete"
     }
```

Calling the Amazon RDS Data API from a Python application

You can call the Amazon RDS Data API (Data API) from a Python application.

The following examples use the Amazon SDK for Python (Boto). For more information about Boto, see the Amazon SDK for Python (Boto 3) documentation.

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

Topics

- Running a SQL query
- Running a DML SQL statement
- Running a SQL transaction

Running a SQL query

You can run a SELECT statement and fetch the results with a Python application.

The following example runs a SQL query.

```
import boto3

 rdsData = boto3.client('rds-data')

 cluster_arn = 'arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster'
 secret_arn = 'arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret'

 response1 = rdsData.execute_statement(
             resourceArn = cluster_arn,
             secretArn = secret_arn,
             database = 'mydb',
             sql = 'select * from employees limit 3')

 print (response1['records'])
 [
     [
         {
             'longValue': 1
         },
         {
             'stringValue': 'ROSALEZ'
         },
         {
             'stringValue': 'ALEJANDRO'
         },
         {
             'stringValue': '2016-02-15 04:34:33.0'
         }
     ],
     [
         {
             'longValue': 1
         },
         {
             'stringValue': 'DOE'
         },
         {
             'stringValue': 'JANE'
         },
         {
             'stringValue': '2014-05-09 04:34:33.0'
         }
```

```
    ],
    [
        {
            'longValue': 1
        },
        {
            'stringValue': 'STILES'
        },
        {
            'stringValue': 'JOHN'
        },
        {
            'stringValue': '2017-09-20 04:34:33.0'
        }
    ]
]
```

Running a DML SQL statement

You can run a data manipulation language (DML) statement to insert, update, or delete data in your database. You can also use parameters in DML statements.

> **Important**
>
> If a call isn't part of a transaction because it doesn't include the `transactionID` parameter, changes that result from the call are committed automatically.

The following example runs an insert SQL statement and uses parameters.

```
import boto3

 cluster_arn = 'arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster'
 secret_arn = 'arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret'

 rdsData = boto3.client('rds-data')

 param1 = {'name':'firstname', 'value':{'stringValue': 'JACKSON'}}
 param2 = {'name':'lastname', 'value':{'stringValue': 'MATEO'}}
 paramSet = [param1, param2]
```

```
response2 = rdsData.execute_statement(resourceArn=cluster_arn,
                                      secretArn=secret_arn,
                                      database='mydb',
                                      sql='insert into employees(first_name,
last_name) VALUES(:firstname, :lastname)',
                                      parameters = paramSet)

print (response2["numberOfRecordsUpdated"])
```

Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Python application.

> **Important**
>
> A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.
> If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction that inserts a row in a table.

```
import boto3

rdsData = boto3.client('rds-data')

cluster_arn = 'arn:aws-cn:rds:us-east-1:123456789012:cluster:mydbcluster'
secret_arn = 'arn:aws-cn:secretsmanager:us-east-1:123456789012:secret:mysecret'

tr = rdsData.begin_transaction(
     resourceArn = cluster_arn,
     secretArn = secret_arn,
     database = 'mydb')

response3 = rdsData.execute_statement(
     resourceArn = cluster_arn,
     secretArn = secret_arn,
     database = 'mydb',
     sql = 'insert into employees(first_name, last_name) values('XIULAN', 'WANG')',
```

```
      transactionId = tr['transactionId'])

cr = rdsData.commit_transaction(
      resourceArn = cluster_arn,
      secretArn = secret_arn,
      transactionId = tr['transactionId'])

cr['transactionStatus']
'Transaction Committed'

response3['numberOfRecordsUpdated']
1
```

Note

If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call exceeds the RDS Data API timeout interval of 45 seconds, set the `continueAfterTimeout` parameter to `true`.

Calling the Amazon RDS Data API from a Java application

You can call the Amazon RDS Data API (Data API) from a Java application.

The following examples use the Amazon SDK for Java. For more information, see the Amazon SDK for Java Developer Guide.

In each example, replace the DB cluster's Amazon Resource Name (ARN) with the ARN for your Aurora DB cluster. Also, replace the secret ARN with the ARN of the secret in Secrets Manager that allows access to the DB cluster.

Topics

- Running a SQL query
- Running a SQL transaction
- Running a batch SQL operation

Running a SQL query

You can run a SELECT statement and fetch the results with a Java application.

The following example runs a SQL query.

```
package com.amazonaws.rdsdata.examples;

 import com.amazonaws.services.rdsdata.AWSRDSData;
 import com.amazonaws.services.rdsdata.AWSRDSDataClient;
 import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;
 import com.amazonaws.services.rdsdata.model.ExecuteStatementResult;
 import com.amazonaws.services.rdsdata.model.Field;

 import java.util.List;

 public class FetchResultsExample {
   public static final String RESOURCE_ARN = "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster";
   public static final String SECRET_ARN = "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret";

   public static void main(String[] args) {
     AWSRDSData rdsData = AWSRDSDataClient.builder().build();

     ExecuteStatementRequest request = new ExecuteStatementRequest()
             .withResourceArn(RESOURCE_ARN)
             .withSecretArn(SECRET_ARN)
             .withDatabase("mydb")
             .withSql("select * from mytable");

     ExecuteStatementResult result = rdsData.executeStatement(request);

     for (List<Field> fields: result.getRecords()) {
       String stringValue = fields.get(0).getStringValue();
       long numberValue = fields.get(1).getLongValue();

       System.out.println(String.format("Fetched row: string = %s, number = %d",
 stringValue, numberValue));
     }
   }
 }
```

Running a SQL transaction

You can start a SQL transaction, run one or more SQL statements, and then commit the changes with a Java application.

> **Important**
>
> A transaction times out if there are no calls that use its transaction ID in three minutes. If a transaction times out before it's committed, it's rolled back automatically.
> If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a SQL transaction.

```
package com.amazonaws.rdsdata.examples;

 import com.amazonaws.services.rdsdata.AWSRDSData;
 import com.amazonaws.services.rdsdata.AWSRDSDataClient;
 import com.amazonaws.services.rdsdata.model.BeginTransactionRequest;
 import com.amazonaws.services.rdsdata.model.BeginTransactionResult;
 import com.amazonaws.services.rdsdata.model.CommitTransactionRequest;
 import com.amazonaws.services.rdsdata.model.ExecuteStatementRequest;

 public class TransactionExample {
   public static final String RESOURCE_ARN = "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster";
   public static final String SECRET_ARN = "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret";

   public static void main(String[] args) {
     AWSRDSData rdsData = AWSRDSDataClient.builder().build();

     BeginTransactionRequest beginTransactionRequest = new BeginTransactionRequest()
             .withResourceArn(RESOURCE_ARN)
             .withSecretArn(SECRET_ARN)
             .withDatabase("mydb");
     BeginTransactionResult beginTransactionResult =
 rdsData.beginTransaction(beginTransactionRequest);
     String transactionId = beginTransactionResult.getTransactionId();

     ExecuteStatementRequest executeStatementRequest = new ExecuteStatementRequest()
```

```
            .withTransactionId(transactionId)
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withSql("INSERT INTO test_table VALUES ('hello world!')");
    rdsData.executeStatement(executeStatementRequest);

    CommitTransactionRequest commitTransactionRequest = new CommitTransactionRequest()
            .withTransactionId(transactionId)
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN);
    rdsData.commitTransaction(commitTransactionRequest);
  }
}
```

Note

If you run a data definition language (DDL) statement, we recommend continuing to run the statement after the call times out. When a DDL statement terminates before it is finished running, it can result in errors and possibly corrupted data structures. To continue running a statement after a call exceeds the RDS Data API timeout interval of 45 seconds, set the `continueAfterTimeout` parameter to `true`.

Running a batch SQL operation

You can run bulk insert and update operations over an array of data with a Java application. You can run a DML statement with array of parameter sets.

Important

If you don't specify a transaction ID, changes that result from the call are committed automatically.

The following example runs a batch insert operation.

```
package com.amazonaws.rdsdata.examples;

 import com.amazonaws.services.rdsdata.AWSRDSData;
 import com.amazonaws.services.rdsdata.AWSRDSDataClient;
 import com.amazonaws.services.rdsdata.model.BatchExecuteStatementRequest;
```

```
import com.amazonaws.services.rdsdata.model.Field;
import com.amazonaws.services.rdsdata.model.SqlParameter;

import java.util.Arrays;

public class BatchExecuteExample {
  public static final String RESOURCE_ARN = "arn:aws-cn:rds:us-
east-1:123456789012:cluster:mydbcluster";
  public static final String SECRET_ARN = "arn:aws-cn:secretsmanager:us-
east-1:123456789012:secret:mysecret";

  public static void main(String[] args) {
      AWSRDSData rdsData = AWSRDSDataClient.builder().build();

    BatchExecuteStatementRequest request = new BatchExecuteStatementRequest()
            .withDatabase("test")
            .withResourceArn(RESOURCE_ARN)
            .withSecretArn(SECRET_ARN)
            .withSql("INSERT INTO test_table2 VALUES (:string, :number)")
            .withParameterSets(Arrays.asList(
                    Arrays.asList(
                            new SqlParameter().withName("string").withValue(new
Field().withStringValue("Hello")),
                            new SqlParameter().withName("number").withValue(new
Field().withLongValue(1L))
                    ),
                    Arrays.asList(
                            new SqlParameter().withName("string").withValue(new
Field().withStringValue("World")),
                            new SqlParameter().withName("number").withValue(new
Field().withLongValue(2L))
                    )
            ));

    rdsData.batchExecuteStatement(request);
  }
}
```

Controlling Data API timeout behavior

All calls to the Data API are synchronous. Suppose that you perform a Data API operation that runs a SQL statement such as `INSERT` or `CREATE TABLE`. If the Data API call returns successfully, the SQL processing is finished when the call returns.

By default, the Data API cancels an operation and returns a timeout error if the operation doesn't finish processing within 45 seconds. In that case, the data isn't inserted, the table isn't created, and so on.

You can use the Data API to perform long-running operations that can't complete within 45 seconds. If you expect that an operation such as a bulk `INSERT` or a DDL operation on a large table takes longer than 45 seconds, you can specify the `continueAfterTimeout` parameter for the `ExecuteStatement` operation. Your application still receives the timeout error. However, the operation continues running and isn't canceled. For an example, see Running a SQL transaction.

If the Amazon SDK for your programming language has its own timeout period for API calls or HTTP socket connections, make sure that all such timeout periods are more than 45 seconds. For some SDKs, the timeout period is less than 45 seconds by default. We recommend setting any SDK-specific or client-specific timeout periods to at least one minute. Doing so avoids the possibility that your application receives a timeout error while the Data API operation still completes successfully. That way, you can be sure whether to retry the operation or not.

For example, suppose that the SDK returns a timeout error to your application, but the Data API operation still completes within the Data API timeout interval. In that case, retrying the operation might insert duplicate data or otherwise produce incorrect results. The SDK might retry the operation automatically, causing incorrect data without any action from your application.

The timeout interval is especially important for the Java 2 SDK. In that SDK, the API call timeout and the HTTP socket timeout are both 30 seconds by default. Here is an example of setting those timeouts to a higher value:

```
public RdsDataClient createRdsDataClient() {
     return RdsDataClient.builder()
         .region(Region.US_EAST_1) // Change this to your desired Region
         .overrideConfiguration(createOverrideConfiguration())
         .httpClientBuilder(createHttpClientBuilder())
         .credentialsProvider(defaultCredentialsProvider()) // Change this to your
 desired credentials provider
         .build();
 }

 private static ClientOverrideConfiguration createOverrideConfiguration() {
     return ClientOverrideConfiguration.builder()
         .apiCallTimeout(Duration.ofSeconds(60))
         .build();
 }
```

```
 private HttpClientBuilder createHttpClientBuilder() {
     return ApacheHttpClient.builder() // Change this to your desired HttpClient
         .socketTimeout(Duration.ofSeconds(60));
 }
```

Here is an equivalent example using the asynchronous data client:

```
public static RdsDataAsyncClient createRdsDataAsyncClient() {
     return RdsDataAsyncClient.builder()
         .region(Region.US_EAST_1) // Change this to your desired Region
         .overrideConfiguration(createOverrideConfiguration())
         .credentialsProvider(defaultCredentialsProvider())  // Change this to your
 desired credentials provider
         .build();
 }

 private static ClientOverrideConfiguration createOverrideConfiguration() {
     return ClientOverrideConfiguration.builder()
         .apiCallAttemptTimeout(Duration.ofSeconds(60))
         .build();
 }

 private HttpClientBuilder createHttpClientBuilder() {
     return NettyNioAsyncHttpClient.builder() // Change this to your desired
 AsyncHttpClient
         .readTimeout(Duration.ofSeconds(60));
 }
```

Using the Java client library for RDS Data API

You can download and use a Java client library for RDS Data API (Data API). This Java client library provides an alternative way to use Data API. Using this library, you can map your client-side classes to Data API requests and responses. This mapping support can ease integration with some specific Java types, such as `Date`, `Time`, and `BigDecimal`.

Downloading the Java client library for Data API

The Data API Java client library is open source in GitHub at the following location:

https://github.com/awslabs/rds-data-api-client-library-java

You can build the library manually from the source files, but the best practice is to consume the library using Apache Maven dependency management. Add the following dependency to your Maven POM file.

For version 2.x, which is compatible with Amazon SDK 2.x, use the following:

```
<dependency>
    <groupId>software.amazon.rdsdata</groupId>
    <artifactId>rds-data-api-client-library-java</artifactId>
    <version>2.0.0</version>
 </dependency>
```

For version 1.x, which is compatible with Amazon SDK 1.x, use the following:

```
<dependency>
     <groupId>software.amazon.rdsdata</groupId>
     <artifactId>rds-data-api-client-library-java</artifactId>
     <version>1.0.8</version>
 </dependency>
```

Java client library examples

Following, you can find some common examples of using the Data API Java client library. These examples assume that you have a table `accounts` with two columns: `accountId` and `name`. You also have the following data transfer object (DTO).

```
public class Account {
     int accountId;
     String name;
     // getters and setters omitted
 }
```

The client library enables you to pass DTOs as input parameters. The following example shows how customer DTOs are mapped to input parameters sets.

```
var account1 = new Account(1, "John");
```

```
 var account2 = new Account(2, "Mary");
 client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)")
          .withParamSets(account1, account2)
          .execute();
```

In some cases, it's easier to work with simple values as input parameters. You can do so with the following syntax.

```
client.forSql("INSERT INTO accounts(accountId, name) VALUES(:accountId, :name)")
          .withParameter("accountId", 3)
          .withParameter("name", "Zhang")
          .execute();
```

The following is another example that works with simple values as input parameters.

```
 client.forSql("INSERT INTO accounts(accountId, name) VALUES(?, ?)", 4, "Carlos")
          .execute();
```

The client library provides automatic mapping to DTOs when a result is returned. The following examples show how the result is mapped to your DTOs.

```
List<Account> result = client.forSql("SELECT * FROM accounts")
           .execute()
           .mapToList(Account.class);

 Account result = client.forSql("SELECT * FROM accounts WHERE account_id = 1")
           .execute()
           .mapToSingle(Account.class);
```

In many cases, the database result set contains only a single value. In order to simplify retrieving such results, the client library offers the following API:

```
int numberOfAccounts = client.forSql("SELECT COUNT(*) FROM accounts")
           .execute()
           .singleValue(Integer.class);
```

> **Note**
>
> The `mapToList` function converts a SQL result set into a user-defined object list. We don't support using the `.withFormatRecordsAs(RecordsFormatType.JSON)` statement in an `ExecuteStatement` call for the Java client library, because it serves the same purpose. For more information, see Processing Amazon RDS Data API query results in JSON format.

Processing Amazon RDS Data API query results in JSON format

When you call the `ExecuteStatement` operation, you can choose to have the query results returned as a string in JSON format. That way, you can use your programming language's JSON parsing capabilities to interpret and reformat the result set. Doing so can help to avoid writing extra code to loop through the result set and interpret each column value.

To request the result set in JSON format, you pass the optional `formatRecordsAs` parameter with a value of `JSON`. The JSON-formatted result set is returned in the `formattedRecords` field of the `ExecuteStatementResponse` structure.

The `BatchExecuteStatement` action doesn't return a result set. Thus, the JSON option doesn't apply to that action.

To customize the keys in the JSON hash structure, define column aliases in the result set. You can do so by using the AS clause in the column list of your SQL query.

You might use the JSON capability to make the result set easier to read and map its contents to language-specific frameworks. Because the volume of the ASCII-encoded result set is larger than the default representation, you might choose the default representation for queries that return large numbers of rows or large column values that consume more memory than is available to your application.

Topics

- Retrieving query results in JSON format
- Data Type Mapping
- Troubleshooting
- Examples

Retrieving query results in JSON format

To receive the result set as a JSON string, include `.withFormatRecordsAs(RecordsFormatType.JSON)` in the `ExecuteStatement` call. The return value comes back as a JSON string in the `formattedRecords` field. In this case, the `columnMetadata` is `null`. The column labels are the keys of the object that represents each row. These column names are repeated for each row in the result set. The column values are quoted strings, numeric values, or special values representing `true`, `false`, or `null`. Column metadata such as length constraints and the precise type for numbers and strings isn't preserved in the JSON response.

If you omit the `.withFormatRecordsAs()` call or specify a parameter of `NONE`, the result set is returned in binary format using the `Records` and `columnMetadata` fields.

Data Type Mapping

The SQL values in the result set are mapped to a smaller set of JSON types. The values are represented in JSON as strings, numbers, and some special constants such as `true`, `false`, and `null`. You can convert these values into variables in your application, using strong or weak typing as appropriate for your programming language.

JDBC data type	JSON data type
`INTEGER`, `TINYINT`, `SMALLINT`, `BIGINT`	Number by default. String if the `LongReturnType` option is set to `STRING`.
`FLOAT`, `REAL`, `DOUBLE`	Number
`DECIMAL`	String by default. Number if the `DecimalReturnType` option is set to `DOUBLE_OR_LONG`.
`STRING`	String
`BOOLEAN`, `BIT`	Boolean
`BLOB`, `BINARY`, `VARBINARY`, `LONGVARBINARY`	String in base64 encoding.

JDBC data type	JSON data type
CLOB	String
ARRAY	Array
NULL	null
Other types (including types related to date and time)	String

Troubleshooting

The JSON response is limited to 10 megabytes. If the response is larger than this limit, your program receives a `BadRequestException` error. In this case, you can resolve the error using one of the following techniques:

- Reduce the number of rows in the result set. To do so, add a `LIMIT` clause. You might split a large result set into multiple smaller ones by submitting several queries with `LIMIT` and `OFFSET` clauses.

  If the result set includes rows that are filtered out by application logic, you can remove those rows from the result set by adding more conditions in the `WHERE` clause.
- Reduce the number of columns in the result set. To do so, remove items from the select list of the query.
- Shorten the column labels by using column aliases in the query. Each column name is repeated in the JSON string for each row in the result set. Thus, a query result with long column names and many rows could exceed the size limit. In particular, use column aliases for complicated expressions to avoid having the entire expression repeated in the JSON string.
- Although with SQL you can use column aliases to produce a result set having more than one column with the same name, duplicate key names aren't allowed in JSON. The RDS Data API returns an error if you request the result set in JSON format and more than one column has the same name. Thus, make sure that all the column labels have unique names.

Examples

The following Java examples show how to call `ExecuteStatement` with the response as a JSON-formatted string, then interpret the result set. Substitute the appropriate values for the *`databaseName`*, *`secretStoreArn`*, and *`clusterArn`* parameters.

The following Java example demonstrates a query that returns a decimal numeric value in the result set. The `assertThat` calls test that the fields of the response have the expected properties based on the rules for JSON result sets.

This example works with the following schema and sample data:

```
create table test_simplified_json (a float);
insert into test_simplified_json values(10.0);
```

```
public void JSON_result_set_demo() {
    var sql = "select * from test_simplified_json";
    var request = new ExecuteStatementRequest()
      .withDatabase(databaseName)
      .withSecretArn(secretStoreArn)
      .withResourceArn(clusterArn)
      .withSql(sql)
      .withFormatRecordsAs(RecordsFormatType.JSON);
    var result = rdsdataClient.executeStatement(request);
}
```

The value of the `formattedRecords` field from the preceding program is:

```
[{"a":10.0}]
```

The `Records` and `ColumnMetadata` fields in the response are both null, due to the presence of the JSON result set.

The following Java example demonstrates a query that returns an integer numeric value in the result set. The example calls `getFormattedRecords` to return only the JSON-formatted string and ignore the other response fields that are blank or null. The example deserializes the result into a structure representing a list of records. Each record has fields whose names correspond to the column aliases from the result set. This technique simplifies the code that parses the result set. Your application doesn't have to loop through the rows and columns of the result set and convert each value to the appropriate type.

This example works with the following schema and sample data:

```
create table test_simplified_json (a int);
insert into test_simplified_json values(17);
```

```
public void JSON_deserialization_demo() {
    var sql = "select * from test_simplified_json";
    var request = new ExecuteStatementRequest()
      .withDatabase(databaseName)
      .withSecretArn(secretStoreArn)
      .withResourceArn(clusterArn)
      .withSql(sql)
      .withFormatRecordsAs(RecordsFormatType.JSON);
    var result = rdsdataClient.executeStatement(request)
      .getFormattedRecords();

/* Turn the result set into a Java object, a list of records.
   Each record has a field 'a' corresponding to the column
   labelled 'a' in the result set. */
    private static class Record { public int a; }
    var recordsList = new ObjectMapper().readValue(
        response, new TypeReference<List<Record>>() {
        });
}
```

The value of the `formattedRecords` field from the preceding program is:

```
[{"a":17}]
```

To retrieve the a column of result row 0, the application would refer to `recordsList.get(0).a`.

In contrast, the following Java example shows the kind of code that's required to construct a data structure holding the result set when you don't use the JSON format. In this case, each row of the result set contains fields with information about a single user. Building a data structure to represent the result set requires looping through the rows. For each row, the code retrieves the value of each field, performs an appropriate type conversion, and assigns the result to the corresponding field in the object representing the row. Then the code adds the object representing each user to the data structure representing the entire result set. If the query was changed to reorder, add, or remove fields in the result set, the application code would have to change also.

```
/* Verbose result-parsing code that doesn't use the JSON result set format */
```

```
for (var row: response.getRecords()) {
    var user = User.builder()
      .userId(row.get(0).getLongValue())
      .firstName(row.get(1).getStringValue())
      .lastName(row.get(2).getStringValue())
      .dob(Instant.parse(row.get(3).getStringValue()))
      .build();
    result.add(user);
  }
```

The following sample values show the values of the `formattedRecords` field for result sets with different numbers of columns, column aliases, and column data types.

If the result set includes multiple rows, each row is represented as an object that is an array element. Each column in the result set becomes a key in the object. The keys are repeated for each row in the result set. Thus, for result sets consisting of many rows and columns, you might need to define short column aliases to avoid exceeding the length limit for the entire response.

This example works with the following schema and sample data:

```
create table sample_names (id int, name varchar(128));
insert into sample_names values (0, "Jane"), (1, "Mohan"), (2, "Maria"), (3, "Bruce"),
 (4, "Jasmine");
```

```
[{"id":0,"name":"Jane"},{"id":1,"name":"Mohan"},
{"id":2,"name":"Maria"},{"id":3,"name":"Bruce"},{"id":4,"name":"Jasmine"}]
```

If a column in the result set is defined as an expression, the text of the expression becomes the JSON key. Thus, it's typically convenient to define a descriptive column alias for each expression in the select list of the query. For example, the following query includes expressions such as function calls and arithmetic operations in its select list.

```
select count(*), max(id), 4+7 from sample_names;
```

Those expressions are passed through to the JSON result set as keys.

```
[{"count(*)":5,"max(id)":4,"4+7":11}]
```

Adding AS columns with descriptive labels makes the keys simpler to interpret in the JSON result set.

```
select count(*) as rows, max(id) as largest_id, 4+7 as addition_result from
 sample_names;
```

With the revised SQL query, the column labels defined by the AS clauses are used as the key names.

```
[{"rows":5,"largest_id":4,"addition_result":11}]
```

The value for each key-value pair in the JSON string can be a quoted string. The string might contain unicode characters. If the string contains escape sequences or the " or \ characters, those characters are preceded by backslash escape characters. The following examples of JSON strings demonstrate these possibilities. For example, the `string_with_escape_sequences` result contains the special characters backspace, newline, carriage return, tab, form feed, and \.

```
[{"quoted_string":"hello"}]
[{"unicode_string":"####"}]
[{"string_with_escape_sequences":"\b \n \r \t \f \\ '"}]
```

The value for each key-value pair in the JSON string can also represent a number. The number might be an integer, a floating-point value, a negative value, or a value represented as exponential notation. The following examples of JSON strings demonstrate these possibilities.

```
[{"integer_value":17}]
[{"float_value":10.0}]
[{"negative_value":-9223372036854775808,"positive_value":9223372036854775807}]
[{"very_small_floating_point_value":4.9E-324,"very_large_floating_point_value":1.79769313486231
```

Boolean and null values are represented with the unquoted special keywords `true`, `false`, and `null`. The following examples of JSON strings demonstrate these possibilities.

```
[{"boolean_value_1":true,"boolean_value_2":false}]
[{"unknown_value":null}]
```

If you select a value of a BLOB type, the result is represented in the JSON string as a base64-encoded value. To convert the value back to its original representation, you can use the appropriate decoding function in your application's language. For example, in Java you call the function `Base64.getDecoder().decode()`. The following sample output shows the result of selecting a BLOB value of `hello world` and returning the result set as a JSON string.

```
[{"blob_column":"aGVsbG8gd29ybGQ="}]
```

The following Python example shows how to access the values from the result of a call to the Python `execute_statement` function. The result set is a string value in the field `response['formattedRecords']`. The code turns the JSON string into a data structure by calling the `json.loads` function. Then each row of the result set is a list element within the data structure, and within each row you can refer to each field of the result set by name.

```
import json

result = json.loads(response['formattedRecords'])
print (result[0]["id"])
```

The following JavaScript example shows how to access the values from the result of a call to the JavaScript `executeStatement` function. The result set is a string value in the field `response.formattedRecords`. The code turns the JSON string into a data structure by calling the `JSON.parse` function. Then each row of the result set is an array element within the data structure, and within each row you can refer to each field of the result set by name.

```
<script>
    const result = JSON.parse(response.formattedRecords);
    document.getElementById("display").innerHTML = result[0].id;
</script>
```

Troubleshooting Amazon RDS Data API

Use the following sections, titled with common error messages, to help troubleshoot problems that you have with the Amazon RDS Data API (Data API).

Topics

- Transaction <transaction_ID> isn't found
- Packet for query is too large
- Database response exceeded size limit
- HttpEndpoint isn't enabled for cluster <cluster_ID>
- DatabaseErrorException: Transaction is still running a query

- Unsupported result exception
- Multi-statements aren't supported
- Schema parameter isn't supported
- IPv6 connectivity issues

Transaction <transaction_ID> isn't found

In this case, the transaction ID specified in a Data API call wasn't found. The cause for this issue is appended to the error message, and is one of the following:

- Transaction may be expired.

  Make sure that each transactional call runs within three minutes of the previous one.

  It's also possible that the specified transaction ID wasn't created by a BeginTransaction call. Make sure that your call has a valid transaction ID.
- One previous call resulted in a termination of your transaction.

  The transaction was already ended by your `CommitTransaction` or `RollbackTransaction` call.
- Transaction has been aborted due to an error from a previous call.

  Check whether your previous calls have thrown any exceptions.

For information about running transactions, see Calling the Amazon RDS Data API.

Packet for query is too large

In this case, the result set returned for a row was too large. The Data API size limit is 64 KB per row in the result set returned by the database.

To solve this issue, make sure that each row in a result set is 64 KB or less.

Database response exceeded size limit

In this case, the size of the result set returned by the database was too large. The Data API limit is 1 MiB in the result set returned by the database.

To solve this issue, make sure that calls to Data API return 1 MiB of data or less. If you need to return more than 1 MiB, you can use multiple `ExecuteStatement` calls with the `LIMIT` clause in your query.

For more information about the `LIMIT` clause, see SELECT syntax in the MySQL documentation.

HttpEndpoint isn't enabled for cluster <cluster_ID>

Check the following potential causes for this issue:

- The Aurora DB cluster doesn't support Data API. For information about the types of DB clusters RDS Data API supports, see the section called “Region and version availability for the Amazon RDS Data API”.
- Data API isn't enabled for the Aurora DB cluster. To use Data API with an Aurora DB cluster, Data API must be enabled for the DB cluster. For information about enabling Data API, see Enabling the Amazon RDS Data API.
- The DB cluster was renamed after Data API was enabled for it. In that case, turn off Data API for that cluster and then enable it again.
- The ARN you specified doesn't precisely match the ARN of the cluster. Check that the ARN returned from another source or constructed by program logic matches the ARN of the cluster exactly. For example, make sure that the ARN you use has the correct letter case for all alphabetic characters.

DatabaseErrorException: Transaction is still running a query

If your application sends a request with a transaction ID and that transaction is currently processing another request, Data API returns this error to your application immediately. This condition might arise if your application makes asynchronous requests, using a mechanism such as "promises" in Javascript.

To solve this issue, wait until the previous request finishes and then retry the request. You can keep retrying until the error no longer occurs, or the application receives some different kind of error.

This condition can happen with Data API for Aurora serverless and provisioned instances.

Unsupported result exception

The Data API doesn't support all data types. This error occurs when you execute a query that returns an unsupported data type.

To work around this issue, cast the unsupported data type to TEXT. For example:

```
SELECT custom_type::TEXT FROM my_table;
 -- OR
 SELECT CAST(custom_type AS TEXT) FROM my_table;
```

Multi-statements aren't supported

Multi-statements are not supported in the Data API for Aurora serverless and provisioned clusters. Attempting to execute multiple statements in a single API call results in this error.

To execute multiple statements, use separate `ExecuteStatement` API calls or use the `BatchExecuteStatement` API for batch processing.

Schema parameter isn't supported

Aurora serverless and provisioned clusters explicitly reject API calls that include the schema parameter.

To solve this issue, remove the schema parameter from all calls to the Data API when you use Aurora serverless or provisioned clusters.

IPv6 connectivity issues

If you experience issues when connecting to Data API using IPv6 endpoints, check the following potential causes:

- **Network doesn't support IPv6**: Verify that your network infrastructure supports IPv6 and that IPv6 routing is configured correctly.
- **DNS resolution issues**: Ensure that your DNS resolver can resolve AAAA records for the dual-stack endpoints (for example, `rds-data.us-east-1.api.aws`).
- **Security group configuration**: Update security group rules to allow IPv6 traffic on port 443 (HTTPS). Add rules for IPv6 CIDR blocks (for example, `::/0` for all IPv6 addresses).
- **Network ACL configuration**: Ensure that network ACLs allow IPv6 traffic on the required ports.
- **Client library compatibility**: Verify that your HTTP client libraries and Amazon SDKs support IPv6 and dual-stack connectivity.
- **VPC endpoint configuration**: If using PrivateLink, ensure that your VPC endpoint is configured to support IPv6 and that the associated subnets have IPv6 CIDR blocks assigned.

To troubleshoot IPv6 connectivity issues:

1. Test connectivity using the IPv4-only endpoints (`.amazonaws.com`) to verify that the issue is specific to IPv6.
2. Use network diagnostic tools to verify IPv6 connectivity to the dual-stack endpoints.
3. Check CloudTrail logs for any authentication or authorization errors when using IPv6 endpoints.
4. Verify that your application is correctly configured to use the new dual-stack endpoint URLs.

Logging Amazon RDS Data API calls with Amazon CloudTrail

RDS Data API (Data API) is integrated with Amazon CloudTrail, a service that provides a record of actions taken by a user, role, or an Amazon service in Data API. CloudTrail captures all API calls for Data API as events, including calls from the Amazon RDS console and from code calls to Data API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Data API. Using the data collected by CloudTrail, you can determine a lot of information. This information includes the request that was made to Data API, the IP address the request was made from, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the Amazon CloudTrail User Guide.

Working with Data API information in CloudTrail

CloudTrail is enabled on your Amazon account when you create the account. When supported activity (management events) occurs in Data API, that activity is recorded in a CloudTrail event along with other Amazon service events in **Event history**. You can view, search, and download recent management events in your Amazon account. For more information, see Working with CloudTrail Event history in the *Amazon CloudTrail User Guide.*

For an ongoing record of events in your Amazon account, including events for Data API, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all Amazon Regions. The trail logs events from all Amazon Regions in the Amazon partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other Amazon services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in the *Amazon CloudTrail User Guide*:

- Overview for creating a trail

- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

All Data API operations are logged by CloudTrail and documented in the *Amazon RDS data service API reference*. For example, calls to the `BatchExecuteStatement`, `BeginTransaction`, `CommitTransaction`, and `ExecuteStatement` operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another Amazon service.

For more information, see the CloudTrail userIdentity element.

Including and excluding Data API events from an Amazon CloudTrail trail

Most Data API users rely on the events in an Amazon CloudTrail trail to provide a record of Data API operations. Event data doesn't reveal the database name, schema name, or SQL statements in requests to the Data API. However, knowing which user made a type of call against a specific DB cluster at a given time can help to detect anomalous access patterns.

Including Data API events in an Amazon CloudTrail trail

For Aurora MySQL and Aurora PostgreSQL Aurora serverless and provisioned databases, the following Data API operations are logged to Amazon CloudTrail as *data events*. Data events are high-volume data-plane API operations that CloudTrail doesn't log by default. Additional charges apply for data events. For information about CloudTrail pricing, see Amazon CloudTrail Pricing.

- BatchExecuteStatement
- BeginTransaction
- CommitTransaction

- ExecuteStatement
- RollbackTransaction

You can use the CloudTrail console,Amazon CLI, or CloudTrail API operations to log these Data API operations. In the CloudTrail console, choose **RDS Data API - DB Cluster** for the Data event type. For more information, see Logging data events with the Amazon Web Services Management Console in the *Amazon CloudTrail User Guide*.

Using the Amazon CLI, run the `aws cloudtrail put-event-selectors` command to log these Data API operations for your trail. To log all Data API events on DB clusters, specify `AWS::RDS::DBCluster` for the resource type. The following example logs all Data API events on DB clusters. For more information, see Logging data events with the Amazon Command Line Interface in the *Amazon CloudTrail User Guide*.

```
aws cloudtrail put-event-selectors --trail-name trail_name --advanced-event-selectors \
'{
   "Name": "RDS Data API Selector",
   "FieldSelectors": [
      {
         "Field": "eventCategory",
         "Equals": [
            "Data"
         ]
      },
      {
         "Field": "resources.type",
         "Equals": [
            "AWS::RDS::DBCluster"
         ]
      }
   ]
}'
```

You can configure advanced event selectors to additionally filter on the `readOnly`, `eventName`, and `resources.ARN` fields. For more information on these fields, see AdvancedFieldSelector.

Understanding Data API log file entries

A *trail* is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An *event* represents a single

request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

Aurora MySQL and Aurora PostgreSQL Aurora serverless and provisioned

The following example shows a CloudTrail log entry that demonstrates the `ExecuteStatement` operation for Aurora PostgreSQL Aurora serverless and provisioned databases. For these databases, all Data API events are data events where the event source is **rdsdataapi.amazonaws.com** and the event type is **Rds Data Service**.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AKIAIOSFODNN7EXAMPLE",
        "arn": "arn:aws-cn:iam::123456789012:user/johndoe",
        "accountId": "123456789012",
        "accessKeyId": "AKIAI44QH8DHBEXAMPLE",
        "userName": "johndoe"
    },
    "eventTime": "2019-12-18T00:49:34Z",
    "eventSource": "rdsdataapi.amazonaws.com",
    "eventName": "ExecuteStatement",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "192.0.2.0",

Monitoring RDS Data API queries with Performance Insights

If your Aurora cluster is running Aurora serverless or provisioned instances, you can use Performance Insights with RDS Data API.

For more information about how to use Performance Insights with Aurora, see Monitoring DB load with Amazon CloudWatch Database Insights on Amazon Aurora.

How RDS Data API queries are represented in Performance Insights

With Data API, your Aurora cluster processes queries based on Data API calls that you submit from your application. Data API also performs some SQL statements as part of its own internal workings, such as canceling queries that exceed the timeout threshold. Both kinds of SQL operations are shown in Performance Insights statistics and charts.

- For Data API queries that you submit to an Aurora cluster, the **Host** field in the PI dashboard is marked as **RDS Data API**. For Aurora PostgreSQL, the **application_name** field has the value `rds-data-api`. Look for these labels when you analyze database load using **Top hosts** or **Top Applications** as a dimension.
- All internal queries that Data API runs to manage database aspects such as the connection pool and query timeouts are annotated with a prefix **RDS Data API**. Example: `/* RDS Data API */ select * from my_table;` Looks for these prefixes when you analyze database load by **Top SQL** as a dimension. statements are annotated with a SQL comment of `/* RDS Data API */`.

Using the Aurora query editor

The Aurora query editor lets you run SQL statements on your Aurora DB cluster through the Amazon Web Services Management Console. You can run SQL queries, data manipulation (DML) statements, and data definition (DDL) statements. Using the console interface lets you perform database maintenance, produce reports, and conduct SQL experiments. You can avoid setting up the network configuration to connect to your DB cluster from a separate client system such as an EC2 instance or a laptop computer.

The query editor requires an Aurora DB cluster with RDS Data API (Data API) enabled. For information about DB clusters that support Data API and how to enable it, see Using the Amazon RDS Data API. The SQL that you can run is subject to the Data API limitations. For more information, see the section called "Limitations".

Availability of the query editor

The query editor is available for Aurora DB clusters using Aurora MySQL and Aurora PostgreSQL engine versions that support Data API, and in the Amazon Web Services Regions where Data API is available. For more information, see Supported Regions and Aurora DB engines for RDS Data API.

Authorizing access to the query editor

A user must be authorized to run queries in the query editor. You can authorize a user to run queries in the query editor by adding the `AmazonRDSDataFullAccess` policy, a predefined Amazon Identity and Access Management (IAM) policy, to that user.

> **Note**
>
> Make sure to use the same user name and password when you create the IAM user as you did for the database user, such as the administrative user name and password. For more information, see Creating an IAM user in your Amazon Web Services account in the *Amazon Identity and Access Management User Guide*.

You can also create an IAM policy that grants access to the query editor. After you create the policy, add it to each user that requires access to the query editor.

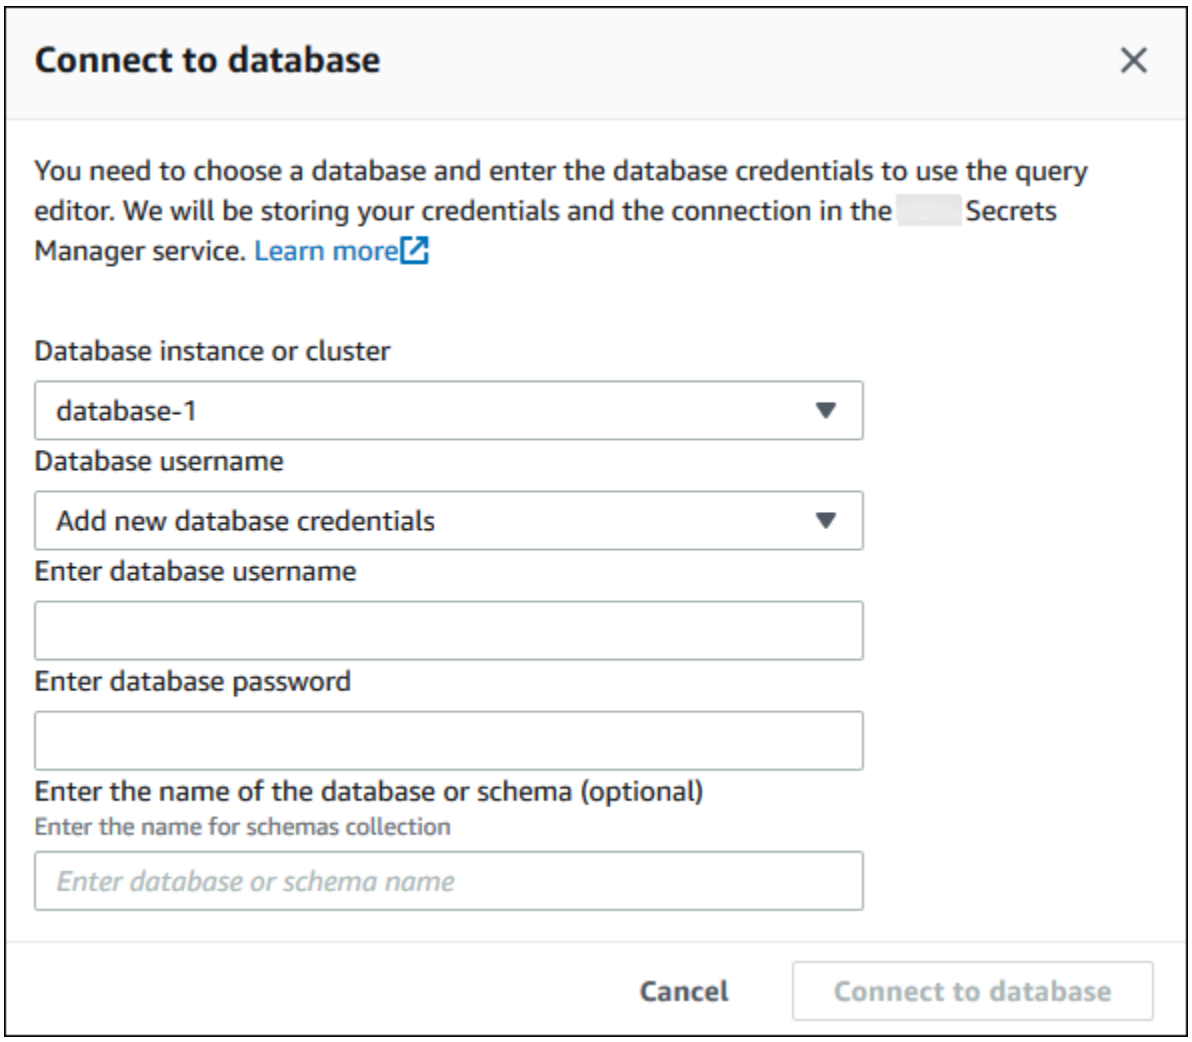
The following policy provides the minimum required permissions for a user to access the query editor.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "QueryEditor0",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue",
                "secretsmanager:PutResourcePolicy",
                "secretsmanager:PutSecretValue",
                "secretsmanager:DeleteSecret",
                "secretsmanager:DescribeSecret",
                "secretsmanager:TagResource"
            ],
            "Resource": "arn:aws-cn:secretsmanager:*:*:secret:rds-db-credentials/
*"
        },
        {
            "Sid": "QueryEditor1",
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetRandomPassword",
                "tag:GetResources",
                "secretsmanager:CreateSecret",
                "secretsmanager:ListSecrets",
                "dbqms:CreateFavoriteQuery",
                "dbqms:DescribeFavoriteQueries",
                "dbqms:UpdateFavoriteQuery",
                "dbqms:DeleteFavoriteQueries",
                "dbqms:GetQueryString",
                "dbqms:CreateQueryHistory",
                "dbqms:UpdateQueryHistory",
                "dbqms:DeleteQueryHistory",
                "dbqms:DescribeQueryHistory",
                "rds-data:BatchExecuteStatement",
                "rds-data:BeginTransaction",
                "rds-data:CommitTransaction",
```

```
                "rds-data:ExecuteStatement",
                "rds-data:RollbackTransaction"
            ],
            "Resource": "*"
        }
    ]
}
```

For information about creating an IAM policy, see Creating IAM policies in the *Amazon Identity and Access Management User Guide*.



For information about adding an IAM policy to a user, see Adding and removing IAM identity permissions in the *Amazon Identity and Access Management User Guide*.

Running queries in the query editor

You can run SQL statements on an Aurora DB cluster in the query editor. The SQL that you can run is subject to the Data API limitations. For more information, see the section called “Limitations”.

To run a query in the query editor

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the Amazon Web Services Management Console, choose the Amazon Web Services Region in which you created the Aurora DB clusters that you want to query.
3. In the navigation pane, choose **Databases**.
4. Choose the Aurora DB cluster that you want to run SQL queries on.
5. For **Actions**, choose **Query**. If you haven't connected to the database before, the **Connect to database** page opens.

6. Enter the following information:

   a. For **Database instance or cluster**, choose the Aurora DB cluster that you want to run SQL queries on.

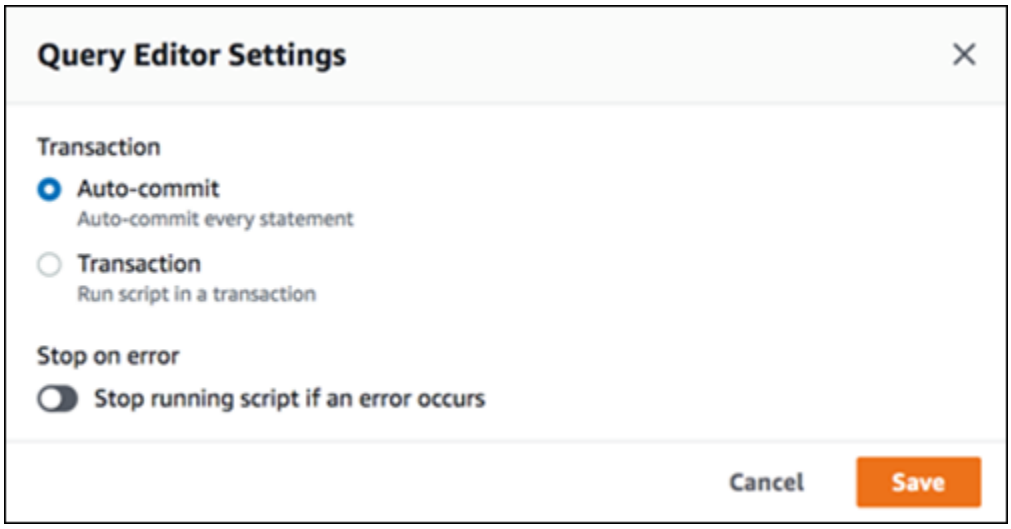
   b. For **Database username**, choose the user name of the database user to connect with, or choose **Add new database credentials**. If you choose **Add new database credentials**, enter the user name for the new database credentials in **Enter database username**.

   c. For **Enter database password**, enter the password for the database user that you chose.

   d. In the last box, enter the name of the database or schema that you want to use for the Aurora DB cluster.

   e. Choose **Connect to database**.

> **Note**
>
> If your connection is successful, your connection and authentication information are stored in Amazon Secrets Manager. You don't need to enter the connection information again.



7. In the query editor, enter the SQL query that you want to run on the database.

Each SQL statement can commit automatically, or you can run SQL statements in a script as part of a transaction. To control this behavior, choose the gear icon above the query window.

The **Query Editor Settings** window appears.

If you choose **Auto-commit**, every SQL statement commits automatically. If you choose **Transaction**, you can run a group of statements in a script. Statements are automatically committed at the end of the script unless explicitly committed or rolled back before then. Also, you can choose to stop a running script if an error occurs by enabling **Stop on error**.

> **Note**
>
> In a group of statements, data definition language (DDL) statements can cause previous data manipulation language (DML) statements to commit. You can also include `COMMIT` and `ROLLBACK` statements in a group of statements in a script.

After you make your choices in the **Query Editor Settings** window, choose **Save**.

8. Choose **Run** or press Ctrl+Enter, and the query editor displays the results of your query.

   After running the query, save it to **Saved queries** by choosing **Save**.

   Export the query results to spreadsheet format by choosing **Export to csv**.

You can find, edit, and rerun previous queries. To do so, choose the **Recent** tab or the **Saved queries** tab, choose the query text, and then choose **Run**.

To change the database, choose **Change database**.

Database Query Metadata Service (DBQMS) API reference

The Database Query Metadata Service (dbqms) is an internal-only service. It provides your recent and saved queries for the query editor on the Amazon Web Services Management Console for multiple Amazon services, including Amazon RDS.

Supported DBQMS actions

- CreateFavoriteQuery
- CreateQueryHistory
- CreateTab
- DeleteFavoriteQueries
- DeleteQueryHistory
- DeleteTab
- DescribeFavoriteQueries
- DescribeQueryHistory
- DescribeTabs

- GetQueryString
- UpdateFavoriteQuery
- UpdateQueryHistory
- UpdateTab

CreateFavoriteQuery

Save a new favorite query. Each user can create up to 1000 saved queries. This limit is subject to change in the future.

CreateQueryHistory

Save a new query history entry.

CreateTab

Save a new query tab. Each user can create up to 10 query tabs.

DeleteFavoriteQueries

Delete one or more saved queries.

DeleteQueryHistory

Delete query history entries.

DeleteTab

Delete query tab entries.

DescribeFavoriteQueries

List saved queries created by a user in a given account.

DescribeQueryHistory

List query history entries.

DescribeTabs

List query tabs created by a user in a given account.

GetQueryString

Retrieve full query text from a query ID.

UpdateFavoriteQuery

Update the query string, description, name, or expiration date.

UpdateQueryHistory

Update the status of query history.

UpdateTab

Update the query tab name and query string.

Using Amazon Aurora machine learning

By using Amazon Aurora machine learning, you can integrate your Aurora DB cluster with the following Amazon machine learning service.

SageMaker AI

Amazon SageMaker AI is a fully managed machine learning service. Data scientists and developers use Amazon SageMaker AI to build, train, and test machine learning models for a variety of inference tasks, such as fraud detection and product recommendation. When a machine learning model is ready for use in production, it can be deployed to the Amazon SageMaker AI hosted environment. For more information, see What Is Amazon SageMaker AI? in the *Amazon SageMaker AI Developer Guide*.

Requirements for using Aurora machine learning with Aurora MySQL

Amazon machine learning services are managed services that are set up and run in their own production environments. Aurora machine learning supports integration with Amazon Bedrock, Amazon Comprehend, and SageMaker AI. Before trying to set up your Aurora MySQL DB cluster to use Aurora machine learning, be sure you understand the following requirements and prerequisites.

- The machine learning services must be running in the same Amazon Web Services Region as your Aurora MySQL DB cluster. You can't use machine learning services from an Aurora MySQL DB cluster in a different Region.
- If your Aurora MySQL DB cluster is in a different virtual public cloud (VPC) from your Amazon Bedrock, Amazon Comprehend, or SageMaker AI service, the VPC's Security group needs to allow outbound connections to the target Aurora machine learning service. For more information, see Control traffic to your Amazon resources using security groups in the *Amazon VPC User Guide*.
- You can upgrade an Aurora cluster that's running a lower version of Aurora MySQL to a supported higher version if you want to use Aurora machine learning with that cluster. For more information, see Database engine updates for Amazon Aurora MySQL.
- Your Aurora MySQL DB cluster must use a custom DB cluster parameter group. At the end of the setup process for each Aurora machine learning service that you want to use, you add the

Amazon Resource Name (ARN) of the associated IAM role that was created for the service. We recommend that you create a custom DB cluster parameter group for your Aurora MySQL in advance and configure your Aurora MySQL DB cluster to use it so that it's ready for you to modify at the end of the setup process.

- For SageMaker AI:
  - The machine learning components that you want to use for inferences must be set up and ready to use. During the configuration process for your Aurora MySQL DB cluster, make sure to have the ARN of the SageMaker AI endpoint available. The data scientists on your team are likely best able to handle working with SageMaker AI to prepare the models and handle the other such tasks. To get started with Amazon SageMaker AI, see Get Started with Amazon SageMaker AI. For more information about inferences and endpoints, see Real-time inference.
  - To use SageMaker AI with your own training data, you must set up an Amazon S3 bucket as part of your Aurora MySQL configuration for Aurora machine learning. To do so, you follow the same general process as for setting up the SageMaker AI integration. For a summary of this optional setup process, see Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker AI (Optional).
- For Aurora global databases, you set up the Aurora machine learning services that you want to use in all Amazon Web Services Regions that make up your Aurora global database. For example, if you want to use Aurora machine learning with SageMaker AI for your Aurora global database, you do the following for every Aurora MySQL DB cluster in every Amazon Web Services Region:
  - Set up the Amazon SageMaker AI services with the same SageMaker AI training models and endpoints. These must also use the same names.
  - Create the IAM roles as detailed in Setting up your Aurora MySQL DB cluster to use Aurora machine learning.
  - Add the ARN of the IAM role to the custom DB cluster parameter group for each Aurora MySQL DB cluster in every Amazon Web Services Region.

  These tasks require that Aurora machine learning is available for your version of Aurora MySQL in all Amazon Web Services Regions that make up your Aurora global database.

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across Amazon Web Services Regions.

- For information on version and Region availability for Amazon Comprehend and Amazon SageMaker AI with Aurora MySQL, see Aurora machine learning with Aurora MySQL.
- Amazon Bedrock is supported only on Aurora MySQL version 3.06 and higher.

  For information on Region availability for Amazon Bedrock, see Model support by Amazon Web Services Region in the *Amazon Bedrock User Guide*.

Supported features and limitations of Aurora machine learning with Aurora MySQL

When using Aurora MySQL with Aurora machine learning, the following limitations apply:

- The Aurora machine learning extension doesn't support vector interfaces.
- Aurora machine learning integrations aren't supported when used in a trigger.
- Aurora machine learning functions aren't compatible with binary logging (binlog) replication.
  - The setting `--binlog-format=STATEMENT` throws an exception for calls to Aurora machine learning functions.
  - Aurora machine learning functions are nondeterministic, and nondeterministic stored functions aren't compatible with the binlog format.

  For more information, see Binary Logging Formats in the MySQL documentation.
- Stored functions that call tables with generated-always columns aren't supported. This applies to any Aurora MySQL stored function. To learn more about this column type, see CREATE TABLE and Generated Columns in the MySQL documentation.
- Amazon Bedrock functions don't support `RETURNS JSON`. You can use `CONVERT` or `CAST` to convert from `TEXT` to `JSON` if needed.
- Amazon Bedrock doesn't support batch requests.
- Aurora MySQL supports any SageMaker AI endpoint that reads and writes the comma-separated value (CSV) format, through a `ContentType` of `text/csv`. This format is accepted by the following built-in SageMaker AI algorithms:
  - Linear Learner
  - Random Cut Forest
  - XGBoost

To learn more about these algorithms, see Choose an Algorithm in the *Amazon SageMaker AI Developer Guide*.

Setting up your Aurora MySQL DB cluster to use Aurora machine learning

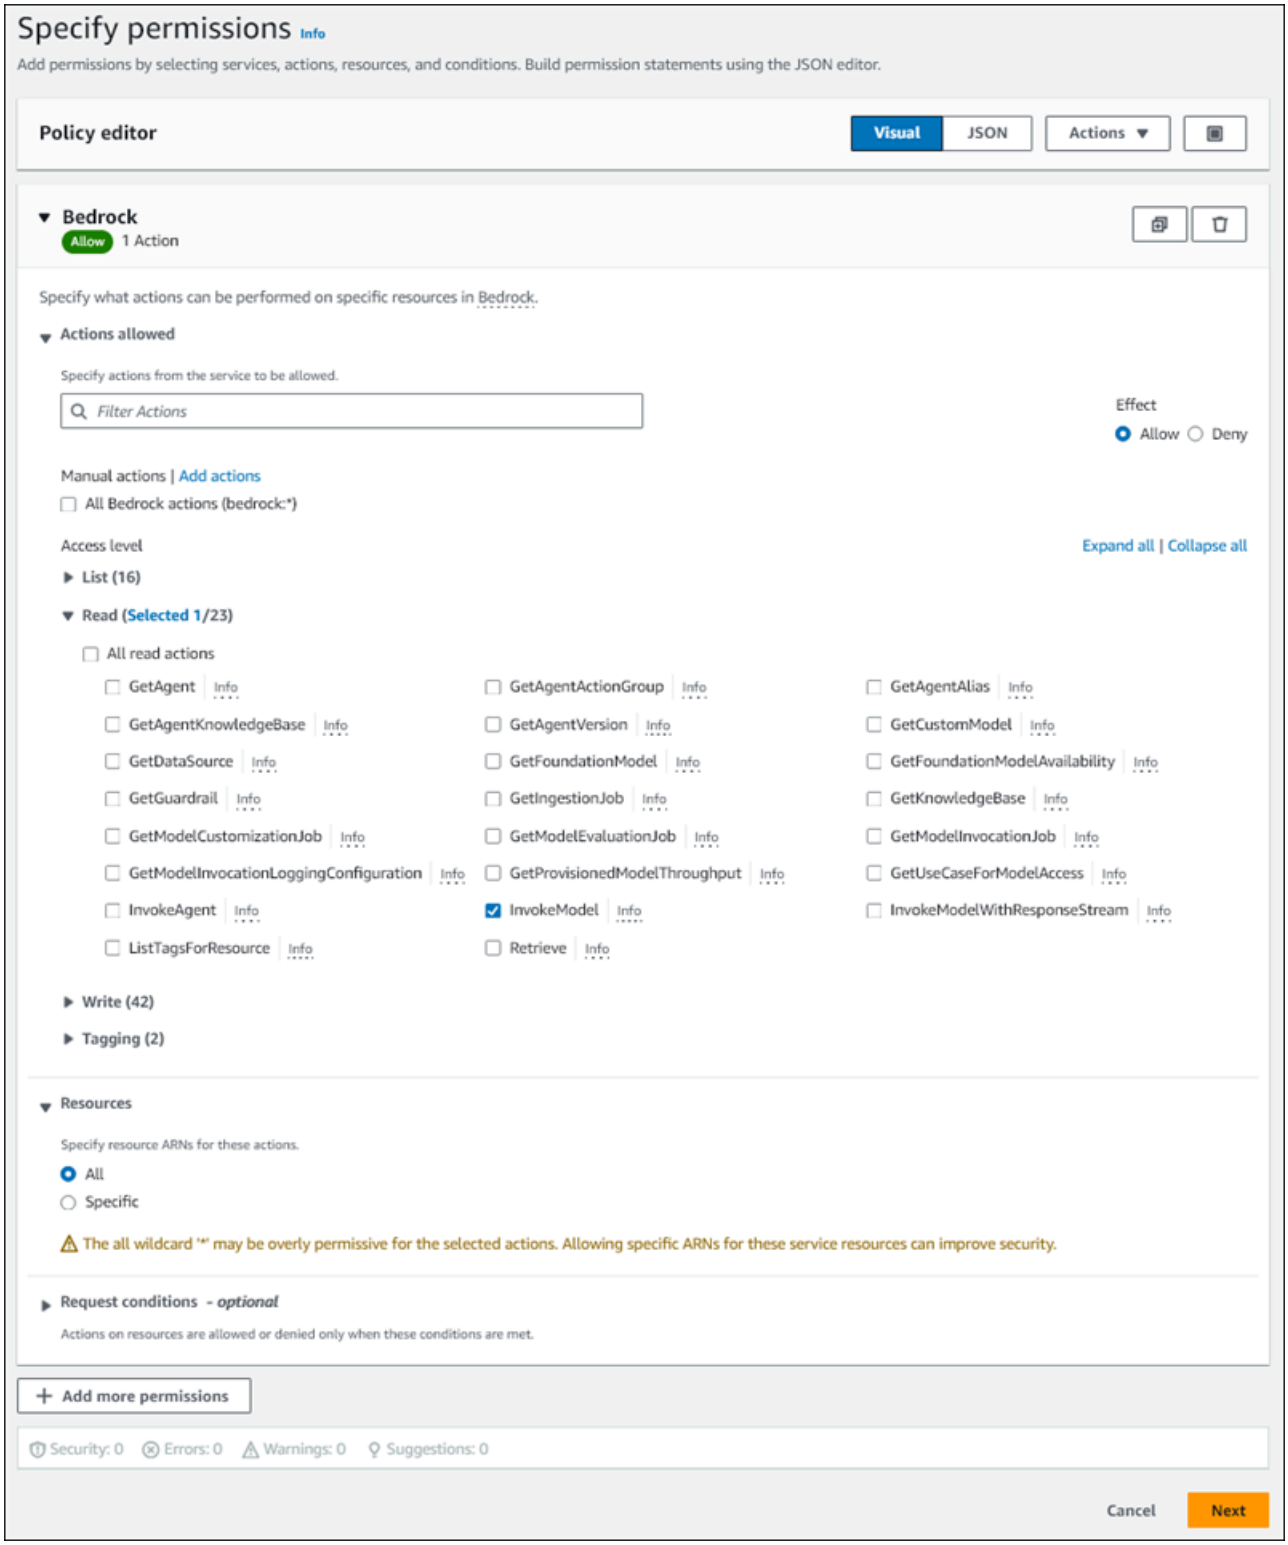
In the following topics, you can find separate setup procedures for each of these Aurora machine learning services.

Topics

- Setting up your Aurora MySQL DB cluster to use Amazon Bedrock
- Setting up your Aurora MySQL DB cluster to use Amazon Comprehend
- Setting up your Aurora MySQL DB cluster to use SageMaker AI
  - Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker AI (Optional)
- Granting database users access to Aurora machine learning
  - Granting access to Amazon Bedrock functions
  - Granting access to Amazon Comprehend functions
  - Granting access to SageMaker AI functions

Setting up your Aurora MySQL DB cluster to use Amazon Bedrock

Aurora machine learning relies on Amazon Identity and Access Management (IAM) roles and policies to allow your Aurora MySQL DB cluster to access and use the Amazon Bedrock services. The following procedures create an IAM permission policy and role so that your DB cluster can integrate with Amazon Bedrock.



To create the IAM policy

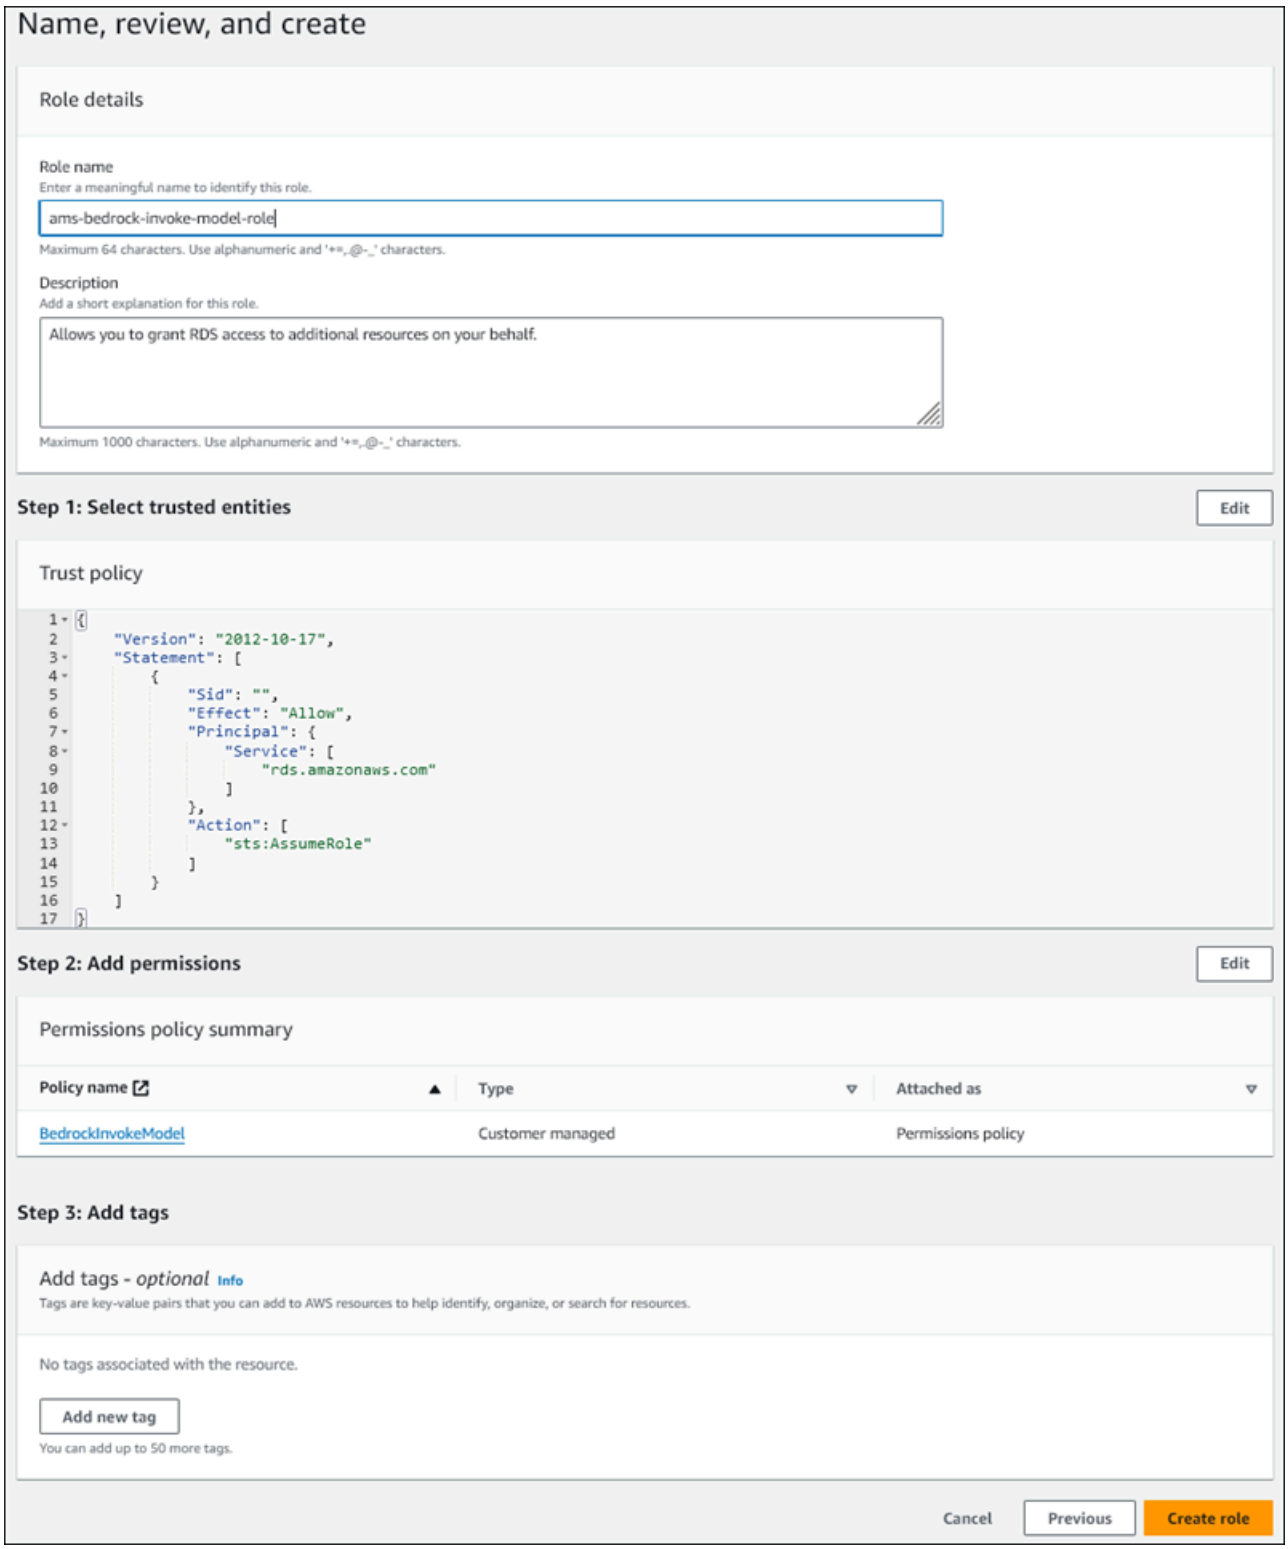
1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. Choose **Policies** in the navigation pane.
3. Choose **Create a policy**.
4. On the **Specify permissions** page, for **Select a service**, choose **Bedrock**.

The Amazon Bedrock permissions display.

5. Expand **Read**, then select **InvokeModel**.
6. For **Resources**, select **All**.

The **Specify permissions** page should resemble the following figure.

7. Choose **Next**.
8. On the **Review and create** page, enter a name for your policy, for example **`BedrockInvokeModel`**.



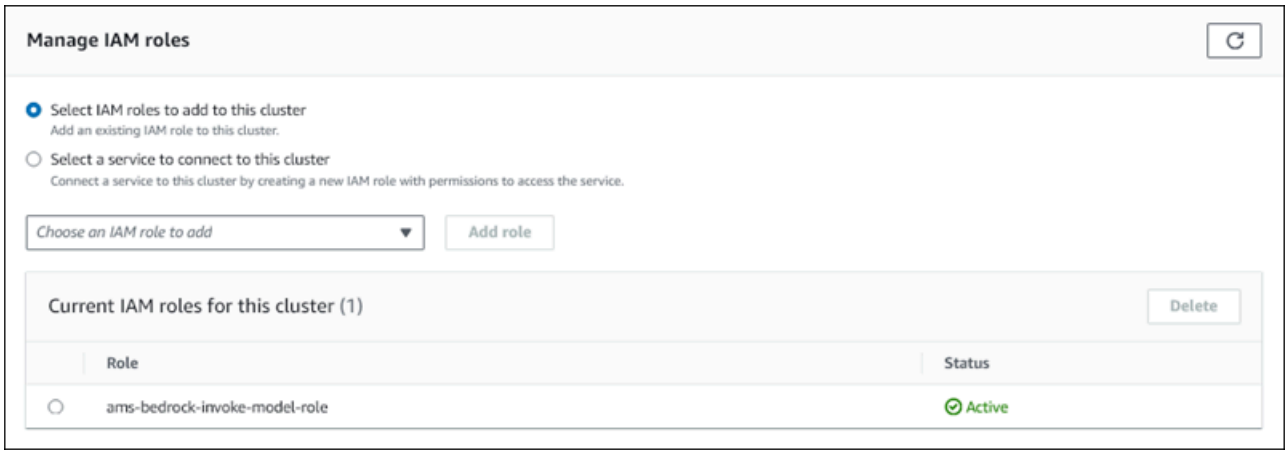
9. Review your policy, then choose **Create policy**.

Next you create the IAM role that uses the Amazon Bedrock permission policy.

To create the IAM role

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. Choose **Roles** in the navigation pane.
3. Choose **Create role**.
4. On the **Select trusted entity** page, for **Use case**, choose **RDS**.
5. Select **RDS - Add Role to Database**, then choose **Next**.
6. On the **Add permissions** page, for **Permissions policies**, select the IAM policy that you created, then choose **Next**.
7. On the **Name, review, and create** page, enter a name for your role, for example **`ams-bedrock-invoke-model-role`**.

   The role should resemble the following figure.



8. Review your role, then choose **Create role**.

Next you associate the Amazon Bedrock IAM role with your DB cluster.

To associate the IAM role with your DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. Choose **Databases** from the navigation pane.
3. Choose the Aurora MySQL DB cluster that you want to connect to Amazon Bedrock services.
4. Choose the **Connectivity & security** tab.
5. For **Manage IAM roles** section, choose **Select IAM to add to this cluster**.
6. Choose the IAM that you created, and then choose **Add role**.

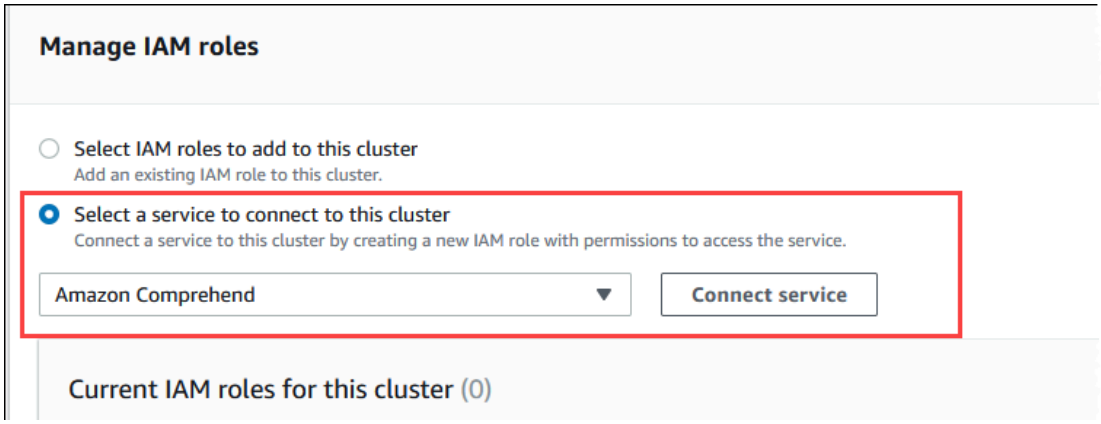
   The IAM role is associated with your DB cluster, first with the status **Pending**, then **Active**. When the process completes, you can find the role in the **Current IAM roles for this cluster** list.

You must add the ARN of this IAM role to the `aws_default_bedrock_role` parameter of the custom DB cluster parameter group associated with your Aurora MySQL DB cluster. If your Aurora MySQL DB cluster doesn't use a custom DB cluster parameter group, you need to create one to use with your Aurora MySQL DB cluster to complete the integration. For more information, see DB cluster parameter groups for Amazon Aurora DB clusters.

To configure the DB cluster parameter

1. In the Amazon RDS Console, open the **Configuration** tab of your Aurora MySQL DB cluster.
2. Locate the DB cluster parameter group configured for your cluster. Choose the link to open your custom DB cluster parameter group, then choose **Edit**.

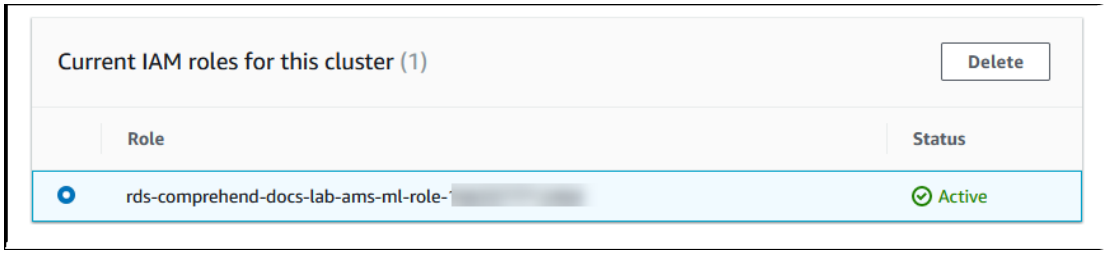
3. Find the `aws_default_bedrock_role` parameter in your custom DB cluster parameter group.
4. In the **Value** field, enter the ARN of the IAM role.
5. Choose **Save changes** to save the setting.
6. Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.



The IAM integration for Amazon Bedrock is complete. Continue setting up your Aurora MySQL DB cluster to work with Amazon Bedrock by Granting database users access to Aurora machine learning.

Setting up your Aurora MySQL DB cluster to use Amazon Comprehend

Aurora machine learning relies on Amazon Identity and Access Management roles and policies to allow your Aurora MySQL DB cluster to access and use the Amazon Comprehend services. The following procedure automatically creates an IAM role and policy for your cluster so that it can use Amazon Comprehend.



To set up your Aurora MySQL DB cluster to use Amazon Comprehend

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. Choose **Databases** from the navigation pane.
3. Choose the Aurora MySQL DB cluster that you want to connect to Amazon Comprehend services.
4. Choose the **Connectivity & security** tab.
5. For **Manage IAM roles** section, choose **Select a service to connect to this cluster**.
6. Choose **Amazon Comprehend** from the menu, and then choose **Connect service**.

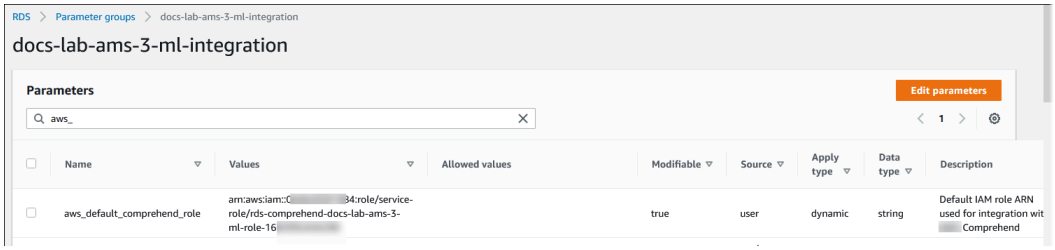
7. The **Connect cluster to Amazon Comprehend** dialog doesn't require any additional information. However, you might see a message notifying you that the integration between Aurora and Amazon Comprehend is currently in preview. Be sure to read the message before you continue. You can choose **Cancel** if you prefer not to proceed.
8. Choose **Connect service** to complete the integration process.

   Aurora creates the IAM role. It also creates the policy that allows the Aurora MySQL DB cluster to use Amazon Comprehend services and attaches the policy to the role. When the process completes, you can find the role in the **Current IAM roles for this cluster** list as shown in the following image.

   You need to add the ARN of this IAM role to the `aws_default_comprehend_role` parameter of the custom DB cluster parameter group associated with your Aurora MySQL DB cluster. If your Aurora MySQL DB cluster doesn't use a custom DB cluster parameter group, you need to create one to use with your Aurora MySQL DB cluster to complete the integration. For more information, see DB cluster parameter groups for Amazon Aurora DB clusters.

   After creating your custom DB cluster parameter group and associating it with your Aurora MySQL DB cluster, you can continue following these steps.

   If your cluster uses a custom DB cluster parameter group, do as follows.



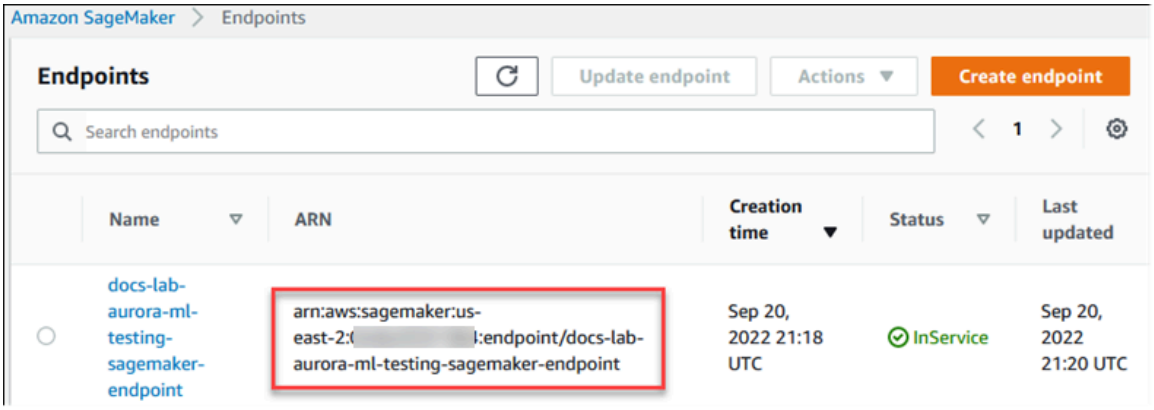
a. In the Amazon RDS Console, open the **Configuration** tab of your Aurora MySQL DB cluster.

b. Locate the DB cluster parameter group configured for your cluster. Choose the link to open your custom DB cluster parameter group, then choose **Edit**.

c. Find the `aws_default_comprehend_role` parameter in your custom DB cluster parameter group.

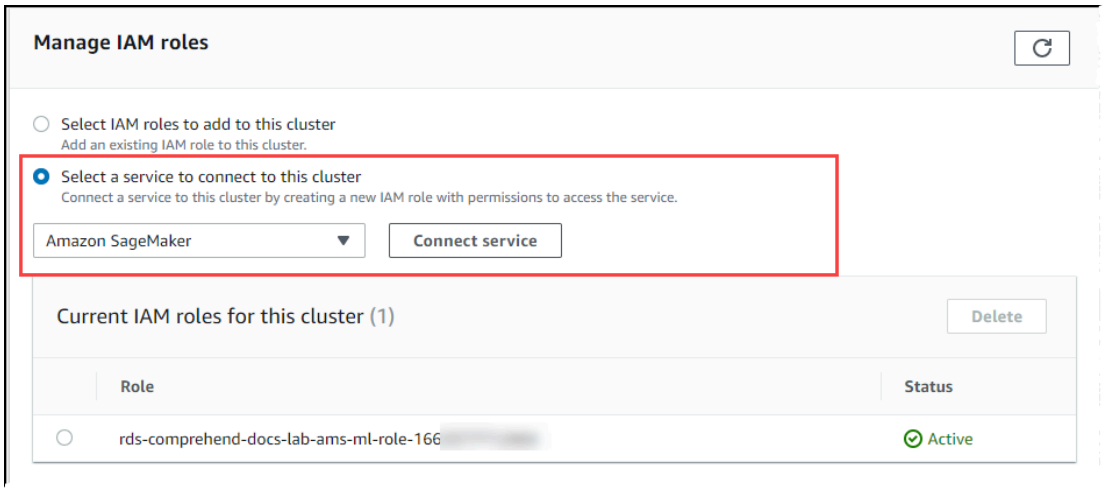
d. In the **Value** field, enter the ARN of the IAM role.

e. Choose **Save changes** to save the setting. In the following image, you can find an example.



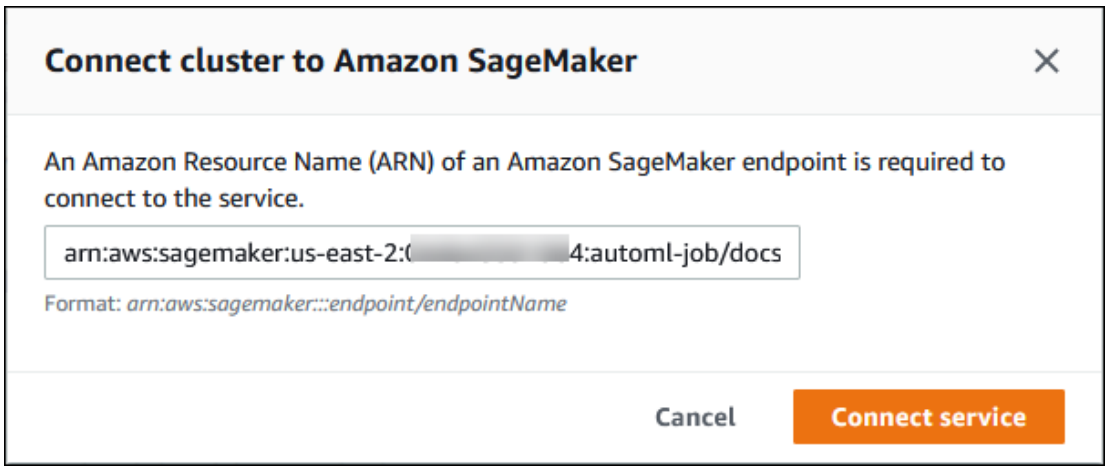
Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.

The IAM integration for Amazon Comprehend is complete. Continue setting up your Aurora MySQL DB cluster to work with Amazon Comprehend by granting access to the appropriate database users.



Setting up your Aurora MySQL DB cluster to use SageMaker AI

The following procedure automatically creates the IAM role and policy for your Aurora MySQL DB cluster so that it can use SageMaker AI. Before trying to follow this procedure, be sure that you have the SageMaker AI endpoint available so that you can enter it when needed. Typically, data scientists on your team would do the work to produce an endpoint that you can use from your Aurora MySQL DB cluster. You can find such endpoints in the SageMaker AI console. In the navigation pane, open the **Inference** menu and choose **Endpoints**. In the following image, you can find an example.



To set up your Aurora MySQL DB cluster to use SageMaker AI

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. Choose **Databases** from the Amazon RDS navigation menu and then choose the Aurora MySQL DB cluster that you want to connect to SageMaker AI services.
3. Choose the **Connectivity & security** tab.
4. Scroll to the **Manage IAM roles** section, and then choose **Select a service to connect to this cluster**. Choose **SageMaker AI** from the selector.

5. Choose **Connect service**.
6. In the **Connect cluster to SageMaker AI** dialog, enter the ARN of the SageMaker AI endpoint.

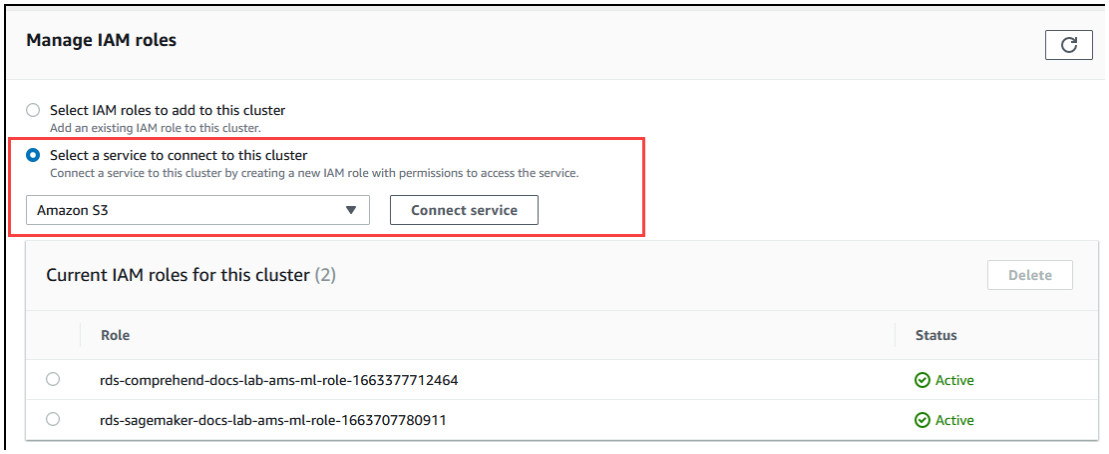
7. Aurora creates the IAM role. It also creates the policy that allows the Aurora MySQL DB cluster to use SageMaker AI services and attaches the policy to the role. When the process completes, you can find the role in the **Current IAM roles for this cluster** list.
8. Open the IAM console at https://console.amazonaws.cn/iam/.
9. Choose **Roles** from the Access management section of the Amazon Identity and Access Management navigation menu.
10. Find the role from among those listed. Its name uses the following pattern.

    ```
    rds-sagemaker-your-cluster-name-role-auto-generated-digits
    ```

11. Open the role's Summary page and locate the ARN. Note the ARN or copy it using the copy widget.
12. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.
13. Choose your Aurora MySQL DB cluster, and then choose its **Configuration** tab.
14. Locate the DB cluster parameter group, and choose the link to open your custom DB cluster parameter group. Find the `aws_default_sagemaker_role` parameter and enter the ARN of the IAM role in the Value field and Save the setting.
15. Reboot the primary instance of your Aurora MySQL DB cluster so that this parameter setting takes effect.

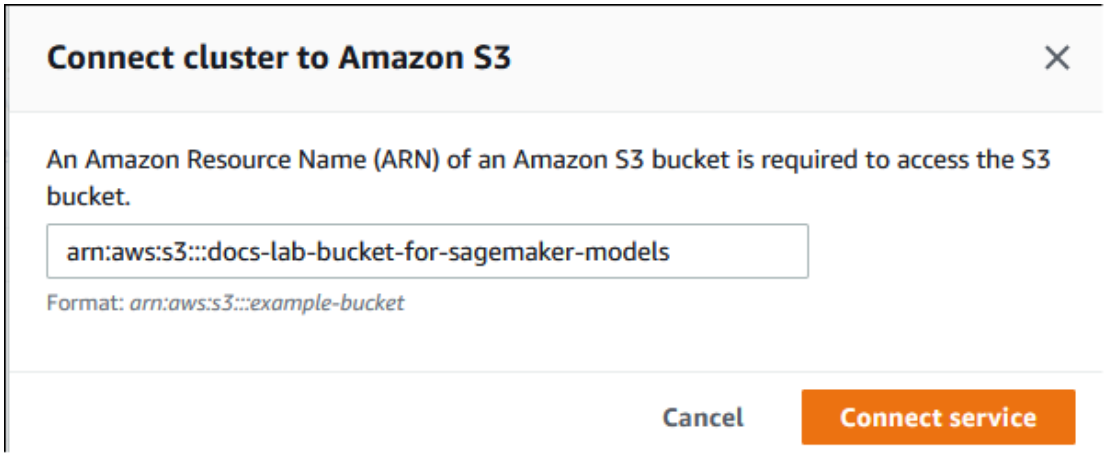
The IAM setup is now complete. Continue setting up your Aurora MySQL DB cluster to work with SageMaker AI by granting access to the appropriate database users.

If you want to use your SageMaker AI models for training rather than using pre-built SageMaker AI components, you also need to add the Amazon S3 bucket to your Aurora MySQL DB cluster,



as outlined in the Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker AI (Optional) that follows.

Setting up your Aurora MySQL DB cluster to use Amazon S3 for SageMaker AI (Optional)



To use SageMaker AI with your own models rather than using the pre-built components provided by SageMaker AI, you need to set up an Amazon S3 bucket for the Aurora MySQL DB cluster to use. For more information about creating an Amazon S3 bucket, see Creating a bucket in the *Amazon Simple Storage Service User Guide*.

To set up your Aurora MySQL DB cluster to use an Amazon S3 bucket for SageMaker AI

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. Choose **Databases** from the Amazon RDS navigation menu and then choose the Aurora MySQL DB cluster that you want to connect to SageMaker AI services.
3. Choose the **Connectivity & security** tab.
4. Scroll to the **Manage IAM roles** section, and then choose **Select a service to connect to this cluster**. Choose **Amazon S3** from the selector.

5. Choose **Connect service**.
6. In the **Connect cluster to Amazon S3** dialog, enter the ARN of the Amazon S3 bucket, as shown in the following image.

7. Choose **Connect service** to complete this process.

For more information about using Amazon S3 buckets with SageMaker AI, see Specify an Amazon S3 Bucket to Upload Training Datasets and Store Output Data in the *Amazon SageMaker AI Developer Guide*. To learn more about working with SageMaker AI, see Get Started with Amazon SageMaker AI Notebook Instancesin the in the *Amazon SageMaker AI Developer Guide*.

Granting database users access to Aurora machine learning

Database users must be granted permission to invoke Aurora machine learning functions. How you grant permission depends on the version of MySQL that you use for your Aurora MySQL DB cluster, as outlined in the following. How you do so depends on the version of MySQL that your Aurora MySQL DB cluster uses.

- For Aurora MySQL version 3 (MySQL 8.0 compatible), database users must be granted the appropriate *database role*. For more informations, see Using Roles in the *MySQL 8.0 Reference Manual*.
- For Aurora MySQL version 2 (MySQL 5.7 compatible), database users are granted *privileges*. For more information, see Access Control and Account Management in the *MySQL 5.7 Reference Manual*.

The following table shows the roles and privileges that database users need to work with machine learning functions.

Aurora MySQL version 3 (role)	Aurora MySQL version 2 (privilege)
Amazon_BEDROCK_ACCESS	–
Amazon_COMPREHEND_ACCESS	INVOKE COMPREHEND
Amazon_SAGEMAKER_ACCESS	INVOKE SAGEMAKER

Granting access to Amazon Bedrock functions

To give database users access to Amazon Bedrock functions, use the following SQL statement:

```
GRANT Amazon_BEDROCK_ACCESS TO user@domain-or-ip-address;
```

Database users also need to be granted EXECUTE permissions for the functions that you create for working with Amazon Bedrock:

```
GRANT EXECUTE ON FUNCTION database_name.function_name TO user@domain-or-ip-address;
```

Finally, database users must have their roles set to Amazon_BEDROCK_ACCESS:

```
SET ROLE Amazon_BEDROCK_ACCESS;
```

The Amazon Bedrock functions are now available for use.

Granting access to Amazon Comprehend functions

To give database users access to Amazon Comprehend functions, use the appropriate statement for your Aurora MySQL version.

- Aurora MySQL version 3 (MySQL 8.0 compatible)

  ```
  GRANT Amazon_COMPREHEND_ACCESS TO user@domain-or-ip-address;
  ```

- Aurora MySQL version 2 (MySQL 5.7 compatible)

  ```
  GRANT INVOKE COMPREHEND ON *.* TO user@domain-or-ip-address;
  ```

The Amazon Comprehend functions are now available for use. For usage examples, see Using Amazon Comprehend with your Aurora MySQL DB cluster.

Granting access to SageMaker AI functions

To give database users access to SageMaker AI functions, use the appropriate statement for your Aurora MySQL version.

- Aurora MySQL version 3 (MySQL 8.0 compatible)

```
GRANT Amazon_SAGEMAKER_ACCESS TO user@domain-or-ip-address;
```

- Aurora MySQL version 2 (MySQL 5.7 compatible)

```
GRANT INVOKE SAGEMAKER ON *.* TO user@domain-or-ip-address;
```

Database users also need to be granted EXECUTE permissions for the functions that you create for working with SageMaker AI. Suppose that you created two functions, `db1.anomoly_score` and `db2.company_forecasts`, to invoke the services of your SageMaker AI endpoint. You grant execute privileges as shown in the following example.

```
GRANT EXECUTE ON FUNCTION db1.anomaly_score TO user1@domain-or-ip-address1;
GRANT EXECUTE ON FUNCTION db2.company_forecasts TO user2@domain-or-ip-address2;
```

The SageMaker AI functions are now available for use. For usage examples, see Using SageMaker AI with your Aurora MySQL DB cluster.

Using Amazon Bedrock with your Aurora MySQL DB cluster

To use Amazon Bedrock, you create a user-defined function (UDF) in your Aurora MySQL database that invokes a model. For more information, see Supported models in Amazon Bedrock in the *Amazon Bedrock User Guide*.

A UDF uses the following syntax:

```
CREATE FUNCTION function_name (argument type)
        [DEFINER = user]
    RETURNS mysql_data_type
    [SQL SECURITY {DEFINER | INVOKER}]
    ALIAS AWS_BEDROCK_INVOKE_MODEL
```

```
    MODEL ID 'model_id'
    [CONTENT_TYPE 'content_type']
    [ACCEPT 'content_type']
    [TIMEOUT_MS timeout_in_milliseconds];
```

- Amazon Bedrock functions don't support `RETURNS JSON`. You can use `CONVERT` or `CAST` to convert from `TEXT` to `JSON` if needed.
- If you don't specify `CONTENT_TYPE` or `ACCEPT`, the default is `application/json`.
- If you don't specify `TIMEOUT_MS`, the value for `aurora_ml_inference_timeout` is used.

For example, the following UDF invokes the Amazon Titan Text Express model:

```
CREATE FUNCTION invoke_titan (request_body TEXT)
    RETURNS TEXT
    ALIAS AWS_BEDROCK_INVOKE_MODEL
    MODEL ID 'amazon.titan-text-express-v1'
    CONTENT_TYPE 'application/json'
    ACCEPT 'application/json';
```

To allow a DB user to use this function, use the following SQL command:

```
GRANT EXECUTE ON FUNCTION database_name.invoke_titan TO user@domain-or-ip-address;
```

Then the user can call `invoke_titan` like any other function, as shown in the following example. Make sure to format the request body according to the Amazon Titan text models.

```
CREATE TABLE prompts (request varchar(1024));
INSERT INTO prompts VALUES (
'{
    "inputText": "Generate synthetic data for daily product sales in various categories
 - include row number, product name, category, date of sale and price. Produce output
 in JSON format. Count records and ensure there are no more than 5.",
    "textGenerationConfig": {
        "maxTokenCount": 1024,
        "stopSequences": [],
        "temperature":0,
        "topP":1
    }
}');
```

```
SELECT invoke_titan(request) FROM prompts;

{"inputTextTokenCount":44,"results":[{"tokenCount":296,"outputText":"
```tabular-data-json
{
    "rows": [
        {
            "Row Number": "1",
            "Product Name": "T-Shirt",
            "Category": "Clothing",
            "Date of Sale": "2024-01-01",
            "Price": "$20"
        },
        {
            "Row Number": "2",
            "Product Name": "Jeans",
            "Category": "Clothing",
            "Date of Sale": "2024-01-02",
            "Price": "$30"
        },
        {
            "Row Number": "3",
            "Product Name": "Hat",
            "Category": "Accessories",
            "Date of Sale": "2024-01-03",
            "Price": "$15"
        },
        {
            "Row Number": "4",
            "Product Name": "Watch",
            "Category": "Accessories",
            "Date of Sale": "2024-01-04",
            "Price": "$40"
        },
        {
            "Row Number": "5",
            "Product Name": "Phone Case",
            "Category": "Accessories",
            "Date of Sale": "2024-01-05",
            "Price": "$25"
        }
    ]
}
```
```

```
```","completionReason":"FINISH"}]}
```

For other models that you use, make sure to format the request body appropriately for them. For more information, see Inference parameters for foundation models in the *Amazon Bedrock User Guide*.

## Using Amazon Comprehend with your Aurora MySQL DB cluster

For Aurora MySQL, Aurora machine learning provides the following two built-in functions for working with Amazon Comprehend and your text data. You provide the text to analyze (`input_data`) and specify the language (`language_code`).

**aws_comprehend_detect_sentiment**

This function identifies the text as having a positive, negative, neutral, or mixed emotional posture. This function's reference documentation is as follows.

```
aws_comprehend_detect_sentiment(
  input_text,
  language_code
  [,max_batch_size]
)
```

To learn more, see Sentiment in the *Amazon Comprehend Developer Guide*.

aws_comprehend_detect_sentiment_confidence

This function measures the confidence level of the sentiment detected for a given text. It returns a value (type, `double`) that indicates the confidence of the sentiment assigned by the aws_comprehend_detect_sentiment function to the text. Confidence is a statistical metric between 0 and 1. The higher the confidence level, the more weight you can give the result. A summary of the function's documentation is as follows.

```
aws_comprehend_detect_sentiment_confidence(
  input_text,
  language_code
  [,max_batch_size]
)
```
```

In both functions (aws_comprehend_detect_sentiment_confidence, aws_comprehend_detect_sentiment) the `max_batch_size` uses a default value of 25 if none is specified. Batch size should always be greater than 0. You can use `max_batch_size` to tune the performance of the Amazon Comprehend function calls. A large batch size trades off faster performance for greater memory usage on the Aurora MySQL DB cluster. For more information, see Performance considerations for using Aurora machine learning with Aurora MySQL.

For more information about parameters and return types for the sentiment detection functions in Amazon Comprehend, see DetectSentiment

Example: A simple query using Amazon Comprehend functions

Here's an example of a simple query that invokes these two functions to see how happy your customers are with your support team. Suppose you have a database table (`support`) that stores customer feedback after each request for help. This example query applies both built-in functions to the text in the `feedback` column of the table and outputs the results. The confidence values returned by the function are doubles between 0.0 and 1.0. For more readable output, this query rounds the results to 6 decimal points. For easier comparisons, this query also sorts the results in descending order, from the result having the highest degree of confidence, first.

```
SELECT feedback AS 'Customer feedback',
    aws_comprehend_detect_sentiment(feedback, 'en') AS Sentiment,
    ROUND(aws_comprehend_detect_sentiment_confidence(feedback, 'en'), 6)
    AS Confidence FROM support
    ORDER BY Confidence DESC;
+-----------------------------------------------------------+-----------+------------+
| Customer feedback                                         | Sentiment | Confidence |
+-----------------------------------------------------------+-----------+------------+
| Thank you for the excellent customer support!             | POSITIVE  |   0.999771 |
| The latest version of this product stinks!                | NEGATIVE  |   0.999184 |
| Your support team is just awesome! I am blown away.       | POSITIVE  |   0.997774 |
| Your product is too complex, but your support is great.   | MIXED     |   0.957958 |
| Your support tech helped me in fifteen minutes.           | POSITIVE  |   0.949491 |
| My problem was never resolved!                            | NEGATIVE  |   0.920644 |
| When will the new version of this product be released?    | NEUTRAL   |   0.902706 |
| I cannot stand that chatbot.                              | NEGATIVE  |   0.895219 |
| Your support tech talked down to me.                      | NEGATIVE  |   0.868598 |
| It took me way too long to get a real person.             | NEGATIVE  |   0.481805 |
+-----------------------------------------------------------+-----------+------------+
 10 rows in set (0.1898 sec)
```

Example: Determining the average sentiment for text above a specific confidence level

A typical Amazon Comprehend query looks for rows where the sentiment is a certain value, with a confidence level greater than a certain number. For example, the following query shows how you can determine the average sentiment of documents in your database. The query considers only documents where the confidence of the assessment is at least 80%.

```
SELECT AVG(CASE aws_comprehend_detect_sentiment(productTable.document, 'en')
  WHEN 'POSITIVE' THEN 1.0
  WHEN 'NEGATIVE' THEN -1.0
  ELSE 0.0 END) AS avg_sentiment, COUNT(*) AS total
FROM productTable
WHERE productTable.productCode = 1302 AND
    aws_comprehend_detect_sentiment_confidence(productTable.document, 'en') >= 0.80;
```

Using SageMaker AI with your Aurora MySQL DB cluster

To use SageMaker AI functionality from your Aurora MySQL DB cluster, you need to create stored functions that embed your calls to the SageMaker AI endpoint and its inference features. You do so by using MySQL's `CREATE FUNCTION` in generally the same way that you do for other processing tasks on your Aurora MySQL DB cluster.

To use models deployed in SageMaker AI for inference, you create user-defined functions using MySQL data definition language (DDL) statements for stored functions. Each stored function represents the SageMaker AI endpoint hosting the model. When you define such a function, you specify the input parameters to the model, the specific SageMaker AI endpoint to invoke, and the return type. The function returns the inference computed by the SageMaker AI endpoint after applying the model to the input parameters.

All Aurora machine learning stored functions return numeric types or `VARCHAR`. You can use any numeric type except `BIT`. Other types, such as `JSON`, `BLOB`, `TEXT`, and `DATE` aren't allowed.

The following example shows the `CREATE FUNCTION` syntax for working with SageMaker AI.

```
CREATE FUNCTION function_name (
     arg1 type1,
     arg2 type2, ...)
     [DEFINER = user]
  RETURNS mysql_type
  [SQL SECURITY { DEFINER | INVOKER } ]
  ALIAS Amazon_SAGEMAKER_INVOKE_ENDPOINT
```

```
  ENDPOINT NAME 'endpoint_name'
  [MAX_BATCH_SIZE max_batch_size];
```

This is an extension of the regular `CREATE FUNCTION` DDL statement. In the `CREATE FUNCTION` statement that defines the SageMaker AI function, you don't specify a function body. Instead, you specify the keyword `ALIAS` where the function body usually goes. Currently, Aurora machine learning only supports `aws_sagemaker_invoke_endpoint` for this extended syntax. You must specify the `endpoint_name` parameter. An SageMaker AI endpoint can have different characteristics for each model.

> **Note**
>
> For more information about `CREATE FUNCTION`, see CREATE PROCEDURE and CREATE FUNCTION Statements in the MySQL 8.0 Reference Manual.

The `max_batch_size` parameter is optional. By default, maximum batch size is 10,000. You can use this parameter in your function to restrict the maximum number of inputs processed in a batched request to SageMaker AI. The `max_batch_size` parameter can help to avoid an error caused by inputs that are too large, or to make SageMaker AI return a response more quickly. This parameter affects the size of an internal buffer used for SageMaker AI request processing. Specifying too large a value for `max_batch_size` might cause substantial memory overhead on your DB instance.

We recommend that you leave the `MANIFEST` setting at its default value of `OFF`. Although you can use the `MANIFEST ON` option, some SageMaker AI features can't directly use the CSV exported with this option. The manifest format is not compatible with the expected manifest format from SageMaker AI.

You create a separate stored function for each of your SageMaker AI models. This mapping of functions to models is required because an endpoint is associated with a specific model, and each model accepts different parameters. Using SQL types for the model inputs and the model output type helps to avoid type conversion errors passing data back and forth between the Amazon services. You can control who can apply the model. You can also control the runtime characteristics by specifying a parameter representing the maximum batch size.

Currently, all Aurora machine learning functions have the `NOT DETERMINISTIC` property. If you don't specify that property explicitly, Aurora sets `NOT DETERMINISTIC` automatically. This

requirement is because the SageMaker AI model can be changed without any notification to the database. If that happens, calls to an Aurora machine learning function might return different results for the same input within a single transaction.

You can't use the characteristics `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, or `MODIFIES SQL DATA` in your `CREATE FUNCTION` statement.

Following is an example usage of invoking an SageMaker AI endpoint to detect anomalies. There is an SageMaker AI endpoint `random-cut-forest-model`. The corresponding model is already trained by the `random-cut-forest` algorithm. For each input, the model returns an anomaly score. This example shows the data points whose score is greater than 3 standard deviations (approximately the 99.9th percentile) from the mean score.

```
CREATE FUNCTION anomaly_score(value real) returns real
  alias aws_sagemaker_invoke_endpoint endpoint name 'random-cut-forest-model-demo';

set @score_cutoff = (select avg(anomaly_score(value)) + 3 * std(anomaly_score(value))
 from nyc_taxi);

select *, anomaly_detection(value) score from nyc_taxi
  where anomaly_detection(value) > @score_cutoff;
```

Character set requirement for SageMaker AI functions that return strings

We recommend specifying a character set of `utf8mb4` as the return type for your SageMaker AI functions that return string values. If that isn't practical, use a large enough string length for the return type to hold a value represented in the `utf8mb4` character set. The following example shows how to declare the `utf8mb4` character set for your function.

```
CREATE FUNCTION my_ml_func(...) RETURNS VARCHAR(5) CHARSET utf8mb4 ALIAS ...
```

Currently, each SageMaker AI function that returns a string uses the character set `utf8mb4` for the return value. The return value uses this character set even if your SageMaker AI function declares a different character set for its return type implicitly or explicitly. If your SageMaker AI function declares a different character set for the return value, the returned data might be silently truncated if you store it in a table column that isn't long enough. For example, a query with a `DISTINCT` clause creates a temporary table. Thus, the SageMaker AI function result might be truncated due to the way strings are handled internally during a query.

Exporting data to Amazon S3 for SageMaker AI model training (Advanced)

We recommend that you get started with Aurora machine learning and SageMaker AI by using some of the provided algorithms, and that the data scientists on your team provide you with the SageMaker AI endpoints that you can use with your SQL code. In the following, you can find minimal information about using your own Amazon S3 bucket with your your own SageMaker AI models and your Aurora MySQL DB cluster.

Machine learning consists of two major steps: training, and inference. To train SageMaker AI models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by a Jupyter SageMaker AI notebook instance to train your model before it is deployed. You can use the `SELECT INTO OUTFILE S3` statement to query data from an Aurora MySQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then the notebook instance consumes the data from the Amazon S3 bucket for training.

Aurora machine learning extends the existing `SELECT INTO OUTFILE` syntax in Aurora MySQL to export data to CSV format. The generated CSV file can be directly consumed by models that need this format for training purposes.

```
SELECT * INTO OUTFILE S3 's3_uri' [FORMAT {CSV|TEXT} [HEADER]] FROM table_name;
```

The extension supports the standard CSV format.

- Format `TEXT` is the same as the existing MySQL export format. This is the default format.
- Format `CSV` is a newly introduced format that follows the specification in RFC-4180.
- If you specify the optional keyword `HEADER`, the output file contains one header line. The labels in the header line correspond to the column names from the `SELECT` statement.
- You can still use the keywords `CSV` and `HEADER` as identifiers.

The extended syntax and grammar of `SELECT INTO` is now as follows:

```
INTO OUTFILE S3 's3_uri'
[CHARACTER SET charset_name]
[FORMAT {CSV|TEXT} [HEADER]]
[{FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
```

```
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
```

Performance considerations for using Aurora machine learning with Aurora MySQL

The Amazon Bedrock, Amazon Comprehend, and SageMaker AI services do most of the work when invoked by an Aurora machine learning function. That means that you can scale those resources as needed, independently. For your Aurora MySQL DB cluster, you can make your function calls as efficient as possible. Following, you can find some performance considerations to note when working with Aurora machine learning.

Model and prompt

Performance when using Amazon Bedrock is highly dependent on the model and prompt that you use. Choose a model and prompt that are optimal for your use case.

Query cache

The Aurora MySQL query cache doesn't work for Aurora machine learning functions. Aurora MySQL doesn't store query results in the query cache for any SQL statements that call Aurora machine learning functions.

Batch optimization for Aurora machine learning function calls

The main Aurora machine learning performance aspect that you can influence from your Aurora cluster is the batch mode setting for calls to the Aurora machine learning stored functions. Machine learning functions typically require substantial overhead, making it impractical to call an external service separately for each row. Aurora machine learning can minimize this overhead by combining the calls to the external Aurora machine learning service for many rows into a single batch. Aurora machine learning receives the responses for all the input rows, and delivers the responses, one row at a time, to the query as it runs. This optimization improves the throughput and latency of your Aurora queries without changing the results.

When you create an Aurora stored function that's connected to an SageMaker AI endpoint, you define the batch size parameter. This parameter influences how many rows are transferred

for every underlying call to SageMaker AI. For queries that process large numbers of rows, the overhead to make a separate SageMaker AI call for each row can be substantial. The larger the data set processed by the stored procedure, the larger you can make the batch size.

If the batch mode optimization can be applied to an SageMaker AI function, you can tell by checking the query plan produced by the `EXPLAIN PLAN` statement. In this case, the `extra` column in the execution plan includes `Batched machine learning`. The following example shows a call to an SageMaker AI function that uses batch mode.

```
mysql> CREATE FUNCTION anomaly_score(val real) returns real alias
 aws_sagemaker_invoke_endpoint endpoint name 'my-rcf-model-20191126';
Query OK, 0 rows affected (0.01 sec)

```

When you call one of the built-in Amazon Comprehend functions, you can control the batch size by specifying the optional `max_batch_size` parameter. his parameter restricts the maximum number of `input_text` values processed in each batch. By sending multiple items at once, it reduces the number of round trips between Aurora and Amazon Comprehend. Limiting the batch size is useful in situations such as a query with a `LIMIT` clause. By using a small value for `max_batch_size`, you can avoid invoking Amazon Comprehend more times than you have input texts.

The batch optimization for evaluating Aurora machine learning functions applies in the following cases:

- Function calls within the select list or the `WHERE` clause of `SELECT` statements
- Function calls in the `VALUES` list of `INSERT` and `REPLACE` statements
- SageMaker AI functions in `SET` values in `UPDATE` statements:

```
INSERT INTO MY_TABLE (col1, col2, col3) VALUES
  (ML_FUNC(1), ML_FUNC(2), ML_FUNC(3)),
  (ML_FUNC(4), ML_FUNC(5), ML_FUNC(6));
UPDATE MY_TABLE SET col1 = ML_FUNC(col2), SET col3 = ML_FUNC(col4) WHERE ...;
```

Monitoring Aurora machine learning

You can monitor Aurora machine learning batch operations by querying several global variables, as shown in the following example.

```
show status like 'Aurora_ml%';
```

You can reset the status variables by using a `FLUSH STATUS` statement. Thus, all of the figures represent totals, averages, and so on, since the last time the variable was reset.

`Aurora_ml_logical_request_cnt`

The number of logical requests that the DB instance has evaluated to be sent to the Aurora machine learning services since the last status reset. Depending on whether batching has been used, this value can be higher than `Aurora_ml_actual_request_cnt`.

`Aurora_ml_logical_response_cnt`

The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

`Aurora_ml_actual_request_cnt`

The aggregate request count that Aurora MySQL makes to the Aurora machine learning services across all queries run by users of the DB instance.

`Aurora_ml_actual_response_cnt`

The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

`Aurora_ml_cache_hit_cnt`

The aggregate internal cache hit count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance.

`Aurora_ml_retry_request_cnt`

The number of retried requests that the DB instance has sent to the Aurora machine learning services since the last status reset.

`Aurora_ml_single_request_cnt`

The aggregate count of Aurora machine learning functions that are evaluated by non-batch mode across all queries run by users of the DB instance.

For information about monitoring the performance of the SageMaker AI operations called from Aurora machine learning functions, see Monitor Amazon SageMaker AI.

Using Amazon Aurora machine learning with Aurora PostgreSQL

By using Amazon Aurora machine learning with your Aurora PostgreSQL DB cluster, you can use Amazon Comprehend or Amazon SageMaker AI or Amazon Bedrock, depending on your needs. These services each support specific machine learning use cases.

Aurora machine learning is supported in certain Amazon Web Services Regions and for specific versions of Aurora PostgreSQL only. Before trying to set up Aurora machine learning, check availability for your Aurora PostgreSQL version and your Region. For details, see Aurora machine learning with Aurora PostgreSQL.

Requirements for using Aurora machine learning with Aurora PostgreSQL

Amazon machine learning services are managed services that are set up and run in their own production environments. Aurora machine learning supports integration with Amazon Comprehend, SageMaker AI, and Amazon Bedrock. Before trying to set up your Aurora PostgreSQL DB cluster to use Aurora machine learning, be sure you understand the following requirements and prerequisites.

- The Amazon Comprehend, SageMaker AI, and Amazon Bedrock services must be running in the same Amazon Web Services Region as your Aurora PostgreSQL DB cluster. You can't use Amazon Comprehend or SageMaker AI or Amazon Bedrock services from an Aurora PostgreSQL DB cluster in a different Region.
- If your Aurora PostgreSQL DB cluster is in a different virtual public cloud (VPC) based on the Amazon VPC service than your Amazon Comprehend and SageMaker AI services, the VPC's Security group needs to allow outbound connections to the target Aurora machine learning service. For more information, see Enabling network communication from Amazon Aurora to other Amazon services.
- For SageMaker AI, the machine learning components that you want to use for inferences must be set up and ready to use. During the configuration process for your Aurora PostgreSQL DB cluster, you need to have the Amazon Resource Name (ARN) of the SageMaker AI endpoint available. The data scientists on your team are likely best able to handle working with SageMaker AI to prepare the models and handle the other such tasks. To get started with Amazon SageMaker AI, see Get Started with Amazon SageMaker AI. For more information about inferences and endpoints, see Real-time inference.
- For Amazon Bedrock, you need to have the model ID of the Bedrock models that you want to use for inferences available during the configuration process of your Aurora PostgreSQL DB cluster. The data scientists on your team are likely best able to work with Bedrock to decide which models to use, fine tune them if needed and handle other such tasks. To get started with Amazon Bedrock, see How to setup Bedrock.
- Amazon Bedrock users need to request access to models before they are available for use. If you want to add additional models for text, chat, and image generation, you need to request access to models in Amazon Bedrock. For more information, see Model access.

Supported features and limitations of Aurora machine learning with Aurora PostgreSQL

Aurora machine learning supports any SageMaker AI endpoint that can read and write the comma-separated value (CSV) format through a `ContentType` value of `text/csv`. The built-in SageMaker AI algorithms that currently accept this format are the following.

- Linear Learner
- Random Cut Forest
- XGBoost

  To learn more about these algorithms, see Choose an Algorithm in the *Amazon SageMaker AI Developer Guide*.

When using Amazon Bedrock with Aurora machine learning, the following limitations apply:

- The user-defined functions (UDFs) provide a native way to interact with Amazon Bedrock. The UDFs don't have specific request or response requirements, so they can use any model.
- You can use UDFs to build any work flow desired. For example, you can combine base primitives such as `pg_cron` to run a query, fetch data, generate inferences, and write to tables to serve queries directly.
- UDFs don't support batched or parallel calls.
- The Aurora Machine Learning extension doesn't support vector interfaces. As part of the extension, a function is available to output the embeddings of model's response in the `float8[]` format to store those embeddings in Aurora. For more information on the usage of `float8[]`, see Using Amazon Bedrock with your Aurora PostgreSQL DB cluster.

Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning

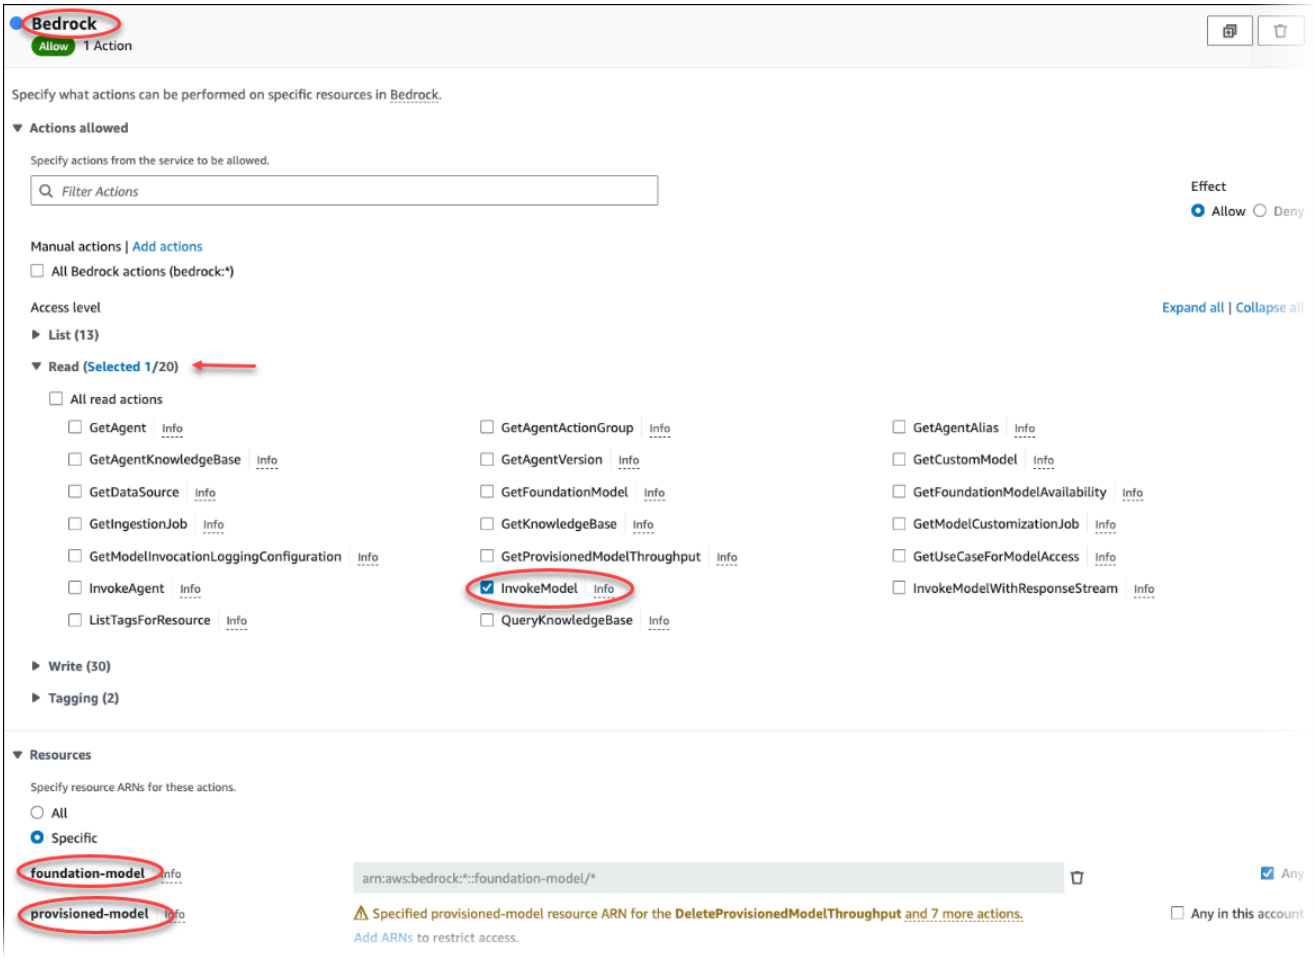
For Aurora machine learning to work with your Aurora PostgreSQL DB cluster, you need to create an Amazon Identity and Access Management (IAM) role for each of the services that you want to use. The IAM role allows your Aurora PostgreSQL DB cluster to use the Aurora machine learning service on the cluster's behalf. You also need to install the Aurora machine learning extension.

In the following topics, you can find setup procedures for each of these Aurora machine learning services.

Topics

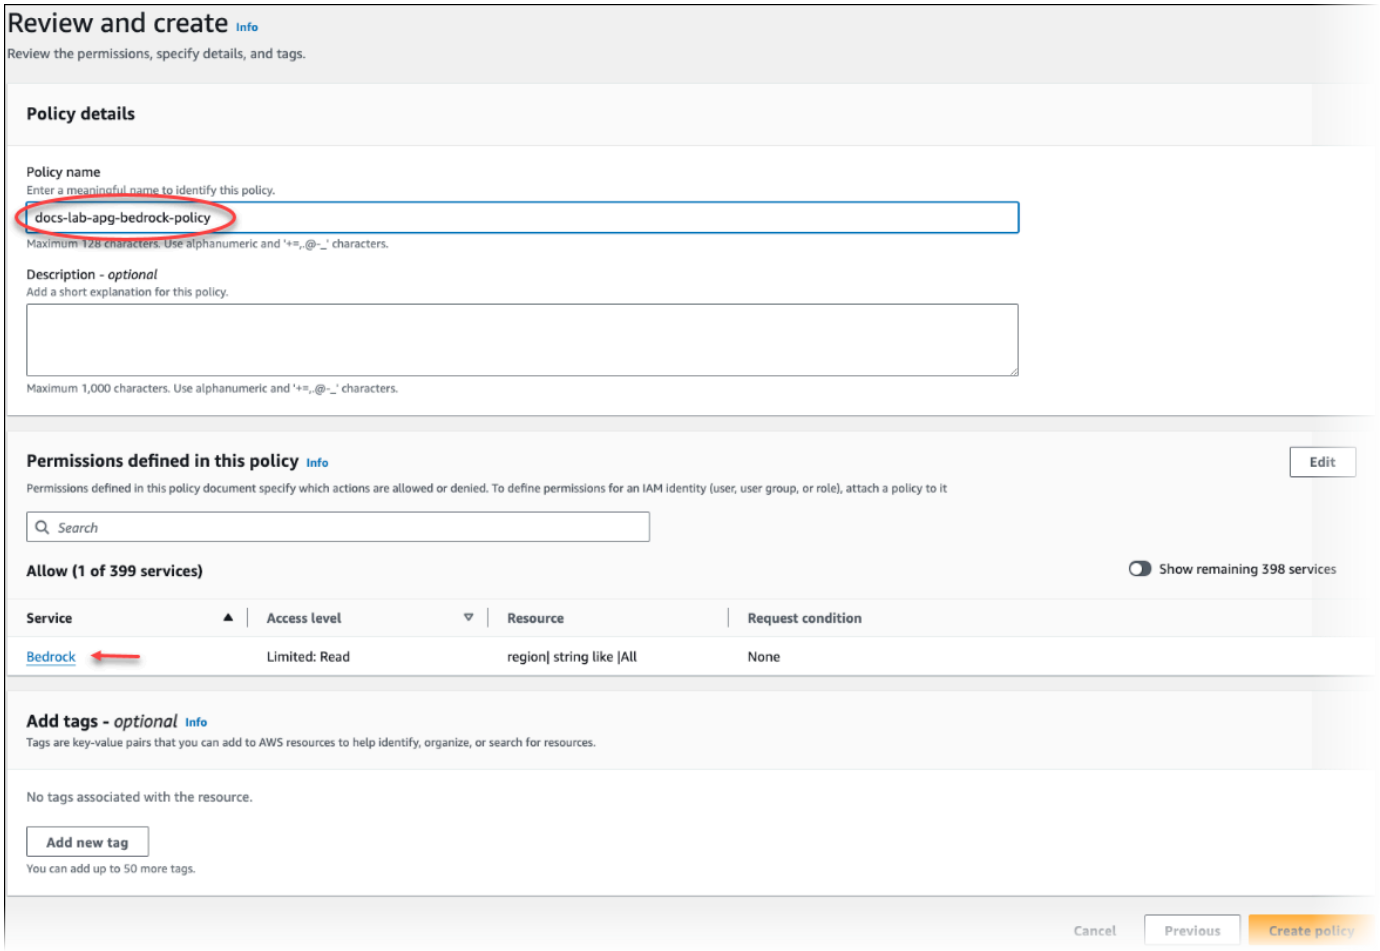
- Setting up Aurora PostgreSQL to use Amazon Bedrock
- Setting up Aurora PostgreSQL to use Amazon Comprehend
- Setting up Aurora PostgreSQL to use Amazon SageMaker AI
  - Setting up Aurora PostgreSQL to use Amazon S3 for SageMaker AI (Advanced)
- Installing the Aurora machine learning extension

Setting up Aurora PostgreSQL to use Amazon Bedrock



In the procedure following, you first create the IAM role and policy that gives your Aurora PostgreSQL permission to use Amazon Bedrock on the cluster's behalf. You then attach the policy to an IAM role that your Aurora PostgreSQL DB cluster uses to work with Amazon Bedrock. For simplicity's sake, this procedure uses the Amazon Web Services Management Console to complete all tasks.

To set up your Aurora PostgreSQL DB cluster to use Amazon Bedrock

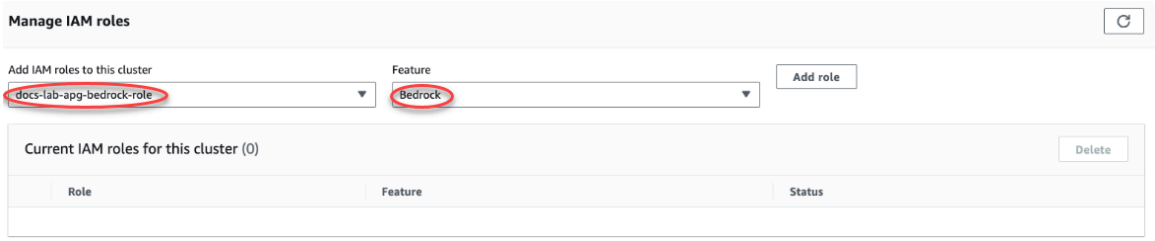


1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. Open the IAM console at https://console.amazonaws.cn/iam/.
3. Choose **Policies** (under Access management) on the Amazon Identity and Access Management (IAM) Console menu.

    a. Choose **Create policy**. In the Visual editor page, choose **Service** and then enter **Bedrock** in the Select a service field. Expand the Read access level. Choose **InvokeModel** from the Amazon Bedrock read settings.

    b. Choose the Foundation/Provisioned model you want to grant read access via the policy.

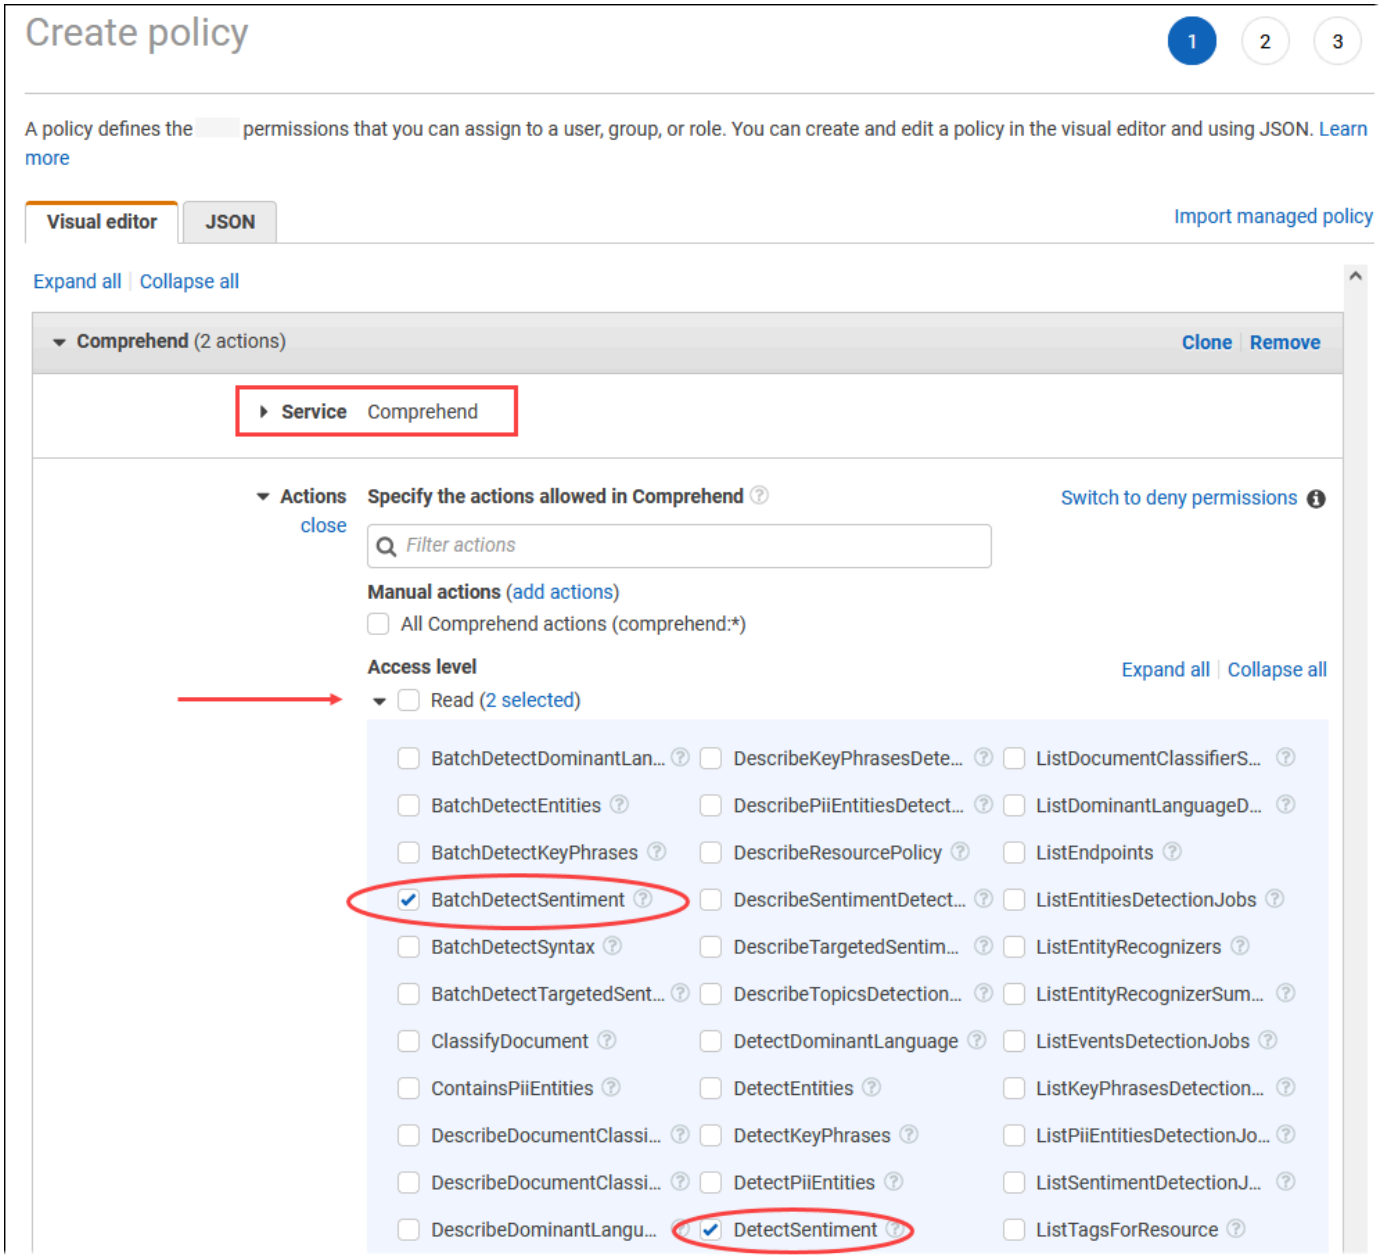
4. Choose **Next: Tags** and define any tags (this is optional). Choose **Next: Review**. Enter a Name for the policy and description, as shown in the image.



5. Choose **Create policy**. The Console displays an alert when the policy has been saved. You can find it in the list of Policies.
6. Choose **Roles** (under Access management) on the IAM Console.
7. Choose **Create role**.
8. On the Select trusted entity page, choose the **Amazon service** tile, and then choose **RDS** to open the selector.
9. Choose **RDS – Add Role to Database**.

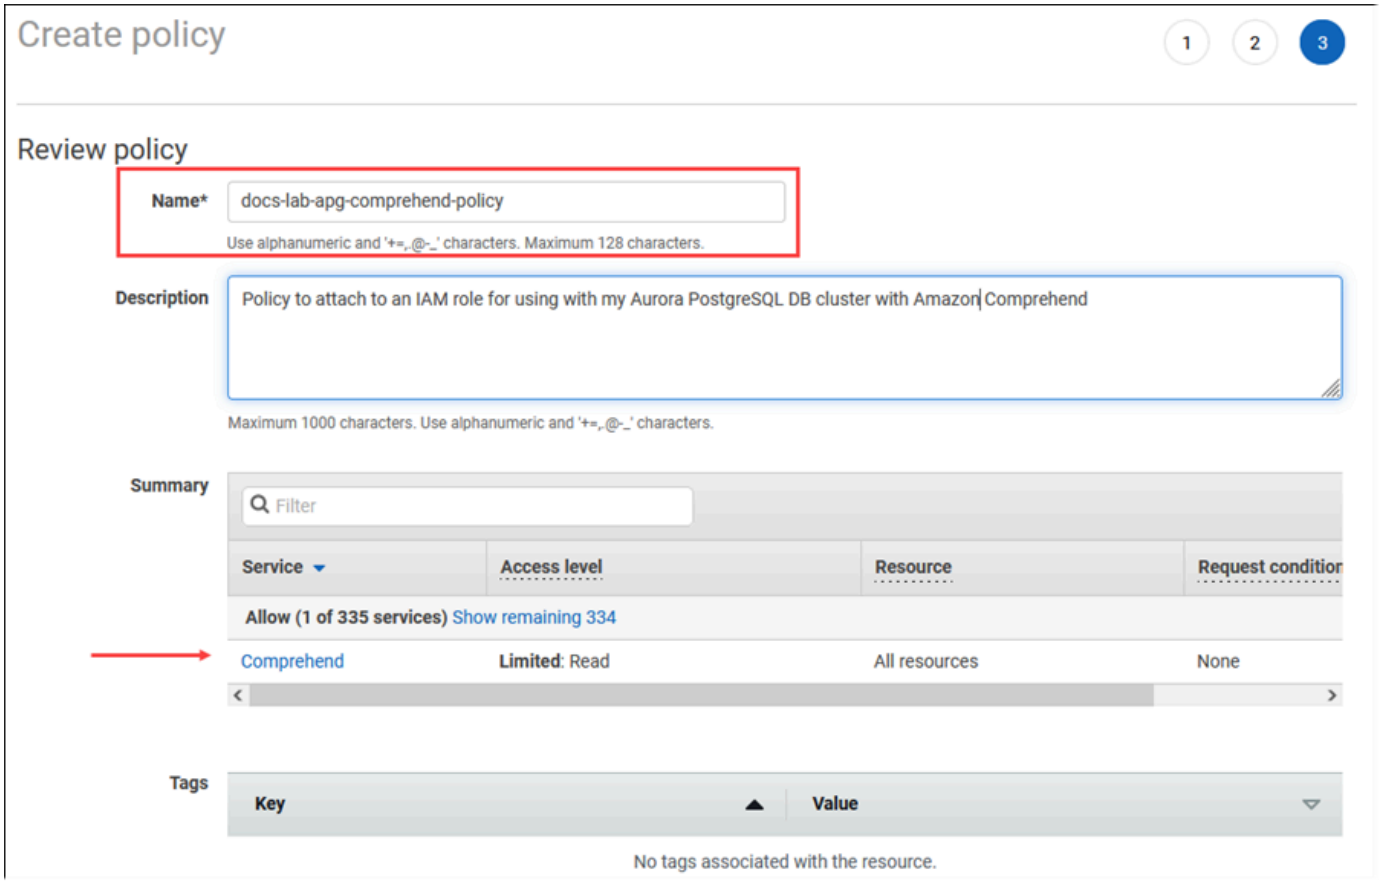
10. Choose **Next**. On the Add permissions page, find the policy that you created in the previous step and choose it from among those listed. Choose **Next**.
11. **Next: Review**. Enter a name for the IAM role and a description.
12. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.
13. Navigate to the Amazon Web Services Region where your Aurora PostgreSQL DB cluster is located.
14. In the navigation pane, choose **Databases**, and then choose the Aurora PostgreSQL DB cluster that you want to use with Bedrock.
15. Choose the **Connectivity & security** tab and scroll to find the **Manage IAM roles** section of the page. From the **Add IAM roles to this cluster** selector, choose the role that you created in the previous steps. In the **Feature** selector, choose Bedrock, and then choose **Add role**.

The role (with its policy) are associated with the Aurora PostgreSQL DB cluster. When the process completes, the role is listed in the Current IAM roles for this cluster listing, as shown following.



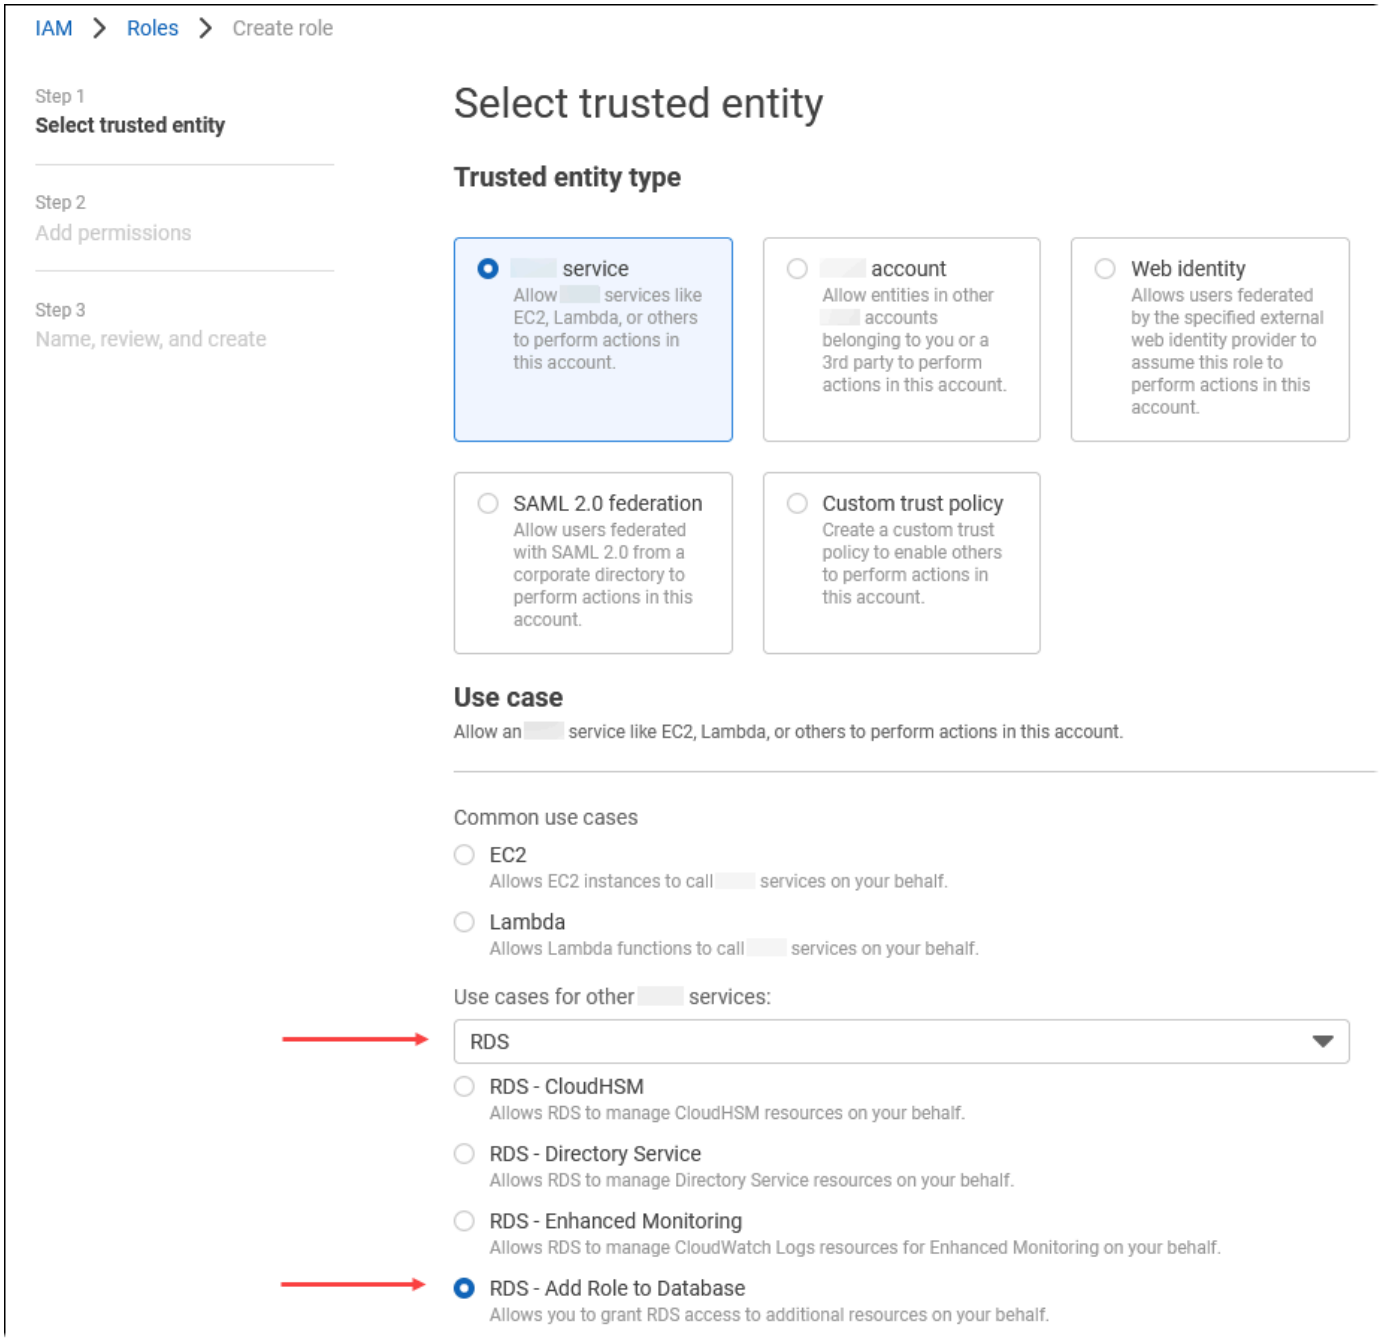
The IAM setup for Amazon Bedrock is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in Installing the Aurora machine learning extension

Setting up Aurora PostgreSQL to use Amazon Comprehend



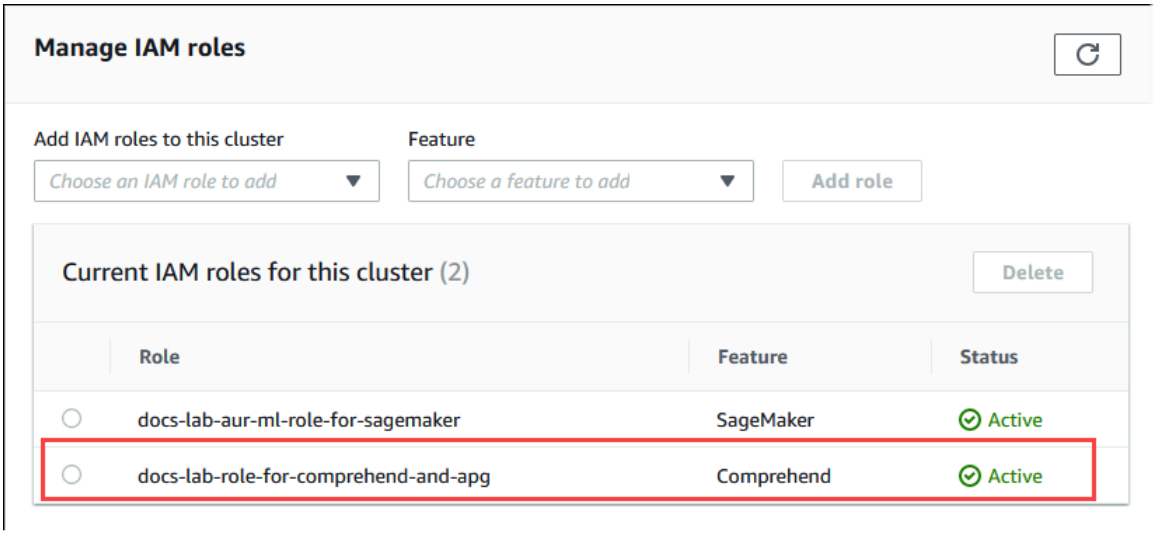
In the procedure following, you first create the IAM role and policy that gives your Aurora PostgreSQL permission to use Amazon Comprehend on the cluster's behalf. You then attach the policy to an IAM role that your Aurora PostgreSQL DB cluster uses to work with Amazon Comprehend For simplicity's sake, this procedure uses the Amazon Web Services Management Console to complete all tasks.

To set up your Aurora PostgreSQL DB cluster to use Amazon Comprehend



1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. Open the IAM console at https://console.amazonaws.cn/iam/.
3. Choose **Policies** (under Access management) on the Amazon Identity and Access Management (IAM) Console menu.

4. Choose **Create policy**. In the Visual editor page, choose **Service** and then enter **Comprehend** in the Select a service field. Expand the Read access level. Choose **BatchDetectSentiment** and **DetectSentiment** from the Amazon Comprehend read settings.
5. Choose **Next: Tags** and define any tags (this is optional). Choose **Next: Review**. Enter a Name for the policy and description, as shown in the image.



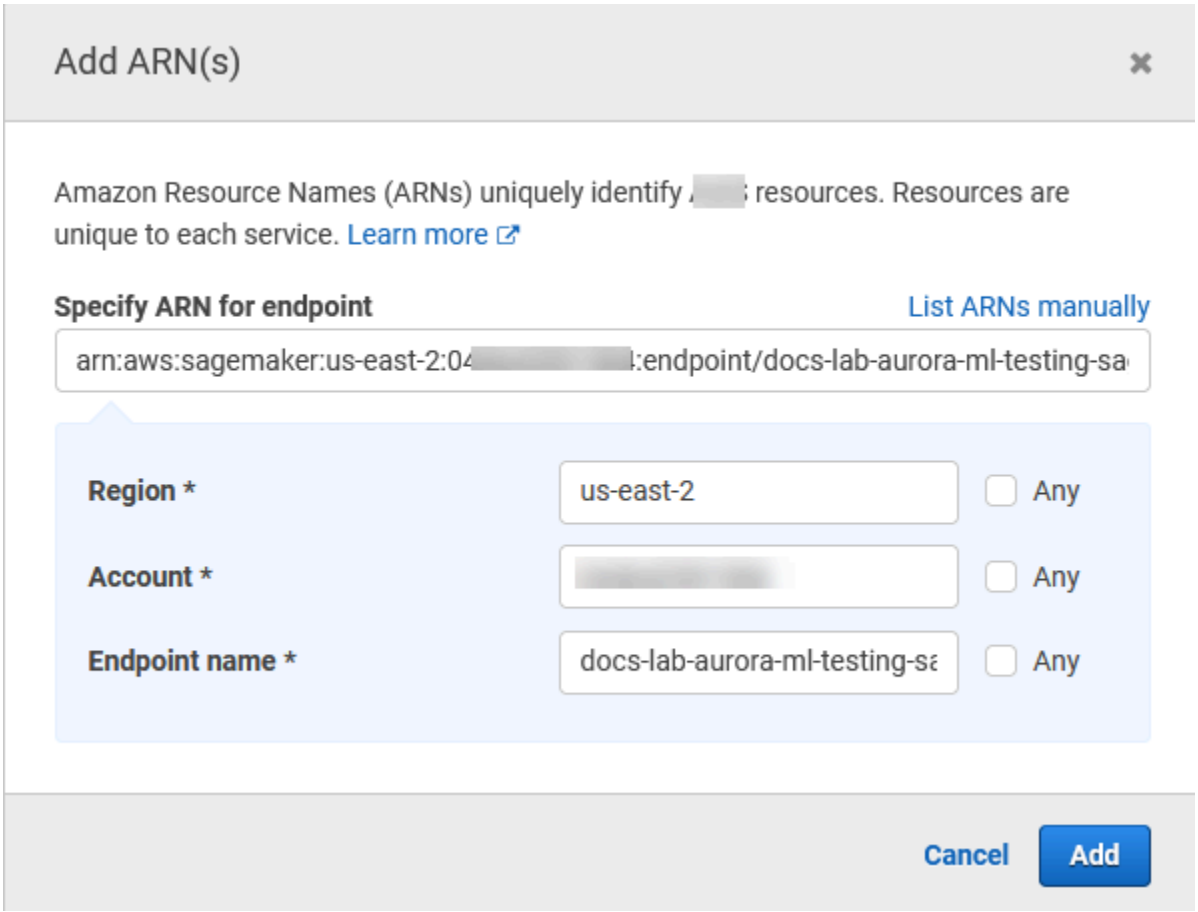
6. Choose **Create policy**. The Console displays an alert when the policy has been saved. You can find it in the list of Policies.
7. Choose **Roles** (under Access management) on the IAM Console.
8. Choose **Create role**.
9. On the Select trusted entity page, choose the **Amazon service** tile, and then choose **RDS** to open the selector.
10. Choose **RDS – Add Role to Database**.

11. Choose **Next**. On the Add permissions page, find the policy that you created in the previous step and choose it from among those listed. Choose **Next**
12. **Next: Review**. Enter a name for the IAM role and a description.
13. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.
14. Navigate to the Amazon Web Services Region where your Aurora PostgreSQL DB cluster is located.

15. In the navigation pane, choose **Databases**, and then choose the Aurora PostgreSQL DB cluster that you want to use with Amazon Comprehend.
16. Choose the **Connectivity & security** tab and scroll to find the **Manage IAM roles** section of the page. From the **Add IAM roles to this cluster** selector, choose the role that you created in the previous steps. In the **Feature** selector, choose Comprehend, and then choose **Add role**.

The role (with its policy) are associated with the Aurora PostgreSQL DB cluster. When the process completes, the role is listed in the Current IAM roles for this cluster listing, as shown following.

The IAM setup for Amazon Comprehend is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in Installing the Aurora machine learning extension



Setting up Aurora PostgreSQL to use Amazon SageMaker AI

Before you can create the IAM policy and role for your Aurora PostgreSQL DB cluster, you need to have your SageMaker AI model setup and your endpoint available.

To set up your Aurora PostgreSQL DB cluster to use SageMaker AI

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. Choose **Policies** (under Access management) on the Amazon Identity and Access Management (IAM) Console menu, and then choose **Create policy**. In the Visual editor, choose **SageMaker** for the Service. For Actions, open the Read selector (under Access level) and choose **InvokeEndpoint**. When you this, a warning icon displays.

3. Open the Resources selector and choose the **Add ARN to restrict access** link under the Specify endpoint resource ARN for the InvokeEndpoint action.
4. Enter the Amazon Web Services Region of your SageMaker AI resources and the name of your endpoint. Your Amazon account is prefilled.

5. Choose **Add** to save. Choose **Next: Tags** and **Next: Review** to get to the last page of the policy creation process.
6. Enter a Name and Description for this policy, and then choose **Create policy**. The policy is created and is added to the Policies list. You see an alert in the Console as this occurs.
7. On the IAM Console, choose **Roles**.
8. Choose **Create role**.
9. On the Select trusted entity page, choose the **Amazon service** tile, and then choose **RDS** to open the selector.
10. Choose **RDS – Add Role to Database**.
11. Choose **Next**. On the Add permissions page, find the policy that you created in the previous step and choose it from among those listed. Choose **Next**

12. **Next: Review**. Enter a name for the IAM role and a description.
13. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.
14. Navigate to the Amazon Web Services Region where your Aurora PostgreSQL DB cluster is located.
15. In the navigation pane, choose **Databases**, and then choose the Aurora PostgreSQL DB cluster that you want to use with SageMaker AI.
16. Choose the **Connectivity & security** tab and scroll to find the **Manage IAM roles** section of the page. From the **Add IAM roles to this cluster** selector, choose the role that you created in the previous steps. In the **Feature** selector, choose SageMaker AI, and then choose **Add role**.

The role (with its policy) are associated with the Aurora PostgreSQL DB cluster. When the process completes, the role is listed in the Current IAM roles for this cluster listing.

The IAM setup for SageMaker AI is complete. Continue setting up your Aurora PostgreSQL to work with Aurora machine learning by installing the extension as detailed in Installing the Aurora machine learning extension.

Setting up Aurora PostgreSQL to use Amazon S3 for SageMaker AI (Advanced)

To use SageMaker AI with your own models rather than using the pre-built components provided by SageMaker AI, you need to set up an Amazon Simple Storage Service (Amazon S3) bucket for Aurora PostgreSQL DB cluster to use. This is an advanced topic, and isn't fully documented in this *Amazon Aurora User Guide*. The general process is the same as for integrating support for SageMaker AI, as follows.

1. Create the IAM policy and role for Amazon S3.
2. Add the IAM role and the Amazon S3 import or export as a feature on the Connectivity & security tab of your Aurora PostgreSQL DB cluster.
3. Add the ARN of the role to your custom DB cluster parameter group for your Aurora DB cluster.

For basic usage information, see Exporting data to Amazon S3 for SageMaker AI model training (Advanced).

Installing the Aurora machine learning extension

The Aurora machine learning extensions `aws_ml 1.0` provides two functions that you can use to invoke Amazon Comprehend, SageMaker AI services and `aws_ml 2.0` provides two additional

functions that you can use to invoke Amazon Bedrock services. Installing these extensions on your Aurora PostgreSQL DB cluster also creates an administrative role for the feature.

> **Note**
>
> Using these functions depends on having the IAM setup for the Aurora machine learning service (Amazon Comprehend, SageMaker AI, Amazon Bedrock) complete, as detailed in Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning.

- **aws_comprehend.detect_sentiment** – You use this function to apply sentiment analysis to text stored in in the database on your Aurora PostgreSQL DB cluster.
- **aws_sagemaker.invoke_endpoint** – You use this function in your SQL code to communicate with the SageMaker AI endpoint from your cluster.
- **aws_bedrock.invoke_model** – You use this function in your SQL code to communicate with the Bedrock Models from your cluster. The response of this function will be in the format of a TEXT, so if a model responds in the format of a JSON body then the output of this function will be relayed in the format of a string to the end user.
- **aws_bedrock.invoke_model_get_embeddings** – You use this function in your SQL code to invoke Bedrock Models that return output embeddings within a JSON response. This can be leveraged when you want to extract the embeddings directly associated with the json-key to streamline the response with any self-managed workflows.

To install the Aurora machine learning extension in your Aurora PostgreSQL DB cluster

- Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster. Connect to the specific database in which to install the `aws_ml` extension.

```
psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --
port=5432 --username=postgres --password --dbname=labdb
```

```
labdb=> CREATE EXTENSION IF NOT EXISTS aws_ml CASCADE;
NOTICE:  installing required extension "aws_commons"
CREATE EXTENSION
labdb=>
```

Installing the aws_ml extensions also creates the aws_ml administrative role and three new schemas, as follows.

- aws_comprehend – Schema for the Amazon Comprehend service and source of the detect_sentiment function (aws_comprehend.detect_sentiment).
- aws_sagemaker – Schema for the SageMaker AI service and source of the invoke_endpoint function (aws_sagemaker.invoke_endpoint).
- aws_bedrock – Schema for the Amazon Bedrock service and source of the invoke_model(aws_bedrock.invoke_model) and invoke_model_get_embeddings(aws_bedrock.invoke_model_get_embeddings) functions.

The rds_superuser role is granted the aws_ml administrative role and is made the OWNER of these three Aurora machine learning schemas. To allow other database users to access the Aurora machine learning functions, the rds_superuser needs to grant EXECUTE privileges on the Aurora machine learning functions. By default, EXECUTE privileges are revoked from PUBLIC on the functions in the two Aurora machine learning schemas.

In a multi-tenant database configuration, you can prevent tenants from accessing Aurora machine learning functions by using REVOKE USAGE on the specific Aurora machine learning schema that you want to protect.

Using Amazon Bedrock with your Aurora PostgreSQL DB cluster

For Aurora PostgreSQL, Aurora machine learning provides the following Amazon Bedrock function for working with your text data. This function is available only after you install the aws_ml 2.0 extension and complete all setup procedures. For more information, see Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning.

aws_bedrock.invoke_model

This function takes text formatted in JSON as input and processes it for variety of models hosted on Amazon Bedrock and gets back the JSON text response from the model. This response could contain text, image, or embeddings. A summary of the function's documentation is as follows.

```
aws_bedrock.invoke_model(
   IN model_id      varchar,
```

```
    IN content_type  text,
    IN accept_type   text,
    IN model_input   text,
    OUT model_output varchar)
```

The inputs and outputs of this function are as follows.

- `model_id` – Identifier of the model.
- `content_type` – The type of the request to Bedrock's model.
- `accept_type` – The type of the response to expect from Bedrock's model. Usually application/JSON for most of the models.
- `model_input` – Prompts; a specific set of inputs to the model in the format as specified by content_type. For more information on the request format/structure the model accepts, see Inference parameters for foundation models.
- `model_output` – The Bedrock model's output as text.

The following example shows how to invoke a Anthropic Claude 2 model for Bedrock using invoke_model.

Example: A simple query using Amazon Bedrock functions

```
SELECT aws_bedrock.invoke_model (
    model_id    := 'anthropic.claude-v2',
    content_type:= 'application/json',
    accept_type := 'application/json',
    model_input := '{"prompt": "\n\nHuman: You are a helpful assistant that answers
 questions directly and only using the information provided in the context below.
\nDescribe the answer
    in detail.\n\nContext: %s \n\nQuestion: %s \n
\nAssistant:","max_tokens_to_sample":4096,"temperature":0.5,"top_k":250,"top_p":0.5,"stop_seque
[]}'
);
```

aws_bedrock.invoke_model_get_embeddings

The model output can point to vector embeddings for some cases. Given the response varies per model, another function invoke_model_get_embeddings can be leveraged which works exactly like invoke_model but outputs the embeddings by specifying the appropriate json-key.

```
aws_bedrock.invoke_model_get_embeddings(
   IN model_id      varchar,
   IN content_type  text,
   IN json_key      text,
   IN model_input   text,
   OUT model_output float8[])
```

The inputs and outputs of this function are as follows.

- `model_id` – Identifier of the model.
- `content_type` – The type of the request to Bedrock's model. Here, the accept_type is set to default value `application/json`.
- `model_input` – Prompts; a specific set of inputs to the Model in the format as specified by content_type. For more information on the request format/structure the Model accepts, see Inference parameters for foundation models.
- `json_key` – Reference to the field to extract the embedding from. This may vary if the embedding model changes.
- `model_output` – The Bedrock model's output as an array of embeddings having 16 bit decimals.

The following example shows how to generate an embedding using the Titan Embeddings G1 – Text embedding model for the phrase PostgreSQL I/O monitoring views.

Example: A simple query using Amazon Bedrock functions

```
SELECT aws_bedrock.invoke_model_get_embeddings(
   model_id      := 'amazon.titan-embed-text-v1',
   content_type  := 'application/json',
   json_key      := 'embedding',
   model_input   := '{ "inputText": "PostgreSQL I/O monitoring views"}') AS embedding;
```

Using Amazon Comprehend with your Aurora PostgreSQL DB cluster

For Aurora PostgreSQL, Aurora machine learning provides the following Amazon Comprehend function for working with your text data. This function is available only after you install the `aws_ml` extension and complete all setup procedures. For more information, see Setting up your Aurora PostgreSQL DB cluster to use Aurora machine learning.

aws_comprehend.detect_sentiment

This function takes text as input and evaluates whether the text has a a positive, negative, neutral, or mixed emotional posture. It outputs this sentiment along with a confidence level for its evaluation. A summary of the function's documentation is as follows.

```
aws_comprehend.detect_sentiment(
   IN input_text varchar,
   IN language_code varchar,
   IN max_rows_per_batch int,
   OUT sentiment varchar,
   OUT confidence real)
```

The inputs and outputs of this function are as follows.

- `input_text` – The text to evaluate and to assign sentiment (negative, positive, neutral, mixed).
- `language_code` – The language of the `input_text` identified using the 2-letter ISO 639-1 identifier with regional subtag (as needed) or the ISO 639-2 three-letter code, as appropriate. For example, `en` is the code for English, `zh` is the code for simplified Chinese. For more information, see Supported languages in the *Amazon Comprehend Developer Guide*.
- `max_rows_per_batch` – The maximum number of rows per batch for batch-mode processing. For more information, see Understanding batch mode and Aurora machine learning functions.
- `sentiment` – The sentiment of the input text, identified as POSITIVE, NEGATIVE, NEUTRAL, or MIXED.
- `confidence` – The degree of confidence in the accuracy of the specified `sentiment`. Values range from 0.0 to 1.0.

In the following, you can find examples of how to use this function.

Example: A simple query using Amazon Comprehend functions

Here's an example of a simple query that invokes this function to assess customer satisfaction with your support team. Suppose you have a database table (`support`) that stores customer feedback after each request for help. This example query applies the `aws_comprehend.detect_sentiment` function to the text in the `feedback` column of the table and outputs the sentiment and the confidence level for that sentiment. This query also outputs results in descending order.

```
SELECT feedback, s.sentiment,s.confidence
    FROM support,aws_comprehend.detect_sentiment(feedback, 'en') s
    ORDER BY s.confidence DESC;
 feedback                          | sentiment | confidence
 ------------------------------------------------------------+-----------+------------
 Thank you for the excellent customer support!              | POSITIVE  |   0.999771
 The latest version of this product stinks!                 | NEGATIVE  |   0.999184
 Your support team is just awesome! I am blown away.        | POSITIVE  |   0.997774
 Your product is too complex, but your support is great.    | MIXED     |   0.957958
 Your support tech helped me in fifteen minutes.            | POSITIVE  |   0.949491
 My problem was never resolved!                             | NEGATIVE  |   0.920644
 When will the new version of this product be released?     | NEUTRAL   |   0.902706
 I cannot stand that chatbot.                               | NEGATIVE  |   0.895219
 Your support tech talked down to me.                       | NEGATIVE  |   0.868598
 It took me way too long to get a real person.              | NEGATIVE  |   0.481805

 (10 rows)
```

To avoid being charged for sentiment detection more than once per table row, you can materialize the results. Do this on the rows of interest. For example, the clinician's notes are being updated so that only those in French (`fr`) use the sentiment detection function.

```
UPDATE clinician_notes
SET sentiment = (aws_comprehend.detect_sentiment (french_notes, 'fr')).sentiment,
    confidence = (aws_comprehend.detect_sentiment (french_notes, 'fr')).confidence
WHERE
    clinician_notes.french_notes IS NOT NULL AND
    LENGTH(TRIM(clinician_notes.french_notes)) > 0 AND
    clinician_notes.sentiment IS NULL;
```

For more information on optimizing your function calls, see Performance considerations for using Aurora machine learning with Aurora PostgreSQL.

Using SageMaker AI with your Aurora PostgreSQL DB cluster

After setting up your SageMaker AI environment and integrating with Aurora PostgreSQL as outlined in Setting up Aurora PostgreSQL to use Amazon SageMaker AI, you can invoke operations by using the `aws_sagemaker.invoke_endpoint` function. The `aws_sagemaker.invoke_endpoint` function connects only to a model endpoint in the same Amazon Web Services Region. If your database instance has replicas in multiple Amazon Web

Services Regions be sure that you setup and deploy each SageMaker AI model to every Amazon Web Services Region.

Calls to `aws_sagemaker.invoke_endpoint` are authenticated using the IAM role that you set up to associated your Aurora PostgreSQL DB cluster with the SageMaker AI service and the endpoint that you provided during the setup process. SageMaker AI model endpoints are scoped to an individual account and are not public. The `endpoint_name` URL doesn't contain the account ID. SageMaker AI determines the account ID from the authentication token that is supplied by the SageMaker AI IAM role of the database instance.

aws_sagemaker.invoke_endpoint

This function takes the SageMaker AI endpoint as input and the number of rows that should be processed as a batch. It also takes as input the various parameters expected by the SageMaker AI model endpoint. This function's reference documentation is as follows.

```
aws_sagemaker.invoke_endpoint(
  IN endpoint_name varchar,
  IN max_rows_per_batch int,
  VARIADIC model_input "any",
  OUT model_output varchar
  )
```

The inputs and outputs of this function are as follows.

- `endpoint_name` – An endpoint URL that is Amazon Web Services Region–independent.
- `max_rows_per_batch` – The maximum number of rows per batch for batch-mode processing. For more information, see Understanding batch mode and Aurora machine learning functions.
- `model_input` – One or more input parameters for the model. These can be any data type needed by the SageMaker AI model. PostgreSQL allows you to specify up to 100 input parameters for a function. Array data types must be one-dimensional, but can contain as many elements as are expected by the SageMaker AI model. The number of inputs to a SageMaker AI model is limited only by the SageMaker AI 6 MB message size limit.
- `model_output` – The SageMaker AI model's output as text.

Creating a user-defined function to invoke a SageMaker AI model

Create a separate user-defined function to call `aws_sagemaker.invoke_endpoint` for each of your SageMaker AI models. Your user-defined function represents the SageMaker AI endpoint hosting the model. The `aws_sagemaker.invoke_endpoint` function runs within the user-defined function. User-defined functions provide many advantages:

- You can give your SageMaker AI model its own name instead of only calling `aws_sagemaker.invoke_endpoint` for all of your SageMaker AI models.
- You can specify the model endpoint URL in just one place in your SQL application code.
- You can control `EXECUTE` privileges to each Aurora machine learning function independently.
- You can declare the model input and output types using SQL types. SQL enforces the number and type of arguments passed to your SageMaker AI model and performs type conversion if necessary. Using SQL types will also translate SQL `NULL` to the appropriate default value expected by your SageMaker AI model.
- You can reduce the maximum batch size if you want to return the first few rows a little faster.

To specify a user-defined function, use the SQL data definition language (DDL) statement `CREATE FUNCTION`. When you define the function, you specify the following:

- The input parameters to the model.
- The specific SageMaker AI endpoint to invoke.
- The return type.

The user-defined function returns the inference computed by the SageMaker AI endpoint after running the model on the input parameters. The following example creates a user-defined function for an SageMaker AI model with two input parameters.

```
CREATE FUNCTION classify_event (IN arg1 INT, IN arg2 DATE, OUT category INT)
AS $$
    SELECT aws_sagemaker.invoke_endpoint (
        'sagemaker_model_endpoint_name', NULL,
        arg1, arg2                        -- model inputs are separate arguments
        )::INT                            -- cast the output to INT
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

- The `aws_sagemaker.invoke_endpoint` function input can be one or more parameters of any data type.
- This example uses an INT output type. If you cast the output from a `varchar` type to a different type, then it must be cast to a PostgreSQL builtin scalar type such as `INTEGER`, `REAL`, `FLOAT`, or `NUMERIC`. For more information about these types, see Data types in the PostgreSQL documentation.
- Specify `PARALLEL SAFE` to enable parallel query processing. For more information, see Improving response times with parallel query processing.
- Specify `COST 5000` to estimate the cost of running the function. Use a positive number giving the estimated run cost for the function, in units of `cpu_operator_cost`.

Passing an array as input to a SageMaker AI model

The `aws_sagemaker.invoke_endpoint` function can have up to 100 input parameters, which is the limit for PostgreSQL functions. If the SageMaker AI model requires more than 100 parameters of the same type, pass the model parameters as an array.

The following example defines a function that passes an array as input to the SageMaker AI regression model. The output is cast to a `REAL` value.

```
CREATE FUNCTION regression_model (params REAL[], OUT estimate REAL)
AS $$
    SELECT aws_sagemaker.invoke_endpoint (
      'sagemaker_model_endpoint_name',
      NULL,
      params
      )::REAL
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Specifying batch size when invoking a SageMaker AI model

The following example creates a user-defined function for a SageMaker AI model that sets the batch size default to NULL. The function also allows you to provide a different batch size when you invoke it.

```
CREATE FUNCTION classify_event (
    IN event_type INT, IN event_day DATE, IN amount REAL, -- model inputs
    max_rows_per_batch INT DEFAULT NULL,  -- optional batch size limit
    OUT category INT)                     -- model output
```

```
AS $$
    SELECT aws_sagemaker.invoke_endpoint (
        'sagemaker_model_endpoint_name', max_rows_per_batch,
        event_type, event_day, COALESCE(amount, 0.0)
        )::INT              -- casts output to type INT
$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

Note the following:

- Use the optional `max_rows_per_batch` parameter to provide control of the number of rows for a batch-mode function invocation. If you use a value of NULL, then the query optimizer automatically chooses the maximum batch size. For more information, see Understanding batch mode and Aurora machine learning functions.
- By default, passing NULL as a parameter's value is translated to an empty string before passing to SageMaker AI. For this example the inputs have different types.
- If you have a non-text input, or text input that needs to default to some value other than an empty string, use the `COALESCE` statement. Use `COALESCE` to translate NULL to the desired null replacement value in the call to `aws_sagemaker.invoke_endpoint`. For the `amount` parameter in this example, a NULL value is converted to 0.0.

Invoking a SageMaker AI model that has multiple outputs

The following example creates a user-defined function for a SageMaker AI model that returns multiple outputs. Your function needs to cast the output of the `aws_sagemaker.invoke_endpoint` function to a corresponding data type. For example, you could use the built-in PostgreSQL point type for (x,y) pairs or a user-defined composite type.

This user-defined function returns values from a model that returns multiple outputs by using a composite type for the outputs.

```
CREATE TYPE company_forecasts AS (
    six_month_estimated_return real,
    one_year_bankruptcy_probability float);
CREATE FUNCTION analyze_company (
    IN free_cash_flow NUMERIC(18, 6),
    IN debt NUMERIC(18,6),
    IN max_rows_per_batch INT DEFAULT NULL,
    OUT prediction company_forecasts)
AS $$
```

```
    SELECT (aws_sagemaker.invoke_endpoint('endpt_name',
       max_rows_per_batch,free_cash_flow, debt))::company_forecasts;

$$ LANGUAGE SQL PARALLEL SAFE COST 5000;
```

For the composite type, use fields in the same order as they appear in the model output and cast the output of `aws_sagemaker.invoke_endpoint` to your composite type. The caller can extract the individual fields either by name or with PostgreSQL ".*" notation.

Exporting data to Amazon S3 for SageMaker AI model training (Advanced)

We recommend that you become familiar with Aurora machine learning and SageMaker AI by using the provided algorithms and examples rather than trying to train your own models. For more information, see Get Started with Amazon SageMaker AI

To train SageMaker AI models, you export data to an Amazon S3 bucket. The Amazon S3 bucket is used by SageMaker AI to train your model before it is deployed. You can query data from an Aurora PostgreSQL DB cluster and save it directly into text files stored in an Amazon S3 bucket. Then SageMaker AI consumes the data from the Amazon S3 bucket for training. For more about SageMaker AI model training, see Train a model with Amazon SageMaker AI.

> **Note**
>
> When you create an Amazon S3 bucket for SageMaker AI model training or batch scoring, use `sagemaker` in the Amazon S3 bucket name. For more information, see Specify a Amazon S3 Bucket to Upload Training Datasets and Store Output Data in the *Amazon SageMaker AI Developer Guide*.

For more information about exporting your data, see Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3.

Performance considerations for using Aurora machine learning with Aurora PostgreSQL

The Amazon Comprehend and SageMaker AI services do most of the work when invoked by an Aurora machine learning function. That means that you can scale those resources as needed,

independently. For your Aurora PostgreSQL DB cluster, you can make your function calls as efficient as possible. Following, you can find some performance considerations to note when working with Aurora machine learning from Aurora PostgreSQL.

Topics

- Understanding batch mode and Aurora machine learning functions
- Improving response times with parallel query processing
- Using materialized views and materialized columns

Understanding batch mode and Aurora machine learning functions

Typically, PostgreSQL runs functions one row at a time. Aurora machine learning can reduce this overhead by combining the calls to the external Aurora machine learning service for many rows into batches with an approach called *batch-mode execution*. In batch mode, Aurora machine learning receives the responses for a batch of input rows, and then delivers the responses back to the running query one row at a time. This optimization improves the throughput of your Aurora queries without limiting the PostgreSQL query optimizer.

Aurora automatically uses batch mode if the function is referenced from the `SELECT` list, a `WHERE` clause, or a `HAVING` clause. Note that top-level simple `CASE` expressions are eligible for batch-mode execution. Top-level searched `CASE` expressions are also eligible for batch-mode execution provided that the first `WHEN` clause is a simple predicate with a batch-mode function call.

Your user-defined function must be a `LANGUAGE SQL` function and should specify `PARALLEL SAFE` and `COST 5000`.

Function migration from the SELECT statement to the FROM clause

Usually, an `aws_ml` function that is eligible for batch-mode execution is automatically migrated by Aurora to the `FROM` clause.

The migration of eligible batch-mode functions to the FROM clause can be examined manually on a per-query level. To do this, you use EXPLAIN statements (and ANALYZE and VERBOSE) and find the "Batch Processing" information below each batch-mode `Function Scan`. You can also use EXPLAIN (with VERBOSE) without running the query. You then observe whether the calls to the function appear as a `Function Scan` under a nested loop join that was not specified in the original statement.

In the following example, the nested loop join operator in the plan shows that Aurora migrated the anomaly_score function. It migrated this function from the SELECT list to the FROM clause, where it's eligible for batch-mode execution.

```
EXPLAIN (VERBOSE, COSTS false)
SELECT anomaly_score(ts.R.description) from ts.R;
                         QUERY PLAN
-------------------------------------------------------------
 Nested Loop
   Output: anomaly_score((r.description)::text)
   ->  Seq Scan on ts.r
         Output: r.id, r.description, r.score
   ->  Function Scan on public.anomaly_score
         Output: anomaly_score.anomaly_score
         Function Call: anomaly_score((r.description)::text)
```

To disable batch-mode execution, set the apg_enable_function_migration parameter to false. This prevents the migration of aws_ml functions from the SELECT to the FROM clause. The following shows how.

```
SET apg_enable_function_migration = false;
```

The apg_enable_function_migration parameter is a Grand Unified Configuration (GUC) parameter that is recognized by the Aurora PostgreSQL apg_plan_mgmt extension for query plan management. To disable function migration in a session, use query plan management to save the resulting plan as an approved plan. At runtime, query plan management enforces the approved plan with its apg_enable_function_migration setting. This enforcement occurs regardless of the apg_enable_function_migration GUC parameter setting. For more information, see Managing query execution plans for Aurora PostgreSQL.

Using the max_rows_per_batch parameter

Both the aws_comprehend.detect_sentiment and the aws_sagemaker.invoke_endpoint functions have a max_rows_per_batch parameter. This parameter specifies the number of rows that can be sent to the Aurora machine learning service. The larger the dataset processed by your function, the larger you can make the batch size.

Batch-mode functions improve efficiency by building batches of rows that spread the cost of the Aurora machine learning function calls over a large number of rows. However, if a SELECT

statement finishes early due to a LIMIT clause, then the batch can be constructed over more rows than the query uses. This approach can result in additional charges to your Amazon account. To gain the benefits of batch-mode execution but avoid building batches that are too large, use a smaller value for the max_rows_per_batch parameter in your function calls.

If you do an EXPLAIN (VERBOSE, ANALYZE) of a query that uses batch-mode execution, you see a FunctionScan operator that is below a nested loop join. The number of loops reported by EXPLAIN equals the number of times a row was fetched from the FunctionScan operator. If a statement uses a LIMIT clause, the number of fetches is consistent. To optimize the size of the batch, set the max_rows_per_batch parameter to this value. However, if the batch-mode function is referenced in a predicate in the WHERE clause or HAVING clause, then you probably can't know the number of fetches in advance. In this case, use the loops as a guideline and experiment with max_rows_per_batch to find a setting that optimizes performance.

Verifying batch-mode execution

To see if a function ran in batch mode, use EXPLAIN ANALYZE. If batch-mode execution was used, then the query plan will include the information in a "Batch Processing" section.

```
EXPLAIN ANALYZE SELECT user-defined-function();
 Batch Processing: num batches=1 avg/min/max batch size=3333.000/3333.000/3333.000
                                 avg/min/max batch call time=146.273/146.273/146.273
```

In this example, there was 1 batch that contained 3,333 rows, which took 146.273 ms to process. The "Batch Processing" section shows the following:

- How many batches there were for this function scan operation
- The batch size average, minimum, and maximum
- The batch execution time average, minimum, and maximum

Typically the final batch is smaller than the rest, which often results in a minimum batch size that is much smaller than the average.

To return the first few rows more quickly, set the max_rows_per_batch parameter to a smaller value.

To reduce the number of batch mode calls to the ML service when you use a LIMIT in your user-defined function, set the max_rows_per_batch parameter to a smaller value.

Improving response times with parallel query processing

To get results as fast as possible from a large number of rows, you can combine parallel query processing with batch mode processing. You can use parallel query processing for `SELECT`, `CREATE TABLE AS SELECT`, and `CREATE MATERIALIZED VIEW` statements.

> **Note**
>
> PostgreSQL doesn't yet support parallel query for data manipulation language (DML) statements.

Parallel query processing occurs both within the database and within the ML service. The number of cores in the instance class of the database limits the degree of parallelism that can be used when running a query. The database server can construct a parallel query execution plan that partitions the task among a set of parallel workers. Then each of these workers can build batched requests containing tens of thousands of rows (or as many as are allowed by each service).

The batched requests from all of the parallel workers are sent to the SageMaker AI endpoint. The degree of parallelism that the endpoint can support is constrained by the number and type of instances that support it. For *K* degrees of parallelism, you need a database instance class that has at least *K* cores. You also need to configure the SageMaker AI endpoint for your model to have *K* initial instances of a sufficiently high-performing instance class.

To use parallel query processing, you can set the `parallel_workers` storage parameter of the table that contains the data that you plan to pass. You set `parallel_workers` to a batch-mode function such as `aws_comprehend.detect_sentiment`. If the optimizer chooses a parallel query plan, the Amazon ML services can be called both in batch and in parallel.

You can use the following parameters with the `aws_comprehend.detect_sentiment` function to get a plan with four-way parallelism. If you change either of the following two parameters, you must restart the database instance for the changes to take effect

```
-- SET max_worker_processes to 8;  -- default value is 8
-- SET max_parallel_workers to 8;  -- not greater than max_worker_processes
SET max_parallel_workers_per_gather to 4;  -- not greater than max_parallel_workers

-- You can set the parallel_workers storage parameter on the table that the data
```

```
-- for the Aurora machine learning function is coming from in order to manually
 override the degree of
-- parallelism that would otherwise be chosen by the query optimizer
--
ALTER TABLE yourTable SET (parallel_workers = 4);

-- Example query to exploit both batch-mode execution and parallel query
EXPLAIN (verbose, analyze, buffers, hashes)
SELECT aws_comprehend.detect_sentiment(description, 'en')).*
FROM yourTable
WHERE id < 100;
```

For more information about controlling parallel query, see Parallel plans in the PostgreSQL documentation.

Using materialized views and materialized columns

When you invoke an Amazon service such as SageMaker AI or Amazon Comprehend from your database, your account is charged according to the pricing policy of that service. To minimize charges to your account, you can materialize the result of calling the Amazon service into a materialized column so that the Amazon service is not called more than once per input row. If desired, you can add a `materializedAt` timestamp column to record the time at which the columns were materialized.

The latency of an ordinary single-row `INSERT` statement is typically much less than the latency of calling a batch-mode function. Thus, you might not be able to meet the latency requirements of your application if you invoke the batch-mode function for every single-row `INSERT` that your application performs. To materialize the result of calling an Amazon service into a materialized column, high-performance applications generally need to populate the materialized columns. To do this, they periodically issue an `UPDATE` statement that operates on a large batch of rows at the same time.

`UPDATE` takes a row-level lock that can impact a running application. So you might need to use `SELECT ... FOR UPDATE SKIP LOCKED`, or use `MATERIALIZED VIEW`.

Analytic queries that operate on a large number of rows in real time can combine batch-mode materialization with real-time processing. To do this, these queries assemble a `UNION ALL` of the pre-materialized results with a query over the rows that don't yet have materialized results. In some cases, such a `UNION ALL` is needed in multiple places, or the query is generated by a third-

party application. If so, you can create a `VIEW` to encapsulate the `UNION ALL` operation so this detail isn't exposed to the rest of the SQL application.

You can use a materialized view to materialize the results of an arbitrary `SELECT` statement at a snapshot in time. You can also use it to refresh the materialized view at any time in the future. Currently PostgreSQL doesn't support incremental refresh, so each time the materialized view is refreshed the materialized view is fully recomputed.

You can refresh materialized views with the `CONCURRENTLY` option, which updates the contents of the materialized view without taking an exclusive lock. Doing this allows a SQL application to read from the materialized view while it's being refreshed.

Monitoring Aurora machine learning

You can monitor the `aws_ml` functions by setting the `track_functions` parameter in your custom DB cluster parameter group to `all`. By default, this parameter is set to `pl` which means that only procedure-language functions are tracked. By changing this to `all`, the `aws_ml` functions are also tracked. For more information, see Run-time Statistics in the PostgreSQL documentation.

For information about monitoring the performance of the SageMaker AI operations called from Aurora machine learning functions, see Monitor Amazon SageMaker AI in the *Amazon SageMaker AI Developer Guide*.

With `track_functions` set to `all`, you can query the `pg_stat_user_functions` view to get statistics about the functions that you define and use to invoke Aurora machine learning services. For each function, the view provides the number of `calls`, `total_time`, and `self_time`.

To view the statistics for the `aws_sagemaker.invoke_endpoint` and the `aws_comprehend.detect_sentiment` functions, you can filter results by schema name using the following query.

```
SELECT * FROM pg_stat_user_functions
    WHERE schemaname
    LIKE 'aws_%';
```

To clear the statistics, do as follows.

```
SELECT pg_stat_reset();
```

You can get the names of your SQL functions that call the `aws_sagemaker.invoke_endpoint` function by querying the PostgreSQL `pg_proc` system catalog. This catalog stores information about functions, procedures, and more. For more information, see pg_proc in the PostgreSQL documentation. Following is an example of querying the table to get the names of functions (`proname`) whose source (`prosrc`) includes the text *invoke_endpoint*.

```
SELECT proname FROM pg_proc WHERE prosrc LIKE '%invoke_endpoint%';
```

Code examples for Aurora using Amazon SDKs

The following code examples show how to use Aurora with an Amazon software development kit (SDK).

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

For a complete list of Amazon SDK developer guides and code examples, see Using this service with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Hello Aurora

The following code examples show how to get started using Aurora.

.NET

Amazon SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
using Amazon.RDS;
using Amazon.RDS.Model;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;

namespace AuroraActions;

public static class HelloAurora
{
    static async Task Main(string[] args)
    {
        // Use the AWS .NET Core Setup package to set up dependency injection for
 the
        // Amazon Relational Database Service (Amazon RDS).
        // Use your AWS profile name, or leave it blank to use the default
 profile.
        using var host = Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonRDS>()
            ).Build();

        // Now the client is available for injection. Fetching it directly here
 for example purposes only.
        var rdsClient = host.Services.GetRequiredService<IAmazonRDS>();

        // You can use await and any of the async methods to get a response.
```

```
        var response = await rdsClient.DescribeDBClustersAsync(new
 DescribeDBClustersRequest { IncludeShared = true });
        Console.WriteLine($"Hello Amazon RDS Aurora! Let's list some clusters in
 this account:");
        if (response.DBClusters == null)
        {
            Console.WriteLine($"\tNo clusters found.");
        }
        else
        {
            foreach (var cluster in response.DBClusters)
            {
                Console.WriteLine(
                    $"\tCluster: database: {cluster.DatabaseName} identifier:
 {cluster.DBClusterIdentifier}.");
            }
        }
    }
}
```

- For API details, see DescribeDBClusters in *Amazon SDK for .NET API Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Code for the CMakeLists.txt CMake file.

```
# Set the minimum required version of CMake for this project.
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS rds)

# Set this project's name.
```

```
project("hello_aurora")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed
 libraries for the AWS SDK.
    string(REPLACE ";" "/aws-cpp-sdk-all;" SYSTEM_MODULE_PATH
 "${CMAKE_SYSTEM_PREFIX_PATH}/aws-cpp-sdk-all")
    list(APPEND CMAKE_PREFIX_PATH ${SYSTEM_MODULE_PATH})
endif ()

# Find the AWS SDK for C++ package.
find_package(AWSSDK REQUIRED COMPONENTS ${SERVICE_COMPONENTS})

if (WINDOWS_BUILD AND AWSSDK_INSTALL_AS_SHARED_LIBS)
     # Copy relevant AWS SDK for C++ libraries into the current binary directory
 for running and debugging.

     # set(BIN_SUB_DIR "/Debug") # If you are building from the command line, you
 may need to uncomment this
                                     # and set the proper subdirectory to the
 executables' location.

     AWSSDK_CPY_DYN_LIBS(SERVICE_COMPONENTS ""
 ${CMAKE_CURRENT_BINARY_DIR}${BIN_SUB_DIR})
endif ()

add_executable(${PROJECT_NAME}
        hello_aurora.cpp)

target_link_libraries(${PROJECT_NAME}
        ${AWSSDK_LINK_LIBRARIES})
```

```
#include <aws/core/Aws.h>
#include <aws/rds/RDSClient.h>
```

```
#include <aws/rds/model/DescribeDBClustersRequest.h>
#include <iostream>

/*
 *  A "Hello Aurora" starter application which initializes an Amazon Relational
 Database Service (Amazon RDS) client
 *  and describes the Amazon Aurora (Aurora) clusters.
 *
 *  main function
 *
 *  Usage: 'hello_aurora'
 *
 */
int main(int argc, char **argv) {
    Aws::SDKOptions options;
    // Optionally change the log level for debugging.
//   options.loggingOptions.logLevel = Utils::Logging::LogLevel::Debug;
    Aws::InitAPI(options); // Should only be called once.
    int result = 0;
    {
        Aws::Client::ClientConfiguration clientConfig;
        // Optional: Set to the AWS Region (overrides config file).
        // clientConfig.region = "us-east-1";

        Aws::RDS::RDSClient rdsClient(clientConfig);

        Aws::String marker; // Used for pagination.
        std::vector<Aws::String> clusterIds;
        do {
            Aws::RDS::Model::DescribeDBClustersRequest request;

            Aws::RDS::Model::DescribeDBClustersOutcome outcome =
                    rdsClient.DescribeDBClusters(request);

            if (outcome.IsSuccess()) {
                for (auto &cluster: outcome.GetResult().GetDBClusters()) {
                    clusterIds.push_back(cluster.GetDBClusterIdentifier());
                }
                marker = outcome.GetResult().GetMarker();
            } else {
                result = 1;
                std::cerr << "Error with Aurora::GDescribeDBClusters. "
                          << outcome.GetError().GetMessage()
                          << std::endl;
```

```
                break;
            }
        } while (!marker.empty());

        std::cout << clusterIds.size() << " Aurora clusters found." << std::endl;
        for (auto &clusterId: clusterIds) {

For a complete list of Amazon SDK developer guides and code examples, see Using this service with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Learn the basics of Aurora with an Amazon SDK

The following code examples show how to:

- Create a custom Aurora DB cluster parameter group and set parameter values.
- Create a DB cluster that uses the parameter group.
- Create a DB instance that contains a database.
- Take a snapshot of the DB cluster, then clean up resources.

.NET

Amazon SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Run an interactive scenario at a command prompt.

```
using Amazon.RDS;
using Amazon.RDS.Model;
using AuroraActions;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;
using Microsoft.Extensions.Logging;
using Microsoft.Extensions.Logging.Console;
using Microsoft.Extensions.Logging.Debug;

namespace AuroraScenario;

/// <summary>
/// Scenario for Amazon Aurora examples.
/// </summary>
public class AuroraScenario
{
    /*
```

```
   Before running this .NET code example, set up your development environment,
including your credentials.

   This .NET example performs the following tasks:
   1.  Return a list of the available DB engine families for Aurora MySql using
the DescribeDBEngineVersionsAsync method.
   2.  Select an engine family and create a custom DB cluster parameter group
using the CreateDBClusterParameterGroupAsync method.
   3.  Get the parameter group using the DescribeDBClusterParameterGroupsAsync
method.
   4.  Get some parameters in the group using the
DescribeDBClusterParametersAsync method.
   5.  Parse and display some parameters in the group.
   6.  Modify the auto_increment_offset and auto_increment_increment parameters
       using the ModifyDBClusterParameterGroupAsync method.
   7.  Get and display the updated parameters using the
DescribeDBClusterParametersAsync method with a source of "user".
   8.  Get a list of allowed engine versions using the
DescribeDBEngineVersionsAsync method.
   9.  Create an Aurora DB cluster that contains a MySql database and uses the
parameter group.
       using the CreateDBClusterAsync method.
   10. Wait for the DB cluster to be ready using the DescribeDBClustersAsync
method.
   11. Display and select from a list of instance classes available for the
selected engine and version
       using the paginated DescribeOrderableDBInstanceOptions method.
   12. Create a database instance in the cluster using the CreateDBInstanceAsync
method.
   13. Wait for the DB instance to be ready using the DescribeDBInstances
method.
   14. Display the connection endpoint string for the new DB cluster.
   15. Create a snapshot of the DB cluster using the
CreateDBClusterSnapshotAsync method.
   16. Wait for DB snapshot to be ready using the
DescribeDBClusterSnapshotsAsync method.
   17. Delete the DB instance using the DeleteDBInstanceAsync method.
   18. Delete the DB cluster using the DeleteDBClusterAsync method.
   19. Wait for DB cluster to be deleted using the DescribeDBClustersAsync
methods.
   20. Delete the cluster parameter group using the
DeleteDBClusterParameterGroupAsync.

> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
/**
 * Before running this Java (v2) code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
started.html
 *
 * This example requires an AWS Secrets Manager secret that contains the
 * database credentials. If you do not create a
 * secret, this example will not work. For details, see:
 *
 * https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html
 *
 * This Java example performs the following tasks:
 *
 * 1. Gets available engine families for Amazon Aurora MySQL-Compatible Edition
 * by calling the DescribeDbEngineVersions(Engine='aurora-mysql') method.
 * 2. Selects an engine family and creates a custom DB cluster parameter group
 * by invoking the describeDBClusterParameters method.
 * 3. Gets the parameter groups by invoking the describeDBClusterParameterGroups
 * method.
 * 4. Gets parameters in the group by invoking the describeDBClusterParameters
 * method.
 * 5. Modifies the auto_increment_offset parameter by invoking the
 * modifyDbClusterParameterGroupRequest method.
 * 6. Gets and displays the updated parameters.
 * 7. Gets a list of allowed engine versions by invoking the
 * describeDbEngineVersions method.
 * 8. Creates an Aurora DB cluster database cluster that contains a MySQL
```

```
 * database.
 * 9. Waits for DB instance to be ready.
 * 10. Gets a list of instance classes available for the selected engine.
 * 11. Creates a database instance in the cluster.
 * 12. Waits for DB instance to be ready.
 * 13. Creates a snapshot.
 * 14. Waits for DB snapshot to be ready.
 * 15. Deletes the DB cluster.
 * 16. Deletes the DB cluster group.

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
/**
Before running this Kotlin code example, set up your development environment,
 including your credentials.

For more information, see the following documentation topic:

https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html

This example requires an AWS Secrets Manager secret that contains the database
 credentials. If you do not create a
secret, this example will not work. For more details, see:

https://docs.aws.amazon.com/secretsmanager/latest/userguide/integrating_how-
services-use-secrets_RS.html

This Kotlin example performs the following tasks:

1. Returns a list of the available DB engines.
2. Creates a custom DB parameter group.
3. Gets the parameter groups.
4. Gets the parameters in the group.
5. Modifies the auto_increment_increment parameter.
6. Displays the updated parameter value.
7. Gets a list of allowed engine versions.
8. Creates an Aurora DB cluster database.
9. Waits for DB instance to be ready.
10. Gets a list of instance classes available for the selected engine.
11. Creates a database instance in the cluster.
12. Waits for the database instance in the cluster to be ready.
13. Creates a snapshot.
14. Waits for DB snapshot to be ready.
15. Deletes the DB instance.
16. Deletes the DB cluster.
17. Deletes the DB cluster group.
 */

Actions for Aurora using Amazon SDKs

The following code examples demonstrate how to perform individual Aurora actions with Amazon SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the Aurora API and are code excerpts from larger programs that must be run in context. You can see actions in context in Scenarios for Aurora using Amazon SDKs.

The following examples include only the most commonly used actions. For a complete list, see the Amazon Aurora API Reference.

Examples

- Use CreateDBCluster with an Amazon SDK
- Use CreateDBClusterParameterGroup with an Amazon SDK
- Use CreateDBClusterSnapshot with an Amazon SDK
- Use CreateDBInstance with an Amazon SDK
- Use DeleteDBCluster with an Amazon SDK

- Use DeleteDBClusterParameterGroup with an Amazon SDK
- Use DeleteDBInstance with an Amazon SDK
- Use DescribeDBClusterParameterGroups with an Amazon SDK
- Use DescribeDBClusterParameters with an Amazon SDK
- Use DescribeDBClusterSnapshots with an Amazon SDK
- Use DescribeDBClusters with an Amazon SDK
- Use DescribeDBEngineVersions with an Amazon SDK
- Use DescribeDBInstances with an Amazon SDK
- Use DescribeOrderableDBInstanceOptions with an Amazon SDK or CLI
- Use ModifyDBClusterParameterGroup with an Amazon SDK

Use `CreateDBCluster` with an Amazon SDK

The following code examples show how to use `CreateDBCluster`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

Amazon SDK for .NET (v4)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

For a complete list of Amazon SDK developer guides and code examples, see Using this service with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `CreateDBClusterParameterGroup` with an Amazon SDK

The following code examples show how to use `CreateDBClusterParameterGroup`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

Amazon SDK for .NET (v4)

For a complete list of Amazon SDK developer guides and code examples, see Using this service with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `CreateDBClusterSnapshot` with an Amazon SDK

The following code examples show how to use `CreateDBClusterSnapshot`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

Amazon SDK for .NET (v4)

For a complete list of Amazon SDK developer guides and code examples, see Using this service with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `CreateDBInstance` with an Amazon SDK

The following code examples show how to use `CreateDBInstance`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

Amazon SDK for .NET (v4)

For a complete list of Amazon SDK developer guides and code examples, see Using this service with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `DeleteDBCluster` with an Amazon SDK

The following code examples show how to use `DeleteDBCluster`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

Amazon SDK for .NET (v4)

Use `DeleteDBClusterParameterGroup` with an Amazon SDK

The following code examples show how to use `DeleteDBClusterParameterGroup`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

Amazon SDK for .NET (v4)

Use `DeleteDBInstance` with an Amazon SDK

The following code examples show how to use `DeleteDBInstance`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

Amazon SDK for .NET (v4)

For a complete list of Amazon SDK developer guides and code examples, see Using this service with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `DescribeDBEngineVersions` with an Amazon SDK

The following code examples show how to use `DescribeDBEngineVersions`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

PowerShell

Tools for PowerShell V4

Example 1: This example lists the DB engine versions that support a specific DB instance class in an Amazon Web Services Region.

```
$params = @{
  Engine = 'aurora-postgresql'
  DBInstanceClass = 'db.r5.large'
  Region = 'us-east-1'
}
Get-RDSOrderableDBInstanceOption @params
```

Example 2: This example lists the DB instance classes that are supported for a specific DB engine version in an Amazon Web Services Region.

```
$params = @{
  Engine = 'aurora-postgresql'
  EngineVersion = '13.6'
```

```
  Region = 'us-east-1'
}
Get-RDSOrderableDBInstanceOption @params
```

- For API details, see DescribeOrderableDBInstanceOptions in *Amazon Tools for PowerShell Cmdlet Reference (V4)*.

Tools for PowerShell V5

Example 1: This example lists the DB engine versions that support a specific DB instance class in an Amazon Web Services Region.

```
$params = @{
  Engine = 'aurora-postgresql'
  DBInstanceClass = 'db.r5.large'
  Region = 'us-east-1'
}
Get-RDSOrderableDBInstanceOption @params
```

Example 2: This example lists the DB instance classes that are supported for a specific DB engine version in an Amazon Web Services Region.

```
$params = @{
  Engine = 'aurora-postgresql'
  EngineVersion = '13.6'
  Region = 'us-east-1'
}
Get-RDSOrderableDBInstanceOption @params
```

For a complete list of Amazon SDK developer guides and code examples, see Using this service with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Scenarios for Aurora using Amazon SDKs

The following code examples show you how to implement common scenarios in Aurora with Amazon SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within Aurora or combined with other Amazon Web Services services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

Examples

- Create a lending library REST API
- Create an Aurora Serverless work item tracker

Create a lending library REST API

The following code example shows how to create a lending library where patrons can borrow and return books by using a REST API backed by an Amazon Aurora database.

Python

SDK for Python (Boto3)

Shows how to use the Amazon SDK for Python (Boto3) with the Amazon Relational Database Service (Amazon RDS) API and Amazon Chalice to create a REST API backed by an Amazon Aurora database. The web service is fully serverless and represents a simple lending library where patrons can borrow and return books. Learn how to:

- Create and manage a serverless Aurora database cluster.
- Use Amazon Secrets Manager to manage database credentials.
- Implement a data storage layer that uses Amazon RDS to move data into and out of the database.

- Use Amazon Chalice to deploy a serverless REST API to Amazon API Gateway and Amazon Lambda.
- Use the Requests package to send requests to the web service.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- API Gateway
- Aurora
- Lambda
- Secrets Manager

For a complete list of Amazon SDK developer guides and code examples, see Using this service with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Create an Aurora Serverless work item tracker

The following code examples show how to create a web application that tracks work items in an Amazon Aurora Serverless database and uses Amazon Simple Email Service (Amazon SES) to send reports.

.NET

Amazon SDK for .NET

Shows how to use the Amazon SDK for .NET to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful .NET backend.

- Integrate a React web application with Amazon services.
- List, add, update, and delete items in an Aurora table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included Amazon CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

C++

SDK for C++

Shows how to create a web application that tracks and reports on work items stored in an Amazon Aurora Serverless database.

For complete source code and instructions on how to set up a C++ REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Java

SDK for Java 2.x

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

For complete source code and instructions on how to set up and run an example that uses the JDBC API, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

JavaScript

SDK for JavaScript (v3)

Shows how to use the Amazon SDK for JavaScript (v3) to create a web application that tracks work items in an Amazon Aurora database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with an Express Node.js backend.

- Integrate a React.js web application with Amazon Web Services services.
- List, add, and update items in an Aurora table.
- Send an email report of filtered work items by using Amazon SES.
- Deploy and manage example resources with the included Amazon CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

Kotlin

SDK for Kotlin

Shows how to create a web application that tracks and reports on work items stored in an Amazon RDS database.

For complete source code and instructions on how to set up a Spring REST API that queries Amazon Aurora Serverless data and for use by a React application, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

PHP

SDK for PHP

Shows how to use the Amazon SDK for PHP to create a web application that tracks work items in an Amazon RDS database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses a front end built with React.js to interact with a RESTful PHP backend.

- Integrate a React.js web application with Amazon services.
- List, add, update, and delete items in an Amazon RDS table.
- Send an email report of filtered work items using Amazon SES.
- Deploy and manage example resources with the included Amazon CloudFormation script.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service

- Amazon SES

Python

SDK for Python (Boto3)

Shows how to use the Amazon SDK for Python (Boto3) to create a REST service that tracks work items in an Amazon Aurora Serverless database and emails reports by using Amazon Simple Email Service (Amazon SES). This example uses the Flask web framework to handle HTTP routing and integrates with a React webpage to present a fully functional web application.

- Build a Flask REST service that integrates with Amazon Web Services services.
- Read, write, and update work items that are stored in an Aurora Serverless database.
- Create an Amazon Secrets Manager secret that contains database credentials and use it to authenticate calls to the database.
- Use Amazon SES to send email reports of work items.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- Aurora
- Amazon RDS
- Amazon RDS Data Service
- Amazon SES

For a complete list of Amazon SDK developer guides and code examples, see Using this service with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Best practices with Amazon Aurora

Following, you can find information on general best practices and options for using or migrating data to an Amazon Aurora DB cluster.

Some of the best practices for Amazon Aurora are specific to a particular database engine. For more information about Aurora best practices specific to a database engine, see the following.

Database engine	Best practices
Amazon Aurora MySQL	See Best practices with Amazon Aurora MySQL
Amazon Aurora PostgreSQL	See Best practices with Amazon Aurora PostgreSQL

> **Note**
>
> For common recommendations for Aurora, see Recommendations from Amazon Aurora.

Topics

- Basic operational guidelines for Amazon Aurora
- DB instance RAM recommendations
- Amazon database drivers
- Monitoring Amazon Aurora
- Working with DB parameter groups and DB cluster parameter groups
- Amazon Aurora best practices video

Basic operational guidelines for Amazon Aurora

The following are basic operational guidelines that everyone should follow when working with Amazon Aurora. The Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Monitor your memory, CPU, and storage usage. You can set up Amazon CloudWatch to notify you when usage patterns change or when you approach the capacity of your deployment. This way, you can maintain system performance and availability.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. The underlying IP address of a DB instance can change after a failover. Thus, caching the DNS data for an extended time can lead to connection failures if your application tries to connect to an IP address that no longer is in service. Aurora DB clusters with multiple read replicas can experience connection failures also when connections use the reader endpoint and one of the read replica instances is in maintenance or is deleted.
- Test failover for your DB cluster to understand how long the process takes for your use case. Testing failover can help you ensure that the application that accesses your DB cluster can automatically connect to the new DB cluster after failover.

DB instance RAM recommendations

To optimize performance, allocate enough RAM so that your working set resides almost completely in memory. To determine whether your working set is almost all in memory, examine the following metrics in Amazon CloudWatch:

- `VolumeReadIOPS` – This metric measures the average number of read I/O operations from a cluster volume, reported at 5-minute intervals. The value of `VolumeReadIOPS` should be small and stable. In some cases, you might find your read I/O is spiking or is higher than usual. If so, investigate the DB instances in your DB cluster to see which DB instances are causing the increased I/O.

  > **Tip**
  >
  > If your Aurora MySQL cluster uses parallel query, you might see an increase in `VolumeReadIOPS` values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

- `BufferCacheHitRatio` – This metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. This metric gives you an insight into the amount of data that is being served from memory.

A high hit ratio indicates that your DB instance has enough memory available. A low hit ratio indicates that your queries on this DB instance are frequently going to disk. Investigate your workload to see which queries are causing this behavior.

If, after investigating your workload, you find that you need more memory, consider scaling up the DB instance class to a class with more RAM. After doing so, you can investigate the metrics discussed preceding and continue to scale up as necessary. If your Aurora cluster is larger than 40 TB, don't use db.t2, db.t3, or db.t4g instance classes.

For more information, see Amazon CloudWatch metrics for Amazon Aurora.

Amazon database drivers

We recommend the Amazon suite of drivers for application connectivity. The drivers have been designed to provide support for faster switchover and failover times, and authentication with Amazon Secrets Manager, Amazon Identity and Access Management (IAM), and Federated Identity. The Amazon drivers rely on monitoring DB cluster status and being aware of the cluster topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

As new service features are introduced, the goal of the Amazon suite of drivers is to have built-in support for these service features.

For more information, see Connecting to Aurora DB clusters with the Amazon drivers.

Monitoring Amazon Aurora

Amazon Aurora provides various metrics and insights that you can monitor to determine the health and performance of your Aurora DB cluster. You can use various tools, such as the Amazon Web Services Management Console, Amazon CLI, and CloudWatch API, to view Aurora metrics. You can view the combined Performance Insights and CloudWatch metrics in the Performance Insights dashboard and monitor your DB instance. To use this monitoring view, Performance Insights must be turned on for your DB instance. For information about this monitoring view, see Database Insights.

You can create a performance analysis report for a specific time period and view the insights identified and the recommendations to resolve the issues. For more information, see Database Insights.

Working with DB parameter groups and DB cluster parameter groups

We recommend that you try out DB parameter group and DB cluster parameter group changes on a test DB cluster before applying parameter group changes to your production DB cluster. Improperly setting DB engine parameters can have unintended adverse effects, including degraded performance and system instability.

Always use caution when modifying DB engine parameters, and back up your DB cluster before modifying a DB parameter group. For information about backing up your DB cluster, see Backing up and restoring an Amazon Aurora DB cluster.

Amazon Aurora best practices video

The Amazon Online Tech Talks channel on YouTube includes a video presentation on best practices for creating and configuring an Amazon Aurora DB cluster to be more secure and highly available. See Amazon Aurora best practices for high availability.

Performing a proof of concept with Amazon Aurora

Following, you can find an explanation of how to set up and run a proof of concept for Aurora. A *proof of concept* is an investigation that you do to see if Aurora is a good fit with your application. The proof of concept can help you understand Aurora features in the context of your own database applications and how Aurora compares with your current database environment. It can also show what level of effort you need to move data, port SQL code, tune performance, and adapt your current management procedures.

In this topic, you can find an overview and a step-by-step outline of the high-level procedures and decisions involved in running a proof of concept, listed following. For detailed instructions, you can follow links to the full documentation for specific subjects.

Overview of an Aurora proof of concept

When you conduct a proof of concept for Amazon Aurora, you learn what it takes to port your existing data and SQL applications to Aurora. You exercise the important aspects of Aurora at scale, using a volume of data and activity that's representative of your production environment. The objective is to feel confident that the strengths of Aurora match up well with the challenges that cause you to outgrow your previous database infrastructure. At the end of a proof of concept, you have a solid plan to do larger-scale performance benchmarking and application testing. At this point, you understand the biggest work items on your way to a production deployment.

The following advice about best practices can help you avoid common mistakes that cause problems during benchmarking. However, this topic doesn't cover the step-by-step process of performing benchmarks and doing performance tuning. Those procedures vary depending on your workload and the Aurora features that you use. For detailed information, consult performance-related documentation such as Managing performance and scaling for Aurora DB clusters, Amazon Aurora MySQL performance enhancements, Performance and scaling for Amazon Aurora PostgreSQL, and Monitoring DB load with Amazon CloudWatch Database Insights on Amazon Aurora.

The information in this topic applies mainly to applications where your organization writes the code and designs the schema and that support the MySQL and PostgreSQL open-source database engines. If you're testing a commercial application or code generated by an application framework, you might not have the flexibility to apply all of the guidelines. In such cases, check with your

Amazon representative to see if there are Aurora best practices or case studies for your type of application.

1. Identify your objectives

When you evaluate Aurora as part of a proof of concept, you choose what measurements to make and how to evaluate the success of the exercise.

You must ensure that all of the functionality of your application is compatible with Aurora. Because Aurora major versions are wire-compatible with corresponding major versions of MySQL and PostgreSQL, most applications developed for those engines are also compatible with Aurora. However, you must still validate compatibility on a per-application basis.

For example, some of the configuration choices that you make when you set up an Aurora cluster influence whether you can or should use particular database features. You might start with the most general-purpose kind of Aurora cluster, known as *provisioned*. You might then decide if a specialized configuration such as serverless or parallel query offers benefits for your workload.

Use the following questions to help identify and quantify your objectives:

- Does Aurora support all functional use cases of your workload?
- What dataset size or load level do you want? Can you scale to that level?
- What are your specific query throughput or latency requirements? Can you reach them?
- What is the minimum acceptable amount of planned or unplanned downtime for your workload? Can you achieve it?
- What are the necessary metrics for operational efficiency? Can you accurately monitor them?
- Does Aurora support your specific business goals, such as cost reduction, increase in deployment, or provisioning speed? Do you have a way to quantify these goals?
- Can you meet all security and compliance requirements for your workload?

Take some time to build knowledge about Aurora database engines and platform capabilities, and review the service documentation. Take note of all the features that can help you achieve your desired outcomes. One of these might be workload consolidation, described in the Amazon Database Blog post How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads. Another might be demand-based scaling, described in Amazon Aurora Auto Scaling with Aurora Replicas in the *Amazon Aurora User Guide.* Others might be performance gains or simplified database operations.

2. Understand your workload characteristics

Evaluate Aurora in the context of your intended use case. Aurora is a good choice for online transaction processing (OLTP) workloads. You can also run reports on the cluster that holds the real-time OLTP data without provisioning a separate data warehouse cluster. You can recognize if your use case falls into these categories by checking for the following characteristics:

- High concurrency, with dozens, hundreds, or thousands of simultaneous clients.
- Large volume of low-latency queries (milliseconds to seconds).
- Short, real-time transactions.
- Highly selective query patterns, with index-based lookups.
- For HTAP, analytical queries that can take advantage of Aurora parallel query.

One of the key factors affecting your database choices is the velocity of the data. *High velocity* involves data being inserted and updated very frequently. Such a system might have thousands of connections and hundreds of thousands of simultaneous queries reading from and writing to a database. Queries in high-velocity systems usually affect a relatively small number of rows, and typically access multiple columns in the same row.

Aurora is designed to handle high-velocity data. Depending on the workload, an Aurora cluster with a single r4.16xlarge DB instance can process more than 600,000 `SELECT` statements per second. Again depending on workload, such a cluster can process 200,000 `INSERT`, `UPDATE`, and `DELETE` statements per second. Aurora is a row store database and is ideally suited for high-volume, high-throughput, and highly parallelized OLTP workloads.

Aurora can also run reporting queries on the same cluster that handles the OLTP workload. Aurora supports up to 15 replicas, each of which is on average within 10–20 milliseconds of the primary instance. Analysts can query OLTP data in real time without copying the data to a separate data warehouse cluster. With Aurora clusters using the parallel query feature, you can offload much of the processing, filtering, and aggregation work to the massively distributed Aurora storage subsystem.

Use this planning phase to familiarize yourself with the capabilities of Aurora, other Amazon services, the Amazon Web Services Management Console, and the Amazon CLI. Also, check how these work with the other tooling that you plan to use in the proof of concept.

3. Practice with the Amazon Web Services Management Console or Amazon CLI

As a next step, practice with the Amazon Web Services Management Console or the Amazon CLI, to become familiar with these tools and with Aurora.

Practice with the Amazon Web Services Management Console

The following initial activities with Aurora database clusters are mainly so you can familiarize yourself with the Amazon Web Services Management Console environment and practice setting up and modifying Aurora clusters. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

By taking advantage of the Aurora shared storage model and features such as replication and snapshots, you can treat entire database clusters as another kind of object that you freely manipulate. You can set up, tear down, and change the capacity of Aurora clusters frequently during the proof of concept. You aren't locked into early choices about capacity, database settings, and physical data layout.

To get started, set up an empty Aurora cluster. Choose the **provisioned** capacity type and **regional** location for your initial experiments.

Connect to that cluster using a client program such as a SQL command-line application. Initially, you connect using the cluster endpoint. You connect to that endpoint to perform any write operations, such as data definition language (DDL) statements and extract, transform, load (ETL) processes. Later in the proof of concept, you connect query-intensive sessions using the reader endpoint, which distributes the query workload among multiple DB instances in the cluster.

Scale the cluster out by adding more Aurora Replicas. For those procedures, see Replication with Amazon Aurora. Scale the DB instances up or down by changing the Amazon instance class. Understand how Aurora simplifies these kinds of operations, so that if your initial estimates for system capacity are inaccurate, you can adjust later without starting over.

Create a snapshot and restore it to a different cluster.

Examine cluster metrics to see activity over time, and how the metrics apply to the DB instances in the cluster.

It's useful to become familiar with how to do these things through the Amazon Web Services Management Console in the beginning. After you understand what you can do with Aurora, you

can progress to automating those operations using the Amazon CLI. In the following sections, you can find more details about the procedures and best practices for these activities during the proof-of-concept period.

Practice with the Amazon CLI

We recommend automating deployment and management procedures, even in a proof-of-concept setting. To do so, become familiar with the Amazon CLI if you're not already. If you use the MySQL-compatible and PostgreSQL-compatible database engines with Amazon RDS, you can build on that knowledge when you use Aurora.

Aurora typically involves groups of DB instances arranged in clusters. Thus, many operations involve determining which DB instances are associated with a cluster and then performing administrative operations in a loop for all the instances.

For example, you might automate steps such as creating Aurora clusters, then scaling them up with larger instance classes or scaling them out with additional DB instances. Doing so helps you to repeat any stages in your proof of concept and explore what-if scenarios with different kinds or configurations of Aurora clusters.

Learn the capabilities and limitations of infrastructure deployment tools such as Amazon CloudFormation. You might find activities that you do in a proof-of-concept context aren't suitable for production use. For example, the Amazon CloudFormation behavior for modification is to create a new instance and delete the current one, including its data. For more details on this behavior, see Update behaviors of stack resources in the *Amazon CloudFormation User Guide.*

4. Create your Aurora cluster

With Aurora, you can explore what-if scenarios by adding DB instances to the cluster and scaling up the DB instances to more powerful instance classes. You can also create clusters with different configuration settings to run the same workload side by side. With Aurora, you have a lot of flexibility to set up, tear down, and reconfigure DB clusters. Given this, it's helpful to practice these techniques in the early stages of the proof-of-concept process. For the general procedures to create Aurora clusters, see Creating an Amazon Aurora DB cluster.

Where practical, start with a cluster using the following settings. Skip this step only if you have certain specific use cases in mind. For example, you might skip this step if your use case requires a specialized kind of Aurora cluster. Or you might skip it if you need a particular combination of database engine and version.

- Turn off **Easy create**. For the proof of concept, we recommend that you be aware of all the settings you choose so that you can create identical or slightly different clusters later.
- Use a recent DB engine version. These combinations of database engine and version have wide compatibility with other Aurora features and substantial customer usage for production applications.
  - Aurora MySQL version 3.x (MySQL 8.0 compatibility)
  - Aurora PostgreSQL version 15.x or 16.x
- Choose the **Dev/Test** template. This choice isn't significant for your proof-of-concept activities.
- For **DB instance class**, choose **Memory optimized classes** and one of the **xlarge** instance classes. You can adjust the instance class up or down later.
- Under **Multi-AZ Deployment**, choose **Create an Aurora Replica or Reader node in a different AZ**. Many of the most useful aspects of Aurora involve clusters of multiple DB instances. It makes sense to always start with at least two DB instances in any new cluster. Using a different Availability Zone for the second DB instance helps to test different high availability scenarios.
- When you pick names for the DB instances, use a generic naming convention. Don't refer to any cluster DB instance as the "writer," because different DB instances assume those roles as needed. We recommend using something like `clustername-az-serialnumber`, for example `myprodappdb-a-01`. These pieces uniquely identify the DB instance and its placement.
- Set the backup retention high for the Aurora cluster. With a long retention period, you can do point-in-time recovery (PITR) for a period up to 35 days. You can reset your database to a known state after running tests involving DDL and data manipulation language (DML) statements. You can also recover if you delete or change data by mistake.
- Turn on additional recovery, logging, and monitoring features at cluster creation. Turn on all the choices that are available under **Backtrack**, **Performance Insights**, **Monitoring**, and **Log exports**. With these features enabled, you can test the suitability of features such as backtracking, Enhanced Monitoring, or Performance Insights for your workload. You can also easily investigate performance and perform troubleshooting during the proof of concept.

5. Set up your schema

On the Aurora cluster, set up databases, tables, indexes, foreign keys, and other schema objects for your application. If you're moving from another MySQL-compatible or PostgreSQL-compatible database system, expect this stage to be simple and straightforward. You use the same SQL syntax and command line or other client applications that you're familiar with for your database engine.

To issue SQL statements on your cluster, find its cluster endpoint and supply that value as the connection parameter to your client application. You can find the cluster endpoint on the **Connectivity** tab of the detail page of your cluster. The cluster endpoint is the one labeled **Writer**. The other endpoint, labeled **Reader**, represents a read-only connection that you can supply to end users who run reports or other read-only queries. For help with any issues around connecting to your cluster, see Connecting to an Amazon Aurora DB cluster.

If you're porting your schema and data from a different database system, expect to make some schema changes at this point. These schema changes are to match the SQL syntax and capabilities available in Aurora. You might leave out certain columns, constraints, triggers, or other schema objects at this point. Doing so can be useful particularly if these objects require rework for Aurora compatibility and aren't significant for your objectives with the proof of concept.

If you're migrating from a database system with a different underlying engine than Aurora's, consider using the Amazon Schema Conversion Tool (Amazon SCT) to simplify the process. For details, see the Amazon Schema Conversion Tool User Guide. For general details about migration and porting activities, see the Migrating Your Databases to Amazon Aurora Amazon whitepaper.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Such inefficiencies can be amplified when you deploy your application on a cluster with multiple DB instances and a heavy workload. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

6. Import your data

During the proof of concept, you bring across the data, or a representative sample, from your former database system. If practical, set up at least some data in each of your tables. Doing so helps to test compatibility of all data types and schema features. After you have exercised the basic Aurora features, scale up the amount of data. By the time you finish the proof of concept, you should test your ETL tools, queries, and overall workload with a dataset that's big enough to draw accurate conclusions.

You can use several techniques to import either physical or logical backup data to Aurora. For details, see Migrating data to an Amazon Aurora MySQL DB cluster or Migrating data to Amazon Aurora with PostgreSQL compatibility depending on the database engine you're using in the proof of concept.

Experiment with the ETL tools and technologies that you're considering. See which one best meets your needs. Consider both throughput and flexibility. For example, some ETL tools perform a one-time transfer, and others involve ongoing replication from the old system to Aurora.

If you're migrating from a MySQL-compatible system to Aurora MySQL, you can use the native data transfer tools. The same applies if you're migrating from a PostgreSQL-compatible system to Aurora PostgreSQL. If you're migrating from a database system that uses a different underlying engine than Aurora does, you can experiment with the Amazon Database Migration Service (Amazon DMS). For details about Amazon DMS, see the Amazon Database Migration Service User Guide.

For details about migration and porting activities, see the Amazon whitepaper Aurora migration handbook.

7. Port your SQL code

Trying out SQL and associated applications requires different levels of effort depending on different cases. In particular, the level of effort depends on whether you move from a MySQL-compatible or PostgreSQL-compatible system or another kind.

- If you're moving from RDS for MySQL or RDS for PostgreSQL, the SQL changes are small enough that you can try the original SQL code with Aurora and manually incorporate needed changes.
- Similarly, if you move from an on-premises database compatible with MySQL or PostgreSQL, you can try the original SQL code and manually incorporate changes.
- If you're coming from a different commercial database, the required SQL changes are more extensive. In this case, consider using the Amazon SCT.

During this stage, you can evaluate whether there are inefficiencies in your schema setup, for example in your indexing strategy or other table structures such as partitioned tables. Consider whether you can fine-tune such performance aspects now, or during later activities such as a full benchmark test.

You can verify the database connection logic in your application. To take advantage of Aurora distributed processing, you might need to use separate connections for read and write operations, and use relatively short sessions for query operations. For information about connections, see 9. Connect to Aurora.

Consider if you had to make compromises and tradeoffs to work around issues in your production database. Build time into the proof-of-concept schedule to make improvements to your schema design and queries. To judge if you can achieve easy wins in performance, operating cost, and scalability, try the original and modified applications side by side on different Aurora clusters.

For details about migration and porting activities, see the Amazon whitepaper Aurora migration handbook.

8. Specify configuration settings

You can also review your database configuration parameters as part of the Aurora proof-of-concept exercise. You might already have MySQL or PostgreSQL configuration settings tuned for performance and scalability in your current environment. The Aurora storage subsystem is adapted and tuned for a distributed cloud-based environment with a high-speed storage subsystem. As a result, many former database engine settings don't apply. We recommend conducting your initial experiments with the default Aurora configuration settings. Reapply settings from your current environment only if you encounter performance and scalability bottlenecks. If you're interested, you can look more deeply into this subject in Introducing the Aurora storage engine on the Amazon Database Blog.

Aurora makes it easy to reuse the optimal configuration settings for a particular application or use case. Instead of editing a separate configuration file for each DB instance, you manage sets of parameters that you assign to entire clusters or specific DB instances. For example, the time zone setting applies to all DB instances in the cluster, and you can adjust the page cache size setting for each DB instance.

You start with one of the default parameter sets, and apply changes to only the parameters that you need to fine-tune. For details about working with parameter groups, see Amazon Aurora DB cluster and DB instance parameters. For the configuration settings that are or aren't applicable to Aurora clusters, see Aurora MySQL configuration parameters or Amazon Aurora PostgreSQL parameters depending on your database engine.

9. Connect to Aurora

As you find when doing your initial schema and data setup and running sample queries, you can connect to different endpoints in an Aurora cluster. The endpoint to use depends on whether the operation is a read such as `SELECT` statement, or a write such as a `CREATE` or `INSERT` statement.

As you increase the workload on an Aurora cluster and experiment with Aurora features, it's important for your application to assign each operation to the appropriate endpoint.

By using the cluster endpoint for write operations, you always connect to a DB instance in the cluster that has read/write capability. By default, only one DB instance in an Aurora cluster has read/write capability. This DB instance is called the *primary instance*. If the original primary instance becomes unavailable, Aurora activates a failover mechanism and a different DB instance takes over as the primary.

Similarly, by directing SELECT statements to the reader endpoint, you spread the work of processing queries among the DB instances in the cluster. The reader endpoint uses DNS resolution to route each new connection to one of the available Aurora Replicas, rather than distributing connections in a strict round-robin order. Doing most of the query work on the read-only DB Aurora Replicas reduces the load on the primary instance, freeing it to handle DDL and DML statements.

Using these endpoints reduces the dependency on hard-coded hostnames, and helps your application to recover more quickly from DB instance failures.

> **Note**
>
> Aurora also has custom endpoints that you create. Those endpoints usually aren't needed during a proof of concept.

The Aurora Replicas are subject to a replica lag, even though that lag is usually 10 to 20 milliseconds. You can monitor the replication lag and decide whether it is within the range of your data consistency requirements. In some cases, your read queries might require strong read consistency (read-after-write consistency). In these cases, you can continue using the cluster endpoint for them and not the reader endpoint.

To take full advantage of Aurora capabilities for distributed parallel execution, you might need to change the connection logic. Your objective is to avoid sending all read requests to the primary instance. The read-only Aurora Replicas are standing by, with all the same data, ready to handle SELECT statements. Code your application logic to use the appropriate endpoint for each kind of operation. Follow these general guidelines:

- Avoid using a single hard-coded connection string for all database sessions.

- If practical, enclose write operations such as DDL and DML statements in functions in your client application code. That way, you can make different kinds of operations use specific connections.
- Make separate functions for query operations. Aurora assigns each new connection to the reader endpoint to a different Aurora Replica to balance the load for read-intensive applications.
- For operations involving sets of queries, close and reopen the connection to the reader endpoint when each set of related queries is finished. Use connection pooling if that feature is available in your software stack. Directing queries to different connections helps Aurora to distribute the read workload among the DB instances in the cluster.

For general information about connection management and endpoints for Aurora, see Connecting to an Amazon Aurora DB cluster. For a deep dive on this subject, see Aurora MySQL database administrator's handbook – Connection management.

10. Run your workload

After the schema, data, and configuration settings are in place, you can begin exercising the cluster by running your workload. Use a workload in the proof of concept that mirrors the main aspects of your production workload. We recommend always making decisions about performance using real-world tests and workloads rather than synthetic benchmarks such as sysbench or TPC-C. Wherever practical, gather measurements based on your own schema, query patterns, and usage volume.

As much as practical, replicate the actual conditions under which the application will run. For example, you typically run your application code on Amazon EC2 instances in the same Amazon Region and the same virtual private cloud (VPC) as the Aurora cluster. If your production application runs on multiple EC2 instances spanning multiple Availability Zones, set up your proof-of-concept environment in the same way. For more information on Amazon Regions, see Regions and Availability Zones in the *Amazon RDS User Guide.* To learn more about the Amazon VPC service, see What is Amazon VPC? in the *Amazon VPC User Guide.*

After you've verified that the basic features of your application work and you can access the data through Aurora, you can exercise aspects of the Aurora cluster. Some features you might want to try are concurrent connections with load balancing, concurrent transactions, and automatic replication.

By this point, the data transfer mechanisms should be familiar, and so you can run tests with a larger proportion of sample data.

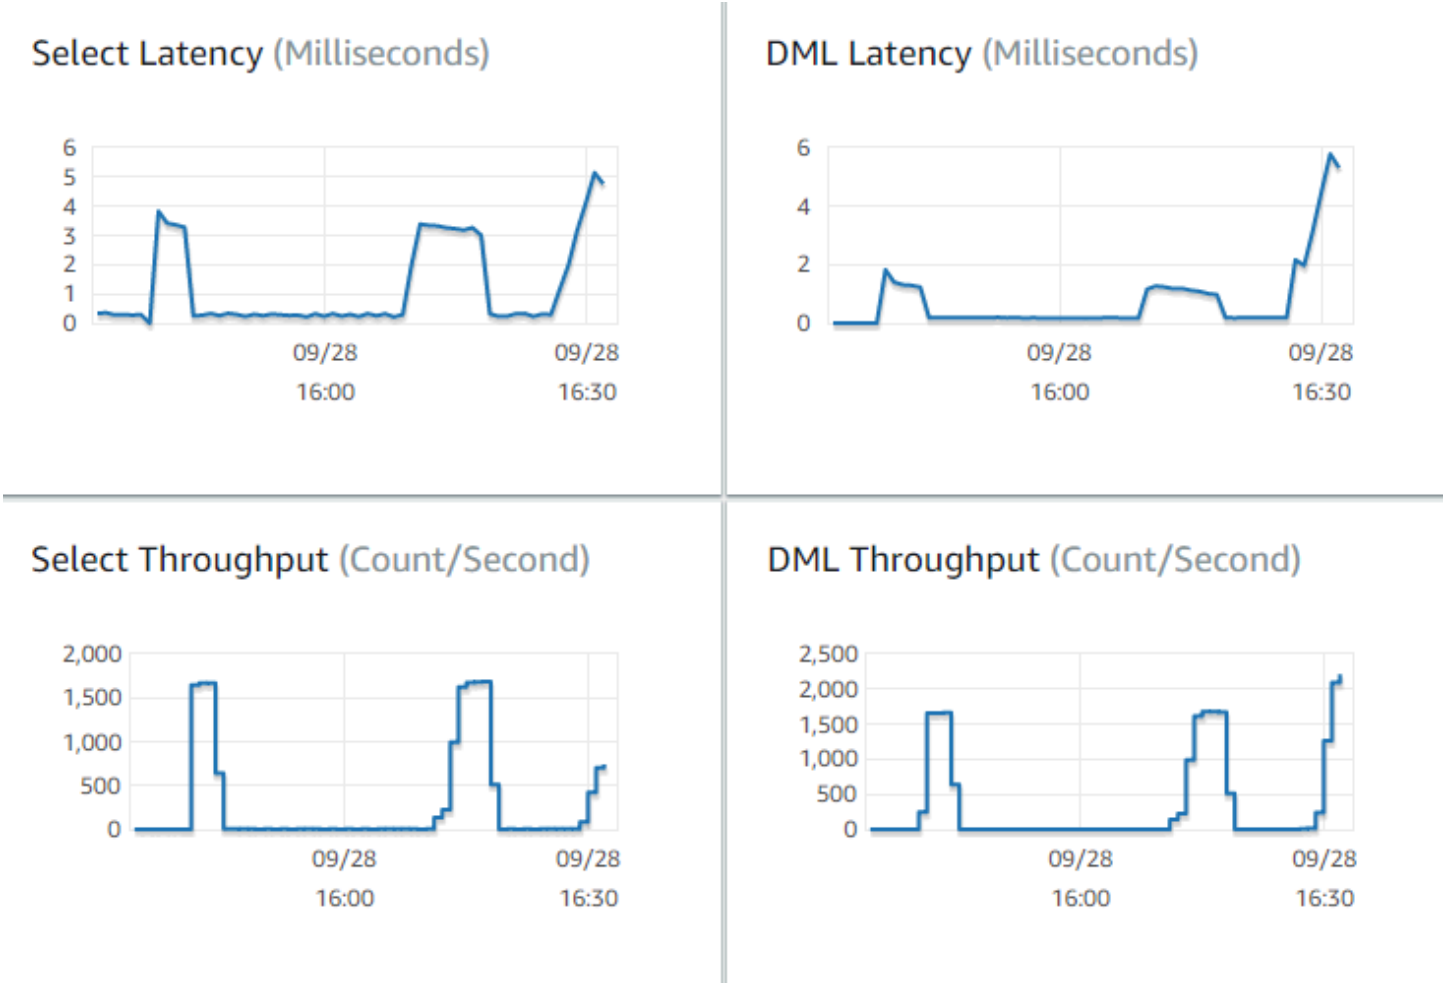
This stage is when you can see the effects of changing configuration settings such as memory limits and connection limits. Revisit the procedures that you explored in 8. Specify configuration settings.

You can also experiment with mechanisms such as creating and restoring snapshots. For example, you can create clusters with different Amazon instance classes, numbers of Amazon Replicas, and so on. Then on each cluster, you can restore the same snapshot containing your schema and all your data. For the details of that cycle, see Creating a DB cluster snapshot and Restoring from a DB cluster snapshot.

11. Measure performance

Best practices in this area are designed to ensure that all the right tools and processes are set up to quickly isolate abnormal behaviors during workload operations. They're also set up to see that you can reliably identify any applicable causes.

You can always see the current state of your cluster, or examine trends over time, by examining the **Monitoring** tab. This tab is available from the console detail page for each Aurora cluster or DB instance. It displays metrics from the Amazon CloudWatch monitoring service in the form of charts. You can filter the metrics by name, by DB instance, and by time period.



To have more choices on the **Monitoring** tab, enable Enhanced Monitoring and Performance Insights in the cluster settings. You can also enable those choices later if you didn't choose them when setting up the cluster.

To measure performance, you rely mostly on the charts showing activity for the whole Aurora cluster. You can verify whether the Aurora Replicas have similar load and response times. You can also see how the work is split up between the read/write primary instance and the read-only Aurora Replicas. If there is some imbalance between the DB instances or an issue affecting only one DB instance, you can examine the **Monitoring** tab for that specific instance.

After the environment and the actual workload are set up to emulate your production application, you can measure how well Aurora performs. The most important questions to answer are as follows:

- How many queries per second is Aurora processing? You can examine the **Throughput** metrics to see the figures for various kinds of operations.
- How long does it take, on average for Aurora to process a given query? You can examine the **Latency** metrics to see the figures for various kinds of operations.

To view the throughput and latency metrics, check the **Monitoring** tab for a given Aurora cluster in the Amazon RDS console. The following screenshot shows an example of the **Select Latency**, **DML Latency**, **Select Throughput**, and **DML Throughput** metrics on the **Monitoring** tab.

If you can, establish baseline values for these metrics in your current environment. If that's not practical, construct a baseline on the Aurora cluster by executing a workload equivalent to your production application. For example, run your Aurora workload with a similar number of simultaneous users and queries. Then observe how the values change as you experiment with different instance classes, cluster size, configuration settings, and so on.

If the throughput numbers are lower than you expect, investigate further the factors affecting database performance for your workload. Similarly, if the latency numbers are higher than you expect, further investigate. To do so, monitor the secondary metrics for the DB server (CPU, memory, and so on). You can see whether the DB instances are close to their limits. You can also see how much extra capacity your DB instances have to handle more concurrent queries, queries against larger tables, and so on.

> **Tip**
>
> To detect metric values that fall outside the expected ranges, set up CloudWatch alarms.

When evaluating the ideal Aurora cluster size and capacity, you can find the configuration that achieves peak application performance without over-provisioning resources. One important factor is finding the appropriate size for the DB instances in the Aurora cluster. Start by selecting an instance size that has similar CPU and memory capacity to your current production environment. Collect throughput and latency numbers for the workload at that instance size. Then, scale the instance up to the next larger size. See if the throughput and latency numbers improve. Also scale the instance size down, and see if the latency and throughput numbers remain the same. Your goal is to get the highest throughput, with the lowest latency, on the smallest instance possible.

> **Tip**
>
> Size your Aurora clusters and associated DB instances with enough existing capacity to handle sudden, unpredictable traffic spikes. For mission-critical databases, leave at least 20 percent spare CPU and memory capacity.

Run performance tests long enough to measure database performance in a warm, steady state. You might need to run the workload for many minutes or even a few hours before reaching this steady state. It's normal at the beginning of a run to have some variance. This variance happens because each Aurora Replica warms up its caches based on the SELECT queries that it handles.

Aurora performs best with transactional workloads involving multiple concurrent users and queries. To ensure that you're driving enough load for optimal performance, run benchmarks that use multithreading, or run multiple instances of the performance tests concurrently. Measure performance with hundreds or even thousands of concurrent client threads. Simulate the number of concurrent threads that you expect in your production environment. You might also perform additional stress tests with more threads to measure Aurora scalability.

12. Exercise Aurora high availability

Many of the main Aurora features involve high availability. These features include automatic replication, automatic failover, automatic backups with point-in-time restore, and ability to add

DB instances to the cluster. The safety and reliability from features like these are important for mission-critical applications.

To evaluate these features requires a certain mindset. In earlier activities, such as performance measurement, you observe how the system performs when everything works correctly. Testing high availability requires you to think through worst-case behavior. You must consider various kinds of failures, even if such conditions are rare. You might intentionally introduce problems to make sure that the system recovers correctly and quickly.

> **Tip**
>
> For a proof of concept, set up all the DB instances in an Aurora cluster with the same Amazon instance class. Doing so makes it possible to try out Aurora availability features without major changes to performance and scalability as you take DB instances offline to simulate failures.

We recommend using at least two instances in each Aurora cluster. The DB instances in an Aurora cluster can span up to three Availability Zones (AZs). Locate each of the first two or three DB instances in a different AZ. When you begin using larger clusters, spread your DB instances across all of the AZs in your Amazon Region. Doing so increases fault tolerance capability. Even if a problem affects an entire AZ, Aurora can fail over to a DB instance in a different AZ. If you run a cluster with more than three instances, distribute the DB instances as evenly as you can over all three AZs.

> **Tip**
>
> The storage for an Aurora cluster is independent from the DB instances. The storage for each Aurora cluster always spans three AZs.
> When you test high availability features, always use DB instances with identical capacity in your test cluster. Doing so avoids unpredictable changes in performance, latency, and so on whenever one DB instance takes over for another.

To learn how to simulate failure conditions to test high availability features, see Testing Amazon Aurora MySQL using fault injection queries.

As part of your proof-of-concept exercise, one objective is to find the ideal number of DB instances and the optimal instance class for those DB instances. Doing so requires balancing the requirements of high availability and performance.

For Aurora, the more DB instances that you have in a cluster, the greater the benefits for high availability. Having more DB instances also improves scalability of read-intensive applications. Aurora can distribute multiple connections for SELECT queries among the read-only Aurora Replicas.

On the other hand, limiting the number of DB instances reduces the replication traffic from the primary node. The replication traffic consumes network bandwidth, which is another aspect of overall performance and scalability. Thus, for write-intensive OLTP applications, prefer to have a smaller number of large DB instances rather than many small DB instances.

In a typical Aurora cluster, one DB instance (the primary instance) handles all the DDL and DML statements. The other DB instances (the Aurora Replicas) handle only SELECT statements. Although the DB instances don't do exactly the same amount of work, we recommend using the same instance class for all the DB instances in the cluster. That way, if a failure happens and Aurora promotes one of the read-only DB instances to be the new primary instance, the primary instance has the same capacity as before.

If you need to use DB instances of different capacities in the same cluster, set up failover tiers for the DB instances. These tiers determine the order in which Aurora Replicas are promoted by the failover mechanism. Put DB instances that are a lot larger or smaller than the others into a lower failover tier. Doing so ensures that they are chosen last for promotion.

Exercise the data recovery features of Aurora, such as automatic point-in-time restore, manual snapshots and restore, and cluster backtracking. If appropriate, copy snapshots to other Amazon Regions and restore into other Amazon Regions to mimic DR scenarios.

Investigate your organization's requirements for restore time objective (RTO), restore point objective (RPO), and geographic redundancy. Most organizations group these items under the broad category of disaster recovery. Evaluate the Aurora high availability features described in this section in the context of your disaster recovery process to ensure that your RTO and RPO requirements are met.

13. What to do next

At the end of a successful proof-of-concept process, you confirm that Aurora is a suitable solution for you based on the anticipated workload. Throughout the preceding process, you've checked how Aurora works in a realistic operational environment and measured it against your success criteria.

After you get your database environment up and running with Aurora, you can move on to more detailed evaluation steps, leading to your final migration and production deployment. Depending on your situation, these other steps might or might not be included in the proof-of-concept process. For details about migration and porting activities, see the Amazon whitepaper Aurora migration handbook.

In another next step, consider the security configurations relevant for your workload and designed to meet your security requirements in a production environment. Plan what controls to put in place to protect access to the Aurora cluster master user credentials. Define the roles and responsibilities of database users to control access to data stored in the Aurora cluster. Take into account database access requirements for applications, scripts, and third-party tools or services. Explore Amazon services and features such as Amazon Secrets Manager and Amazon Identity and Access Management (IAM) authentication.

At this point, you should understand the procedures and best practices for running benchmark tests with Aurora. You might find you need to do additional performance tuning. For details, see Managing performance and scaling for Aurora DB clusters, Amazon Aurora MySQL performance enhancements, Performance and scaling for Amazon Aurora PostgreSQL, and Monitoring DB load with Amazon CloudWatch Database Insights on Amazon Aurora. If you do additional tuning, make sure that you're familiar with the metrics that you gathered during the proof of concept. For a next step, you might create new clusters with different choices for configuration settings, database engine, and database version. Or you might create specialized kinds of Aurora clusters to match the needs of specific use cases.

For example, you can explore Aurora parallel query clusters for hybrid transaction/analytical processing (HTAP) applications. If wide geographic distribution is crucial for disaster recovery or to minimize latency, you can explore Aurora global databases. If your workload is intermittent or you're using Aurora in a development/test scenario, you can explore Aurora Serverless clusters.

Your production clusters might also need to handle high volumes of incoming connections. To learn those techniques, see the Amazon whitepaper Aurora MySQL database administrator's handbook – Connection management.

If, after the proof of concept, you decide that your use case is not suited for Aurora, consider these other Amazon services:

- For purely analytic use cases, workloads benefit from a columnar storage format and other features more suitable to OLAP workloads. Amazon services that address such use cases include the following:
  - Amazon Redshift
  - Amazon EMR
  - Amazon Athena
- Many workloads benefit from a combination of Aurora with one or more of these services. You can move data between these services by using these:
  - Amazon Glue
  - Amazon DMS
  - Importing from Amazon S3, as described in the *Amazon Aurora User Guide*
  - Exporting to Amazon S3, as described in the *Amazon Aurora User Guide*
  - Many other popular ETL tools

Security in Amazon Aurora

Cloud security at Amazon is the highest priority. As an Amazon customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between Amazon and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – Amazon is responsible for protecting the infrastructure that runs Amazon services in the Amazon Cloud. Amazon also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the Amazon compliance programs. To learn about the compliance programs that apply to Amazon Aurora (Aurora), see Amazon services in scope by compliance program.
- **Security in the cloud** – Your responsibility is determined by the Amazon service that you use. You are also responsible for other factors including the sensitivity of your data, your organization's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon Aurora. The following topics show you how to configure Amazon Aurora to meet your security and compliance objectives. You also learn how to use other Amazon services that help you monitor and secure your Amazon Aurora resources.

You can manage access to your Amazon Aurora resources and your databases on a DB cluster. The method you use to manage access depends on what type of task the user needs to perform with Amazon Aurora:

- Run your DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service for the greatest possible network access control. For more information about creating a DB cluster in a VPC, see Amazon VPC and Amazon Aurora .
- Use Amazon Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage Amazon Aurora resources. For example, you can use IAM to determine who is allowed to create, describe, modify, and delete DB clusters, tag resources, or modify security groups.

  To review IAM policy examples, see Identity-based policy examples for Amazon Aurora .

- Use security groups to control what IP addresses or Amazon EC2 instances can connect to your databases on a DB cluster. When you first create a DB cluster, its firewall prevents any database access except through rules specified by an associated security group.
- Use Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections with DB clusters running the Aurora MySQL or Aurora PostgreSQL. For more information on using SSL/TLS with a DB cluster, see Using SSL/TLS to encrypt a connection to a DB cluster .
- Use Amazon Aurora encryption to secure your DB clusters and snapshots at rest. Amazon Aurora encryption uses the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your DB cluster. For more information, see Encrypting Amazon Aurora resources .
- Use the security features of your DB engine to control who can log in to the databases on a DB cluster. These features work just as if the database was on your local network.

  For information about security with Aurora MySQL, see Security with Amazon Aurora MySQL . For information about security with Aurora PostgreSQL, see Security with Amazon Aurora PostgreSQL .

Aurora is part of the managed database service Amazon Relational Database Service (Amazon RDS). Amazon RDS is a web service that makes it easier to set up, operate, and scale a relational database in the cloud. If you are not already familiar with Amazon RDS, see the *Amazon RDS user guide*.

Aurora includes a high-performance storage subsystem. Its MySQL- and PostgreSQL-compatible database engines are customized to take advantage of that fast distributed storage. Aurora also automates and standardizes database clustering and replication, which are typically among the most challenging aspects of database configuration and administration.

For both Amazon RDS and Aurora, you can access the RDS API programmatically, and you can use the Amazon CLI to access the RDS API interactively. Some RDS API operations and Amazon CLI commands apply to both Amazon RDS and Aurora, while others apply to either Amazon RDS or Aurora. For information about RDS API operations, see Amazon RDS API reference. For more information about the Amazon CLI, see Amazon Command Line Interface reference for Amazon RDS.

> **Note**
>
> You have to configure security only for your use cases. You don't have to configure security access for processes that Amazon Aurora manages. These include creating backups, automatic failover, and other processes.

For more information on managing access to Amazon Aurora resources and your databases on a DB cluster, see the following topics.

Database authentication with Amazon Aurora

Amazon Aurora supports several ways to authenticate database users.

Password authentication is available by default for all DB clusters. For Aurora MySQL and Aurora PostgreSQL, you can also add either or both IAM database authentication and Kerberos authentication for the same DB cluster.

Password, Kerberos, and IAM database authentication use different methods of authenticating to the database. Therefore, a specific user can log in to a database using only one authentication method.

For PostgreSQL, use only one of the following role settings for a user of a specific database:

- To use IAM database authentication, assign the `rds_iam` role to the user.
- To use Kerberos authentication, assign the `rds_ad` role to the user.
- To use password authentication, don't assign either the `rds_iam` or `rds_ad` roles to the user.

Don't assign both the `rds_iam` and `rds_ad` roles to a user of a PostgreSQL database either directly or indirectly by nested grant access. If the `rds_iam` role is added to the master user, IAM authentication takes precedence over password authentication so the master user has to log in as an IAM user.

> **Important**
>
> We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Topics

- Password authentication
- IAM database authentication
- Kerberos authentication

Password authentication

With *password authentication,* your database performs all administration of user accounts. You create users with SQL statements such as `CREATE USER`, with the appropriate clause required by the DB engine for specifying passwords. For example, in MySQL the statement is `CREATE USER` *`name`* `IDENTIFIED BY` *`password`*, while in PostgreSQL, the statement is `CREATE USER` *`name`* `WITH PASSWORD` *`password`*.

With password authentication, your database controls and authenticates user accounts. If a DB engine has strong password management features, they can enhance security. Database

authentication might be easier to administer using password authentication when you have small user communities. Because clear text passwords are generated in this case, integrating with Amazon Secrets Manager can enhance security.

For information about using Secrets Manager with Amazon Aurora, see Creating a basic secret and Rotating secrets for supported Amazon RDS databases in the *Amazon Secrets Manager User Guide*. For information about programmatically retrieving your secrets in your custom applications, see Retrieving the secret value in the *Amazon Secrets Manager User Guide*.

IAM database authentication

You can authenticate to your DB cluster using Amazon Identity and Access Management (IAM) database authentication. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

For more information about IAM database authentication, including information about availability for specific DB engines, see IAM database authentication .

Kerberos authentication

Amazon Aurora supports external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

Amazon Aurora support for Kerberos and Active Directory provides the benefits of single sign-on and centralized authentication of database users. You can keep your user credentials in Active Directory. Active Directory provides a centralized place for storing and managing credentials for multiple DB clusters.

To use credentials from your self-managed Active Directory, you need to setup a trust relationship to the Amazon Directory Service for Microsoft Active Directory that the DB cluster is joined to.

Aurora PostgreSQL and Aurora MySQL support one-way and two-way forest trust relationships with forest-wide authentication or selective authentication.

In some scenarios, you can configure Kerberos authentication over an external trust relationship. This requires your self-managed Active Directory to have additional settings. This includes but is not limited to Kerberos Forest Search Order.

Aurora supports Kerberos authentication for Aurora MySQL and Aurora PostgreSQL DB clusters. For more information, see Using Kerberos authentication for Aurora MySQL and Using Kerberos authentication with Aurora PostgreSQL .

Password management with Amazon Aurora and Amazon Secrets Manager

Amazon Aurora integrates with Secrets Manager to manage master user passwords for your DB clusters.

Topics

- Region and version availability
- Limitations for Secrets Manager integration with Amazon Aurora
- Overview of managing master user passwords with Amazon Secrets Manager
- Benefits of managing master user passwords with Secrets Manager
- Permissions required for Secrets Manager integration
- Enforcing Aurora management of the master user password in Amazon Secrets Manager
- Managing the master user password for a DB cluster with Secrets Manager
- Rotating the master user password secret for a DB cluster
- Viewing the details about a secret for a DB cluster

Region and version availability

Feature availability and support varies across specific versions of each database engine and across Amazon Web Services Regions. For more information about version and Region availability with Secrets Manager integration with Amazon Aurora, see Supported Regions and Aurora DB engines for Secrets Manager integration.

Limitations for Secrets Manager integration with Amazon Aurora

Managing master user passwords with Secrets Manager isn't supported for the following features:

- Amazon RDS Blue/Green Deployments
- DB clusters that are part of an Aurora global database
- Cross-Region read replicas
- Binary log external replication
- Managed master user passwords with the `validate_password` plugin or component enabled on Aurora MySQL

- If the Amazon RDS-managed secret has cross-Region replication enabled (using Amazon Secrets Manager multi-Region secret replication), you can't opt out of Secrets Manager-managed credentials. The `modify-db-cluster` API call with `--no-manage-master-user-password` appears to succeed, but the DB cluster remains on Secrets Manager-managed credentials. To opt out, you must first remove replication from the secret using `aws secretsmanager remove-regions-from-replication`, and then retry the modification.

Overview of managing master user passwords with Amazon Secrets Manager

With Amazon Secrets Manager, you can replace hard-coded credentials in your code, including database passwords, with an API call to Secrets Manager to retrieve the secret programmatically. For more information about Secrets Manager, see the Amazon Secrets Manager User Guide.

When you store database secrets in Secrets Manager, your Amazon Web Services account incurs charges. For information about pricing, see Amazon Secrets Manager Pricing.

You can specify that Aurora manages the master user password in Secrets Manager for an Amazon Aurora DB cluster when you perform one of the following operations:

- Create a DB cluster
- Modify a DB cluster
- Restore a DB cluster from Amazon S3 (Aurora MySQL only)

When you specify that Aurora manages the master user password in Secrets Manager, Aurora generates the password and stores it in Secrets Manager. You can interact directly with the secret to retrieve the credentials for the master user. You can also specify a customer managed key to encrypt the secret, or use the KMS key that is provided by Secrets Manager.

Aurora manages the settings for the secret and rotates the secret every seven days by default. You can modify some of the settings, such as the rotation schedule. If you delete a DB cluster that manages a secret in Secrets Manager, the secret and its associated metadata are also deleted.

To connect to a DB cluster with the credentials in a secret, you can retrieve the secret from Secrets Manager. For more information, see Retrieve secrets from Amazon Secrets Manager and Connect to a SQL database with credentials in an Amazon Secrets Manager secret in the *Amazon Secrets Manager User Guide*.

Benefits of managing master user passwords with Secrets Manager

Managing Aurora master user passwords with Secrets Manager provides the following benefits:

- Aurora automatically generates database credentials.
- Aurora automatically stores and manages database credentials in Amazon Secrets Manager.
- Aurora rotates database credentials regularly, without requiring application changes.
- Secrets Manager secures database credentials from human access and plain text view.
- Secrets Manager allows retrieval of database credentials in secrets for database connections.
- Secrets Manager allows fine-grained control of access to database credentials in secrets using IAM.
- You can optionally separate database encryption from credentials encryption with different KMS keys.
- You can eliminate manual management and rotation of database credentials.
- You can monitor database credentials easily with Amazon CloudTrail and Amazon CloudWatch.

For more information about the benefits of Secrets Manager, see the Amazon Secrets Manager User Guide.

Permissions required for Secrets Manager integration

Users must have the required permissions to perform operations related to Secrets Manager integration. You can create IAM policies that grant permissions to perform specific API operations on the specified resources they need. You can then attach those policies to the IAM permission sets or roles that require those permissions. For more information, see Identity and access management for Amazon Aurora.

For create, modify, or restore operations, the user who specifies that Aurora manages the master user password in Secrets Manager must have permissions to perform the following operations:

- `kms:DescribeKey`
- `secretsmanager:CreateSecret`
- `secretsmanager:TagResource`

The `kms:DescribeKey` permission is required to access your customer-managed key for the `MasterUserSecretKmsKeyId` and to describe `aws/secretsmanager`.

For create, modify, or restore operations, the user who specifies the customer managed key to encrypt the secret in Secrets Manager must have permissions to perform the following operations:

- `kms:Decrypt`
- `kms:GenerateDataKey`
- `kms:CreateGrant`

For modify operations, the user who rotates the master user password in Secrets Manager must have permissions to perform the following operation:

- `secretsmanager:RotateSecret`

Enforcing Aurora management of the master user password in Amazon Secrets Manager

You can use IAM condition keys to enforce Aurora management of the master user password in Amazon Secrets Manager. The following policy doesn't allow users to create or restore DB instances or DB clusters unless the master user password is managed by Aurora in Secrets Manager.

        {
            "Effect": "Deny",
            "Action": ["rds:CreateDBInstance", "rds:CreateDBCluster",
 "rds:RestoreDBInstanceFromS3", "rds:RestoreDBClusterFromS3"],
            "Resource": "*",
            "Condition": {
                "Bool": {
                    "rds:ManageMasterUserPassword": false
                }
            }
        }
    ]
}
```

Note

This policy enforces password management in Amazon Secrets Manager at creation. However, you can still disable Secrets Manager integration and manually set a master password by modifying the cluster.
To prevent this, include `rds:ModifyDBInstance`, `rds:ModifyDBCluster` in the action block of the policy. Be aware, this prevents the user from applying any further modifications to existing clusters that don't have Secrets Manager integration enabled.

For more information about using condition keys in IAM policies, see Policy condition keys for Aurora and Example policies: Using condition keys.

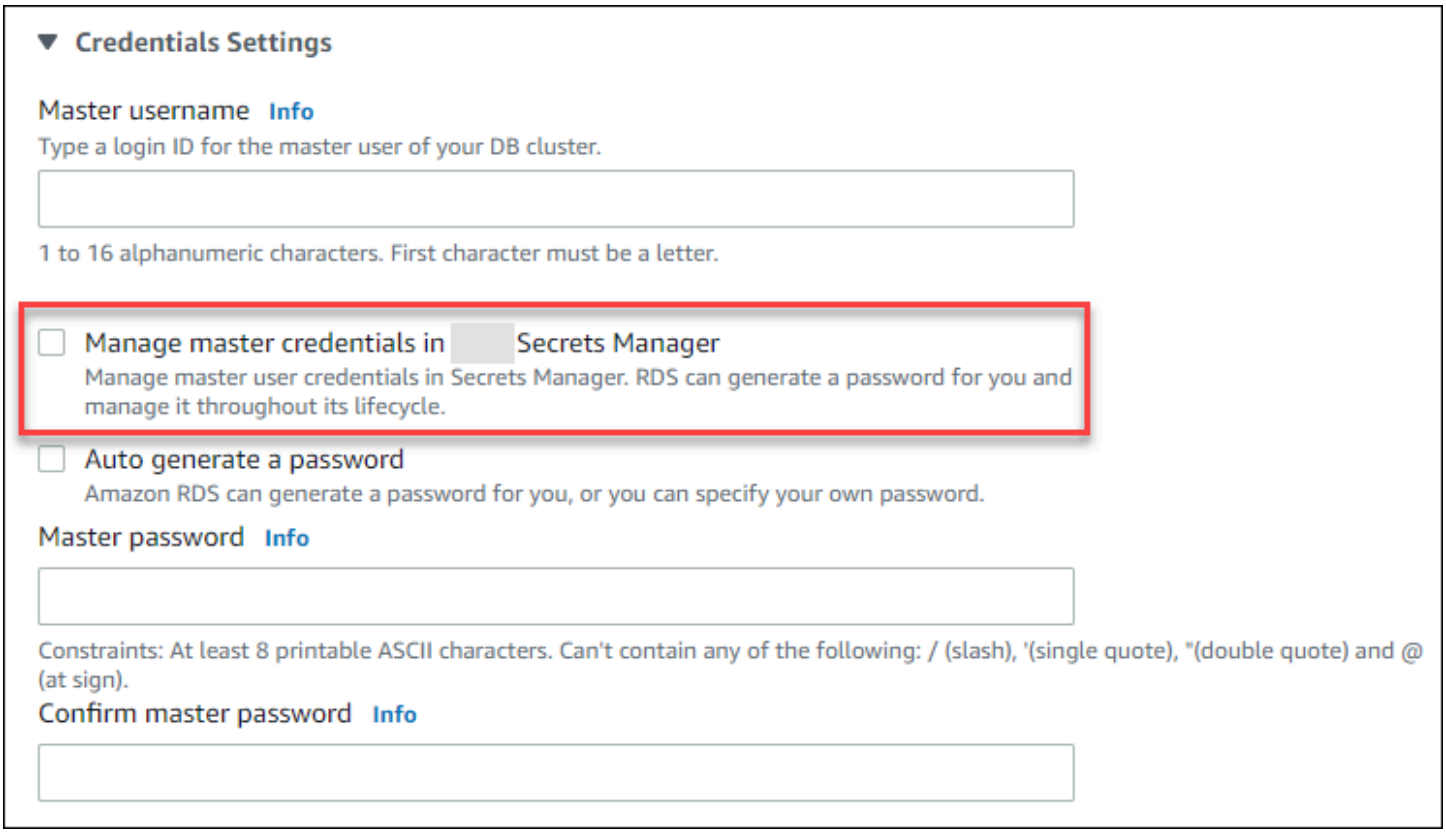
Managing the master user password for a DB cluster with Secrets Manager

You can configure Aurora management of the master user password in Secrets Manager when you perform the following actions:

- Creating an Amazon Aurora DB cluster
- Modifying an Amazon Aurora DB cluster
- Migrating data from an external MySQL database to an Amazon Aurora MySQL DB cluster

You can use the RDS console, the Amazon CLI, or the RDS API to perform these actions.

Console



Follow the instructions for creating or modifying a DB cluster with the RDS console:

- Creating a DB cluster
- Modifying a DB instance in a DB cluster

  In the RDS console, you can modify any DB instance to specify the master user password management settings for the entire DB cluster.
- Restoring an Amazon Aurora MySQL DB cluster from an Amazon S3 bucket

When you use the RDS console to perform one of these operations, you can specify that the master user password is managed by Aurora in Secrets Manager. To do so when you are creating or restoring a DB cluster, select **Manage master credentials in Amazon Secrets Manager** in **Credential settings**. When you are modifying a DB cluster, select **Manage master credentials in Amazon Secrets Manager** in **Settings**.

The following image is an example of the **Manage master credentials in Amazon Secrets Manager** setting when you are creating or restoring a DB cluster.

When you select this option, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

You can choose to encrypt the secret with a KMS key that Secrets Manager provides or with a customer managed key that you create. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a DB cluster, see Settings for Aurora DB clusters. For more information about the available settings when you are modifying a DB cluster, see Settings for Amazon Aurora.

Amazon CLI

To specify that Aurora manages the master user password in Secrets Manager, specify the `--manage-master-user-password` option in one of the following commands:

- create-db-cluster
- modify-db-cluster
- restore-db-cluster-from-s3

When you specify the `--manage-master-user-password` option in these commands, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `--master-user-secret-kms-key-id` option to specify

a customer managed key. The Amazon KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different Amazon Web Services account, specify the key ARN or alias ARN. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

You can choose other settings to meet your requirements.

For more information about the available settings when you are creating a DB cluster, see Settings for Aurora DB clusters. For more information about the available settings when you are modifying a DB cluster, see Settings for Amazon Aurora.

This example creates a DB cluster and specifies that Aurora manages the password in Secrets Manager. The secret is encrypted using the KMS key that is provided by Secrets Manager.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
     --db-cluster-identifier sample-cluster \
     --engine aurora-mysql \
     --engine-version 8.0 \
     --master-username admin \
     --manage-master-user-password
```

For Windows:

```
aws rds create-db-cluster ^
     --db-cluster-identifier sample-cluster ^
     --engine aurora-mysql ^
     --engine-version 8.0 ^
     --master-username admin ^
     --manage-master-user-password
```

RDS API

To specify that Aurora manages the master user password in Secrets Manager, set the `ManageMasterUserPassword` parameter to `true` in one of the following operations:

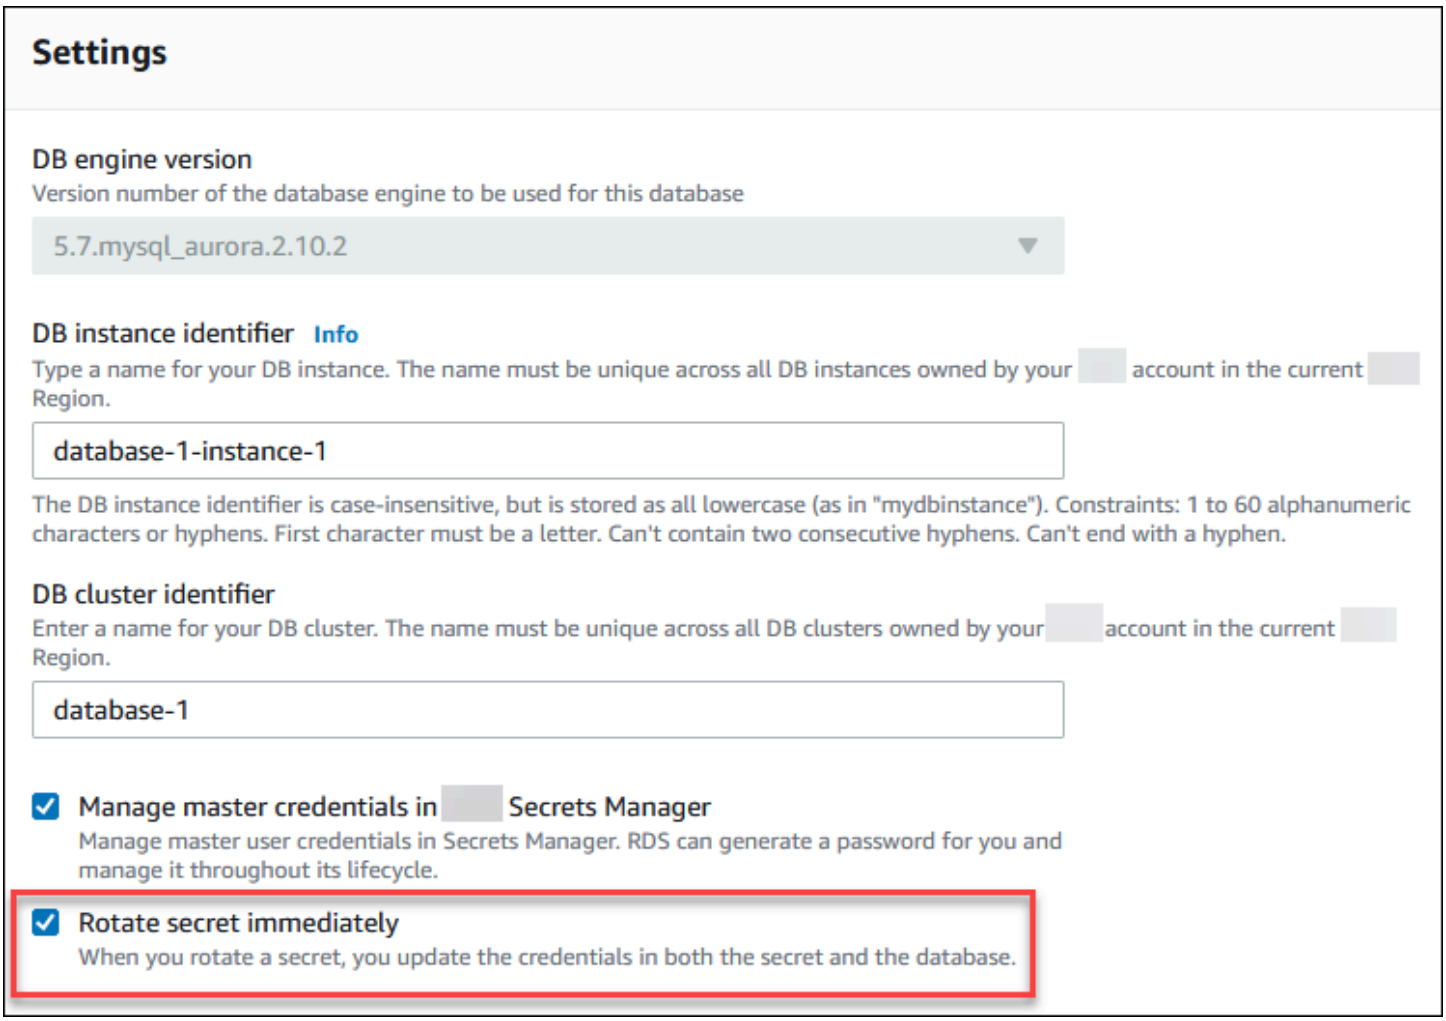
- CreateDBCluster

- ModifyDBCluster
- RestoreDBClusterFromS3

When you set the `ManageMasterUserPassword` parameter to `true` in one of these operations, Aurora generates the master user password and manages it throughout its lifecycle in Secrets Manager.

To encrypt the secret, you can specify a customer managed key or use the default KMS key that is provided by Secrets Manager. Use the `MasterUserSecretKmsKeyId` parameter to specify a customer managed key. The Amazon KMS key identifier is the key ARN, key ID, alias ARN, or alias name for the KMS key. To use a KMS key in a different Amazon Web Services account, specify the key ARN or alias ARN. After Aurora is managing the database credentials for a DB cluster, you can't change the KMS key that is used to encrypt the secret.

Rotating the master user password secret for a DB cluster



When Aurora rotates a master user password secret, Secrets Manager generates a new secret version for the existing secret. The new version of the secret contains the new master user password. Aurora changes the master user password for the DB cluster to match the password for the new secret version.

You can rotate a secret immediately instead of waiting for a scheduled rotation. To rotate a master user password secret in Secrets Manager, modify the DB cluster. For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster.

You can rotate a master user password secret immediately with the RDS console, the Amazon CLI, or the RDS API. The new password is always 28 characters long and contains atleast one upper and lowercase character, one number, and one punctuation.

Console

To rotate a master user password secret using the RDS console, modify the DB cluster and select **Rotate secret immediately** in **Settings**.

Follow the instructions for modifying a DB cluster with the RDS console in Modifying the DB cluster by using the console, CLI, and API. You must choose **Apply immediately** on the confirmation page.

Amazon CLI

To rotate a master user password secret using the Amazon CLI, use the modify-db-cluster command and specify the `--rotate-master-user-password` option. You must specify the `--apply-immediately` option when you rotate the master password.

This example rotates a master user password secret.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
```

```
    --db-cluster-identifier mydbcluster \
    --rotate-master-user-password \
    --apply-immediately
```

For Windows:

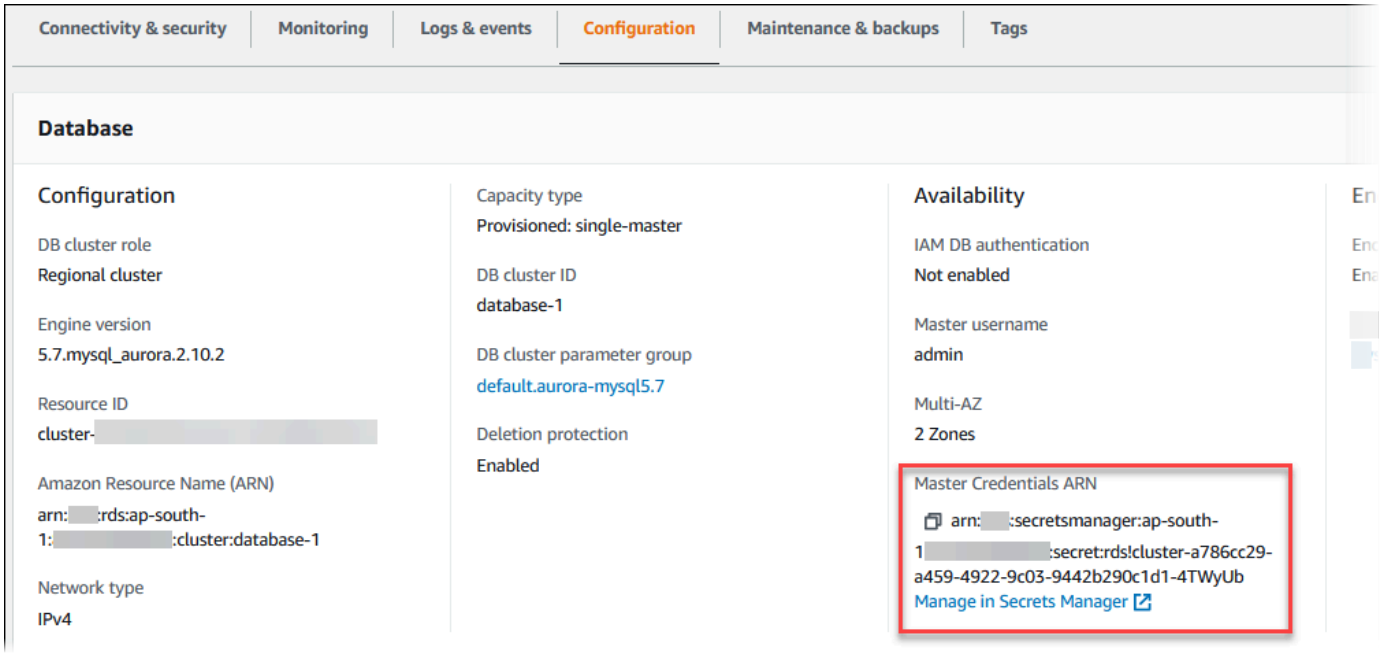
```
aws rds modify-db-cluster ^
    --db-cluster-identifier mydbcluster ^
    --rotate-master-user-password ^
    --apply-immediately
```

RDS API

You can rotate a master user password secret using the ModifyDBCluster operation and setting the `RotateMasterUserPassword` parameter to `true`. You must set the `ApplyImmediately` parameter to `true` when you rotate the master password.

Viewing the details about a secret for a DB cluster

You can retrieve your secrets using the console (https://console.amazonaws.cn/secretsmanager/) or the Amazon CLI (get-secret-value Secrets Manager command).



You can find the Amazon Resource Name (ARN) of a secret managed by Aurora in Secrets Manager with the RDS console, the Amazon CLI, or the RDS API.

Console

To view the details about a secret managed by Aurora in Secrets Manager

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB cluster to show its details.
4. Choose the **Configuration** tab.

   In **Master Credentials ARN**, you can view the secret ARN.

You can follow the **Manage in Secrets Manager** link to view and manage the secret in the Secrets Manager console.

Amazon CLI

You can use the RDS Amazon CLI describe-db-clusters command to find the following information about a secret managed by Aurora in Secrets Manager:

- `SecretArn` – The ARN of the secret
- `SecretStatus` – The status of the secret

  The possible status values include the following:

  - `creating` – The secret is being created.
  - `active` – The secret is available for normal use and rotation.
  - `rotating` – The secret is being rotated.
  - `impaired` – The secret can be used to access database credentials, but it can't be rotated. A secret might have this status if, for example, permissions are changed so that RDS can no longer access the secret or the KMS key for the secret.

    When a secret has this status, you can correct the condition that caused the status. If you correct the condition that caused status, the status remains `impaired` until the next rotation. Alternatively, you can modify the DB cluster to turn off automatic management of database

credentials, and then modify the DB cluster again to turn on automatic management of database credentials. To modify the DB cluster, use the `--manage-master-user-password` option in the modify-db-cluster command.

- `KmsKeyId` – The ARN of the KMS key that is used to encrypt the secret

Specify the `--db-cluster-identifier` option to show output for a specific DB cluster. This example shows the output for a secret that is used by a DB cluster.

Example

```
aws rds describe-db-clusters --db-cluster-identifier mydbcluster
```

The following sample shows the output for a secret:

```
"MasterUserSecret": {
                "SecretArn": "arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx",
                "SecretStatus": "active",
                "KmsKeyId": "arn:aws:kms:eu-
west-1:123456789012:key/0987dcba-09fe-87dc-65ba-ab0987654321"
            }
```

When you have the secret ARN, you can view details about the secret using the get-secret-value Secrets Manager CLI command.

This example shows the details for the secret in the previous sample output.

Example

For Linux, macOS, or Unix:

```
aws secretsmanager get-secret-value \
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

For Windows:

```
aws secretsmanager get-secret-value ^
    --secret-id 'arn:aws:secretsmanager:eu-west-1:123456789012:secret:rds!
cluster-033d7456-2c96-450d-9d48-f5de3025e51c-xmJRDx'
```

RDS API

You can view the ARN, status, and KMS key for a secret managed by Aurora in Secrets Manager using the DescribeDBClusters RDS operation and setting the `DBClusterIdentifier` parameter to a DB cluster identifier. Details about the secret are included in the output.

When you have the secret ARN, you can view details about the secret using the GetSecretValue Secrets Manager operation.

Data protection in Amazon RDS

The Amazon shared responsibility model applies to data protection in Amazon Relational Database Service. As described in this model, Amazon is responsible for protecting the global infrastructure that runs all of the Amazon Web Services Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the Amazon Web Services services that you use. For more information about data privacy, see Amazon China Region Legal Terms.

For data protection purposes, we recommend that you protect Amazon Web Services account credentials and set up individual users with Amazon IAM Identity Center or Amazon Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with Amazon resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with Amazon CloudTrail. For information about using CloudTrail trails to capture Amazon activities, see Working with CloudTrail trails in the *Amazon CloudTrail User Guide*.
- Use Amazon encryption solutions, along with all default security controls within Amazon Web Services services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing Amazon through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Amazon RDS or other Amazon Web Services services using the console, API, Amazon CLI, or Amazon SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

- Amazon KMS key management
- Using SSL/TLS to encrypt a connection to a DB cluster
- Rotating your SSL/TLS certificate

Encrypting Amazon Aurora resources

Amazon Aurora protects your data both at rest and in transit—whether moving between on-premises clients and Amazon Aurora, or between Amazon Aurora and other Amazon resources. Amazon Aurora encrypts all user data in your Amazon Aurora DB clusters including logs, automated backups, and snapshots.

After your data is encrypted, Amazon Aurora handles authentication of access and decryption of your data transparently with a minimal impact on performance. You don't need to modify your database client applications to use encryption.

> **Note**
>
> For encrypted and unencrypted DB clusters, data that is in transit between the source and the read replicas is encrypted, even when replicating across Amazon Regions.

Topics

- Overview of encryption in Amazon Aurora resources
- Encrypting an Amazon Aurora DB cluster
- Determining whether encryption is turned on for a DB cluster
- Availability of Amazon Aurora encryption
- Encryption in transit
- Limitations of Amazon Aurora encrypted DB clusters

Overview of encryption in Amazon Aurora resources

Amazon Aurora encrypted DB clusters provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. All new database clusters created on or after March 3, 2026, in Amazon Aurora are encrypted at rest using industry standard AES-256 encryption. This encryption happens automatically in the background, securing your data without requiring any action from you. It also helps reduce the operational burden and complexity involved in protecting sensitive data. With encryption at rest, you can secure compliance-sensitive and security-critical applications against both accidental and malicious threats while meeting regulatory requirements.

Amazon Aurora uses an Amazon Key Management Service key to encrypt these resources. Amazon KMS combines secure, highly available hardware and software to provide a key management system scaled for the cloud. When creating a new database cluster, Amazon Aurora uses Server-Side Encryption (SSE) with an Amazon-owned key by default. This default applies only to the new cluster itself. Clones, snapshot copies, and Amazon Aurora replicas (read instances) created from an unencrypted source are not automatically encrypted. They inherit the encryption state of their source. However, you can choose from three encryption types based on your security and compliance needs:

- **Amazon owned key (SSE-RDS)** – A fully Amazon-controlled encryption key that you cannot view or manage, used automatically by Aurora for default encryption.

- **Amazon managed key (AMK)** – This key is created and managed by Amazon and is visible in your account but not customizable. There is no monthly fee, but Amazon KMS API charges will apply.
- **Customer managed key (CMK)** – The key is stored in your account and is created, owned, and managed by you. You have full control over the KMS key (Amazon KMS charges apply).

Amazon managed keys are a legacy encryption option that remains available for backward compatibility. Amazon Aurora uses Amazon-owned keys by default to encrypt your data, providing strong security protection without additional charges or management overhead. For most use cases, we recommend using either the default Amazon-owned key for simplicity and cost efficiency, or a customer managed key (CMK) if you require full control over your encryption keys. For more information about key types, see customer managed keys and Amazon managed keys.

> **Note**
>
> **Important:** For source database instances or clusters created before March 3, 2026, where you did not opt in for encryption, snapshots, clones, and Amazon Aurora replicas (read instance) created from those sources will remain unencrypted. However, restore operations outside the Amazon Aurora cluster will produce encrypted instances.

For an Amazon Aurora encrypted DB cluster, all DB instances, logs, backups, and snapshots are encrypted. For more information about the availability and limitations of encryption, see Availability of Amazon Aurora encryption and Limitations of Amazon Aurora encrypted DB clusters.

When you create an encrypted DB cluster, you can choose a customer managed key or the Amazon managed key for Amazon Aurora to encrypt your DB cluster, if you don't specify the key identifier for a customer managed key, Amazon Aurora uses the Amazon managed key for your new DB cluster. Amazon Aurora creates an Amazon managed key for Amazon Aurora for your Amazon account. Your Amazon account has a different Amazon managed key for Amazon Aurora for each Amazon Region.

To manage the customer managed keys used for encrypting and decrypting your Amazon Aurora resources, you use the Amazon Key Management Service (Amazon KMS).

Using Amazon KMS, you can create customer managed keys and define the policies to control the use of these customer managed keys. Amazon KMS supports CloudTrail, so you can audit KMS key usage to verify that customer managed keys are being used appropriately. You can use your customer managed keys with Amazon Aurora and supported Amazon services such as Amazon S3,

Amazon EBS, and Amazon Redshift. For a list of services that are integrated with Amazon KMS, see Amazon Service Integration. Some considerations about using KMS keys:

- Once you create an encrypted DB instance, you cannot change the KMS key used by that instance. Be sure to determine your KMS key requirements before creating your encrypted DB instance. If you need to change the encryption key for your DB cluster, follow these steps:
  - Create a manual snapshot of your cluster.
  - Restore the snapshot and enable encryption with your desired KMS key during the restore operation. You cannot enable encryption with an Amazon owned key if your cluster was originally encrypted with an Amazon managed key or a customer managed key.
- If you restore an unencrypted snapshot and choose no encryption, the database cluster created will be encrypted using the default encryption at rest (Amazon-owned key).
- You can't share a snapshot that has been encrypted using the Amazon managed key of the Amazon account that shared the snapshot.
- Each DB instance in the DB cluster shares the same storage encrypted with the same KMS key.

Important

Amazon Aurora can lose access to the KMS key for a DB cluster when you disable the KMS key. In these cases, the encrypted DB cluster goes into `inaccessible-encryption-credentials-recoverable` state. The DB cluster remains in this state for seven days, during which the instance is stopped. API calls made to the DB cluster during this time might not succeed. To recover the DB cluster, enable the KMS key and restart this DB cluster. You can enable the KMS key from the Amazon Web Services Management Console, Amazon CLI, or RDS API. Restart the DB cluster using the Amazon CLI command start-db-cluster or Amazon Web Services Management Console.

The `inaccessible-encryption-credentials-recoverable` state only applies to DB clusters that can stop. This recoverable state is not applicable to instances that can't stop, such as clusters with cross-Region read replicas. For more information, see the section called “Limitations”.

If the DB cluster isn't recovered within seven days, it goes into the terminal `inaccessible-encryption-credentials` state. In this state, the DB cluster is not usable anymore and you can only restore the DB cluster from a backup. We strongly recommend that you always turn on backups to guard against the loss of data in your databases.

During the creation of a DB cluster, Aurora checks if the calling principal has access to the KMS key and generates a grant from the KMS key that it uses for the entire lifetime of the DB cluster. Revoking the calling principals access to the KMS key does not affect a running database. When using KMS keys in cross-account scenarios, such as copying a snapshot to another account, the KMS key needs to be shared with the other account. If you create a DB cluster from the snapshot without specifying a different KMS key, the new cluster uses the KMS key from the source account. Revoking access to the key after you create the DB cluster does not affect the cluster. However, disabling the key impacts all DB clusters encrypted with that key. To prevent this, specify a different key during the snapshot copy operation.

For more information about KMS keys, see Amazon KMS keys in the *Amazon Key Management Service Developer Guide* and Amazon KMS key management.

Encrypting an Amazon Aurora DB cluster

All new DB clusters created on or after March 3, 2026, are encrypted by default with an Amazon owned key.

To encrypt a new DB cluster, using Amazon managed key or customer managed key, choose the option on the console. For information on creating a DB cluster, see Creating an Amazon Aurora DB cluster.

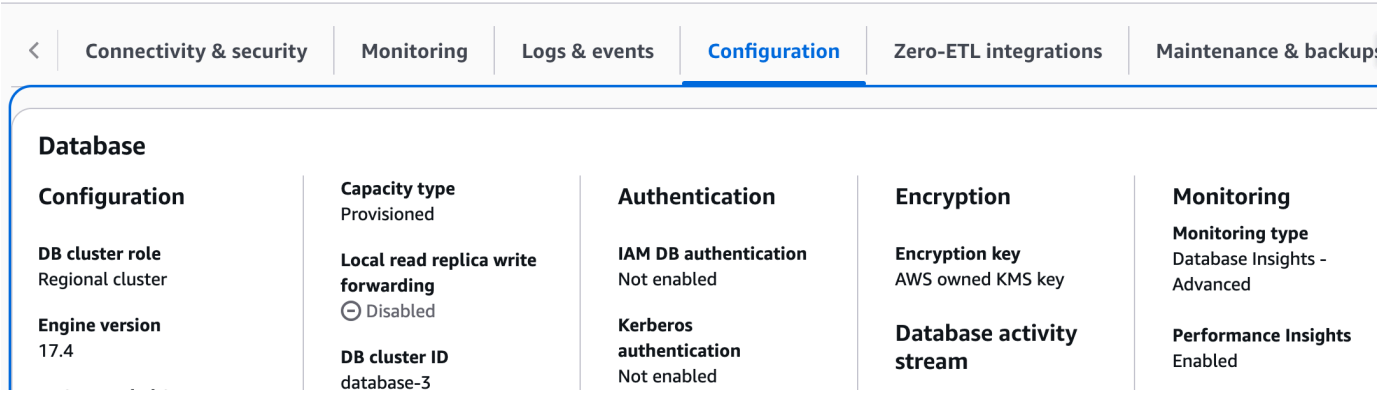
If you use the create-db-cluster Amazon CLI command to create an encrypted DB cluster, set the `--storage-encrypted` parameter. If you use the CreateDBCluster API operation, set the `StorageEncrypted` parameter to true.

Once you have created an encrypted DB cluster, you can't change the KMS key used by that DB cluster. Therefore, be sure to determine your KMS key requirements before you create your encrypted DB cluster.

You can also use a blue/green deployment to create a green environment that's encrypted with a different KMS key than the blue environment. Use this deployment to encrypt an unencrypted DB cluster or to change the KMS key of an encrypted DB cluster. For more information about blue/green deployments, see Limitations and considerations for Amazon Aurora blue/green deployments.

If you use the Amazon CLI `create-db-cluster` command to create an encrypted DB cluster with a customer managed key, set the `--kms-key-id` parameter to any key identifier for the KMS key.

If you use the Amazon RDS API `CreateDBInstance` operation, set the `KmsKeyId` parameter to any key identifier for the KMS key. To use a customer managed key in a different Amazon account, specify the key ARN or alias ARN.



Determining whether encryption is turned on for a DB cluster

You can use the Amazon Web Services Management Console, Amazon CLI, or RDS API to determine whether encryption at rest is turned on for a DB cluster.

Console

To determine whether encryption at rest is turned on for a DB cluster

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB cluster that you want to check to view its details.
4. Choose the **Configuration** tab and check the **Encryption** value.

Amazon CLI

To determine whether encryption at rest is turned on for a DB cluster by using the Amazon CLI, call the describe-db-clusters command with the following option:

- `--db-cluster-identifier` – The name of the DB cluster.

The following example uses a query to return either TRUE or FALSE regarding encryption at rest for the `mydb` DB cluster.

Example

```
aws rds describe-db-clusters --db-cluster-identifier mydb --query "*[].
{StorageEncrypted:StorageEncrypted}" --output text
```

RDS API

To determine whether encryption at rest is turned on for a DB cluster by using the Amazon RDS API, call the DescribeDBClusters operation with the following parameter:

- `DBClusterIdentifier` – The name of the DB cluster.

Availability of Amazon Aurora encryption

Amazon Aurora encryption is currently available for all database engines and storage types.

> **Note**
>
> Amazon Aurora encryption is not available for the db.t2.micro DB instance class.

Encryption in transit

Encryption at the physical layer

All data flowing accross Amazon Web Services Regions over the Amazon global network is automatically encrypted at the physical layer before it leaves Amazon secured facilities. All traffic between AZs is encrypted. Additional layers of encryption, including those listed in this section may provide additional protections.

Encryption provided by Amazon VPC peering and Transit Gateway cross-Region peering

All cross-Region traffic that uses Amazon VPC and Transit Gateway peering is automatically bulk-encrypted when it exits a Region. An additional layer of encryption is automatically provided at the physical layer for all traffic before it leaves Amazon secured facilities.

Encryption between instances

Amazon provides secure and private connectivity between DB instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. This encryption uses Authenticated

Encryption with Associated Data (AEAD) algorithms, with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
  - **General purpose**: M6i, M6id, M6in, M6idn, M7g
  - **Memory optimized**: R6i, R6id, R6in, R6idn, R7g, X2idn, X2iedn, X2iezn
- The instances are in the same Amazon Web Services Region.
- The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.

Limitations of Amazon Aurora encrypted DB clusters

The following limitations exist for Amazon Aurora encrypted DB clusters:

- You can't turn off encryption on an encrypted DB cluster.
- If you have an existing unencrypted cluster, all snapshots created from that cluster are also unencrypted. You can't encrypt an unencrypted Aurora DB cluster snapshot by copying it.
- You can't create an encrypted snapshot of an unencrypted DB cluster.
- A snapshot of an encrypted DB cluster must be encrypted using the same KMS key as the DB cluster.
- You can't convert an unencrypted DB cluster to an encrypted one. However, you can restore an unencrypted snapshot to an encrypted Aurora DB cluster. To do this, specify a KMS key when you restore from the unencrypted snapshot.
- If you have an existing unencrypted cluster, any Amazon Aurora replica (read instance) created from that cluster will also be unencrypted. To create an encrypted cluster from an unencrypted cluster, you need to restore the database cluster. The restored cluster will be encrypted by default after the restore operation.
- To copy an encrypted snapshot from one Amazon Region to another, you must specify the KMS key in the destination Amazon Region. This is because KMS keys are specific to the Amazon Region that they are created in.

  The source snapshot remains encrypted throughout the copy process. Amazon Aurora uses envelope encryption to protect data during the copy process. For more information about envelope encryption, see Envelope encryption in the *Amazon Key Management Service Developer Guide*.

- You can't unencrypt an encrypted DB cluster. However, you can export data from an encrypted DB cluster and import the data into an unencrypted DB cluster.

Amazon KMS key management

Amazon Aurora automatically integrates with Amazon Key Management Service (Amazon KMS) for key management. Amazon Aurora uses envelope encryption. For more information about envelope encryption, see Envelope encryption in the *Amazon Key Management Service Developer Guide*.

You can use two types of Amazon KMS keys to encrypt your DB clusters.

- If you want full control over a KMS key, you must create a *customer managed key*. For more information about customer managed keys, see Customer managed keys in the *Amazon Key Management Service Developer Guide*.
- *Amazon managed keys* are KMS keys in your account that are created, managed, and used on your behalf by an Amazon service that is integrated with Amazon KMS. By default, the RDS Amazon managed key (`aws/rds`) is used for encryption. You can't manage, rotate, or delete the RDS Amazon managed key. For more information about Amazon managed keys, see Amazon managed keys in the *Amazon Key Management Service Developer Guide*.

To manage KMS keys used for Amazon Aurora encrypted DB clusters, use the Amazon Key Management Service (Amazon KMS) in the Amazon KMS console, the Amazon CLI, or the Amazon KMS API. To view audit logs of every action taken with an Amazon managed or customer managed key, use Amazon CloudTrail. For more information about key rotation, see Rotating Amazon KMS keys.

Authorizing use of a customer managed key

When Aurora uses a customer managed key in cryptographic operations, it acts on behalf of the user who is creating or changing the Aurora resource.

To create an Aurora resource using a customer managed key, a user must have permissions to call the following operations on the customer managed key:

- `kms:CreateGrant`
- `kms:DescribeKey`

You can specify these required permissions in a key policy, or in an IAM policy if the key policy allows it.

> **Important**
>
> When you use explicit deny statements for all resources (*) in Amazon KMS key policies with managed services like Amazon RDS, you must specify a condition to allow the resource owning account. Operations might fail without this condition, even if the deny rule includes exceptions for your IAM user.

> **Tip**
>
> To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the kms:ViaService condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an Amazon service.

You can make the IAM policy stricter in various ways. For example, if you want to allow the customer managed key to be used only for requests that originate in Aurora, use the kms:ViaService condition key with the `rds.<region>.amazonaws.com` value. Also, you can use the keys or values in the Amazon RDS encryption context as a condition for using the customer managed key for encryption.

For more information, see Allowing users in other accounts to use a KMS key in the *Amazon Key Management Service Developer Guide* and Key policies in Amazon KMS.

Amazon RDS encryption context

When Aurora uses your KMS key, or when Amazon EBS uses the KMS key on behalf of Aurora, the service specifies an encryption context. The encryption context is additional authenticated data (AAD) that Amazon KMS uses to ensure data integrity. When an encryption context is specified for an encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your Amazon CloudTrail logs to help you understand why a given KMS key was used. Your CloudTrail logs might contain many entries describing the use of a KMS key, but the encryption context in each log entry can help you determine the reason for that particular use.

At minimum, Aurora always uses the DB cluster ID for the encryption context, as in the following JSON-formatted example:

```
{ "aws:rds:dbc-id": "cluster-CQYSMDPBRZ7BPMH7Y3RTDG5QY" }
```

This encryption context can help you identify the DB cluster for which your KMS key was used.

When your KMS key is used for a specific DB cluster and a specific Amazon EBS volume, both the DB cluster ID and the Amazon EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```
{
  "aws:rds:dbc-id": "cluster-BRG7VYS3SVIFQW7234EJQOM5RQ",
  "aws:ebs:id": "vol-ad8c6542"
}
```

Using SSL/TLS to encrypt a connection to a DB cluster

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB cluster running Aurora MySQL or Aurora PostgreSQL.

SSL/TLS connections provide a layer of security by encrypting data that moves between your client and DB cluster. Optionally, your SSL/TLS connection can perform server identity verification by validating the server certificate installed on your database. To require server identity verification, follow this general process:

1. Choose the **certificate authority (CA)** that signs the **DB server certificate,** for your database. For more information about certificate authorities, see Certificate authorities .
2. Download a certificate bundle to use when you are connecting to the database. To download a certificate bundle, see Certificate bundles for specific Amazon Web Services Regions .

   > **Note**
   >
   > All certificates are only available for download using SSL/TLS connections.

3. Connect to the database using your DB engine's process for implementing SSL/TLS connections. Each DB engine has its own process for implementing SSL/TLS. To learn how to implement SSL/TLS for your database, follow the link that corresponds to your DB engine:
   - Security with Amazon Aurora MySQL

- Security with Amazon Aurora PostgreSQL

Certificate authorities

The **certificate authority (CA)** is the certificate that identifies the root CA at the top of the certificate chain. The CA signs the **DB server certificate,** which is installed on each DB instance. The DB server certificate identifies the DB instance as a trusted server.

Amazon RDS provides the following CAs to sign the DB server certificate for a database.

Certificate authority (CA)	Description	Common name (CN)
rds-ca-rsa2048-g1	Uses a certificate authority with RSA 2048 private key algorithm and SHA256 signing algorithm in most Amazon Web Services Regions. In the Amazon GovCloud (US) Regions, this CA uses a certificate authority with	Amazon RDS *region-id entifier* Root CA RSA2048 G1

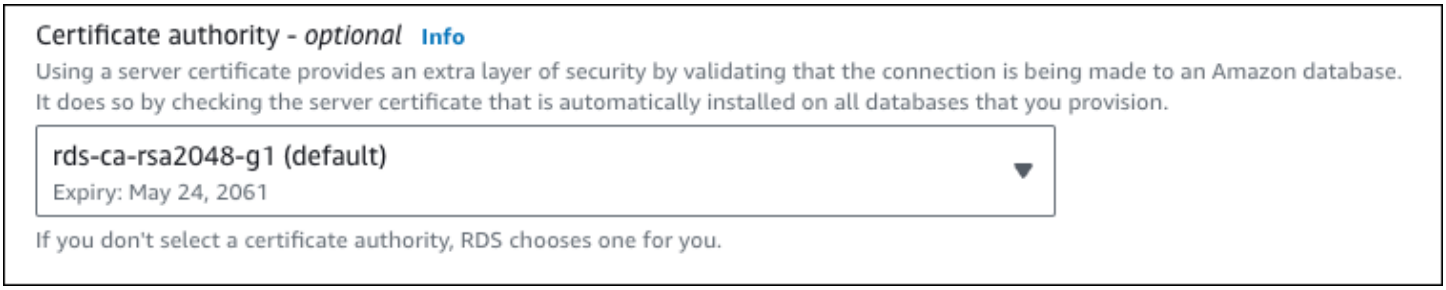
Certificate authority (CA)	Description	Common name (CN)
	RSA 2048 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	
rds-ca-rsa4096-g1	Uses a certificate authority with RSA 4096 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS *region-id entifier* Root CA RSA4096 G1
rds-ca-ecc384-g1	Uses a certificate authority with ECC 384 private key algorithm and SHA384 signing algorithm. This CA supports automatic server certificate rotation.	Amazon RDS *region-id entifier* Root CA ECC384 G1

Note

If you are using the Amazon CLI, you can see the validities of the certificate authorities listed above by using describe-certificates.

These CA certificates are included in the regional and global certificate bundle. When you use the rds-ca-rsa2048-g1 CA with a database, RDS manages the DB server certificate on the database. RDS rotates the DB server certificate automatically before it expires.

Setting the CA for your database



You can set the CA for a database when you perform the following tasks:

- Create an Aurora DB cluster – You can set the CA for a DB instance in an Aurora cluster when you create the first DB instance in the DB cluster using the Amazon CLI or RDS API. Currently, you can't set the CA for the DB instances in a DB cluster when you create the DB cluster using the RDS console. For instructions, see Creating an Amazon Aurora DB cluster .

- Modify a DB instance – You can set the CA for a DB instance in a DB cluster by modifying it. For instructions, see Modifying a DB instance in a DB cluster .

> **Note**
>
> The default CA is set to rds-ca-rsa2048-g1. You can override the default CA for your Amazon Web Services account by using the modify-certificates command.

The available CAs depend on the DB engine and DB engine version. When you use the Amazon Web Services Management Console, you can choose the CA using the **Certificate authority** setting, as shown in the following image.

The console only shows the CAs that are available for the DB engine and DB engine version. If you're using the Amazon CLI, you can set the CA for a DB instance using the create-db-instance or modify-db-instance command.

If you're using the Amazon CLI, you can see the available CAs for your account by using the describe-certificates command. This command also shows the expiration date for each CA in `ValidTill` in the output. You can find the CAs that are available for a specific DB engine and DB engine version using the describe-db-engine-versions command.

The following example shows the CAs available for the default RDS for PostgreSQL DB engine version.

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

Your output is similar to the following. The available CAs are listed in `SupportedCACertificateIdentifiers`. The output also shows whether the DB engine version supports rotating the certificate without restart in `SupportsCertificateRotationWithoutRestart`.

```
{
    "DBEngineVersions": [
        {
            "Engine": "postgres",
            "MajorEngineVersion": "13",
            "EngineVersion": "13.4",
            "DBParameterGroupFamily": "postgres13",
            "DBEngineDescription": "PostgreSQL",
            "DBEngineVersionDescription": "PostgreSQL 13.4-R1",
            "ValidUpgradeTarget": [],
            "SupportsLogExportsToCloudwatchLogs": false,
            "SupportsReadReplica": true,
            "SupportedFeatureNames": [
                "Lambda"
            ],
            "Status": "available",
            "SupportsParallelQuery": false,
            "SupportsGlobalDatabases": false,
            "SupportsBabelfish": false,
            "SupportsCertificateRotationWithoutRestart": true,
            "SupportedCACertificateIdentifiers": [
                "rds-ca-rsa2048-g1",
                "rds-ca-ecc384-g1",
                "rds-ca-rsa4096-g1"
            ]
        }
    ]
}
```

DB server certificate validities

The validity of DB server certificate depends on the DB engine and DB engine version. If the DB engine version supports rotating the certificate without restart, the validity of the DB server certificate is 1 year. Otherwise the validity is 3 years.

For more information about DB server certificate rotation, see Automatic server certificate rotation .

Viewing the CA for your DB instance

To view the details about the CA for a DB instance in the console, choose the **Connectivity & security** tab on the details page for the DB instance. For **Connect using**, choose **Endpoints**. The

CA details appear in the **Security** section under **Additional configurations**. This section shows **Certificate authority** and, when available, **Certificate authority date** and **DB instance certificate expiration date**.

For an Aurora DB cluster, you can view the CA details only on the details page for each DB instance, not on the details page for the DB cluster.

If you're using the Amazon CLI, you can view the details about the CA for a DB instance by using the describe-db-instances command.

Download certificate bundles for Aurora

When you connect to your database with SSL or TLS, the database instance requires a trust certificate from Amazon RDS. Select the appropriate link in the following table to download the bundle that corresponds with the Amazon Web Services Region where you host your database.

Certificate bundles for specific Amazon Web Services Regions

To get a certificate bundle for the China (Beijing) Amazon Region or China (Ningxia) Amazon Region, download it from https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-bundle.pem. If your application is on Microsoft Windows and requires a PKCS7 file, you can download the PKCS7 certificate bundle from https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-bundle.p7b.

The bundle contains the `rds-ca-rsa2048-g1`,`rds-ca-rsa4096-g1`, and `rds-ca-ecc384-g1` root CA certificates. Your application trust store only needs to register the root CA certificate.

To get a certificate bundle, download from the link for the Amazon Region in the following table.

Amazon Region	Certificate bundle (PEM)	Certificate bundle (PKCS7)
China (Beijing)	cn-north-1-bundle.pem	cn-north-1-bundle.p7b
China (Ningxia)	cn-northwest-1-bundle.pem	cn-northwest-1-bundle.p7b

Viewing the contents of your CA certificate

To check the contents of your CA certificate bundle, use the following command:

```
keytool -printcert -v -file global-bundle.pem
```

Rotating your SSL/TLS certificate

Amazon RDS Certificate Authority certificates rds-ca-2019 expired in August, 2024. If you use or plan to use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) with certificate verification to connect to your RDS DB instances , consider using the new CA certificate rds-ca-rsa2048-g1. If you currently do not use SSL/TLS with certificate verification, you might still have an expired CA certificate and must update them to a new CA certificate if you plan to use SSL/TLS with certificate verification to connect to your RDS databases.

Amazon RDS provides new CA certificates as an Amazon security best practice. For information about the new certificates and the supported Amazon Regions, see Using SSL/TLS to encrypt a connection to a DB cluster .

To update the CA certificate for your database, use the following methods:

- Updating your CA certificate by modifying your DB instance
- Updating your CA certificate by applying maintenance

Before you update your DB instances to use the new CA certificate, make sure that you update your clients or applications connecting to your RDS databases.

Considerations for rotating certificates

Consider the following situations before rotating your certificate:

- Amazon RDS Proxy uses certificates from the Amazon Certificate Manager (ACM). If you're using RDS Proxy, when you rotate your SSL/TLS certificate, you don't need to update applications that use RDS Proxy connections. For more information, see Using TLS/SSL with RDS Proxy .
- If you're using a Go version 1.15 application with a DB instance that was created or updated to the rds-ca-2019 certificate prior to July 28, 2020, you must update the certificate again. Update the certificate to rds-ca-rsa2048-g1.

  Use the `modify-db-instance` command , using the new CA certificate identifier. You can find the CAs that are available for a specific DB engine and DB engine version using the `describe-db-engine-versions` command.

  If you created your database or updated its certificate after July 28, 2020, no action is required. For more information, see Go GitHub issue #39568.

Updating your CA certificate by modifying your DB instance

The following example updates your CA certificate from *rds-ca-2019* to *rds-ca-rsa2048-g1*.

Update your application trust store to reduce any down time associated with updating your CA certificate. For more information about restarts associated with CA certificate rotation, see Automatic server certificate rotation .

To update your CA certificate by modifying your DB instance

1. Download the new SSL/TLS certificate as described in Using SSL/TLS to encrypt a connection to a DB cluster .
2. Update your applications to use the new SSL/TLS certificate.

   The methods for updating applications for new SSL/TLS certificates depend on your specific applications. Work with your application developers to update the SSL/TLS certificates for your applications.

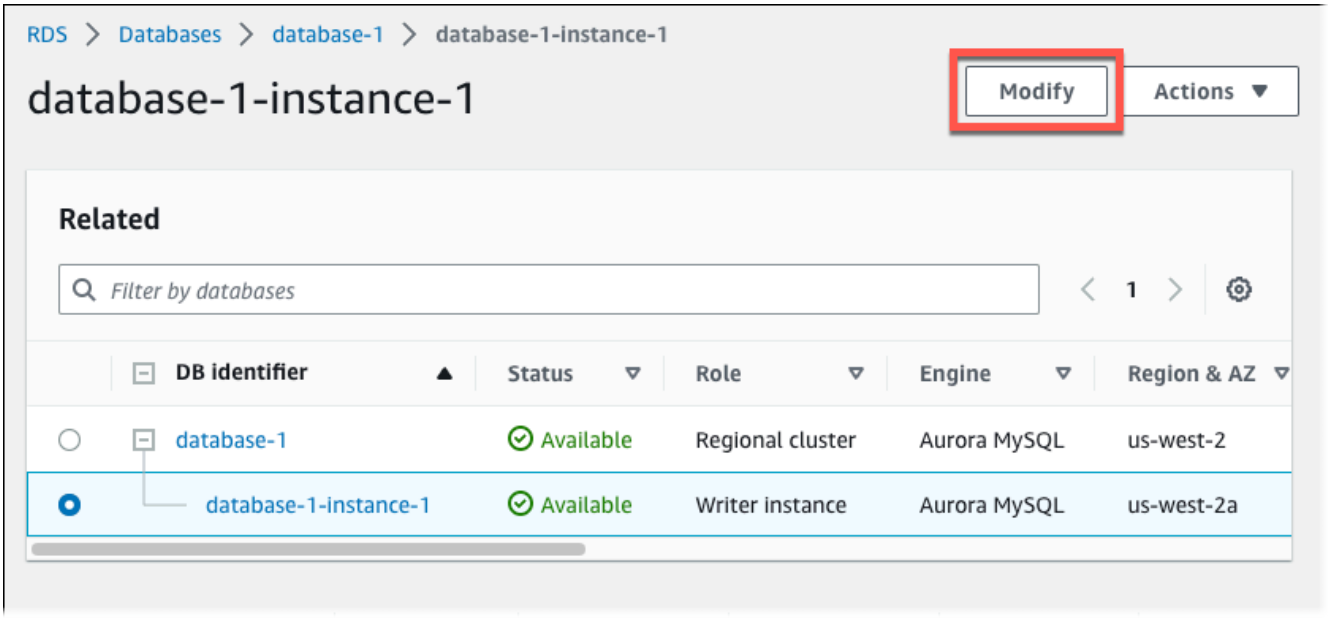
   For information about checking for SSL/TLS connections and updating applications for each DB engine, see the following topics:

   - Updating applications to connect to Aurora MySQL DB clusters using new TLS certificates
   - Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates

   For a sample script that updates a trust store for a Linux operating system, see Sample script for importing certificates into your trust store .

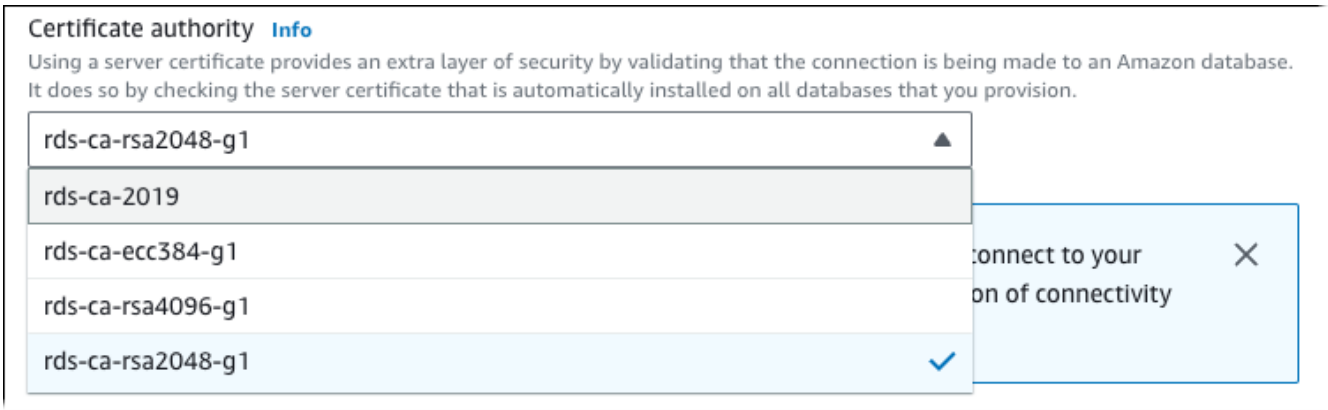
   > **Note**
   >
   > The certificate bundle contains certificates for both the old and new CA, so you can upgrade your application safely and maintain connectivity during the transition period. If you are using the Amazon Database Migration Service to migrate a database to a DB cluster, we recommend using the certificate bundle to ensure connectivity during the migration.

3. Modify the DB instance to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1**. To check if your database requires a restart to update the CA certificates, use the describe-db-engine-versions command and check the `SupportsCertificateRotationWithoutRestart` flag.



> **Note**
>
> Reboot your Babelfish cluster after modifying to update the CA certificate.

> **Important**
>
> If you are experiencing connectivity issues after certificate expiry, use the apply immediately option by specifying **Apply immediately** in the console or by specifying the `--apply-immediately` option using the Amazon CLI. By default, this operation is scheduled to run during your next maintenance window.
> To set an override for your cluster CA that's different from the default RDS CA, use the modify-certificates CLI command.



You can use the Amazon Web Services Management Console or the Amazon CLI to change the CA certificate from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance .

Console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.

4. In the **Connectivity** section, choose **rds-ca-rsa2048-g1**.

5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**.
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

> **Important**
>
> When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

Amazon CLI

To use the Amazon CLI to change the CA from **rds-ca-2019** to **rds-ca-rsa2048-g1** for a DB instance , call the modify-db-instance or modify-db-cluster command. Specify the DB instance identifier and the `--ca-certificate-identifier` option.

Use the `--apply-immediately` parameter to apply the update immediately. By default, this operation is scheduled to run during your next maintenance window.

> **Important**
>
> When you schedule this operation, make sure that you have updated your client-side trust store beforehand.

Example

The following example modifies `mydbinstance` by setting the CA certificate to `rds-ca-rsa2048-g1`.

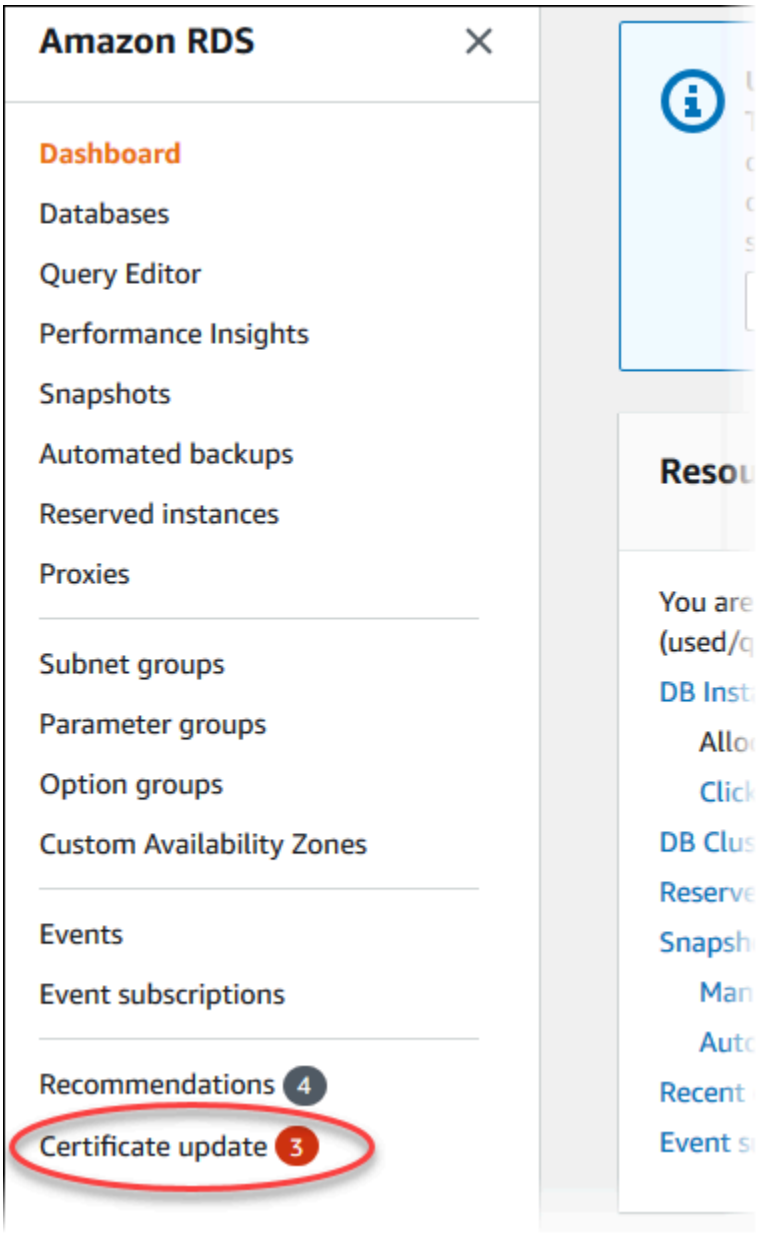
For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

For Windows:

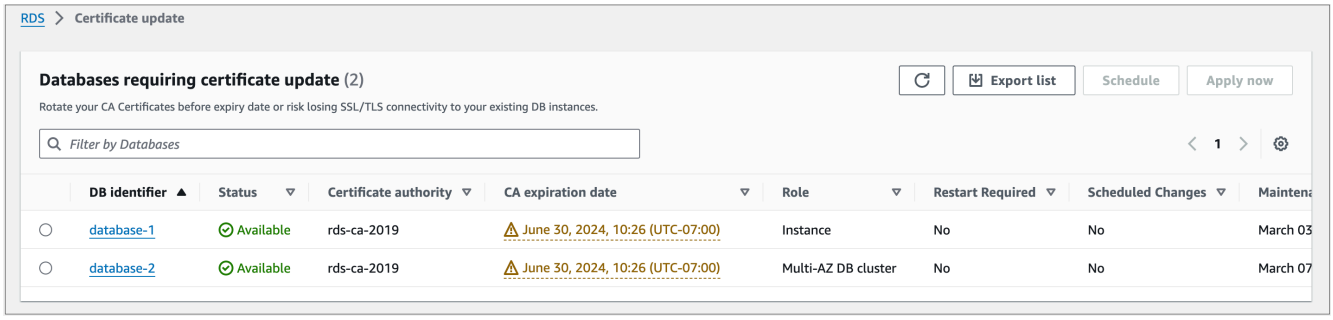
```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --ca-certificate-identifier rds-ca-rsa2048-g1
```

> **Note**
>
> If your instance requires reboot, you can use the modify-db-instance CLI command and specify the `--no-certificate-rotation-restart` option.



Updating your CA certificate by applying maintenance

Perform the following steps to update your CA certificate by applying maintenance.

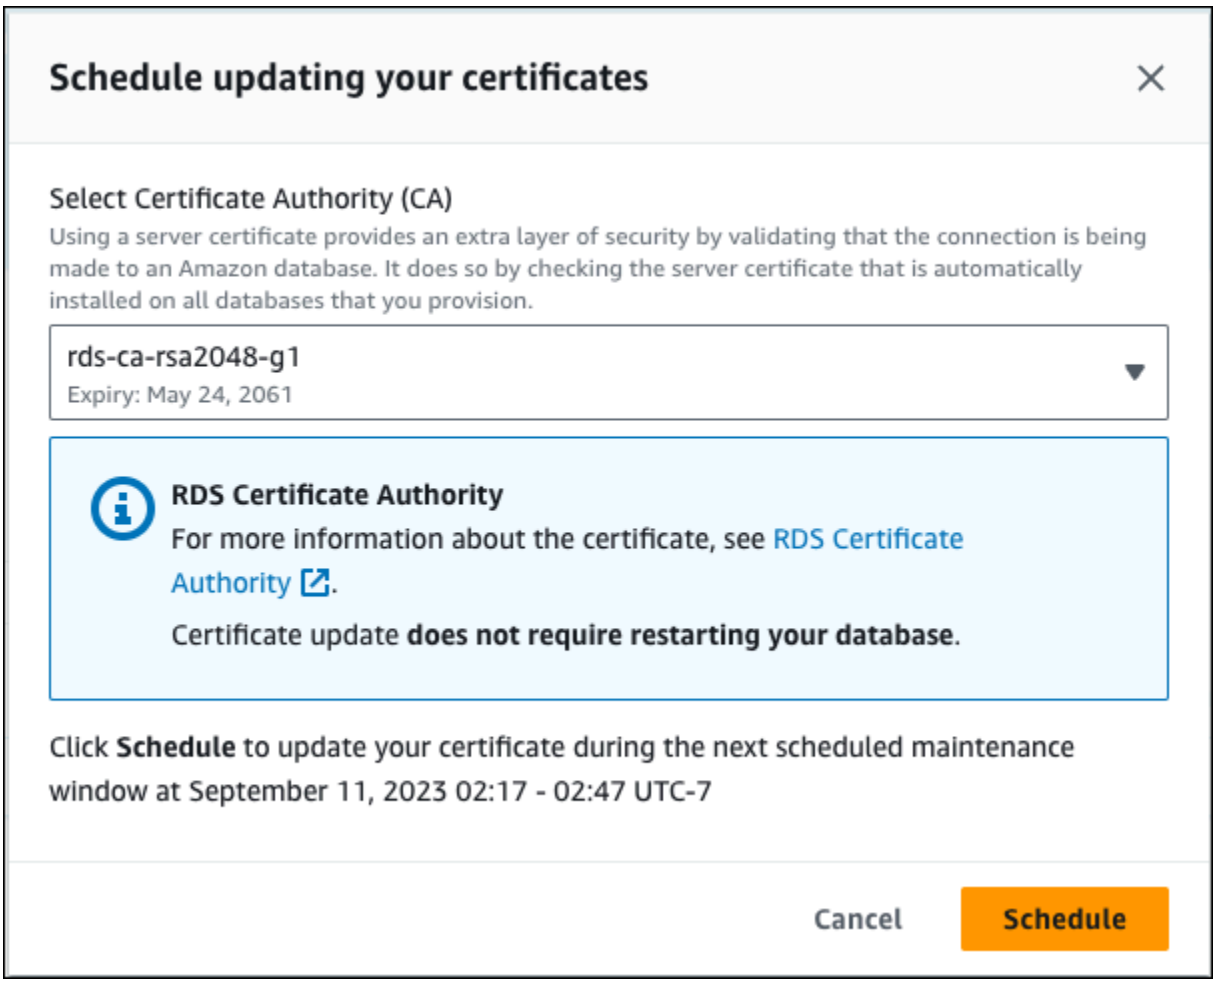


Console

To update your CA certificate by applying maintenance

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Certificate update**.

The **Databases requiring certificate update** page appears.



> **Note**
>
> This page only shows the DB instances for the current Amazon Web Services Region. If you have databases in more than one Amazon Web Services Region, check this page in each Amazon Web Services Region to see all DB instances with old SSL/TLS certificates.

3. Choose the DB instance that you want to update.

   You can schedule the certificate rotation for your next maintenance window by choosing **Schedule**. Apply the rotation immediately by choosing **Apply now**.

> **Important**
>
> If you experience connectivity issues after certificate expiry, use the **Apply now** option.

4. a. If you choose **Schedule**, you are prompted to confirm the CA certificate rotation. This prompt also states the scheduled window for your update.

b. If you choose **Apply now**, you are prompted to confirm the CA certificate rotation.

> **Important**
>
> Before scheduling the CA certificate rotation on your database, update any client applications that use SSL/TLS and the server certificate to connect. These updates are specific to your DB engine. After you have updated these client applications, you can confirm the CA certificate rotation.

To continue, choose the check box, and then choose **Confirm**.

5. Repeat steps 3 and 4 for each DB instance that you want to update.

Automatic server certificate rotation

If your root CA supports automatic server certificate rotation, RDS automatically handles the rotation of the DB server certificate. RDS uses the same root CA for this automatic rotation, so you don't need to download a new CA bundle. See Certificate authorities .

The rotation and validity of your DB server certificate depend on your DB engine:

- If your DB engine supports rotation without restart, RDS automatically rotates the DB server certificate without requiring any action from you. RDS attempts to rotate your DB server certificate in your preferred maintenance window at the DB server certificate half life. The new DB server certificate is valid for 12 months.
- If your DB engine doesn't support rotation without restart, Amazon RDS makes a `server-certificate-rotation` Pending Maintenance Action visible via Describe-pending-maintenance-actions API, at the half life of the certificate, or at least 3 months before expiry. You can apply the rotation using the apply-pending-maintenance-action API. The new DB server certificate is valid for 36 months.

Use the describe-db-engine-versions command and inspect the `SupportsCertificateRotationWithoutRestart` flag to identify whether the DB engine version supports rotating the certificate without restart. For more information, see Setting the CA for your database .

> **Important**
>
> For Amazon RDS for Oracle DB instances, you will see the `SupportsCertificateRotationWithoutRestart` flag of the DB engine versions marked as FALSE. However, Amazon RDS for Oracle DB instances do NOT require restart, but the database listener is restarted during the server certificate rotation. Existing database connections are unaffected, but new connections will encounter errors for a brief period while the listener is restarted. If you want to manually rotate the server certificate, use the apply-pending-maintenance-action Amazon CLI command.

Sample script for importing certificates into your trust store

The following are sample shell scripts that import the certificate bundle into a trust store.

Each sample shell script uses keytool, which is part of the Java Development Kit (JDK). For information about installing the JDK, see JDK Installation Guide.

Linux

The following is a sample shell script that imports the certificate bundle into a trust store on a Linux operating system.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi truststore=${mydir}/rds-truststore.jks storepassword=changeit

curl -sS "https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-
bundle.pem"> ${mydir}/global-bundle.pem
awk 'split_after == 1 {n++;split_after=0} /-----END CERTIFICATE-----/
 {split_after=1}{print > "rds-ca-" n+1 ".pem"}' < ${mydir}/global-bundle.pem

for CERT in rds-ca-*; do alias=$(openssl x509 -noout -text -in $CERT | perl -ne
 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
keystore ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
 cut -d " " -f3- | while read alias
do expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
   echo " Certificate ${alias} expires in '$expiry'"
done
```

macOS

The following is a sample shell script that imports the certificate bundle into a trust store on macOS.

```
mydir=tmp/certs
if [ ! -e "${mydir}" ]
then
mkdir -p "${mydir}"
fi truststore=${mydir}/rds-truststore.jks storepassword=changeit

curl -sS "https://rds-truststore.s3.cn-north-1.amazonaws.com.cn/global/global-
bundle.pem"> ${mydir}/global-bundle.pem
split -p "-----BEGIN CERTIFICATE-----" ${mydir}/global-bundle.pem rds-ca-

for CERT in rds-ca-*; do alias=$(openssl x509 -noout -text -in $CERT | perl -ne
 'next unless /Subject:/; s/.*(CN=|CN = )//; print')
  echo "Importing $alias"
  keytool -import -file ${CERT} -alias "${alias}" -storepass ${storepassword} -
keystore ${truststore} -noprompt
  rm $CERT
done

rm ${mydir}/global-bundle.pem

echo "Trust store content is: "

keytool -list -v -keystore "$truststore" -storepass ${storepassword} | grep Alias |
 cut -d " " -f3- | while read alias
do expiry=`keytool -list -v -keystore "$truststore" -storepass ${storepassword} -
alias "${alias}" | grep Valid | perl -ne 'if(/until: (.*?)\n/) { print "$1\n"; }'`
   echo " Certificate ${alias} expires in '$expiry'"
done
```

To learn more best practices about using SSL with Amazon RDS, see Best practices for successful SSL connections to Amazon RDS for Oracle .

Internetwork traffic privacy

Connections are protected both between Amazon Aurora and on-premises applications and between Amazon Aurora and other Amazon resources within the same Amazon Region.

Traffic between service and on-premises clients and applications

You have two connectivity options between your private network and Amazon:

- An Amazon Site-to-Site VPN connection. For more information, see What is Amazon Site-to-Site VPN?
- An Amazon Direct Connect connection. For more information, see What is Amazon Direct Connect?

You get access to Amazon Aurora through the network by using Amazon-published API operations. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the Amazon Security Token Service (Amazon STS) to generate temporary security credentials to sign requests.

Identity and access management for Amazon Aurora

Amazon Identity and Access Management (IAM) is an Amazon Web Services service that helps an administrator securely control access to Amazon resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon RDS resources. IAM is an Amazon Web Services service that you can use with no additional charge.

For information about updates to the Amazon managed policies for Amazon Aurora, see Amazon RDS updates to Amazon managed policies.

Topics

- Audience
- Authenticating with identities
- Managing access using policies
- How Amazon Aurora works with IAM
- Identity-based policy examples for Amazon Aurora
- Amazon managed policies for Amazon RDS
- Amazon RDS updates to Amazon managed policies
- Preventing cross-service confused deputy problems
- IAM database authentication
- Troubleshooting Amazon Aurora identity and access

Audience

How you use Amazon Identity and Access Management (IAM) differs, depending on the work you do in Amazon Aurora.

Service user – If you use the Aurora service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Aurora features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Aurora, see Troubleshooting Amazon Aurora identity and access.

Service administrator – If you're in charge of Aurora resources at your company, you probably have full access to Aurora. It's your job to determine which Aurora features and resources your

employees should access. You must then submit requests to your administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Aurora, see How Amazon Aurora works with IAM.

Administrator – If you're an administrator, you might want to learn details about how you can write policies to manage access to Aurora. To view example Aurora identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon Aurora.

Authenticating with identities

Authentication is how you sign in to Amazon using your identity credentials. You must be authenticated as the Amazon Web Services account root user, an IAM user, or by assuming an IAM role.

For programmatic access, Amazon provides an SDK and CLI to cryptographically sign requests. For more information, see Amazon Signature Version 4 for API requests in the *IAM User Guide*.

Amazon account root user

When you create an Amazon Web Services account, you begin with one sign-in identity called the Amazon Web Services account *root user* that has complete access to all Amazon Web Services services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users to use federation with an identity provider to access Amazon Web Services services using temporary credentials.

A *federated identity* is a user from your enterprise directory, web identity provider, or Amazon Directory Service that accesses Amazon Web Services services using credentials from an identity source. Federated identities assume roles that provide temporary credentials.

IAM users and groups

An *IAM user* is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more

information, see Require human users to use federation with an identity provider to access Amazon using temporary credentials in the *IAM User Guide*.

An *IAM group* specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see Use cases for IAM users in the *IAM User Guide*.

You can authenticate to your DB cluster using IAM database authentication.

IAM database authentication works with Aurora. For more information about authenticating to your DB cluster using IAM, see IAM database authentication .

IAM roles

An *IAM role* is an identity within your Amazon Web Services account that has specific permissions. It is similar to a user, but is not associated with a specific person. You can temporarily assume an IAM role in the Amazon Web Services Management Console by switching roles. You can assume a role by calling an Amazon CLI or Amazon API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Temporary user permissions** – A user can assume an IAM role to temporarily take on different permissions for a specific task.
- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Create a role for a third-party identity provider (federation) in the *IAM User Guide*.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some Amazon Web Services services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the *IAM User Guide*.
- **Cross-service access** – Some Amazon Web Services services use features in other Amazon Web Services services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Forward access sessions** – Forward access sessions (FAS) use the permissions of the principal calling an Amazon Web Services service, combined with the requesting Amazon Web Services service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.
- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an Amazon Web Services service in the *IAM User Guide*.
- **Service-linked role** – A service-linked role is a type of service role that is linked to an Amazon Web Services service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your Amazon Web Services account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making Amazon CLI or Amazon API requests. This is preferable to storing access keys within the EC2 instance. To assign an Amazon role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Use an IAM role to grant permissions to applications running on Amazon EC2 instances in the *IAM User Guide*.

To learn whether to use IAM roles, see When to create an IAM role (instead of a user) in the *IAM User Guide*.

Managing access using policies

You control access in Amazon by creating policies and attaching them to IAM identities or Amazon resources. A policy is an object in Amazon that, when associated with an identity or resource, defines their permissions. Amazon evaluates these policies when an entity (root user, user, or IAM role) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in Amazon as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

An administrator can use policies to specify who has access to Amazon resources, and what actions they can perform on those resources. Every IAM entity (permission set or role) starts with no

permissions. In other words, by default, users can do nothing, not even change their own password. To give a user permission to do something, an administrator must attach a permissions policy to a user. Or the administrator can add the user to a group that has the intended permissions. When an administrator gives permissions to a group, all users in that group are granted those permissions.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the Amazon Web Services Management Console, the Amazon CLI, or the Amazon API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as a permission set or role. These policies control what actions that identity can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single permission set or role. Managed policies are standalone policies that you can attach to multiple permission sets and roles in your Amazon account. Managed policies include Amazon managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the *IAM User Guide*.

For information about Amazon managed policies that are specific to Amazon Aurora, see Amazon managed policies for Amazon RDS.

Other policy types

Amazon supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (permission set or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the permission set or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the *IAM User Guide*.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in Amazon Organizations. Amazon Organizations is a service for grouping and centrally managing multiple Amazon accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each Amazon Web Services account root user. For more information about Organizations and SCPs, see How SCPs work in the *Amazon Organizations User Guide*.
- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the permission sets or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how Amazon determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon Aurora works with IAM

Before you use IAM to manage access to Amazon Aurora, you should understand what IAM features are available to use with Aurora.

The following table lists IAM features you can use with Amazon Aurora:

IAM feature	Amazon Aurora support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes

IAM feature	Amazon Aurora support
ACLs	No
Attribute-based access control (ABAC) (tags in policies)	Yes
Temporary credentials	Yes
Forward access sessions	Yes
Service roles	Yes
Service-linked roles	Yes

To get a high-level view of how Amazon Aurora and other Amazon services work with IAM, see Amazon services that work with IAM in the *IAM User Guide*.

Topics

- Aurora identity-based policies
- Resource-based policies within Aurora
- Policy actions for Aurora
- Policy resources for Aurora
- Policy condition keys for Aurora
- Access control lists (ACLs) in Aurora
- Attribute-based access control (ABAC) in policies with Aurora tags
- Using temporary credentials with Aurora
- Forward access sessions for Aurora
- Service roles for Aurora
- Service-linked roles for Aurora

Aurora identity-based policies

Supports identity-based policies: Yes.

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for Aurora

To view examples of Aurora identity-based policies, see Identity-based policy examples for Amazon Aurora.

Resource-based policies within Aurora

Supports resource-based policies: No.

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or Amazon Web Services services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Policy actions for Aurora

Supports policy actions: Yes.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Aurora use the following prefix before the action: `rds:`. For example, to grant someone permission to describe DB instances with the Amazon RDS `DescribeDBInstances` API operation, you include the `rds:DescribeDBInstances` action in their policy. Policy statements must include either an `Action` or `NotAction` element. Aurora defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows.

```
"Action": [
      "rds:action1",
      "rds:action2"
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Describe`, include the following action.

```
"Action": "rds:Describe*"
```

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Policy resources for Aurora

Supports policy resources: Yes.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its Amazon Resource Name (ARN). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

The DB instance resource has the following Amazon Resource Name (ARN).

```
arn:${Partition}:rds:${Region}:${Account}:{ResourceType}/${Resource}
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) and Amazon service namespaces.

For example, to specify the `dbtest` DB instance in your statement, use the following ARN.

```
"Resource": "arn:aws-cn:rds:us-west-2:123456789012:db:dbtest"
```

To specify all DB instances that belong to a specific account, use the wildcard (*).

```
"Resource": "arn:aws-cn:rds:us-east-1:123456789012:db:*"
```

Some RDS API operations, such as those for creating resources, can't be performed on a specific resource. In those cases, use the wildcard (*).

```
"Resource": "*"
```

Many Amazon RDS API operations involve multiple resources. For example, `CreateDBInstance` creates a DB instance. You can specify that an user must use a specific security group and parameter group when creating a DB instance. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
      "resource1",
      "resource2"
```

To see a list of Aurora resource types and their ARNs, see Resources Defined by Amazon RDS in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon RDS.

Policy condition keys for Aurora

Supports service-specific policy condition keys: Yes.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use condition operators, such as equals or less than, to match

the condition in the policy with values in the request. To see all Amazon global condition keys, see Amazon global condition context keys in the *IAM User Guide*.

Aurora defines its own set of condition keys and also supports using some global condition keys. To see all Amazon global condition keys, see Amazon global condition context keys in the *IAM User Guide*.

All RDS API operations support the `aws:RequestedRegion` condition key.

To see a list of Aurora condition keys, see Condition Keys for Amazon RDS in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions Defined by Amazon RDS.

Access control lists (ACLs) in Aurora

Supports access control lists (ACLs): No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Attribute-based access control (ABAC) in policies with Aurora tags

Supports attribute-based access control (ABAC) tags in policies: Yes

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes called tags. You can attach tags to IAM entities and Amazon resources, then design ABAC policies to allow operations when the principal's tag matches the tag on the resource.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/`*`key-name`*, `aws:RequestTag/`*`key-name`*, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

For more information about tagging Aurora resources, see Specifying conditions: Using custom tags. To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Grant permission for actions on a resource with a specific tag with two different values.

Using temporary credentials with Aurora

Supports temporary credentials: Yes.

Temporary credentials provide short-term access to Amazon resources and are automatically created when you use federation or switch roles. Amazon recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM and Amazon Web Services services that work with IAM in the *IAM User Guide*.

Forward access sessions for Aurora

Supports forward access sessions: Yes.

Forward access sessions (FAS) use the permissions of the principal calling an Amazon Web Services service, combined with the requesting Amazon Web Services service to make requests to downstream services. For policy details when making FAS requests, see Forward access sessions.

Service roles for Aurora

Supports service roles: Yes.

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an Amazon Web Services service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break Aurora functionality. Edit service roles only when Aurora provides guidance to do so.

Service-linked roles for Aurora

Supports service-linked roles: Yes.

A service-linked role is a type of service role that is linked to an Amazon Web Services service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your Amazon Web Services account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about using Aurora service-linked roles, see Using service-linked roles for Amazon Aurora.

Identity-based policy examples for Amazon Aurora

By default, permission sets and roles don't have permission to create or modify Aurora resources. They also can't perform tasks using the Amazon Web Services Management Console, Amazon CLI, or Amazon API. An administrator must create IAM policies that grant permission sets and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions.

To learn how to create an IAM identity-based policy using these example JSON policy documents, see Creating policies on the JSON tab in the *IAM User Guide*.

Topics

- Policy best practices
- Using the Aurora console
- Permissions required to use the console
- Allow users to view their own permissions
- Permission policies to create, modify and, delete resources in Aurora
- Example policies: Using condition keys
- Specifying conditions: Using custom tags
- Grant permission to tag Aurora resources during creation

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon RDS resources in your account. These actions can incur costs for your Amazon Web Services account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with Amazon managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *Amazon managed policies* that grant permissions for many common use cases. They are available in your Amazon Web Services account. We recommend that you reduce permissions further by defining Amazon customer managed policies that are specific to your use cases. For more information, see Amazon managed policies or Amazon managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific Amazon Web Services service, such as Amazon CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your Amazon Web Services account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the Aurora console

To access the Amazon Aurora console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Amazon Aurora resources in your Amazon Web Services account. If you create an identity-based policy that is more restrictive than

the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the Amazon CLI or the Amazon API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To ensure that those entities can still use the Aurora console, also attach the following Amazon managed policy to the entities.

```
AmazonRDSReadOnlyAccess
```

For more information, see Adding permissions to a user in the *IAM User Guide*.

Permissions required to use the console

For a user to work with the console, that user must have a minimum set of permissions. These permissions allow the user to describe the Amazon Aurora resources for their Amazon account and to provide other related information, including Amazon EC2 security and network information.

If you create an IAM policy that is more restrictive than the minimum required permissions, the console doesn't function as intended for users with that IAM policy. To ensure that those users can still use the console, also attach the `AmazonRDSReadOnlyAccess` managed policy to the user, as described in Managing access using policies.

You don't need to allow minimum console permissions for users that are making calls only to the Amazon CLI or the Amazon RDS API.

The following policy grants full access to all Amazon Aurora resources for the root Amazon account:

```
AmazonRDSFullAccess
```

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the Amazon CLI or Amazon API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws-cn:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
        }
    ]
}
```

Permission policies to create, modify and, delete resources in Aurora

The following sections present examples of permission policies that grant and restrict access to resources:

Allow a user to create DB instances in an Amazon account

The following is an example policy that allows the account with the ID `123456789012` to create DB instances for your Amazon account. The policy requires that the name of the new DB instance begin with `test`. The new DB instance must also use the MySQL database engine and the

db.t2.micro DB instance class. In addition, the new DB instance must use an option group and a DB parameter group that starts with default, and it must use the default subnet group.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "AllowCreateDBInstanceOnly",
         "Effect": "Allow",
         "Action": [
            "rds:CreateDBInstance"
         ],
         "Resource": [
            "arn:aws-cn:rds:*:123456789012:db:test*",
            "arn:aws-cn:rds:*:123456789012:og:default*",
            "arn:aws-cn:rds:*:123456789012:pg:default*",
            "arn:aws-cn:rds:*:123456789012:subgrp:default"
         ],
         "Condition": {
            "StringEquals": {
               "rds:DatabaseEngine": "mysql",
               "rds:DatabaseClass": "db.t2.micro"
            }
         }
      }
   ]
}
```

The policy includes a single statement that specifies the following permissions for the user:

- The policy allows the account to create a DB instance using the CreateDBInstance API operation (this also applies to the create-db-instance Amazon CLI command and the Amazon Web Services Management Console).
- The Resource element specifies that the user can perform actions on or with resources. You specify resources using an Amazon Resources Name (ARN). This ARN includes the name of the service that the resource belongs to (rds), the Amazon Region (* indicates any region in this example), the Amazon account number (123456789012 is the account number in this example),

and the type of resource. For more information about creating ARNs, see Amazon Resource Names (ARNs) in Amazon RDS.

The `Resource` element in the example specifies the following policy constraints on resources for the user:

- The DB instance identifier for the new DB instance must begin with `test` (for example, `testCustomerData1`, `test-region2-data`).
- The option group for the new DB instance must begin with `default`.
- The DB parameter group for the new DB instance must begin with `default`.
- The subnet group for the new DB instance must be the `default` subnet group.

- The `Condition` element specifies that the DB engine must be MySQL and the DB instance class must be `db.t2.micro`. The `Condition` element specifies the conditions when a policy should take effect. You can add additional permissions or restrictions by using the `Condition` element. For more information about specifying conditions, see Policy condition keys for Aurora. This example specifies the `rds:DatabaseEngine` and `rds:DatabaseClass` conditions. For information about the valid condition values for `rds:DatabaseEngine`, see the list under the `Engine` parameter in CreateDBInstance. For information about the valid condition values for `rds:DatabaseClass`, see Supported DB engines for DB instance classes.

The policy doesn't specify the `Principal` element because in an identity-based policy you don't specify the principal who gets the permission. When you attach policy to a user, the user is the implicit principal. When you attach a permission policy to an IAM role, the principal identified in the role's trust policy gets the permissions.

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Allow a user to perform any describe action on any RDS resource

The following permissions policy grants permissions to a user to run all of the actions that begin with `Describe`. These actions show information about an RDS resource, such as a DB instance. The wildcard character (*) in the `Resource` element indicates that the actions are allowed for all Amazon Aurora resources owned by the account.

JSON

```
{
```

```
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "AllowRDSDescribe",
         "Effect": "Allow",
         "Action": "rds:Describe*",
         "Resource": "*"
      }
   ]
}
```

Allow a user to create a DB instance that uses the specified DB parameter group and subnet group

The following permissions policy grants permissions to allow a user to only create a DB instance that must use the `mydbpg` DB parameter group and the `mydbsubnetgroup` DB subnet group.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": "rds:CreateDBInstance",
         "Resource": [
            "arn:aws-cn:rds:*:*:pg:mydbpg",
            "arn:aws-cn:rds:*:*:subgrp:mydbsubnetgroup"
         ]
      }
   ]
}
```

Grant permission for actions on a resource with a specific tag with two different values

You can use conditions in your identity-based policy to control access to Aurora resources based on tags. The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAnySnapshotName",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws-cn:rds:*:123456789012:snapshot:*"
      },
      {
         "Sid":"AllowDevTestToCreateSnapshot",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws-cn:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the `stage` tag set to `development` or `test`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
```

```
      {
         "Sid":"AllowChangingParameterOptionSecurityGroups",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource": [
            "arn:aws-cn:rds:*:123456789012:pg:*",
            "arn:aws-cn:rds:*:123456789012:secgrp:*",
            "arn:aws-cn:rds:*:123456789012:og:*"
         ]
      },
      {
         "Sid":"AllowDevTestToModifyInstance",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
         ],
         "Resource":"arn:aws-cn:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

Prevent a user from deleting a DB instance

The following permissions policy grants permissions to prevent a user from deleting a specific DB instance. For example, you might want to deny the ability to delete your production DB instances to any user that is not an administrator.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "DenyDelete1",
         "Effect": "Deny",
         "Action": "rds:DeleteDBInstance",
         "Resource": "arn:aws-cn:rds:us-west-2:123456789012:db:my-mysql-instance"
      }
   ]
}
```

Deny all access to a resource

You can explicitly deny access to a resource. Deny policies take precedence over allow policies. The following policy explicitly denies a user the ability to manage a resource:

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": "rds:*",
         "Resource": "arn:aws-cn:rds:us-east-1:123456789012:db:mydb"
      }
   ]
}
```

Example policies: Using condition keys

Following are examples of how you can use condition keys in Amazon Aurora IAM permissions policies.

Example 1: Grant permission to create a DB instance that uses a specific DB engine and isn't MultiAZ

The following policy uses an RDS condition key and allows a user to create only DB instances that use the MySQL database engine and don't use MultiAZ. The `Condition` element indicates the requirement that the database engine is MySQL.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "AllowMySQLCreate",
         "Effect": "Allow",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "rds:DatabaseEngine": "mysql"
            },
            "Bool": {
               "rds:MultiAz": false
            }
         }
      }
   ]
}
```

Example 2: Explicitly deny permission to create DB instances for certain DB instance classes and create DB instances that use Provisioned IOPS

The following policy explicitly denies permission to create DB instances that use the DB instance classes `r3.8xlarge` and `m4.10xlarge`, which are the largest and most expensive DB instance classes. This policy also prevents users from creating DB instances that use Provisioned IOPS, which incurs an additional cost.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Sid": "DenyLargeCreate",
         "Effect": "Deny",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "rds:DatabaseClass": [
                  "db.r3.8xlarge",
                  "db.m4.10xlarge"
               ]
            }
         }
      },
      {
         "Sid": "DenyPIOPSCreate",
         "Effect": "Deny",
         "Action": "rds:CreateDBInstance",
         "Resource": "*",
         "Condition": {
            "NumericNotEquals": {
               "rds:Piops": "0"
            }
         }
      }
   ]
}
```

Example 3: Limit the set of tag keys and values that can be used to tag a resource

The following policy uses an RDS condition key and allows the addition of a tag with the key `stage` to be added to a resource with the values `test`, qa, and `production`.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AllowTagEdits",
      "Effect": "Allow",
      "Action": [
        "rds:AddTagsToResource",
        "rds:RemoveTagsFromResource"
      ],
      "Resource": "arn:aws-cn:rds:us-east-1:123456789012:db:db-123456",
      "Condition": {
        "StringEquals": {
          "rds:req-tag/stage": [
            "test",
            "qa",
            "production"
          ]
        }
      }
    }
  ]
}
```

Specifying conditions: Using custom tags

Amazon Aurora supports specifying conditions in an IAM policy using custom tags.

For example, suppose that you add a tag named `environment` to your DB instances with values such as `beta`, `staging`, `production`, and so on. If you do, you can create a policy that restricts certain users to DB instances based on the `environment` tag value.

> **Note**
>
> Custom tag identifiers are case-sensitive.

The following table lists the RDS tag identifiers that you can use in a `Condition` element.

RDS tag identifier	Applies to
`db-tag`	DB instances, including read replicas
`snapshot-tag`	DB snapshots
`ri-tag`	Reserved DB instances
`og-tag`	DB option groups
`pg-tag`	DB parameter groups
`subgrp-tag`	DB subnet groups
`es-tag`	Event subscriptions
`cluster-tag`	DB clusters
`cluster-pg-tag`	DB cluster parameter groups
`cluster-snapshot-tag`	DB cluster snapshots

The syntax for a custom tag condition is as follows:

```
"Condition":{"StringEquals":{"rds:rds-tag-identifier/tag-name":
["value"]} }
```

For example, the following `Condition` element applies to DB instances with a tag named `environment` and a tag value of `production`.

```
"Condition":{"StringEquals":{"rds:db-tag/environment": ["production"]} }
```

For information about creating tags, see Tagging Amazon Aurora andAmazon RDS resources.

Important

If you manage access to your RDS resources using tagging, we recommend that you secure access to the tags for your RDS resources. You can manage access to tags by creating policies for the `AddTagsToResource` and `RemoveTagsFromResource` actions.

For example, the following policy denies users the ability to add or remove tags for all resources. You can then create policies to allow specific users to add or remove tags.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"DenyTagUpdates",
         "Effect":"Deny",
         "Action":[
            "rds:AddTagsToResource",
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"*"
      }
   ]
}
```

To see a list of Aurora actions, see Actions Defined by Amazon RDS in the *Service Authorization Reference*.

Example policies: Using custom tags

Following are examples of how you can use custom tags in Amazon Aurora IAM permissions policies. For more information about adding tags to an Amazon Aurora resource, see Amazon Resource Names (ARNs) in Amazon RDS.

Note

All examples use the us-west-2 region and contain fictitious account IDs.

Example 1: Grant permission for actions on a resource with a specific tag with two different values

The following policy allows permission to perform the `CreateDBSnapshot` API operation on DB instances with either the `stage` tag set to `development` or `test`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowAnySnapshotName",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws-cn:rds:*:123456789012:snapshot:*"
      },
      {
         "Sid":"AllowDevTestToCreateSnapshot",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBSnapshot"
         ],
         "Resource":"arn:aws-cn:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
                "rds:db-tag/stage":[
                  "development",
                  "test"
               ]
            }
         }
      }
   ]
}
```

The following policy allows permission to perform the `ModifyDBInstance` API operation on DB instances with either the `stage` tag set to `development` or `test`.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
```

```
      {
         "Sid":"AllowChangingParameterOptionSecurityGroups",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
            ],
          "Resource": [
            "arn:aws-cn:rds:*:123456789012:pg:*",
            "arn:aws-cn:rds:*:123456789012:secgrp:*",
            "arn:aws-cn:rds:*:123456789012:og:*"
            ]
       },
       {
         "Sid":"AllowDevTestToModifyInstance",
         "Effect":"Allow",
         "Action":[
            "rds:ModifyDBInstance"
            ],
         "Resource":"arn:aws-cn:rds:*:123456789012:db:*",
         "Condition":{
            "StringEquals":{
               "rds:db-tag/stage":[
                  "development",
                  "test"
                  ]
               }
            }
       }
    ]
}
```

Example 2: Explicitly deny permission to create a DB instance that uses specified DB parameter groups

The following policy explicitly denies permission to create a DB instance that uses DB parameter groups with specific tag values. You might apply this policy if you require that a specific customer-created DB parameter group always be used when creating DB instances. Policies that use `Deny` are most often used to restrict access that was granted by a broader policy.

Explicitly denying permission supersedes any other permissions granted. This ensures that identities to not accidentally get permission that you never want to grant.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"DenyProductionCreate",
         "Effect":"Deny",
         "Action":"rds:CreateDBInstance",
         "Resource":"arn:aws-cn:rds:*:123456789012:pg:*",
         "Condition":{
            "StringEquals":{
               "rds:pg-tag/usage":"prod"
            }
         }
      }
   ]
}
```

Example 3: Grant permission for actions on a DB instance with an instance name that is prefixed with a user name

The following policy allows permission to call any API (except to `AddTagsToResource` or `RemoveTagsFromResource`) on a DB instance that has a DB instance name that is prefixed with the user's name and that has a tag called `stage` equal to `devo` or that has no tag called `stage`.

The `Resource` line in the policy identifies a resource by its Amazon Resource Name (ARN). For more information about using ARNs with Amazon Aurora resources, see Amazon Resource Names (ARNs) in Amazon RDS.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"AllowFullDevAccessNoTags",
         "Effect":"Allow",
         "NotAction":[
            "rds:AddTagsToResource",
```

```
            "rds:RemoveTagsFromResource"
         ],
         "Resource":"arn:aws-cn:rds:*:123456789012:db:${aws:username}*",
         "Condition":{
            "StringEqualsIfExists":{
               "rds:db-tag/stage":"devo"
            }
         }
      }
   ]
}
```

Grant permission to tag Aurora resources during creation

Some RDS API operations allow you to specify tags when you create the resource. You can use resource tags to implement attribute-based control (ABAC). For more information, see What is ABAC for Amazon? and Controlling access to Amazon resources using tags.

To enable users to tag resources on creation, they must have permissions to use the action that creates the resource, such as `rds:CreateDBCluster`. If tags are specified in the create action, RDS performs additional authorization on the `rds:AddTagsToResource` action to verify if users have permissions to create tags. Therefore, users must also have explicit permissions to use the `rds:AddTagsToResource` action.

In the IAM policy definition for the `rds:AddTagsToResource` action, you can use the `aws:RequestTag` condition key to require tags in a request to tag a resource.

For example, the following policy allows users to create DB instances and apply tags during DB instance creation, but only with specific tag keys (`environment` or `project`):

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
       {
           "Effect": "Allow",
           "Action": [
               "rds:CreateDBInstance"
           ],
```

```
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "rds:AddTagsToResource"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/environment": ["production", "development"],
                    "aws:RequestTag/project": ["dataanalytics", "webapp"]
                },
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": ["environment", "project"]
                }
            }
        }
    ]
}
```

This policy denies any create DB instance request that includes tags other than the `environment` or `project` tags, or that doesn't specify either of these tags. Additionally, users must specify values for the tags that match the allowed values in the policy.

The following policy allows users to create DB clusters and apply any tags during creation except the `environment=prod` tag:

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
       {
           "Effect": "Allow",
           "Action": [
               "rds:CreateDBCluster"
           ],
           "Resource": "*"
       },
       {
```

```
            "Effect": "Allow",
            "Action": [
                "rds:AddTagsToResource"
            ],
            "Resource": "*",
            "Condition": {
                "StringNotEquals": {
                    "aws:RequestTag/environment": "prod"
                }
            }
        }
    ]
}
```

Supported RDS API actions for tagging on creation

The following RDS API actions support tagging when you create a resource. For these actions, you can specify tags when you create the resource:

- `CreateBlueGreenDeployment`
- `CreateCustomDBEngineVersion`
- `CreateDBCluster`
- `CreateDBClusterEndpoint`
- `CreateDBClusterParameterGroup`
- `CreateDBClusterSnapshot`
- `CreateDBInstance`
- `CreateDBInstanceReadReplica`
- `CreateDBParameterGroup`
- `CreateDBProxy`
- `CreateDBProxyEndpoint`
- `CreateDBSecurityGroup`
- `CreateDBShardGroup`
- `CreateDBSnapshot`
- `CreateDBSubnetGroup`
- `CreateEventSubscription`

- CreateGlobalCluster
- CreateIntegration
- CreateOptionGroup
- CreateTenantDatabase
- CopyDBClusterParameterGroup
- CopyDBClusterSnapshot
- CopyDBParameterGroup
- CopyDBSnapshot
- CopyOptionGroup
- RestoreDBClusterFromS3
- RestoreDBClusterFromSnapshot
- RestoreDBClusterToPointInTime
- RestoreDBInstanceFromDBSnapshot
- RestoreDBInstanceFromS3
- RestoreDBInstanceToPointInTime
- PurchaseReservedDBInstancesOffering

If you use the Amazon CLI or API to create a resource with tags, the Tags parameter is used to apply tags to resources during creation.

For these API actions, if tagging fails, the resource is not created, and the request fails with an error. This ensures that resources are either created with tags or not created at all, preventing resources from being created without the intended tags.

Amazon managed policies for Amazon RDS

To add permissions to permission sets and roles, it's easier to use Amazon managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our Amazon managed policies. These policies cover common use cases and are available in your Amazon Web Services account. For more information about Amazon managed policies, see Amazon managed policies in the *IAM User Guide*.

Amazon Web Services services maintain and update Amazon managed policies. You can't change the permissions in Amazon managed policies. Services occasionally add additional permissions to an Amazon managed policy to support new features. This type of update affects all identities (permission sets and roles) where the policy is attached. Services are most likely to update an Amazon managed policy when a new feature is launched or when new operations become available. Services don't remove permissions from an Amazon managed policy, so policy updates don't break your existing permissions.

Additionally, Amazon supports managed policies for job functions that span multiple services. For example, the `ReadOnlyAccess` Amazon managed policy provides read-only access to all Amazon Web Services services and resources. When a service launches a new feature, Amazon adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see Amazon managed policies for job functions in the *IAM User Guide*.

Topics

- Amazon managed policy: AmazonRDSReadOnlyAccess
- Amazon managed policy: AmazonRDSFullAccess
- Amazon managed policy: AmazonRDSDataFullAccess
- Amazon managed policy: AmazonRDSEnhancedMonitoringRole
- Amazon managed policy: AmazonRDSPerformanceInsightsReadOnly
- Amazon managed policy: AmazonRDSPerformanceInsightsFullAccess
- Amazon managed policy: AmazonRDSDirectoryServiceAccess
- Amazon managed policy: AmazonRDSServiceRolePolicy
- Amazon managed policy: AmazonRDSPreviewServiceRolePolicy
- Amazon managed policy: AmazonRDSBetaServiceRolePolicy

Amazon managed policy: AmazonRDSReadOnlyAccess

This policy allows read-only access to Amazon RDS through the Amazon Web Services Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS resources and list the tags for Amazon RDS resources.
- `cloudwatch` – Allows principals to get Amazon CloudWatch metric statistics.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSReadOnlyAccess in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSFullAccess

This policy provides full access to Amazon RDS through the Amazon Web Services Management Console.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals full access to Amazon RDS.
- `application-autoscaling` – Allows principals describe and manage Application Auto Scaling scaling targets and policies.
- `cloudwatch` – Allows principals get CloudWatch metric statics and manage CloudWatch alarms.
- `ec2` – Allows principals to describe Availability Zones and networking resources.
- `logs` – Allows principals to describe CloudWatch Logs log streams of log groups, and get CloudWatch Logs log events.

- `outposts` – Allows principals to get Amazon Outposts instance types.
- `pi` – Allows principals to get Performance Insights metrics.
- `sns` – Allows principals to Amazon Simple Notification Service (Amazon SNS) subscriptions and topics, and to publish Amazon SNS messages.
- `devops-guru` – Allows principals to describe resources that have Amazon DevOps Guru coverage, which is specified either by CloudFormation stack names or resource tags.

For more information about this policy, including the JSON policy document, see AmazonRDSFullAccess in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSDataFullAccess

This policy allows full access to use the Data API and the query editor on Aurora Serverless clusters in a specific Amazon Web Services account. This policy allows the Amazon Web Services account to get the value of a secret from Amazon Secrets Manager.

You can attach the `AmazonRDSDataFullAccess` policy to your IAM identities.

Permissions details

This policy includes the following permissions:

- `dbqms` – Allows principals to access, create, delete, describe, and update queries. The Database Query Metadata Service (`dbqms`) is an internal-only service. It provides your recent and saved queries for the query editor on the Amazon Web Services Management Console for multiple Amazon Web Services services, including Amazon RDS.
- `rds-data` – Allows principals to run SQL statements on Aurora Serverless databases.
- `secretsmanager` – Allows principals to get the value of a secret from Amazon Secrets Manager.

For more information about this policy, including the JSON policy document, see AmazonRDSDataFullAccess in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSEnhancedMonitoringRole

This policy provides access to Amazon CloudWatch Logs for Amazon RDS Enhanced Monitoring.

Permissions details

This policy includes the following permissions:

- `logs` – Allows principals to create CloudWatch Logs log groups and retention policies, and to create and describe CloudWatch Logs log streams of log groups. It also allows principals to put and get CloudWatch Logs log events.

For more information about this policy, including the JSON policy document, see AmazonRDSEnhancedMonitoringRole in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSPerformanceInsightsReadOnly

This policy provides read-only access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API and access Performance Insights metrics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsReadOnly in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSPerformanceInsightsFullAccess

This policy provides full access to Amazon RDS Performance Insights for Amazon RDS DB instances and Amazon Aurora DB clusters.

This policy now includes `Sid` (statement ID) as an identifier for the policy statement.

Permissions details

This policy includes the following permissions:

- `rds` – Allows principals to describe Amazon RDS DB instances and Amazon Aurora DB clusters.
- `pi` – Allows principals make calls to the Amazon RDS Performance Insights API, and create, view, and delete performance analysis reports.

- `cloudwatch` – Allows principals to list all the Amazon CloudWatch metrics, and get metric data and statistics.

For more information about this policy, including the JSON policy document, see AmazonRDSPerformanceInsightsFullAccess in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSDirectoryServiceAccess

This policy allows Amazon RDS to make calls to the Amazon Directory Service.

Permissions details

This policy includes the following permission:

- `ds` – Allows principals to describe Amazon Directory Service directories and control authorization to Amazon Directory Service directories.

For more information about this policy, including the JSON policy document, see AmazonRDSDirectoryServiceAccess in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSServiceRolePolicy

You can't attach the `AmazonRDSServiceRolePolicy` policy to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to perform actions on your behalf. For more information, see Service-linked role permissions for Amazon Aurora.

Amazon managed policy: AmazonRDSPreviewServiceRolePolicy

You shouldn't attach `AmazonRDSPreviewServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call Amazon services on behalf of your RDS DB resources. For more information, see Service-linked role for Amazon RDS Preview.

Permissions details

This policy includes the following permissions:

- `ec2` - Allows principals to describe Availability Zones and networking resources.
- `secretsmanager` – Allows principals to get the value of a secret from Amazon Secrets Manager.
- `cloudwatch`, `logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see AmazonRDSPreviewServiceRolePolicy in the *Amazon Managed Policy Reference Guide*.

Amazon managed policy: AmazonRDSBetaServiceRolePolicy

You shouldn't attach `AmazonRDSBetaServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role that allows Amazon RDS to call Amazon services on behalf of your RDS DB resources. For more information, see Service-linked role permissions for Amazon RDS Beta.

Permissions details

This policy includes the following permissions:

- `ec2` - Allows Amazon RDS to perform backup operations on the DB instance that provides point-in-time restore capabilities.
- `secretsmanager` - Allows Amazon RDS to manage DB instance specific secrets created by Amazon RDS.
- `cloudwatch`, `logs` - Allows Amazon RDS to upload DB instance metrics and logs to CloudWatch through CloudWatch agent.

For more information about this policy, including the JSON policy document, see AmazonRDSBetaServiceRolePolicy in the *Amazon Managed Policy Reference Guide*.

Amazon RDS updates to Amazon managed policies

View details about updates to Amazon managed policies for Amazon RDS since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon RDS Document history page.

Change	Description	Date
Amazon managed policy: AmazonRDSPreviewServiceRolePolicy – Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSPreviewServiceRolePolicy` of the `AWSServiceRoleForRDSPreview` service-linked role. For more information, see Amazon managed policy: AmazonRDSPreviewServiceRolePolicy.	August 7, 2024
Amazon managed policy: AmazonRDSBetaServiceRolePolicy – Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSBetaServiceRolePolicy` of the `AWSServiceRoleForRDSBeta` service-linked role. For more information, see Amazon managed policy: AmazonRDSBetaServiceRolePolicy.	August 7, 2024
Amazon managed policy: AmazonRDSServiceRolePolicy – Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role. For more informati	July 2, 2024

Change	Description	Date
	on, see Amazon managed policy: AmazonRDSServiceRolePolicy.	
Amazon managed policies for Amazon RDS – Update to existing policy	Amazon RDS added a new permission to the `AmazonRDSCustomServiceRolePolicy` of the `AWSServiceRoleForRDSCustom` service-linked role to allow RDS Custom for SQL Server to modify the underlying database host instance type. RDS also added the `ec2:DescribeInstanceTypes` permission to get instance type information for database host. For more information, see Amazon managed policies for Amazon RDS.	April 8, 2024
Amazon managed policies for Amazon RDS – New policy	Amazon RDS added a new managed policy named `AmazonRDSCustomInstanceProfileRolePolicy` to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see Amazon managed policies for Amazon RDS.	February 27, 2024

Change	Description	Date
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added new statement IDs to the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role. For more information, see Service-linked role permissions for Amazon Aurora.	January 19, 2024
Amazon managed policies for Amazon RDS – Update to existing policies	The `AmazonRDSPerformanceInsightsReadOnly` and `AmazonRDSPerformanceInsightsFullAccess` managed policies now includes `Sid` (statement ID) as an identifier in the policy statement. For more information, see Amazon managed policy: AmazonRDSPerformanceInsightsReadOnly and Amazon managed policy: AmazonRDSPerformanceInsightsFullAccess	October 23, 2023

Change	Description	Date
Amazon managed policies for Amazon RDS – Update to existing policy	Amazon RDS added new permissions to `AmazonRDSFullAccess` managed policy. The permissions allow you to generate, view, and delete the performance analysis report for a time period. For more information about configuring access policies for Performance Insights, see Configuring access policies for Database Insights	August 17, 2023
Amazon managed policies for Amazon RDS – New policy and update to existing policy	Amazon RDS added new permissions to `AmazonRDSPerformanceInsightsReadOnly` managed policy and a new managed policy named `AmazonRDSPerformanceInsightsFullAccess`. These permissions allow you to analyse the Performance Insights for a time period, view the analysis results along with the recommendations, and delete the reports. For more information about configuring access policies for Performance Insights, see Configuring access policies for Database Insights	August 16, 2023

Change	Description	Date
Amazon managed policies for Amazon RDS – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace `ListMetrics` to `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess`. This namespace is required for Amazon RDS to list specific resource usage metrics. For more information, see Overview of managing access permissions to your CloudWatch resources in the *Amazon CloudWatch User Guide*.	April 4, 2023

Change	Description	Date
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added new permissions to the `AmazonRDSServiceRolePolicy` of the `AWSServiceRoleForRDS` service-linked role for integration with Amazon Secrets Manager. RDS requires integration with Secrets Manager for managing master user passwords in Secrets Manager. The secret uses a reserved naming convention and restricts customer updates. For more information, see Password management with Amazon Aurora and Amazon Secrets Manager.	December 22, 2022

Change	Description	Date
Amazon managed policies for Amazon RDS – Update to existing policies	Amazon RDS added a new permission to the `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` managed policies to allow you to turn on Amazon DevOps Guru in the RDS console. This permission is required to check whether DevOps Guru is turned on. For more information, see Configuring IAM access policies for DevOps Guru for RDS.	December 19, 2022
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AmazonRDSPreviewServiceRolePolicy` for `PutMetricData`. This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	June 7, 2022

Change	Description	Date
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AmazonRDSBetaServiceRolePolicy` for `PutMetricData`. This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	June 7, 2022
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added a new Amazon CloudWatch namespace to `AWSServiceRoleForRDS` for `PutMetricData`. This namespace is required for Amazon RDS to publish resource usage metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	April 22, 2022

Change	Description	Date
Amazon managed policies for Amazon RDS – New policy	Amazon RDS added a new managed policy named `AmazonRDSPerformanceInsightsReadOnly` to allow Amazon RDS to call Amazon services on behalf of your DB instances. For more information about configuring access policies for Performance Insights, see Configuring access policies for Database Insights	March 10, 2022
Service-linked role permissions for Amazon Aurora – Update to an existing policy	Amazon RDS added new Amazon CloudWatch namespaces to `AWSServiceRoleForRDS` for `PutMetricData` . These namespaces are required for Amazon DocumentDB (with MongoDB compatibility) and Amazon Neptune to publish CloudWatch metrics. For more information, see Using condition keys to limit access to CloudWatch namespaces in the *Amazon CloudWatch User Guide*.	March 4, 2022
Amazon RDS started tracking changes	Amazon RDS started tracking changes for its Amazon managed policies.	October 26, 2021

Preventing cross-service confused deputy problems

The *confused deputy problem* is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In Amazon, cross-service impersonation can result in the confused deputy problem.

Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way that it shouldn't have permission to access. To prevent this, Amazon provides tools that can help you protect your data for all services with service principals that have been given access to resources in your account. For more information, see The confused deputy problem in the *IAM User Guide*.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies.

In some cases, the `aws:SourceArn` value doesn't contain the account ID, for example when you use the Amazon Resource Name (ARN) for an Amazon S3 bucket. In these cases, make sure to use both global condition context keys to limit permissions. In some cases, you use both global condition context keys and the `aws:SourceArn` value contains the account ID. In these cases, make sure that the `aws:SourceAccount` value and the account in the `aws:SourceArn` use the same account ID when they're used in the same policy statement. If you want only one resource to be associated with the cross-service access, use `aws:SourceArn`. If you want to allow any resource in the specified Amazon account to be associated with the cross-service use, use `aws:SourceAccount`.

Make sure that the value of `aws:SourceArn` is an ARN for an Amazon RDS resource type. For more information, see Amazon Resource Names (ARNs) in Amazon RDS.

The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of the resource. In some cases, you might not know the full ARN of the resource or you might be specifying multiple resources. In these cases, use the `aws:SourceArn` global context condition key with wildcards (`*`) for the unknown portions of the ARN. An example is `arn:aws-cn:rds:*:123456789012:*`.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws-cn:rds:us-east-1:123456789012:db:mydbinstance"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}
```

For more examples of policies that use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys, see the following sections:

- Granting permissions to publish notifications to an Amazon SNS topic
- Setting up access to an Amazon S3 bucket (PostgreSQL import)
- Setting up access to an Amazon S3 bucket (PostgreSQL export)

IAM database authentication

You can authenticate to your DB cluster using Amazon Identity and Access Management (IAM) database authentication. IAM database authentication works with Aurora MySQL, and Aurora PostgreSQL. With this authentication method, you don't need to use a password when you connect to a DB cluster. Instead, you use an authentication token.

An *authentication token* is a unique string of characters that Amazon Aurora generates on request. Authentication tokens are generated using Amazon Signature Version 4. Each token has a lifetime of 15 minutes. You don't need to store user credentials in the database, because authentication is managed externally using IAM. You can also still use standard database authentication. The token is only used for authentication and doesn't affect the session after it is established.

IAM database authentication provides the following benefits:

- Network traffic to and from the database is encrypted using Secure Socket Layer (SSL) or Transport Layer Security (TLS). For more information about using SSL/TLS with Amazon Aurora, see Using SSL/TLS to encrypt a connection to a DB cluster.
- You can use IAM to centrally manage access to your database resources, instead of managing access individually on each DB cluster.
- For applications running on Amazon EC2, you can use profile credentials specific to your EC2 instance to access your database instead of a password, for greater security.

In general, consider using IAM database authentication when you don't want to manage usernames and passwords directly in your application code.

The Amazon Web Services (Amazon) JDBC Driver supports IAM database authentication. For more information, see Amazon IAM Authentication Plugin in the Amazon Web Services (Amazon) JDBC Driver GitHub repository.

The Amazon Web Services (Amazon) Python Driver supports IAM database authentication. For more information, see Amazon IAM Authentication Plugin in the Amazon Web Services (Amazon) Python Driver GitHub repository.

Navigate through the following topics to learn the process to set IAM for DB authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access

- Creating a database account using IAM authentication
- Connecting to your DB cluster using IAM authentication

Region and version availability

Feature availability and support varies across specific versions of each Aurora database engine, and across Amazon Web Services Regions. For more information on version and Region availability with Aurora and IAM database authentication, see Supported Regions and Aurora DB engines for IAM database authentication.

For Aurora MySQL, all supported DB instance classes support IAM database authentication, except for db.t2.small and db.t3.small. For information about the supported DB instance classes, see Supported DB engines for DB instance classes.

CLI and SDK support

IAM database authentication is available for the Amazon CLI and for the following language-specific Amazon SDKs:

- Amazon SDK for .NET
- Amazon SDK for C++
- Amazon SDK for Go
- Amazon SDK for Java
- Amazon SDK for JavaScript
- Amazon SDK for PHP
- Amazon SDK for Python (Boto3)
- Amazon SDK for Ruby

Limitations for IAM database authentication

When using IAM database authentication, the following limitations apply:

- Currently, IAM database authentication doesn't support all global condition context keys.

  For more information about global condition context keys, see Amazon global condition context keys in the *IAM User Guide*.

- For PostgreSQL, if the IAM role (`rds_iam`) is added to a user (including the RDS master user), IAM authentication takes precedence over password authentication, so the user must log in as an IAM user.
- You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.
- CloudWatch and CloudTrail don't log IAM authentication. These services do not track `generate-db-auth-token` API calls that authorize the IAM role to enable database connection.
- IAM DB authentication requires compute resources on the database cluster. You must have between 300 and 1000 MiB extra memory on your database for reliable connectivity. To see the memory needed for your workload, compare the RES column for RDS processes in the Enhanced Monitoring processlist before and after enabling IAM DB authentication. See Viewing OS metrics in the RDS console.

  If you are using a burstable class instance, avoid running out of memory by reducing the memory used by other parameters like buffers and cache by the same amount.
- For Aurora MySQL, you can't use password based authentication for a database user you configure with IAM authentication.
- IAM DB authentication is not supported for RDS on Outposts for any engine.

Recommendations for IAM database authentication

We recommend the following when using IAM database authentication:

- The size of an IAM database authentication token depends on many things including the number of IAM tags, IAM service policies, ARN lengths, as well as other IAM and database properties. The minimum size of this token is generally about 1 KB but can be larger. Since this token is used as the password in the connection string to the database using IAM authentication, you should ensure that your database driver (for example, ODBC) and/or any tools do not limit or otherwise truncate this token due to its size. A truncated token will cause the authentication validation done by the database and IAM to fail.
- If you are using temporary credentials when creating an IAM database authentication token, the temporary credentials must still be valid when using the IAM database authentication token to make a connection request.

Unsupported Amazon global condition context keys

IAM database authentication does not support the following subset of Amazon global condition context keys.

- `aws:Referer`
- `aws:SourceIp`
- `aws:SourceVpc`
- `aws:SourceVpce`
- `aws:UserAgent`
- `aws:VpcSourceIp`

For more information, see Amazon global condition context keys in the *IAM User Guide*.

Enabling and disabling IAM database authentication

By default, IAM database authentication is disabled on DB clusters. You can enable or disable IAM database authentication using the Amazon Web Services Management Console, Amazon CLI, or the API.

You can enable IAM database authentication when you perform one of the following actions:

- To create a new DB cluster with IAM database authentication enabled, see Creating an Amazon Aurora DB cluster.
- To modify a DB cluster to enable IAM database authentication, see Modifying an Amazon Aurora DB cluster.
- To restore a DB cluster from a snapshot with IAM database authentication enabled, see Restoring from a DB cluster snapshot.
- To restore a DB cluster to a point in time with IAM database authentication enabled, see Restoring a DB cluster to a specified time.

Console

Each creation or modification workflow has a **Database authentication** section, where you can enable or disable IAM database authentication. In that section, choose **Password and IAM database authentication** to enable IAM database authentication.

To enable or disable IAM database authentication for an existing DB cluster

1. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Databases**.
3. Choose the DB cluster that you want to modify.

   > **Note**
   >
   > You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Region and version availability.

4. Choose **Modify**.
5. In the **Database authentication** section, choose **IAM database authentication** to enable IAM database authentication. Choose **Password authentication** or **Password and Kerberos authentication** to disable IAM authentication.
6. You can also choose to enable publishing IAM DB authentication logs to CloudWatch Logs. Under **Log exports**, choose the **iam-db-auth-error log** option. Publishing your logs to CloudWatch Logs consumes storage and you incur charges for that storage. Be sure to delete any CloudWatch Logs that you no longer need.
7. Choose **Continue**.
8. To apply the changes immediately, choose **Immediately** in the **Scheduling of modifications** section.
9. Choose **Modify cluster**.

Amazon CLI

To create a new DB cluster with IAM authentication by using the Amazon CLI, use the `create-db-cluster` command. Specify the `--enable-iam-database-authentication` option.

To update an existing DB cluster to have or not have IAM authentication, use the Amazon CLI command `modify-db-cluster`. Specify either the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

> **Note**
>
> You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Region and version availability.

By default, Aurora performs the modification during the next maintenance window. If you want to override this and enable IAM DB authentication as soon as possible, use the `--apply-immediately` parameter.

If you are restoring a DB cluster, use one of the following Amazon CLI commands:

- `restore-db-cluster-to-point-in-time`
- `restore-db-cluster-from-db-snapshot`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `--enable-iam-database-authentication` or `--no-enable-iam-database-authentication` option, as appropriate.

RDS API

To create a new DB instance with IAM authentication by using the API, use the API operation `CreateDBCluster`. Set the `EnableIAMDatabaseAuthentication` parameter to `true`.

To update an existing DB cluster to have IAM authentication, use the API operation `ModifyDBCluster`. Set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

> **Note**
>
> You can only enable IAM authentication if all DB instances in the DB cluster are compatible with IAM. Check the compatibility requirements in Region and version availability.

If you are restoring a DB cluster, use one of the following API operations:

- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`

The IAM database authentication setting defaults to that of the source snapshot. To change this setting, set the `EnableIAMDatabaseAuthentication` parameter to `true` to enable IAM authentication, or `false` to disable it.

Creating and using an IAM policy for IAM database access

To allow a user or role to connect to your DB cluster, you must create an IAM policy. After that, you attach the policy to a permissions set or role.

> **Note**
>
> To learn more about IAM policies, see Identity and access management for Amazon Aurora.

The following example policy allows a user to connect to a DB cluster using IAM database authentication.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws-cn:rds-db:us-east-2:111122223333:dbuser:cluster-
ABCDEFGHIJKL01234/db_user"
            ]
        }
    ]
}
```

> **Important**
>
> A user with administrator permissions can access DB clusters without explicit permissions in an IAM policy. If you want to restrict administrator access to DB clusters, you can

create an IAM role with the appropriate, lesser privileged permissions and assign it to the administrator.

Note

Don't confuse the `rds-db:` prefix with other RDS API operation prefixes that begin with `rds:`. You use the `rds-db:` prefix and the `rds-db:connect` action only for IAM database authentication. They aren't valid in any other context.

The example policy includes a single statement with the following elements:

- `Effect` – Specify `Allow` to grant access to the DB cluster. If you don't explicitly allow access, then access is denied by default.
- `Action` – Specify `rds-db:connect` to allow connections to the DB cluster.
- `Resource` – Specify an Amazon Resource Name (ARN) that describes one database account in one DB cluster. The ARN format is as follows.

```
arn:aws-cn:rds-db:region:account-id:dbuser:DbClusterResourceId/db-user-name
```

In this format, replace the following:

- *`region`* is the Amazon Region for the DB cluster. In the example policy, the Amazon Region is `us-east-2`.
- *`account-id`* is the Amazon account number for the DB cluster. In the example policy, the account number is `1234567890`. The user must be in the same account as the account for the DB cluster.

  To perform cross-account access, create an IAM role with the policy shown above in the account for the DB cluster and allow your other account to assume the role.
- *`DbClusterResourceId`* is the identifier for the DB cluster. This identifier is unique to an Amazon Region and never changes. In the example policy, the identifier is `cluster-ABCDEFGHIJKL01234`.

To find a DB cluster resource ID in the Amazon Web Services Management Console for Amazon Aurora, choose the DB cluster to see its details. Then choose the **Configuration** tab. The **Resource ID** is shown in the **Configuration** section.

Alternatively, you can use the Amazon CLI command to list the identifiers and resource IDs for all of your DB cluster in the current Amazon Region, as shown following.

```
aws rds describe-db-clusters --query "DBClusters[*].
[DBClusterIdentifier,DbClusterResourceId]"
```

> **Note**
>
> If you are connecting to a database through RDS Proxy, specify the proxy resource ID, such as `prx-ABCDEFGHIJKL01234`. For information about using IAM database authentication with RDS Proxy, see Connecting to a database using IAM authentication.

- *`db-user-name`* is the name of the database account to associate with IAM authentication. In the example policy, the database account is `db_user`.

You can construct other ARNs to support various access patterns. The following policy allows access to two different database accounts in a DB cluster.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
             "rds-db:connect"
         ],
         "Resource": [
             "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:cluster-
ABCDEFGHIJKL01234/jane_doe",
```

```
            "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:cluster-
ABCDEFGHIJKL01234/mary_roe"
         ]
      }
   ]
}
```

The following policy uses the "*" character to match all DB clusters and database accounts for a particular Amazon account and Amazon Region.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws-cn:rds-db:us-east-2:111122223333:dbuser:*/*"
            ]
        }
    ]
}
```

The following policy matches all of the DB clusters for a particular Amazon account and Amazon Region. However, the policy only grants access to DB clusters that have a `jane_doe` database account.

JSON

```
{
   "Version":"2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
```

```
            "Action": [
                "rds-db:connect"
            ],
            "Resource": [
                "arn:aws-cn:rds-db:us-east-2:123456789012:dbuser:*/jane_doe"
            ]
        }
    ]
}
```

The user or role has access to only those databases that the database user does. For example, suppose that your DB cluster has a database named *dev*, and another database named *test*. If the database user `jane_doe` has access only to *dev*, any users or roles that access that DB cluster with the `jane_doe` user also have access only to *dev*. This access restriction is also true for other database objects, such as tables, views, and so on.

An administrator must create IAM policies that grant entities permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the permission sets or roles that require those permissions. For examples of policies, see Identity-based policy examples for Amazon Aurora.

Attaching an IAM policy to a permission set or role

After you create an IAM policy to allow database authentication, you need to attach the policy to a permission set or role. For a tutorial on this topic, see Create and attach your first customer managed policy in the *IAM User Guide*.

As you work through the tutorial, you can use one of the policy examples shown in this section as a starting point and tailor it to your needs. At the end of the tutorial, you have a permission set with an attached policy that can make use of the `rds-db:connect` action.

Note

You can map multiple permission sets or roles to the same database user account. For example, suppose that your IAM policy specified the following resource ARN.

```
arn:aws-cn:rds-db:us-
east-2:123456789012:dbuser:cluster-12ABC34DEFG5HIJ6KLMNOP78QR/jane_doe
```

If you attach the policy to *Jane*, *Bob*, and *Diego*, then each of those users can connect to the specified DB cluster using the `jane_doe` database account.

Creating a database account using IAM authentication

With IAM database authentication, you don't need to assign database passwords to the user accounts you create. If you remove a user that is mapped to a database account, you should also remove the database account with the `DROP USER` statement.

Note

The user name used for IAM authentication must match the case of the user name in the database.

Topics

- Using IAM authentication with Aurora MySQL
- Using IAM authentication with AuroraPostgreSQL

Using IAM authentication with Aurora MySQL

With Aurora MySQL, authentication is handled by `AWSAuthenticationPlugin`—an Amazon-provided plugin that works seamlessly with IAM to authenticate your users. Connect to the DB cluster as the master user or a different user who can create users and grant privileges. After connecting, issue the `CREATE USER` statement, as shown in the following example.

```
CREATE USER 'jane_doe' IDENTIFIED WITH AWSAuthenticationPlugin AS 'RDS';
```

The `IDENTIFIED WITH` clause allows Aurora MySQL to use the `AWSAuthenticationPlugin` to authenticate the database account (`jane_doe`). The `AS 'RDS'` clause refers to the authentication method. Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access.

Note

If you see the following message, it means that the Amazon-provided plugin is not available for the current DB cluster.

```
ERROR 1524 (HY000): Plugin 'AWSAuthenticationPlugin' is not loaded
```

To troubleshoot this error, verify that you are using a supported configuration and that you have enabled IAM database authentication on your DB cluster. For more information, see Region and version availability and Enabling and disabling IAM database authentication.

After you create an account using `AWSAuthenticationPlugin`, you manage it in the same way as other database accounts. For example, you can modify account privileges with `GRANT` and `REVOKE` statements, or modify various account attributes with the `ALTER USER` statement.

Database network traffic is encrypted using SSL/TLS when using IAM. To allow SSL connections, modify the user account with the following command.

```
ALTER USER 'jane_doe'@'%' REQUIRE SSL;
```

Using IAM authentication with AuroraPostgreSQL

To use IAM authentication with Aurora PostgreSQL, connect to the DB cluster as the master user or a different user who can create users and grant privileges. After connecting, create database users and then grant them the `rds_iam` role as shown in the following example.

```
CREATE USER db_userx;
GRANT rds_iam TO db_userx;
```

Make sure the specified database user name is the same as a resource in the IAM policy for IAM database access. For more information, see Creating and using an IAM policy for IAM database access. You must grant the `rds_iam` role to use IAM authentication. You can use nested memberships or indirect grants of the role as well.

Note that a PostgreSQL database user can use either IAM or Kerberos authentication but not both, so this user can't also have the `rds_ad` role. This also applies to nested memberships. For more information, see Step 7: Create PostgreSQL users for your Kerberos principals.

Connecting to your DB cluster using IAM authentication

With IAM database authentication, you use an authentication token when you connect to your DB cluster. An *authentication token* is a string of characters that you use instead of a password. After you generate an authentication token, it's valid for 15 minutes before it expires. If you try to connect using an expired token, the connection request is denied.

Every authentication token must be accompanied by a valid signature, using Amazon signature version 4. (For more information, see Signature Version 4 signing process in the *Amazon Web Services General Reference.*) The Amazon CLI and an Amazon SDK, such as the Amazon SDK for Java or Amazon SDK for Python (Boto3), can automatically sign each token you create.

You can use an authentication token when you connect to Amazon Aurora from another Amazon service, such as Amazon Lambda. By using a token, you can avoid placing a password in your code. Alternatively, you can use an Amazon SDK to programmatically create and programmatically sign an authentication token.

After you have a signed IAM authentication token, you can connect to an Aurora DB cluster. Following, you can find out how to do this using either a command line tool or an Amazon SDK, such as the Amazon SDK for Java or Amazon SDK for Python (Boto3).

For more information, see the following blog posts:

- Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL
- Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Topics

- Connecting to your DB cluster using IAM authentication with the Amazon drivers
- Connecting to your DB cluster using IAM authentication from the command line: Amazon CLI and mysql client
- Connecting to your DB cluster using IAM authentication from the command line: Amazon CLI and psql client
- Connecting to your DB cluster using IAM authentication and the Amazon SDK for .NET
- Connecting to your DB cluster using IAM authentication and the Amazon SDK for Go
- Connecting to your DB cluster using IAM authentication and the Amazon SDK for Java
- Connecting to your DB cluster using IAM authentication and the Amazon SDK for Python (Boto3)

Connecting to your DB cluster using IAM authentication with the Amazon drivers

The Amazon suite of drivers has been designed to provide support for faster switchover and failover times, and authentication with Amazon Secrets Manager, Amazon Identity and Access Management (IAM), and Federated Identity. The Amazon drivers rely on monitoring DB cluster status and being aware of the cluster topology to determine the new writer. This approach reduces switchover and failover times to single-digit seconds, compared to tens of seconds for open-source drivers.

For more information on the Amazon drivers, see the corresponding language driver for your Aurora MySQL or Aurora PostgreSQL DB cluster.

Connecting to your DB cluster using IAM authentication from the command line: Amazon CLI and mysql client

You can connect from the command line to an Aurora DB cluster with the Amazon CLI and `mysql` command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

> **Note**
>
> For information about connecting to your database using SQL Workbench/J with IAM authentication, see the blog post Use IAM authentication to connect with SQL Workbench/J to Aurora MySQL or Amazon RDS for MySQL.

Topics

- Generating an IAM authentication token
- Connecting to a DB cluster

Generating an IAM authentication token

The following example shows how to get a signed authentication token using the Amazon CLI.

```
aws rds generate-db-auth-token \
   --hostname rdsmysql.123456789012.us-west-2.rds.amazonaws.com \
   --port 3306 \
   --region us-west-2 \
   --username jane_doe
```

In the example, the parameters are as follows:

- `--hostname` – The host name of the DB cluster that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--region` – The Amazon Region where the DB cluster is running
- `--username` – The database account that you want to access

The first several characters of the token look like the following.

```
rdsmysql.123456789012.us-west-2.rds.amazonaws.com:3306/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.

Connecting to a DB cluster

The general format for connecting is shown following.

```
mysql --host=hostName --port=portNumber --ssl-ca=full_path_to_ssl_certificate --enable-cleartext-plugin --user=userName --password=authToken
```

The parameters are as follows:

- `--host` – The host name of the DB cluster that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--ssl-ca` – The full path to the SSL certificate file that contains the public key

  For more information, see TLS connections to Aurora MySQL DB clusters.

  To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.
- `--enable-cleartext-plugin` – A value that specifies that `AWSAuthenticationPlugin` must be used for this connection

  If you are using a MariaDB client, the `--enable-cleartext-plugin` option isn't required.
- `--user` – The database account that you want to access
- `--password` – A signed IAM authentication token

The authentication token consists of several hundred characters. It can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows one way to perform this workaround. In the example, */sample_dir/* is the full path to the SSL certificate file that contains the public key.

```
RDSHOST="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
```

```
TOKEN="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 3306 --region us-
west-2 --username jane_doe )"

mysql --host=$RDSHOST --port=3306 --ssl-ca=/sample_dir/global-bundle.pem --enable-
cleartext-plugin --user=jane_doe --password=$TOKEN
```

When you connect using `AWSAuthenticationPlugin`, the connection is secured using SSL. To verify this, type the following at the `mysql>` command prompt.

```
show status like 'Ssl%';
```

The following lines in the output show more details.

```
+---------------+-------------+
| Variable_name | Value

                                                                    |

+---------------+-------------+
| ...           | ...
| Ssl_cipher    | AES256-SHA

                                                                    |

| ...           | ...
| Ssl_version   | TLSv1.1

                                                                    |

| ...           | ...
+-----------------------------+
```

If you want to connect to a DB cluster through a proxy, see Connecting to a database using IAM authentication.

Connecting to your DB cluster using IAM authentication from the command line: Amazon CLI and psql client

You can connect from the command line to an Aurora PostgreSQL DB cluster with the Amazon CLI and psql command line tool as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

> **Note**
>
> For information about connecting to your database using pgAdmin with IAM authentication, see the blog post Using IAM authentication to connect with pgAdmin Amazon Aurora PostgreSQL or Amazon RDS for PostgreSQL.

Topics

- Generating an IAM authentication token
- Connecting to an Aurora PostgreSQL cluster

Generating an IAM authentication token

The authentication token consists of several hundred characters so it can be unwieldy on the command line. One way to work around this is to save the token to an environment variable, and then use that variable when you connect. The following example shows how to use the Amazon CLI to get a signed authentication token using the `generate-db-auth-token` command, and store it in a PGPASSWORD environment variable.

```
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"
```

In the example, the parameters to the `generate-db-auth-token` command are as follows:

- `--hostname` – The host name of the DB cluster (cluster endpoint) that you want to access
- `--port` – The port number used for connecting to your DB cluster
- `--region` – The Amazon Region where the DB cluster is running
- `--username` – The database account that you want to access

The first several characters of the generated token look like the following.

```
mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com:5432/?
Action=connect&DBUser=jane_doe&X-Amz-Algorithm=AWS4-HMAC-SHA256&X-Amz-Expires=900...
```

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.

Connecting to an Aurora PostgreSQL cluster

The general format for using psql to connect is shown following.

```
psql "host=hostName port=portNumber sslmode=verify-full
 sslrootcert=full_path_to_ssl_certificate dbname=DBName user=userName
 password=authToken"
```

The parameters are as follows:

- `host` – The host name of the DB cluster (cluster endpoint) that you want to access
- `port` – The port number used for connecting to your DB cluster
- `sslmode` – The SSL mode to use

  When you use `sslmode=verify-full`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.
- `sslrootcert` – The full path to the SSL certificate file that contains the public key

  For more information, see Securing Aurora PostgreSQL data with SSL/TLS.

  To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.
- dbname – The database that you want to access
- `user` – The database account that you want to access
- `password` – A signed IAM authentication token

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.

The following example shows using psql to connect. In the example, psql uses the environment variable RDSHOST for the host and the environment variable PGPASSWORD for the generated token. Also, */sample_dir/* is the full path to the SSL certificate file that contains the public key.

```
export RDSHOST="mypostgres-cluster.cluster-123456789012.us-west-2.rds.amazonaws.com"
export PGPASSWORD="$(aws rds generate-db-auth-token --hostname $RDSHOST --port 5432 --
region us-west-2 --username jane_doe )"

psql "host=$RDSHOST port=5432 sslmode=verify-full sslrootcert=/sample_dir/global-
bundle.pem dbname=DBName user=jane_doe password=$PGPASSWORD"
```

If you want to connect to a DB cluster through a proxy, see Connecting to a database using IAM authentication.

Connecting to your DB cluster using IAM authentication and the Amazon SDK for .NET

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for .NET as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Examples

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the Amazon SDK for .NET, found on the Amazon site. The AWSSDK.CORE and the AWSSDK.RDS packages are required. To connect to a DB cluster, use

the .NET database connector for the DB engine, such as MySqlConnector for MariaDB or MySQL, or Npgsql for PostgreSQL.

This code connects to an Aurora MySQL DB cluster. Modify the values of the following variables as needed:

- `server` – The endpoint of the DB cluster that you want to access
- `user` – The database account that you want to access
- `database` – The database that you want to access
- `port` – The port number used for connecting to your DB cluster
- `SslMode` – The SSL mode to use

  When you use `SslMode=Required`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.
- `SslCa` – The full path to the SSL certificate for Amazon Aurora

  To download a certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.

```
using System;
using System.Data;
using MySql.Data;
using MySql.Data.MySqlClient;
using Amazon;

namespace ubuntu
{
  class Program
  {
    static void Main(string[] args)
    {
      var pwd =
 Amazon.RDS.Util.RDSAuthTokenGenerator.GenerateAuthToken(RegionEndpoint.USEast1,
 "mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com", 3306, "jane_doe");
```

```
      // for debug only Console.Write("{0}\n", pwd);  //this verifies the token is
 generated

      MySqlConnection conn = new
 MySqlConnection($"server=mysqlcluster.cluster-123456789012.us-
east-1.rds.amazonaws.com;user=jane_doe;database=mydB;port=3306;password={pwd};SslMode=Required;
      conn.Open();

      // Define a query
      MySqlCommand sampleCommand = new MySqlCommand("SHOW DATABASES;", conn);

      // Execute a query
      MySqlDataReader mysqlDataRdr = sampleCommand.ExecuteReader();

      // Read all rows and output the first column in each row
      while (mysqlDataRdr.Read())
        Console.WriteLine(mysqlDataRdr[0]);

      mysqlDataRdr.Close();
      // Close connection
      conn.Close();
    }
  }
}
```

This code connects to an Aurora PostgreSQL DB cluster.

Modify the values of the following variables as needed:

- `Server` – The endpoint of the DB cluster that you want to access
- `User ID` – The database account that you want to access
- `Database` – The database that you want to access
- `Port` – The port number used for connecting to your DB cluster
- `SSL Mode` – The SSL mode to use

  When you use `SSL Mode=Required`, the SSL connection verifies the DB cluster endpoint against the endpoint in the SSL certificate.
- `Root Certificate` – The full path to the SSL certificate for Amazon Aurora

  To download a certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.

Note

You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.

```
using System;
using Npgsql;
using Amazon.RDS.Util;

namespace ConsoleApp1
{
    class Program
    {
        static void Main(string[] args)
        {
            var pwd =
 RDSAuthTokenGenerator.GenerateAuthToken("postgresmycluster.cluster-123456789012.us-
east-1.rds.amazonaws.com", 5432, "jane_doe");
// for debug only Console.Write("{0}\n", pwd);  //this verifies the token is generated

            NpgsqlConnection conn = new
 NpgsqlConnection($"Server=postgresmycluster.cluster-123456789012.us-
east-1.rds.amazonaws.com;User Id=jane_doe;Password={pwd};Database=mydb;SSL
 Mode=Require;Root Certificate=full_path_to_ssl_certificate");
            conn.Open();

            // Define a query
                   NpgsqlCommand cmd = new NpgsqlCommand("select count(*) FROM
 pg_user", conn);

            // Execute a query
            NpgsqlDataReader dr = cmd.ExecuteReader();

            // Read all rows and output the first column in each row
            while (dr.Read())
                Console.Write("{0}\n", dr[0]);

            // Close connection
            conn.Close();
        }
    }
```

```
}
```

If you want to connect to a DB cluster through a proxy, see Connecting to a database using IAM authentication.

Connecting to your DB cluster using IAM authentication and the Amazon SDK for Go

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for Go as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

Examples

To run these code examples, you need the Amazon SDK for Go, found on the Amazon site.

Modify the values of the following variables as needed:

- `dbName` – The database that you want to access
- `dbUser` – The database account that you want to access
- `dbHost` – The endpoint of the DB cluster that you want to access

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.

- `dbPort` – The port number used for connecting to your DB cluster
- `region` – The Amazon Region where the DB cluster is running

In addition, make sure the imported libraries in the sample code exist on your system.

Important

The examples in this section use the following code to provide credentials that access a database from a local environment:

```
creds := credentials.NewEnvCredentials()
```

If you are accessing a database from an Amazon service, such as Amazon EC2 or Amazon ECS, you can replace the code with the following code:

```
sess := session.Must(session.NewSession())
creds := sess.Config.Credentials
```

If you make this change, make sure you add the following import:

```
"github.com/aws/aws-sdk-go/aws/session"
```

If you want to connect to a DB cluster through a proxy, see Connecting to a database using IAM authentication.

Connecting to your DB cluster using IAM authentication and the Amazon SDK for Java

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for Java as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication
- Set up the Amazon SDK for Java

For examples on how to use the SDK for Java 2.x, see Amazon RDS examples using SDK for Java 2.x. You can also use the Amazon Advanced JDBC Wrapper, see Amazon Advanced JDBC Wrapper documentation.

Topics

- Generating an IAM authentication token
- Manually constructing an IAM authentication token
- Connecting to a DB cluster

Generating an IAM authentication token

If you are writing programs using the Amazon SDK for Java, you can get a signed authentication token using the `RdsIamAuthTokenGenerator` class. Using this class requires that you provide Amazon credentials. To do this, you create an instance of the

`DefaultAWSCredentialsProviderChain` class. `DefaultAWSCredentialsProviderChain` uses the first Amazon access key and secret key that it finds in the default credential provider chain. For more information about Amazon access keys, see Managing access keys for users.

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.

After you create an instance of `RdsIamAuthTokenGenerator`, you can call the `getAuthToken` method to obtain a signed token. Provide the Amazon Region, host name, port number, and user name. The following code example illustrates how to do this.

```
package com.amazonaws.codesamples;

import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.services.rds.auth.GetIamAuthTokenRequest;
import com.amazonaws.services.rds.auth.RdsIamAuthTokenGenerator;

public class GenerateRDSAuthToken {

    public static void main(String[] args) {

     String region = "us-west-2";
     String hostname = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
     String port = "3306";
     String username = "jane_doe";

     System.out.println(generateAuthToken(region, hostname, port, username));
    }

    static String generateAuthToken(String region, String hostName, String port, String
 username) {

     RdsIamAuthTokenGenerator generator = RdsIamAuthTokenGenerator.builder()
      .credentials(new DefaultAWSCredentialsProviderChain())
      .region(region)
      .build();

     String authToken = generator.getAuthToken(
      GetIamAuthTokenRequest.builder()
```

```
      .hostname(hostName)
      .port(Integer.parseInt(port))
      .userName(username)
      .build());

     return authToken;
    }

}
```

Manually constructing an IAM authentication token

In Java, the easiest way to generate an authentication token is to use `RdsIamAuthTokenGenerator`. This class creates an authentication token for you, and then signs it using Amazon signature version 4. For more information, see Signature version 4 signing process in the *Amazon Web Services General Reference.*

However, you can also construct and sign an authentication token manually, as shown in the following code example.

```
package com.amazonaws.codesamples;

import com.amazonaws.SdkClientException;
import com.amazonaws.auth.DefaultAWSCredentialsProviderChain;
import com.amazonaws.auth.SigningAlgorithm;
import com.amazonaws.util.BinaryUtils;
import org.apache.commons.lang3.StringUtils;

import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import java.nio.charset.Charset;
import java.security.MessageDigest;
import java.text.SimpleDateFormat;
import java.util.Date;
import java.util.SortedMap;
import java.util.TreeMap;

import static com.amazonaws.auth.internal.SignerConstants.AWS4_TERMINATOR;
import static com.amazonaws.util.StringUtils.UTF8;

public class CreateRDSAuthTokenManually {
    public static String httpMethod = "GET";
    public static String action = "connect";
```

```
    public static String canonicalURIParameter = "/";
    public static SortedMap<String, String> canonicalQueryParameters = new TreeMap();
    public static String payload = StringUtils.EMPTY;
    public static String signedHeader = "host";
    public static String algorithm = "AWS4-HMAC-SHA256";
    public static String serviceName = "rds-db";
    public static String requestWithoutSignature;

    public static void main(String[] args) throws Exception {

        String region = "us-west-2";
        String instanceName = "rdsmysql.123456789012.us-west-2.rds.amazonaws.com";
        String port = "3306";
        String username = "jane_doe";

        Date now = new Date();
        String date = new SimpleDateFormat("yyyyMMdd").format(now);
        String dateTimeStamp = new
SimpleDateFormat("yyyyMMdd'T'HHmmss'Z'").format(now);
        DefaultAWSCredentialsProviderChain creds = new
DefaultAWSCredentialsProviderChain();
    String awsAccessKey = creds.getCredentials().getAWSAccessKeyId();
    String awsSecretKey = creds.getCredentials().getAWSSecretKey();
        String expiryMinutes = "900";

        System.out.println("Step 1:  Create a canonical request:");
        String canonicalString = createCanonicalString(username, awsAccessKey, date,
dateTimeStamp, region, expiryMinutes, instanceName, port);
        System.out.println(canonicalString);
        System.out.println();

        System.out.println("Step 2:  Create a string to sign:");
        String stringToSign = createStringToSign(dateTimeStamp, canonicalString,
awsAccessKey, date, region);
        System.out.println(stringToSign);
        System.out.println();

        System.out.println("Step 3:  Calculate the signature:");
        String signature = BinaryUtils.toHex(calculateSignature(stringToSign,
newSigningKey(awsSecretKey, date, region, serviceName)));
        System.out.println(signature);
        System.out.println();
```

```
        System.out.println("Step 4:  Add the signing info to the request");

        System.out.println(appendSignature(signature));
        System.out.println();

    }

    //Step 1: Create a canonical request date should be in format YYYYMMDD and dateTime
should be in format YYYYMMDDTHHMMSSZ
    public static String createCanonicalString(String user, String accessKey, String
date, String dateTime, String region, String expiryPeriod, String hostName, String
port) throws Exception {

        }
    }
}
```

Connecting to a DB cluster

The following code example shows how to generate an authentication token, and then use it to connect to a cluster running Aurora MySQL.

To run this code example, you need the Amazon SDK for Java, found on the Amazon site. In addition, you need the following:

- MySQL Connector/J. This code example was tested with `mysql-connector-java-5.1.33-bin.jar`.
- An intermediate certificate for Amazon Aurora that is specific to an Amazon Region. (For more information, see Using SSL/TLS to encrypt a connection to a DB cluster.) At runtime, the class

loader looks for the certificate in the same directory as this Java code example, so that the class loader can find it.

- Modify the values of the following variables as needed:
  - `RDS_INSTANCE_HOSTNAME` – The host name of the DB cluster that you want to access.
  - `RDS_INSTANCE_PORT` – The port number used for connecting to your PostgreSQL DB cluster.
  - `REGION_NAME` – The Amazon Region where the DB cluster is running.
  - `DB_USER` – The database account that you want to access.
  - `SSL_CERTIFICATE` – An SSL certificate for Amazon Aurora that is specific to an Amazon Region.

    To download a certificate for your Amazon Region, see Using SSL/TLS to encrypt a connection to a DB cluster. Place the SSL certificate in the same directory as this Java program file, so that the class loader can find the certificate at runtime.

This code example obtains Amazon credentials from the default credential provider chain.

> **Note**
>
> Specify a password for `DEFAULT_KEY_STORE_PASSWORD` other than the prompt shown here as a security best practice.

If you want to connect to a DB cluster through a proxy, see Connecting to a database using IAM authentication.

Connecting to your DB cluster using IAM authentication and the Amazon SDK for Python (Boto3)

You can connect to an Aurora MySQL or Aurora PostgreSQL DB cluster with the Amazon SDK for Python (Boto3) as described following.

Prerequisites

The following are prerequisites for connecting to your DB cluster using IAM authentication:

- Enabling and disabling IAM database authentication
- Creating and using an IAM policy for IAM database access
- Creating a database account using IAM authentication

In addition, make sure the imported libraries in the sample code exist on your system.

Examples

The code examples use profiles for shared credentials. For information about the specifying credentials, see Credentials in the Amazon SDK for Python (Boto3) documentation.

The following code examples show how to generate an authentication token, and then use it to connect to a DB cluster.

To run this code example, you need the Amazon SDK for Python (Boto3), found on the Amazon site.

Modify the values of the following variables as needed:

- `ENDPOINT` – The endpoint of the DB cluster that you want to access
- `PORT` – The port number used for connecting to your DB cluster
- `USER` – The database account that you want to access
- `REGION` – The Amazon Region where the DB cluster is running
- `DBNAME` – The database that you want to access
- `SSLCERTIFICATE` – The full path to the SSL certificate for Amazon Aurora

For `ssl_ca`, specify an SSL certificate. To download an SSL certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.

> **Note**
>
> You cannot use a custom Route 53 DNS record instead of the DB cluster endpoint to generate the authentication token.

This code connects to an Aurora MySQL DB cluster.

Before running this code, install the PyMySQL driver by following the instructions in the Python Package Index.

```
import pymysql
import sys
import boto3
import os

ENDPOINT="mysqlcluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="3306"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"
os.environ['LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN'] = '1'

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='default')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
 Region=REGION)

try:
    conn =
 pymysql.connect(auth_plugin_map={'mysql_clear_password':None},host=ENDPOINT,
 user=USER, password=token, port=PORT, database=DBNAME, ssl_ca='SSLCERTIFICATE',
 ssl_verify_identity=True, ssl_verify_cert=True)
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
```

```
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

This code connects to an Aurora PostgreSQL DB cluster.

Before running this code, install psycopg2 by following the instructions in Psycopg documentation.

```
import psycopg2
import sys
import boto3
import os

ENDPOINT="postgresmycluster.cluster-123456789012.us-east-1.rds.amazonaws.com"
PORT="5432"
USER="jane_doe"
REGION="us-east-1"
DBNAME="mydb"

#gets the credentials from .aws/credentials
session = boto3.Session(profile_name='RDSCreds')
client = session.client('rds')

token = client.generate_db_auth_token(DBHostname=ENDPOINT, Port=PORT, DBUsername=USER,
 Region=REGION)

try:
    conn = psycopg2.connect(host=ENDPOINT, port=PORT, database=DBNAME, user=USER,
 password=token, sslrootcert="SSLCERTIFICATE")
    cur = conn.cursor()
    cur.execute("""SELECT now()""")
    query_results = cur.fetchall()
    print(query_results)
except Exception as e:
    print("Database connection failed due to {}".format(e))
```

If you want to connect to a DB cluster through a proxy, see Connecting to a database using IAM authentication.

Troubleshooting for IAM DB authentication

Following, you can find troubleshooting ideas for some common IAM DB authentication issues and information on CloudWatch logs and metrics for IAM DB authentication.

Exporting IAM DB authentication error logs to CloudWatch Logs

IAM DB authentication error logs are stored on the database host, and you can export these logs your CloudWatch Logs account. Use the logs and remediation methods in this page to troubleshoot IAM DB authentication issues.

You can enable log exports to CloudWatch Logs from the console, Amazon CLI, and RDS API. For console instructions, see Publishing database logs to Amazon CloudWatch Logs.

To export your IAM DB authentication error logs to CloudWatch Logs when creating a DB cluster from the Amazon CLI, use the following command:

```
aws rds create-db-cluster --db-cluster-identifier mydbcluster \
--region us-east-1 \
--engine aurora-postgresql \
--engine-version 16 \
--master-username master \
--master-user-password password \
--enable-iam-database-authentication \
--enable-cloudwatch-logs-exports=iam-db-auth-error
```

To export your IAM DB authentication error logs to CloudWatch Logs when modifying a DB clusterfrom the Amazon CLI, use the following command:

```
aws rds modify-db-cluster --db-cluster-identifier mydbcluster \
--region us-east-1 \
--cloudwatch-logs-export-configuration '{"EnableLogTypes":["iam-db-auth-error"]}'
```

To verify if your DB cluster is exporting IAM DB authentication logs to CloudWatch Logs, check if the `EnabledCloudwatchLogsExports` parameter is set to `iam-db-auth-error` in the output for the `describe-db-instances` command.

```
aws rds describe-db-cluster --region us-east-1 --db-cluster-identifier mydbcluster
            ...
```

```
            "EnabledCloudwatchLogsExports": [
               "iam-db-auth-error"
            ],
            ...
```

IAM DB authentication CloudWatch metrics

Amazon Aurora delivers near-real time metrics about IAM DB authentication to your Amazon CloudWatch account. The following table lists the IAM DB authentication metrics available using CloudWatch:

Metric	Description
`IamDbAuthConnectionRequests`	Total number of connection requests made with IAM DB authentication.
`IamDbAuthConnectionSuccess`	Total number of successful IAM DB authentic ation requests.
`IamDbAuthConnectionFailure`	Total number of failed IAM DB authentication requests.
`IamDbAuthConnectionFailureI nvalidToken`	Total number of failed IAM DB authentication requests due to invalid token.
`IamDbAuthConnectionFailureI nsufficientPermissions`	Total number of failed IAM DB authentication requests due to incorrect policies or permissio ns.
`IamDbAuthConnectionFailureT hrottling`	Total number of failed IAM DB authentic ation requests due to IAM DB authentication throttling.
`IamDbAuthConnectionFailureS erverError`	Total number of failed IAM DB authentication requests due to an internal server error in the IAM DB authentication feature.

Common issues and solutions

You might encounter the following issues when using IAM DB authention. Use the remediation steps in the table to solve the issues:

Error	Metric(s)	Cause	Solution

`[ERROR] Failed to authenticate the connection request for user db_user because the provided token is malformed or otherwise invalid. (Status Code: 400, Error Code: InvalidToken)`	`IamDbAuthConnectionFailure`
	
	`IamDbAuthConnectionFailureInvalidToken`
		The IAM DB authentiation token in the connection request is either not a valid SigV4a token, or it is not formatted correctly.	Check your token generation strategy in your application. In some cases, make sure you are passing the token with valid formatting. Truncating the token (or incorrect string formatting) will make the token invalid.

`[ERROR] Failed to authenticate the connection request for user db_user because the token age is longer than 15 minutes. (Status Code: 400, Error Code:ExpiredToken)`	`IamDbAuthConnectionFailure`
	
	`IamDbAuthConnectionFailureInvalidToken`
		The IAM DB authentication token has expired. Tokens are only valid for 15 minutes.	Check your token caching and/or token re-use logic in your application. You should not re-use tokens that are older than 15 minutes.

`[ERROR] Failed to authorize the connection request for user`	`IamDbAuthConnectionFailure`	This error might be due to the following reasons:	Verify that the IAM role and/or policy you are assuming in your applicati

Error	Metric(s)	Cause	Solution
db_user because the IAM policy assumed by the caller 'arn:aws:sts::123456789012:assumed-role/ <RoleName>/ <RoleSession>' is not authorized to perform `rds-db:connect` on the DB instance. (Status Code: 403, Error Code:NotAuthorized)	IamDbAuthConnectionFailureInsufficientPermissions	• The IAM policy assumed by the application does not authorize the rds-db:connect action. • You are assuming the incorrect role/policy for *db_user* to connect to the database. • You are assuming the correct policy for *db_user*, but you are not connecting to the correct database.	on. Make sure you assume the same policy to generate the token as to connect to the DB.
[ERROR] Failed to authorize the connection request for user *db_user* due to IAM DB authentication throttling. (Status Code: 429, Error Code: ThrottlingException)	IamDbAuthConnectionFailure IamDbAuthConnectionFailureThrottling	You are making too many connection requests to your DB in a short amount of time.	Reduce the rate of establishing new connections with IAM authentication. Consider implementing connection pooling using RDS Proxy in order to reuse established connections in your application.

Error	Metric(s)	Cause	Solution

`[ERROR] Failed to authorize the connection request for user db_user due to an internal IAM DB authentication error. (Status Code: 500, Error Code: InternalError)`	`IamDbAuthConnectionFailure`
	
	`IamDbAuthConnectionFailureThrottling`
		There was an internal error while authorizing the DB connecito n with IAM DB authentication.	Reach out to http://www.amazonaws.cn/support-plans/ to investigate the issue.

Troubleshooting Amazon Aurora identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Aurora and IAM.

Topics

- I'm not authorized to perform an action in Aurora
- I'm not authorized to perform iam:PassRole
- I want to allow people outside of my Amazon account to access my Aurora resources

I'm not authorized to perform an action in Aurora

If the Amazon Web Services Management Console tells you that you're not authorized to perform an action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials.

The following example error occurs when the `mateojackson` user tries to use the console to view details about a *widget* but does not have `rds:GetWidget` permissions.

```
User: arn:aws-cn:iam::123456789012:user/mateojackson is not authorized to perform:
 rds:GetWidget on resource: my-example-widget
```

In this case, Mateo asks his administrator to update his policies to allow him to access the *my-example-widget* resource using the `rds:GetWidget` action.

I'm not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, then you must contact your administrator for assistance. Your administrator is the person that provided you with your sign-in credentials. Ask that person to update your policies to allow you to pass a role to Aurora.

Some Amazon services allow you to pass an existing role to that service, instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when a user named `marymajor` tries to use the console to perform an action in Aurora. However, the action requires the service to have permissions granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws-cn:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary asks her administrator to update her policies to allow her to perform the `iam:PassRole` action.

I want to allow people outside of my Amazon account to access my Aurora resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Aurora supports these features, see How Amazon Aurora works with IAM.
- To learn how to provide access to your resources across Amazon accounts that you own, see Providing access to an IAM user in another Amazon account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party Amazon accounts, see Providing access to Amazon accounts owned by third parties in the *IAM User Guide*.

- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the *IAM User Guide*.

Logging and monitoring in Amazon Aurora

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Aurora and your Amazon solutions. You should collect monitoring data from all of the parts of your Amazon solution so that you can more easily debug a multi-point failure if one occurs. Amazon provides several tools for monitoring your Amazon Aurora resources and responding to potential incidents:

Amazon CloudWatch Alarms

Using Amazon CloudWatch alarms, you watch a single metric over a time period that you specify. If the metric exceeds a given threshold, a notification is sent to an Amazon SNS topic or Amazon Auto Scaling policy. CloudWatch alarms do not invoke actions because they are in a particular state. Rather the state must have changed and been maintained for a specified number of periods.

Amazon CloudTrail Logs

CloudTrail provides a record of actions taken by a user, role, or an Amazon service in Amazon Aurora. CloudTrail captures all API calls for Amazon Aurora as events, including calls from the console and from code calls to Amazon RDS API operations. Using the information collected by CloudTrail, you can determine the request that was made to Amazon Aurora, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see Monitoring Amazon Aurora API calls in Amazon CloudTrail .

Enhanced Monitoring

Amazon Aurora provides metrics in real time for the operating system (OS) that your DB cluster runs on. You can view the metrics for your DB cluster using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information, see Monitoring OS metrics with Enhanced Monitoring .

Amazon RDS Performance Insights

Performance Insights expands on existing Amazon Aurora monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance

Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users. For more information, see Monitoring DB load with Amazon CloudWatch Database Insights on Amazon Aurora .

Database Logs

You can view, download, and watch database logs using the Amazon Web Services Management Console, Amazon CLI, or RDS API. For more information, see Monitoring Amazon Aurora log files .

Amazon Aurora Recommendations

Amazon Aurora provides automated recommendations for database resources. These recommendations provide best practice guidance by analyzing DB cluster configuration, usage, and performance data. For more information, see Recommendations from Amazon Aurora .

Amazon Aurora Event Notification

Amazon Aurora uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon Aurora event occurs. These notifications can be in any notification form supported by Amazon SNS for an Amazon Region, such as an email, a text message, or a call to an HTTP endpoint. For more information, see Working with Amazon RDS event notification .

Amazon Trusted Advisor

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of Amazon customers. Trusted Advisor inspects your Amazon environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All Amazon customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

Trusted Advisor has the following Amazon Aurora-related checks:

- Amazon Aurora Idle DB Instances
- Amazon Aurora Security Group Access Risk
- Amazon Aurora Backups
- Amazon Aurora Multi-AZ
- Aurora DB Instance Accessibility

For more information on these checks, see Trusted Advisor best practices (checks).

Database activity streams

Database activity streams can protect your databases from internal threats by controlling DBA access to the database activity streams. Thus, the collection, transmission, storage, and subsequent processing of the database activity stream is beyond the access of the DBAs that manage the database. Database activity streams can provide safeguards for your database and meet compliance and regulatory requirements. For more information, seeMonitoring Amazon Aurora with Database Activity Streams .

For more information about monitoring Aurora see Monitoring metrics in an Amazon Aurora cluster .

Compliance validation for Amazon Aurora

Third-party auditors assess the security and compliance of Amazon Aurora as part of multiple Amazon compliance programs. These include SOC, PCI, FedRAMP, HIPAA, and others.

For a list of Amazon services in scope of specific compliance programs, see Amazon services in scope by compliance program. For general information, see Amazon compliance programs.

You can download third-party audit reports using Amazon Artifact. For more information, see Downloading reports in Amazon Artifact.

Your compliance responsibility when using Amazon Aurora is determined by the sensitivity of your data, your organization's compliance objectives, and applicable laws and regulations. Amazon provides the following resources to help with compliance:

- Security and compliance quick start guides – These deployment guides discuss architectural considerations and provide steps for deploying security- and compliance-focused baseline environments on Amazon.
- Architecting for HIPAA Security and Compliance on Amazon Web Services – This whitepaper describes how companies can use Amazon to create HIPAA-compliant applications.
- Amazon compliance resources – This collection of workbooks and guides that might apply to your industry and location.
- Amazon Config – This Amazon service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- Amazon Security Hub CSPM – This Amazon Web Services service provides a comprehensive view of your security state within Amazon. Security Hub CSPM uses security controls to evaluate your Amazon resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub CSPM controls reference.

Resilience in Amazon Aurora

The Amazon global infrastructure is built around Amazon Regions and Availability Zones. Amazon Regions provide multiple physically separated and isolated Availability Zones, which are connected with low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between Availability Zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about Amazon Regions and Availability Zones, see Amazon global infrastructure.

In addition to the Amazon global infrastructure, Aurora offers features to help support your data resiliency and backup needs.

Backup and restore

Aurora backs up your cluster volume automatically and retains restore data for the length of the *backup retention period*. Aurora backups are continuous and incremental so you can quickly restore to any point within the backup retention period. No performance impact or interruption of database service occurs as backup data is being written. You can specify a backup retention period, from 1 to 35 days, when you create or modify a DB cluster.

If you want to retain a backup beyond the backup retention period, you can also take a snapshot of the data in your cluster volume. Aurora retains incremental restore data for the entire backup retention period. Thus, you need to create a snapshot only for data that you want to retain beyond the backup retention period. You can create a new DB cluster from the snapshot.

You can recover your data by creating a new Aurora DB cluster from the backup data that Aurora retains, or from a DB cluster snapshot that you have saved. You can quickly create a new copy of a DB cluster from backup data to any point in time during your backup retention period. The continuous and incremental nature of Aurora backups during the backup retention period means you don't need to take frequent snapshots of your data to improve restore times.

For more information, see Backing up and restoring an Amazon Aurora DB cluster.

Replication

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the

Availability Zones that a DB cluster spans within an Amazon Region. The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary DB instance and to Aurora Replicas in the DB cluster. If the primary DB instance fails, an Aurora Replica is promoted to be the primary DB instance.

Aurora also supports replication options that are specific to Aurora MySQL and Aurora PostgreSQL.

For more information, see Replication with Amazon Aurora.

Failover

Aurora stores copies of the data in a DB cluster across multiple Availability Zones in a single Amazon Region. This storage occurs regardless of whether the DB instances in the DB cluster span multiple Availability Zones. When you create Aurora Replicas across Availability Zones, Aurora automatically provisions and maintains them synchronously. The primary DB instance is synchronously replicated across Availability Zones to Aurora Replicas to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups. Running a DB cluster with high availability can enhance availability during planned system maintenance, and help protect your databases against failure and Availability Zone disruption.

For more information, see High availability for Amazon Aurora.

Infrastructure security in Amazon Aurora

As a managed service, Amazon Relational Database Service is protected by Amazon global network security. For information about Amazon security services and how Amazon protects infrastructure, see Amazon Cloud Security. To design your Amazon environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar Amazon Well-Architected Framework*.

You use Amazon published API calls to access Amazon RDS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

In addition, Aurora offers features to help support infrastructure security.

Security groups

Security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off to a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group.

For more information, see Controlling access with security groups.

Public accessibility

When you launch a DB instance inside a virtual private cloud (VPC) based on the Amazon VPC service, you can turn on or off public accessibility for that DB instance. To designate whether the DB instance that you create has a DNS name that resolves to a public IP address, you use the *Public accessibility* parameter. By using this parameter, you can designate whether there is public access to the DB instance. You can modify a DB instance to turn on or off public accessibility by modifying the *Public accessibility* parameter.

For more information, see Hiding a DB cluster in a VPC from the internet.

Note

If your DB instance is in a VPC but isn't publicly accessible, you can also use an Amazon Site-to-Site VPN connection or an Amazon Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy.

Amazon RDS API and interface VPC endpoints (Amazon PrivateLink)

You can establish a private connection between your VPC and Amazon RDS API endpoints by creating an *interface VPC endpoint*. Interface endpoints are powered by Amazon PrivateLink.

Amazon PrivateLink enables you to privately access Amazon RDS API operations without an internet gateway, NAT device, VPN connection, or Amazon Direct Connect connection. DB instances in your VPC don't need public IP addresses to communicate with Amazon RDS API endpoints to launch, modify, or terminate DB instances and DB clusters. Your DB instances also don't need public IP addresses to use any of the available RDS API operations. Traffic between your VPC and Amazon RDS doesn't leave the Amazon network.

Each interface endpoint is represented by one or more elastic network interfaces in your subnets. For more information on elastic network interfaces, see Elastic network interfaces in the *Amazon EC2 User Guide.*

For more information about VPC endpoints, see Interface VPC endpoints (Amazon PrivateLink) in the *Amazon VPC User Guide*. For more information about RDS API operations, see Amazon RDS API Reference.

You don't need an interface VPC endpoint to connect to a DB cluster. For more information, see Scenarios for accessing a DB cluster in a VPC.

Considerations for VPC endpoints

Before you set up an interface VPC endpoint for Amazon RDS API endpoints, ensure that you review Interface endpoint properties and limitations in the *Amazon VPC User Guide*.

All RDS API operations relevant to managing Amazon Aurora resources are available from your VPC using Amazon PrivateLink.

VPC endpoint policies are supported for RDS API endpoints. By default, full access to RDS API operations is allowed through the endpoint. For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

Availability

Amazon RDS API currently supports VPC endpoints in the following Amazon Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (New Zealand)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Taipei)
- Asia Pacific (Thailand)
- Asia Pacific (Tokyo)
- Canada (Central)
- Canada West (Calgary)
- China (Beijing)
- China (Ningxia)
- Europe (Frankfurt)
- Europe (Zurich)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Europe (Stockholm)
- Europe (Milan)
- Israel (Tel Aviv)
- Mexico (Central)
- Middle East (Bahrain)

- South America (São Paulo)

Creating an interface VPC endpoint for Amazon RDS API

You can create a VPC endpoint for the Amazon RDS API using either the Amazon VPC console or the Amazon Command Line Interface (Amazon CLI). For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

Create a VPC endpoint for Amazon RDS API using the service name `com.amazonaws.region.rds`.

Excluding Amazon Regions in China, if you enable private DNS for the endpoint, you can make API requests to Amazon RDS with the VPC endpoint using its default DNS name for the Amazon Region, for example `rds.us-east-1.amazonaws.com`. For the China (Beijing) and China (Ningxia) Amazon Regions, you can make API requests with the VPC endpoint using `rds-api.cn-north-1.amazonaws.com.cn` and `rds-api.cn-northwest-1.amazonaws.com.cn`, respectively.

For more information, see Accessing a service through an interface endpoint in the *Amazon VPC User Guide*.

Creating a VPC endpoint policy for Amazon RDS API

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon RDS API. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

Example: VPC endpoint policy for Amazon RDS API actions

The following is an example of an endpoint policy for Amazon RDS API. When attached to an endpoint, this policy grants access to the listed Amazon RDS API actions for all principals on all resources.

```
{
   "Statement":[
      {
         "Principal":"*",
         "Effect":"Allow",
         "Action":[
            "rds:CreateDBInstance",
            "rds:ModifyDBInstance",
            "rds:CreateDBSnapshot"
         ],
         "Resource":"*"
      }
   ]
}
```

Example: VPC endpoint policy that denies all access from a specified Amazon account

The following VPC endpoint policy denies Amazon account 123456789012 all access to resources using the endpoint. The policy allows all actions from other accounts.

```
{
  "Statement": [
    {
      "Action": "*",
      "Effect": "Allow",
      "Resource": "*",
      "Principal": "*"
    },
    {
      "Action": "*",
      "Effect": "Deny",
      "Resource": "*",
      "Principal": { "AWS": [ "123456789012" ] }
     }
   ]
}
```

Security best practices for Amazon Aurora

Use Amazon Identity and Access Management (IAM) accounts to control access to Amazon RDS API operations, especially operations that create, modify, or delete Amazon Aurora resources.

Such resources include DB clusters, security groups, and parameter groups. Also use IAM to control actions that perform common administrative actions such as backing up and restoring DB clusters.

- Create an individual user for each person who manages Amazon Aurora resources, including yourself. Don't use Amazon root credentials to manage Amazon Aurora resources.
- Grant each user the minimum set of permissions required to perform his or her duties.
- Use IAM groups to effectively manage permissions for multiple users.
- Rotate your IAM credentials regularly.
- Configure Amazon Secrets Manager to automatically rotate the secrets for Amazon Aurora. For more information, see Rotating your Amazon Secrets Manager secrets in the *Amazon Secrets Manager User Guide*. You can also retrieve the credential from Amazon Secrets Manager programmatically. For more information, see Retrieving the secret value in the *Amazon Secrets Manager User Guide*.

For more information about Amazon Aurora security, see Security in Amazon Aurora . For more information about IAM, see Amazon Identity and Access Management. For information on IAM best practices, see IAM best practices.

Amazon Security Hub CSPM uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub CSPM to evaluate RDS resources, see Amazon Relational Database Service controls in the Amazon Security Hub User Guide.

You can monitor your usage of RDS as it relates to security best practices by using Security Hub CSPM. For more information, see What is Amazon Security Hub CSPM?.

Use the Amazon Web Services Management Console, the Amazon CLI, or the RDS API to change the password for your master user. If you use another tool, such as a SQL client, to change the master user password, it might result in privileges being revoked for the user unintentionally.

Amazon GuardDuty is a continuous security monitoring service that analyzes and processes various data sources, including Amazon RDS login activity. It uses threat intelligence feeds and machine learning to identify unexpected, potentially unauthorized, suspicious login behavior, and malicious activity within your Amazon environment.

When Amazon GuardDuty RDS Protection detects a potentially suspicious or anomalous login attempt that indicates a threat to your database, GuardDuty generates a new finding with details

about the potentially compromised database. For more information, see Monitoring threats with Amazon GuardDuty RDS Protectionfor Amazon Aurora .

Controlling access with security groups

VPC security groups control the access that traffic has in and out of a DB cluster. By default, network access is turned off for a DB cluster. You can specify rules in a security group that allow access from an IP address range, port, or security group. After ingress rules are configured, the same rules apply to all DB clusters that are associated with that security group. You can specify up to 20 rules in a security group.

Overview of VPC security groups

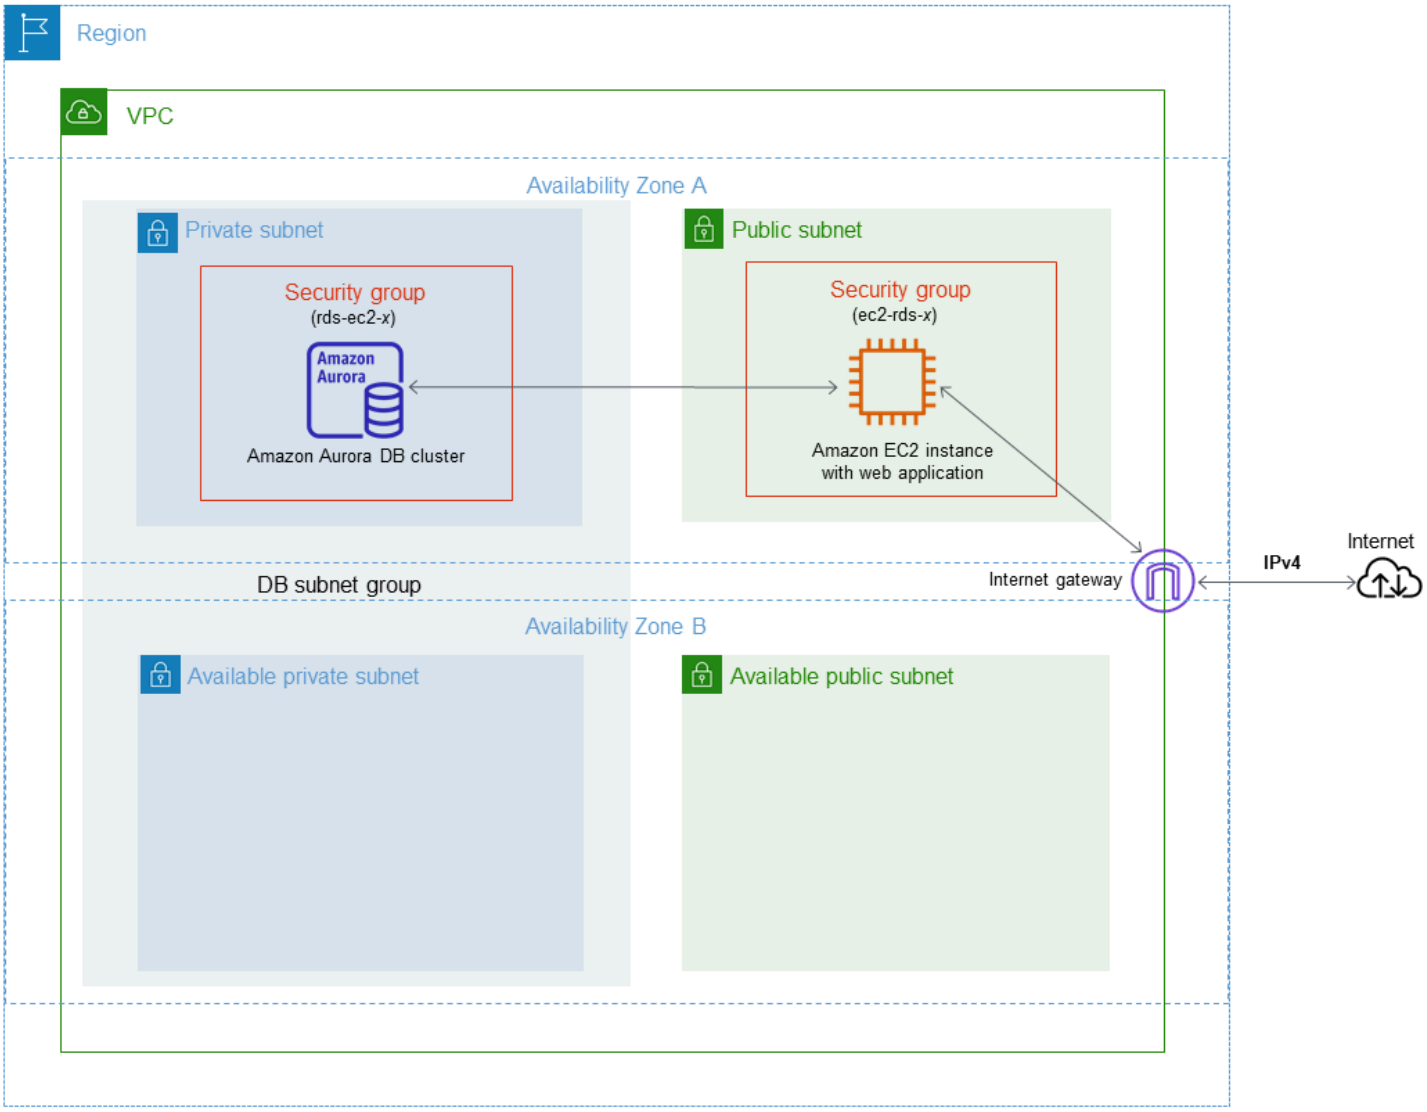
Each VPC security group rule makes it possible for a specific source to access a DB cluster in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group. VPC security groups can have rules that govern both inbound and outbound traffic. However, the outbound traffic rules typically don't apply to DB clusters. Outbound traffic rules apply only if the DB cluster acts as a client. You must use the Amazon EC2 API or the **Security Group** option on the VPC console to create VPC security groups.

When you create rules for your VPC security group that allow access to the clusters in your VPC, you must specify a port for each range of addresses that the rule allows access for. For example, if you want to turn on Secure Shell (SSH) access for instances in the VPC, create a rule allowing access to TCP port 22 for the specified range of addresses.

You can configure multiple VPC security groups that allow access to different ports for different instances in your VPC. For example, you can create a VPC security group that allows access to TCP port 80 for web servers in your VPC. You can then create another VPC security group that allows access to TCP port 3306 for Aurora MySQL DB instances in your VPC.

> **Note**
>
> In an Aurora DB cluster, the VPC security group associated with the DB cluster is also associated with all of the DB instances in the DB cluster. If you change the VPC security group for the DB cluster or for a DB instance, the change is applied automatically to all of the DB instances in the DB cluster.

For more information on VPC security groups, see Security groups in the *Amazon Virtual Private Cloud User Guide*.



> **Note**
>
> If your DB cluster is in a VPC but isn't publicly accessible, you can also use an Amazon Site-to-Site VPN connection or an Amazon Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy .

Security group scenario

A common use of a DB cluster in a VPC is to share data with an application server running in an Amazon EC2 instance in the same VPC, which is accessed by a client application outside the VPC. For this scenario, you use the RDS and VPC pages on the Amazon Web Services Management Console or the RDS and EC2 API operations to create the necessary instances and security groups:

1. Create a VPC security group (for example, `sg-0123ec2example`) and define inbound rules that use the IP addresses of the client application as the source. This security group allows your client application to connect to EC2 instances in a VPC that uses this security group.
2. Create an EC2 instance for the application and add the EC2 instance to the VPC security group (`sg-0123ec2example`) that you created in the previous step.
3. Create a second VPC security group (for example, `sg-6789rdsexample`) and create a new rule by specifying the VPC security group that you created in step 1 (`sg-0123ec2example`) as the source.
4. Create a new DB cluster and add the DB cluster to the VPC security group (`sg-6789rdsexample`) that you created in the previous step. When you create the DB cluster, use the same port number as the one specified for the VPC security group (`sg-6789rdsexample`) rule that you created in step 3.

The following diagram shows this scenario.

For detailed instructions about configuring a VPC for this scenario, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only) . For more information about using a VPC, see Amazon VPC and Amazon Aurora .

Creating a VPC security group

You can create a VPC security group for a DB instance by using the VPC console. For information about creating a security group, see Provide access to the DB cluster in the VPC by creating a security group and Security groups in the *Amazon Virtual Private Cloud User Guide*.

Associating a security group with a DB cluster

You can associate a security group with a DB cluster by using **Modify cluster** on the RDS console, the `ModifyDBCluster` Amazon RDS API, or the `modify-db-cluster` Amazon CLI command.

The following CLI example associates a specific VPC group and removes DB security groups from the DB cluster

```
aws rds modify-db-cluster --db-cluster-identifier dbName --vpc-security-group-ids sg-ID
```

For information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster .

Master user account privileges

When you create a new DB cluster, the default master user that you use gets certain privileges for that DB cluster. You can't change the master user name after the DB cluster is created.

Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Note

If you accidentally delete the permissions for the master user, you can restore them by modifying the DB cluster and setting a new master user password. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster .

The following table shows the privileges and database roles the master user gets for each of the database engines.

Database engine	System privilege	Database role
Aurora MySQL	Version 2: ALTER,ALTER ROUTINE, CREATE,CREATE ROUTINE,CREATE TEMPORARY TABLES,CREATE USER,CREATE VIEW,DELETE,DROP, EVENT,EXECUTE,GRANT OPTION,INDEX,INSERT, LOAD FROM S3,LOCK TABLES, PROCESS,REFERENCES , RELOAD,REPLICATI ON CLIENT , REPLICATION SLAVE ,SELECT, SELECT INTO S3,SHOW DATABASES , SHOW VIEW,TRIGGER, UPDATE	—
	Version 3: ALTER,APPLICATION_PASSWORD_ADMIN , ALTER ROUTINE,CONNECTION_ADMIN , CREATE,CREATE ROLE,CREATE ROUTINE,CREATE TEMPORARY TABLES, CREATE USER,CREATE VIEW, DELETE,DROP,DROP ROLE, EVENT,EXECUTE,INDEX, INSERT,LOCK TABLES, PROCESS,REFERENCES , RELOAD,REPLICATION CLIENT , REPLICATI ON SLAVE ,ROLE_ADMIN , SET_USER_ ID ,SELECT,SHOW DATABASES ,SHOW VIEW,TRIGGER, UPDATE,XA_RECOVER_ADMIN Starting with Aurora MySQL version 3.04.0, the master user also gets the SHOW_ROUTINE privilege . Starting with Aurora MySQL version 3.09.0, the master user also gets the FLUSH_OPTIMIZER_CO STS ,FLUSH_STATUS ,FLUSH_TABLES , and FLUSH_USER_RESOURCES privileges.	rds_superuser_role For more information about rds_superuser_role, see Role-based privilege model .
	Version 8.4:	rds_superuser_role

Database engine	System privilege	Database role
	ALTER,ALLOW_NONEXISTENT_DEFINER , APPLICATION_PASSWORD_ADMIN , ALTER ROUTINE,CONNECTION_ADMIN , CREATE,CREATE ROLE,CREATE ROUTINE,CREATE TEMPORARY TABLES, CREATE USER,CREATE VIEW, DELETE,DROP,DROP ROLE, EVENT,EXECUTE, FLUSH_OPTIMIZER_COSTS ,FLUSH_PRI VILEGES , FLUSH_STATUS ,FLUSH_TABLES , FLUSH_USER_RESOURCES , INDEX,INSERT, LOCK TABLES,OPTIMIZE_LOCAL_TABLE , PROCESS,REFERENCES , RELOAD,REPLICATION CLIENT, REPLICATION SLAVE ,ROLE_ADMIN , SELECT,SET_ANY_DEFINER , SHOW DATABASES ,SHOW_ROUTINE , SHOW VIEW,TRIGGER, UPDATE,XA_RECOVER_ADMIN	For more information about rds_superuser_role, see Role-based privilege model .
Aurora PostgreSQL	LOGIN,NOSUPERUSER , INHERIT,CREATEDB, CREATEROLE ,NOREPLICATION ,VALID UNTIL 'infinity'	RDS_SUPERUSER For more information about RDS_SUPERUSER, see Understanding PostgreSQL roles and permissions .

Using service-linked roles for Amazon Aurora

Amazon Aurora uses Amazon Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon Aurora. Service-linked roles are predefined by Amazon Aurora and include all the permissions that the service requires to call other Amazon services on your behalf.

A service-linked role makes using Amazon Aurora easier because you don't have to manually add the necessary permissions. Amazon Aurora defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon Aurora can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This protects your Amazon Aurora resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see Amazon services that work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Amazon Aurora

Amazon Aurora uses the service-linked role named AWSServiceRoleForRDS to allow Amazon RDS to call Amazon services on behalf of your DB clusters.

The AWSServiceRoleForRDS service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSServiceRolePolicy` that grants it permissions to operate in your account.

For more information about this policy, including the JSON policy document, see AmazonRDSServiceRolePolicy in the *Amazon Managed Policy Reference Guide*.

> **Note**
>
> You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message:

Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.
Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws-cn:iam::*:role/aws-service-role/rds.amazonaws.com/
AWSServiceRoleForRDS",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Creating a service-linked role for Amazon Aurora

You don't need to manually create a service-linked role. When you create a DB cluster, Amazon Aurora creates the service-linked role for you.

Important

If you were using the Amazon Aurora service before December 1, 2017, when it began supporting service-linked roles, then Amazon Aurora created the AWSServiceRoleForRDS role in your account. To learn more, see A new role appeared in my Amazon account.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a DB cluster, Amazon Aurora creates the service-linked role for you again.

Editing a service-linked role for Amazon Aurora

Amazon Aurora does not allow you to edit the AWSServiceRoleForRDS service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities

might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for Amazon Aurora

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete all of your DB clusters before you can delete the service-linked role.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane of the IAM console, choose **Roles**. Then choose the name (not the check box) of the AWSServiceRoleForRDS role.
3. On the **Summary** page for the chosen role, choose the **Last Accessed** tab.
4. On the **Last Accessed** tab, review recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether Amazon Aurora is using the AWSServiceRoleForRDS role, you can try to delete the role. If the service is using the role, then the deletion fails and you can view the Amazon Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

If you want to remove the AWSServiceRoleForRDS role, you must first delete *all* of your DB clusters.

Deleting all of your clusters

Use one of the following procedures to delete a single cluster. Repeat the procedure for each of your clusters.

To delete a cluster (console)

1. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the **Databases** list, choose the cluster that you want to delete.
3. For **Cluster Actions**, choose **Delete**.
4. Choose **Delete**.

To delete a cluster (CLI)

See `delete-db-cluster` in the *Amazon CLI Command Reference*.

To delete a cluster (API)

See `DeleteDBCluster` in the *Amazon RDS API Reference*.

You can use the IAM console, the IAM CLI, or the IAM API to delete the AWSServiceRoleForRDS service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Service-linked role permissions for Amazon RDS Beta

Amazon Aurora uses the service-linked role named `AWSServiceRoleForRDSBeta` to allow Amazon Aurora to call Amazon services on behalf of your RDS DB resources.

The AWSServiceRoleForRDSBeta service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSBetaServiceRolePolicy` that grants it permissions to operate in your account. For more information, see Amazon managed policy: AmazonRDSBetaServiceRolePolicy.

> **Note**
>
> You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**
> Make sure you have the following permissions enabled:

```
{
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws-cn:iam::*:role/aws-service-role/
custom.rds.amazonaws.com/AmazonRDSBetaServiceRolePolicy",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"custom.rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Service-linked role for Amazon RDS Preview

Amazon Aurora uses the service-linked role named `AWSServiceRoleForRDSPreview` to allow Amazon Aurora to call Amazon services on behalf of your RDS DB resources.

The AWSServiceRoleForRDSPreview service-linked role trusts the following services to assume the role:

- `rds.amazonaws.com`

This service-linked role has a permissions policy attached to it called `AmazonRDSPreviewServiceRolePolicy` that grants it permissions to operate in your account. For more information, see Amazon managed policy: AmazonRDSPreviewServiceRolePolicy.

Note

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. If you encounter the following error message: **Unable to create the resource. Verify that you have permission to create service linked role. Otherwise wait and try again later.**
Make sure you have the following permissions enabled:

```
{
```

```
    "Action": "iam:CreateServiceLinkedRole",
    "Effect": "Allow",
    "Resource": "arn:aws-cn:iam::*:role/aws-service-role/
custom.rds.amazonaws.com/AmazonRDSPreviewServiceRolePolicy",
    "Condition": {
        "StringLike": {
            "iam:AWSServiceName":"custom.rds.amazonaws.com"
        }
    }
}
```

For more information, see Service-linked role permissions in the *IAM User Guide*.

Amazon VPC and Amazon Aurora

Amazon Virtual Private Cloud (Amazon VPC) makes it possible for you to launch Amazon resources, such as Aurora DB clusters, into a virtual private cloud (VPC).

When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. There is no additional cost to run your DB cluster in a VPC.

Accounts have a default VPC. All new DB clusters are created in the default VPC unless you specify otherwise.

Topics

- Working with a DB cluster in a VPC
- Scenarios for accessing a DB cluster in a VPC
- Tutorial: Create a VPC for use with a DB cluster (IPv4 only)
- Tutorial: Create a VPC for use with a DB cluster (dual-stack mode)

Following, you can find a discussion about VPC functionality relevant to Amazon Aurora DB clusters. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

Working with a DB cluster in a VPC

Your DB cluster is in a virtual private cloud (VPC). A VPC is a virtual network that is logically isolated from other virtual networks in the Amazon Cloud. Amazon VPC makes it possible for you to launch Amazon resources, such as an Amazon Aurora DB cluster or Amazon EC2 instance, into a VPC. The VPC can either be a default VPC that comes with your account or one that you create. All VPCs are associated with your Amazon account.

Your default VPC has three subnets that you can use to isolate resources inside the VPC. The default VPC also has an internet gateway that can be used to provide access to resources inside the VPC from outside the VPC.

For a list of scenarios involving Amazon Aurora DB clusters in a VPC , see Scenarios for accessing a DB cluster in a VPC.

Topics

- Working with a DB cluster in a VPC
- VPC encryption control
- Working with DB subnet groups
- Shared subnets
- Amazon Aurora IP addressing
- Hiding a DB cluster in a VPC from the internet
- Creating a DB cluster in a VPC

In the following tutorials, you can learn to create a VPC that you can use for a common Amazon Aurora scenario:

- Tutorial: Create a VPC for use with a DB cluster (IPv4 only)
- Tutorial: Create a VPC for use with a DB cluster (dual-stack mode)

Working with a DB cluster in a VPC

Here are some tips on working with a DB cluster in a VPC:

- Your VPC must have at least two subnets. These subnets must be in two different Availability Zones in the Amazon Web Services Region where you want to deploy your DB cluster. A *subnet* is a segment of a VPC's IP address range that you can specify and that you can use to group DB clusters based on your security and operational needs.
- If you want your DB cluster in the VPC to be publicly accessible, make sure to turn on the VPC attributes *DNS hostnames* and *DNS resolution*.
- Your VPC must have a DB subnet group that you create. You create a DB subnet group by specifying the subnets you created. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The primary DB instance uses the Availability Zone that contains the subnet.
- Your VPC must have a VPC security group that allows access to the DB cluster.

  For more information, see Scenarios for accessing a DB cluster in a VPC.
- The CIDR blocks in each of your subnets must be large enough to accommodate spare IP addresses for Amazon Aurora to use during maintenance activities, including failover and compute scaling. For example, a range such as 10.0.0.0/24 and 10.0.1.0/24 is typically large enough.

- A VPC can have an *instance tenancy* attribute of either *default* or *dedicated*. All default VPCs have the instance tenancy attribute set to default, and a default VPC can support any DB instance class.

  If you choose to have your DB cluster in a dedicated VPC where the instance tenancy attribute is set to dedicated, the DB instance class of your DB cluster must be one of the approved Amazon EC2 dedicated instance types. For example, the r5.large EC2 dedicated instance corresponds to the db.r5.large DB instance class. For information about instance tenancy in a VPC, see Dedicated instances in the *Amazon Elastic Compute Cloud User Guide*.

  > **Note**
  >
  > When you set the instance tenancy attribute to dedicated for a DB cluster, it doesn't guarantee that the DB cluster will run on a dedicated host.

VPC encryption control

VPC encryption controls allow you to enforce encryption-in-transit for all network traffic within your VPCs. Use encryption control to meet regulatory compliance requirements by ensuring that only encryption-capable Nitro-based hardware can be provisioned in designated VPCs. Encryption control also catches compatibility issues at API request time rather than during provisioning. Your existing workloads continue operating and only new incompatible requests are blocked.

Set your VPC encryption controls by setting the VPC control mode to :

- *disabled* (default)
- *monitor*
- *enforced*

To check the current control mode for your VPC, use the Amazon Web Services Management Console or DescribeVpcs CLI or API command.

If your VPC enforces encryption, you can only provision Nitro-based DB clusters that support encryption in transit in that VPC. For more information see, DB instance class types. For information about Nitro instances, see Instances built on the Amazon Nitro System in the *Amazon EC2 User Guide*.

> **Note**
>
> If you try to provision incompatible DB clusters in an encryption-enforced VPC, Aurora returns a `VpcEncryptionControlViolationException` exception.

For Aurora Serverless for MySQL and PostreSQL, encryption control requires platform version 3 or higher.

Working with DB subnet groups

Subnets are segments of a VPC's IP address range that you designate to group your resources based on security and operational needs. A *DB subnet group* is a collection of subnets (typically private) that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters using the Amazon CLI or RDS API. If you use the console, you can choose the VPC and subnet groups you want to use.

Each DB subnet group should have subnets in at least two Availability Zones in a given Amazon Web Services Region. When creating a DB cluster in a VPC, you choose a DB subnet group for it. From the DB subnet group, Amazon Aurora chooses a subnet and an IP address within that subnet to associate with the primary DB instance in your DB cluster. The DB uses the Availability Zone that contains the subnet. Aurora assigns an IP address from a subnet that has free IP address space.

The subnets in a DB subnet group are either public or private. The subnets are public or private, depending on the configuration that you set for their network access control lists (network ACLs) and routing tables. For a DB cluster to be publicly accessible, all of the subnets in its DB subnet group must be public. If a subnet that's associated with a publicly accessible DB cluster changes from public to private, it can affect DB cluster availability.

To create a DB subnet group that supports dual-stack mode, make sure that each subnet that you add to the DB subnet group has an Internet Protocol version 6 (IPv6) CIDR block associated with it. For more information, see Amazon Aurora IP addressing and Migrating to IPv6 in the *Amazon VPC User Guide.*

When Amazon Aurora creates a DB cluster in a VPC, it assigns a network interface to your DB cluster by using an IP address from your DB subnet group. However, we strongly recommend that you use the Domain Name System (DNS) name to connect to your DB cluster. We recommend this because the underlying IP address changes during failover.

Note

For each DB cluster that you run in a VPC, make sure to reserve at least one address in each subnet in the DB subnet group for use by Amazon Aurora for recovery actions.

Shared subnets

You can create a DB cluster in a shared VPC.

Some considerations to keep in mind while using shared VPCs:

- You can move a DB cluster from a shared VPC subnet to a non-shared VPC subnet and vice-versa.
- Participants in a shared VPC must create a security group in the VPC to allow them to create a DB cluster.
- Owners and participants in a shared VPC can access the database by using SQL queries. However, only the creator of a resource can make any API calls on the resource.

Amazon Aurora IP addressing

IP addresses enable resources in your VPC to communicate with each other, and with resources over the internet. Amazon Aurora supports both IPv4 and IPv6 addressing protocols. By default, Amazon Aurora and Amazon VPC use the IPv4 addressing protocol. You can't turn off this behavior. When you create a VPC, make sure to specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and subnets, and assign IPv6 addresses from that block to DB clusters in your subnet.

Support for the IPv6 protocol expands the number of supported IP addresses. By using the IPv6 protocol, you ensure that you have sufficient available addresses for the future growth of the internet. New and existing RDS resources can use IPv4 and IPv6 addresses within your VPC. Configuring, securing, and translating network traffic between the two protocols used in different parts of an application can cause operational overhead. You can standardize on the IPv6 protocol for Amazon RDS resources to simplify your network configuration.

Topics

- IPv4 addresses
- IPv6 addresses

- Dual-stack mode

IPv4 addresses

When you create a VPC, you must specify a range of IPv4 addresses for the VPC in the form of a CIDR block, such as `10.0.0.0/16`. A *DB subnet group* defines the range of IP addresses in this CIDR block that a DB cluster can use. These IP addresses can be private or public.

A private IPv4 address is an IP address that's not reachable over the internet. You can use private IPv4 addresses for communication between your DB cluster and other resources, such as Amazon EC2 instances, in the same VPC. Each DB cluster has a private IP address for communication in the VPC.

A public IP address is an IPv4 address that's reachable from the internet. You can use public addresses for communication between your DB cluster and resources on the internet, such as a SQL client. You control whether your DB cluster receives a public IP address.

Amazon RDS uses Public Elastic IPv4 addresses from EC2's public IPv4 address pool for publicly accessible database instances. These IP addresses are visible in your Amazon account when using the `describe-addresses` CLI, API or viewing the Elastic IPs (EIP) section in the Amazon Web Services Management Console. Each RDS-managed IP address is marked with a `service_managed` attribute set to `"rds"`.

While these IPs are visible in your account, they remain fully managed by Amazon RDS and cannot be modified or released. Amazon RDS releases IPs back into the public IPv4 address pool when no longer in use.

CloudTrail logs API calls related to RDS's EIP, such as the `AllocateAddress`. These API calls are invoked by the Service Principal `rds.amazonaws.com`.

> **Note**
>
> IPs allocated by Amazon RDS do not count against your account's EIP limits.

For a tutorial that shows you how to create a VPC with only private IPv4 addresses that you can use for a common Amazon Aurora scenario, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only).

IPv6 addresses

You can optionally associate an IPv6 CIDR block with your VPC and subnets, and assign IPv6 addresses from that block to the resources in your VPC. Each IPv6 address is globally unique.

The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses. You can't choose the range yourself.

When connecting to an IPv6 address, make sure that the following conditions are met:

- The client is configured so that client to database traffic over IPv6 is allowed.
- RDS security groups used by the DB instance are configured correctly so that client to database traffic over IPv6 is allowed.
- The client operating system stack allows traffic on the IPv6 address, and operating system drivers and libraries are configured to choose the correct default DB instance endpoint (either IPv4 or IPv6).

For more information about IPv6, see IP Addressing in the *Amazon VPC User Guide*.

Dual-stack mode

A DB cluster runs in dual-stack mode when it can communicate over both IPv4 and IPv6 addressing protocols. Resources can then communicate with the DB cluster using either IPv4, IPv6, or both protocols. Private dual-stack mode DB instances have IPv6 endpoints that RDS restricts to VPC access only, ensuring your IPv6 endpoints remain private. Public dual-stack mode DB instances provide both IPv4 and IPv6 endpoints that you can access from the internet.

Topics

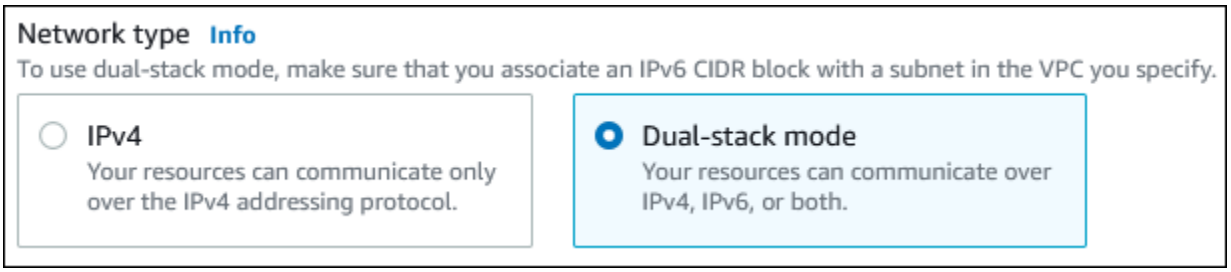
- Dual-stack mode and DB subnet groups
- Working with dual-stack mode DB instances
- Modifying IPv4-only DB clusters to use dual-stack mode
- Availability of dual-stack network DB clusters
- Limitations for dual-stack network DB clusters

For a tutorial that shows you how to create a VPC with both IPv4 and IPv6 addresses that you can use for a common Amazon Aurora scenario, see Tutorial: Create a VPC for use with a DB cluster (dual-stack mode).

Dual-stack mode and DB subnet groups

To use dual-stack mode, make sure that each subnet in the DB subnet group that you associate with the DB cluster has an IPv6 CIDR block associated with it. You can create a new DB subnet group or modify an existing DB subnet group to meet this requirement. After a DB cluster is in dual-stack mode, clients can connect to it normally. Make sure that client security firewalls and RDS DB instance security groups are accurately configured to allow traffic over IPv6. To connect, clients use the DB cluster primary instance's endpoint. Client applications can specify which protocol is preferred when connecting to a database. In dual-stack mode, the DB cluster detects the client's preferred network protocol, either IPv4 or IPv6, and uses that protocol for the connection.

If a DB subnet group stops supporting dual-stack mode because of subnet deletion or CIDR disassociation, there's a risk of an incompatible network state for DB instances that are associated with the DB subnet group. Also, you can't use the DB subnet group when you create a new dual-stack mode DB cluster.



To determine whether a DB subnet group supports dual-stack mode by using the Amazon Web Services Management Console, view the **Network type** on the details page of the DB subnet group. To determine whether a DB subnet group supports dual-stack mode by using the Amazon CLI, run the describe-db-subnet-groups command and view `SupportedNetworkTypes` in the output.

Read replicas are treated as independent DB instances and can have a network type that's different from the primary DB instance. If you change the network type of a read replica's primary DB instance, the read replica isn't affected. When you are restoring a DB instance, you can restore it to any network type that's supported.

Working with dual-stack mode DB instances

When you create or modify a DB cluster, you can specify dual-stack mode to allow your resources to communicate with your DB cluster over IPv4, IPv6, or both.

When you use the Amazon Web Services Management Console to create or modify a DB instance, you can specify dual-stack mode in the **Network type** section. The following image shows the **Network type** section in the console.

When you use the Amazon CLI to create or modify a DB cluster, set the `--network-type` option to `DUAL` to use dual-stack mode. When you use the RDS API to create or modify a DB cluster, set the `NetworkType` parameter to `DUAL` to use dual-stack mode. When you are modifying the network type of a DB instance, downtime is possible. If dual-stack mode isn't supported by the specified DB engine version or DB subnet group, the `NetworkTypeNotSupported` error is returned.

For more information about creating a DB cluster, see Creating an Amazon Aurora DB cluster. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster.

To determine whether a DB cluster is in dual-stack mode by using the console, view the **Network type** on the **Connectivity & security** tab for the DB cluster.

Modifying IPv4-only DB clusters to use dual-stack mode

You can modify an IPv4-only DB cluster to use dual-stack mode. To do so, change the network type of the DB cluster. The modification might result in downtime.

It is recommended that you change the network type of your Amazon Aurora DB clusters during a maintenance window. Currently, setting the network type of new instances to dual-stack mode isn't supported. You can set network type manually by using the `modify-db-cluster` command.

Before modifying a DB cluster to use dual-stack mode, make sure that its DB subnet group supports dual-stack mode. If the DB subnet group associated with the DB cluster doesn't support dual-stack mode, specify a different DB subnet group that supports it when you modify the DB cluster. Modifying the DB subnet group of a DB cluster can cause downtime.

If you modify the DB subnet group of a DB cluster before you change the DB cluster to use dual-stack mode, make sure that the DB subnet group is valid for the DB cluster before and after the change.

We recommend that you run the modify-db-cluster API with only the `--network-type` parameter with value `DUAL` to change the network of an Amazon Aurora cluster to dual-stack mode. Adding other parameters along with the `--network-type` parameter in the same API call could result in downtime.

If you can't connect to the DB cluster after the change, make sure that the client and database security firewalls and route tables are accurately configured to allow traffic to the database on the selected network (either IPv4 or IPv6). You might also need to modify operating system parameter, libraries, or drivers to connect using an IPv6 address.

To modify an IPv4-only DB cluster to use dual-stack mode

1. Modify a DB subnet group to support dual-stack mode, or create a DB subnet group that supports dual-stack mode:

   a. Associate an IPv6 CIDR block with your VPC.

      For instructions, see Add an IPv6 CIDR block to your VPC in the *Amazon VPC User Guide*.

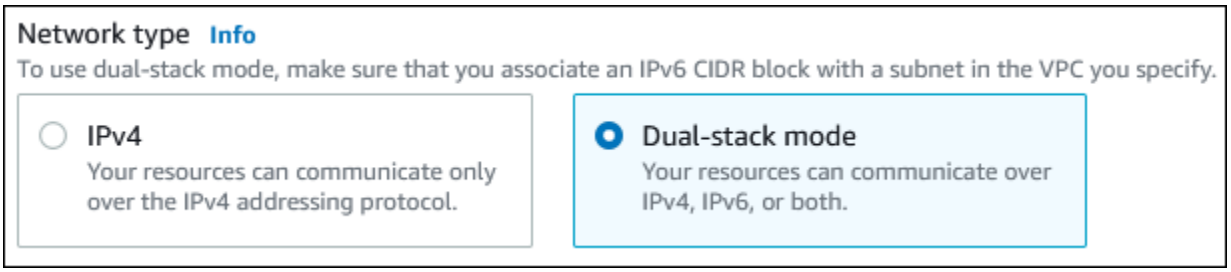
   b. Attach the IPv6 CIDR block to all of the subnets in your the DB subnet group.

      For instructions, see Add an IPv6 CIDR block to your subnet in the *Amazon VPC User Guide*.

   c. Confirm that the DB subnet group supports dual-stack mode.

      If you are using the Amazon Web Services Management Console, select the DB subnet group, and make sure that the **Supported network types** value is **Dual, IPv4**.

      If you are using the Amazon CLI, run the describe-db-subnet-groups command, and make sure that the `SupportedNetworkType` value for the DB instance is `Dual, IPv4`.



2. Modify the security group associated with the DB cluster to allow IPv6 connections to the database, or create a new security group that allows IPv6 connections.

   For instructions, see Security group rules in the *Amazon VPC User Guide*.

3. Modify the DB cluster to support dual-stack mode. To do so, set the **Network type** to **Dual-stack mode**.

   If you are using the console, make sure that the following settings are correct:

   - **Network type** – **Dual-stack mode**

   - **DB subnet group** – The DB subnet group that you configured in a previous step
   - **Security group** – The security that you configured in a previous step

If you are using the Amazon CLI, make sure that the following settings are correct:

- `--network-type` – `dual`
- `--db-subnet-group-name` – The DB subnet group that you configured in a previous step
- `--vpc-security-group-ids` – The VPC security group that you configured in a previous step

For example:

```
aws rds modify-db-cluster --db-cluster-identifier my-cluster --network-type "DUAL"
```

4. Confirm that the DB cluster supports dual-stack mode.

   If you are using the console, choose the **Configuration** tab for the DB cluster. On that tab, make sure that the **Network type** value is **Dual-stack mode**.

   If you are using the Amazon CLI, run the describe-db-clusters command, and make sure that the `NetworkType` value for the DB cluster is `dual`.

   Run the `dig` command on the writer DB instance endpoint to identify the IPv6 address associated with it.

   ```
   dig db-instance-endpoint AAAA
   ```

   Use the writer DB instance endpoint, not the IPv6 address, to connect to the DB cluster.

Availability of dual-stack network DB clusters

Dual-stack network DB clusters are available in all Amazon Web Services Regions except for the following:

- Asia Pacific (Hyderabad)
- Asia Pacific (Malaysia)
- Asia Pacific (Melbourne)
- Asia Pacific (Thailand)
- Canada West (Calgary)

- Europe (Spain)
- Europe (Zurich)
- Israel (Tel Aviv)
- Mexico (Central)
- Middle East (UAE)

The following DB engine versions support dual-stack network DB clusters:

- Aurora MySQL versions:
  - 3.02 and higher 3 versions
  - 2.09.1 and higher 2 versions

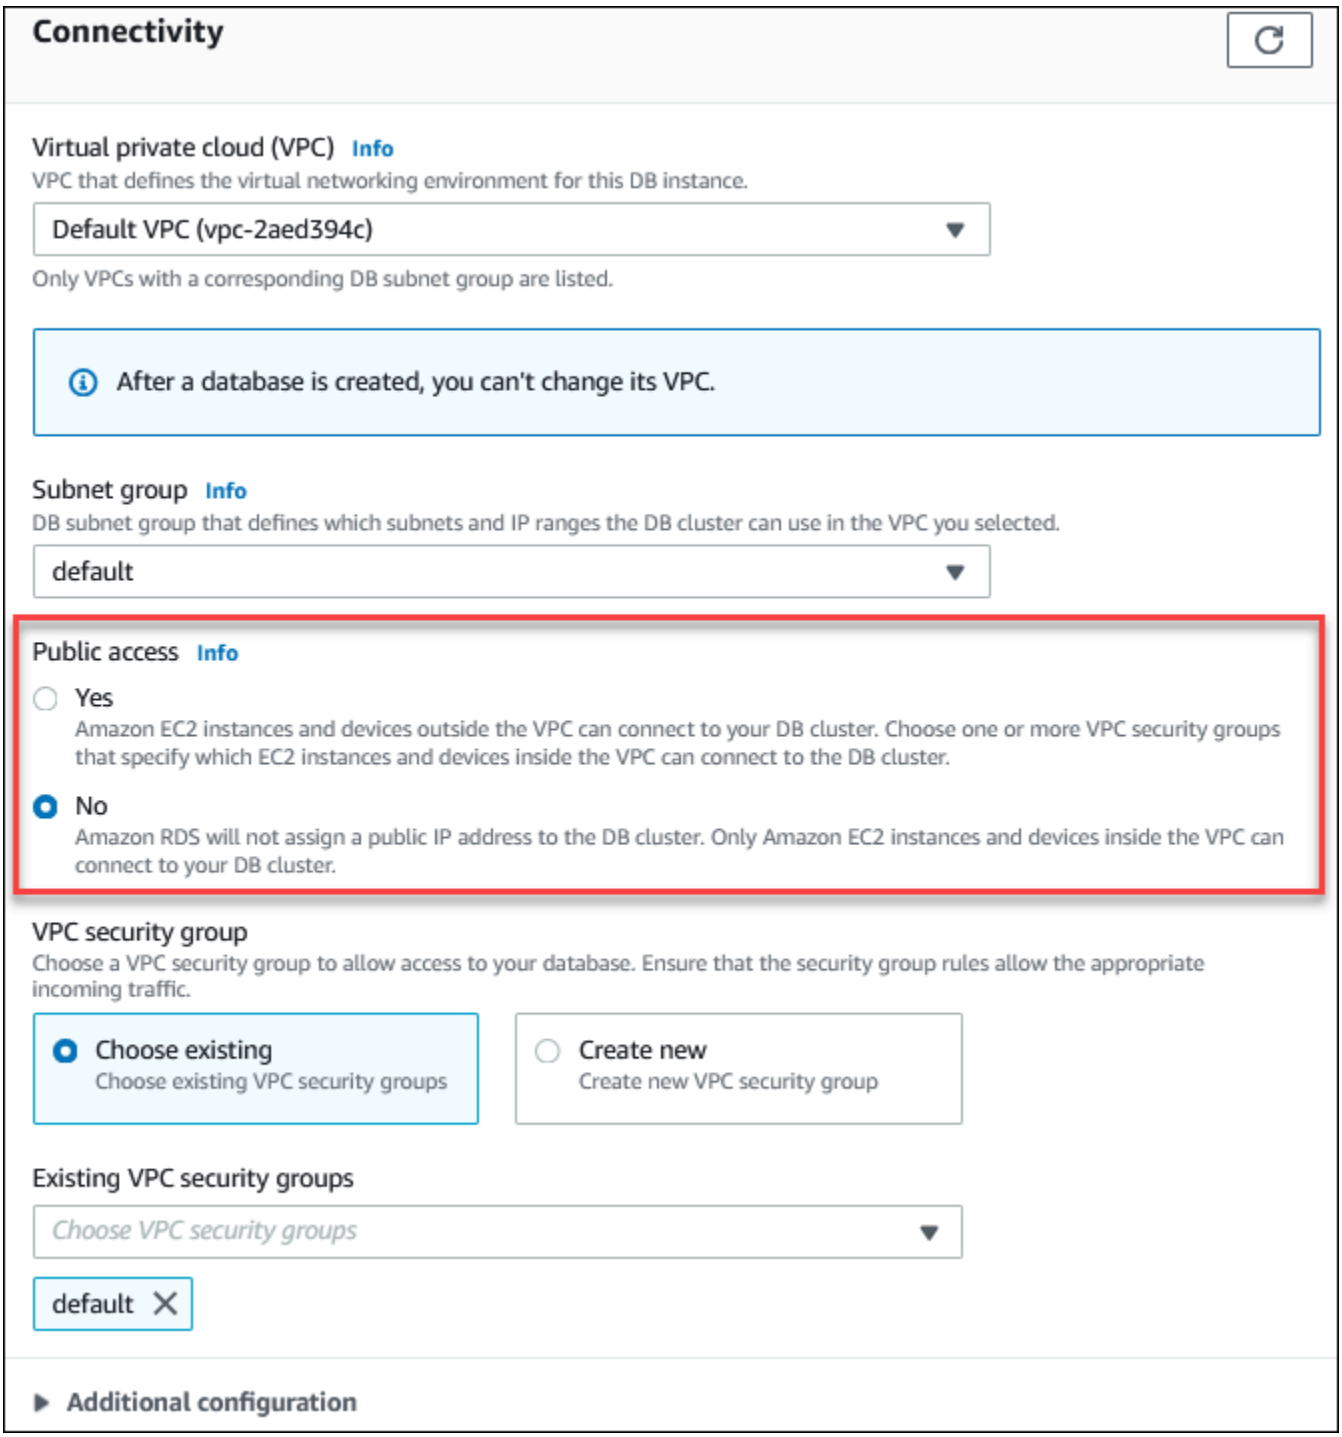
  For more information about Aurora MySQL versions, see the *Release Notes for Aurora MySQL*.
- Aurora PostgreSQL versions:
  - 15.2 and all higher versions
  - 14.3 and higher 14 versions
  - 13.7 and higher 13 versions

  For more information about Aurora PostgreSQL versions, see the *Release Notes for Aurora PostgreSQL*.

Limitations for dual-stack network DB clusters

The following limitations apply to dual-stack network DB clusters:

- DB clusters can't use the IPv6 protocol exclusively. They can use IPv4 exclusively, or they can use the IPv4 and IPv6 protocol (dual-stack mode).
- Amazon RDS doesn't support native IPv6 subnets.
- You can't use RDS Proxy with dual-stack mode DB clusters.



Hiding a DB cluster in a VPC from the internet

One common Amazon Aurora scenario is to have a VPC in which you have an Amazon EC2 instance with a public-facing web application and a DB cluster with a database that isn't publicly accessible. For example, you can create a VPC that has a public subnet and a private subnet. EC2 instances

that function as web servers can be deployed in the public subnet. The DB clusters are deployed in the private subnet. In such a deployment, only the web servers have access to the DB clusters. For an illustration of this scenario, see A DB cluster in a VPC accessed by an Amazon EC2 instance in the same VPC.

When you launch a DB cluster inside a VPC, the DB cluster has a private IP address for traffic inside the VPC. This private IP address isn't publicly accessible. You can use the **Public access** option to designate whether the DB cluster also has a public IP address in addition to the private IP address. If the DB cluster is designated as publicly accessible, its DNS endpoint resolves to the private IP address from within the VPC. It resolves to the public IP address from outside of the VPC. Access to the DB cluster is ultimately controlled by the security group it uses. That public access is not permitted if the security group assigned to the DB cluster doesn't include inbound rules that permit it. In addition, for a DB cluster to be publicly accessible, the subnets in its DB subnet group must have an internet gateway. For more information, see Can't connect to Amazon RDS DB instance

You can modify a DB cluster to turn on or off public accessibility by modifying the **Public access** option. The following illustration shows the **Public access** option in the **Additional connectivity configuration** section. To set the option, open the **Additional connectivity configuration** section in the **Connectivity** section.

For information about modifying a DB instance to set the **Public access** option, see Modifying a DB instance in a DB cluster.

Creating a DB cluster in a VPC

The following procedures help you create a DB cluster in a VPC. To use the default VPC, you can begin with step 2, and use the VPC and DB subnet group have already been created for you. If you want to create an additional VPC, you can create a new VPC.

> **Note**
>
> If you want your DB cluster in the VPC to be publicly accessible, you must update the DNS information for the VPC by enabling the VPC attributes *DNS hostnames* and *DNS resolution*. For information about updating the DNS information for a VPC instance, see Updating DNS support for your VPC.

Follow these steps to create a DB instance in a VPC:

- Step 1: Create a VPC
- Step 2: Create a DB subnet group
- Step 3: Create a VPC security group
- Step 4: Create a DB instance in the VPC

Step 1: Create a VPC

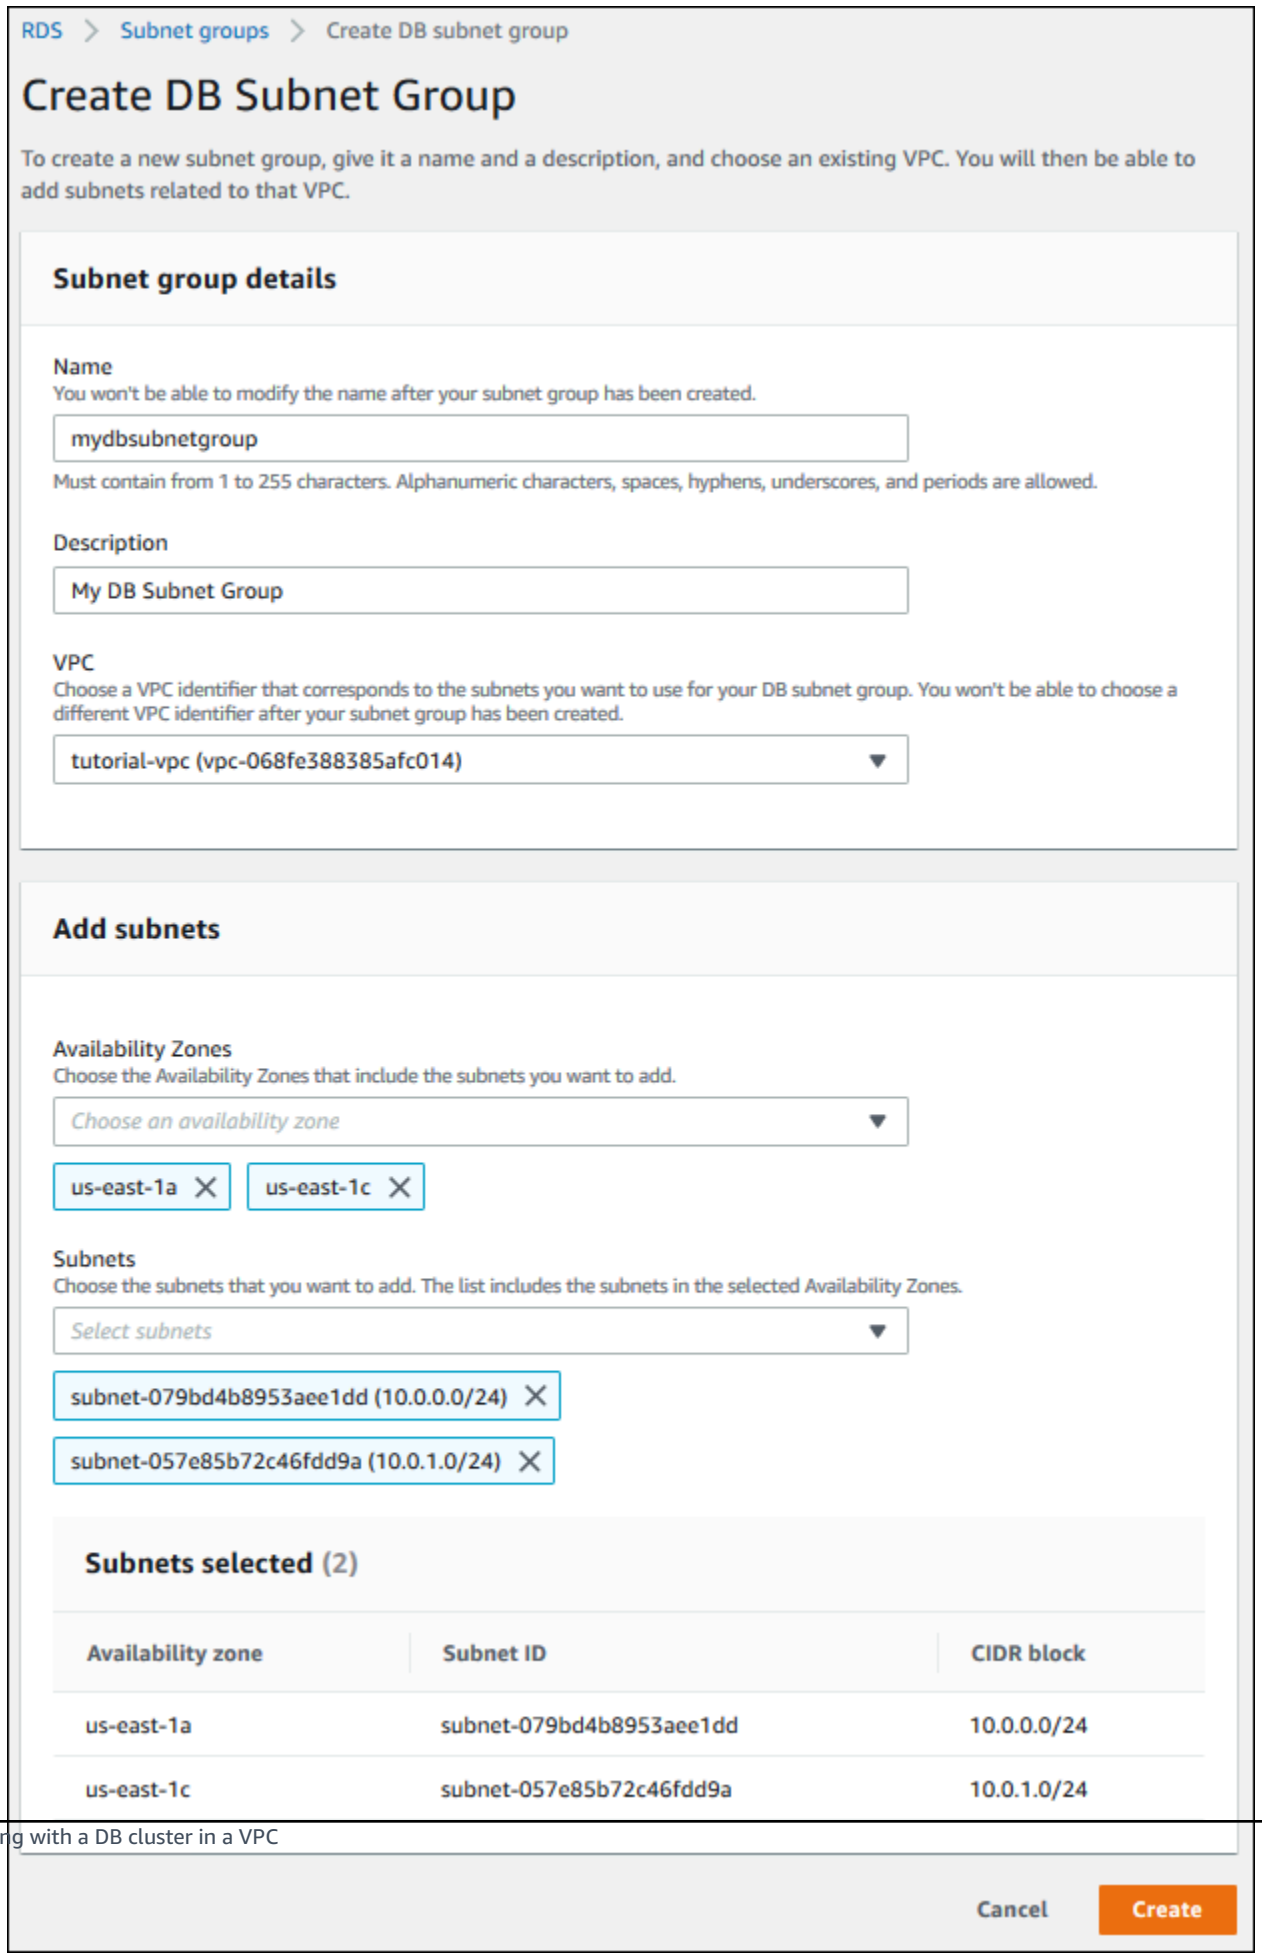
Create a VPC with subnets in at least two Availability Zones. You use these subnets when you create a DB subnet group. If you have a default VPC, a subnet is automatically created for you in each Availability Zone in the Amazon Web Services Region.

For more information, see Create a VPC with private and public subnets, or see Create a VPC in the *Amazon VPC User Guide*.

Step 2: Create a DB subnet group

A DB subnet group is a collection of subnets (typically private) that you create for a VPC and that you then designate for your DB clusters. A DB subnet group allows you to specify a particular VPC when you create DB clusters using the Amazon CLI or RDS API. If you use the console, you can just choose the VPC and subnets you want to use. Each DB subnet group must have at least one subnet in at least two Availability Zones in the Amazon Web Services Region. As a best practice,

each DB subnet group should have at least one subnet for every Availability Zone in the Amazon Web Services Region.



For a DB cluster to be publicly accessible, the subnets in the DB subnet group must have an internet gateway. For more information about internet gateways for subnets, see Connect to the internet using an internet gateway in the *Amazon VPC User Guide*.

When you create a DB cluster in a VPC, you can choose a DB subnet group. Amazon Aurora chooses a subnet and an IP address within that subnet to associate with your DB cluster. If no DB subnet groups exist, Amazon Aurora creates a default subnet group when you create a DB cluster. Amazon Aurora creates and associates an Elastic Network Interface to your DB cluster with that IP address. The DB cluster uses the Availability Zone that contains the subnet.

In this step, you create a DB subnet group and add the subnets that you created for your VPC.

To create a DB subnet group

1. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the navigation pane, choose **Subnet groups**.
3. Choose **Create DB Subnet Group**.
4. For **Name**, type the name of your DB subnet group.
5. For **Description**, type a description for your DB subnet group.
6. For **VPC**, choose the default VPC or the VPC that you created.
7. In the **Add subnets** section, choose the Availability Zones that include the subnets from **Availability Zones**, and then choose the subnets from **Subnets**.

RDS > Subnet groups > Create DB subnet group
Create DB Subnet Group
To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.
Subnet group details
Name
You won't be able to modify the name after your subnet group has been created.
mydbsubnetgroup
Must contain from 1 to 255 characters. Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.
Description
My DB Subnet Group
VPC
Choose a VPC identifier that corresponds to the subnets you want to use for your DB subnet group. You won't be able to choose a different VPC identifier after your subnet group has been created.
tutorial-vpc (vpc-068fe388385afc014)
Add subnets
Availability Zones
Choose the Availability Zones that include the subnets you want to add.
Choose an availability zone
us-east-1a
us-east-1c
Subnets
Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.
Select subnets
subnet-079bd4b8953aee1dd (10.0.0.0/24)
subnet-057e85b72c46fdd9a (10.0.1.0/24)
Subnets selected (2)
Availability zone
Subnet ID
CIDR block
us-east-1a
subnet-079bd4b8953aee1dd
10.0.0.0/24
us-east-1c
subnet-057e85b72c46fdd9a
10.0.1.0/24
Cancel
Create

8. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details, including all of the subnets associated with the group, in the detail pane.

Step 3: Create a VPC security group

Before you create your DB cluster, you can create a VPC security group to associate with your DB cluster. If you don't create a VPC security group, you can use the default security group when you create a DB cluster. For instructions on how to create a security group for your DB cluster, see Create a VPC security group for a private DB cluster, or see Control traffic to resources using security groups in the *Amazon VPC User Guide*.

Step 4: Create a DB instance in the VPC

In this step, you create a DB cluster and use the VPC name, the DB subnet group, and the VPC security group you created in the previous steps.

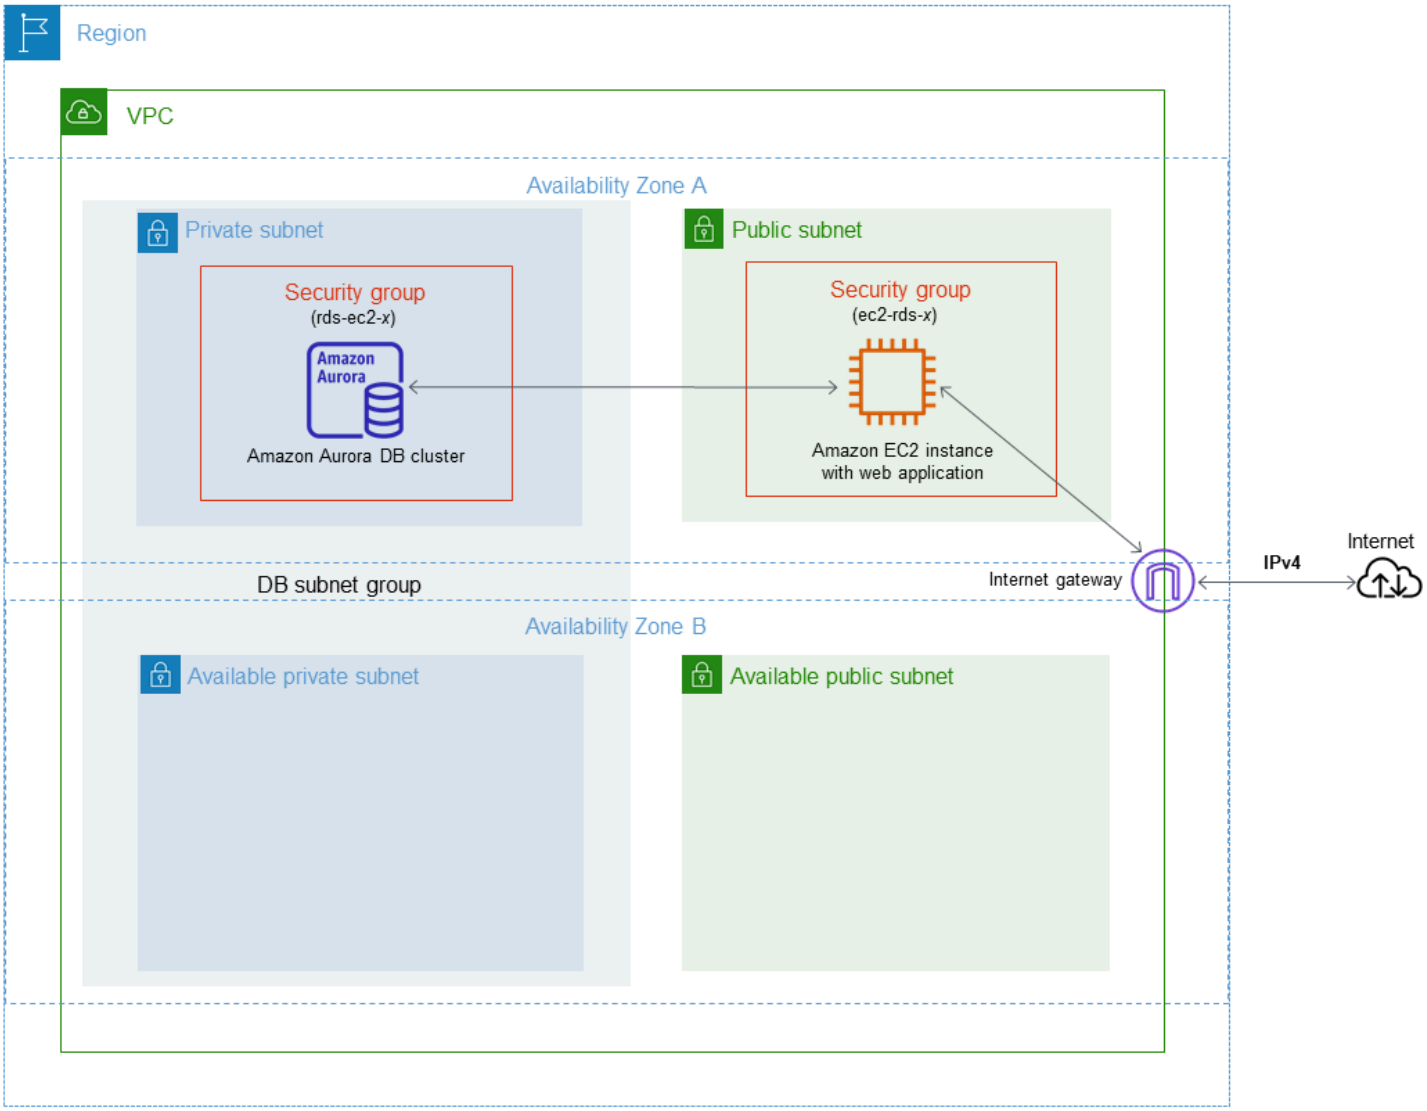
> **Note**
>
> If you want your DB cluster in the VPC to be publicly accessible, you must enable the VPC attributes *DNS hostnames* and *DNS resolution*. For more information, see DNS attributes for your VPC in the *Amazon VPC User Guide*.

For details on how to create a DB cluster, see Creating an Amazon Aurora DB cluster.

When prompted in the **Connectivity** section, enter the VPC name, the DB subnet group, and the VPC security group.

> **Note**
>
> Updating VPCs isn't currently supported for Aurora DB clusters.

Scenarios for accessing a DB cluster in a VPC



Amazon Aurora supports the following scenarios for accessing a DB cluster in a VPC:

- An Amazon EC2 instance in the same VPC
- An EC2 instance in a different VPC
- A client application through the internet
- A private network

A DB cluster in a VPC accessed by an Amazon EC2 instance in the same VPC

A common use of a DB cluster in a VPC is to share data with an application server that is running in an Amazon EC2 instance in the same VPC.

The following diagram shows this scenario.

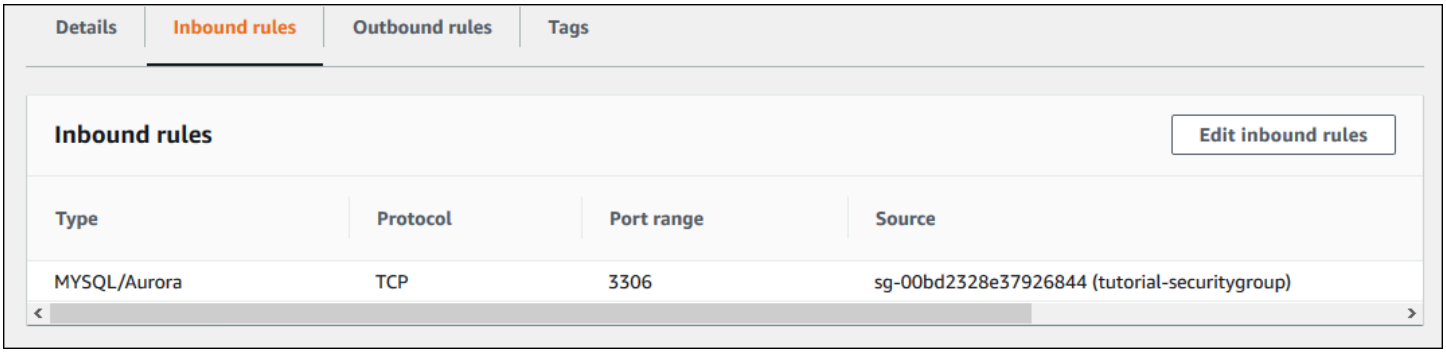
The simplest way to manage access between EC2 instances and DB clusters in the same VPC is to do the following:

- Create a VPC security group for your DB clusters to be in. This security group can be used to restrict access to the DB clusters. For example, you can create a custom rule for this security group. This might allow TCP access using the port that you assigned to the DB cluster when you created it and an IP address you use to access the DB cluster for development or other purposes.
- Create a VPC security group for your EC2 instances (web servers and clients) to be in. This security group can, if needed, allow access to the EC2 instance from the internet by using the VPC's routing table. For example, you can set rules on this security group to allow TCP access to the EC2 instance over port 22.
- Create custom rules in the security group for your DB clusters that allow connections from the security group you created for your EC2 instances. These rules might allow any member of the security group to access the DB clusters.

There is an additional public and private subnet in a separate Availability Zone. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to switch to a Multi-AZ DB instance deployment in the future.

For a tutorial that shows you how to create a VPC with both public and private subnets for this scenario, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only).

Tip



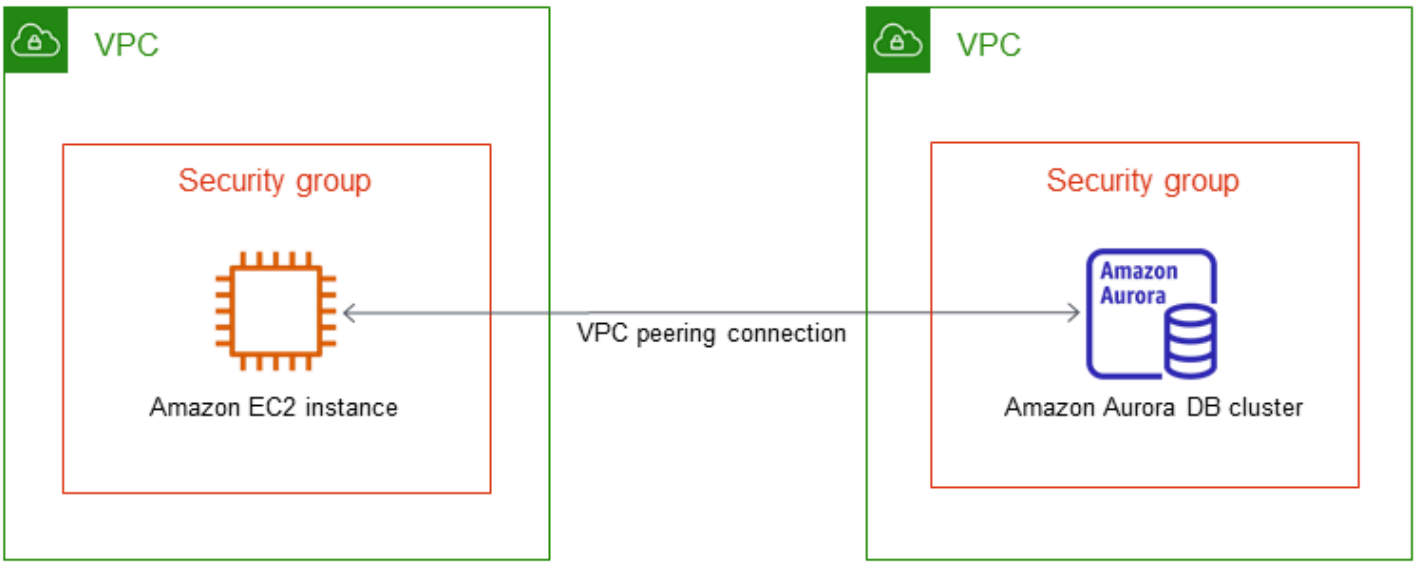
You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. For more information, see Configure automatic network connectivity with an EC2 instance .

To create a rule in a VPC security group that allows connections from another security group, do the following:

1. Sign in to the Amazon Web Services Management Console and open the Amazon VPC console at https://console.amazonaws.cn/vpc.
2. In the navigation pane, choose **Security groups**.

3. Choose or create a security group for which you want to allow access to members of another security group. In the preceding scenario, this is the security group that you use for your DB clusters. Choose the **Inbound rules** tab, and then choose **Edit inbound rules**.
4. On the **Edit inbound rules** page, choose **Add rule**.
5. For **Type**, choose the entry that corresponds to the port you used when you created your DB cluster, such as **MYSQL/Aurora**.
6. In the **Source** box, start typing the ID of the security group, which lists the matching security groups. Choose the security group with members that you want to have access to the resources protected by this security group. In the scenario preceding, this is the security group that you use for your EC2 instance.
7. If required, repeat the steps for the TCP protocol by creating a rule with **All TCP** as the **Type** and your security group in the **Source** box. If you intend to use the UDP protocol, create a rule with **All UDP** as the **Type** and your security group in **Source**.
8. Choose **Save rules**.

The following screen shows an inbound rule with a security group for its source.

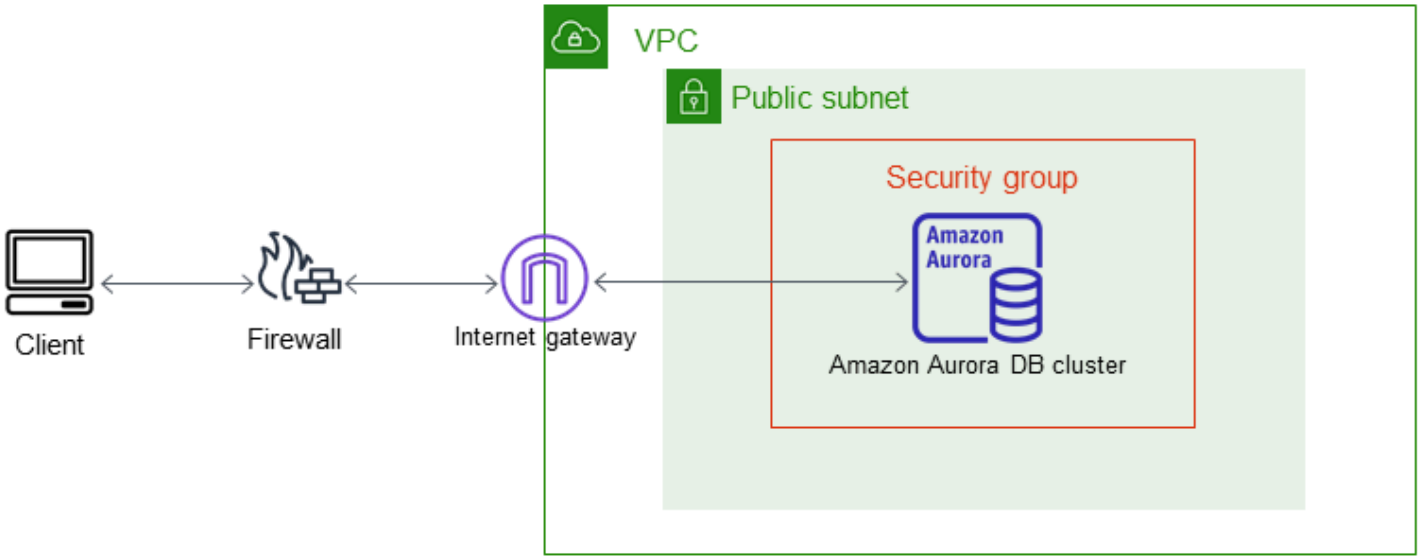


For more information about connecting to the DB cluster from your EC2 instance, see Connecting to an Amazon Aurora DB cluster.

A DB cluster in a VPC accessed by an EC2 instance in a different VPC

When your DB clusters is in a different VPC from the EC2 instance you are using to access it, you can use VPC peering to access the DB cluster.

The following diagram shows this scenario.



A VPC peering connection is a networking connection between two VPCs that enables you to route traffic between them using private IP addresses. Resources in either VPC can communicate with each other as if they are within the same network. You can create a VPC peering connection between your own VPCs, with a VPC in another Amazon account, or with a VPC in a different Amazon Web Services Region. To learn more about VPC peering, see VPC peering in the *Amazon Virtual Private Cloud User Guide*.

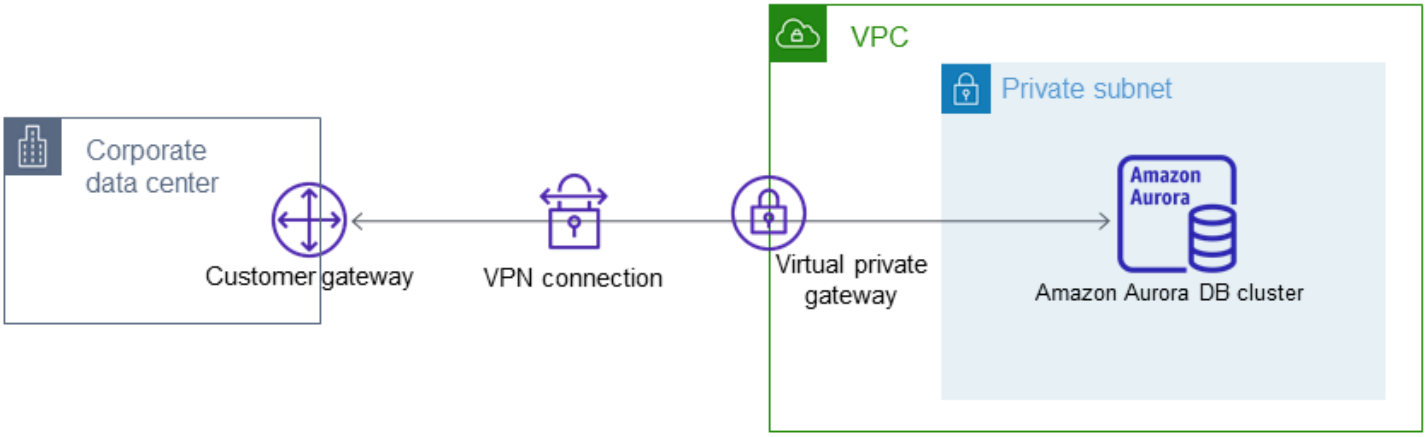
A DB cluster in a VPC accessed by a client application through the internet

To access a DB clusters in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

The following diagram shows this scenario.

We recommend the following configuration:

- A VPC of size /16 (for example CIDR: 10.0.0.0/16). This size provides 65,536 private IP addresses.
- A subnet of size /24 (for example CIDR: 10.0.0.0/24). This size provides 256 private IP addresses.
- An Amazon Aurora DB cluster that is associated with the VPC and the subnet. Amazon RDS assigns an IP address within the subnet to your DB cluster.
- An internet gateway which connects the VPC to the internet and to other Amazon products.
- A security group associated with the DB cluster. The security group's inbound rules allow your client application to access to your DB cluster.



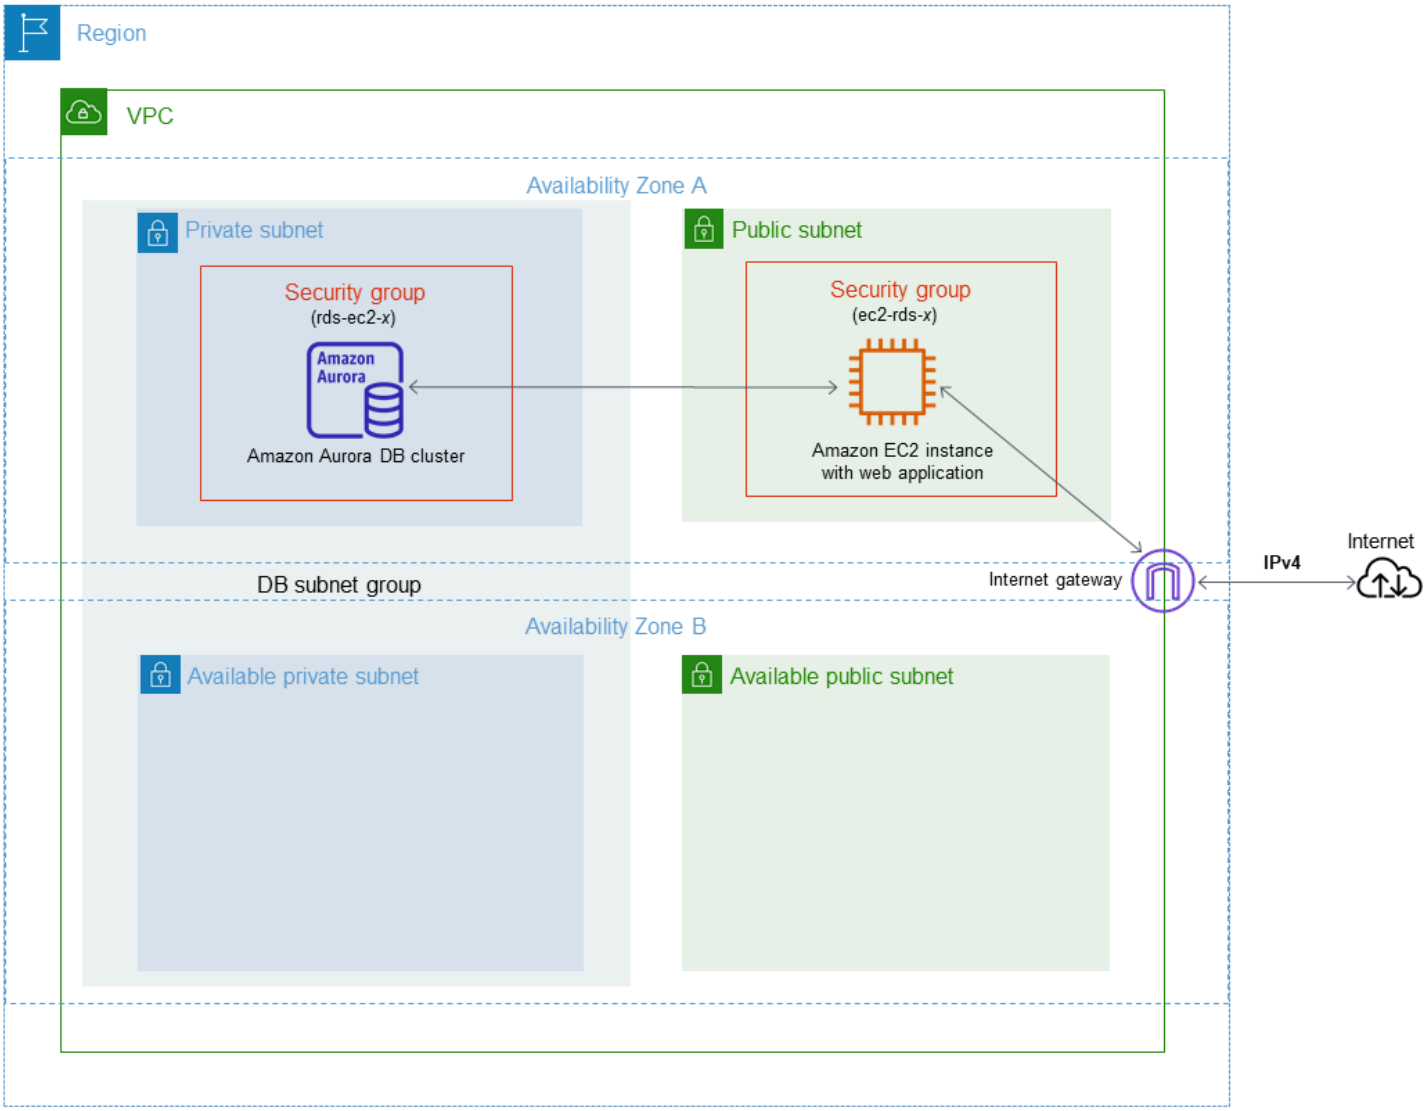
For information about creating a DB clusters in a VPC, see Creating a DB cluster in a VPC.

A DB cluster in a VPC accessed by a private network

If your DB cluster isn't publicly accessible, you have the following options for accessing it from a private network:

- An Amazon Site-to-Site VPN connection. For more information, see What is Amazon Site-to-Site VPN?
- An Amazon Direct Connect connection. For more information, see What is Amazon Direct Connect?
- An Amazon Client VPN connection. For more information, see What is Amazon Client VPN?

The following diagram shows a scenario with an Amazon Site-to-Site VPN connection.



For more information, see Internetwork traffic privacy.

Tutorial: Create a VPC for use with a DB cluster (IPv4 only)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a web server that is running in the same VPC. In this tutorial, you create the VPC for this scenario.

The following diagram shows this scenario. For information about other scenarios, see Scenarios for accessing a DB cluster in a VPC.

Your DB cluster needs to be available only to your web server, and not to the public internet. Thus, you create a VPC with both public and private subnets. The web server is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The web server can connect to the DB cluster because it is hosted within the same VPC. But the DB cluster isn't available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easier to configure more than one Aurora DB instance.

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For a tutorial that shows you how to create a web server for this VPC scenario, see Tutorial: Create a web server and an Amazon Aurora DB cluster. For more information about Amazon VPC, see Amazon VPC Getting Started Guide and Amazon VPC User Guide.

> **Tip**
>
> You can set up network connectivity between an Amazon EC2 instance and a DB cluster automatically when you create the DB cluster. The network configuration is similar to the one described in this tutorial. For more information, see Configure automatic network connectivity with an EC2 instance.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
2. In the Amazon Web Services Management Console, choose the Region to create your VPC in. This example uses the US West (Oregon) Region.
3. Choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the **VPC settings**, set these values:

   - **Name tag auto-generation** – `tutorial`
   - **IPv4 CIDR block** – `10.0.0.0/16`
   - **IPv6 CIDR block** – **No IPv6 CIDR block**
   - **Tenancy** – **Default**
   - **Number of Availability Zones (AZs)** – **2**
   - **Customize AZs** – Keep the default values.

- **Number of public subnet** – **2**
- **Number of private subnets** – **2**
- **Customize subnets CIDR blocks** – Keep the default values.
- **NAT gateways ($)** – **None**
- **VPC endpoints** – **None**
- **DNS options** – Keep the default values.

6. Choose **Create VPC**.

Create a VPC security group for a public web server

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, you add inbound rules to your VPC security group. These allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:

   - **Security group name: `tutorial-securitygroup`**
   - **Description: `Tutorial Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-vpc)**

4. Add inbound rules to the security group.

   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH). To determine your public IP address, in a different browser window or tab, you can use the service at https://checkip.amazonaws.com. An example of an IP address is `203.0.113.25/32`.

      In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for SSH access, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances using SSH.

b. In the **Inbound rules** section, choose **Add rule**.

c. Set the following values for your new inbound rule to allow SSH access to your Amazon EC2 instance. If you do this, you can connect to your Amazon EC2 instance to install the web server and other utilities. You also connect to your EC2 instance to upload content for your web server.

- **Type: SSH**
- **Source:** The IP address or range from Step a, for example: **`203.0.113.25/32`**.

d. Choose **Add rule**.

e. Set the following values for your new inbound rule to allow HTTP access to your web server:

- **Type: HTTP**
- **Source: `0.0.0.0/0`**

5. Choose **Create security group** to create the security group.

   Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, you add inbound rules to your VPC security group that allow traffic from your web server only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.

3. On the **Create security group** page, set these values:

   - **Security group name: `tutorial-db-securitygroup`**
   - **Description: `Tutorial DB Instance Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-vpc)**

4. Add inbound rules to the security group.

   a. In the **Inbound rules** section, choose **Add rule**.

   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do this, you can connect from your web server to your DB cluster. By doing so, you can store and retrieve data from your web application to your database.

      - **Type: `MySQL/Aurora`**
      - **Source:** The identifier of the **tutorial-securitygroup** security group that you created previously in this tutorial, for example: **sg-9edd5cfb**.

5. Choose **Create security group** to create the security group.

Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. A DB subnet group makes it possible for you to specify a particular VPC when creating DB clusters.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.

   a. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.

   b. Choose **VPC Dashboard**, and then choose **Subnets**.

   c. Note the subnet IDs of the subnets named **tutorial-subnet-private1-us-west-2a** and **tutorial-subnet-private2-us-west-2b**.

      You need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.
4. Choose **Create DB subnet group**.
5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
   - **Name: `tutorial-db-subnet-group`**
   - **Description: `Tutorial DB Subnet Group`**
   - **VPC: tutorial-vpc (vpc-*`identifier`*)**
6. In the **Add subnets** section, choose the **Availability Zones** and **Subnets**.

   For this tutorial, choose **us-west-2a** and **us-west-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.
7. Choose **Create**.

   Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see details in the details pane. These details include all of the subnets associated with the group.

> **Note**
>
> If you created this VPC to complete Tutorial: Create a web server and an Amazon Aurora DB cluster, create the DB cluster by following the instructions in Create an Amazon Aurora DB cluster.

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

> **Note**
>
> If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. For example, these resources might include Amazon EC2 instances or Amazon RDS DB clusters. For more information, see Delete your VPC in the *Amazon VPC User Guide*.

To delete a VPC and related resources

1. Delete the DB subnet group.

   a. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.

   b. In the navigation pane, choose **Subnet groups**.

   c. Select the DB subnet group you want to delete, such as **tutorial-db-subnet-group**.

   d. Choose **Delete**, and then choose **Delete** in the confirmation window.

2. Note the VPC ID.

   a. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.

   b. Choose **VPC Dashboard**, and then choose **VPCs**.

   c. In the list, identify the VPC that you created, such as **tutorial-vpc**.

   d. Note the **VPC ID** of the VPC that you created. You need the VPC ID in later steps.

3. Delete the security groups.

   a. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.

   b. Choose **VPC Dashboard**, and then choose **Security Groups**.

   c. Select the security group for the Amazon RDS DB instance, such as **tutorial-db-securitygroup**.

   d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

   e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-securitygroup**.

   f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the VPC.

   a. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.

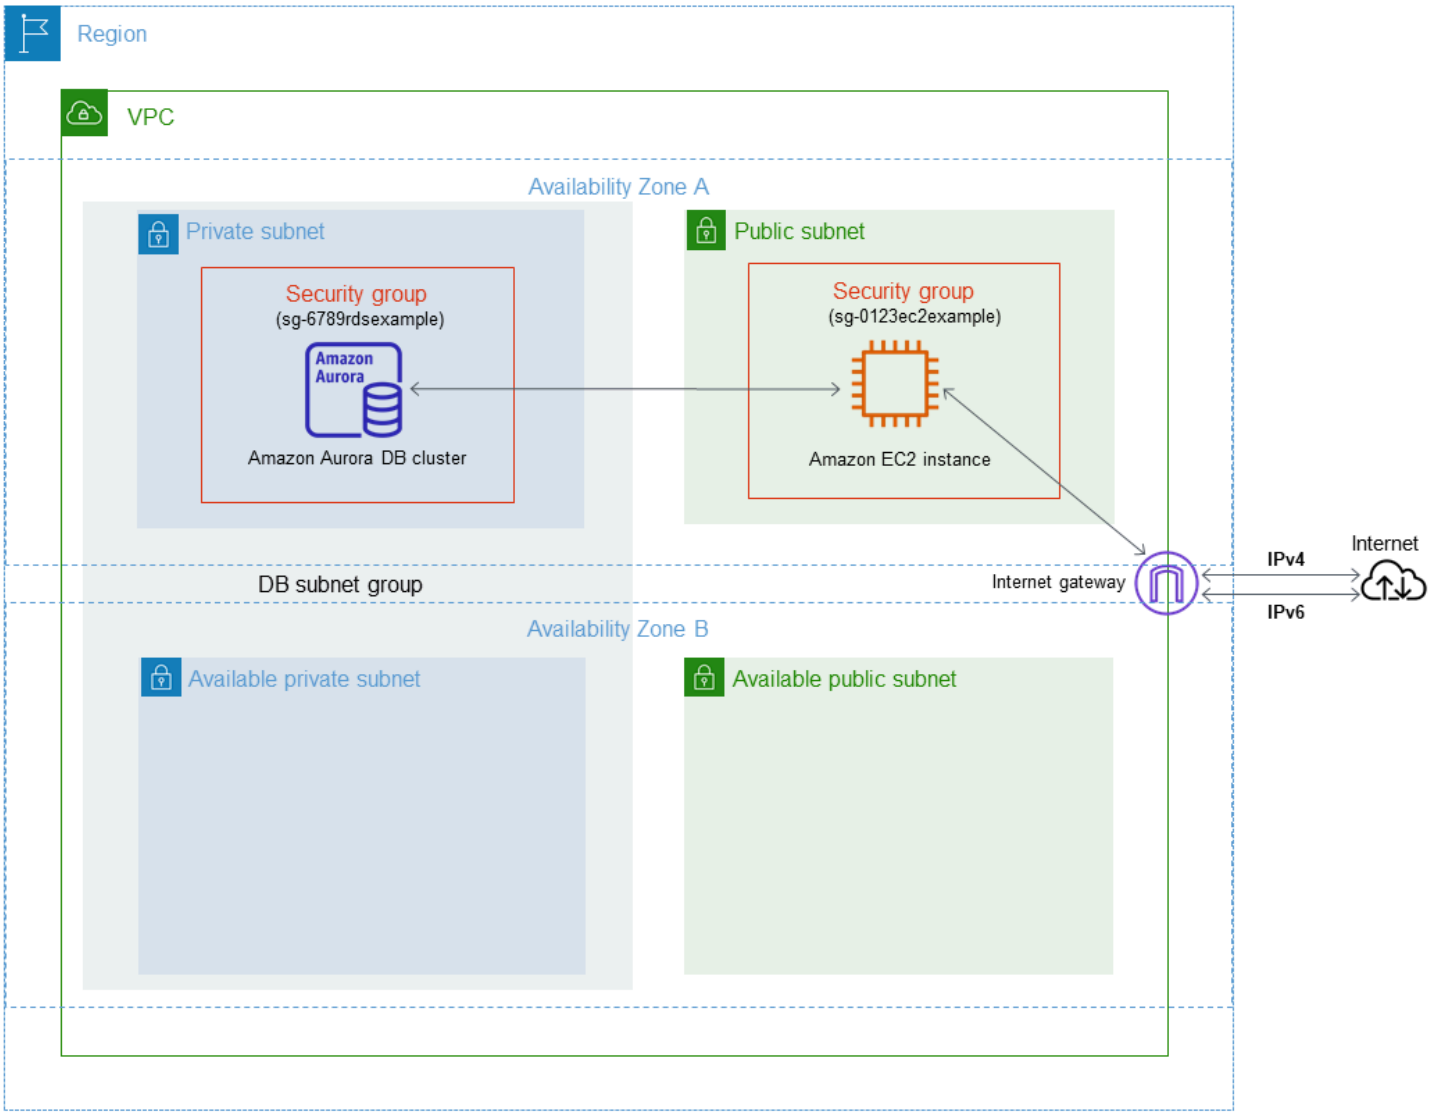
   b. Choose **VPC Dashboard**, and then choose **VPCs**.

   c. Select the VPC you want to delete, such as **tutorial-vpc**.

   d. For **Actions**, choose **Delete VPC**.

   The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

e. On the confirmation page, enter **`delete`**, and then choose **Delete**.



Tutorial: Create a VPC for use with a DB cluster (dual-stack mode)

A common scenario includes a DB cluster in a virtual private cloud (VPC) based on the Amazon VPC service. This VPC shares data with a public Amazon EC2 instance that is running in the same VPC.

In this tutorial, you create the VPC for this scenario that works with a database running in dual-stack mode. Dual-stack mode to enable connection over the IPv6 addressing protocol. For more information about IP addressing, see Amazon Aurora IP addressing.

Dual-stack network clusters are supported in most regions. For more information see Availability of dual-stack network DB clusters. To see the limitations of dual-stack mode, see Limitations for dual-stack network DB clusters.

The following diagram shows this scenario.

For information about other scenarios, see Scenarios for accessing a DB cluster in a VPC.

Your DB cluster needs to be available only to your Amazon EC2 instance, and not to the public internet. Thus, you create a VPC with both public and private subnets. The Amazon EC2 instance is hosted in the public subnet, so that it can reach the public internet. The DB cluster is hosted in a private subnet. The Amazon EC2 instance can connect to the DB cluster because it's hosted within the same VPC. However, the DB cluster is not available to the public internet, providing greater security.

This tutorial configures an additional public and private subnet in a separate Availability Zone. These subnets aren't used by the tutorial. An RDS DB subnet group requires a subnet in at least two Availability Zones. The additional subnet makes it easy to configure more than one Aurora DB instance.

To create a DB cluster that uses dual-stack mode, specify **Dual-stack mode** for the **Network type** setting. You can also modify a DB cluster with the same setting. For more information about creating a DB cluster, see Creating an Amazon Aurora DB cluster. For more information about modifying a DB cluster, see Modifying an Amazon Aurora DB cluster.

This tutorial describes configuring a VPC for Amazon Aurora DB clusters. For more information about Amazon VPC, see Amazon VPC User Guide.

Create a VPC with private and public subnets

Use the following procedure to create a VPC with both public and private subnets.

To create a VPC and subnets

1. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
2. In the Amazon Web Services Management Console, choose the Region to create your VPC in. This example uses the US East (Ohio) Region.
3. Choose **VPC dashboard**. To begin creating a VPC, choose **Create VPC**.
4. For **Resources to create** under **VPC settings**, choose **VPC and more**.
5. For the remaining **VPC settings**, set these values:
   - **Name tag auto-generation** – `tutorial-dual-stack`
   - **IPv4 CIDR block** – `10.0.0.0/16`
   - **IPv6 CIDR block** – **Amazon-provided IPv6 CIDR block**
   - **Tenancy** – **Default**
   - **Number of Availability Zones (AZs)** – **2**
   - **Customize AZs** – Keep the default values.
   - **Number of public subnet** – **2**
   - **Number of private subnets** – **2**
   - **Customize subnets CIDR blocks** – Keep the default values.
   - **NAT gateways ($)** – **None**
   - **Egress only internet gateway** – **No**
   - **VPC endpoints** – **None**
   - **DNS options** – Keep the default values.

> **Note**
>
> Amazon RDS requires at least two subnets in two different Availability Zones to support Multi-AZ DB instance deployments. This tutorial creates a Single-AZ deployment, but the requirement makes it easy to convert to a Multi-AZ DB instance deployment in the future.

6. Choose **Create VPC**.

Create a VPC security group for a public Amazon EC2 instance

Next, you create a security group for public access. To connect to public EC2 instances in your VPC, add inbound rules to your VPC security group that allow traffic to connect from the internet.

To create a VPC security group

1. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:
   - **Security group name: `tutorial-dual-stack-securitygroup`**
   - **Description: `Tutorial Dual-Stack Security Group`**
   - **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-dual-stack-vpc)**
4. Add inbound rules to the security group.
   a. Determine the IP address to use to connect to EC2 instances in your VPC using Secure Shell (SSH).

      An example of an Internet Protocol version 4 (IPv4) address is `203.0.113.25/32`. An example of an Internet Protocol version 6 (IPv6) address range is `2001:db8:1234:1a00::/64`.

      In many cases, you might connect through an internet service provider (ISP) or from behind your firewall without a static IP address. If so, find the range of IP addresses used by client computers.

> **Warning**
>
> If you use `0.0.0.0/0` for IPv4 or `::0` for IPv6, you make it possible for all IP addresses to access your public instances using SSH. This approach is acceptable for a short time in a test environment, but it's unsafe for production environments. In production, authorize only a specific IP address or range of addresses to access your instances.

b. In the **Inbound rules** section, choose **Add rule**.

c. Set the following values for your new inbound rule to allow Secure Shell (SSH) access to your Amazon EC2 instance. If you do this, you can connect to your EC2 instance to install SQL clients and other applications. Specify an IP address so you can access your EC2 instance:

- **Type: SSH**
- **Source:** The IP address or range from step a. An example of an IPv4 IP address is **`203.0.113.25/32`**. An example of an IPv6 IP address is **`2001:DB8::/32`**.

5. Choose **Create security group** to create the security group.

   Note the security group ID because you need it later in this tutorial.

Create a VPC security group for a private DB cluster

To keep your DB cluster private, create a second security group for private access. To connect to private DB clusters in your VPC, add inbound rules to your VPC security group. These allow traffic from your Amazon EC2 instance only.

To create a VPC security group

1. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
2. Choose **VPC Dashboard**, choose **Security Groups**, and then choose **Create security group**.
3. On the **Create security group** page, set these values:

- **Security group name: `tutorial-dual-stack-db-securitygroup`**
- **Description: `Tutorial Dual-Stack DB Instance Security Group`**

- **VPC:** Choose the VPC that you created earlier, for example: **vpc-*identifier* (tutorial-dual-stack-vpc)**

4. Add inbound rules to the security group:

   a. In the **Inbound rules** section, choose **Add rule**.

   b. Set the following values for your new inbound rule to allow MySQL traffic on port 3306 from your Amazon EC2 instance. If you do, you can connect from your EC2 instance to your DB cluster. Doing this means that you can send data from your EC2 instance to your database.

      - **Type: MySQL/Aurora**
      - **Source:** The identifier of the **tutorial-dual-stack-securitygroup** security group that you created previously in this tutorial, for example **sg-9edd5cfb**.

5. To create the security group, choose **Create security group**.

Create a DB subnet group

A *DB subnet group* is a collection of subnets that you create in a VPC and that you then designate for your DB clusters. By using a DB subnet group, you can specify a particular VPC when creating DB clusters. To create a DB subnet group that is DUAL compatible, all subnets must be DUAL compatible. To be DUAL compatible, a subnet must have an IPv6 CIDR associated with it.

To create a DB subnet group

1. Identify the private subnets for your database in the VPC.

   a. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.

   b. Choose **VPC Dashboard**, and then choose **Subnets**.

   c. Note the subnet IDs of the subnets named **tutorial-dual-stack-subnet-private1-us-west-2a** and **tutorial-dual-stack-subnet-private2-us-west-2b**.

      You will need the subnet IDs when you create your DB subnet group.

2. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.

   Make sure that you connect to the Amazon RDS console, not to the Amazon VPC console.

3. In the navigation pane, choose **Subnet groups**.

4. Choose **Create DB subnet group**.

5. On the **Create DB subnet group** page, set these values in **Subnet group details**:
   - **Name: `tutorial-dual-stack-db-subnet-group`**
   - **Description: `Tutorial Dual-Stack DB Subnet Group`**
   - **VPC: tutorial-dual-stack-vpc (vpc-*`identifier`*)**
6. In the **Add subnets** section, choose values for the **Availability Zones** and **Subnets** options.

   For this tutorial, choose **us-east-2a** and **us-east-2b** for the **Availability Zones**. For **Subnets**, choose the private subnets you identified in the previous step.
7. Choose **Create**.

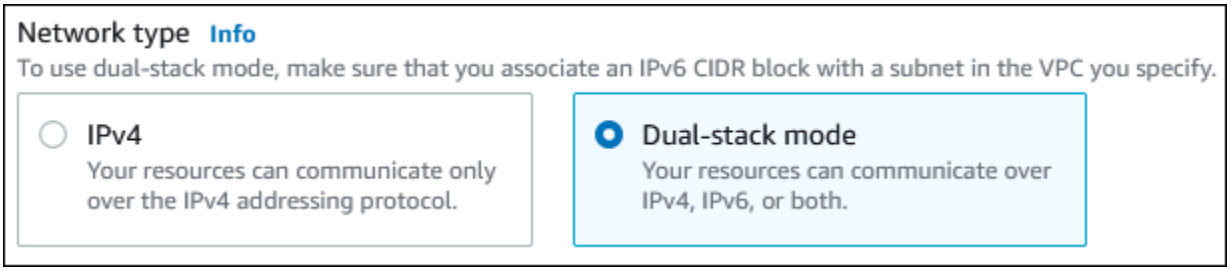
Your new DB subnet group appears in the DB subnet groups list on the RDS console. You can choose the DB subnet group to see its details. These include the supported addressing protocols and all of the subnets associated with the group and the network type supported by the DB subnet group.

Create an Amazon EC2 instance in dual-stack mode

To create an Amazon EC2 instance, follow the instructions in Launch an instance using the new launch instance wizard in the *Amazon EC2 User Guide*.

On the **Configure Instance Details** page, set these values and keep the other values as their defaults:

- **Network** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*`identifier`*) created in Create a VPC with private and public subnets.
- **Subnet** – Choose an existing public subnet, such as **subnet-*`identifier`* | tutorial-dual-stack-subnet-public1-us-east-2a | us-east-2a** created in Create a VPC security group for a public Amazon EC2 instance.
- **Auto-assign Public IP** – Choose **Enable**.
- **Auto-assign IPv6 IP** – Choose **Enable**.
- **Firewall (security groups)** – Choose **Select an existing security group**.
- **Common security groups** – Choose an existing security group, such as the `tutorial-securitygroup` created in Create a VPC security group for a public Amazon EC2 instance. Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.



Create a DB cluster in dual-stack mode

In this step, you create a DB cluster that runs in dual-stack mode.

To create a DB instance

1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
2. In the console, choose the Amazon Web Services Region where you want to create the DB cluster. This example uses the US East (Ohio) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, make sure that the **Standard create** option is chosen, and then choose the Aurora MySQL DB engine type.
6. In the **Connectivity** section, set these values:

   - **Network type** – Choose **Dual-stack mode**.

   - **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as **tutorial-dual-stack-vpc** (vpc-*identifier*) created in Create a VPC with private and public subnets.

     The VPC must have subnets in different Availability Zones.

   - **DB subnet group** – Choose a DB subnet group for the VPC, such as **tutorial-dual-stack-db-subnet-group** created in Create a DB subnet group.
   - **Public access** – Choose **No**.
   - **VPC security group (firewall)** – Select **Choose existing**.
   - **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as **tutorial-dual-stack-db-securitygroup** created in Create a VPC security group for a private DB cluster.

Remove other security groups, such as the default security group, by choosing the **X** associated with each.

- **Availability Zone** – Choose **us-west-2a**.

  To avoid cross-AZ traffic, make sure the DB instance and the EC2 instance are in the same Availability Zone.

7. For the remaining sections, specify your DB cluster settings. For information about each setting, see Settings for Aurora DB clusters.

Connect to your Amazon EC2 instance and DB cluster

After you create your Amazon EC2 instance and DB cluster in dual-stack mode, you can connect to each one using the IPv6 protocol. To connect to an Amazon EC2 instance using the IPv6 protocol, follow the instructions in Connect to your Linux instance in the *Amazon EC2 User Guide*.

To connect to your Aurora MySQL DB cluster from the Amazon EC2 instance, follow the instructions in Connect to an Aurora MySQL DB cluster.

Deleting the VPC

After you create the VPC and other resources for this tutorial, you can delete them if they are no longer needed.

If you added resources in the VPC that you created for this tutorial, you might need to delete these before you can delete the VPC. Examples of resources are Amazon EC2 instances or DB clusters. For more information, see Delete your VPC in the *Amazon VPC User Guide*.

To delete a VPC and related resources

1. Delete the DB subnet group:

   a. Open the Amazon RDS console at https://console.amazonaws.cn/rds/.
   b. In the navigation pane, choose **Subnet groups**.
   c. Select the DB subnet group to delete, such as **tutorial-db-subnet-group**.
   d. Choose **Delete**, and then choose **Delete** in the confirmation window.
2. Note the VPC ID:

   a. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.

b. Choose **VPC Dashboard**, and then choose **VPCs**.

c. In the list, identify the VPC you created, such as **tutorial-dual-stack-vpc**.

d. Note the **VPC ID** value of the VPC that you created. You need this VPC ID in subsequent steps.

3. Delete the security groups:

a. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.

b. Choose **VPC Dashboard**, and then choose **Security Groups**.

c. Select the security group for the Amazon RDS DB instance, such as **tutorial-dual-stack-db-securitygroup**.

d. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

e. On the **Security Groups** page, select the security group for the Amazon EC2 instance, such as **tutorial-dual-stack-securitygroup**.

f. For **Actions**, choose **Delete security groups**, and then choose **Delete** on the confirmation page.

4. Delete the NAT gateway:

a. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.

b. Choose **VPC Dashboard**, and then choose **NAT Gateways**.

c. Select the NAT gateway of the VPC that you created. Use the VPC ID to identify the correct NAT gateway.

d. For **Actions**, choose **Delete NAT gateway**.

e. On the confirmation page, enter **`delete`**, and then choose **Delete**.

5. Delete the VPC:

a. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.

b. Choose **VPC Dashboard**, and then choose **VPCs**.

c. Select the VPC that you want to delete, such as **tutorial-dual-stack-vpc**.

d. For **Actions**, choose **Delete VPC**.

The confirmation page shows other resources that are associated with the VPC that will also be deleted, including the subnets associated with it.

e. On the confirmation page, enter **`delete`**, and then choose **Delete**.

6. Release the Elastic IP addresses:

    a. Open the Amazon EC2 console at https://console.amazonaws.cn/ec2/.

    b. Choose **EC2 Dashboard**, and then choose **Elastic IPs**.

    c. Select the Elastic IP address that you want to release.

    d. For **Actions**, choose **Release Elastic IP addresses**.

    e. On the confirmation page, choose **Release**.

Quotas and constraints for Amazon Aurora

Following, you can find a description of the resource quotas and naming constraints for Amazon Aurora.

Topics

- Quotas in Amazon Aurora
- Naming constraints in Amazon Aurora
- Amazon Aurora size limits

Quotas in Amazon Aurora

Each Amazon account has quotas, for each Amazon Region, on the number of Amazon Aurora resources that can be created. After a quota for a resource has been reached, additional calls to create that resource fail with an exception.

The following table lists the resources and their quotas per Amazon Region.

Name	Default	Adjustable	Description
Authorizations per DB security group	Each supported Region: 20	No	Number of security group authorizations per DB security group
Custom endpoints per DB cluster	Each supported Region: 5	Yes	The maximum number of custom endpoints that you can create per Aurora DB cluster in this account in the current Region. This value reflects the highest number of custom endpoints in a DB cluster in the account. Other DB clusters in the account

Name	Default	Adjustable	Description
			might have a lower number of custom endpoints.
Custom engine versions	Each supported Region: 40	Yes	The maximum number of custom engine versions allowed in this account in the current Region
DB cluster parameter groups	Each supported Region: 50	Yes	The maximum number of DB cluster parameter groups
DB clusters	Each supported Region: 40	Yes	The maximum number of Aurora clusters allowed in this account in the current Region
DB instances	ap-south-1: 20 Each of the other supported Regions: 40	Yes	The maximum number of DB instances allowed in this account in the current Region
DB shard groups	Each supported Region: 5	Yes	The maximum number of DB shard groups for Aurora Limitless Database in this account in the current Region
DB subnet groups	ap-south-1: 20 Each of the other supported Regions: 50	Yes	The maximum number of DB subnet groups

Name	Default	Adjustable	Description
Data API HTTP request body size	Each supported Region: 4 Megabytes	No	The maximum size allowed for the HTTP request body.
Data API maximum concurrent cluster-secret pairs	Each supported Region: 30	No	The maximum number of unique pairs of Aurora Serverless v1 DB clusters and secrets in concurrent Data API requests for this account in the current Amazon Region.
Data API maximum concurrent requests	Each supported Region: 500	No	The maximum number of Data API requests to an Aurora Serverless v1 DB cluster that use the same secret and can be processed at the same time. Additional requests are queued and processed as in-process requests complete.
Data API maximum result set size	Each supported Region: 1 Megabytes	No	The maximum size of the database result set that can be returned by the Data API.
Data API maximum size of JSON response string	Each supported Region: 10 Megabytes	No	The maximum size of the simplified JSON response string returned by the RDS Data API.

Name	Default	Adjustable	Description
Data API requests per second	Each supported Region: 1,000 per second	No	The maximum number of requests to the Data API per second allowed for this account in the current Amazon Region. This quota only applies to Amazon Aurora Serverless v1 clusters.
Event subscriptions	Each supported Region: 20	Yes	The maximum number of event subscriptions
IAM roles per DB cluster	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB cluster
IAM roles per DB instance	Each supported Region: 5	Yes	The maximum number of IAM roles associated with a DB instance
Integrations	Each supported Region: 100	No	The maximum number of integrations allowed in this account in the current Amazon Region
Manual DB cluster snapshots	Each supported Region: 100	Yes	The maximum number of manual DB cluster snapshots
Manual DB instance snapshots	Each supported Region: 100	Yes	The maximum number of manual DB instance snapshots
Option groups	Each supported Region: 20	Yes	The maximum number of option groups

Name	Default	Adjustable	Description
Parameter groups	ap-south-1: 20 Each of the other supported Regions: 50	Yes	The maximum number of parameter groups
Proxies	Each supported Region: 20	Yes	The maximum number of proxies allowed in this account in the current Amazon Region
Read replicas per primary	Each supported Region: 15	Yes	The maximum number of read replicas per primary DB instance. This quota cant be adjusted for Amazon Aurora.
Reserved DB instances	ap-south-1: 20 Each of the other supported Regions: 40	Yes	The maximum number of reserved DB instances allowed in this account in the current Amazon Region
Security groups	ap-south-1: 20 Each of the other supported Regions: 25	Yes	The maximum number of DB security groups
Subnets per DB subnet group	Each supported Region: 20	No	The maximum number of subnets per DB subnet group

Name	Default	Adjustable	Description
Total storage for all DB instances	Each supported Region: 100,000	Yes	The maximum total storage (in GB) on EBS volumes for all Amazon RDS DB instances added together. This quota does not apply to Amazon Aurora, which has a maximum cluster volume of 128 TiB for each DB cluster.

Note

By default, you can have up to a total of 40 DB instances. RDS DB instances, Aurora DB instances, Amazon Neptune instances, and Amazon DocumentDB instances apply to this quota.

If your application requires more DB instances, you can request additional DB instances by opening the Service Quotas console. In the navigation pane, choose **Amazon services**. Choose **Amazon Relational Database Service (Amazon RDS)**, choose a quota, and follow the directions to request a quota increase. For more information, see Requesting a quota increase in the *Service Quotas User Guide*.

For RDS for Oracle, you can create up to 15 read replicas per source DB instance in each Region, but we recommend limiting replicas to 5 to minimize replication lag.

Backups managed by Amazon Backup are considered manual DB clustersnapshots, but don't count toward the manual cluster snapshot quota. For information about Amazon Backup, see the *Amazon Backup Developer Guide*.

Amazon RDS also limits the rate of API requests for each Amazon Web Services account in each Amazon Region. These limits are separate from the resource quotas in the table and don't appear in Service Quotas. If you exceed them, API requests fail with a `ThrottlingException` error and the message `Rate exceeded`. For the default limits and how to request an increase, see Request throttling for the Amazon RDS API.

Naming constraints in Amazon Aurora

The naming constraints in Amazon Aurora are as follows:

- DB cluster identifier:
  - Must contain 1–63 alphanumeric characters or hyphens.
  - First character must be a letter.
  - Can't end with a hyphen or contain two consecutive hyphens.
  - Must be unique for all DB instances per Amazon account, per Amazon Region.
- Initial database name – Database name constraints differ between Aurora MySQL and Aurora PostgreSQL. For more information, see the available settings when creating each DB cluster.
- Master username – Master username constraints differ for each database engine. For more information, see the available settings when creating the DB cluster.
- Master password:
  - The password for the database master user can include any printable ASCII character except `/`, `'`, `"`, `@`, or a space.
  - The password can contain the following number of printable ASCII characters depending on the DB engine:
    - Aurora MySQL: 8–41
    - Aurora PostgreSQL: 8–99
- DB parameter group:
  - Must contain 1–255 alphanumeric characters.
  - First character must be a letter.
  - Hyphens are allowed, but the name cannot end with a hyphen or contain two consecutive hyphens.
- DB subnet group:
  - Must contain 1–255 characters.
  - Alphanumeric characters, spaces, hyphens, underscores, and periods are allowed.

Amazon Aurora size limits

Storage size limits

Aurora cluster volume maximum size varies by engine version:

256 TiB maximum:

- Aurora PostgreSQL versions:
  - 17.5 and all higher versions
  - 16.9 and higher
  - 15.13 and higher
- Aurora MySQL version 3.10 (compatible with MySQL 8.0.42) and higher

128 TiB maximum:

- All earlier Aurora PostgreSQL versions
- Aurora MySQL 3 versions lower than 3.10; Aurora MySQL version 2, versions 2.09 and higher

For more information on automatic storage scaling, see How Aurora storage automatically resizes.

To monitor the remaining storage space, you can use the `AuroraVolumeBytesLeftTotal` metric. For more information, see Cluster-level metrics for Amazon Aurora.

SQL table size limits

For an Aurora MySQL DB cluster, the maximum table size is 64 tebibytes (TiB). For an Aurora PostgreSQL DB cluster, the maximum table size is 32 tebibytes (TiB). We recommend that you follow table design best practices, such as partitioning of large tables.

Table space ID limits

The maximum table space ID for Aurora MySQL is 2147483647. If you frequently create and drop tables, make sure to be aware of your table space IDs and plan to use logical dumps. For more information, see Logical migration from MySQL to Amazon Aurora MySQL by using mysqldump.

Request throttling for the Amazon RDS API

Amazon RDS throttles API requests for each Amazon Web Services account in each Amazon Region. This helps the performance of the service and ensures fair usage for all Amazon RDS customers. Throttling ensures that requests to the Amazon RDS API don't exceed the maximum allowed API request limits. The request limits apply to API requests from any source, including the following.

- Your own application code using an Amazon SDK
- A command line tool, such as the Amazon CLI
- The Amazon Aurora console
- A third-party tool that uses your account's credentials, such as an infrastructure-as-code or monitoring tool

Amazon Aurora uses the Amazon RDS API, so the same limits apply to Aurora API requests.

If you use any Amazon RDS API operations and exceed the default limit for the number of calls per second, the Amazon RDS API issues an error like the following one.

ClientError: An error occurred (ThrottlingException) when calling the *API_name* operation: Rate exceeded.

This error means that your account exceeded its API request limit. By default, you can make up to 300 requests in a burst and a sustained 12 requests per second. To avoid this error, retry the request with exponential backoff, reduce your request rate, or request a limit increase. For more information, see Retries and exponential backoff, Reduce the number of API requests, and Request a limit increase.

Topics

- How throttling is applied
- Token bucket size and refill rate
- Retries and exponential backoff
- Reduce the number of API requests
- Identify the source of throttled requests
- View your current API limits
- Request a limit increase

How throttling is applied

Amazon RDS uses a token bucket to throttle API requests. Understanding how the bucket works helps you predict when throttling occurs and plan your request rate.

Your account has a *bucket* that holds a number of *tokens*. Each request spends one token, and Amazon RDS adds tokens back at a steady rate. The number of tokens in the bucket is the number of requests you can make at that moment.

Your account has one bucket for each Amazon Region, shared by all Amazon RDS API actions. Each request that you make removes one token from the bucket. Suppose the bucket size is 300 tokens. You can make up to 300 requests in one second. If you exceed 300 requests in a second, you are throttled and the remaining requests within that second fail.

Buckets automatically refill at a set rate. If the bucket is below its maximum capacity, Amazon RDS adds a set number of tokens back to it every second until it reaches its maximum capacity.

If the bucket is full when refill tokens arrive, the bucket discards them. The bucket can't hold more than its maximum number of tokens.

Suppose the bucket size is 300 tokens and the refill rate is 12 tokens per second. If you make 300 requests in one second, the bucket drops to zero (0) tokens.

The bucket then refills by 12 tokens every second. It reaches its maximum capacity of 300 tokens after 25 seconds if you make no requests during that time.

You don't need to wait for the bucket to be completely full before you can make API requests. You can use refill tokens as they are added to the bucket. If you deplete the bucket by making 300 requests in a second, you can continue to make 12 requests per second by using the refill tokens as they are added to the bucket. The bucket can refill to the maximum capacity only if you make fewer than 12 requests per second.

Amazon RDS separately limits requests that Amazon services, such as Amazon CloudFormation, make on your behalf. These requests don't consume tokens from your account's bucket.

Token bucket size and refill rate

The following table shows the default API request throttling limits for each Amazon Web Services account in each Amazon Region.

API actions	Bucket maximum capacity	Bucket refill rate (per second)
All Amazon RDS API actions	300	12

These are the default limits. If Amazon has increased the limits for your account, your limits are higher.

For more information about quotas on the number of Amazon RDS resources that you can create in your account, see Quotas in Amazon Aurora. For more information about Amazon RDS service endpoints and quotas, see Amazon Relational Database Service endpoints and quotas in the *Amazon Web Services General Reference*.

Retries and exponential backoff

Your application might need to retry an API request. For example:

- To check for an update in the status of a resource, such as a DB instance that is being created or modified
- To enumerate a large number of resources (for example, all your DB snapshots)
- To retry a request after it fails with a server error (5xx) or a throttling error

However, for a client error (4xx) other than a throttling error, revise the request to correct the problem before trying the request again.

Resource status changes

Before you start polling to check for status updates, give the request time to potentially complete. For example, wait a few minutes before checking whether your DB instance is available. When you begin polling, use an appropriate sleep interval between successive requests to lower the rate of API requests. For best results, use an increasing or variable sleep interval.

Alternatively, you can use Amazon EventBridge to notify you of the status of your resources instead of polling. For example, you can receive an event when a DB instance becomes available or when a snapshot finishes. For more information, see Creating a rule that triggers on an Amazon Aurora event.

Retries

When you need to poll or retry an API request, use an exponential backoff algorithm to calculate the sleep interval between requests. Wait progressively longer between retries. Set a maximum delay and a maximum number of retries. Add jitter (randomized delay) to prevent successive collisions. For implementation guidance, see Timeouts, retries, and backoff with jitter on the Amazon Builders' Library website.

Each Amazon SDK implements automatic retry logic, and retries `ThrottlingException` errors by default. For more information, see Retry behavior in the *Amazon SDKs and Tools Reference Guide*.

Reduce the number of API requests

Because all API actions share one bucket, reducing requests from any caller frees capacity for every other caller in your account. Before requesting a limit increase, consider the following.

Cache responses

: Information returned by `Describe*` actions, such as `DescribeDBInstances` and `DescribeDBClusters`, usually changes infrequently. Cache the results and reuse them instead of calling the API every time you need the information.

Limit your request rate on the client side

: Shape your outbound request rate to stay below the sustained rate before sending requests, rather than relying on retries after throttling.

Replace polling with events

: Use Amazon EventBridge to be notified of resource state changes instead of repeatedly calling `Describe*` actions.

Request only what you need

: Specify an identifier or use the `Filters` parameter so that a `Describe*` action returns only the resources you are interested in, and page through large result sets with `MaxRecords` and `Marker`.

Spread out scheduled requests

: If many workers, scheduled jobs, or monitoring agents call the API at the same moment, add a random delay to each so that requests are spread over time instead of arriving in a burst.

Identify the source of throttled requests

Amazon CloudTrail records every API request in your account. Each record shows you who made the request, which tool made it, and whether it succeeded. Use Amazon CloudTrail to find which users, roles, or tools make most of your requests. For more information about Amazon CloudTrail logging, see Monitoring Amazon Aurora API calls in Amazon CloudTrail.

View your current API limits

Service Quotas doesn't manage Amazon RDS API throttling limits, and they don't appear in the Service Quotas console. Unless Amazon has increased the limits for your account, the default limits apply. If your account has received an increase and you don't know your current limits, open a support case to confirm them.

Request a limit increase

You can request an increase for API throttling limits for your Amazon Web Services account by opening a support case. Limit increases aren't self-service, and Amazon doesn't approve them automatically. Amazon reviews your request and your recent traffic before applying a new limit. Allow time for the review and for the new limit to take effect.

Recommendations

Consider the following recommendations before you request an increase.

- Base your request on your measured peak request rate. Amazon reviews your traffic pattern before approving an increase.
- Prioritize increasing the bucket refill rate if you are throttled during sustained traffic. Increase the bucket maximum capacity if you are throttled during short bursts.
- Spread out scheduled jobs or groups of workers that start at the same time before you request an increase. Spreading requests out usually resolves the throttling without a limit increase.
- Submit requests for planned events, such as a migration or a large deployment, well before the event.

Open a support case

If you still need a higher limit after reviewing the recommendations, create a case in the Amazon Support Center console. If you haven't created a case before, see Creating support cases and case management in the *Amazon Support User Guide*.

To speed up the review, copy the following template into the case description. Replace *account_id*, *region*, and the other values with your own information:

```
Please increase the Amazon RDS API throttling limits for my account.
Account ID(s): account_id
Region(s): region
Description: use_case
API actions: api_actions
Time window: time_window
Changes already made: changes_made
Requested limits:
    Bucket maximum capacity: current_bucket_capacity -> requested_bucket_capacity
    Bucket refill rate: current_refill_rate -> requested_refill_rate
```

The template uses the following values.

account_id

The Amazon Web Services account ID, or IDs, that need the increase.

region

The Amazon Region, or Regions, where you are throttled.

use_case

Your use case and the tools that call the Amazon RDS API, such as your application, the Amazon CLI, an infrastructure-as-code tool, or a monitoring agent.

api_actions

The Amazon RDS API actions that generate most of your requests.

time_window

A one-hour window, in UTC, when you saw peak throttling or usage. For a planned event, the planned start and end dates.

changes_made

Anything you've already tried to reduce requests, such as retries with exponential backoff, caching, or less frequent polling.

current_bucket_capacity, *requested_bucket_capacity*

Your current and requested bucket maximum capacity (burst).

current_refill_rate, *requested_refill_rate*

Your current and requested bucket refill rate, in requests per second (sustained).

The more context you provide about your traffic, the faster Amazon can find the right limit for you.

Troubleshooting for Amazon Aurora

Use the following sections to help troubleshoot problems you have with DB instances in Amazon RDS and Amazon Aurora.

Topics

- Can't connect to Amazon RDS DB instance
- Amazon RDS security issues
- Resetting the DB instance owner password
- Amazon RDS DB instance outage or reboot
- Amazon RDS DB parameter changes not taking effect
- Freeable memory issues in Amazon Aurora
- Amazon Aurora MySQL replication issues

For information about debugging problems using the Amazon RDS API, see Troubleshooting applications on Aurora.

Can't connect to Amazon RDS DB instance

When you can't connect to a DB instance, the following are common causes:

- **Inbound rules** – The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.

  By default, DB instances don't allow access. Access is granted through a security group associated with the VPC that allows traffic into and out of the DB instance. If necessary, add inbound and outbound rules for your particular situation to the security group. You can specify an IP address, a range of IP addresses, or another VPC security group.

  > **Note**
  >
  > When adding a new inbound rule, you can choose **My IP** for **Source** to allow access to the DB instance from the IP address detected in your browser.

For more information about setting up security groups, see Provide access to the DB cluster in the VPC by creating a security group.

> **Note**
>
> Client connections from IP addresses within the range 169.254.0.0/16 aren't permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.

- **Public accessibility** – To connect to your DB instance from outside of the VPC, such as by using a client application, the instance must have a public IP address assigned to it.

  To make the instance publicly accessible, modify it and choose **Yes** under **Public accessibility**. For more information, see Hiding a DB cluster in a VPC from the internet.

- **Port** – The port that you specified when you created the DB instance can't be used to send or receive communications because of your local firewall restrictions. To determine if your network allows the specified port to be used for inbound and outbound communication, check with your network administrator.

- **Availability** – For a newly created DB instance, the DB instance has a status of `creating` until the DB instance is ready to use. When the state changes to `available`, you can connect to the DB instance. Depending on the size of your DB instance, it can take up to 20 minutes before an instance is available.

- **Internet gateway** – For a DB instance to be publicly accessible, the subnets in its DB subnet group must have an internet gateway.

  To configure an internet gateway for a subnet

  1. Sign in to the Amazon Web Services Management Console and open the Amazon RDS console at https://console.amazonaws.cn/rds/.
  2. In the navigation pane, choose **Databases**, and then choose the name of the DB instance.
  3. In the **Connectivity & security** tab, write down the values of the VPC ID under **VPC** and the subnet ID under **Subnets**.
  4. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
  5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet

gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.

6. In the navigation pane, choose **Subnets**, and then select your subnet.
7. On the **Route Table** tab, verify that there is a route with `0.0.0.0/0` as the destination and the internet gateway for your VPC as the target.

   If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (`::/0`) that points to the internet gateway. Otherwise, do the following:

   a. Choose the ID of the route table (rtb-*xxxxxxxx*) to navigate to the route table.
   b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use `0.0.0.0/0` as the destination and the internet gateway as the target.

      For IPv6, choose **Add route**, use `::/0` as the destination and the internet gateway as the target.
   c. Choose **Save routes**.

   Also, if you are trying to connect to IPv6 endpoint, make sure that client IPv6 address range is authorized to connect to the DB instance.

For more information, see Working with a DB cluster in a VPC.

Testing a connection to a DB instance

You can test your connection to a DB instance using common Linux or Microsoft Windows tools.

From a Linux or Unix terminal, you can test the connection by entering the following. Replace *DB-instance-endpoint* with the endpoint and *port* with the port of your DB instance.

```
nc -zv DB-instance-endpoint port
```

For example, the following shows a sample command and the return value.

```
nc -zv postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299

  Connection to postgresql1.c6c8mn7fake0.us-west-2.rds.amazonaws.com 8299 port [tcp/
vvr-data] succeeded!
```

Windows users can use Telnet to test the connection to a DB instance. Telnet actions aren't supported other than for testing the connection. If a connection is successful, the action returns no message. If a connection isn't successful, you receive an error message such as the following.

```
C:\>telnet sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com 819

 Connecting To sg-postgresql1.c6c8mntfake0.us-west-2.rds.amazonaws.com...Could not
open
 connection to the host, on port 819: Connect failed
```

If Telnet actions return success, your security group is properly configured.

> **Note**
>
> Amazon RDS doesn't accept internet control message protocol (ICMP) traffic, including ping.

Troubleshooting connection authentication

In some cases, you can connect to your DB instance but you get authentication errors. In these cases, you might want to reset the master user password for the DB instance. You can do this by modifying the RDS instance.

Amazon RDS security issues

To avoid security issues, never use your Amazon Web Services account root user email address and password for a user account. Best practice is to use your root user to create users and assign those to DB user accounts. You can also use your root user to create other user accounts, if necessary.

For information about creating users, see Creating an IAM user in your Amazon Web Services account. For information about creating users in Amazon IAM Identity Center, see Manage identities in IAM Identity Center.

Error message "failed to retrieve account attributes, certain console functions may be impaired."

You can get this error for several reasons. It might be because your account is missing permissions, or your account hasn't been properly set up. If your account is new, you might not have waited

for the account to be ready. If this is an existing account, you might lack permissions in your access policies to perform certain actions such as creating a DB instance. To fix the issue, your administrator needs to provide the necessary roles to your account. For more information, see the IAM documentation.

Resetting the DB instance owner password

If you get locked out of your DB cluster, you can log in as the master user. Then you can reset the credentials for other administrative users or roles. If you can't log in as the master user, the Amazon account owner can reset the master user password. For details of which administrative accounts or roles you might need to reset, see Master user account privileges.

You can change the DB instance password by using the Amazon RDS console, the Amazon CLI command modify-db-instance, or by using the ModifyDBInstance API operation. For more information about modifying a DB instance in a DB cluster, see Modifying a DB instance in a DB cluster.

Amazon RDS DB instance outage or reboot

A DB instance outage can occur when a DB instance is rebooted. It can also occur when the DB instance is put into a state that prevents access to it, and when the database is restarted. A reboot can occur when you manually reboot your DB instance. A reboot can also occur when you change a DB instance setting that requires a reboot before it can take effect.

A DB instance reboot occurs when you change a setting that requires a reboot, or when you manually cause a reboot. A reboot can occur immediately if you change a setting and request that the change take effect immediately. Or it can occur during the DB instance's maintenance window.

A DB instance reboot occurs immediately when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0. You then set **Apply Immediately** to `true`.
- You change the DB instance class, and **Apply Immediately** is set to `true`.

A DB instance reboot occurs during the maintenance window when one of the following occurs:

- You change the backup retention period for a DB instance from 0 to a nonzero value or from a nonzero value to 0, and **Apply Immediately** is set to `false`.

- You change the DB instance class, and **Apply Immediately** is set to `false`.

When you change a static parameter in a DB parameter group, the change doesn't take effect until the DB instance associated with the parameter group is rebooted. The change requires a manual reboot. The DB instance isn't automatically rebooted during the maintenance window.

Amazon RDS DB parameter changes not taking effect

In some cases, you might change a parameter in a DB parameter group but don't see the changes take effect. If so, you likely need to reboot the DB instance associated with the DB parameter group. When you change a dynamic parameter, the change takes effect immediately. When you change a static parameter, the change doesn't take effect until you reboot the DB instance associated with the parameter group.

You can reboot a DB instance using the RDS console. Or you can explicitly call the `RebootDBInstance` API operation. You can reboot without failover if the DB instance is in a Multi-AZ deployment. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call. An example of this is calling `ModifyDBInstance` to change the DB instance class. For more information, see Modifying parameters in a DB parameter group in Amazon Aurora.

Freeable memory issues in Amazon Aurora

Freeable memory is the total random access memory (RAM) on a DB instance that can be made available to the database engine. It's the sum of the free operating-system (OS) memory and the available buffer and page cache memory. The database engine uses most of the memory on the host, but OS processes also use some RAM. Memory currently allocated to the database engine or used by OS processes isn't included in freeable memory. When the database engine is running out of memory, the DB instance can use the temporary space that is normally used for buffering and caching. As previously mentioned, this temporary space is included in freeable memory.

You use the `FreeableMemory` metric in Amazon CloudWatch to monitor the freeable memory. For more information, see Monitoring tools for Amazon Aurora.

If your DB instance consistently runs low on freeable memory or uses swap space, consider scaling up to a larger DB instance class. For more information, see Amazon AuroraDB instance classes.

You can also change the memory settings. For example, on Aurora MySQL , you might adjust the size of the `innodb_buffer_pool_size` parameter. This parameter is set by default to 75 percent of physical memory. For more MySQL troubleshooting tips, see How can I troubleshoot low freeable memory in an Amazon RDS for MySQL database?

For Aurora serverless, `FreeableMemory` represents the amount of unused memory that's available when the Aurora serverless DB instance is scaled to its maximum capacity. You might have the instance scaled down to relatively low capacity, but it still reports a high value for `FreeableMemory`, because the instance can scale up. That memory isn't available right now, but you can get it if you need it.

For every Aurora capacity unit (ACU) that the current capacity is below the maximum capacity, `FreeableMemory` increases by approximately 2 GiB. Thus, this metric doesn't approach zero until the DB instance is scaled up as high as it can.

If this metric approaches a value of `0`, the DB instance has scaled up as much as it can. It's nearing the limit of its available memory. Consider increasing the maximum ACU setting for the cluster. If this metric approaches a value of `0` on a reader DB instance, consider adding additional reader DB instances to the cluster. That way, the read-only part of the workload can be spread across more DB instances, reducing the memory usage on each reader DB instance. For more information, see Important Amazon CloudWatch metrics for Aurora serverless.

Amazon Aurora MySQL replication issues

Some MySQL replication issues also apply to Aurora MySQL. You can diagnose and correct these.

Topics

- Diagnosing and resolving lag between read replicas
- Diagnosing and resolving a MySQL read replication failure
- Replication stopped error
- Read replica replication fails to initialize metadata structure

Diagnosing and resolving lag between read replicas

After you create a MySQL read replica and the replica is available, Amazon RDS first replicates the changes made to the source DB instance from the time the read replica create operation started. During this phase, the replication lag time for the read replica is greater than 0. You can monitor

this lag time in Amazon CloudWatch by viewing the Amazon RDS `AuroraBinlogReplicaLag` metric.

The `AuroraBinlogReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the MySQL `SHOW REPLICA STATUS` command. For more information, see SHOW REPLICA STATUS Statement in the MySQL documentation.

When the `AuroraBinlogReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `AuroraBinlogReplicaLag` metric returns -1, replication might not be active. To troubleshoot a replication error, see Diagnosing and resolving a MySQL read replication failure. A `AuroraBinlogReplicaLag` value of -1 can also mean that the `Seconds_Behind_Master` value can't be determined or is `NULL`.

> **Note**
>
> Previous versions of Aurora MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using Aurora MySQL version 1 or 2, then use `SHOW SLAVE STATUS`. Use `SHOW REPLICA STATUS` for Aurora MySQL version 3 and higher.

The `AuroraBinlogReplicaLag` metric returns -1 during a network outage or when a patch is applied during the maintenance window. In this case, wait for network connectivity to be restored or for the maintenance window to end before you check the `AuroraBinlogReplicaLag` metric again.

The MySQL read replication technology is asynchronous. Thus, you can expect occasional increases for the `BinLogDiskUsage` metric on the source DB instance and for the `AuroraBinlogReplicaLag` metric on the read replica. For example, consider a situation where a high volume of write operations to the source DB instance occur in parallel. At the same time, write operations to the read replica are serialized using a single I/O thread. Such a situation can lead to a lag between the source instance and read replica.

For more information about read replicas and MySQL, see Replication implementation details in the MySQL documentation.

You can reduce the lag between updates to a source DB instance and the subsequent updates to the read replica by doing the following:

- Set the DB instance class of the read replica to have a storage size comparable to that of the source DB instance.

- Make sure that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter in the next section.
- Disable the query cache. For tables that are modified often, using the query cache can increase replica lag because the cache is locked and refreshed often. If this is the case, you might see less replica lag if you disable the query cache. You can disable the query cache by setting the `query_cache_type parameter` to 0 in the DB parameter group for the DB instance. For more information on the query cache, see Query cache configuration.
- Warm the buffer pool on the read replica for InnoDB for MySQL. For example, suppose that you have a small set of tables that are being updated often and you're using the InnoDB or XtraDB table schema. In this case, dump those tables on the read replica. Doing this causes the database engine to scan through the rows of those tables from the disk and then cache them in the buffer pool. This approach can reduce replica lag. The following shows an example.

  For Linux, macOS, or Unix:

```
PROMPT> mysqldump \
    -h <endpoint> \
    --port=<port> \
    -u=<username> \
    -p <password> \
    database_name table1 table2 > /dev/null
```

  For Windows:

```
PROMPT> mysqldump ^
    -h <endpoint> ^
    --port=<port> ^
    -u=<username> ^
    -p <password> ^
    database_name table1 table2 > /dev/null
```

Diagnosing and resolving a MySQL read replication failure

Amazon RDS monitors the replication status of your read replicas. RDS updates the **Replication State** field of the read replica instance to `Error` if replication stops for any reason. You can review the details of the associated error thrown by the MySQL engines by viewing the **Replication Error** field. Events that indicate the status of the read replica are also generated, including RDS-

EVENT-0045, RDS-EVENT-0046, and RDS-EVENT-0057. For more information about events and subscribing to events, see Working with Amazon RDS event notification. If a MySQL error message is returned, check the error in the MySQL error message documentation.

Common situations that can cause replication errors include the following:

- The value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance.

  The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. The `max_allowed_packet` parameter is used to specify the maximum size of data manipulation language (DML) that can be run on the database. In some cases, the `max_allowed_packet` value for the source DB instance might be larger than the `max_allowed_packet` value for the read replica. If so, the replication process can throw an error and stop replication. The most common error is `packet bigger than 'max_allowed_packet' bytes`. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.
- Writing to tables on a read replica. If you're creating indexes on a read replica, you need to have the `read_only` parameter set to *0* to create the indexes. If you're writing to tables on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the following storage engines: InnoDB for MySQL or MariaDB.

  You can convert a MyISAM table to InnoDB with the following command:

  ```
  alter table <schema>.<table_name> engine=innodb;
  ```
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see Determination of safe and unsafe statements in binary logging in the MySQL documentation.

The following steps can help resolve your replication error:

- If you encounter a logical error and you can safely skip the error, follow the steps described in Skipping the current replication error. Your Aurora MySQL DB instance must be running a version that includes the `mysql_rds_skip_repl_error` procedure. For more information, see mysql_rds_skip_repl_error.

- If you encounter a binary log (binlog) position issue, you can change the replica replay position. You do so with the `mysql.rds_next_master_log` command for Aurora MySQL version 1 and 2. You do so with the `mysql.rds_next_source_log` command for Aurora MySQL version 3 and higher. Your Aurora MySQL DB instance must be running a version that supports this command to change the replica replay position. For version information, see mysql_rds_next_master_log.
- If you encounter a temporary performance issue because of high DML load, you can set the `innodb_flush_log_at_trx_commit` parameter to 2 in the DB parameter group on the read replica. Doing this can help the read replica catch up, though it temporarily reduces atomicity, consistency, isolation, and durability (ACID).
- You can delete the read replica and create an instance using the same DB instance identifier. This way, the endpoint remains the same as that of your old read replica.

If a replication error is fixed, the **Replication State** changes to **replicating**. For more information, see Troubleshooting a MySQL read replica problem.

Replication stopped error

When you call the `mysql.rds_skip_repl_error` command, you might receive an error message stating that replication is down or disabled.

This error message appears because replication is stopped and can't be restarted.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log files. In this case, you might encounter a fatal error because of binary log files being purged before they have been replayed on the replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binary log files are retained on your replication source. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the mysql_rds_set_configuration procedure. Specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster, up to 2160 (90 days). The default for Aurora MySQL is 24 (1 day). The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

Read replica replication fails to initialize metadata structure

When you attempted to start replication, you received the following error message:

```
Read Replica Replication Error - SQLError: 13124, reason: Replica failed to initialize
 applier metadata structure from the repository
```

This error occurs when there is a problem with the metadata structure of the replica. To fix the metadata structure, you must create a new replica.

To prevent this from happening in the future, perform one of the following actions:

- If possible, disable multi-threading on your replicas. Starting with MySQL 8.0.27, multi-threading is enabled by default.
- If you need to use multi-threading on your replicas, then we recommend that you use GTID-based replication. For more information, see Using GTID-based replication.

Amazon RDS API reference

In addition to the Amazon Web Services Management Console and the Amazon Command Line Interface (Amazon CLI), Amazon RDS also provides an API. You can use the API to automate tasks for managing your DB instances and other objects in Amazon RDS.

- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the Amazon CLI, see Amazon Command Line Interface reference for Amazon RDS.

Topics

- Using the Query API
- Troubleshooting applications on Aurora

Using the Query API

The following sections briefly discuss the parameters and request authentication used with the Query API.

For general information about how the Query API works, see Query requests in the *Amazon EC2 API Reference.*

Query parameters

HTTP Query-based requests are HTTP requests that use the HTTP verb GET or POST and a Query parameter named `Action`.

Each Query request must include some common parameters to handle authentication and selection of an action.

Some operations take lists of parameters. These lists are specified using the `param.`*n* notation. Values of *n* are integers starting from 1.

For information about Amazon RDS Regions and endpoints, go to Amazon Relational Database Service (RDS) in the Regions and Endpoints section of the *Amazon Web Services General Reference*.

Query request authentication

You can only send Query requests over HTTPS, and you must include a signature in every Query request. You must use either Amazon signature version 4 or signature version 2. For more information, see Signature Version 4 signing process and Signature version 2 signing process.

Troubleshooting applications on Aurora

Amazon RDS provides specific and descriptive errors to help you troubleshoot problems while interacting with the Amazon RDS API.

Topics

- Retrieving errors
- Troubleshooting tips

For information about troubleshooting for Amazon RDS DB instances, see Troubleshooting for Amazon Aurora.

Retrieving errors

Typically, you want your application to check whether a request generated an error before you spend any time processing results. The easiest way to find out if an error occurred is to look for an `Error` node in the response from the Amazon RDS API.

XPath syntax provides a simple way to search for the presence of an `Error` node. It also provides a relatively easy way to retrieve the error code and message. The following code snippet uses Perl and the XML::XPath module to determine if an error occurred during a request. If an error occurred, the code prints the first error code and message in the response.

```
use XML::XPath;
    my $xp = XML::XPath->new(xml =>$response);
    if ( $xp->find("//Error") )
    {print "There was an error processing your request:\n", " Error code: ",
    $xp->findvalue("//Error[1]/Code"), "\n", " ",
    $xp->findvalue("//Error[1]/Message"), "\n\n"; }
```

Troubleshooting tips

We recommend the following processes to diagnose and resolve problems with the Amazon RDS API:

- Verify that Amazon RDS is operating normally in the Amazon Region that you're targeting by checking the Amazon Health Dashboard website.
- Check the structure of your request.

  Each Amazon RDS operation has a reference page in the *Amazon RDS API Reference*. Double-check that you are using parameters correctly. For ideas about what might be wrong, look at the sample requests or user scenarios to see if those examples do similar operations.
- Check Amazon re:Post.

  Amazon RDS has a development community where you can search for solutions to problems others have experienced along the way. To view the topics, go to Amazon re:Post.

Document history

Current API version: 2014-10-31

The following table describes important changes to the *Amazon Aurora User Guide*. For notification about updates to this documentation, you can subscribe to an RSS feed. For information about Amazon Relational Database Service (Amazon RDS), see the *Amazon Relational Database Service User Guide*.

> **Note**
>
> Before August 31, 2018, Amazon Aurora was documented in the *Amazon Relational Database Service User Guide*. For earlier Aurora document history, see Document history in the *Amazon Relational Database Service User Guide*.

Change	Description	Date
Aurora supports the db.r9g instance class	Added support for db.r9g instance class on Aurora. You can now create Aurora DB clusters that use the db.r9g instance class. For more information, see Aurora DB instance classes.	November 12, 2026
pgvector requirements for knowledge bases	Updated documentation for using Aurora PostgreSQL as a knowledge base for Amazon Bedrock to clarify the `pgvector` extension version requirements and the supported Regions. For more information, see Using Aurora PostgreSQL as a Knowledge Base for Amazon Bedrock and Supported	November 10, 2026

	features in Amazon Aurora by Amazon Web Services Region and Aurora DB engine.	
Logical replication across major upgrades	Added information about retaining logical replication slots when you perform a major version upgrade of Aurora PostgreSQL DB clusters, which requires the `rds.logical_replication` parameter on the target version. For more information, see Upgrading Amazon Aurora PostgreSQL DB clusters.	November 10, 2026
Amazon RDS Data API array types	Added information about how Aurora PostgreSQL array types in the Amazon RDS Data API apply only to query results and can't be passed as `arrayValue` input parameters. For more information, see Using the Amazon RDS Data API.	November 10, 2026
Aurora Serverless v2 CPU pressure	Added information about CPU pressure as a cause of the `incompatible-parameters` status for Aurora Serverless v2 DB instances. For more information, see Performance and scaling for Aurora Serverless v2.	November 9, 2026

Aurora PostgreSQL upgrade targets	Updated documentation for the Aurora PostgreSQL major version upgrade targets to reflect the current supported versions. For more information, see Upgrading Amazon Aurora PostgreSQL DB clusters.	November 9, 2026
Query plan tracking prerequisites	Added information about the prerequisite that `pg_stat_statements` must be in the `shared_preload_libraries` parameter to track Aurora PostgreSQL query execution plans. For more information, see Monitoring query execution plans and peak memory for Aurora PostgreSQL.	November 7, 2026
Aurora PostgreSQL security and query plans	Updated documentation for Aurora PostgreSQL to clarify that you can create `INSTEAD OF` triggers only on views, and to add analysis of query execution plans in the Amazon CloudWatch Database Insights **Advanced** mode. For more information, see Security with Amazon Aurora PostgreSQL and Monitoring query execution plans and peak memory for Aurora PostgreSQL.	November 6, 2026

Analytics and Babelfish updates	Added documentation for the Babelfish ANTLR parse cache and temporary tables on read replicas, and updated documentation for querying Apache Iceberg and Parquet data directly in Aurora PostgreSQL. For more information, see Querying Apache Iceberg and Parquet data directly in Aurora PostgreSQL, Using ANTLR parse cache in Babelfish, Babelfish temporary tables on read replicas, Best practices , Configuration parameters, and Execution plan.	November 6, 2026
Aurora Serverless v2 version support	Added information about Aurora PostgreSQL 17.4 and 18.3 support for the 0–256 ACU capacity range in Aurora Serverless v2. For more information, see How Aurora Serverless v2 works.	November 5, 2026
pgstattuple_approx for large tables	Added information about using `pgstattuple_approx` instead of `pgstattuple` to diagnose bloat on large Aurora PostgreSQL tables with less I/O load. For more information, see Diagnosing table and index bloat.	November 4, 2026

Unsupported data types for upgrades	Added information about removing the `abstime`, `reltime`, and `tinterval` data types before a Aurora PostgreSQL major version upgrade to version 12 or later. For more information, see Upgrading Amazon Aurora PostgreSQL DB clusters.	November 4, 2026
FTS sync inconsistency precheck	Added information about the `auroraUpgradeCheckForFtsSyncInconsistency` precheck that detects InnoDB Full-Text Search sync inconsistencies before upgrading Aurora MySQL version 2 to version 3 and version 3 to version 8.4. For more information, see Precheck descriptions for upgrading Aurora MySQL version 3 to version 8.4 and Precheck descriptions for upgrading Aurora MySQL version 2 to version 3.	November 2, 2026
Capacity Reservation Blue/Green limitation	Added information about the limitation that Amazon Aurora On-Demand Capacity Reservations aren't supported with Amazon RDS Blue/Green Deployments. For more information, see Amazon Aurora On-Demand Capacity Reservations.	October 30, 2026

Aurora PostgreSQL 18 for Data API	Added information about Aurora PostgreSQL 18 support for the Amazon RDS Data API, including availability in the Amazon GovCloud (US) Regions. For more information, see Supported features in Amazon Aurora by Amazon Web Services Region and Aurora DB engine.	October 29, 2026
384 ACU maximum capacity	Updated documentation for Aurora Serverless v2 to reflect the new maximum capacity of 384 ACUs for Aurora PostgreSQL. For more information, see How Aurora Serverless v2 works, Creating a DB cluster that uses Aurora Serverless v2, and Requirements and limitations for Aurora Serverless v2.	October 23, 2026
tds_ssl_encrypt value mapping	Updated documentation for the `tds_ssl_encrypt` parameter in Babelfish to correct the value mapping, where `1` turns encryption on and `0` turns it off. For more information, see DB cluster parameter group settings for Babelfish.	October 22, 2026

db.serverless in preview environment	Added information about using the `db.serverless` instance class in the Aurora PostgreSQL database preview environment. For more information, see Working with the database preview environment.	October 20, 2026
Amazon Aurora On-Demand Capacity Reservations	Added documentation for Amazon Aurora On-Demand Capacity Reservations, which let you reserve compute capacity for your Aurora DB instances in specific Avai lability Zones. For more information, see Amazon Aurora On-Demand Capacity Reservations.	October 19, 2026
Aurora PostgreSQL analytics updates	Updated documentation for Aurora PostgreSQL analytics , including best practices for full query pushdown, monitoring and troublesh ooting, and querying Apache Iceberg and Parquet data. For more information, see Best practices, Execution plan, Monitoring and troublesh ooting, Querying Apache Iceberg and Parquet data directly in Aurora PostgreSQ L, How it works, and Prerequis ites.	October 17, 2026

Data API session management	Added information about how the Amazon RDS Data API resets session state when it reuses database connections, including releasing extension-owned state such as `dblink` connections. For more information, see Using the Amazon RDS Data API and Supported features in Amazon Aurora by Amazon Web Services Region and Aurora DB engine.	October 8, 2026
Higher `max_connections` for Aurora MySQL	Added information about the higher `max_connections` maximum of 50,000 for Aurora MySQL version 8.4.10 and higher. For more information, see Comparing Aurora MySQL version 3 and Aurora MySQL version 8.4 and Managing performance and scaling for Amazon Aurora MySQL.	October 7, 2026
`pg_columnmask` cursor and masking behavior	Added information about `pg_columnmask` cursor behavior and the shared plan cache masking limitation in Aurora PostgreSQL. For more information, see Using shared plan cache and Security with Amazon Aurora PostgreSQL.	October 6, 2026

Ruby driver support	Added information about the Amazon Advanced Ruby Wrapper driver for connecting to Aurora DB clusters. For more information, see Connecting to an Amazon Aurora DB cluster.	October 5, 2026
Babelfish limitations	Updated documentation for Babelfish limitations related to the Amazon RDS Data API, Amazon RDS Proxy, and querying Iceberg and Parquet data with Aurora PostgreSQL. For more information, see Babelfish limitations.	October 3, 2026
Cross-Region snapshot copy limit	Updated documentation for the limit of five in-progress cross-Region DB cluster snapshot copy requests to a single destination Region. For more information, see DB cluster snapshot copying.	October 2, 2026
Aurora PostgreSQL supports querying Apache Iceberg and Parquet data directly in Amazon S3	You can now query Apache Iceberg tables and Apache Parquet files in Amazon S3 directly from Aurora PostgreSQL using read-only foreign tables, without loading or copying the data. For more information, see Querying Apache Iceberg and Parquet data directly in Aurora PostgreSQL.	September 30, 2026

Subquery window transformation	Added information about subquery window transformation, which accelerates correlated aggregate subqueries in Aurora PostgreSQL by rewriting them as window functions. For more information, see Optimizing correlated subqueries in Aurora PostgreSQL.	September 29, 2026
Maximum cluster volume size increase	Updated documentation for the maximum Amazon Aurora MySQL cluster volume size, which can now grow up to 256 TiB depending on the engine version. For more information, see Migrating data to an Amazon Aurora MySQL DB cluster.	September 29, 2026
Babelfish XML and geospatial support	Added information about Babelfish support for the XML datatype methods `EXIST()` and `QUERY()`, the `MultiLineString` data type, and spatial indexes. For more information, see Babelfish supports XML datatype methods and Babelfish supports Geospatial data types.	September 29, 2026

Aurora Analytics reference	Added documentation for Aurora PostgreSQL analytics reference topics, including execution plans, SQL functions, and IAM policies. For more information, see Execution plan, How it works, IAM policies reference, Technical reference, and SQL functions reference.	September 29, 2026
Babelfish unsupported functionalities	Updated documentation for the list of unsupported T-SQL functionalities in Babelfish. For more information, see Unsupported functionalities in Babelfish.	September 28, 2026
Aurora supports the db.r8a instance class	Added support for db.r8a instance class on Aurora. You can now create Aurora DB clusters that use the db.r8a instance class. For more information, see Aurora DB instance classes.	September 25, 2026
Aurora PostgreSQL 18 Serverless v2 support	Added information about Aurora Serverless v2 support for Aurora PostgreSQL version 18 across Regions. For more information, see Supported features in Amazon Aurora by Amazon Web Services Region and Aurora DB engine.	September 24, 2026

Zero-ETL integration Region support	Added information about Aurora PostgreSQL zero-ETL integrations with Amazon Redshift and Amazon SageMaker AI, including version 18.3 and higher support. For more informati on, see Supported features in Amazon Aurora by Amazon Web Services Region and Aurora DB engine.	September 16, 2026
Related topic references	Added information about related topics for Aurora PostgreSQL and Aurora MySQL, including write forwarding, Babelfish, volume cloning, and performan ce troubleshooting. For more information, see Working with Amazon Aurora PostgreSQL, Using Babelfish for Aurora PostgreSQL, Working with Babelfish, Best practices with Amazon Aurora PostgreSQL, Cloning a v olume for an Amazon Aurora DB cluster, and Troublesh ooting Amazon Aurora MySQL database performance.	September 14, 2026

Aurora PostgreSQL 17.7 LTS release	Updated documentation for the Aurora PostgreSQL version 17.7 long-term support (LTS) release date. For more information, see Using an Aurora PostgreSQL long-term support (LTS) release.	September 14, 2026
Amazon RDS Proxy with global databases	Updated documentation for using Amazon RDS Proxy with Aurora global databases. For more information, see Connecting to Amazon Aurora Global Database.	September 10, 2026
Transaction timeout in Aurora MySQL	Added documentation for the `aurora_transaction_timeout` parameter, which sets the maximum duration for InnoDB transactions in Aurora MySQL. For more information, see Transaction timeout in Amazon Aurora MySQL.	September 2, 2026
Troubleshooting binary log replication lag	Added documentation for troubleshooting binary log replication lag when Aurora MySQL is configured as a binary log replica. For more information, see Troubleshooting binary log replication lag for Aurora MySQL.	August 24, 2026

Babelfish plan cache and geospatial	Added information about Babelfish shared plan cache support and the `Multipoint` geospatial data type and related spatial functions. For more information, see Using shared plan cache, Supported functionalities in Babelfish by version, and Babelfish supports Geospatial data types.	August 24, 2026
Database Insights and counter metrics	Updated documentation for Database Insights and the detailed per-query and database counter metrics, such as `DBLoadCPU`, available for Aurora Serverless v2 DB instances. For more information, see Best practices with Amazon Aurora, Supported features in Amazon Aurora by Amazon Web Services Region and Aurora DB engine, Performance and scaling for Aurora Serverless v2, cpu, io/socket/sql/client_connection, and io/table/sql/handler.	August 20, 2026

Aurora PostgreSQL 18 and Kerberos support	Added information about Aurora PostgreSQL 18 support for Aurora Global Database and Amazon RDS Proxy, and updated documentation for Kerberos authentication with Aurora MySQL. For more informati on, see Supported features in Amazon Aurora by Amazon Web Services Region and Aurora DB engine and Using Kerberos authentication for Aurora MySQL.	August 20, 2026
Express configuration for Aurora PostgreSQL	Added information about express configuration, which lets you create and query an Aurora PostgreSQL serverless database in seconds. For more information, see Getting started with Amazon Aurora.	August 6, 2026
Multi-source replication for Aurora MySQL	Added documentation for configuring multi-source replication, which lets an A mazon Aurora MySQL DB cluster receive binary log events from more than one source MySQL database. For more information, see Configure multi-source replication for Amazon Aurora MySQL.	July 31, 2026

In-memory relay log feature	Added information about the in-memory relay log feature, which you enable by setting `aurora_in_memory_relaylog` to `ON` in the DB cluster parameter group. For more information, see Replication with Amazon Aurora MySQL.	July 29, 2026
Delayed replication for Aurora MySQL	Added documentation for configuring delayed replication to maintain a time-lagged read replica for disaster recovery with Amazon Aurora MySQL. For more information, see Configure delayed replication with Amazon Aurora MySQL.	July 28, 2026
Documentation updates for Aurora topics	Updated documentation for point-in-time restore, parallel query, replication, DB cluster creation, and the Aurora query editor. For more information, see Restoring a DB cluster to a specified time, Parallel query for Amazon Aurora MySQL, Replication with Amazon Aurora MySQL, Replication with Amazon Aurora PostgreSQL, Creating an Amazon Aurora DB cluster, and Using the Aurora query editor.	July 14, 2026

Aurora Serverless v2 platform upgrades	Updated documentation for upgrading Aurora Serverless v2 to the latest platform version by applying pending maintenance, stopping and restarting the cluster, or using blue/green deployments. For more information, see How Aurora Serverless v2 works.	June 25, 2026
Transaction timeout in Aurora MySQL	Added documentation for the `aurora_transaction_timeout` parameter, which sets the maximum duration for InnoDB transactions in Aurora MySQL. For more information, see Transaction timeout in Amazon Aurora MySQL.	June 15, 2026
Allowed TLS ciphers for Aurora PostgreSQL	Added information about the allowed TLS ciphers for each Aurora PostgreSQL major version. For more information, see Security with Amazon Aurora PostgreSQL.	June 12, 2026
Aurora throughput performance	Updated documentation for Aurora throughput, which delivers up to 6x the throughput of stock PostgreSQL and up to 6x the throughput of stock MySQL on similar hardware. For more information, see What is Amazon Aurora?.	June 11, 2026

Setting up your Amazon account	Updated documentation for setting up your Amazon account and VPC environment for Amazon Aurora. For more information, see Setting up your environment for Amazon Aurora.	May 29, 2026
Aurora MySQL migration and upgrade	Added information about a migration precheck that identifies MyISAM tables, compressed tables, and tables with compressed pages, and updated documentation for major version upgrades to Aurora MySQL version 8.4. For more information, see Migrating data to an Amazon Aurora MySQL DB cluster and Upgrading the major version of an Amazon Aurora MySQL DB cluster.	May 21, 2026

Support for Aurora MySQL version 8.4	Added documentation for Aurora MySQL version 8.4, compatible with MySQL 8.4, including version comparisons, upgrade prechecks and procedures, post-upgrade cleanup, and security considerations such as the protected `rdsproxyadmin` user, and the `aurora_enable_memory_management` parameter that controls whether Aurora automatically manages memory recovery actions. For more information, see Comparing Aurora MySQL version 3 and Aurora MySQL version 8.4, Comparing Aurora MySQL version 8.4 and MySQL 8.4 Community Edition, Security considerations for upgrading from Aurora MySQL version 3 to version 8.4, Aurora MySQL version 8.4 compatible with MySQL 8.4, Security with Amazon Aurora MySQL, Upgrading the major version of an Amazon Aurora MySQL DB cluster, Precheck descriptions for upgrading Aurora MySQL version 3 to version 8.4, Precheck descriptions for upgrading Aurora MySQL version 2 to version	May 20, 2026

	3, Upgrading to Aurora MySQL version 8.4, Amazon Aurora MySQL reference, Post-upgrade cleanup for Aurora MySQL version 8.4, and Password policies and Password validation in Aurora MySQL.	
aws_default_logs_role for log publishing	Updated documentation for the aws_default_logs_role role used when publishing log data from your DB cluster to CloudWatch Logs with the server_audit_logs_upload parameter. For more information, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs and Integrating Amazon Aurora MySQL with other Amazon services.	May 19, 2026
Increased Aurora cluster volume size	Updated documentation for the maximum Aurora cluster volume size, which increased from 128 TiB to 256 TiB. For more information, see What is Amazon Aurora?.	May 18, 2026

Aurora Serverless v2 reader scaling	Updated documentation for how an Aurora Serverless v2 reader determines its minimum and maximum capacity, including whether it follows its associated writer or scales independently. For more information, see How Aurora Serverless v2 works.	May 11, 2026
Aurora Auto Scaling availability requirement	Added information about how Aurora Auto Scaling only scales a DB cluster when all cluster instances are in the `available` state. For more information, see Amazon Aurora Auto Scaling with Aurora Replicas.	May 7, 2026
`evolve_plan_baselines` function behavior	Updated documentation for the `apg_plan_mgmt.evolve_plan_baselines()` function, which runs `EXPLAIN ANALYZE` on a captured query to compare its performance against the best approved plan for Aurora PostgreSQL. For more information, see Managing query execution plans for Aurora PostgreSQL.	April 30, 2026

Aurora MySQL version 8.4 security documentation	Added and updated documentation for security features in Aurora MySQL version 8.4, including authentication policy changes, password policies and the validate_password component, TLS and cipher suite updates, new dynamic privileges, upgrade considerations from version 3 to 8.4, differences between Aurora MySQL 8.4 and MySQL 8.4 Community Edition, new upgrade prechecks, and master user privilege updates. For more information, see Aurora MySQL version 8.4 compatible with MySQL 8.4, Comparing Aurora MySQL version 3 and version 8.4, Security considerations for upgrading from version 3 to 8.4, Comparing Aurora MySQL version 8.4 and MySQL 8.4 Community Edition, Password policies and Password validation, Security with Aurora MySQL, Aurora MySQL reference, Aurora MySQL upgrade precheck descriptions, Master user account privileges, and Password management with Amazon SageMaker AI.	April 20, 2026

Using shared plan cache	Added documentation for the shared plan cache in Aurora PostgreSQL, which lets backend processes share generic plans to reduce memory usage with the `apg_shared_plan_cache.enable` parameter. For more information, see Using shared plan cache.	April 16, 2026
Managing the Amazon RDS Data API	Updated documentation for enabling or disabling the Amazon RDS Data API on an existing database, and to reflect the deprecation of Aurora Serverless v1. For more information, see Using the Amazon RDS Data API.	April 16, 2026
Feature and Region availability updates	Updated documentation for Aurora Serverless v2 engine version support and Aurora Global Database availability in additional Amazon Regions. For more information, see Supported features in Amazon Aurora by Amazon Web Services Region and Aurora DB engine.	April 16, 2026

Express configuration for Aurora PostgreSQL	Added documentation for creating an Aurora PostgreSQL cluster with express configuration on the Amazon Free Tier, including supported Regions, prerequisite IAM permissions, and the `--express-configuration` parameter. For more information, see Getting started with Amazon Aurora.	April 16, 2026
Babelfish geospatial and XML support	Added information about Babelfish support for the polygon spatial data type with the `STPolyFromText` function and for XML datatype methods and procedures such as `OPENXML()`. For more information, see Babelfish supports Geospatial data types, Upgrading Amazon Aurora PostgreSQL DB clusters, and Babelfish supports XML datatype methods.	April 16, 2026

Aurora Serverless v1 deprecation	Updated documentation for Aurora Serverless v2 to reflect the deprecation of Aurora Serverless v1, including reader support and scaling behavior. For more information, see How Aurora Serverless v2 works and Performance and scaling for Aurora Serverless v2.	April 16, 2026
Aurora PostgreSQL wait events and reads	Added information about additional Aurora PostgreSQL wait events and Aurora Optimized Reads support for Graviton-based R8gd instances with NVMe storage. For more information, see Tuning with wait events for Aurora PostgreSQL and Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads.	April 16, 2026

Aurora Limitless Database updates	Updated documentation for the Limitless Data Utility source configurations and added documentation for instance-specific performance and resource monitoring in Aurora PostgreSQL Limitless Database. For more information, see Loading data into Aurora PostgreSQL Limitless Database and Instance-specific performance and resource monitoring.	April 16, 2026
Aurora Global Database enhancements	Added documentation for using Aurora Global Database with Amazon Application Recovery Controller Region Switch and Amazon RDS Blue/Green Deployments, and for managed minor version upgrades across all Regions with a single `modify-global-cluster` operation. For more information, see Using Amazon Aurora Global Database and Supported features in Amazon Aurora by Amazon Web Services Region and Aurora DB engine.	April 16, 2026

New Aurora PostgreSQL LTS release	Updated documentation for the Aurora PostgreSQL long-term support (LTS) release, which is now PostgreSQL 17.7. For more information, see Using an Aurora PostgreSQL long-term support (LTS) release.	April 9, 2026
Aurora PostgreSQL upgrade target versions	Updated documentation for Aurora PostgreSQL DB cluster minor version upgrade target versions, including 17.6 and 16.10. For more information, see Upgrading Amazon Aurora PostgreSQL DB clusters.	March 30, 2026
Aurora PostgreSQL on Amazon Free Tier	Added information about using Aurora PostgreSQL on the Amazon Free Tier, including the cluster and storage restrictions that apply. For more information, see What is Amazon Aurora?.	March 25, 2026
Backup retention during restore	Updated documentation for specifying a backup retention period from 1 to 35 days when you create, modify, or restore an Aurora DB cluster. For more information, see Overview of backing up and restoring an Aurora DB cluster.	February 14, 2026

Monitoring Aurora Limitless Database	Updated documentation for monitoring Aurora PostgreSQL Limitless Database and added information about optimizing user-defined functions for single-shard execution to improve resource efficiency. For more information, see Monitoring Aurora PostgreSQL Limitless Database.	February 13, 2026
Blue/Green Deployments for global databases	Added information about using Amazon RDS Blue/Green Deployments with Aurora Global Database to perform upgrades and maintenance with minimal downtime. For more information, see Using Aurora PostgreSQL extensions with Babelfish and Using Amazon Aurora Global Database.	February 13, 2026
Delegated extension event trigger example	Updated documentation for Aurora PostgreSQL delegated extension support with an example event trigger that grants a delegated user access to extension objects. For more information, see Using Amazon Aurora delegated extension support for PostgreSQL.	December 5, 2025

Aurora PostgreSQL Zero-ETL integrations with Amazon SageMaker support additional Regions	Aurora PostgreSQL Zero-ETL integrations with Amazon SageMaker are now available in additional Regions. For more information, see Supported Regions and Aurora DB engines for zero-ETL integrations.	October 15, 2025
Aurora PostgreSQL Limitless Database available in an additional Amazon Region	Aurora PostgreSQL Limitless Database is now available in the Amazon GovCloud (US) Regions. For more information, see Aurora PostgreSQL Limitless Database requirements and considerations.	September 16, 2025
Amazon RDS Data API supports IPv6	Amazon RDS Data API now supports IPv6 connectivity, enabling you to connect to your Aurora databases using IPv6 addresses. For more information, see Using the Data API.	August 30, 2025
Amazon Aurora is available in the Asia Pacific (New Zealand) Region	Amazon Aurora is now available in the Asia Pacific (New Zealand) Region. For more information, see Regions and Availability Zones.	August 28, 2025

Amazon RDS Data API available in an additional Amazon Region	Amazon RDS Data API is now available in the Europe (Spain) Region. For more information, see Supported Regions and Aurora DB engines for RDS Data API.	August 1, 2025
Zero-ETL integrations with Amazon SageMaker lakehouse is generally available	Zero-ETL integrations make transactional data available in Amazon SageMaker within seconds of it being written to an Aurora MySQL DB instance. For more information, see Working with Aurora zero-ETL integrations.	June 30, 2025
Amazon Aurora is available in the Asia Pacific (Taipei) Region	Amazon Aurora is now available in the Asia Pacific (Taipei) Region. For more information, see Regions and Availability Zones.	June 5, 2025

End-of-life information for Performance Insights	Amazon has announced the end-of-life date for Performance Insights: November 30, 2025. After this date, Amazon RDS will no longer support the Performance Insights console experience, flexible retention periods, and their associated pricing. We recommend upgrading your DB clusters to Database Insights before this date. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora.	May 30, 2025
Aurora PostgreSQL Limitless Database supports CloudWatch Database Insights	You can now use CloudWatch Database Insights to monitor your Amazon Aurora PostgreSQL Limitless Database at scale. For more information, see Monitoring Amazon Aurora PostgreSQL Limitless Database with CloudWatch Database Insights.	May 22, 2025

Viewing support dates for open source engine major versions	You can now view information about the start and end dates for open source engine major versions in RDS standard support and RDS Extended Support by using the Amazon CLI and the RDS API. For more information, see Viewing support dates for engine versions in Amazon RDS Extended Support.	May 20, 2025
Aurora PostgreSQL zero-ETL integrations support additional Regions	Aurora PostgreSQL zero-ETL integrations are now available in additional Regions. For more information, see Supported Regions and Aurora DB engines for zero-ETL integrations with Amazon Redshift.	February 17, 2025
Amazon Aurora is available in the Mexico (Central) Region	Amazon Aurora is now available in the Mexico (Central) Region. For more information, see Regions and Availability Zones.	January 14, 2025
Amazon Aurora is available in the Asia Pacific (Thailand) Region	Amazon Aurora is now available in the Asia Pacific (Thailand) Region. For more information, see Regions and Availability Zones.	January 7, 2025

End-of-life information for Aurora Serverless v1	Amazon has announced the end-of-life date for Aurora Serverless v1: March 31st, 2025. We strongly recommend upgrading any Aurora Serverless v1 DB clusters to Aurora serverless before that date. The upgrade can involve a change in the major version number of the database engine. Thus, it's important to plan, test, and implement this switchover before the end-of-life date. Starting January 8th, 2025, customers will no longer be able to create new Aurora Serverless v1 clusters or instances with either the Amazon Web Services Management Console or the CLI. For information about the upgrade procedure from Aurora Serverless v1 to Aurora serverless, see Upgrading from an Aurora Serverless v1 cluster to Aurora serverless.	December 6, 2024

Aurora supports CloudWatch Database Insights	You can now use CloudWatch Database Insights to monitor your Amazon Aurora DB clusters at scale. For more information, see Monitoring Amazon Aurora databases with CloudWatch Database Insights.	December 1, 2024
Amazon Aurora supports the db.r8g instance classes	You can now use the db.r8g instance classes to create Aurora DB clusters. For more information, see Aurora DB instance classes.	November 21, 2024
Aurora serverless supports automatic pause and resume	Aurora serverless DB instances can now scale all the way down to zero Aurora capacity units (ACUs) after a period of inactivity. To enable this feature, you set the minimum capacity value to 0 ACUs. For more information, see Automatic pause and resume for Aurora serverless.	November 20, 2024

Amazon Aurora supports auto-migrating EC2 databases	You can use the RDS console to migrate an EC2 database to Aurora. Aurora uses Amazon Database Migration Service (Amazon DMS) to migrate your source EC2 database. Amazon DMS allows you to migrate relational databases into your Amazon Web Services Cloud. For more information, see Auto migrating EC2 databases to Amazon Aurora using Amazon Database Migration Service.	November 20, 2024
Amazon Advanced NodeJS Wrapper generally available	The Amazon Web Services (Amazon) Advanced NodeJS Wrapper is complementary to and extends the functionality of an existing NodeJS driver. For more information, see Connecting to Aurora DB clusters with the Amazon drivers.	November 19, 2024
Amazon Aurora supports the db.r7i instance classes	You can now use the db.r7i instance classes to create Aurora DB clusters. For more information, see Aurora DB instance classes.	November 18, 2024

RDS Data API for Aurora MySQL supports all Performance Insights views	You can now use the **Top hosts** or **Top applications** views for Performance Insights to monitor SQL operations performed using RDS Data API for Aurora MySQL. For information about Performance Insights support, see Monitoring RDS Data API queries with Performance Insights.	October 31, 2024
Aurora PostgreSQL Limitless Database	Amazon Aurora PostgreSQL Limitless Database is a new, automated, horizontal scaling (sharding) capability of Amazon Aurora. Aurora PostgreSQL Limitless Database lets you scale beyond the existing Aurora limits for write throughput and storage by distributing a database workload over multiple Aurora writer instances, while maintaining the ability to use it as a single database. For more information, see Amazon Aurora PostgreSQL Limitless Database.	October 31, 2024

Amazon Aurora MySQL version 2 end of standard support	Aurora MySQL version 2 reached the end of standard support on October 31, 2024. For more information, see Preparing for Amazon Aurora MySQL-Compatible Edition version 2 end of standard support.	October 31, 2024
Amazon Aurora supports cluster-level OS upgrades	You can now apply Aurora operating system upgrades at the DB cluster level. Rolling upgrades automatically apply upgrades to a few reader DB instances at a time, thus preserving read availability. For more information, see Operating system updates for Aurora DB clusters.	October 30, 2024
Aurora global clusters support tagging	You can now add tags to Aurora global clusters. An Aurora global cluster is the parent resource that contains the primary and secondary DB clusters in an Aurora global database. For general information about tagging, see Tagging Aurora and Amazon RDS resources. For information about tagging with Aurora Global Database, see Tagging Aurora Global Database resources.	October 24, 2024

Aurora Global Database writer endpoints	Each Aurora Global Database now comes with a writer endpoint that is automatically updated by Aurora to route requests to the current writer instance of the primary DB cluster after an Aurora Global Database switchover and failover operation. To learn more about using the writer endpoint along with Aurora Global Database switchover and failover, see Using switchover or failover in Amazon Aurora Global Database.	October 22, 2024
Aurora PostgreSQL zero-ETL integrations with Amazon Redshift generally available	Zero-ETL integrations make transactional data available in Amazon Redshift within seconds of it being written to an Aurora PostgreSQL source DB cluster. The feature is now generally available. For more information, see Working with Aurora zero-ETL integrations with Amazon Redshift.	October 15, 2024
Aurora serverless supports 256 ACUs	You can now create Aurora serverless DB clusters with a maximum capacity of 256 Aurora capacity units (ACUs). For more information, see Aurora serverless capacity.	October 3, 2024

Amazon Aurora supports Console-to-Code	You can now use Console-to-Code to generate code from actions that you perform in the RDS console. The generated code can help you write code to automate your use of other Amazon services. For more information, see Use Console-to-Code to generate code for your Aurora console actions.	October 3, 2024
RDS Data API supports Performance Insights	You can now use Performance Insights to monitor SQL operations performed using RDS Data API. For information about Performance Insights support, see Monitoring RDS Data API queries with Performance Insights.	September 26, 2024
RDS Data API for Aurora serverless and provisioned is available for Aurora MySQL	RDS Data API is now available for Aurora MySQL clusters that use Aurora serverless or provisioned instances. For usage information for RDS Data API, see Using RDS Data API. For information about Aurora MySQL version and Amazon Region support for RDS Data API, see Data API with Aurora MySQL Serverless v2 and provisioned.	September 26, 2024

Amazon Aurora is available in the Asia Pacific (Malaysia) Region	Amazon Aurora is now available in the Asia Pacific (Malaysia) Region. For more information, see Regions and Availability Zones.	August 22, 2024
Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSBetaServiceRolePolicy` of the `AWSServiceRoleForRDSBeta` service-linked role. For more information, see Amazon RDS updates to Amazon managed policies.	August 7, 2024
Update to existing policy	Amazon RDS removed `sns:Publish` permission from the `AmazonRDSPreviewServiceRolePolicy` of the `AWSServiceRoleForRDSPreview` service-linked role. For more information, see Amazon RDS updates to Amazon managed policies.	August 7, 2024
Aurora serverless supports auto-pause (scale-to-zero)	Aurora serverless DB instances can now scale all the way down to zero Aurora capacity units (ACUs) after a period of inactivity. To enable this feature, you set the minimum capacity value to 0. For more information, see Using Aurora serverless.	July 25, 2024

Amazon ODBC Driver for MySQL generally available	The Amazon Web Services (Amazon) ODBC Driver for MySQL is a client driver designed for the high availability of Aurora MySQL. For more information, see Connecting to Aurora MySQL with the Amazon Web Services (Amazon) ODBC Driver for MySQL.	July 18, 2024
RDS Data API for Aurora serverless is available in more Regions	RDS Data API is now available for Aurora PostgreSQL in several additional Amazon Regions. For information about Region support for RDS Data API, see Data API with Aurora PostgreSQL Serverless v2 and provisioned.	July 9, 2024
Amazon Python Driver generally available	The Amazon Web Services (Amazon) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. For more information, see Connecting to Aurora DB clusters with the Amazon drivers.	May 23, 2024

Zero-ETL integrations available in China Regions	Zero-ETL integrations are now available in the Amazon Web Services Regions China (Beijing) and China (Ningxia) . For more information, see Zero-ETL integrations with Amazon Redshift.	May 21, 2024
RDS Proxy is available in more Regions	RDS Proxy is now available in the Asia Pacific (Hyderabad), Asia Pacific (Melbourne), Middle East (UAE), Israel (Tel Aviv), Canada West (Calgary) , and Europe (Zurich) regions. For more information about RDS Proxy, see Using Amazon RDS Proxy.	May 21, 2024
Amazon RDS supports fine-grained access for Performance Insights	You can now allow or deny access to individual dimensions in Performance Insights. This fine-grained access can be used for `GetResourceMetrics` , `DescribeDimensionKeys` , and `GetDimensionKeyDetails` actions. For more information, see https://docs.amazonaws.cn/AmazonRDS/latest/UserGuide/USER_PerfInsights.access-control.dimensionAccess-policy.html.	May 21, 2024

Amazon RDS Extended Support	Creating or restoring an Aurora MySQL version 2 or 3, or Aurora PostgreSQL version 11 database now automatically enrolls that database into Amazon RDS Extended Support so your existing applications continue to work as they are. You can opt out of RDS Extended Support to avoid charges after the Aurora end of standard support date for your database engine. For more information, see Using Amazon RDS Extended Support.	March 21, 2024
Data filtering for zero-ETL integrations	Amazon RDS supports data filtering at the database and table level for zero-ETL integrations with Amazon Redshift. For more information, see Data filtering for Aurora zero-ETL integrations with Amazon Redshift.	March 20, 2024
Aurora MySQL integrations with Amazon Bedrock	You can now integrate Amazon Aurora MySQL databases with Amazon Bedrock to power generative AI applications. For more information, see Using Amazon Aurora machine learning with Aurora MySQL.	March 8, 2024

New Amazon managed policy	Amazon RDS added a new managed policy named `AmazonRDSCustomInstanceProfileRolePolicy` to allow RDS Custom to perform automation actions and database management tasks through an EC2 instance profile. For more information, see Amazon RDS updates to Amazon managed policies.	February 27, 2024
Amazon RDS support for Amazon Secrets Manager in the Israel (Tel Aviv) Region	Amazon RDS supports Secrets Manager in the Israel (Tel Aviv) Region. For more information, see Password management with Amazon RDS and Amazon Secrets Manager.	February 21, 2024
Amazon RDS Extended Support	Amazon RDS now automatically enables Amazon RDS Extended Support when Aurora MySQL and Aurora PostgreSQL major engine versions in your DB clusters and global clusters reach the Aurora end of standard support date. For more information, see Using Amazon RDS Extended Support.	February 15, 2024

Aurora PostgreSQL 16.1 supports Babelfish for Aurora PostgreSQL 4.0.0	Aurora PostgreSQL 16.1 supports Babelfish 4.0.0. For a list of new features, see 16.1. For a list of features supported in each Babelfish release, see Supported functionality in Babelfish by version. For usage information, see Working with Babelfish for Aurora PostgreSQL.	January 31, 2024
Update to default CA Certificate	The default CA certificate is set to `rds-ca-rsa2048-g1`. For more information, see Using SSL/TLS to encrypt a connection to a DB cluster.	January 26, 2024
RDS Proxy is available in the Europe (Spain) Region	RDS Proxy is now available in the Europe (Spain) region. For more information about RDS Proxy, see Using Amazon RDS Proxy.	January 8, 2024
RDS Data API with Aurora PostgreSQL Aurora serverless and provisioned	You can now use RDS Data API with Aurora PostgreSQL Aurora serverless and provisioned DB clusters. With RDS Data API, you can access your Aurora clusters through a secure HTTP endpoint and run SQL statements without using database drivers or managing connections. For more information, see Using RDS Data API.	December 21, 2023

Aurora PostgreSQL integrations with Amazon Bedrock	You can now integrate Amazon Aurora PostgreSQL databases with Amazon Bedrock to power generative AI applications. For more information, see Using Amazon Aurora machine learning with Aurora PostgreSQL.	December 21, 2023
Amazon Aurora is available in the Canada West (Calgary) Region	Amazon Aurora is now available in the Canada West (Calgary) Region. For more information, see Regions and Availability Zones.	December 20, 2023
Amazon RDS supports viewing and responding to recommendations	Amazon Aurora recommendations now includes threshold based proactive and machine learning based reactive recommendations. For more information, see Recommendations for Amazon Aurora.	December 19, 2023

Aurora PostgreSQL zero-ETL integrations with Amazon Redshift (preview)	You can now create zero-ETL integrations with Amazon Redshift using an Aurora PostgreSQL source DB cluster. For the preview release, you must create all integrations in the Amazon RDS Database Preview Environment, in the US East (Ohio) (us-west-2) Amazon Web Services Region. For more information, see Working with Aurora zero-ETL integrations with Amazon Redshift.	November 28, 2023
Amazon Aurora PostgreSQL supports global database write forwarding	You can now enable write forwarding on secondary clusters in an Aurora PostgreSQL-based global database. For more information, see Using write forwarding in an Aurora PostgreSQL global database.	November 9, 2023
Aurora PostgreSQL support for Optimized Reads	You can achieve faster query processing for Aurora PostgreSQL with Aurora Optimized Reads. For more information, see Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads.	November 8, 2023

Amazon RDS exports Performance Insights metrics to Amazon CloudWatch	Performance Insights lets you export the preconfigured or custom metrics dashboards to Amazon CloudWatch. The exported metrics dashboards are available to view in the CloudWatch console. You can also export a selected Performance Insights metric widget and view the metrics data in the CloudWatch console. For more information, see Exporting Performance Insights metrics to CloudWatch.	November 8, 2023
Aurora MySQL zero-ETL integrations with Amazon Redshift general availability	Zero-ETL integrations with Amazon Redshift are now generally available for Aurora MySQL. For more information, see Working with Aurora zero-ETL integrations with Amazon Redshift.	November 7, 2023
Aurora PostgreSQL support for RDS Blue/Green Deployments	You can now create a blue/green deployment from an Aurora PostgreSQL DB cluster. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	October 26, 2023

Aurora MySQL supports server-side encryption with Amazon KMS keys (SSE-KMS)	In Aurora MySQL version 3.05 and higher, you can use SSE-KMS, including Amazon managed keys and customer managed keys, for server-side encryption of data that you load from or save to Amazon S3. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket and Saving data from an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket.	October 25, 2023
Aurora MySQL optimizations reduce database restart time	In Aurora MySQL version 3.05 and higher, we've introduced optimizations that reduce the database restart time. These optimizations provide up to 65% less downtime than without optimizations, and fewer disruptions to your database workloads, after a restart. For more information, see Optimizations to reduce database restart time.	October 25, 2023

Update to Amazon managed policies	The `AmazonRDSPerformanceInsightsReadOnly` and `AmazonRDSPerformanceInsightsFullAccess` managed policies now includes `Sid` (statement ID) as an identifier in the policy statement. For more information, see Amazon RDS updates to Amazon managed policies.	October 23, 2023
Amazon RDS publishes Performance Insights counter metrics to Amazon CloudWatch	The **DB_PERF_INSIGHTS** metric math function in the CloudWatch console allows you to query Amazon RDS for Performance Insights counter metrics. For more information, see Creating CloudWatch alarms to monitor Amazon Aurora.	September 20, 2023
Amazon Aurora supports point-in-time recovery (PITR) with Amazon Backup	You can now manage Aurora automated (continuous) backups in Amazon Backup and restore to specified times from them. For more information, see Restoring a DB cluster to a specified time using Amazon Backup.	September 7, 2023

Amazon RDS Extended Support	Amazon Aurora announces the upcoming ability to continue running Aurora MySQL and Aurora PostgreSQL major engine versions in your DB instances past the Aurora end of standard support date. For more information, see Using Amazon RDS Extended Support.	September 1, 2023
Amazon Aurora MySQL extends support for Percona XtraBackup	You can now perform physical migrations of MySQL 8.0 databases to Aurora MySQL version 3 DB clusters. For more information, see Physical migration from MySQL by using Percona XtraBackup and Amazon S3.	August 24, 2023

Aurora global database supports global database failover	Aurora global database now supports managed global failover, allowing you to more easily recover from a true Regional disaster or complete service-level outage. To learn more about this feature, see Performing managed failovers for Aurora global databases. The feature previously called "managed planned failover" is now called "switchover." For information about switchovers, see Performing switchovers for Amazon Aurora global databases.	August 21, 2023
Update to Amazon managed policy permissions	The `AmazonRDSFullAccess` managed policy has new permissions that allows you to generate, view, and delete the performance analysis report for a time period. For more information, see Amazon RDS updates to Amazon managed policies.	August 17, 2023

Update to Amazon managed policy permissions	The addition of new permissions to `AmazonRDSPerformanceInsightsReadOnly` managed policy and addition of new managed policy `AmazonRDSPerformanceInsightsFullAccess` allows you generate a DB load analysis report for a time period. For more information, see Amazon RDS updates to Amazon managed policies.	August 16, 2023
Amazon RDS supports DB load time period analysis with Performance Insights	Performance Insights allows you to create performance analysis reports for a specific period of time. The report provides the insights identified and recommendations to resolve the performance issues. For more information, see Analyzing DB load for a period of time.	August 16, 2023
Amazon Aurora supports retaining automated backups for DB clusters	You can now retain automated backups for deleted Aurora clusters and restore them to a specified point in time. For more information, see Retaining automated backups.	August 4, 2023

Amazon Aurora is available in the Israel (Tel Aviv) Region	Amazon Aurora is now available in the Israel (Tel Aviv) Region. For more information, see Regions and Availability Zones.	August 1, 2023
Amazon Aurora MySQL supports local (in-cluster) write forwarding	You can now forward write operations from a reader DB instance to a writer DB instance within an Aurora MySQL DB cluster. For more information, see Using write forwarding in an Amazon Aurora MySQL DB cluster.	July 31, 2023
Amazon Aurora supports Aurora serverless in an additional Amazon Web Services Region	You can now create Aurora serverless DB clusters in the Asia Pacific (Melbourne) Amazon Web Services Region. For information about Aurora serverless, see Using Aurora serverless.	June 28, 2023
Amazon Aurora introduces zero-ETL integrations with Amazon Redshift (preview)	Zero-ETL integrations provide a fully managed solution for making transactional data available in Amazon Redshift within seconds of it being written to an Aurora MySQL DB cluster. For more information, see Working with Aurora zero-ETL integrations with Amazon Redshift.	June 28, 2023

Amazon RDS provides combined Performance Insights and CloudWatch metrics view in the Performance Insights dashboard	Amazon RDS now provides a consolidated view of Performance Insights and CloudWatch metrics in the Performance Insights dashboard. For more information, see Viewing combined metrics with the Performance Insights dashboard.	May 24, 2023
Amazon Aurora supports the db.r7g instance classes	You can now use the db.r7g instance classes to create Aurora DB clusters. For more information, see Aurora DB instance classes.	May 11, 2023
Amazon Aurora supports a new DB cluster storage configuration	With Aurora I/O-Optimized, you pay only for the usage and storage of your DB clusters, with no additional charges for read and write I/O operations. For more information, see Storage configurations for Amazon Aurora DB clusters.	May 11, 2023
Amazon Aurora supports Aurora serverless in additional Amazon Web Services Regions	You can now create Aurora serverless DB clusters in the following Amazon Web Services Regions: Asia Pacific (Hyderabad), Europe (Spain) Europe (Zurich), and Middle East (UAE). For information about Aurora serverless, see Using Aurora serverless.	May 4, 2023

Aurora Serverless v1 supports conversion to provisioned	You can convert an Aurora Serverless v1 DB cluster directly to a provisioned DB cluster. For more informati on, see Converting an Aurora Serverless v1 DB cluster to provisioned.	April 27, 2023
Aurora Serverless v1 supports Amazon Aurora PostgreSQL version 13	You can now create Aurora Serverless v1 DB clusters that run Aurora PostgreSQL ve rsion 13. For more informati on, see Aurora Serverless v1.	April 27, 2023
Amazon Aurora support for Amazon Secrets Manager in the China Regions	Amazon Aurora supports Secrets Manager in the China (Beijing) and China (Ningxia) Regions. For more information, see Password management with Amazon Aurora and Amazon Secrets Manager.	April 20, 2023
Amazon Aurora supports publishing events with tags to topic subscribers	Amazon Aurora event notifications sent to Amazon Simple Notification Service (Amazon SNS) or Amazon EventBridge now contain event tags in the message body. These tags provide the resource data that was affected by the service event. For more information, see Amazon RDS event notificat ion tags and attributes.	April 17, 2023

Update to IAM service-linked role permissions	The `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` policies now grants additional permissions to allow the display of Amazon DevOps Guru findings in the RDS console. For more information, see Amazon RDS updates to Amazon managed policies.	March 30, 2023
Amazon Aurora supports global databases in the Asia Pacific (Melbourne) Region	You can now create Aurora global databases in the Asia Pacific (Melbourne) Region. For information about Aurora global databases, see Using Amazon Aurora global databases.	March 22, 2023
Update to Amazon managed policy permissions	The `AmazonRDSFullAccess` and `AmazonRDSReadOnlyAccess` policies now grants additional permissions to Amazon CloudWatch. For more information, see Amazon RDS updates to Amazon managed policies.	March 16, 2023
RDS Proxy is available in the China Regions	RDS Proxy is now available in the China (Beijing) and China (Ningxia) regions. For more information about RDS Proxy, see Using Amazon RDS Proxy.	March 15, 2023

Amazon Aurora supports Aurora serverless in the China Regions	Aurora serverless is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see Aurora serverless.	March 15, 2023
RDS Proxy is available in the Asia Pacific (Jakarta) Region	RDS Proxy is now available in the Asia Pacific (Jakarta) Region. For more information about RDS Proxy, see Using Amazon RDS Proxy.	March 8, 2023
Amazon Aurora MySQL supports Kerberos authentication	You can now use Kerberos authentication to authenticate users when they connect to your Aurora MySQL DB clusters. For more information, see Using Kerberos authentication for Aurora MySQL.	March 8, 2023
Amazon Aurora supports global databases in additional Amazon Web Services Regions	You can now create Aurora global databases in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Hyderabad), Asia Pacific (Jakarta), Europe (Milan), Europe (Spain) Europe (Zurich), Middle East (Bahrain), and Middle East (UAE). For information about Aurora global databases, see Using Amazon Aurora global databases.	March 6, 2023

Amazon Aurora supports copying DB cluster snapshots in additional Amazon Web Services Regions	You can now copy DB cluster snapshots in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Hyderabad), Asia Pacific (Jakarta), Asia Pacific (Melbourne), Europe (Milan), Europe (Spain) Europe (Zurich), Middle East (Bahrain), and Middle East (UAE). For information about copying DB cluster snapshots , see Copying a DB cluster snapshot.	March 6, 2023
Amazon DevOps Guru for RDS supports proactive insights	Amazon DevOps Guru for RDS publishes proactive insights with recommendations to help you address issues in your Aurora databases before they are predicted to happen. For more information, see How DevOps Guru for RDS works.	February 28, 2023
Amazon Aurora MySQL version 1 is deprecated	Aurora MySQL version 1 (compatible with MySQL 5.6) has been deprecated. For more information, see How long Amazon Aurora major versions remain available.	February 28, 2023

Aurora Serverless v1 supports setting the DB cluster maintenance window	You can now set the maintenance window for Aurora Serverless v1 DB clusters. For more information, see Adjusting the preferred DB cluster maintenance window.	February 27, 2023
Amazon Aurora supports Database Activity Streams in the Asia Pacific (Hyderabad), Europe (Spain), and Middle East (UAE) Regions.	For more information, see Database Activity Streams.	January 27, 2023
Amazon Aurora is available in the Asia Pacific (Melbourne) Region	Amazon Aurora is now available in the Asia Pacific (Melbourne) Region. For more information, see Regions and Availability Zones.	January 23, 2023
Specify certificate authority (CA) during DB cluster creation	You can now specify which CA to use for a DB cluster's server certificate during DB cluster creation. For more information, see Certificate authorities.	January 5, 2023

Aurora MySQL 3.* support for backtracking	Aurora MySQL 3.* versions now offer a quick way to recover from user errors, such as dropping the wrong table or deleting the wrong row. Backtrack allows you to move your database to a prior point in time without needing to restore from a backup, and it completes within seconds, even for large databases. For details, see Backtracking an Aurora DB cluster.	January 4, 2023
Use Amazon RDS Blue/Green Deployments available in additional Amazon Web Services Regions	The Blue/Green Deployments feature is now available in the China (Beijing) and China (Ningxia) Regions. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	December 22, 2022
Update to IAM service-linked role permissions	The AmazonRDSServiceRolePolicy policy now grants additional permissions to Amazon Secrets Manager. For more information, see Amazon RDS updates to Amazon managed policies.	December 22, 2022

Amazon Aurora integrates with Amazon Secrets Manager for password management	Aurora can manage the master user password for a DB cluster in Secrets Manager. For more information, see Password management with Amazon Aurora and Amazon Secrets Manager.	December 22, 2022
Amazon Aurora supports Aurora serverless in additional Amazon Web Services Regions	Aurora serverless is now available in the Africa (Cape Town) and Europe (Milan) Regions. For more information, see Aurora serverless.	December 21, 2022
Aurora PostgreSQL supports RDS Proxy with PostgreSQL 14	You can now create an RDS Proxy with an Aurora PostgreSQL 14 DB cluster. For more information about RDS Proxy, see Using Amazon RDS Proxy.	December 13, 2022
Amazon Aurora alerts you to recent anomalies detected by Amazon DevOps Guru	The database details page of the console alerts you both to current and anomalies that occurred in the past 24 hours. For more information, see How DevOps Guru for RDS works.	December 13, 2022
Amazon RDS Proxy supports global databases	You can now use RDS Proxy with Aurora global databases. For more information, see Using RDS Proxy with Aurora global databases.	December 7, 2022

Aurora PostgreSQL DB clusters support Trusted Language Extensions for PostgreSQL	Trusted Language Extensions for PostgreSQL is an open source development kit that allows you to build high performance PostgreSQL extensions and safely run them on your Aurora PostgreSQL DB cluster. For more information, see Working with Trusted Language Extensions for PostgreSQL.	November 30, 2022
Amazon GuardDuty RDS Protection monitors for access threats	When you turn on GuardDuty RDS Protection, GuardDuty consumes RDS login events from your Aurora databases, monitors these events, and profiles them for potential insider threats or external actors. When GuardDuty RDS Protection detects a potential threat, GuardDuty generates a new finding with details about the potentially compromised database. For more information, see Monitoring threats with GuardDuty RDS Protection.	November 30, 2022

Use Amazon RDS Blue/Green Deployments for database updates	You can make changes to a DB cluster in a staging environment and test the changes without affecting your production DB cluster. When you are ready, you can promote the staging environment to be the new production environment, with minimal downtime. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.	November 27, 2022
Amazon Aurora is available in the Asia Pacific (Hyderabad) Region	Amazon Aurora is now available in the Asia Pacific (Hyderabad) Region. For more information, see Regions and Availability Zones.	November 22, 2022
Amazon Aurora is available in the Europe (Spain) Region	Amazon Aurora is now available in the Europe (Spain) Region. For more information, see Regions and Availability Zones.	November 16, 2022
Amazon Aurora is available in the Europe (Zurich) Region	Amazon Aurora is now available in the Europe (Zurich) Region. For more information, see Regions and Availability Zones.	November 9, 2022

Amazon Aurora supports exporting data to Amazon S3 from DB clusters	You can now export Aurora cluster data directly to S3, without having to create a snapshot first. For more information, see Exporting DB cluster data to Amazon S3.	October 27, 2022
Amazon Aurora MySQL supports faster exports to Amazon S3	You can now see up to 10x faster performance for exporting DB cluster snapshot data to S3 for MySQL 5.7- and 8.0-compatible Aurora MySQL clusters. For more information, see Exporting DB cluster snapshot data to Amazon S3.	October 20, 2022
Amazon Aurora supports automatically setting up connectivity between an Aurora DB cluster and an EC2 instance	You can use the Amazon Web Services Management Console to set up connectivity between an existing Aurora DB cluster and an EC2 instance. For more information, see Connecting an EC2 instance and an Aurora DB cluster automatically.	October 14, 2022
Amazon JDBC Driver for PostgreSQL generally available	The Amazon JDBC Driver for PostgreSQL is a client driver designed for Aurora PostgreSQL. The Amazon JDBC Driver for PostgreSQL is now generally available. For more information, see Connecting with the Amazon JDBC Driver for PostgreSQL.	October 6, 2022

Amazon Aurora supports in-place upgrade for MySQL 5.7-compatible Aurora MySQL	You can perform an in-place upgrade to change an existing MySQL 5.7-compatible Aurora MySQL cluster into a MySQL 8.0-compatible Aurora MySQL cluster. For more information, see Upgrading from Aurora MySQL 2.x to 3.x.	September 26, 2022
Performance Insights shows the top 25 SQL queries	In the Performance Insights dashboard, the **Top SQL** tab shows the 25 SQL queries that are contributing the most to DB load. For more information, see Overview of the Top SQL tab.	September 13, 2022
Aurora MySQL supports a new DB instance class	You can now use the db.r6i DB instance class for Aurora MySQL DB clusters. For more information, see DB instance classes.	September 13, 2022
Amazon Aurora is available in the Middle East (UAE) Region	Amazon Aurora is now available in the Middle East (UAE) Region. For more information, see Regions and Availability Zones.	August 30, 2022

Amazon Aurora supports automatically setting up connectivity with an EC2 instance	When you create an Aurora DB cluster, you can use the Amazon Web Services Management Console to set up connectivity between an Amazon Elastic Compute Cloud instance and the new DB cluster. For more information, see Configure automatic network connectivity with an EC2 instance.	August 22, 2022
Amazon Aurora supports dual-stack mode	DB clusters can now run in dual-stack mode. In dual-stack mode, resources can communicate with the DB cluster over IPv4, IPv6, or both. For more information, see Amazon Aurora IP addressing.	August 17, 2022
Amazon Aurora supports in-place upgrade for PostgreSQL-compatible Aurora Serverless v1	You can perform an in-place upgrade for a PostgreSQL 10-compatible Aurora Serverless v1 cluster to change an existing cluster into a PostgreSQL 11-compatible Aurora Serverless v1 cluster. For the in-place upgrade procedure, see Modifying an Aurora Serverless v1 DB cluster.	August 8, 2022

Performance Insights supports the Asia Pacific (Jakarta) Region	Formerly, you couldn't use Performance Insights in the Asia Pacific (Jakarta) Reg ion. This restriction has been removed. For more informati on, see Amazon Web Services Region support for Performan ce Insights.	July 21, 2022
Amazon Aurora supports a new DB instance class	You can now use the db.r6i DB instance class for Aurora PostgreSQL DB clusters. For more information, see DB instance classes.	July 14, 2022
RDS Performance Insights supports additional retention periods	Previously, Performance Insights offered only two retention periods: 7 days (default) or 2 years (731 days). Now, if you need to retain your performance d ata for longer than 7 days, you can specify from 1–24 months. For more informat ion, see Pricing and data retention for Performance Insights.	July 1, 2022

Amazon Aurora supports in-place upgrade for MySQL-compatible Aurora Serverless v1	You can perform an in-place upgrade for a MySQL 5.6-compatible Aurora Serverless v1 cluster to change an existing cluster into a MySQL 5.7-compatible Aurora Serverless v1 cluster. For the in-place upgrade procedure, see Modifying an Aurora Serverless v1 DB cluster.	June 16, 2022
Aurora supports turning on Amazon DevOps Guru in the RDS console	You can turn on DevOps Guru coverage for your Aurora databases from within the RDS console. For more information, see Setting up DevOps Guru for RDS.	June 9, 2022
Amazon Aurora supports publishing events to encrypted Amazon SNS topics	Amazon Aurora can now publish events to Amazon Simple Notification Service (Amazon SNS) topics that have server-side encryption (SSE) enabled, for additional protection of events that carry sensitive data. For more information, see Subscribing to Amazon RDS event notification.	June 1, 2022

Amazon RDS publishes usage metrics to Amazon CloudWatch	The `AWS/Usage` namespace in Amazon CloudWatch includes account-level usage metrics for your Amazon RDS service quotas. For more information, see Amazon CloudWatch usage metrics for Amazon Aurora.	April 28, 2022
Data API result sets in JSON format	An optional parameter for the `ExecuteStatement` function causes the query result set to be returned as a string in JSON format. The JSON result set is simple and convenient to transform into a data structure in your application's language. For more information, see Processing query results in JSON format.	April 27, 2022
Amazon Aurora serverless is now generally available	Amazon Aurora serverless is generally available for all users. For more information, see Using Aurora serverless.	April 21, 2022
Aurora MySQL supports configurable cipher suites	With Aurora MySQL, you can now use configurable cipher suites to control the connection encryption that your database server accepts. For more information, see Configuring cipher suites for connections to Aurora MySQL DB clusters.	April 15, 2022

Aurora PostgreSQL supports RDS Proxy with PostgreSQL 13	You can now create an RDS Proxy with an Aurora PostgreSQL 13 DB cluster. For more information about RDS Proxy, see Using Amazon RDS Proxy.	April 4, 2022
Release Notes for Aurora PostgreSQL	There is now a separate guide for the Amazon Aurora PostgreSQL release notes. For more information, see *Release Notes for Aurora PostgreSQL*.	March 22, 2022
Release Notes for Aurora MySQL	There is now a separate guide for the Amazon Aurora MySQL release notes. For more information, see *Release Notes for Aurora MySQL*.	March 22, 2022
Aurora PostgreSQL supports multi-major version upgrades	You can now perform version upgrades of Aurora PostgreSQL DB clusters across multiple major versions. For more information, see How to perform a major version upgrade.	March 4, 2022

Aurora PostgreSQL supports configurable cipher suites	With Aurora PostgreSQL versions 11.8 and higher, you can now use configurable cipher suites to control the connection encryption that your database server accepts. For information about using configurable cipher suites with Aurora PostgreSQL, see Configuring cipher suites for connections to Aurora PostgreSQL DB clusters.	March 4, 2022
Amazon JDBC Driver for MySQL generally available	The Amazon JDBC Driver for MySQL is a client driver designed for the high availability of Aurora MySQL. The Amazon JDBC Driver for MySQL is now generally available. For more information, see Connecting with the Amazon Web Services JDBC Driver for MySQL.	March 2, 2022
Aurora PostgreSQL 13.5 supports Babelfish for Aurora PostgreSQL 1.1.0	Aurora PostgreSQL 13.5 supports Babelfish 1.1.0. For a list of new features, see 13.5. For a list of features supported in each Babelfish release, see Supported functionality in Babelfish by version. For usage information, see Working with Babelfish for Aurora PostgreSQL.	February 28, 2022

Amazon Aurora supports Database Activity Streams in the Asia Pacific (Jakarta) Region	For more information, see Support for Amazon Web Services Regions for database activity streams.	February 16, 2022
Performance Insights supports new API operations	Performance Insights now supports the following API operations: `GetResourceMetadata`, `ListAvailableResourceDimensions`, and `ListAvailableResourceMetrics`. For more information, see Retrieving metrics with the Performance Insights API in this manual and the *Amazon RDS Performance Insights API Reference*.	January 12, 2022
Amazon RDS Proxy supports events	RDS Proxy now generates events that you can subscribe to and view in CloudWatch Events or configure to send to Amazon EventBridge. For more information, see Working with RDS Proxy events.	January 11, 2022

RDS Proxy available in additional Amazon Web Services Regions	RDS Proxy is now available in the following Regions: Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Osaka), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo). For more information about RDS Proxy, see Using Amazon RDS Proxy.	January 5, 2022
Amazon Aurora is available in the Asia Pacific (Jakarta) Region	Amazon Aurora is now available in the Asia Pacific (Jakarta) Region. For more information, see Regions and Availability Zones.	December 13, 2021
DevOps Guru for Amazon RDS provides detailed insights and recommendations for Amazon Aurora	DevOps Guru for RDS mines Performance Insights for performance-related data. Using this data, the service analyzes the performance of your Amazon Aurora DB instances and can help you resolve performance issues. To learn more, see Analyzing performance anomalies with DevOps Guru for RDS in this guide and see Overview of DevOps Guru for RDS in the *Amazon DevOps Guru User Guide*.	December 1, 2021

Aurora PostgreSQL supports RDS Proxy with PostgreSQL 12	You can now create an RDS Proxy with an Aurora PostgreSQL 12 database cluster. For more information about RDS Proxy, see Using Amazon RDS Proxy.	November 22, 2021
Aurora supports Amazon Graviton2 instance classes for Database Activity Streams	You can use database activity streams with the db.r6g instance class for Aurora MySQL and Aurora PostgreSQL. For more information, see Supported DB instance classes.	November 3, 2021
Amazon Aurora support for cross-account Amazon KMS keys	You can use a KMS key from a different Amazon Web Services account for encryption when exporting DB snapshots to Amazon S3. For more information, see Exporting DB snapshot data to Amazon S3.	November 3, 2021
Amazon Aurora supports Babelfish for Aurora PostgreSQL	Babelfish for Aurora PostgreSQL extends your Amazon Aurora PostgreSQL-Compatible Edition database with the ability to accept database connections from Microsoft SQL Server clients. For more information, see Working with Babelfish for Aurora PostgreSQL.	October 28, 2021

Aurora Serverless v1 can require SSL for connections	The Aurora cluster parameters `force_ssl` for PostgreSQL and `require_secure_transport` for MySQL are supported now for Aurora Serverless v1. For more information, see Using TLS/SSL with Aurora Serverless v1.	October 26, 2021
Amazon Aurora supports Performance Insights in additional Amazon Web Services Regions	Performance Insights is available in the Middle East (Bahrain), Africa (Cape Town), Europe (Milan), and Asia Pacific (Osaka) Regions. For more information, see Amazon Web Services Region support for Performance Insights.	October 5, 2021
Configurable autoscaling timeout for Aurora Serverless v1	You can choose how long Aurora Serverless v1 waits to find an autoscaling point. If no autoscaling point is found during that period, Aurora Serverless v1 cancels the scaling event or forces the capacity change, depending on the timeout action that you selected. For more information, see Autoscaling for Aurora Serverless v1.	September 10, 2021

Aurora supports X2g and T4g instance classes	Both Aurora MySQL and Aurora PostgreSQL can now use X2g and T4g instance classes. The instance classes that you can use depend on the version of Aurora MySQL or Aurora PostgreSQL. For information about supported instance types, see DB instance classes.	September 10, 2021
Amazon RDS supports RDS Proxy in a shared VPC	You can now create an RDS Proxy in a shared virtual private cloud (VPC). For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora User Guide.	August 6, 2021
Aurora version policy page	The *Amazon Aurora User Guide* now includes a section with general information about Aurora versions and associated policies. For details, see Amazon Aurora versions.	July 14, 2021
Exclude Data API events from an Amazon CloudTrail trail	You can exclude Data API events from a CloudTrail trail. For more information, see Excluding Data API events from an Amazon CloudTrail trail.	July 2, 2021

Amazon Aurora PostgreSQL-Compatible Edition supports additional extensions	Newly supported extensions include pg_bigm, pg_cron, pg_partman, and pg_proctab. For more information, see Extension versions for Amazon Aurora PostgreSQL-Compatible Edition.	June 17, 2021
Cloning for Aurora Serverless clusters	You can now create cloned clusters that are Aurora Serverless. For information about cloning, see Cloning a volume for an Aurora DB cluster.	June 16, 2021
Aurora global databases available in China (Beijing) and China (Ningxia) Regions	You can now create Aurora global databases in the China (Beijing) and China (Ningxia) Regions. For information about Aurora global databases, see Working with Amazon Aurora global databases.	May 19, 2021
FIPS 140-2 support for Data API	The Data API supports the Federal Information Processing Standard Publication 140-2 (FIPS 140-2) for SSL/TLS connections. For more information, see Data API availability.	May 14, 2021

Amazon JDBC Driver for PostgreSQL (preview)	The Amazon JDBC Driver for PostgreSQL, now available in preview, is a client driver designed for the high availability of Aurora PostgreSQL. For more information, see Connecting with the Amazon Web Services JDBC Driver for PostgreSQL (preview).	April 27, 2021
The Data API available in additional Amazon Web Services Regions	The Data API is now available in the Asia Pacific (Seoul) and Canada (Central) Regions. For more information, see Availability of the Data API.	April 9, 2021
Amazon Aurora supports the Graviton2 DB instance classes	You can now use the Graviton2 DB instance classes db.r6g.x to create DB clusters running MySQL or PostgreSQL. For more information, see DB instance class types.	March 12, 2021

RDS Proxy endpoint enhancements	You can create additional endpoints associated with each RDS proxy. Creating an endpoint in a different VPC enables cross-VPC access for the proxy. Proxies for Aurora MySQL clusters can also have read-only endpoints. These reader endpoints connect to reader DB instances in the clusters and can improve read scalability and availability for query-intensive applications. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora user guide.	March 8, 2021
Amazon Aurora is available in the Asia Pacific (Osaka) Region	Amazon Aurora is now available in the Asia Pacific (Osaka) Region. For more information, see Regions and Availability Zones.	March 1, 2021
Aurora PostgreSQL supports enabling both IAM and Kerberos authentication on the same DB cluster	Aurora PostgreSQL now supports enabling both IAM authentication and Kerberos authentication on the same DB cluster. For more information, see Database authentication with Amazon Aurora.	February 24, 2021

Aurora global database now supports managed planned failover	Aurora global database now supports managed planned failover, allowing you to m ore easily change the primary Amazon Region of your Aurora global database. You can use managed planned failover with healthy Aurora global databases only. To learn more, see Disaster recovery and Amazon Aurora global databases. For reference information, see `FailoverGlobalClus ter` in the *Amazon RDS API Reference*.	February 11, 2021
Data API for Aurora Serverles s now supports more data types	With the Data API for Aurora Serverless, you can now use `UUID` and `JSON` data types as input to your database. Also with the Data API for Aurora Serverless, you can now have a `LONG` type value returned from your database as a `STRING` value. To learn more, see Calling the Data API. For reference information about supported data types, see `SqlParameter` in the *Amazon RDS Data Service API Reference*.	February 2, 2021

Aurora PostgreSQL supports major version upgrades to PostgreSQL 12	With Aurora PostgreSQL, you can now upgrade the DB engine to major version 12. For more information, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL.	January 28, 2021
Aurora MySQL supports in-place upgrade	You can upgrade your Aurora MySQL 1.x cluster to Aurora MySQL 2.x, preserving the DB instances, endpoints, and so on of the original cluster. This in-place upgrade technique avoids the inconvenience of setting up a whole new cluster by restoring a snapshot. It also avoids the overhead of copying all your table data into a new cluster. For more information, see Upgrading the major version of an Aurora MySQL DB cluster from 1.x to 2.x.	January 11, 2021
Amazon JDBC Driver for MySQL (preview)	The Amazon JDBC Driver for MySQL, now available in preview, is a client driver designed for the high availability of Aurora MySQL. For more information, see Connecting with the Amazon Web Services JDBC Driver for MySQL (preview).	January 7, 2021

Aurora supports database activity streams on secondary clusters of a global database	You can start a database a database activity stream on a primary or secondary clu ster of Aurora PostgreSQ L or Aurora MySQL. For supported engine versions, see Limitations of Aurora global databases.	December 22, 2020
Multi-master clusters with 4 DB instances	The maximum number of DB instances in an Aurora MySQL multi-master cluster is now four. Formerly, the maximum was two DB instances. For more information, see Working with Aurora Multi-Master Clusters.	December 17, 2020
Aurora PostgreSQL supports Amazon Lambda functions	You can now invoke Amazon Lambda function for your Aurora PostgreSQL DB clusters. For more informati on, see Invoking a Lambda function from an Aurora PostgreSQL DB cluster.	December 11, 2020
Amazon Aurora supports the Graviton2 DB instance classes in preview	You can now use the Graviton2 DB instance classes db.r6g.x in preview to create DB clusters running MySQL or PostgreSQL. For more information, see DB instance class types.	December 11, 2020

Amazon Aurora serverless is now available in preview.	Amazon Aurora serverless is available in preview. To work with Amazon Aurora serverless, apply for access. For more information, see the Aurora serverless page.	December 1, 2020

Aurora PostgreSQL is now available for Aurora Serverless in more Amazon Web Services Regions.	Aurora PostgreSQL is now available for Aurora Serverless in more Amazon Web Services Regions. You can now choose to run Aurora PostgreSQL Serverless v1 in the same Amazon Web Services Regions that offer Aurora MySQL Serverless v1. Additional Amazon Web Services Regions with Aurora Serverless support include US West (N. California), Asia Pacific (Singapore) Asia Pacific (Sydney) Asia Pacific (Seoul) Asia Pacific (Mumbai) Canada (Central) Europe (London) and Europe (Paris). For a list of all Regions and supported Aurora DB engines for Aurora Serverless, see Supported Regions and Aurora DB engines for Aurora Serverless v1. Amazon RDS Data API for Aurora Serverless is also now available in these same Amazon Web Services Regions. For a list of all Regions with support for the Data API for Aurora Serverless, see Data API with Aurora MySQL Serverless v1	November 24, 2020

Amazon RDS Performance Insights introduces new dimensions	You can group database load according to the dimension groups for database, application (PostgreSQL), and session type (PostgreSQL). Amazon RDS also supports the dimensions db.name, db.application.name (PostgreSQL), and db.session_type.name (PostgreSQL). For more information, see Top load table.	November 24, 2020
Aurora Serverless supports Aurora PostgreSQL version 10.12	Aurora PostgreSQL for Aurora Serverless has been upgraded to Aurora PostgreSQL version 10.12 throughout the Amazon Regions where Aurora PostgreSQL for Aurora Serverless is supported. For more information, see Supported Regions and Aurora DB engines for Aurora Serverless v1.	November 4, 2020
The Data API now supports tag-based authorization	The Data API supports tag-based authorization. If you've labeled your RDS cluster resources with tags, you can use these tags in your policy statements to control access through the Data API. For more information, see Authorizing access to the Data API.	October 27, 2020

Amazon Aurora extends support for exporting snapshots to Amazon S3	You can now export DB snapshot data to Amazon S3 in all commercial Amazon Web Services Regions. For more information, see Exporting DB snapshot data to Amazon S3.	October 22, 2020
Aurora global database supports cloning	You can now create clones of the primary and secondary DB clusters of your Aurora global databases. You can do so by using the Amazon Web Services Management Console and choosing the **Create clone** menu option. You can also use the Amazon CLI and run the `restore-db-cluster-to-point-in-time` command with the `--restore-type copy-on-write` option. Using the Amazon Web Services Management Console or the Amazon CLI, you can also clone DB clusters from your Aurora global databases across Amazon accounts. For more information about cloning, see Cloning an Aurora DB cluster volume.	October 19, 2020

Amazon Aurora supports dynamic resizing for the cluster volume	Starting with Aurora MySQL 1.23 and 2.09, and Aurora PostgreSQL 3.3.0 and Aurora PostgreSQL 2.6.0, Aurora reduces the size of the cluster volume after you remove data through operations such as DROP TABLE. To take advantage of this enhancement, upgrade to one of the appropriate versions depending on the database engine that your cluster uses. For information about this feature and how to check used and available storage space for an Aurora cluster, see Managing Performance and Scaling for Aurora DB Clusters.	October 13, 2020
Amazon Aurora supports volume sizes up to 128 TiB	New and existing Aurora cluster volumes can now grow to a maximum size of 128 tebibytes (TiB). For more information, see How Aurora storage grows.	September 22, 2020
Aurora PostgreSQL supports the db.r5 and db.t3 DB instance classes in the China (Ningxia) Region	You can now create Aurora PostgreSQL DB clusters in the China (Ningxia) Region that use the db.r5 and db.t3 DB instance classes. For more information, see DB instance classes.	September 3, 2020

Aurora parallel query enhancements	Starting with Aurora MySQL 2.09 and 1.23, you can take advantage of enhancements to the parallel query feature. Creating a parallel query cluster no longer requires a special engine mode. You can now turn parallel query on and off using the `aurora_parallel_query` configuration option for any provisioned cluster that's running a compatible Aurora MySQL version. You can upgrade an existing cluster to a compatible Aurora MySQL version and use parallel query, instead of creating a new cluster and importing data into it. You can use Performance Insights for parallel query clusters. You can stop and start parallel query clusters. You can create Aurora parallel query clusters that are compatible with MySQL 5.7. Parallel query works for tables that use the `DYNAMIC` row format. Parallel query clusters can use Amazon Identity and Access Management (IAM) authentication. Reader DB instances in parallel query clusters can take advantage of the `READ COMMITTED`	September 2, 2020

	isolation level. You can also now create parallel query clusters in additional Amazon Web Services Regions. For more information about the parallel query feature and these enhancements, see Parallel query for Aurora MySQL.	
Changes to Aurora MySQL parameter binlog_rows_query_log_events	You can now change the value of the Aurora MySQL configuration parameter `binlog_rows_query_log_events` . Formerly, this parameter wasn't modifiable.	August 26, 2020

Support for automatic minor version upgrades for Aurora MySQL	With Aurora MySQL, the setting **Enable auto minor version upgrade** now takes effect when you specify it for an Aurora MySQL DB cluster. When you enable auto minor version upgrade, Aurora automatically upgrades to new minor versions as they are released. The automatic upgrades occur during the maintenance window for the database. For Aurora MySQL, this feature applies only to Aurora MySQL version 2, which is compatible with MySQL 5.7. Initially, the automatic upgrade procedure brings Aurora MySQL DB clusters to version 2.07.2. For more information about how this feature works with Aurora MySQL, see Database Upgrades and Patches for Amazon Aurora MySQL.	August 3, 2020
Aurora PostgreSQL supports major version upgrades to PostgreSQL version 11	With Aurora PostgreSQL, you can now upgrade the DB engine to major version 11. For more information, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL.	July 28, 2020

Amazon Aurora supports Amazon PrivateLink	Amazon Aurora now supports creating Amazon VPC endpoints for Amazon RDS API calls to keep traffic between applications and Aurora in the Amazon network. For more information, see Amazon Aurora and interface VPC endpoints (Amazon PrivateLink).	July 9, 2020
RDS Proxy generally available	RDS Proxy is now generally available. You can use RDS Proxy with RDS for MySQL, Aurora MySQL, RDS for PostgreSQL, and Aurora PostgreSQL for production workloads. For more information about RDS Proxy, see "Managing Connections with Amazon RDS Proxy" in the Amazon RDS User Guide or the Aurora user guide.	June 30, 2020
Automatic plan capture for Aurora PostgreSQL	Performance Insights collects execution plans automatically. You can use these plans to diagnose SQL performance problems. For more information, see Accessing Execution Plans.	June 29, 2020

Aurora global database write forwarding	You can now enable write capability on secondary clusters in a global database. With write forwarding, you issue DML statements on a secondary cluster, Aurora forwards the write to the primary cluster, and the updated data is replicated to all the secondary clusters. For more information, see Write forwarding for secondary Amazon Web Services Regions with an Aurora global database.	June 18, 2020
Aurora supports integration with Amazon Backup	You can use Amazon Backup to manage backups of Aurora DB clusters. For more information, see Overview of backing up and restoring an Aurora DB cluster.	June 10, 2020
Aurora PostgreSQL supports db.t3.large DB instance classes	You can now create Aurora PostgreSQL DB clusters that use the db.t3.large DB instance classes. For more information, see DB instance classes.	June 5, 2020

Aurora global database supports PostgreSQL version 11.7 and managed recovery point objective (RPO)	You can now create Aurora global databases for the PostgreSQL database engine version 11.7. You can also manage how a PostgreSQL global database recovers from a failure using a recovery point objective (RPO). For more information, see Cross-Region Disaster Recovery for Aurora global databases.	June 4, 2020
Aurora MySQL supports database monitoring with database activity streams	Aurora MySQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see Using database activity streams.	June 2, 2020
The query editor available in additional Amazon Web Services Regions	The query editor for Aurora Serverless is now available in additional Amazon Web Services Regions. For more information, see Availability of the query editor.	May 28, 2020
The Data API available in additional Amazon Web Services Regions	The Data API is now available in additional Amazon Web Services Regions. For more information, see Availability of the Data API.	May 28, 2020

RDS Proxy available in Canada (Central) Region	You can now use the RDS Proxy preview in the Canada (Central) Region. For more information about RDS Proxy, see Managing connections with Amazon RDS proxy (preview).	May 28, 2020
Aurora global database and cross-Region read replicas	For an Aurora global database, you can now create an Aurora MySQL cross-Region read replica from the primary cluster in the same region as a secondary cluster. For more information about Aurora Global Database and cross-Region read replicas, see Working with Amazon Aurora global database and Replicating Amazon Aurora MySQL DB.	May 18, 2020
RDS Proxy available in more Amazon Web Services Regions	You can now use the RDS Proxy preview in the US West (N. California) Region, the Europe (London) Region, the Europe (Frankfurt) Region, the Asia Pacific (Seoul) Region, the Asia Pacific (Mumbai) Region, the Asia Pacific (Singapore) Region, and the Asia Pacific (Sydney) Region. For more information about RDS Proxy, see Managing connections with Amazon RDS proxy (preview).	May 13, 2020

Aurora PostgreSQL-Compatible Edition supports on-premises or self-hosted Microsoft active directory	You can now use an on-premises or self-hosted Active Directory for Kerberos authentication of users when they connect to your Aurora PostgreSQL DB clusters. For more information, see Using Kerberos authentication with Aurora PostgreSQL.	May 7, 2020
Aurora MySQL multi-master clusters available in more Amazon Web Services Regions	You can now create Aurora multi-master clusters in the Asia Pacific (Seoul) Region, the Asia Pacific (Tokyo) Region, the Asia Pacific (Mumbai) Region, and the Europe (Frankfurt) Region. For more information about multi-master clusters, see Working with Aurora multi-master clusters.	May 7, 2020
Performance Insights supports analyzing statistics of running Aurora MySQL queries	You can now analyze statistics of running queries with Performance Insights for Aurora MySQL DB instances. For more information, see Analyzing statistics of running queries.	May 5, 2020

Java client library for Data API generally available	The Java client library for the Data API is now generally available. You can download and use a Java client library for Data API. It enables you to map your client-side classes to requests and responses of the Data API. For more information, see Using the Java client library for Data API.	April 30, 2020
Amazon Aurora is available in the Europe (Milan) Region	Amazon Aurora is now available in the Europe (Milan) Region. For more information, see Regions and Availability Zones.	April 28, 2020
Amazon Aurora is available in the Europe (Milan) Region	Amazon Aurora is now available in the Europe (Milan) Region. For more information, see Regions and Availability Zones.	April 27, 2020
Amazon Aurora is available in the Africa (Cape Town) Region	Amazon Aurora is now available in the Africa (Cape Town) Region. For more information, see Regions and Availability Zones.	April 22, 2020

Aurora PostgreSQL now supports db.r5.16xlarge and db.r5.8xlarge DB instance classes	You can now create Aurora PostgreSQL DB clusters running PostgreSQL that use the db.r5.16xlarge and db.r5.8xlarge DB instance classes. For more informati on, see Hardware specifica tions for DB instance classes for Aurora.	April 8, 2020
Amazon RDS proxy for PostgreSQL	Amazon RDS Proxy is now available for PostgreSQL. You can use RDS Proxy to reduce the overhead of connection management on your cluster and also the chance of "too many connections" errors. The RDS Proxy is currently in public preview for PostgreSQ L. For more information, see Managing connections with Amazon RDS proxy (preview).	April 8, 2020
Aurora global databases now support Aurora PostgreSQL	You can now create Aurora global databases for the PostgreSQL database engine. An Aurora global database spans multiple Amazon Web Services Regions, enabling low latency global reads and disaster recovery from region-wide outages. For more information, see Working with Amazon Aurora global database.	March 10, 2020

Support for major version upgrades for Aurora PostgreSQL	With Aurora PostgreSQL, you can now upgrade the DB engine to a major version. By doing so, you can skip ahead to a newer major version when you upgrade select PostgreSQL engine versions. For more information, see Upgrading the PostgreSQL DB engine for Aurora PostgreSQL.	March 4, 2020
Aurora PostgreSQL supports Kerberos authentication	You can now use Kerberos authentication to authenticate users when they connect to your Aurora PostgreSQL DB clusters. For more information, see Using Kerberos authentication with Aurora PostgreSQL.	February 28, 2020
The Data API supports Amazon PrivateLink	The Data API now supports creating Amazon VPC endpoints for Data API calls to keep traffic between applications and the Data API in the Amazon network. For more information, see Creating an Amazon VPC endpoint (Amazon PrivateLink) for the Data API.	February 6, 2020

Aurora machine learning support in Aurora PostgreSQL	The aws_ml Aurora PostgreSQL extension provides functions you use in your database queries to call Amazon Comprehend for sentiment analysis and SageMaker AI to run your own machine learning models. For more information, see Using machine learning (ML) capabilities with Aurora.	February 5, 2020
Aurora PostgreSQL supports exporting data to Amazon S3	You can query data from an Aurora PostgreSQL DB cluster and export it directly into files stored in an Amazon S3 bucket. For more information, see Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3.	February 5, 2020
Support for exporting DB snapshot data to Amazon S3	Amazon Aurora supports exporting DB snapshot data to Amazon S3 for MySQL and PostgreSQL. For more information, see Exporting DB snapshot data to Amazon S3.	January 9, 2020

Aurora MySQL release notes in document history	This section now includes history entries for Aurora MySQL-Compatible Edition release notes for versions released after August 31, 2018. For the full release notes for a specific version, choose the link in the first column of the history entry.	December 13, 2019
Amazon RDS proxy	You can reduce the overhead of connection management on your cluster, and reduce the chance of "too many connections" errors, by using the Amazon RDS Proxy. You associate each proxy with an RDS DB instance or Aurora DB cluster. Then you use the proxy endpoint in the connection string for your application. The Amazon RDS Proxy is currently in a public preview state. It supports the Aurora MySQL database engine. For more informati on, see Managing connectio ns with Amazon RDS proxy (preview).	December 3, 2019

Data API for Aurora Serverless v1 supports data type mapping hints	You can now use a hint to instruct the Data API for Aurora Serverless v1 to send a `String` value to the database as a different type. For more information, see Calling the data API.	November 26, 2019
Data API for Aurora Serverless v1 supports a Java client library (preview)	You can download and use a Java client library for Data API. It enables you to map your client-side classes to requests and responses of the Data API. For more information, see Using the Java client library for Data API.	November 26, 2019
Aurora PostgreSQL is FedRAMP HIGH eligible	Aurora PostgreSQL is FedRAMP HIGH eligible. For details about Amazon and compliance efforts, see Amazon services in scope by compliance program.	November 26, 2019

READ COMMITTED isolation level enabled for Amazon Aurora MySQL replicas	You can now enable the `READ COMMITTED` isolation level on Aurora MySQL Replicas. Doing so requires enabling the `aurora_read_replica_read_committed_isolation_enabled` configuration setting at the session level. Using the `READ COMMITTED` isolation level for long-running queries on OLTP clusters can help address issues with history list length. Before enabling this setting, be sure to understand how the isolation behavior on Aurora Replicas differs from the usual MySQL implementation of `READ COMMITTED`. For more information, see Aurora MySQL isolation levels.	November 25, 2019
Performance Insights supports analyzing statistics of running Aurora PostgreSQL queries	You can now analyze statistics of running queries with Performance Insights for Aurora PostgreSQL DB instances. For more information, see Analyzing statistics of running queries.	November 25, 2019

More clusters in an Aurora global database	You can now add multiple secondary regions to an Aurora global database. You can take advantage of low latency global reads and disaster recovery across a wider geographic area. For more information about Aurora global databases, see Working with Amazon Aurora global databases.	November 25, 2019
Aurora machine learning support in Aurora MySQL	In Aurora MySQL 2.07 and higher, you can call Amazon Comprehend for sentiment analysis and SageMaker AI for a wide variety of machine learning algorithms. You use the results directly in your database application by embedding calls to stored functions in your queries. For more information, see Using machine learning (ML) capabilities with Aurora.	November 25, 2019

Aurora global database no longer requires engine mode setting	You no longer need to specify `--engine-mode=global` when creating a cluster that is intended to be part of an Aurora global database. All Aurora clusters that meet the compatibility requirements are eligible to be part of a gl obal database. For example, the cluster currently must use Aurora MySQL version 1 with MySQL 5.6 compatibility. For information about Aurora global databases, see Working with Amazon Aurora global databases.	November 25, 2019
Aurora global database is available for Aurora MySQL version 2	Starting in Aurora MySQL 2.07, you can create an Aurora global database with MySQL 5.7 compatibility. You don't need to specify the `global` engine mode for the primary or secondary clusters. You can add any new provisioned cluster with Aurora MySQL 2.07 or higher to an Aurora Global Database. For information about Aurora Global Database, see Working with Amazon Aurora global database.	November 25, 2019

Aurora MySQL hot row contention optimization available without lab mode	The hot row contention optimization is now generally available for Aurora MySQL and does not require the Aurora lab mode setting to be ON. This feature substantially improves throughput for workloads with many transactions contending for rows on the same page. The improvement involves changing the lock release algorithm used by Aurora MySQL.	November 19, 2019
Aurora MySQL hash joins available without lab mode	The hash join feature is now generally available for Aurora MySQL and does not require the Aurora lab mode setting to be ON. This feature can improve query performance when you need to join a large amount of data by using an equijoin. For more information about using this feature, see Working with hash joins in Aurora MySQL.	November 19, 2019
Aurora MySQL 2.* support for more db.r5 instance classes	Aurora MySQL clusters now support the instance types db.r5.8xlarge, db.r5.16xlarge, and db.r5.24xlarge. For more information about instance types for Aurora MySQL clusters, see Choosing the DB instance class.	November 19, 2019

Aurora MySQL 2.* support for backtracking	Aurora MySQL 2.* versions now offer a quick way to recover from user errors, such as dropping the wrong table or deleting the wrong row. Backtrack allows you to move your database to a prior point in time without needing to restore from a backup, and it completes within seconds, even for large databases. For details, see Backtracking an Aurora DB cluster.	November 19, 2019
Billing tag support for Aurora	You can now use tags to keep track of cost allocation for resources such as Aurora clusters, DB instances within Aurora clusters, I/O, backups, snapshots, and so on. You can see costs associated with each tag using Amazon Cost Explorer. For more informati on about using tags with Aurora, see Tagging Amazon RDS resources. For general information about tags and ways to use them for cost analysis, see Using cost allocation tags and User-defi ned cost allocation tags.	October 23, 2019

Data API for Aurora PostgreSQL	Aurora PostgreSQL now supports using the Data API with Amazon Aurora Serverless v1 DB clusters. For more information, see Using the Data API for Aurora Serverless v1.	September 23, 2019
Aurora PostgreSQL supports uploading database logs to CloudWatch Logs	You can configure your Aurora PostgreSQL DB cluster to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage. For more information, see Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs.	August 9, 2019
Multi-master clusters for Aurora MySQL	You can set up Aurora MySQL multi-master clusters. In these clusters, each DB instance has read/write capability. For more information, see Working with Aurora multi-master clusters.	August 8, 2019

Aurora PostgreSQL supports Aurora Serverless v1	You can now use Amazon Aurora Serverless v1 with Aurora PostgreSQL. An Aurora Serverless DB cluster automatically starts up, shuts down, and scales up or down its compute capacity based on your application's needs. For more information, see Using Amazon Aurora Serverless v1.	July 9, 2019
Cross-account cloning for Aurora MySQL	You can now clone the cluster volume for an Aurora MySQL DB cluster between Amazon accounts. You authorize the sharing through Amazon Resource Access Manager (Amazon RAM). The cloned cluster volume uses a copy-on-write mechanism, which only requires additional storage for new or changed data. For more information about cloning for Aurora, see Cloning databases in an Aurora DB cluster.	July 2, 2019
Aurora PostgreSQL supports db.t3 DB instance classes	You can now create Aurora PostgreSQL DB clusters that use the db.t3 DB instance classes. For more information, see DB instance class.	June 20, 2019

Support for importing data from Amazon S3 for Aurora PostgreSQL	You can now import data from an Amazon S3 file into a table in an Aurora PostgreSQL DB cluster. For more informati on, see Importing Amazon S3 data into an Aurora PostgreSQL DB cluster.	June 19, 2019
Aurora PostgreSQL now provides fast failover recovery with cluster cache management	Aurora PostgreSQL now provides cluster cache management to ensure fast recovery of the primary DB instance in the event of a failover. For more informati on, see Fast recovery after failover with cluster cache management.	June 11, 2019
Data API for Aurora Serverless v1 generally available	You can access Aurora Serverless v1 clusters with web services-based applicati ons using the Data API. For more information, see Using the Data API for Aurora Serv erless v1.	May 30, 2019
Aurora PostgreSQL supports database monitoring with database activity streams	Aurora PostgreSQL now includes database activity streams, which provide a near-real-time data stream of the database activity in your relational database. For more information, see Using database activity streams.	May 30, 2019

Amazon Aurora recommendations	Amazon Aurora now provides automated recommendations for Aurora resources. For more information, see Using Amazon Aurora recommendations.	May 22, 2019
Performance Insights support for Aurora global database	You can now use Performance Insights with Aurora Global Database. For information about Performance Insights for Aurora, see Using Amazon RDS performance insights. For information about Aurora global databases, see Working with Aurora global database.	May 13, 2019
Performance Insights is available for Aurora MySQL 5.7	Amazon RDS Performance Insights is now available for Aurora MySQL 2.x versions, which are compatible with MySQL 5.7. For more information, see Using Amazon RDS performance insights.	May 3, 2019
Aurora global databases available in more Amazon Web Services Regions	You can now create Aurora global databases in most Amazon Web Services Regions where Aurora is available. For information about Aurora global databases, see Working with Amazon Aurora global databases.	April 30, 2019

Minimum capacity of 1 for Aurora Serverless v1	The minimum capacity setting you can use for an Aurora Serverless v1 cluster is 1. Formerly, the minimum was 2. For information about specifying Aurora Serverless capacity values, see Setting the capacity of an Aurora Serverless v1 DB cluster.	April 29, 2019
Aurora Serverless v1 timeout action	You can now specify the action to take when an Aurora Serverless v1 capacity change times out. For more information, see Timeout action for capacity changes.	April 29, 2019
Per-second billing	Amazon RDS is now billed in 1-second increments in all Amazon Web Services Regions except Amazon GovCloud (US) for on-demand instances. For more information, see DB instance billing for Aurora.	April 25, 2019
Sharing Aurora Serverless v1 snapshots across Amazon Web Services Regions	With Aurora Serverless v1, snapshots are always encrypted. If you encrypt the snapshot with your own Amazon KMS key, you can now copy or share the snapshot across Amazon Web Services Regions. For information about snapshots of Aurora Serverless v1 DB clusters, see Aurora Serverless v1 and snapshots.	April 17, 2019

Restore MySQL 5.7 backups from Amazon S3	You can now create a backup of your MySQL version 5.7 database, store it on Amazon S3, and then restore the backup file onto a new Aurora MySQL DB cluster. For more information, see Migrating data from an external MySQL database to an Aurora MySQL DB cluster.	April 17, 2019
Sharing Aurora Serverless v1 snapshots across regions	With Aurora Serverless v1, snapshots are always encrypted. If you encrypt the snapshot with your own Amazon KMS key, you can now copy or share the snapshot across regions. For information about snapshots of Aurora Serverless v1 DB clusters, see Aurora Serverless and snapshots.	April 16, 2019
Aurora proof-of-concept tutorial	You can learn how to perform a proof of concept to try your application and workload with Aurora. For the full tutorial, see Performing an Aurora proof of concept.	April 16, 2019
Aurora Serverless v1 supports restoring from an Amazon S3 backup	You can now import backups from Amazon S3 to an Aurora Serverless cluster. For details about that procedure, see Migrating data from MySQL by using an Amazon S3 bucket.	April 16, 2019

New modifiable parameters for Aurora Serverless v1	You can now modify the following DB parameters for an Aurora Serverless v1 cluster: `innodb_file_format`, `innodb_file_per_table`, `innodb_large_prefix`, `innodb_lock_wait_timeout`, `innodb_monitor_disable`, `innodb_monitor_enable`, `innodb_monitor_reset`, `innodb_monitor_reset_all`, `innodb_print_all_deadlocks`, `log_warnings`, `net_read_timeout`, `net_retry_count`, `net_write_timeout`, `sql_mode`, and `tx_isolation`. For more information about configuration parameters for Aurora Serverless v1 clusters, see Aurora Serverless v1 and parameter groups.	April 4, 2019
Aurora PostgreSQL supports db.r5 DB instance classes	You can now create Aurora PostgreSQL DB clusters that use the db.r5 DB instance classes. For more information, see DB instance class.	April 4, 2019

Aurora PostgreSQL logical replication	You can now use PostgreSQL logical replication to replicate parts of a database for an Aurora PostgreSQL DB cluster. For more information, see Using PostgreSQL logical replication.	March 28, 2019
GTID support for Aurora MySQL 2.04	You can now use replicati on with the global transacti on ID (GTID) feature of MySQL 5.7. This feature simplifies performing binary log (binlog) replication b etween Aurora MySQL and an external MySQL 5.7-compa tible database. The replicati on can use the Aurora MySQL cluster as the source or the destination. This feature is available for Aurora MySQL 2.04 and higher. For more information about GTID-based replication and Aurora MySQL, see Using GTID-based replication for Aurora MySQL.	March 25, 2019

Uploading Aurora Serverless v1 logs to Amazon CloudWatch	You can now have Aurora upload database logs to CloudWatch for an Aurora Serverless v1 cluster. For more information, see Viewing Aurora Serverless DB clusters. As part of this enhancement, you can now define values for instance-level parameters in a DB cluster parameter group, and those values apply to all DB instances in the cluster unless you override them in the DB parameter group. For more information, see Working with DB parameter groups and DB cluster parameter groups.	February 25, 2019
Aurora MySQL supports db.t3 DB instance classes	You can now create Aurora MySQL DB clusters that use the db.t3 DB instance classes. For more information, see DB instance class.	February 25, 2019
Aurora MySQL supports db.r5 DB instance classes	You can now create Aurora MySQL DB clusters that use the db.r5 DB instance classes. For more information, see DB instance class.	February 25, 2019

Performance Insights counters for Aurora MySQL	You can now add performance counters to your Performance Insights charts for Aurora MySQL DB instances. For more information, see Performance Insights dashboard components.	February 19, 2019
Amazon RDS Performance Insights supports viewing more SQL text for Aurora MySQL	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Aurora MySQL DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	February 6, 2019
Amazon RDS Performance Insights supports viewing more SQL text for Aurora PostgreSQL	Amazon RDS Performance Insights now supports viewing more SQL text in the Performance Insights dashboard for Aurora PostgreSQL DB instances. For more information, see Viewing more SQL text in the Performance Insights dashboard.	January 24, 2019

Aurora backup billing	You can use the Amazon CloudWatch metrics `TotalBackupStorageBilled` , `SnapshotStorageUsed` , and `BackupRetentionPeriodStorageUsed` to monitor the space usage of your Aurora backups. For more information about how to use CloudWatch metrics, see Overview of monitoring. For more information about how to manage storage for backup data, see Understanding Aurora backup storage usage.	January 3, 2019
Performance Insights counters	You can now add performance counters to your Performance Insights charts. For more information, see Performance Insights dashboard components.	December 6, 2018
Aurora global database	You can now create Aurora global databases. An Aurora global database spans multiple Amazon Web Services Regions, enabling low latency global reads and disaster recovery from region-wide outages. For more information, see Working with Amazon Aurora global database.	November 28, 2018

Query plan management in Aurora PostgreSQL	Aurora PostgreSQL now provides query plan management that you can use to manage PostgreSQL query execution plans. For more information, see Managing query execution plans for Aurora PostgreSQL.	November 20, 2018
Query editor for Aurora Serverless v1 (beta)	You can run SQL statements in the Amazon RDS console on Aurora Serverless v1 clusters. For more information, see Using the query editor for Aurora Serverless v1.	November 20, 2018
Data API for Aurora Serverless v1 (beta)	You can access Aurora Serverless v1 clusters with web services-based applications using the Data API. For more information, see Using the Data API for Aurora Serverless.	November 20, 2018
TLS support for Aurora Serverless v1	Aurora Serverless v1 clusters support TLS/SSL encryption. For more information, see TLS/SSL for Aurora Serverless.	November 19, 2018

Custom endpoints	You can now create endpoints that are associated with an arbitrary set of DB instances. This feature helps with load balancing and high availabil ity for Aurora clusters where some DB instances have different capacity or configura tion than others. You can use custom endpoints instead of connecting to a specific DB i nstance through its instance endpoint. For more informati on, see Amazon Aurora endpoints.	November 12, 2018
IAM authentication support in Aurora PostgreSQL	Aurora PostgreSQL now supports IAM authentication. For more information see IAM database authentication.	November 8, 2018
Custom parameter groups for restore and point in time recovery	You can now specify a custom parameter group when you restore a snapshot or perform a point in time recovery operation. For more informati on, see Restoring from a DB cluster snapshot and Restoring a DB cluster to a specified time.	October 15, 2018
Deletion protection for Aurora DB clusters	When you enable deletion protection for a DB cluster, the database cannot be d eleted by any user. For more information, see Deleting a DB cluster.	September 26, 2018

Stop/Start feature Aurora	You can now stop or start an entire Aurora cluster with a single operation. For more information, see Stopping and starting an Aurora cluster.	September 24, 2018
Parallel query feature for Aurora MySQL	Aurora MySQL now offers an option to parallelize I/O work for queries across the Aurora storage infrastructure. This feature speeds up data-inte nsive analytic queries, which are often the most time-consuming operations in a workload. For more informati on, see Parallel query for Aurora MySQL.	September 20, 2018
New guide	This is the first release of the *Amazon Aurora User Guide.*	August 31, 2018

Amazon Glossary

For the latest Amazon terminology, see the Amazon glossary in the *Amazon Web Services Glossary Reference*.
