For more control over detection behavior, you can define log pattern rules with configurable timeouts and actions. Custom rules let you detect domain-specific stalls (for example, no new training-step log line for 10 minutes) or error conditions (for example, OOM) and choose whether HyperPod should notify or automatically cancel the hung worker.

Follow these steps to enable custom detection rules.

1. **Add the host IP environment variable to your RayCluster manifest**

   Add the following environment variable to both `headGroupSpec` and `workerGroupSpecs` in your RayCluster YAML. This allows the Python library running inside the training container to communicate with the job monitoring service on the host.

```
spec:
  headGroupSpec:
    template:
      spec:
        containers:
        - name: ray-head
          env:
          - name: HYPERPOD_JMA_HOST
            valueFrom:
              fieldRef:
                fieldPath: status.hostIP
  workerGroupSpecs:
  - template:
      spec:
        containers:
        - name: ray-worker
```

```
          env:
          - name: HYPERPOD_JMA_HOST
            valueFrom:
              fieldRef:
                fieldPath: status.hostIP
```

> **Note**
>
> This environment variable is only required for custom detection rules. Default detection works without it.

2. **Install the toolkit library in your training container image**

   Add the toolkit-for-ray-on-sagemaker-ai package from the PyPI website to your training container image. The library is preinstalled in SageMaker Distribution images.

```
pip install toolkit-for-ray-on-sagemaker-ai
```

3. **Add monitoring to your training function**

   Call `SageMakerLogMonitoring.start()` inside your training function *before* doing any meaningful work. This ensures monitoring is active from the start of training and can detect hangs that occur during model loading or the first forward pass.

```
from toolkit_for_ray_on_sagemaker_ai.log_monitoring import (
    SageMakerLogMonitoring,
    LogMonitorConfig,
)
from ray.train import RunConfig, FailureConfig, ScalingConfig
from ray.train.torch import TorchTrainer

def train_func():
    # Start monitoring BEFORE any meaningful work
    SageMakerLogMonitoring(config=LogMonitorConfig(
        enabled=True,
        rules=[
            {
                "name": "training_progress",
                "type": "log_pattern",
                "enabled": True,
                "log_pattern": "(Epoch|Step|Iteration) \\d+",
```

```
                "timeout_minutes": 10,
                "start_timeout_minutes": 30,
                "stop_pattern": "Training complete",
                "fault_on_match": False,
            },
            {
                "name": "oom_detection",
                "type": "log_pattern",
                "enabled": True,
                "log_pattern": "CUDA out of memory|OutOfMemoryError|OOM",
                "fault_on_match": True,
            },
        ],
        action="cancel",
    )).start()

    # ... your training loop
    for epoch in range(num_epochs):
        print(f"Epoch {epoch}")  # This output is what the rule monitors
        train_one_epoch(model, dataloader)

    print("Training complete")  # Matches stop_pattern, deactivates the rule

# Configure FailureConfig so Ray Train automatically restarts all workers
# when the cancel action terminates a hung worker.
trainer = TorchTrainer(
    train_func,
    scaling_config=ScalingConfig(num_workers=4, use_gpu=True),
    run_config=RunConfig(
        failure_config=FailureConfig(max_failures=3),
    ),
)
```

When the `cancel` action terminates a hung worker, Ray Train's FailureConfig in the Ray documentation detects the worker failure and restarts all workers from the last checkpoint. Set `max_failures` to the number of automatic recovery attempts you want before the job fails permanently. Without `FailureConfig`, a single worker termination fails the entire job.

Because Ray Train restores from the last saved checkpoint on restart, no training progress is lost beyond the work since the most recent checkpoint. If your training code saves checkpoints periodically (for example, at each epoch boundary), the job resumes from the last saved state automatically.

Rule fields

Field	Type	Required	Description
`name`	string	Yes	Human-readable identifier for the rule.
`type`	string	Yes	Rule type. Use `log_pattern` for log-based detection.
`enabled`	bool	No	Whether this rule is active. Defaults to `false`.
`log_pattern`	string	Yes	Regex pattern to match in worker stdout (RE2 syntax, max 256 characters).
`timeout_minutes`	float	No	Maximum minutes between consecutive pattern matches before declaring a hang.
`start_timeout_minutes`	float	No	Maximum minutes from job start for the first pattern match. Useful for allowing startup time (model loading, data download). If the pattern has not appeared within this window, the job is considered hung.
`stop_pattern`	string	No	Regex that deactivates this rule when matched (for example, `"Training complete"`).
`fault_on_match`	bool	No	If `true`, declares a hang immediately when the pattern matches. Use for error patterns like OOM. When `true`, `timeout_minutes` is not required.
`metric_evaluation_data_points`	int	No	Number of consecutive evaluation cycles that must confirm the condition before declaring a hang. Defaults to 1.

Detection actions

Action	Description
`notify`	Emit a detection event to CloudWatch and Grafana but take no automatic action. This is the default.
`cancel`	Terminate the hung worker process. Ray Train's built-in `FailureConfig` restarts all workers from the last checkpoint. To use this action, configure `FailureConfig` with sufficient retries in your `RunConfig`.

Opting out of detection

To disable all hung job detection for a specific job, including both default detection and any custom rules:

```
from toolkit_for_ray_on_sagemaker_ai.log_monitoring import (
    SageMakerLogMonitoring,
    LogMonitorConfig,
)

def train_func():
    SageMakerLogMonitoring(config=LogMonitorConfig(enabled=False)).start()
    # ... training continues with no monitoring
```

Viewing detection events

When a hung job is detected, the event appears in the following locations:

- **CloudWatch Logs**: Log group `/aws/sagemaker/Clusters/`*`cluster-name`*`/`*`cluster-id`*, log stream `SageMakerHangJobDetectionEvents/`*`instance-group-name`*`/`*`instance-id`*. Search for `HANG_DETECTED` to find detection events.
- **Grafana**: If the HyperPod Observability add-on is installed, detection events appear in the Ray Train dashboard under the Hung job detection panel. For more information, see the section called “Observability”.

Each detection event includes the job ID, the evidence that triggered the detection, and the action taken (`notify` or `cancel`).

Queueing with task governance

SageMaker HyperPod task governance streamlines resource allocation and keeps compute used efficiently across teams and projects on your Amazon EKS clusters. Administrators set priority levels for tasks, compute allocation for each team, how teams lend and borrow idle compute, and whether a team preempts its own tasks.

Task Governance holds a workload until the team compute allocation has room, then starts the head and workers together.

For the general concepts and the console setup, see the section called “Task governance”.

Topics

- Setting up task governance for Ray
- Quota and scheduling behavior for Ray workloads

Setting up task governance for Ray

Set up Task Governance on your cluster first, then complete the Ray-specific steps on this page. For the concepts and the console setup, see the section called “Setup”.

Namespaces that need a compute allocation

Task Governance admits a Ray workload only in a namespace that has a compute allocation. Create an allocation for every namespace where you create Ray workloads. A workload in a namespace with no allocation stays pending and is never admitted. For the console steps, see the section called “Policies”.

Gang scheduling

Confirm that gang scheduling is enabled for your cluster. A Ray cluster needs its head and all of its workers running together, so without gang scheduling a partially scheduled cluster holds capacity without making progress. Task Governance implements gang scheduling with the Kueue `waitForPodsReady` feature, which evicts and requeues a workload whose pods do not all become ready within the configured timeout. For the configuration settings, see the section called “Gang scheduling”.

Verify

Create a small `RayCluster` in an allocated namespace and confirm it reaches a running state. If it stays pending, confirm the namespace has a compute allocation with room for the declared cluster size.

Quota and scheduling behavior for Ray workloads

Task Governance accounts quota at `RayCluster` granularity. A cluster reserves quota for its full declared size when it is admitted, and holds that quota for its whole lifetime regardless of load. A long-lived cluster that sits idle still counts against your team quota until you delete it.

Gang scheduling

Task Governance admits the head and all workers together. A `RayCluster` is not admitted until quota exists for the entire declared size, so a partially scheduled cluster never starts.

Preemption

When higher-priority work needs capacity, Task Governance preempts a lower-priority Ray workload. Preemption deletes the whole cluster, including the head.

Accelerated inference with Ray Serve

Ray Serve is the open source model-serving library for Ray. You deploy a model as a Serve application, and Ray Serve handles request routing, batching, and replica scaling. On HyperPod, Ray Serve runs on KubeRay through a `RayService` resource, so your Serve code and deployment graph are unchanged.

Requirements

Ray Serve on HyperPod requires only the KubeRay operator. KubeRay reconciles the `RayService` resource, creates the Ray cluster that backs it, and manages the Serve applications on it. For more information, see the section called “Installing KubeRay”.

You do not install a separate inference operator to serve models with Ray Serve. The JumpStart deployment path additionally uses the `toolkit-for-ray-on-sagemaker-ai` library, which you install with `pip`.

What you can do

- Deploy a model from your own code as a `RayService` and reach it over HTTP.

- Deploy an JumpStart model into a Ray Serve deployment.
- Lower time to first token for long-context and multi-turn workloads with a managed tiered KV cache and prefix-aware routing.
- Scale serving replicas within the cluster, and scale cluster capacity with managed Karpenter.

For the Ray Serve API and deployment concepts, see Ray Serve: Scalable and Programmable Serving in the Ray documentation.

Topics

- Deploying a model with Ray Serve
- Deploying a JumpStart model with Ray Serve
- Managed tiered KV cache and routing
- Setting up tiered KV cache
- Autoscaling serving capacity

Deploying a model with Ray Serve

You deploy a model with a `RayService` resource. The `serveConfigV2` field holds your Serve applications and their deployments, and KubeRay creates the Ray cluster that runs them. HyperPod does not modify KubeRay, so a `RayService` you already run continues to work.

A RayService manifest

The following manifest runs one Serve application with a single GPU-backed deployment. Replace `import_path` with the module and application object in your working directory.

```
apiVersion: ray.io/v1
kind: RayService
metadata:
  name: my-service
  namespace: my-namespace
spec:
  serveConfigV2: |
    applications:
      - name: my-app
        import_path: my_module:app
        route_prefix: /
```

```
        deployments:
          - name: Model
            num_replicas: 2
            ray_actor_options:
              num_gpus: 1
  rayClusterConfig:
    rayVersion: "2.56.1"
    headGroupSpec:
      rayStartParams:
        dashboard-host: "0.0.0.0"
      template:
        spec:
          containers:
            - name: ray-head
              image: rayproject/ray:2.56.1
              ports:
                - { containerPort: 8265, name: dashboard }
                - { containerPort: 8000, name: serve }
    workerGroupSpecs:
      - groupName: gpu-workers
        replicas: 1
        rayStartParams: {}
        template:
          spec:
            nodeSelector:
              node.kubernetes.io/instance-type: ml.g5.xlarge
            containers:
              - name: ray-worker
                image: rayproject/ray:2.56.1-gpu
                resources:
                  limits: { nvidia.com/gpu: "1" }
                  requests: { cpu: "4", memory: "16Gi", nvidia.com/gpu: "1" }
```

Apply and confirm the service is ready:

```
kubectl apply -f my-service.yaml -n my-namespace
kubectl get rayservice my-service -n my-namespace
```

Reaching the endpoint

Ray Serve listens on port `8000` on the head pod. From inside the cluster, send requests to the service that KubeRay creates for the `RayService`. For quick testing, you can use `kubectl port-forward`:

```
kubectl port-forward svc/ray-service-head-svc 8000:8000
curl http://localhost:8000/
```

For the Serve deployment API and request handling, see Ray Serve API in the Ray documentation.

Deploying a JumpStart model with Ray Serve

You can deploy JumpStart models into Ray Serve on HyperPod without manually downloading model weights, writing model-loading code, or configuring a serving container. The toolkit-for-ray-on-sagemaker-ai library on the PyPI website provides a `JumpStartModelLoaderCallback` that integrates with Ray Serve's LLM API to handle model artifact download from JumpStart at deployment time.

Prerequisites

Before you begin, make sure that you have the following:

- A running Ray cluster or a `RayService` you deploy in the following steps. For more information, see the section called “Deploy a model”.
- The KubeRay operator installed. For more information, see the section called “Installing KubeRay”.
- The Amazon EKS Pod Identity Agent add-on installed on your cluster. For more information, see Set up the EKS Pod Identity Agent in the *Amazon EKS User Guide*.

Configure IAM permissions

The `JumpStartModelLoaderCallback` calls the SageMaker AI API to retrieve presigned URLs for downloading model artifacts. Your Ray Serve pods need an IAM role with the following permissions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sagemaker:CreateHubContentPresignedUrls",
      "Resource": "*"
    }
  ]
```

```
}
```

Create a Pod Identity association that maps a Kubernetes service account to this IAM role. For more information, see Configuring a Kubernetes service account to assume an IAM role with EKS Pod Identity in the *Amazon EKS User Guide*.

```
aws eks create-pod-identity-association \
  --cluster-name eks-cluster-name \
  --namespace namespace \
  --service-account jumpstart-ray-serve \
  --role-arn arn:aws:iam::account-id:role/role-name
```

Reference this service account in your `RayService` manifest using the `serviceAccountName` field (shown in the following example).

Deploy the model

The following example deploys a JumpStart model using Ray Serve's `LLMConfig` with the `JumpStartModelLoaderCallback`. The callback downloads model artifacts from JumpStart using presigned URLs when the serve replica starts and loads them into the serving engine (vLLM), exposing an OpenAI-compatible API.

```
from ray.serve.llm import LLMConfig, build_openai_app
from ray.llm._internal.common.callbacks.base import CallbackConfig
from toolkit_for_ray_on_sagemaker_ai import JumpStartModelLoaderCallback

llm_config = LLMConfig(
    model_loading_config={
        "model_id": "my-llm",
        "model_source": "placeholder",
    },
    callback_config=CallbackConfig(
        callback_class=JumpStartModelLoaderCallback,
        callback_kwargs={
            "jumpstart_model_id": "huggingface-reasoning-qwen3-4b",
            "region": "us-east-1",
            "accept_eula": False,  # Set to True after reviewing the model's EULA
        },
    ),
    accelerator_type="A10G",
)
```

```
app = build_openai_app({"llm_configs": [llm_config]})
```

Reference app from the `import_path` in your `RayService` manifest, then deploy it as described in the section called “Deploy a model”. Make sure both `headGroupSpec` and `workerGroupSpecs` set `serviceAccountName` to the service account associated with the IAM role created in the previous step.

> **Note**
>
> For information about model licensing and EULA requirements, see Choose a foundation model.

Reaching the endpoint

The deployment exposes an OpenAI-compatible chat completions API on port 8000 through the KubeRay service created for the `RayService`. For quick testing, use `kubectl port-forward`:

```
kubectl port-forward svc/ray-service-head-svc 8000:8000
```

Then send requests to `http://localhost:8000`:

```
curl http://localhost:8000/v1/chat/completions \
  -H "Content-Type: application/json" \
  -d '{
    "model": "my-llm",
    "messages": [{"role": "user", "content": "What is Ray Serve?"}]
  }'
```

Managed tiered KV cache and routing

Large language model serving spends compute rebuilding the key-value (KV) cache for tokens it has already processed. HyperPod adds a managed two-tier KV cache and prefix-aware routing to Ray Serve, which cut redundant recomputation and lower time to first token for long-context and multi-turn workloads.

How the tiered cache works

The cache has two tiers:

- A **local tier** in the memory of the node serving the request, for the fastest reuse.
- A **cluster-wide tier** on HyperPod Tiered Storage, a pooled memory tier that spans cluster nodes. A replica reads a prefix computed by another replica instead of recomputing it.

When a request shares a token prefix with earlier work, the deployment reads the cached KV state from the local tier, then the cluster-wide tier, before recomputing anything.

Prefix-aware routing

Prefix-aware routing sends a request to a replica that already holds the KV cache for its prefix. Multi-turn conversations and shared system prompts route to the same replica, so the cache hit rate stays high and time to first token drops.

Prerequisite

The cluster-wide tier runs on HyperPod Tiered Storage, so set up Tiered Storage on the cluster before you turn on the cluster-wide cache. For more information, see the section called “Setting up tiered KV cache”.

Setting up tiered KV cache

The managed tiered KV cache adds a cluster-wide cache tier to Ray Serve deployments, so one replica reads a token prefix that another replica already computed. This reduces time to first token for long documents, multi-turn conversations, and shared system prompts. The cluster-wide tier runs on HyperPod Tiered Storage using LMCache with the HyperPod storage backend in the LMCache documentation, which integrates with Ray Serve and vLLM to provide distributed KV caching backed by HyperPod Tiered Storage.

The cache has two tiers:

- A **local tier** in the memory of the node serving the request, for the fastest reuse.
- A **cluster-wide tier** on HyperPod Tiered Storage, a pooled memory tier that spans cluster nodes. A replica reads a prefix computed by another replica instead of recomputing it.

When a request shares a token prefix with earlier work, the deployment reads the cached KV state from the local tier, then the cluster-wide tier, before recomputing anything.

Prerequisites

- A HyperPod cluster orchestrated by Amazon EKS, with the KubeRay operator installed.

- HyperPod Tiered Storage enabled on the cluster. For setup instructions, see Setting up managed tiered checkpointing.

Configure your RayCluster

Add the following to your worker group spec to expose the Tiered Storage endpoint and shared memory to the Ray Serve replicas.

```
workerGroupSpecs:
- template:
    spec:
      volumes:
        - name: host-shm
          hostPath:
            path: /dev/shm
      containers:
      - name: ray-worker
        env:
          - name: NODE_IP
            valueFrom:
              fieldRef:
                fieldPath: status.hostIP
        volumeMounts:
          - name: host-shm
            mountPath: /dev/shm/ai_toolkit_cache
            subPath: ai_toolkit_cache
```

The `NODE_IP` environment variable provides the host IP address so the LMCache client can connect to the Tiered Storage service on port 9200. The shared memory volume mount enables the CPU offloading path for local KV cache.

Configure your Ray Serve application

Use the `LLMConfig` API with the LMCache connector to enable KV caching in your Ray Serve deployment. The following example serves a model with tiered KV caching enabled:

```
from ray.serve.llm import LLMConfig, build_openai_app

llm_config = LLMConfig(
    model_loading_config={
        "model_id": "my-llm",
```

```
        "model_source": "Qwen/Qwen-7B-Chat",
    },
    engine_kwargs={
        "trust_remote_code": True,
        "kv_transfer_config": {
            "kv_connector": "LMCacheConnectorV1",
            "kv_role": "kv_both",
        },
    },
    runtime_env={
        "env_vars": {
            "LMCACHE_REMOTE_URL": "sagemaker-hyperpod://$(NODE_IP):9200",
            "LMCACHE_EXTRA_CONFIG": '{"sagemaker_hyperpod_bucket": "lmcache",
 "sagemaker_hyperpod_shared_memory_name": "ai_toolkit_cache"}',
            "LMCACHE_CHUNK_SIZE": "256",
        },
    },
    accelerator_type="A10G",
)

app = build_openai_app({"llm_configs": [llm_config]})
```

The key configuration values are:

- `kv_connector`: Set to `LMCacheConnectorV1` to enable the LMCache integration with vLLM.
- `kv_role`: Set to `kv_both` so each replica both reads from and writes to the shared cache.
- `LMCACHE_REMOTE_URL`: The Tiered Storage endpoint on the local node. Uses the `NODE_IP` environment variable configured in the RayCluster manifest.
- `LMCACHE_CHUNK_SIZE`: The number of tokens per cache chunk. Smaller values increase cache hit rate for shared prefixes at the cost of more cache entries.

Enable CPU offloading (optional)

To add a local CPU memory tier that caches KV entries before they are written to Tiered Storage, add the following environment variables to `runtime_env`:

```
"env_vars": {
    "LMCACHE_REMOTE_URL": "sagemaker-hyperpod://$(NODE_IP):9200",
    "LMCACHE_EXTRA_CONFIG": '{"sagemaker_hyperpod_bucket": "lmcache",
 "sagemaker_hyperpod_shared_memory_name": "ai_toolkit_cache"}',
    "LMCACHE_CHUNK_SIZE": "256",
```

```
    "LMCACHE_LOCAL_CPU": "True",
    "LMCACHE_MAX_LOCAL_CPU_SIZE": "100",
}
```

When CPU offloading is enabled, KV cache entries are stored in CPU memory on the local node before being written to the cluster-wide Tiered Storage. This provides faster cache reads for replicas on the same node.

Autoscaling serving capacity

Serving capacity scales at two levels on HyperPod. Ray Serve scales replicas inside the cluster to match request load, and managed Karpenter scales cluster nodes to hold those replicas. The two work together: replica autoscaling reacts first, and node autoscaling adds capacity when the existing nodes run out.

Ray Serve replica autoscaling

Ray Serve adjusts the number of replicas for a deployment based on request load. Set an autoscaling configuration on the deployment instead of a fixed replica count:

```
deployments:
  - name: Model
    autoscaling_config:
      min_replicas: 1
      max_replicas: 8
      target_ongoing_requests: 5
```

For replica autoscaling to add and remove worker pods, the Ray autoscaler must be turned on for the cluster. Set `enableInTreeAutoscaling: true` in the `RayCluster` spec, or in the `rayClusterConfig` of a `RayService`:

```
spec:
  enableInTreeAutoscaling: true
```

Without it, the deployment's `autoscaling_config` changes the target replica count, but KubeRay does not create the worker pods to meet it.

Replica autoscaling stays within the cluster's current node capacity. When Ray Serve needs more replicas than the nodes can hold, the pods stay pending until a node is available.

Node autoscaling with managed Karpenter

Managed Karpenter on HyperPod adds nodes when Ray pods are pending and removes them when they are idle, so serving capacity follows demand without a fixed node pool. Spot Instances are supported for node capacity, which lowers cost for interruption-tolerant serving. For the setup and configuration, see the section called “Autoscaling on HyperPod EKS”.

Using both together

Set replica autoscaling on the deployment and node autoscaling on the cluster. The two levels work together in a chain that responds to increasing request load:

1. **Ray Serve detects load increase.** The autoscaler observes that ongoing requests exceed `target_ongoing_requests` and decides to add another replica.
2. **KubeRay creates a new worker pod.** Ray Serve signals KubeRay to scale the worker group, and KubeRay creates a pod for the new replica.
3. **Pod stays pending if no capacity.** If the existing nodes cannot fit the new pod (insufficient GPU or memory), the pod enters `Pending` state.
4. **Managed Karpenter provisions a node.** HyperPod managed Karpenter detects the pending pod, selects an appropriate instance type, and launches a new node.
5. **Node comes up and pod starts running.** Once the node is ready and joins the cluster, Kubernetes schedules the pending pod onto it. The new replica loads the model and begins serving requests.

On scale-down, the process reverses: Ray Serve removes idle replicas, KubeRay deletes the worker pods, and managed Karpenter terminates nodes that have no running pods after the consolidation window.

Observability

The SageMaker HyperPod Observability add-on collects Ray metrics and provisions Grafana dashboards for your Ray workloads. Installing the add-on deploys a collector that scrapes the Ray head pods, worker pods, and the KubeRay operator. The collector writes the metrics to Amazon Managed Service for Prometheus, and dashboards are imported into Amazon Managed Grafana. You skip the manual Prometheus and Grafana setup.

The add-on is not specific to Ray. It also collects cluster metrics for hardware health, resource utilization, and task performance. The sources include NVIDIA DCGM, Kubernetes node exporters,

Elastic Fabric Adapter, integrated file systems, and Kueue. One installation covers your Ray workloads and the cluster they run on.

For the general observability setup, see the section called “Observability”.

Topics

- Setting up Ray metrics collection
- Ray Grafana dashboards
- Ray metrics reference

Setting up Ray metrics collection

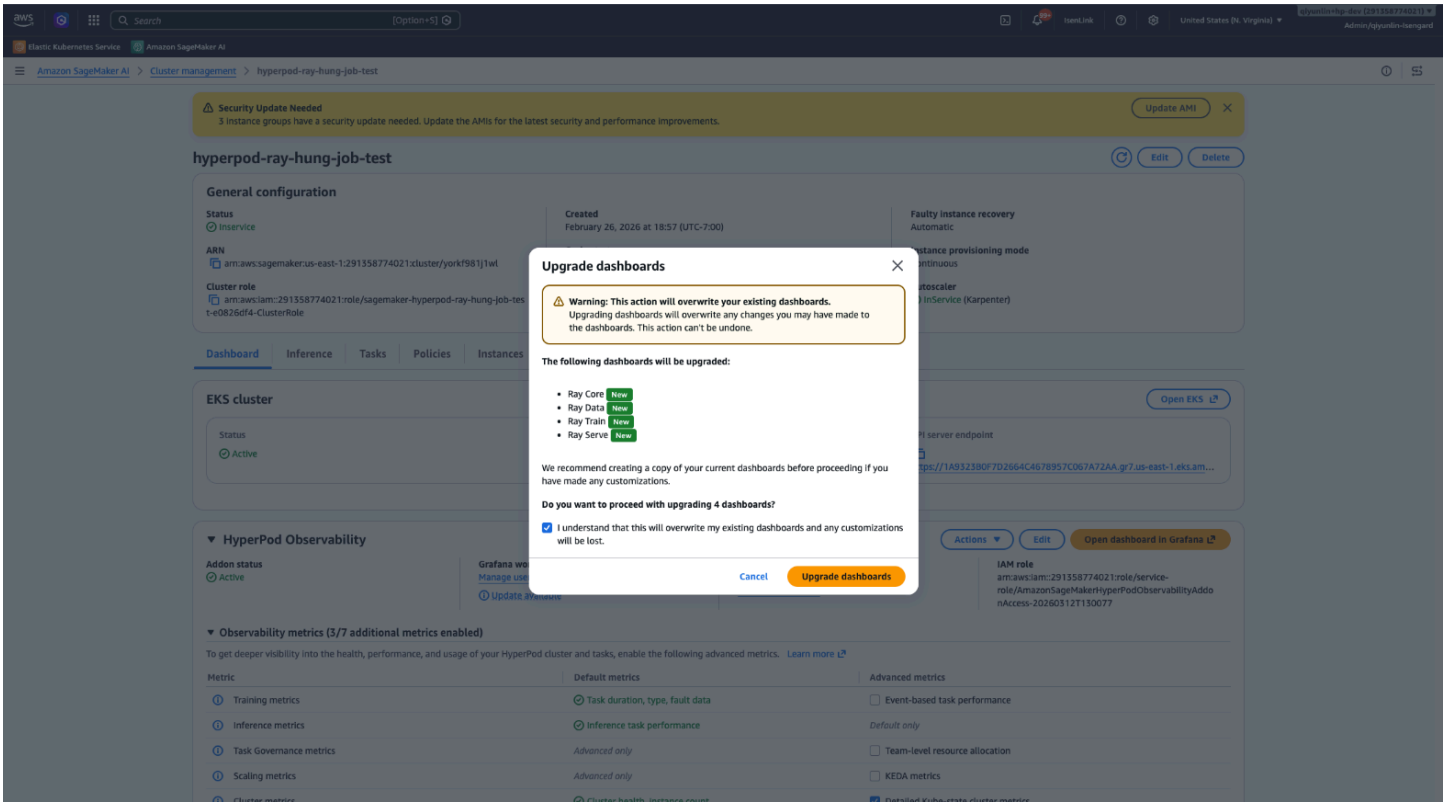
To collect Ray metrics, install or update the SageMaker HyperPod Observability add-on and turn on Ray metrics. The add-on deploys a collector with scrape configuration for Ray head pods, worker pods, and the KubeRay operator, so you do not hand-author scrape configuration per cluster. Metrics land in Amazon Managed Service for Prometheus and are visualized in Amazon Managed Grafana.

Prerequisites

Before you set up Ray metrics collection, make sure you have the following:

- The KubeRay operator installed on your HyperPod cluster. For more information, see the section called “Installing KubeRay”.
- The Observability add-on on version 1.0.6 or later. Earlier versions run, but Ray metrics do not appear.

Turn on Ray metrics



> **Note**
>
> Any newly created HyperPod cluster, with either **Quick setup** or **Custom setup** in the console, has Ray metrics turned on by default. Use the following steps for a cluster created another way, or one where Ray metrics are off.

To turn on Ray metrics

1. Open the HyperPod cluster in the console, then go to the Observability add-on configuration on the **Add-ons** or **Dashboard** tab.
2. Install the add-on, or update it if it is already installed.
3. Confirm the **Ray metrics** checkbox is selected. It is selected by default.
4. Save the configuration.

> **Important**
>
> If the Observability add-on is already installed, upgrade it to version 1.0.6 or later, then upgrade the Grafana dashboards from the SageMaker AI console. New Ray metrics and dashboard panels do not appear until both the add-on and the dashboards are upgraded.

To upgrade the dashboards, open your cluster in the SageMaker AI console, choose the **Dashboard** tab, and in the **HyperPod Observability** section choose **Actions**, then **Upgrade dashboards**. Confirm the upgrade in the dialog. Upgrading overwrites the Ray Core, Ray Data, Ray Train, and Ray Serve dashboards, so copy any customizations first.

For the general add-on setup and the console steps, see the section called “Observability” and the section called “Observability”.

Verify

Confirm the add-on reports the Ray pods as scrape targets, then open Grafana and confirm a Ray dashboard shows data for a running cluster. If a dashboard is empty, confirm the add-on is on version 1.0.6 or later first.

Ray Grafana dashboards

The SageMaker HyperPod Observability add-on provisions Grafana dashboards for your Ray workloads. You get them without importing dashboard JSON yourself.

The add-on provisions the following dashboards:

- **Ray Core** — cluster resources, tasks, actors, and node state.
- **Ray Data** — dataset throughput and operator progress.
- **Ray Train** — training run progress and worker state.
- **Ray Serve** — request rate, latency, and replica state.

Filtering a dashboard

Each dashboard exposes filters so you can scope a view to one workload:

- **Cluster name** — the HyperPod cluster, backed by the `cluster_name` label
- **Cluster ID** — the HyperPod cluster, backed by `cluster_id`
- **Namespace** — backed by `namespace`
- **Ray cluster** — the Ray cluster, backed by `ray_io_cluster`

Set the filters to a running cluster to see its metrics. For more information about opening Grafana and access roles, see the section called “Observability”.

Ray metrics reference

The SageMaker HyperPod Observability add-on collects the metrics that Ray exports. We do not add, rename, or remove Ray metrics, so metric names and labels match open source Ray.

The following sections list the metric groups each provisioned dashboard covers. For the individual metric names, definitions, and types, see Ray system metrics in the Ray documentation.

Ray Core metrics

The **Ray Core** dashboard covers system-level Ray state and the hardware the cluster runs on, across these groups:

- Tasks, actors, and placement groups
- Cluster resources and object store
- Node hardware and OS
- Per-component usage
- Autoscaler state

Ray Data metrics

The **Ray Data** dashboard covers dataset throughput, task lifecycle, iteration, and memory pressure, across these groups:

- Rows, bytes, and blocks
- Task counts and lifecycle
- Other operator counters
- Iteration
- Object store and memory budget
- Cluster utilization and budgets

Ray Train metrics

The **Ray Train** dashboard covers training run and worker state, checkpointing, and node hardware, across these groups:

- Run and worker state
- Checkpointing and reporting
- Node hardware and OS

Ray Serve metrics

The **Ray Serve** dashboard covers request rate, latency, errors, and replica health, across these groups:

- Requests and latency
- Errors and queueing
- Replica and controller health
- Node hardware and cluster state

Labels for querying

Metrics land in Amazon Managed Service for Prometheus, so you can query them outside Grafana. The collector adds `cluster_name`, `cluster_id`, and `namespace`. Ray adds `ray_io_cluster`, which identifies the Ray cluster and is the label the dashboards pivot on.

For more information about visualizing these metrics, see the section called “Grafana dashboards”.

Ray on HyperPod reference

This section collects reference material for Ray on HyperPod: how to resolve common problems, and answers to frequent questions about how the capabilities work.

Topics

- Troubleshooting Ray on HyperPod
- Ray on HyperPod FAQs

Troubleshooting Ray on HyperPod

Use this page to diagnose common problems with Ray clusters, dashboards, jobs, and observability on HyperPod. Each entry gives the symptom, the cause, and the resolution.

Ray cluster stuck in Pending

Symptom

The head or worker pods stay `Pending` and the cluster never reaches `Running`.

Cause

The requested vCPU or memory is higher than the Kubernetes allocatable capacity on the chosen instance type. Allocatable is lower than the instance nameplate because kube-system reserves and DaemonSets consume part of each node.

Resolution

Lower the vCPU and memory requests so they fit allocatable capacity, or choose a larger instance type. Check allocatable with `kubectl describe node` *`my-node`* and set requests below the reported values.

ray.init() fails with a version error

Symptom

`ray.init()` fails, or the cluster starts but clients cannot connect.

Cause

The Ray version in the space or client image does not match `spec.rayVersion` in the cluster manifest.

Resolution

Set `spec.rayVersion` to the Ray version in the container image, and use the same Ray version in the space or client. For more information, see the section called “Installing KubeRay”.

Dashboard link returns an authorization error

Symptom

The Ray Dashboard link opens but returns an authorization error.

Cause

Under the private access strategy, the dashboard is scoped to the identity that created the connection. A different identity is denied.

Resolution

Open the dashboard as the identity that created the cluster, or use the public access strategy to grant access to anyone with connect permission in the namespace. For more information, see the section called “Access strategies”.

Ray workload never admitted

Symptom

A `RayCluster` or `RayJob` stays unadmitted and no pods are created.

Cause

The namespace has no compute allocation in HyperPod Task Governance, so Task Governance holds the workload with no quota to admit it against.

Resolution

Assign a compute allocation to the namespace, or submit to a namespace that has one. For more information, see the section called “Setting up”.

Grafana dashboards are empty

Symptom

The Ray Grafana dashboards load but show no data for a running cluster.

Cause

Ray metrics are not turned on in the HyperPod Observability add-on, so no Ray metrics are scraped.

Resolution

Turn on Ray metrics in the Observability add-on and confirm the add-on version supports Ray metric scraping. For more information, see the section called “Setting up metrics”.

Job submission fails to reach the endpoint

Symptom

`ray job submit` fails to connect, or returns an authorization error.

Cause

The job submission endpoint is unreachable, or the session token expired. A dashboard or endpoint session is valid for up to six hours.

Resolution

Confirm the endpoint address, then generate a new connection URL to refresh the token and retry. For more information, see the section called “Generating a connection URL”.

Ray on HyperPod FAQs

Does HyperPod modify Ray or KubeRay?

HyperPod runs the upstream, open source Ray and KubeRay without changes. Your Ray code, the Ray APIs, and the `RayCluster`, `RayJob`, `RayCronJob`, and `RayService` custom resources behave as they do in open source. HyperPod adds capabilities around Ray, such as a managed Studio experience, secure dashboard access, observability, and resiliency.

Can I keep my existing KubeRay installation?

You can keep the KubeRay operator you already run. HyperPod capabilities install alongside it, and manifests you already apply continue to work. If your cluster has no KubeRay operator yet, install it as described in the section called “Installing KubeRay”.

Do I need SageMaker Studio?

Amazon SageMaker Studio is required only for the managed experience, where data scientists create and manage Ray clusters without Kubernetes knowledge. On an existing Ray platform, you use `kubectl`, Helm, and the toolkit library, and nothing requires Studio. For more information, see the section called “Getting started with Ray on HyperPod”.

Can I use my own Prometheus and Grafana?

You can keep your own Prometheus and Grafana. The HyperPod Observability add-on is one option that arrives configured, but you can scrape Ray metrics with your own stack instead. For more information, see the section called “Setting up metrics”.

How does quota work with a long-lived Ray cluster?

HyperPod Task Governance accounts for quota at the `RayCluster` level, so a long-lived cluster holds its full declared capacity for as long as it runs. Size a persistent cluster to the capacity you intend to reserve, and use `RayJob` for work that acquires and releases capacity per job. For more information, see the section called “Task governance”.

What happens to my Ray job when a GPU node fails?

HyperPod detects the fault through health checks and reboots or replaces the node, and KubeRay reschedules the affected Ray pods. Your job resumes from its last checkpoint, so write checkpoints to recover in-progress work. For more information, see the section called “Node recovery”.

Which Ray libraries are supported?

HyperPod supports the open source Ray libraries, including Ray Core, Ray Train, Ray Data, and Ray Serve, because it runs Ray unmodified. Match `spec.rayVersion` to the Ray version in your container image. For the library APIs, see the Ray documentation on the Ray website.

Can I adopt one capability without the others?

Each HyperPod capability installs independently as an add-on or a Python package, so you can adopt one and stop. A team with its own Ray platform can add observability or authenticated dashboard access without changing the rest. For the full list and dependencies, see the section called “Getting started with Ray on HyperPod”.

Using topology-aware scheduling in Amazon SageMaker HyperPod

Data transfer efficiency is a critical factor in high-performance computing (HPC) and machine learning workloads. When using UltraServers with Amazon SageMaker HyperPod, SageMaker HyperPod automatically applies topology labels to your resources. Topology-aware scheduling helps allocate resources to minimize data transfer overheads by considering both instance topology (how resources are connected within an instance) and network topology (how instances are connected with each other). For more information about instance topology, see Amazon EC2 instance topology.

Topology-aware scheduling works with both clusters on Slurm and Amazon EKS. For general information about how topology works with Slurm, see the Topology guide in the Slurm documentation.

In Amazon SageMaker HyperPod, data transfer overheads typically come from three main sources:

- **GPU-to-GPU data transfer**: Modern technologies like NVLink and NVLink switches allow high-throughput data transfer between GPUs without involving other compute resources. This is extremely efficient but usually limited to a single instance.
- **GPU-to-CPU data transfer**: Non-uniform memory access (NUMA) systems have multiple system buses on a single motherboard. In a typical EC2 instance architecture like p5.48xlarge, there are

two different system buses, each with a CPU and 4 GPUs. For optimal performance, processes that load or read data to/from GPUs should execute on a CPU connected to the same system bus as the GPU.

- **Network communications between instances**: Instances transfer data through a chain of network switches. The shortest path typically corresponds to the lowest latency.

UltraServer architecture

SageMaker HyperPod supports UltraServer architecture with p6e-gb200.36xlarge instances. An UltraServer contains up to 18 p6e-gb200.36xlarge instances, with 4 GPUs on each instance. All GPUs across all nodes are interconnected through NVLink switches, enabling data transfer between any two GPUs without using network interfaces.

This architecture provides a significant performance boost compared to individual instances. To leverage this architecture effectively, jobs should be submitted to compute nodes from a single UltraServer.

EKS topology label

In accordance with EC2 instance topology, HyperPod automatically labels your nodes with the following labels:

- **topology.kubernetes.io/region** - the Amazon Web Services Region that the node resides in.
- **topology.kubernetes.io/zone** - the Availability Zone that the node resides in.
- **topology.k8s.aws/network-node-layer** - NetworkNodes describes the network node set of an instance. In each network node set, the network nodes are listed in a hierarchical order from top to bottom. The network node that is connected to the instance is the last network node in the list. There are up to four network node layers, and each node is tagged with a label. Available layers are `topology.k8s.aws/network-node-layer-1`, `topology.k8s.aws/network-node-layer-2`, `topology.k8s.aws/network-node-layer-3`.
- **topology.k8s.aws/ultraserver-id** - An identifier used to label each of the instances belonging to the same NVLink domain in an Ultraserver. To learn more about using UltraServers with SageMaker HyperPod, see the section called “UltraServers”.

Using these labels, you can use topology-aware scheduling in HyperPod task governance to apply topology labels and annotations to optimize training efficiency of your workloads. For

more information, see Using topology-aware scheduling in Amazon SageMaker HyperPod task governance.

Slurm network topology plugins

Slurm provides built-in plugins for network topology awareness. SageMaker HyperPod automatically selects and configures the appropriate topology plugin based on the instance types in your cluster.

Automatic topology selection

When you create a HyperPod Slurm cluster, the system inspects all instance groups and their associated instance types, identifies the GPU communication characteristics of each instance type, and configures Slurm with the appropriate topology plugin. This process runs automatically and does not require any configuration.

HyperPod manages topology through dynamically generated configuration files. On Slurm 25.11 and later, topology is defined in a `topology.yaml` file, which is the source of truth and supports multiple topology definitions and per-partition assignment. On Slurm 24.x, topology is defined in a `topology.conf` file with a single cluster-wide topology. As the cluster evolves through scaling operations or node replacements, HyperPod continuously reconciles the topology configuration to reflect the current cluster state. For more information, see Dynamic topology updates.

Instance types that support network topology

HyperPod configures tree or block topology for instance types that support Amazon EC2 instance topology. For the authoritative, up-to-date list of supported instance types, see Prerequisites for Amazon EC2 topology in the *Amazon EC2 User Guide*.

Supported instance types include accelerated computing families such as G6e, G7e, P4d, P4de, P5, P5e, P5en, and P6e-GB200, as well as AWS Trainium families such as Trn1, Trn1n, and Trn2. UltraServer instance types (for example, `ml.p6e-gb200.36xlarge`) use block topology, and other topology-capable instance types use tree topology.

Using the topology/tree plugin

The `topology/tree` plugin models hierarchical communication structures with multiple bandwidth tiers. Tree topology enables Slurm to place jobs in a way that minimizes cross-tier communication and maximizes locality.

Tree topology is used for instance types with hierarchical interconnects, where distributed training workloads benefit from locality-aware placement. This includes instance types such as `ml.p5.48xlarge`, `ml.p5e.48xlarge`, and `ml.p5en.48xlarge`.

SageMaker HyperPod automatically configures the `topology/tree` plugin when your cluster uses these instance types. The generated topology configuration maps nodes into a switch hierarchy that reflects the communication tiers of your hardware.

Ensure your `slurm.conf` includes:

```
TopologyPlugin=topology/tree
```

Configuration

SageMaker HyperPod automatically configures tree topology based on information provided by Amazon EC2. For more details about Amazon EC2 topology, see Amazon EC2 instance topology.

On Slurm 25.11 and later, HyperPod defines topology in `topology.yaml`, which is the source of truth. A tree topology entry maps nodes into a switch hierarchy that reflects the communication tiers of your hardware:

```
- topology: tree
  cluster_default: true
  tree:
    switches:
      - switch: root
        children: leaf-0,leaf-1
      - switch: leaf-0
        nodes: compute-1,compute-2
      - switch: leaf-1
        nodes: compute-3,compute-4
```

On Slurm 24.x, tree topology is defined in `topology.conf` instead, which uses the following format:

```
SwitchName=nn-6fe9d8a965d34d181 Switches=nn-0b53107754517bf0e

SwitchName=nn-0b53107754517bf0e Switches=nn-424c855d4ad825aa4,nn-95acd7c656329fc30

SwitchName=nn-424c855d4ad825aa4 Nodes=ip-10-1-111-198
```

```
SwitchName=nn-95acd7c656329fc30 Nodes=ip-10-1-53-231
```

Usage

When the `topology/tree` plugin is configured, Slurm tries to allocate machines that are close to each other. You can force Slurm to allocate machines on a single switch by passing the `--switch` command line parameter to `sbatch` or `srun`:

```
sbatch --switch=1 ....
```

Using the topology/block plugin

NVIDIA developed a `topology/block` plugin that provides hierarchical scheduling across blocks of nodes with the following characteristics:

- A block is a consecutive range of nodes
- Blocks cannot overlap with each other
- All nodes in a block are allocated to a job before the next block is used
- The planning block size is the smallest block size configured
- Every higher block level size is a power of two than the previous one

This plugin allocates nodes based on the defined network topology.

Block topology models uniform, high-bandwidth communication domains where all GPUs participate in a single high-speed domain with near-uniform latency. Block topology treats all nodes as part of a single cohesive communication unit. UltraServer architecture in SageMaker HyperPod supports the block plugin.

Block topology is used for UltraServer instance types such as `ml.p6e-gb200.36xlarge`.

Ensure your `slurm.conf` includes:

```
TopologyPlugin=topology/block
```

Configuration

SageMaker HyperPod automatically configures block topology. On Slurm 25.11 and later, block topology is defined in `topology.yaml`, which is the source of truth. Block and tree topologies for

a cluster are defined together in the same file. The following example shows a cluster with a P5 partition (tree) and an UltraServer partition (block):

```
- topology: tree
  cluster_default: true
  tree:
    switches:
      - switch: root
        children: leaf-0,leaf-1
      - switch: leaf-0
        nodes: compute-p5-1,compute-p5-2
      - switch: leaf-1
        nodes: compute-p5-3,compute-p5-4
- topology: block
  cluster_default: false
  block:
    block_sizes:
      - 18
    blocks:
      - block: cb-001
        nodes: ultraserver-1-[1-18]
```

On Slurm 24.x, block topology is defined in `topology.conf` instead, which uses the following format:

```
BlockName=us1 Nodes=ultraserver1-[0-17]
BlockName=us2 Nodes=ultraserver2-[0-17]
BlockSizes=18
```

Usage

When submitting jobs, you can use the following additional arguments with `sbatch` and `srun` commands:

- `--segment=N`: Specify the number of nodes to group together. The size of the segment must be less than or equal to the planning block size.
- `--exclusive=topo`: Request that no other jobs be placed on the same block. This is useful for benchmarking and performance-sensitive applications.

The following are sample scenarios you might consider when thinking about allocating blocks.

Allocate a whole block of nodes on an empty system

```
sbatch -N18
```

Allocate two blocks of nodes on an empty system

```
sbatch -N36
```

Allocate 18 nodes on one block + 6 nodes on another block

```
sbatch -N24
```

Allocate 12 nodes on one block and 12 nodes on another block

```
sbatch -N24 --segment=12
```

With --exclusive=topo, job must be placed on block with no other jobs

```
sbatch -N12 --exclusive=topo
```

Partition-level topology selection

Starting with Slurm 25.11, HyperPod supports topology configuration at the partition level. Each partition is assigned a topology based on the instance types of its compute instance groups, so a single cluster can run tree topology in one partition and block topology in another. Partitions that contain instance types without network topology support inherit a cluster-wide `flat` default, which keeps their nodes schedulable.

HyperPod resolves the topology for each partition as follows:

- If every compute instance group in the partition is an UltraServer instance type, the partition uses `block` topology.
- If every compute instance group in the partition supports network topology (and the partition is not all UltraServer), the partition uses `tree` topology.
- If a partition contains both UltraServer and other topology-capable instance types, the partition uses `tree` topology.

- If any compute instance group in the partition uses an instance type that does not support network topology, the partition has no topology assignment and inherits the cluster-wide `flat` default.

The cluster-wide default topology is selected based on the topologies present across the cluster: if only one topology type is present, that type is the default; if both block and tree are present with no non-topology groups, tree is the default; and if any non-topology compute group is present, `flat` is the default so that those nodes remain schedulable.

The following table shows an example of how HyperPod resolves topology for a cluster with mixed instance types.

Instance group	Instance type	Applied topology
IG-1	ml.p5.48xlarge	Tree
IG-2	ml.p6e-gb200.36xlarge	Block

In this example, the P5 partition uses tree topology and the UltraServer partition uses block topology. With partition-level topology, each partition uses its optimal topology within the same cluster, so you no longer need to create separate clusters to give each instance type its ideal topology model.

> **Note**
>
> On clusters running Slurm 24.x, only a single cluster-wide topology configuration is supported. Per-partition topology requires Slurm 25.11 or later.

Flat topology default

When a cluster contains a mix of topology-capable and non-topology instance types, HyperPod applies `topology/flat` as the cluster default. Topology-aware partitions are pointed at their tree or block topology through per-partition `Topology=` directives in `slurm.conf` (Slurm 25.11 and later), while partitions with non-topology nodes have no `Topology=` directive and inherit the flat default. This ensures every node remains schedulable.

Disable or change topology plugin

When a Slurm cluster is created, HyperPod automatically selects the optimal topology plugin. To manually change the topology plugin, update the `TopologyPlugin` value in `slurm.conf` on the controller node.

To disable topology-aware placement, set the plugin to `topology/flat` (or `topology/default`):

```
# Set this value to disable topology-aware placement
TopologyPlugin=topology/flat
```

Dynamic topology updates

Topology-aware scheduling continuously maintains topology correctness as your cluster changes. The topology is automatically recalculated and the topology configuration file is regenerated when any of the following events occur:

- **Scale-up**: New nodes are added to the cluster.
- **Scale-down**: Nodes are removed from the cluster.
- **Node replacement**: Failed or unhealthy nodes are replaced, or nodes are manually replaced using the BatchReplaceClusterNodes API.

When the topology is updated, new nodes are incorporated into the correct topology structure, removed nodes are pruned, and the Slurm configuration is updated without requiring manual intervention. This ensures that the topology always reflects the actual cluster state.

> **Note**
>
> Advanced users can override the topology behavior by logging into the Slurm controller node and manually modifying `slurm.conf` and the applicable topology file (`topology.yaml` on Slurm 25.11 and later, or `topology.conf` on Slurm 24.x). However, manual changes may be overwritten by HyperPod during subsequent cluster updates, including scaling operations, node replacements, and other cluster lifecycle events. If you modify these files manually, verify your changes after any cluster update.

Best practices for UltraServer topology

For optimal performance with UltraServer architecture in SageMaker HyperPod:

- **Set appropriate block sizes**: Configure `BlockSizes=18` (or 17 if one node is spare) to match the UltraServer architecture.
- **Use segments for better availability**: Use `--segment=16`, `--segment=8`, or `--segment=9` with `srun` and `sbatch` commands to improve job scheduling flexibility.
- **Consider job size and segment size**:
  - If `BlockSizes=18`, jobs with up to 18 instances will always run on a single UltraServer.
  - If `BlockSizes=16`, jobs with fewer than 16 instances will always run on a single UltraServer, while jobs with 18 instances may run on one or two UltraServers.

When thinking about segmenting, consider the following:

- With `--segment=1`, each instance can run on a separate UltraServer.
- With `-N 18 --segment 9`, 9 nodes will be placed on one UltraServer, and another 9 nodes can be placed on the same or another UltraServer.
- With `-N 24 --segment 8`, the job can run on 2 or 3 UltraServers, with every 8 nodes placed together on the same server.

Limitations in SageMaker HyperPod topology aware scheduling

With Slurm 25.11 and later, heterogeneous clusters (clusters with different instance types) are supported through partition-level topology and the `flat` cluster default. Each partition receives the topology best suited to its instance types, and non-topology and UltraServer nodes remain schedulable within the same cluster. For more information, see Partition-level topology selection.

On clusters running Slurm 24.x, a single cluster-wide topology applies, and the `topology/block` plugin has the following limitations with heterogeneous clusters:

- Only nodes listed in blocks are schedulable by Slurm.
- Every block must have at least `BlockSizes[0]` nodes.

For heterogeneous clusters on Slurm 24.x, consider these alternatives:

- Do not use the block plugin with heterogeneous clusters. Instead, isolate UltraServer nodes in a different partition.
- Create a separate cluster with UltraServers only in the same VPC and use Slurm's multicluster setup.

Deploying models on Amazon SageMaker HyperPod

Amazon SageMaker HyperPod now extends beyond training to deliver a comprehensive inference platform that combines the flexibility of Kubernetes with the operational excellence of Amazon managed services. Deploy, scale, and optimize your machine learning models with enterprise-grade reliability using the same HyperPod compute throughout the entire model lifecycle.

Amazon SageMaker HyperPod offers flexible deployment interfaces that allow you to deploy models through multiple methods including kubectl, Python SDK, Amazon SageMaker Studio UI, or HyperPod CLI. The service provides advanced autoscaling capabilities with dynamic resource allocation that automatically adjusts based on demand. Additionally, it includes comprehensive observability and monitoring features that track critical metrics such as time-to-first-token, latency, and GPU utilization to help you optimize performance.

> **Note**
>
> When deploying on GPU-enabled instances, you can use GPU partitioning with Multi-Instance GPU (MIG) technology to run multiple inference workloads on a single GPU. This allows for better GPU utilization and cost optimization. For more information about configuring GPU partitioning, see Using GPU partitions in Amazon SageMaker HyperPod.

Unified infrastructure for training and inference

Maximize your GPU utilization by seamlessly transitioning compute resources between training and inference workloads. This reduces the total cost of ownership while maintaining operational continuity.

Enterprise-ready deployment options

Deploy models from multiple sources including open-weights and gated models from Amazon SageMaker JumpStart and custom models from Amazon S3 and Amazon FSx with support for both single-node and multi-node inference architectures.

Managed tiered Key-value (KV) caching and intelligent routing

KV caching saves the precomputed key-value vectors after processing previous tokens. When the next token is processed, the vectors don't need to be recalculated. Through a two-tier caching architecture, you can configure an L1 cache that uses CPU memory for low-latency local reuse, and an L2 cache that leverages Redis to enable scalable, node-level cache sharing.

Intelligent routing analyzes incoming requests and directs them to the inference instance most likely to have relevant cached key-value pairs. The system examines the request and then routes it based on one of the following routing strategies:

1. `prefixaware` — Subsequent requests with the same prompt prefix are routed to the same instance
2. `kvaware` — Incoming requests are routed to the instance with the highest KV cache hit rate.
3. `session` — Requests from the same user session are routed to the same instance.
4. `roundrobin` — Even distribution of requests without considering the state of the KV cache.

For more information on how to enable this feature, see Configure KV caching and intelligent routing.

Inbuilt L2 cache Tiered Storage Support for KV Caching

Building upon the existing KV cache infrastructure, HyperPod now integrates tiered storage as an additional L2 backend option alongside Redis. With the inbuilt SageMaker managed tiered storage, this offers improved performance. This enhancement provides customers with a more scalable and efficient option for cache offloading, particularly beneficial for high-throughput LLM inference workloads. The integration maintains compatibility with existing vLLM model servers and routing capabilities while offering better performance.

> **Note**
>
> **Data encryption:** KV cache data (attention keys and values) is stored unencrypted at rest to optimize inference latency and improve performance. For workloads with strict encryption-at-rest requirements, consider application-layer encryption of prompts and responses, or disable caching.
> **Data isolation:** When using managed tiered storage as the L2 cache backend, multiple inference deployments within a cluster share cache storage with no isolation. L2 KV cache data (attention keys and values) from different deployments is not separated. For

workloads requiring data isolation (multi-tenant scenarios, different data classification levels), deploy to separate clusters or use dedicated Redis instances.

You can reduce cold start latency when scaling out deployments by caching model weights on host-local NVMe storage and pre-pulling the inference server container image onto target nodes. You can enable these features independently or together through the `modelCacheConfig` field, and they work with models from Amazon SageMaker JumpStart, Amazon S3, and Amazon FSx. For more information, see Model weights caching and image caching.

Multi-instance type deployment with automatic failover

HyperPod Inference supports multi-instance type deployment to improve deployment reliability and resource utilization. Specify a prioritized list of instance types in your deployment configuration, and the system automatically selects from available alternatives when your preferred instance type lacks capacity. The Kubernetes scheduler uses `preferredDuringSchedulingIgnoredDuringExecution` node affinity to evaluate instance types in priority order, placing workloads on the highest-priority available instance type while ensuring deployment even when preferred resources are unavailable. This capability prevents deployment failures due to capacity constraints while maintaining your cost and performance preferences, ensuring continuous service availability even during cluster capacity fluctuations.

Custom node affinity for granular scheduling control

HyperPod Inference supports custom node affinity to control workload placement beyond instance type selection. Specify node selection criteria such as availability zone distribution, capacity type filtering (on-demand vs. spot), or custom node labels through the `nodeAffinity` field. The system supports mandatory placement constraints using `requiredDuringSchedulingIgnoredDuringExecution` and optional preferences through `preferredDuringSchedulingIgnoredDuringExecution`, providing full control over pod scheduling decisions while maintaining deployment flexibility.

Note

We collect certain routine operational metrics to provide essential service availability. The creation of these metrics is fully automated and does not involve human review of the underlying model inference workload. These metrics relate to deployment operations, resource management, and endpoint registration.

Setting up your HyperPod clusters for model deployment

This guide shows you how to enable inference capabilities on Amazon SageMaker HyperPod clusters. You'll set up the infrastructure, permissions, and operators that machine learning engineers need to deploy and manage inference endpoints.

> **Note**
>
> To create a cluster with the inference operator pre-installed, see Create an EKS-orchestrated SageMaker HyperPod cluster. To install the inference operator on an existing cluster, continue with the following procedures.

You can install the inference operator using the SageMaker AI console for a streamlined experience, or use the Amazon CLI for more control. This guide covers both installation methods.

Method 1: Install HyperPod Inference Add-on through SageMaker AI console (Recommended)

The SageMaker AI console provides the most streamlined experience with two installation options:

- **Quick Install:** Automatically creates all required resources with optimized defaults, including IAM roles, Amazon S3 buckets, and dependency add-ons. A new Studio domain will be created with required permissions to deploy a JumpStart model to the relevant cluster. This option is ideal for getting started quickly with minimal configuration decisions.
- **Custom Install:** Provides flexibility to specify existing resources or customize configurations while maintaining the one-click experience. Customers can choose to reuse existing IAM roles, Amazon S3 buckets, or dependency add-ons based on their organizational requirements.

Prerequisites

- An existing HyperPod cluster with Amazon EKS orchestration
- IAM permissions for Amazon EKS cluster administration
- kubectl configured for cluster access

Installation steps

1. Navigate to the SageMaker AI console and go to **HyperPod Clusters** → **Cluster Management**.
2. Select your cluster where you want to install the Inference Operator.
3. Navigate to the **Inference** tab. Select **Quick Install** for automated setup or **Custom Install** for configuration flexibility.
4. If choosing Custom Install, specify existing resources or customize settings as needed.
5. Choose **Install** to begin the automated installation process.
6. Verify the installation status through the console, or by running the following commands:

```
kubectl get pods -n hyperpod-inference-system
```

```
aws eks describe-addon --cluster-name CLUSTER-NAME --addon-name amazon-sagemaker-
hyperpod-inference --region REGION
```

After the add-on is successfully installed, you can deploy models using the model deployment documentation or navigate to Verify the inference operator is working.

Method 2: Installing the Inference Operator using the Amazon CLI

The Amazon CLI installation method provides more control over the installation process and is suitable for automation and advanced configurations.

Prerequisites

The inference operator enables deployment and management of machine learning inference endpoints on your Amazon EKS cluster. Before installation, ensure your cluster has the required security configurations and supporting infrastructure. Complete these steps to configure IAM roles, install the Amazon Load Balancer Controller, set up Amazon S3 and Amazon FSx CSI drivers, and deploy KEDA and cert-manager:

1. Connect to your cluster and set up environment variables
2. Configure IAM roles for inference operator
3. Create the ALB Controller role
4. Create the KEDA operator role
5. Install the dependency EKS Add-Ons

> **Note**
>
> Alternatively, you can use Amazon CloudFormation templates to automate the prerequisite setup. For more information, see Using Amazon CloudFormation templates to create the prerequisite stack.

Connect to your cluster and set up environment variables

Before proceeding, verify that your Amazon credentials are properly configured and have the necessary permissions. Run the following steps using an IAM principal with Administrator privileges and Cluster Admin access to an Amazon EKS cluster. Ensure you've created a HyperPod cluster with Creating a SageMaker HyperPod cluster with Amazon EKS orchestration. Install helm, eksctl, and kubectl command line utilities.

For Kubernetes administrative access to the Amazon EKS cluster, open the Amazon EKS console and select your cluster. In the **Access** tab, select **IAM Access Entries**. If no entry exists for your IAM principal, select **Create Access Entry**. Select the desired IAM principal and associate the `AmazonEKSClusterAdminPolicy` with it.

1. Configure kubectl to connect to the newly created HyperPod cluster orchestrated by Amazon EKS cluster. Specify the Region and HyperPod cluster name.

```
export HYPERPOD_CLUSTER_NAME=<hyperpod-cluster-name>
export REGION=<region>

# S3 bucket where tls certificates will be uploaded
export BUCKET_NAME="hyperpod-tls-<your-bucket-suffix>" # Bucket should have prefix:
 hyperpod-tls-*

export EKS_CLUSTER_NAME=$(aws --region $REGION sagemaker describe-cluster --cluster-
name $HYPERPOD_CLUSTER_NAME \
--query 'Orchestrator.Eks.ClusterArn' --output text | \
cut -d'/' -f2)
aws eks update-kubeconfig --name $EKS_CLUSTER_NAME --region $REGION
```

Note

If using a custom bucket name that doesn't start with `hyperpod-tls-`, attach the following policy to your execution role:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "TLSBucketDeleteObjectsPermission",
            "Effect": "Allow",
            "Action": ["s3:DeleteObject"],
            "Resource": ["arn:aws:s3:::${BUCKET_NAME}/*"],
            "Condition": {
                "StringEquals": {
                    "aws:ResourceAccount": "${aws:PrincipalAccount}"
                }
            }
        },
        {
            "Sid": "TLSBucketGetObjectAccess",
            "Effect": "Allow",
            "Action": ["s3:GetObject"],
            "Resource": ["arn:aws:s3:::${BUCKET_NAME}/*"]
        },
        {
```

```
            "Sid": "TLSBucketPutObjectAccess",
            "Effect": "Allow",
            "Action": ["s3:PutObject", "s3:PutObjectTagging"],
            "Resource": ["arn:aws:s3:::${BUCKET_NAME}/*"],
            "Condition": {
                "StringEquals": {
                    "aws:ResourceAccount": "${aws:PrincipalAccount}"
                }
            }
        }
    ]
}
```

2. Set default env variables.

```
HYPERPOD_INFERENCE_ROLE_NAME="SageMakerHyperPodInference-$HYPERPOD_CLUSTER_NAME"
HYPERPOD_INFERENCE_NAMESPACE="hyperpod-inference-system"
```

3. Extract the Amazon EKS cluster name from the cluster ARN, update the local kubeconfig, and verify connectivity by listing all pods across namespaces.

```
kubectl get pods --all-namespaces
```

4. (Optional) Install the NVIDIA device plugin to enable GPU support on the cluster.

```
# Install nvidia device plugin
kubectl create -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.14.5/
nvidia-device-plugin.yml
# Verify that GPUs are visible to k8s
kubectl get nodes -o=custom-
columns=NAME:.metadata.name,GPU:.status.allocatable.nvidia.com/gpu
```

Configure IAM roles for inference operator

1. Gather essential Amazon resource identifiers and ARNs required for configuring service integrations between Amazon EKS, SageMaker AI, and IAM components.

```
%%bash -x
```

```
export ACCOUNT_ID=$(aws --region $REGION sts get-caller-identity --query 'Account' --
output text)
export OIDC_ID=$(aws --region $REGION eks describe-cluster --name $EKS_CLUSTER_NAME
 --query "cluster.identity.oidc.issuer" --output text | cut -d '/' -f 5)
export EKS_CLUSTER_ROLE=$(aws eks --region $REGION describe-cluster --name
 $EKS_CLUSTER_NAME --query 'cluster.roleArn' --output text)
```

2. Associate an IAM OIDCidentity provider with your EKS cluster.

```
eksctl utils associate-iam-oidc-provider --region=$REGION --cluster=$EKS_CLUSTER_NAME
 --approve
```

3. Create the trust policy required for the HyperPod inference operator IAM role. These policies enable secure cross-service communication between Amazon EKS, SageMaker AI, and other Amazon services.

```
%%bash -x

# Create trust policy JSON
cat << EOF > trust-policy.json
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Service": [
                "sagemaker.amazonaws.com"
            ]
        },
        "Action": "sts:AssumeRole"
    },
    {
        "Effect": "Allow",
        "Principal": {
            "Federated": "arn:aws:iam::${ACCOUNT_ID}:oidc-provider/oidc.eks.
${REGION}.amazonaws.com/id/${OIDC_ID}"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
            "StringLike": {
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:aud":
 "sts.amazonaws.com",
```

```
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:sub":
 "system:serviceaccount:hyperpod-inference-system:hyperpod-inference-controller-
manager"
            }
        }
    }
]
}
EOF
```

4. Create execution Role for the inference operator.

```
aws iam create-role --role-name $HYPERPOD_INFERENCE_ROLE_NAME --assume-role-policy-
document file://trust-policy.json
aws iam attach-role-policy --role-name $HYPERPOD_INFERENCE_ROLE_NAME --policy-arn
 arn:aws:iam::aws:policy/AmazonSageMakerHyperPodInferenceAccess
```

5. Create a namespace for inference operator resources

```
kubectl create namespace $HYPERPOD_INFERENCE_NAMESPACE
```

Create the ALB Controller role

1. Create the trust policy and permissions policy.

```
# Create trust policy
cat <<EOF > /tmp/alb-trust-policy.json
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Federated": "arn:aws:iam::${ACCOUNT_ID}:oidc-provider/oidc.eks.
${REGION}.amazonaws.com/id/${OIDC_ID}"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
            "StringLike": {
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:sub":
 "system:serviceaccount:hyperpod-inference-system:aws-load-balancer-controller",
```

```
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:aud":
 "sts.amazonaws.com"
            }
        }
    }
]
}
EOF

# Create permissions policy
export ALBController_IAM_POLICY_NAME=HyperPodInferenceALBControllerIAMPolicy
curl -o AWSLoadBalancerControllerIAMPolicy.json https://raw.githubusercontent.com/
kubernetes-sigs/aws-load-balancer-controller/v2.13.0/docs/install/iam_policy.json

# Create the role
aws iam create-role \
    --role-name alb-role \
    --assume-role-policy-document file:///tmp/alb-trust-policy.json

# Create the policy
ALB_POLICY_ARN=$(aws iam create-policy \
    --policy-name $ALBController_IAM_POLICY_NAME \
    --policy-document file://AWSLoadBalancerControllerIAMPolicy.json \
    --query 'Policy.Arn' \
    --output text)

# Attach the policy to the role
aws iam attach-role-policy \
    --role-name alb-role \
    --policy-arn $ALB_POLICY_ARN
```

2. Apply Tags (`kubernetes.io.role/elb`) to all subnets in the Amazon EKS cluster (both public and private).

```
export VPC_ID=$(aws --region $REGION eks describe-cluster --name $EKS_CLUSTER_NAME --
query 'cluster.resourcesVpcConfig.vpcId' --output text)

# Add Tags
aws ec2 describe-subnets \
--filters "Name=vpc-id,Values=${VPC_ID}" "Name=map-public-ip-on-launch,Values=true" \
--query 'Subnets[*].SubnetId' --output text | \
tr '\t' '\n' | \
```

```
xargs -I{} aws ec2 create-tags --resources {} --tags Key=kubernetes.io/role/
elb,Value=1

# Verify Tags are added
aws ec2 describe-subnets \
--filters "Name=vpc-id,Values=${VPC_ID}" "Name=map-public-ip-on-launch,Values=true" \
--query 'Subnets[*].SubnetId' --output text | \
tr '\t' '\n' |
xargs -n1 -I{} aws ec2 describe-tags --filters "Name=resource-id,Values={}"
 "Name=key,Values=kubernetes.io/role/elb" --query "Tags[0].Value" --output text
```

3. Create an Amazon S3 VPC endpoint.

```
aws ec2 create-vpc-endpoint \
    --region ${REGION} \
    --vpc-id ${VPC_ID} \
    --vpc-endpoint-type Gateway \
    --service-name "com.amazonaws.${REGION}.s3" \
    --route-table-ids $(aws ec2 describe-route-tables --region $REGION --filters
 "Name=vpc-id,Values=${VPC_ID}" --query 'RouteTables[].Associations[].RouteTableId'
 --output text | tr ' ' '\n' | sort -u | tr '\n' ' ')
```

Create the KEDA operator role

1. Create the trust policy and permissions policy.

```
# Create trust policy
cat <<EOF > /tmp/keda-trust-policy.json
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Federated": "arn:aws:iam::${ACCOUNT_ID}:oidc-provider/oidc.eks.
${REGION}.amazonaws.com/id/${OIDC_ID}"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
            "StringLike": {
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:sub":
 "system:serviceaccount:hyperpod-inference-system:keda-operator",
```

```
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:aud":
 "sts.amazonaws.com"
            }
        }
    }
]
}
EOF

# Create permissions policy
cat <<EOF > /tmp/keda-policy.json
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Action": [
            "cloudwatch:GetMetricData",
            "cloudwatch:GetMetricStatistics",
            "cloudwatch:ListMetrics"
        ],
        "Resource": "*"
    },
    {
        "Effect": "Allow",
        "Action": [
            "aps:QueryMetrics",
            "aps:GetLabels",
            "aps:GetSeries",
            "aps:GetMetricMetadata"
        ],
        "Resource": "*"
    }
]
}
EOF

# Create the role
aws iam create-role \
    --role-name keda-operator-role \
    --assume-role-policy-document file:///tmp/keda-trust-policy.json

# Create the policy
KEDA_POLICY_ARN=$(aws iam create-policy \
```

```
    --policy-name KedaOperatorPolicy \
    --policy-document file:///tmp/keda-policy.json \
    --query 'Policy.Arn' \
    --output text)

# Attach the policy to the role
aws iam attach-role-policy \
    --role-name keda-operator-role \
    --policy-arn $KEDA_POLICY_ARN
```

2. If you're using gated models, create an IAM role to access the gated models.

   a. Create an IAM policy.

```
%%bash -s $REGION

JUMPSTART_GATED_ROLE_NAME="JumpstartGatedRole-${REGION}-${HYPERPOD_CLUSTER_NAME}"

cat <<EOF > /tmp/trust-policy.json
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Federated": "arn:aws:iam::${ACCOUNT_ID}:oidc-provider/oidc.eks.
${REGION}.amazonaws.com/id/${OIDC_ID}"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
            "StringLike": {
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:sub":
 "system:serviceaccount:*:hyperpod-inference-service-account*",
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:aud":
 "sts.amazonaws.com"
            }
        }
    },
        {
        "Effect": "Allow",
        "Principal": {
            "Service": "sagemaker.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
```

```
    }
]
}
EOF
```

b. Create an IAM role.

```
# Create the role using existing trust policy
aws iam create-role \
--role-name $JUMPSTART_GATED_ROLE_NAME \
--assume-role-policy-document file:///tmp/trust-policy.json

aws iam attach-role-policy \
--role-name $JUMPSTART_GATED_ROLE_NAME \
--policy-arn arn:aws:iam::aws:policy/AmazonSageMakerHyperPodGatedModelAccess
```

```
JUMPSTART_GATED_ROLE_ARN_LIST= !aws iam get-role --role-name=
$JUMPSTART_GATED_ROLE_NAME --query "Role.Arn" --output text
JUMPSTART_GATED_ROLE_ARN = JUMPSTART_GATED_ROLE_ARN_LIST[0]
!echo $JUMPSTART_GATED_ROLE_ARN
```

Install the dependency EKS Add-Ons

Before installing the inference operator, you must install the following required EKS add-ons on your cluster. The inference operator will fail to install if any of these dependencies are missing. Each add-on has a minimum version requirement for compatibility with the Inference add-on.

> **Important**
>
> Install all dependency add-ons before attempting to install the inference operator. Missing dependencies will cause installation failures with specific error messages.

Required Add-ons

1. **Amazon S3 Mountpoint CSI Driver** (minimum version: v1.14.1-eksbuild.1)

   Required for mounting S3 buckets as persistent volumes in inference workloads.

```
aws eks create-addon \
```

```
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name aws-mountpoint-s3-csi-driver \
    --region $REGION \
    --service-account-role-arn <S3_CSI_ROLE_ARN>
```

For detailed installation instructions including required IAM permissions, see Mountpoint for Amazon S3 CSI driver.

2. **Amazon FSx CSI Driver** (minimum version: v1.6.0-eksbuild.1)

   Required for mounting FSx file systems for high-performance model storage.

```
aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name aws-fsx-csi-driver \
    --region $REGION \
    --service-account-role-arn $FSX_CSI_ROLE_ARN
```

   For detailed installation instructions including required IAM permissions, see Amazon FSx for Lustre CSI driver.

3. **Metrics Server** (minimum version: v0.7.2-eksbuild.4)

   Required for autoscaling functionality and resource metrics collection.

```
aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name metrics-server \
    --region $REGION
```

   For detailed installation instructions, see Metrics Server.

4. **Cert Manager** (minimum version: v1.18.2-eksbuild.2)

   Required for TLS certificate management for secure inference endpoints.

```
aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name cert-manager \
    --region $REGION
```

   For detailed installation instructions, see cert-manager.

Verify Add-on Installation

After installing the required add-ons, verify they are running correctly:

```
# Check add-on status
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name aws-mountpoint-s3-
csi-driver --region $REGION
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name aws-fsx-csi-driver
 --region $REGION
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name metrics-server --
region $REGION
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name cert-manager --
region $REGION

# Verify pods are running
kubectl get pods -n kube-system | grep -E "(mountpoint|fsx|metrics-server)"
kubectl get pods -n cert-manager
```

All add-ons should show status "ACTIVE" and all pods should be in "Running" state before proceeding with inference operator installation.

> **Note**
>
> If you created your HyperPod cluster using the quick setup or custom setup options, the FSx CSI Driver and Cert Manager may already be installed. Verify their presence using the preceding commands.

Installing the Inference Operator with EKS add-on

The EKS add-on installation method provides a managed experience with automatic updates and integrated dependency validation. This is the recommended approach for installing the inference operator.

Install the inference operator add-on

1. Prepare the add-on configuration by gathering all required ARNs and creating the configuration file:

   ```
   # Gather required ARNs
   ```

```
export EXECUTION_ROLE_ARN=$(aws iam get-role --role-name
 $HYPERPOD_INFERENCE_ROLE_NAME --query "Role.Arn" --output text)
export HYPERPOD_CLUSTER_ARN=$(aws sagemaker describe-cluster --cluster-name
 $HYPERPOD_CLUSTER_NAME --region $REGION --query "ClusterArn" --output text)
export KEDA_ROLE_ARN=$(aws iam get-role --role-name keda-operator-role --query
 'Role.Arn' --output text)
export ALB_ROLE_ARN=$(aws iam get-role --role-name alb-role --query 'Role.Arn' --
output text)

# Verify all ARNs are set correctly
echo "Execution Role ARN: $EXECUTION_ROLE_ARN"
echo "HyperPod Cluster ARN: $HYPERPOD_CLUSTER_ARN"
echo "KEDA Role ARN: $KEDA_ROLE_ARN"
echo "ALB Role ARN: $ALB_ROLE_ARN"
echo "TLS S3 Bucket: $BUCKET_NAME"
```

2. Create the add-on configuration file with all required settings:

```
cat > addon-config.json << EOF
{
  "executionRoleArn": "$EXECUTION_ROLE_ARN",
  "tlsCertificateS3Bucket": "$BUCKET_NAME",
  "hyperpodClusterArn": "$HYPERPOD_CLUSTER_ARN",
  "jumpstartGatedModelDownloadRoleArn": "$JUMPSTART_GATED_ROLE_ARN",
  "alb": {
    "serviceAccount": {
      "create": true,
      "roleArn": "$ALB_ROLE_ARN"
    }
  },
  "keda": {
    "auth": {
      "aws": {
        "irsa": {
          "roleArn": "$KEDA_ROLE_ARN"
        }
      }
    }
  }
}
EOF

# Verify the configuration file
```

```
cat addon-config.json
```

3. Install the inference operator add-on (minimum version: v1.0.0-eksbuild.1):

```
aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --configuration-values file://addon-config.json \
    --region $REGION
```

4. Monitor the installation progress and verify successful completion:

```
# Check installation status (repeat until status shows "ACTIVE")
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION \
    --query "addon.{Status:status,Health:health}" \
    --output table

# Verify pods are running
kubectl get pods -n hyperpod-inference-system

# Check operator logs for any issues
kubectl logs -n hyperpod-inference-system deployment/hyperpod-inference-controller-
manager --tail=50
```

For detailed troubleshooting of installation issues, see HyperPod inference troubleshooting.

To verify the inference operator is working correctly, continue to Verify the inference operator is working.

Using Amazon CloudFormation templates to create the prerequisite stack

As an alternative to manually configuring the prerequisites, you can use Amazon CloudFormation templates to automate the creation of required IAM roles and policies for the inference operator.

1. Set up input variables. Replace the placeholder values with your own:

```
#!/bin/bash
set -e
```

```
# ===== INPUT VARIABLES =====
HP_CLUSTER_NAME="my-hyperpod-cluster"  # Replace with your HyperPod cluster name
REGION="us-east-1"  # Replace with your AWS region
PREFIX="my-prefix"  # Replace with your resource prefix
SHORT_PREFIX="12a34d56"  # Replace with your short prefix (maximum 8 characters)
CREATE_DOMAIN="true"  # Set to "false" if you don't need a SageMaker Studio domain
STACK_NAME="hyperpod-inference-prerequisites"  # Replace with your stack name
TEMPLATE_URL="https://aws-sagemaker-hyperpod-cluster-setup-${REGION}-prod.s3.
${REGION}.amazonaws.com/templates/main-stack-inference-operator-addon-
template.yaml"
```

2. Derive cluster and network information:

```
# ===== DERIVE EKS CLUSTER NAME =====
EKS_CLUSTER_NAME=$(aws sagemaker describe-cluster --cluster-name $HP_CLUSTER_NAME
 --region $REGION --query 'Orchestrator.Eks.ClusterArn' --output text | awk -F'/'
 '{print $NF}')
echo "EKS_CLUSTER_NAME=$EKS_CLUSTER_NAME"

# ===== GET VPC AND OIDC =====
VPC_ID=$(aws eks describe-cluster --name $EKS_CLUSTER_NAME --region $REGION --query
 'cluster.resourcesVpcConfig.vpcId' --output text)
echo "VPC_ID=$VPC_ID"

OIDC_PROVIDER=$(aws eks describe-cluster --name $EKS_CLUSTER_NAME --region $REGION
 --query 'cluster.identity.oidc.issuer' --output text | sed 's|https://||')
echo "OIDC_PROVIDER=$OIDC_PROVIDER"

# ===== GET PRIVATE ROUTE TABLES =====
ALL_ROUTE_TABLES=$(aws ec2 describe-route-tables --region $REGION --filters
 "Name=vpc-id,Values=$VPC_ID" --query 'RouteTables[].RouteTableId' --output text)
EKS_PRIVATE_ROUTE_TABLES=""
for rtb in $ALL_ROUTE_TABLES; do
    HAS_IGW=$(aws ec2 describe-route-tables --region $REGION --route-table-ids $rtb
 --query 'RouteTables[0].Routes[?GatewayId && starts_with(GatewayId, `igw-`)]' --
output text 2>/dev/null)
    if [ -z "$HAS_IGW" ]; then
        EKS_PRIVATE_ROUTE_TABLES="${EKS_PRIVATE_ROUTE_TABLES:+
$EKS_PRIVATE_ROUTE_TABLES,}$rtb"
    fi
done
echo "EKS_PRIVATE_ROUTE_TABLES=$EKS_PRIVATE_ROUTE_TABLES"

# ===== CHECK S3 VPC ENDPOINT =====
```

```
S3_ENDPOINT_EXISTS=$(aws ec2 describe-vpc-endpoints --region $REGION --filters
 "Name=vpc-id,Values=$VPC_ID" "Name=service-name,Values=com.amazonaws.$REGION.s3"
 --query 'VpcEndpoints[0].VpcEndpointId' --output text)
CREATE_S3_ENDPOINT_STACK=$([ "$S3_ENDPOINT_EXISTS" == "None" ] && echo "true" ||
 echo "false")
echo "CREATE_S3_ENDPOINT_STACK=$CREATE_S3_ENDPOINT_STACK"

# ===== GET HYPERPOD DETAILS =====
HYPERPOD_CLUSTER_ARN=$(aws sagemaker describe-cluster --cluster-name
 $HP_CLUSTER_NAME --region $REGION --query 'ClusterArn' --output text)
echo "HYPERPOD_CLUSTER_ARN=$HYPERPOD_CLUSTER_ARN"

# ===== GET DEFAULT VPC FOR DOMAIN =====
DOMAIN_VPC_ID=$(aws ec2 describe-vpcs --region $REGION --filters
 "Name=isDefault,Values=true" --query 'Vpcs[0].VpcId' --output text)
echo "DOMAIN_VPC_ID=$DOMAIN_VPC_ID"

DOMAIN_SUBNET_IDS=$(aws ec2 describe-subnets --region $REGION --filters "Name=vpc-
id,Values=$DOMAIN_VPC_ID" --query 'Subnets[0].SubnetId' --output text)
echo "DOMAIN_SUBNET_IDS=$DOMAIN_SUBNET_IDS"

# ===== GET INSTANCE GROUPS =====
INSTANCE_GROUPS=$(aws sagemaker describe-cluster --cluster-name $HP_CLUSTER_NAME --
region $REGION --query 'InstanceGroups[].InstanceGroupName' --output json | python3
 -c "import sys, json; groups = json.load(sys.stdin); print('[' + ','.join([f'\\\\\
\\"' + g + '\\\\\\\\"' for g in groups]) + ']')")
echo "INSTANCE_GROUPS=$INSTANCE_GROUPS"
```

3. Create parameters file and deploy stack:

```
# ===== CREATE PARAMETERS JSON =====
cat > /tmp/cfn-params.json << EOF
[
  {"ParameterKey":"ResourceNamePrefix","ParameterValue":"$PREFIX"},
  {"ParameterKey":"ResourceNameShortPrefix","ParameterValue":"$SHORT_PREFIX"},
  {"ParameterKey":"VpcId","ParameterValue":"$VPC_ID"},

 {"ParameterKey":"EksPrivateRouteTableIds","ParameterValue":"$EKS_PRIVATE_ROUTE_TABLES"},
  {"ParameterKey":"EKSClusterName","ParameterValue":"$EKS_CLUSTER_NAME"},

 {"ParameterKey":"OIDCProviderURLWithoutProtocol","ParameterValue":"$OIDC_PROVIDER"},
  {"ParameterKey":"HyperPodClusterArn","ParameterValue":"$HYPERPOD_CLUSTER_ARN"},
  {"ParameterKey":"HyperPodClusterName","ParameterValue":"$HP_CLUSTER_NAME"},
  {"ParameterKey":"CreateDomain","ParameterValue":"$CREATE_DOMAIN"},
```

```
  {"ParameterKey":"DomainVpcId","ParameterValue":"$DOMAIN_VPC_ID"},
  {"ParameterKey":"DomainSubnetIds","ParameterValue":"$DOMAIN_SUBNET_IDS"},

 {"ParameterKey":"CreateS3EndpointStack","ParameterValue":"$CREATE_S3_ENDPOINT_STACK"},
  {"ParameterKey":"TieredStorageConfig","ParameterValue":"{\"Mode\":\"Enable\",
\"InstanceMemoryAllocationPercentage\":20}"},
  {"ParameterKey":"TieredKVCacheConfig","ParameterValue":"{\"KVCacheMode\":\"Enable
\",\"InstanceGroup\":$INSTANCE_GROUPS,\"NVMeMode\":\"Enable\"}"}
]
EOF

echo -e "\n===== CREATING CLOUDFORMATION STACK ====="
aws cloudformation create-stack \
    --region $REGION \
    --stack-name $STACK_NAME \
    --template-url $TEMPLATE_URL \
    --parameters file:///tmp/cfn-params.json \
    --capabilities CAPABILITY_NAMED_IAM
```

4. Monitor the stack creation status:

```
aws cloudformation describe-stacks \
    --stack-name $STACK_NAME \
    --region $REGION \
    --query 'Stacks[0].StackStatus'
```

5. Once the stack is created successfully, retrieve the output values for use in the inference operator installation:

```
aws cloudformation describe-stacks \
    --stack-name $STACK_NAME \
    --region $REGION \
    --query 'Stacks[0].Outputs'
```

After the Amazon CloudFormation stack is created, continue with Installing the Inference Operator with EKS add-on to install the inference operator.

Method 3: Helm chart installation

> **Note**
>
> For the simplest installation experience, we recommend using Method 1: Install HyperPod Inference Add-on through SageMaker AI console (Recommended) or Method 2: Installing the Inference Operator using the Amazon CLI. Helm chart installation may be deprecated in a future release.

Prerequisites

Before proceeding, verify that your Amazon credentials are properly configured and have the necessary permissions. The following steps need to be run by an IAM principal with Administrator privileges and Cluster Admin access to an Amazon EKS cluster. Verify that you've created a HyperPod cluster with Creating a SageMaker HyperPod cluster with Amazon EKS orchestration . Verify you have installed helm, eksctl, and kubectl command line utilities.

For Kubernetes administrative access to the Amazon EKS cluster, go to the Amazon EKS console and select the cluster you are using. Look in the **Access** tab and select IAM Access Entries. If there isn't an entry for your IAM principal, select **Create Access Entry**. Then select the desired IAM principal and associate the `AmazonEKSClusterAdminPolicy` with it.

1. Configure kubectl to connect to the newly created HyperPod cluster orchestrated by Amazon EKS cluster. Specify the Region and HyperPod cluster name.

```
export HYPERPOD_CLUSTER_NAME=<hyperpod-cluster-name>
export REGION=<region>

# S3 bucket where tls certificates will be uploaded
BUCKET_NAME="<Enter name of your s3 bucket>" # This should be bucket name, not URI

export EKS_CLUSTER_NAME=$(aws --region $REGION sagemaker describe-cluster --cluster-
name $HYPERPOD_CLUSTER_NAME \
--query 'Orchestrator.Eks.ClusterArn' --output text | \
cut -d'/' -f2)
aws eks update-kubeconfig --name $EKS_CLUSTER_NAME --region $REGION
```

2. Set default env variables.

```
LB_CONTROLLER_POLICY_NAME="AWSLoadBalancerControllerIAMPolicy-$HYPERPOD_CLUSTER_NAME"
```

```
LB_CONTROLLER_ROLE_NAME="aws-load-balancer-controller-$HYPERPOD_CLUSTER_NAME"
S3_MOUNT_ACCESS_POLICY_NAME="S3MountpointAccessPolicy-$HYPERPOD_CLUSTER_NAME"
S3_CSI_ROLE_NAME="SM_HP_S3_CSI_ROLE-$HYPERPOD_CLUSTER_NAME"
KEDA_OPERATOR_POLICY_NAME="KedaOperatorPolicy-$HYPERPOD_CLUSTER_NAME"
KEDA_OPERATOR_ROLE_NAME="keda-operator-role-$HYPERPOD_CLUSTER_NAME"
HYPERPOD_INFERENCE_ROLE_NAME="HyperpodInferenceRole-$HYPERPOD_CLUSTER_NAME"
HYPERPOD_INFERENCE_SA_NAME="hyperpod-inference-operator-controller"
HYPERPOD_INFERENCE_SA_NAMESPACE="hyperpod-inference-system"
JUMPSTART_GATED_ROLE_NAME="JumpstartGatedRole-$HYPERPOD_CLUSTER_NAME"
FSX_CSI_ROLE_NAME="AmazonEKSFSxLustreCSIDriverFullAccess-$HYPERPOD_CLUSTER_NAME"
```

3. Extract the Amazon EKS cluster name from the cluster ARN, update the local kubeconfig, and verify connectivity by listing all pods across namespaces.

```
kubectl get pods --all-namespaces
```

4. (Optional) Install the NVIDIA device plugin to enable GPU support on the cluster.

```
#Install nvidia device plugin
kubectl create -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/v0.14.5/
nvidia-device-plugin.yml
# Verify that GPUs are visible to k8s
kubectl get nodes -o=custom-
columns=NAME:.metadata.name,GPU:.status.allocatable.nvidia.com/gpu
```

Prepare your environment for inference operator installation

1. Gather essential Amazon resource identifiers and ARNs required for configuring service integrations between Amazon EKS, SageMaker AI, and IAM components.

```
%%bash -x

export ACCOUNT_ID=$(aws --region $REGION sts get-caller-identity --query 'Account' --
output text)
export OIDC_ID=$(aws --region $REGION eks describe-cluster --name $EKS_CLUSTER_NAME
 --query "cluster.identity.oidc.issuer" --output text | cut -d '/' -f 5)
export EKS_CLUSTER_ROLE=$(aws eks --region $REGION describe-cluster --name
 $EKS_CLUSTER_NAME --query 'cluster.roleArn' --output text)
```

2. Associate an IAM OIDCidentity provider with your EKS cluster.

```
eksctl utils associate-iam-oidc-provider --region=$REGION --cluster=$EKS_CLUSTER_NAME
 --approve
```

3. Create the trust policy required for the HyperPod inference operator IAM role. This policy enables secure cross-service communication between Amazon EKS, SageMaker AI, and other Amazon services.

```
%%bash -x

# Create trust policy JSON
cat << EOF > trust-policy.json
{
"Version": "2012-10-17",
"Statement": [
{
    "Effect": "Allow",
    "Principal": {
        "Service": [
            "sagemaker.amazonaws.com"
        ]
    },
    "Action": "sts:AssumeRole"
},
{
    "Effect": "Allow",
    "Principal": {
        "Federated": "arn:aws:iam::${ACCOUNT_ID}:oidc-provider/oidc.eks.
${REGION}.amazonaws.com/id/${OIDC_ID}"
    },
    "Action": "sts:AssumeRoleWithWebIdentity",
    "Condition": {
        "StringLike": {
            "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:aud":
 "sts.amazonaws.com",
            "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:sub":
 "system:serviceaccount:hyperpod-inference-system:hyperpod-inference-controller-
manager"
        }
    }
}
]
}
```

```
EOF
```

4. Create execution Role for the inference operator and attach the managed policy.

```
aws iam create-role --role-name $HYPERPOD_INFERENCE_ROLE_NAME --assume-role-policy-
document file://trust-policy.json
aws iam attach-role-policy --role-name $HYPERPOD_INFERENCE_ROLE_NAME --policy-arn
 arn:aws:iam::aws:policy/AmazonSageMakerHyperPodInferenceAccess
```

5. Download and create the IAM policy required for the Amazon Load Balancer Controller to manage Application Load Balancers and Network Load Balancers in your EKS cluster.

```
%%bash -x

export ALBController_IAM_POLICY_NAME=HyperPodInferenceALBControllerIAMPolicy

curl -o AWSLoadBalancerControllerIAMPolicy.json https://raw.githubusercontent.com/
kubernetes-sigs/aws-load-balancer-controller/v2.13.0/docs/install/iam_policy.json
aws iam create-policy --policy-name $ALBController_IAM_POLICY_NAME --policy-document
 file://AWSLoadBalancerControllerIAMPolicy.json
```

6. Create an IAM service account that links the Kubernetes service account with the IAM policy, enabling the Amazon Load Balancer Controller to assume the necessary Amazon permissions through IRSA (IAM Roles for Service Accounts).

```
%%bash -x

export ALB_POLICY_ARN="arn:aws:iam::$ACCOUNT_ID:policy/
$ALBController_IAM_POLICY_NAME"

# Create IAM service account with gathered values
eksctl create iamserviceaccount \
--approve \
--override-existing-serviceaccounts \
--name=aws-load-balancer-controller \
--namespace=kube-system \
--cluster=$EKS_CLUSTER_NAME \
--attach-policy-arn=$ALB_POLICY_ARN \
--region=$REGION

# Print the values for verification
echo "Cluster Name: $EKS_CLUSTER_NAME"
echo "Region: $REGION"
```

```
echo "Policy ARN: $ALB_POLICY_ARN"
```

7. Apply Tags (`kubernetes.io.role/elb`) to all subnets in the Amazon EKS cluster (both public and private).

```
export VPC_ID=$(aws --region $REGION eks describe-cluster --name $EKS_CLUSTER_NAME --
query 'cluster.resourcesVpcConfig.vpcId' --output text)

# Add Tags
aws ec2 describe-subnets \
--filters "Name=vpc-id,Values=${VPC_ID}" "Name=map-public-ip-on-launch,Values=true" \
--query 'Subnets[*].SubnetId' --output text | \
tr '\t' '\n' | \
xargs -I{} aws ec2 create-tags --resources {} --tags Key=kubernetes.io/role/
elb,Value=1

# Verify Tags are added
aws ec2 describe-subnets \
--filters "Name=vpc-id,Values=${VPC_ID}" "Name=map-public-ip-on-launch,Values=true" \
--query 'Subnets[*].SubnetId' --output text | \
tr '\t' '\n' |
xargs -n1 -I{} aws ec2 describe-tags --filters "Name=resource-id,Values={}"
 "Name=key,Values=kubernetes.io/role/elb" --query "Tags[0].Value" --output text
```

8. Create a Namespace for KEDA and the Cert Manager.

```
kubectl create namespace keda
kubectl create namespace cert-manager
```

9. Create an Amazon S3 VPC endpoint.

```
aws ec2 create-vpc-endpoint \
--vpc-id ${VPC_ID} \
--vpc-endpoint-type Gateway \
--service-name "com.amazonaws.${REGION}.s3" \
--route-table-ids $(aws ec2 describe-route-tables --filters "Name=vpc-id,Values=
${VPC_ID}" --query 'RouteTables[].Associations[].RouteTableId' --output text | tr ' '
 '\n' | sort -u | tr '\n' ' ')
```

10. Configure S3 storage access:

    a. Create an IAM policy that grants the necessary S3 permissions for using Mountpoint for Amazon S3, which enables file system access to S3 buckets from within the cluster.

```
%%bash -x

export S3_CSI_BUCKET_NAME="<bucketname_for_mounting_through_filesystem>"

cat <<EOF> s3accesspolicy.json
{
"Version": "2012-10-17",
"Statement": [

    {
        "Sid": "MountpointAccess",
        "Effect": "Allow",
        "Action": [
            "s3:ListBucket",
            "s3:GetObject",
            "s3:PutObject",
            "s3:AbortMultipartUpload",
            "s3:DeleteObject"
        ],
        "Resource": [
                "arn:aws:s3:::${S3_CSI_BUCKET_NAME}",
                "arn:aws:s3:::${S3_CSI_BUCKET_NAME}/*"
        ]
    }
]
}
EOF

aws iam create-policy \
--policy-name S3MountpointAccessPolicy \
--policy-document file://s3accesspolicy.json

cat <<EOF> s3accesstrustpolicy.json
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Federated": "arn:aws:iam::${ACCOUNT_ID}:oidc-provider/oidc.eks.
${REGION}.amazonaws.com/id/${OIDC_ID}"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
```

```
        "Condition": {
            "StringEquals": {
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:aud":
 "sts.amazonaws.com",
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:sub":
 "system:serviceaccount:kube-system:${s3-csi-driver-sa}"
            }
        }
    }
]
}
EOF

aws iam create-role --role-name $S3_CSI_ROLE_NAME --assume-role-policy-document
 file://s3accesstrustpolicy.json

aws iam attach-role-policy --role-name $S3_CSI_ROLE_NAME --policy-arn
 "arn:aws:iam::$ACCOUNT_ID:policy/S3MountpointAccessPolicy"
```

b. (Optional) Create an IAM service account for the Amazon S3 CSI driver. The Amazon S3 CSI driver requires an IAM service account with appropriate permissions to mount S3 buckets as persistent volumes in your Amazon EKS cluster. This step creates the necessary IAM role and Kubernetes service account with the required S3 access policy.

```
%%bash -x

export S3_CSI_ROLE_NAME="SM_HP_S3_CSI_ROLE-$REGION"
export S3_CSI_POLICY_ARN=$(aws iam list-policies --query 'Policies[?
PolicyName==`S3MountpointAccessPolicy`]' | jq '.[0].Arn' |  tr -d '"')

eksctl create iamserviceaccount \
--name s3-csi-driver-sa \
--namespace kube-system \
--cluster $EKS_CLUSTER_NAME \
--attach-policy-arn $S3_CSI_POLICY_ARN \
--approve \
--role-name $S3_CSI_ROLE_NAME \
--region $REGION

kubectl label serviceaccount s3-csi-driver-sa app.kubernetes.io/component=csi-
driver app.kubernetes.io/instance=aws-mountpoint-s3-csi-driver app.kubernetes.io/
managed-by=EKS app.kubernetes.io/name=aws-mountpoint-s3-csi-driver -n kube-system
 --overwrite
```

c. (Optional) Install the Amazon S3 CSI driver add-on. This driver enables your pods to mount S3 buckets as persistent volumes, providing direct access to S3 storage from within your Kubernetes workloads.

```
%%bash -x

export S3_CSI_ROLE_ARN=$(aws iam get-role --role-name $S3_CSI_ROLE_NAME  --query
 'Role.Arn' --output text)
eksctl create addon --name aws-mountpoint-s3-csi-driver --cluster
 $EKS_CLUSTER_NAME --service-account-role-arn $S3_CSI_ROLE_ARN --force
```

d. (Optional) Create a Persistent Volume Claim (PVC) for S3 storage. This PVC enables your pods to request and use S3 storage as if it were a traditional file system.

```
%%bash -x

cat <<EOF> pvc_s3.yaml
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
name: s3-claim
spec:
accessModes:
- ReadWriteMany # supported options: ReadWriteMany / ReadOnlyMany
storageClassName: "" # required for static provisioning
resources:
requests:
    storage: 1200Gi # ignored, required
volumeName: s3-pv
EOF

kubectl apply -f pvc_s3.yaml
```

11. (Optional) Configure FSx storage access. Create an IAM service account for the Amazon FSx CSI driver. This service account will be used by the FSx CSI driver to interact with the Amazon FSx service on behalf of your cluster.

```
%%bash -x

eksctl create iamserviceaccount \
--name fsx-csi-controller-sa \
```

```
--namespace kube-system \
--cluster $EKS_CLUSTER_NAME \
--attach-policy-arn arn:aws:iam::aws:policy/AmazonFSxFullAccess \
--approve \
--role-name FSXLCSI-${EKS_CLUSTER_NAME}-${REGION} \
--region $REGION
```

Create the KEDA operator role

1. Create the trust policy and permissions policy.

```
# Create trust policy
cat <<EOF > /tmp/keda-trust-policy.json
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Federated": "arn:aws:iam::${ACCOUNT_ID}:oidc-provider/oidc.eks.
${REGION}.amazonaws.com/id/${OIDC_ID}"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
            "StringLike": {
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:sub":
 "system:serviceaccount:kube-system:keda-operator",
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:aud":
 "sts.amazonaws.com"
            }
        }
    }
]
}
EOF
# Create permissions policy
cat <<EOF > /tmp/keda-policy.json
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
```

```
        "Action": [
            "cloudwatch:GetMetricData",
            "cloudwatch:GetMetricStatistics",
            "cloudwatch:ListMetrics"
        ],
        "Resource": "*"
    },
    {
        "Effect": "Allow",
        "Action": [
            "aps:QueryMetrics",
            "aps:GetLabels",
            "aps:GetSeries",
            "aps:GetMetricMetadata"
        ],
        "Resource": "*"
    }
]
}
EOF
# Create the role
aws iam create-role \
--role-name keda-operator-role \
--assume-role-policy-document file:///tmp/keda-trust-policy.json
# Create the policy
KEDA_POLICY_ARN=$(aws iam create-policy \
--policy-name KedaOperatorPolicy \
--policy-document file:///tmp/keda-policy.json \
--query 'Policy.Arn' \
--output text)
# Attach the policy to the role
aws iam attach-role-policy \
--role-name keda-operator-role \
--policy-arn $KEDA_POLICY_ARN
```

2. If you're using gated models, create an IAM role to access the gated models.

   a. Create the trust policy and IAM role for gated model access.

```
%%bash -s $REGION

JUMPSTART_GATED_ROLE_NAME="JumpstartGatedRole-${REGION}-${HYPERPOD_CLUSTER_NAME}"

cat <<EOF > /tmp/trust-policy.json
```

```
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Principal": {
            "Federated": "arn:aws:iam::${ACCOUNT_ID}:oidc-provider/oidc.eks.
${REGION}.amazonaws.com/id/${OIDC_ID}"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
            "StringLike": {
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:sub":
 "system:serviceaccount:*:hyperpod-inference-service-account*",
                "oidc.eks.${REGION}.amazonaws.com/id/${OIDC_ID}:aud":
 "sts.amazonaws.com"
            }
        }
    },
        {
        "Effect": "Allow",
        "Principal": {
            "Service": "sagemaker.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
    }
]
}
EOF

# Create the role and attach the managed policy
aws iam create-role \
--role-name $JUMPSTART_GATED_ROLE_NAME \
--assume-role-policy-document file:///tmp/trust-policy.json

aws iam attach-role-policy \
--role-name $JUMPSTART_GATED_ROLE_NAME \
--policy-arn arn:aws:iam::aws:policy/AmazonSageMakerHyperPodGatedModelAccess
```

```
JUMPSTART_GATED_ROLE_ARN_LIST= !aws iam get-role --role-name=
$JUMPSTART_GATED_ROLE_NAME --query "Role.Arn" --output text
JUMPSTART_GATED_ROLE_ARN = JUMPSTART_GATED_ROLE_ARN_LIST[0]
!echo $JUMPSTART_GATED_ROLE_ARN
```

Install the inference operator

1. Install the HyperPod inference operator. This step gathers the required Amazon resource identifiers and generates the Helm installation command with the appropriate configuration parameters.

   Access the helm chart from https://github.com/aws/sagemaker-hyperpod-cli/tree/main/helm_chart .

```
git clone https://github.com/aws/sagemaker-hyperpod-cli
cd sagemaker-hyperpod-cli
cd helm_chart/HyperPodHelmChart
helm dependencies update charts/inference-operator
```

```
%%bash -x

HYPERPOD_INFERENCE_ROLE_ARN=$(aws iam get-role --role-name=
$HYPERPOD_INFERENCE_ROLE_NAME --query "Role.Arn" --output text)
echo $HYPERPOD_INFERENCE_ROLE_ARN

S3_CSI_ROLE_ARN=$(aws iam get-role --role-name=$S3_CSI_ROLE_NAME --query "Role.Arn"
 --output text)
echo $S3_CSI_ROLE_ARN

HYPERPOD_CLUSTER_ARN=$(aws sagemaker describe-cluster --cluster-name
 $HYPERPOD_CLUSTER_NAME --query "ClusterArn")

# Verify values
echo "Cluster Name: $EKS_CLUSTER_NAME"
echo "Execution Role: $HYPERPOD_INFERENCE_ROLE_ARN"
echo "Hyperpod ARN: $HYPERPOD_CLUSTER_ARN"
# Run the the HyperPod inference operator installation.

helm install hyperpod-inference-operator charts/inference-operator \
-n kube-system \
--set region=$REGION \
--set eksClusterName=$EKS_CLUSTER_NAME \
--set hyperpodClusterArn=$HYPERPOD_CLUSTER_ARN \
--set executionRoleArn=$HYPERPOD_INFERENCE_ROLE_ARN \
--set s3.serviceAccountRoleArn=$S3_CSI_ROLE_ARN \
--set s3.node.serviceAccount.create=false \
```

```
--set keda.podIdentity.aws.irsa.roleArn="arn:aws:iam::$ACCOUNT_ID:role/keda-operator-
role" \
--set tlsCertificateS3Bucket="s3://$BUCKET_NAME" \
--set alb.region=$REGION \
--set alb.clusterName=$EKS_CLUSTER_NAME \
--set alb.vpcId=$VPC_ID

# For JumpStart Gated Model usage, Add
# --set jumpstartGatedModelDownloadRoleArn=$UMPSTART_GATED_ROLE_ARN
```

2. Configure the service account annotations for IAM integration. This annotation enables the operator's service account to assume the necessary IAM permissions for managing inference endpoints and interacting with Amazon services.

```
%%bash -x

EKS_CLUSTER_ROLE_NAME=$(echo $EKS_CLUSTER_ROLE | sed 's/.*\///')

# Annotate service account
kubectl annotate serviceaccount hyperpod-inference-controller-manager \
-n hyperpod-inference-system \
eks.amazonaws.com/role-arn=arn:aws:iam::${ACCOUNT_ID}:role/${EKS_CLUSTER_ROLE_NAME} \
--overwrite
```

Verify the inference operator is working

Follow these steps to verify that your inference operator installation is working correctly by deploying and testing a simple model.

Deploy a test model to verify the operator

1. Create a model deployment configuration file. This creates a Kubernetes manifest file that defines a JumpStart model deployment for the HyperPod inference operator.

```
cat <<EOF>> simple_model_install.yaml
---
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: JumpStartModel
metadata:
  name: testing-deployment-bert
  namespace: default
```

```
spec:
  sageMakerEndpoint:
    name: "hp-inf-ep-for-testing"
  model:
    modelId: "huggingface-eqa-bert-base-cased"
  server:
    instanceType: "ml.c5.2xlarge"
  environmentVariables:
    - name: SAMPLE_ENV_VAR
      value: "sample_value"
  maxDeployTimeInSeconds: 1800
EOF
```

2. Deploy the model and clean up the configuration file.

```
kubectl create -f simple_model_install.yaml
rm -f simple_model_install.yaml
```

3. Verify the service account configuration to ensure the operator can assume Amazon permissions.

```
# Get the service account details
kubectl get serviceaccount -n hyperpod-inference-system

# Check if the service account has the Amazon annotations
kubectl describe serviceaccount hyperpod-inference-controller-manager -n hyperpod-
inference-system
```

Configure deployment settings (if using Studio UI)

1. Review the recommended instance type under **Deployment settings**.
2. If modifying the **Instance type**, ensure compatibility with your HyperPod cluster. Contact your admin if compatible instances aren't available.
3. For GPU-partitioned instances with MIG enabled, select an appropriate **GPU partition** from available MIG profiles to optimize GPU utilization. For more information, see Using GPU partitions in Amazon SageMaker HyperPod.
4. If using task governance, configure priority settings for model deployment preemption capabilities.

5. Enter the namespace provided by your admin. Contact your admin for the correct namespace if needed.

(Optional) Set up user access through the JumpStart UI in SageMaker AI Studio Classic

For more background on setting up SageMaker HyperPod access for Studio Classic users and configuring fine-grained Kubernetes RBAC permissions for data scientist users, read Setting up an Amazon EKS cluster in Studio and Setting up Kubernetes role-based access control.

1. Identify the IAM role that Data Scientist users will use to manage and deploy models to SageMaker HyperPod from SageMaker AI Studio Classic. This is typically the User Profile Execution Role or Domain Execution Role for the Studio Classic user.

```
%%bash -x

export DATASCIENTIST_ROLE_NAME="<Execution Role Name used in SageMaker Studio
 Classic>"

export DATASCIENTIST_POLICY_NAME="HyperPodUIAccessPolicy"
export EKS_CLUSTER_ARN=$(aws --region ${REGION} sagemaker describe-cluster --
cluster-name ${HYPERPOD_CLUSTER_NAME} \
  --query 'Orchestrator.Eks.ClusterArn' --output text)

export DATASCIENTIST_HYPERPOD_NAMESPACE="team-namespace"
```

2. Attach an Identity Policy enabling Model Deployment access.

```
%%bash -x

# Create access policy
cat << EOF > hyperpod-deployment-ui-access-policy.json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DescribeHyerpodClusterPermissions",
            "Effect": "Allow",
            "Action": [
                "sagemaker:DescribeCluster"
            ],
            "Resource": "${HYPERPOD_CLUSTER_ARN}"
        },
```

```
        {
            "Sid": "UseEksClusterPermissions",
            "Effect": "Allow",
            "Action": [
                "eks:DescribeCluster",
                "eks:AccessKubernetesApi",
                "eks:MutateViaKubernetesApi",
                "eks:DescribeAddon"
            ],
            "Resource": "${EKS_CLUSTER_ARN}"
        },
        {
            "Sid": "ListPermission",
            "Effect": "Allow",
            "Action": [
                "sagemaker:ListClusters",
                "sagemaker:ListEndpoints"
            ],
            "Resource": "*"
        },
        {
            "Sid": "SageMakerEndpointAccess",
            "Effect": "Allow",
            "Action": [
                "sagemaker:DescribeEndpoint",
                "sagemaker:InvokeEndpoint"
            ],
            "Resource": "arn:aws:sagemaker:${REGION}:${ACCOUNT_ID}:endpoint/*"
        }
    ]
}
EOF

aws iam put-role-policy --role-name ${DATASCIENTIST_ROLE_NAME} --policy-name
 HyperPodDeploymentUIAccessInlinePolicy --policy-document file://hyperpod-
deployment-ui-access-policy.json
```

3. Create an EKS Access Entry for the user mapping them to a kubernetes group.

```
%%bash -x

aws eks create-access-entry --cluster-name ${EKS_CLUSTER_NAME} \
    --principal-arn "arn:aws:iam::${ACCOUNT_ID}:role/${DATASCIENTIST_ROLE_NAME}" \
```

```
    --kubernetes-groups '["hyperpod-scientist-user-namespace-level","hyperpod-
scientist-user-cluster-level"]'
```

4. Create Kubernetes RBAC policies for the user.

```
%%bash -x

cat << EOF > cluster_level_config.yaml
kind: ClusterRole

Deploy foundation models and custom fine-tuned models

Whether you're deploying pre-trained foundation open-weights or gated models from Amazon SageMaker JumpStart or your own custom or fine-tuned models stored in Amazon S3 or Amazon FSx, SageMaker HyperPod provides the flexible, scalable infrastructure you need for production inference workloads.

	Deploy open-weights and gated foundation models from JumpStart	**Deploy custom and fine-tuned models from Amazon S3 and Amazon FSx**	**Deploy models from local NVMe storage**
Description	Deploy from a comprehensive catalog of pre-trained foundation models with automatic optimization and scaling policies tailored to each model family.	Bring your own custom and fine-tuned models and use SageMaker HyperPod's enterprise infrastructure for production-scale inference. Choose between cost-effective storage with Amazon S3 or a high-performance file system with Amazon FSx.	Load model weights from a node's local NVMe storage to eliminate network latency during pod startup. Useful for autoscaling events, scale-from-zero workloads, and latency-sensitive failovers.
Key benefits	• One-click deployment through Amazon SageMaker Studio UI • Auto-scaling based on incoming	• Support for multiple storage backends: Amazon S3, Amazon FSx	• Reduced cold-start time by reading weights locally • No network dependency for model loading

	Deploy open-weights and gated foundation models from JumpStart	Deploy custom and fine-tuned models from Amazon S3 and Amazon FSx	Deploy models from local NVMe storage
	requests automatically enabled • Pre-optimized containers and configurations for each model family • EULA handling for gated models	• Flexible container and framework support • Custom scaling policies based on your model's characteristics	• Optional fallback to Amazon S3 when NVMe cache is missing • Custom Kubernetes volumes and initContainers
Deployment options	• Amazon SageMaker Studio for visual deployment • kubectl for Kubernetes-native operations • Python SDK for programmatic integration • HyperPod CLI for command-line automation	• kubectl for Kubernetes-native operations • Python SDK for programmatic integration • HyperPod CLI for command-line automation	• kubectl for Kubernetes-native operations • Python SDK for programmatic integration • HyperPod CLI for command-line automation

The following sections step you through deploying models from Amazon SageMaker JumpStart, from Amazon S3 and Amazon FSx, and from local NVMe storage.

Topics

- Deploy models from JumpStart using Amazon SageMaker Studio
- Deploy models from JumpStart using kubectl
- Deploy models from Amazon S3, Amazon FSx, or Hugging Face Hub using kubectl
- Deploy models from local NVMe storage using kubectl

- Deploy custom fine-tuned models using the Python SDK and HPCLI
- Deploy models from Amazon SageMaker JumpStart using the Python SDK and HPCLI

Deploy models from JumpStart using Amazon SageMaker Studio

The following steps show you through how to deploy models from JumpStart using Amazon SageMaker Studio.

Prerequisites

Verify that you've set up inference capabilities on your Amazon SageMaker HyperPod clusters. For more information, see Setting up your HyperPod clusters for model deployment.

Create a HyperPod deployment

1. In Amazon SageMaker Studio, open the **JumpStart** landing page from the left navigation pane.
2. Under **All public models**, choose a model you want to deploy.

   > **Note**
   >
   > If you've selected a gated model, you'll have to accept the End User License Agreement (EULA).

3. Choose **SageMaker HyperPod**.
4. Under **Deployment settings**, JumpStart will recommend an instance for deployment. You can modify these settings if necessary.
   a. If you modify **Instance type**, ensure it's compatible with the chosen **HyperPod cluster**. If there aren't any compatible instances, you'll need to select a new **HyperPod cluster** or contact your admin to add compatible instances to the cluster.
   b. To prioritize the model deployment, install the task governance addon, create compute allocations, and set up task rankings for the cluster policy. Once this is done, you should see an option to select a priority for the model deployment which can be used for preemption of other deployments and tasks on the cluster.
   c. Enter the namespace to which your admin has provided you access. You may have to directly reach out to your admin to get the exact namespace. Once a valid namespace is provided, the **Deploy** button should be enabled to deploy the model.
   d. If your instance type is partitioned (MIG enabled), select a **GPU partition type**.

e. If you want to enable L2 KVCache or Intelligent routing for speeding up LLM inference, enable them. By default, only L1 KV Cache is enabled. For more details on KVCache and Intelligent routing, see SageMaker HyperPod model deployment.

5. Choose **Deploy** and wait for the **Endpoint** to be created.
6. After the **Endpoint** has been created, select **Test inference**.

Edit a HyperPod deployment

1. In Amazon SageMaker Studio, select **Compute** and then **HyperPod clusters** from the left navigation pane.
2. Under **Deployments**, choose the HyperPod cluster deployment you want to modify.
3. From the vertical ellipsis icon (⋮), choose **Edit**.
4. Under **Deployment settings**, you can enable or disable **Auto-scaling**, and change the number of **Max replicas**.
5. Select **Save**.
6. The **Status** will change to **Updating**. Once it changes back to **In service**, your changes are complete and you'll see a message confirming it.

Delete a HyperPod deployment

1. In Amazon SageMaker Studio, select **Compute** and then **HyperPod clusters** from the left navigation pane.
2. Under **Deployments**, choose the HyperPod cluster deployment you want to modify.
3. From the vertical ellipsis icon (⋮), choose **Delete**.
4. In the **Delete HyperPod deployment window**, select the checkbox.
5. Choose **Delete**.
6. The **Status** will change to **Deleting**. Once the HyperPod deployment has been deleted, you'll see a message confirming it.

Deploy models from JumpStart using kubectl

The following steps show you how to deploy a JumpStart model to a HyperPod cluster using kubectl.

The following instructions contain code cells and commands designed to run in a terminal. Ensure you have configured your environment with Amazon credentials before executing these commands.

Prerequisites

Before you begin, verify that you've:

- Set up inference capabilities on your Amazon SageMaker HyperPod clusters. For more information, see Setting up your HyperPod clusters for model deployment.
- Installed kubectl utility and configured jq in your terminal.

Setup and configuration

1. Select your Region.

```
export REGION=<region>
```

2. View all SageMaker public hub models and HyperPod clusters.
3. Select a `JumpstartModel` from JumpstartPublic Hub. JumpstartPublic hub has a large number of models available so you can use `NextToken` to iteratively list all available models in the public hub.

```
aws sagemaker list-hub-contents --hub-name SageMakerPublicHub --
hub-content-type Model --query '{Models: HubContentSummaries[].
{ModelId:HubContentName,Version:HubContentVersion}, NextToken: NextToken}' --output
 json
```

```
export MODEL_ID="deepseek-llm-r1-distill-qwen-1-5b"
export MODEL_VERSION="2.0.4"
```

4. Configure the model ID and cluster name you've selected into the following variables.

> **Note**
>
> Check with your cluster admin to ensure permissions are granted for this role or user. You can run `!aws sts get-caller-identity --query "Arn"` to check which role or user you are using in your terminal.

```
aws sagemaker list-clusters --output table

# Select the cluster name where you want to deploy the model.
export HYPERPOD_CLUSTER_NAME="<insert cluster name here>"

# Select the instance that is relevant for your model deployment and exists within
 the selected cluster.
# List availble instances in your HyperPod cluster
aws sagemaker describe-cluster --cluster-name=$HYPERPOD_CLUSTER_NAME --query
 "InstanceGroups[].{InstanceType:InstanceType,Count:CurrentCount}" --output table

# List supported instance types for the selected model
aws sagemaker describe-hub-content --hub-name SageMakerPublicHub --hub-
content-type Model --hub-content-name "$MODEL_ID" --output json | jq -r
 '.HubContentDocument | fromjson | {Default: .DefaultInferenceInstanceType,
 Supported: .SupportedInferenceInstanceTypes}'

# Select and instance type from the cluster that is compatible with the model.
# Make sure that the selected instance is either default or supported instance type
 for the jumpstart model
export INSTANCE_TYPE="<Instance_type_In_cluster"
```

5. Confirm with the cluster admin which namespace you are permitted to use. The admin should have created a `hyperpod-inference` service account in your namespace.

```
export CLUSTER_NAMESPACE="default"
```

6. Set a name for endpoint and custom object to be create.

```
export SAGEMAKER_ENDPOINT_NAME="deepsek-qwen-1-5b-test"
```

7. The following is an example for a `deepseek-llm-r1-distill-qwen-1-5b` model deployment from Jumpstart. Create a similar deployment yaml file based on the model selected in the preceding step.

> **Note**
>
> If your cluster uses GPU partitioning with MIG, you can request specific MIG profiles by adding the `acceleratorPartitionType` field to the server specification. For more information, see Task Submission with MIG.

```
cat << EOF > jumpstart_model.yaml
---
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: JumpStartModel
metadata:
  name: $SAGEMAKER_ENDPOINT_NAME
  namespace: $CLUSTER_NAMESPACE
spec:
  sageMakerEndpoint:
    name: $SAGEMAKER_ENDPOINT_NAME
  model:
    modelHubName: SageMakerPublicHub
    modelId: $MODEL_ID
    modelVersion: $MODEL_VERSION
  server:
    instanceType: $INSTANCE_TYPE
    # Optional: Specify GPU partition profile for MIG-enabled instances
    # acceleratorPartitionType: "1g.10gb"
  metrics:
    enabled: true
  environmentVariables:
    - name: SAMPLE_ENV_VAR
      value: "sample_value"
  maxDeployTimeInSeconds: 1800
  autoScalingSpec:
    cloudWatchTrigger:
      name: "SageMaker-Invocations"
      namespace: "AWS/SageMaker"
      useCachedMetrics: false
      metricName: "Invocations"
      targetValue: 10
      minValue: 0.0
      metricCollectionPeriod: 30
      metricStat: "Sum"
```

```
      metricType: "Average"
      dimensions:
        - name: "EndpointName"
          value: "$SAGEMAKER_ENDPOINT_NAME"
        - name: "VariantName"
          value: "AllTraffic"
EOF
```

> **Note**
>
> To configure KV caching and intelligent routing for improved performance, see Configure KV caching and intelligent routing.

Deploy your model

Update your kubernetes configuration and deploy your model

1. Configure kubectl to connect to the HyperPod cluster orchestrated by Amazon EKS.

```
export EKS_CLUSTER_NAME=$(aws --region $REGION sagemaker describe-cluster --
cluster-name $HYPERPOD_CLUSTER_NAME \
  --query 'Orchestrator.Eks.ClusterArn' --output text | \
  cut -d'/' -f2)
aws eks update-kubeconfig --name $EKS_CLUSTER_NAME --region $REGION
```

2. Deploy your JumpStart model.

```
kubectl apply -f jumpstart_model.yaml
```

Monitor the status of your model deployment

1. Verify that the model is successfully deployed.

```
kubectl describe JumpStartModel $SAGEMAKER_ENDPOINT_NAME -n $CLUSTER_NAMESPACE
```

2. Verify that the endpoint is successfully created.

```
aws sagemaker describe-endpoint --endpoint-name=$SAGEMAKER_ENDPOINT_NAME --output
 table
```

3. Invoke your model endpoint. You can programmatically retrieve example payloads from the `JumpStartModel` object.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name $SAGEMAKER_ENDPOINT_NAME \
  --content-type "application/json" \
  --body '{"inputs": "What is AWS SageMaker?"}' \
  --region $REGION \
  --cli-binary-format raw-in-base64-out \
  /dev/stdout
```

Manage your deployment

Delete your JumpStart model deployment once you no longer need it.

```
kubectl delete JumpStartModel $SAGEMAKER_ENDPOINT_NAME -n $CLUSTER_NAMESPACE
```

Troubleshooting

Use these debugging commands if your deployment isn't working as expected.

1. Check the status of Kubernetes deployment. This command inspects the underlying Kubernetes deployment object that manages the pods running your model. Use this to troubleshoot pod scheduling, resource allocation, and container startup issues.

```
kubectl describe deployment $SAGEMAKER_ENDPOINT_NAME -n $CLUSTER_NAMESPACE
```

2. Check the status of your JumpStart model resource. This command examines the custom `JumpStartModel` resource that manages the high-level model configuration and deployment lifecycle. Use this to troubleshoot model-specific issues like configuration errors or SageMaker AI endpoint creation problems.

```
kubectl describe JumpStartModel $SAGEMAKER_ENDPOINT_NAME -n $CLUSTER_NAMESPACE
```

3. Check the status of all Kubernetes objects. This command provides a comprehensive overview of all related Kubernetes resources in your namespace. Use this for a quick health check to see

the overall state of pods, services, deployments, and custom resources associated with your model deployment.

```
kubectl get pods,svc,deployment,JumpStartModel,sagemakerendpointregistration -n
 $CLUSTER_NAMESPACE
```

Deploy models from Amazon S3, Amazon FSx, or Hugging Face Hub using kubectl

The following steps show you how to deploy models stored on Amazon S3, Amazon FSx, or Hugging Face Hub to a Amazon SageMaker HyperPod cluster using kubectl.

The following instructions contain code cells and commands designed to run in a terminal. Ensure you have configured your environment with Amazon credentials before executing these commands.

Prerequisites

Before you begin, verify that you've:

- Set up inference capabilities on your Amazon SageMaker HyperPod clusters. For more information, see Setting up your HyperPod clusters for model deployment.
- Installed kubectl utility in your terminal.

Setup and configuration

Replace all placeholder values with your actual resource identifiers.

1. Select your Region in your environment.

   ```
   export REGION=<region>
   ```

2. Initialize your cluster name. This identifies the HyperPod cluster where your model will be deployed.

   > **Note**
   >
   > Check with your cluster admin to ensure permissions are granted for this role or user. You can run `!aws sts get-caller-identity --query "Arn"` to check which role or user you are using in your terminal.

```
# Specify your hyperpod cluster name here
HYPERPOD_CLUSTER_NAME="<Hyperpod_cluster_name>"

# NOTE: For sample deployment, we use g5.24xlarge for Llama 3.1 8B model which has
 sufficient memory and GPU
instance_type="ml.g5.24xlarge"
```

3. Initialize your cluster namespace. Your cluster admin should've already created a hyperpod-inference service account in your namespace.

```
cluster_namespace="<namespace>"
```

4. Create a CRD using one of the following options:

   Using Amazon FSx as the model source

   1. Set up a SageMaker endpoint name.

      ```
      export SAGEMAKER_ENDPOINT_NAME="llama-fsx"
      ```

   2. Configure the Amazon FSx file system ID to be used.

      ```
      export FSX_FILE_SYSTEM_ID="fs-1234abcd"
      ```

   3. The following is an example yaml file for creating an endpoint with Amazon FSx and a Llama model.

      Note

      For clusters with GPU partitioning enabled, replace `nvidia.com/gpu` with the appropriate MIG resource name such as `nvidia.com/mig-1g.10gb`. For more information, see Task Submission with MIG.

      ```
      cat <<EOF> deploy_fsx_cluster_inference.yaml
      ---
      apiVersion: inference.sagemaker.aws.amazon.com/v1
      kind: InferenceEndpointConfig
      metadata:
      ```

```
  name: $SAGEMAKER_ENDPOINT_NAME
  namespace: $CLUSTER_NAMESPACE
spec:
  modelName: Llama-3.1-8B-Instruct
  instanceType: ml.g5.24xlarge
  invocationEndpoint: v1/chat/completions
  replicas: 2
  modelSourceConfig:
    fsxStorage:
      fileSystemId: $FSX_FILE_SYSTEM_ID
    modelLocation: Llama-3.1-8B-Instruct
    modelSourceType: fsx
  worker:
    image: vllm/vllm-openai:v0.19.1
    modelInvocationPort:
      containerPort: 8000
      name: http
    modelVolumeMount:
      mountPath: /opt/ml/model
      name: model-weights
    resources:
      limits:
        nvidia.com/gpu: 4
      requests:
        cpu: 30000m
        memory: 100Gi
        nvidia.com/gpu: 4
    args:
      - "--model"
      - "/opt/ml/model"
      - "--port"
      - "8000"
      - "--tensor-parallel-size"
      - "4"
      - "--served-model-name"
      - "Llama-3.1-8B-Instruct"
    environmentVariables:
      - name: VLLM_REQUEST_TIMEOUT
        value: "600"
EOF
```

Using Amazon S3 as the model source

1. Set up a SageMaker endpoint name.

```
export SAGEMAKER_ENDPOINT_NAME="llama-s3"
```

2. Configure the Amazon S3 bucket location where the model is located.

```
export S3_MODEL_LOCATION="<your-s3-bucket-name>"
```

3. The following is an example yaml file for creating an endpoint with Amazon S3 and a Llama model using vLLM as the inference runtime.

> **Note**
>
> For clusters with GPU partitioning enabled, replace `nvidia.com/gpu` with the appropriate MIG resource name such as `nvidia.com/mig-1g.10gb`. For more information, see Task Submission with MIG.

```
cat <<EOF> deploy_s3_inference.yaml
---
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: InferenceEndpointConfig
metadata:
  name: $SAGEMAKER_ENDPOINT_NAME
  namespace: $CLUSTER_NAMESPACE
spec:
  modelName: Llama-3.1-8B-Instruct
  instanceType: ml.g5.24xlarge
  invocationEndpoint: v1/chat/completions
  replicas: 2
  modelSourceConfig:
    modelSourceType: s3
    s3Storage:
      bucketName: $S3_MODEL_LOCATION
      region: $REGION
    modelLocation: Llama-3.1-8B-Instruct
    prefetchEnabled: true
  worker:
```

```
    image: vllm/vllm-openai:v0.19.1
    modelInvocationPort:
      containerPort: 8000
      name: http
    modelVolumeMount:
      name: model-weights
      mountPath: /opt/ml/model
    resources:
      limits:
        nvidia.com/gpu: 4
      requests:
        cpu: 30000m
        memory: 100Gi
        nvidia.com/gpu: 4
    args:
      - "--model"
      - "/opt/ml/model"
      - "--port"
      - "8000"
      - "--tensor-parallel-size"
      - "4"
      - "--served-model-name"
      - "Llama-3.1-8B-Instruct"
    environmentVariables:
      - name: VLLM_REQUEST_TIMEOUT
        value: "600"
EOF
```

Using Hugging Face Hub as the model source

1. Create a Kubernetes Secret containing your Hugging Face API token. This token is required for gated models and recommended for all downloads. You can generate a token at huggingface.co/settings/tokens.

> **Important**
>
> Deploying models from Hugging Face Hub requires outbound internet access from your cluster nodes to Hugging Face domains including `*.huggingface.co` and `*.hf.co`. Ensure that your VPC networking

configuration (NAT gateway, security groups, and network ACLs) allows HTTPS egress to these domains. Without internet access, the model download will fail.

Note

For production environments, we recommend using Amazon S3 or Amazon FSx as the model source instead of Hugging Face Hub. With Amazon S3 and Amazon FSx, model artifacts are stored within your Amazon account, eliminating the dependency on external internet connectivity and providing more predictable deployment times. Hugging Face Hub is best suited for development, experimentation, and quick prototyping where direct access to the Hugging Face model repository is convenient.

```
kubectl create secret generic hf-token-secret \
  --from-literal=token=hf_YOUR_TOKEN_HERE \
  -n $CLUSTER_NAMESPACE
```

2. Set up a SageMaker endpoint name.

```
export SAGEMAKER_ENDPOINT_NAME="mistral7b-hf"
```

3. The following is an example YAML file for deploying a Mistral 7B model from Hugging Face Hub using vLLM as the inference runtime. With `prefetchEnabled: true`, the operator uses an init container to download the model before the inference container starts.

Note

For clusters with GPU partitioning enabled, replace `nvidia.com/gpu` with the appropriate MIG resource name such as `nvidia.com/mig-1g.10gb`. For more information, see Task Submission with MIG.

```
cat <<EOF> deploy_hf_inference.yaml
---
apiVersion: inference.sagemaker.aws.amazon.com/v1
```

```
kind: InferenceEndpointConfig
metadata:
  name: $SAGEMAKER_ENDPOINT_NAME
  namespace: $CLUSTER_NAMESPACE
spec:
  modelName: mistral-7b
  modelSourceConfig:
    modelSourceType: huggingface
    prefetchEnabled: true
    huggingFaceModel:
      modelId: "mistralai/Mistral-7B-Instruct-v0.3"
      tokenSecretRef:
        name: hf-token-secret
        key: token
  instanceType: "ml.g5.24xlarge"
  invocationEndpoint: v1/chat/completions
  worker:
    image: "vllm/vllm-openai:v0.19.1"
    modelInvocationPort:
      containerPort: 8000
      name: http
    modelVolumeMount:
      name: model-weights
      mountPath: /opt/ml/model
    resources:
      requests:
        nvidia.com/gpu: "4"
        memory: "96Gi"
        cpu: "16"
      limits:
        nvidia.com/gpu: "4"
        memory: "96Gi"
        cpu: "16"
    args:
      - "--model"
      - "/opt/ml/model"
      - "--port"
      - "8000"
      - "--tensor-parallel-size"
      - "4"
      - "--served-model-name"
      - "mistralai/Mistral-7B-Instruct-v0.3"
    environmentVariables:
      - name: VLLM_REQUEST_TIMEOUT
```

```
        value: "600"
EOF
```

4. The key Hugging Face configuration fields are:
   - `modelSourceType` (required) — Set to `huggingface`.
   - `huggingFaceModel.modelId` (required) — The Hugging Face Hub model identifier in `org/model` format (for example, `mistralai/Mistral-7B-Instruct-v0.3`).
   - `huggingFaceModel.commitSHA` (optional) — A 40-character Git commit SHA to pin a specific model version. If omitted, defaults to the `main` branch.
   - `huggingFaceModel.tokenSecretRef` (optional) — Reference to a Kubernetes Secret containing your Hugging Face API token. Required for gated models. The token is only used during model download and is not exposed to the inference container.
   - `prefetchEnabled` (optional) — When `true`, an init container downloads the model before the inference container starts. When `false`, the inference runtime (vLLM, TGI, SGLang) downloads the model natively at startup. Defaults to `false`.

> **Note**
>
> To configure KV caching and intelligent routing for improved performance, see Configure KV caching and intelligent routing.

Deploy your model from Amazon S3, Amazon FSx, or Hugging Face Hub

1. Get the Amazon EKS cluster name from the HyperPod cluster ARN for kubectl authentication.

```
export EKS_CLUSTER_NAME=$(aws --region $REGION sagemaker describe-cluster --
cluster-name $HYPERPOD_CLUSTER_NAME \
  --query 'Orchestrator.Eks.ClusterArn' --output text | \
  cut -d'/' -f2)
aws eks update-kubeconfig --name $EKS_CLUSTER_NAME --region $REGION
```

2. Deploy your InferenceEndpointConfig model with one of the following options:

   Deploy with Amazon FSx as a source

```
kubectl apply -f deploy_fsx_luster_inference.yaml
```

Deploy with Amazon S3 as a source

```
kubectl apply -f deploy_s3_inference.yaml
```

Deploy with Hugging Face Hub as a source

```
kubectl apply -f deploy_hf_inference.yaml
```

If the deployment fails, check the InferenceEndpointConfig events for diagnostic information. For common issues such as token errors, network connectivity, and model not found, see Hugging Face Hub model deployment failures.

Verify the status of your deployment

1. Check if the model successfully deployed.

```
kubectl describe InferenceEndpointConfig $SAGEMAKER_ENDPOINT_NAME -n
 $CLUSTER_NAMESPACE
```

2. Check that the endpoint is successfully created.

```
kubectl describe SageMakerEndpointRegistration $SAGEMAKER_ENDPOINT_NAME -n
 $CLUSTER_NAMESPACE
```

3. Test the deployed endpoint to verify it's working correctly. This step confirms that your model is successfully deployed and can process inference requests.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name $SAGEMAKER_ENDPOINT_NAME \
  --content-type "application/json" \
  --body '{"inputs": "What is AWS SageMaker?"}' \
  --region $REGION \
  --cli-binary-format raw-in-base64-out \
  /dev/stdout
```

Manage your deployment

When you're finished testing your deployment, use the following commands to clean up your resources.

> **Note**
>
> Verify that you no longer need the deployed model or stored data before proceeding.

Clean up your resources

1. Delete the inference deployment and associated Kubernetes resources. This stops the running model containers and removes the SageMaker endpoint.

```
kubectl delete inferenceendpointconfig $SAGEMAKER_ENDPOINT_NAME -n
 $CLUSTER_NAMESPACE
```

2. Verify the cleanup was done successfully.

```
# # Check that Kubernetes resources are removed
kubectl get
 pods,svc,deployment,InferenceEndpointConfig,sagemakerendpointregistration -n
 $CLUSTER_NAMESPACE
```

```
# Verify SageMaker endpoint is deleted (should return error or empty)
aws sagemaker describe-endpoint --endpoint-name $SAGEMAKER_ENDPOINT_NAME --region
 $REGION
```

Troubleshooting

Use these debugging commands if your deployment isn't working as expected.

1. Check the Kubernetes deployment status.

```
kubectl describe deployment $SAGEMAKER_ENDPOINT_NAME -n $CLUSTER_NAMESPACE
```

2. Check the InferenceEndpointConfig status to see the high-level deployment state and any configuration issues.

```
kubectl describe InferenceEndpointConfig $SAGEMAKER_ENDPOINT_NAME -n
 $CLUSTER_NAMESPACE
```

3. Check status of all Kubernetes objects. Get a comprehensive view of all related Kubernetes resources in your namespace. This gives you a quick overview of what's running and what might be missing.

```
kubectl get
 pods,svc,deployment,InferenceEndpointConfig,sagemakerendpointregistration -n
 $CLUSTER_NAMESPACE
```

Deploy models from local NVMe storage using kubectl

This topic shows you how to deploy inference endpoints on Amazon SageMaker HyperPod that load model weights from a node's local NVMe storage instead of pulling them over the network from Amazon S3 or Amazon FSx. Reading weights locally eliminates the network hop during pod startup, which reduces inference pod cold-start time and is useful for autoscaling events, scale-from-zero workloads, and latency-sensitive failovers. For workloads where cold-start latency is not a concern, use `modelSourceType: s3` or `fsx` and skip this topic.

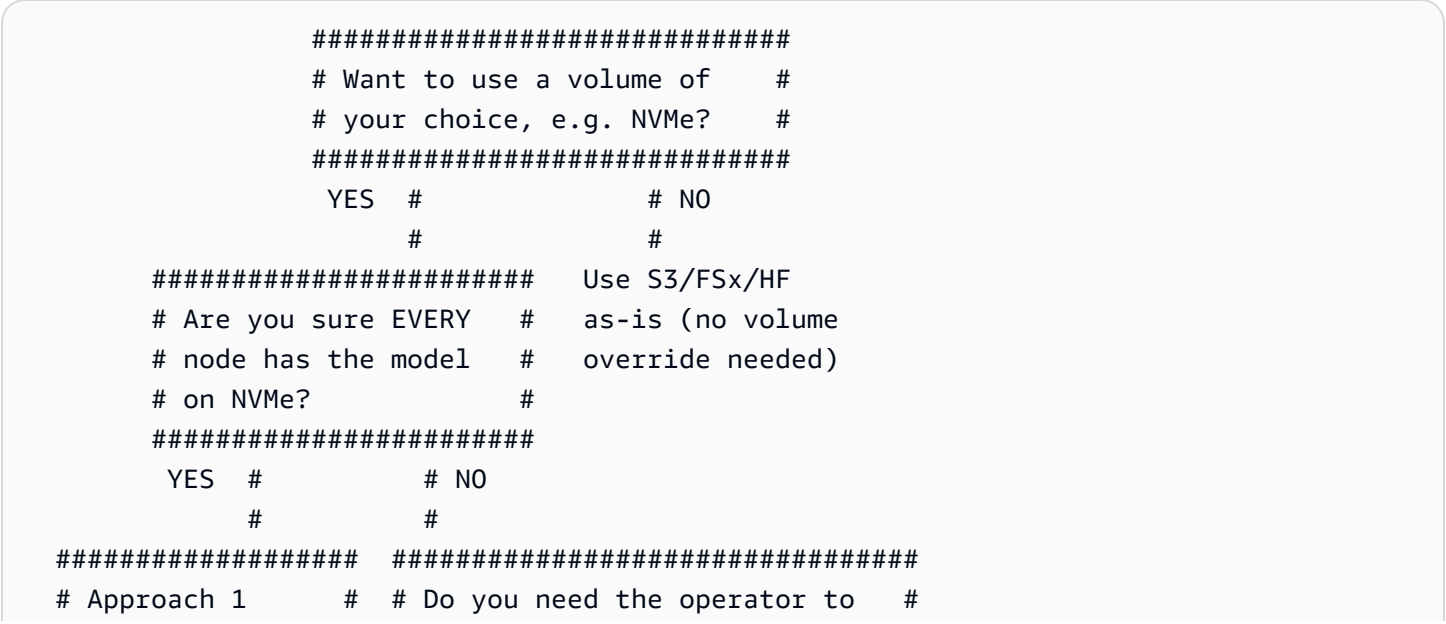
Local NVMe is node-local and ephemeral: data on NVMe is lost when a node is replaced, for example during a spot interruption, hardware failure, or AMI refresh. The approaches in this topic handle this differently — some require you to pre-populate every node, others fall back to Amazon S3 automatically when the model is not cached locally. Local NVMe instance storage is typically found in P, G, and Trn instance families. See Amazon EC2 instance store specifications to validate availability for your instance type.

You can choose from the following approaches based on your storage requirements:

NVMe deployment approaches

#	Approach	Description
1	Kubernetes volume (no fallback)	Use when model weights exist on NVMe on every node. Simplest setup with no Amazon S3, Amazon FSx, PV/PVC, or initContainers required.
2	Kubernetes volume with fallback	Use when the model might not exist on NVMe on every node. You provide a custom `initContainer` that checks

#	Approach	Description
		NVMe first and downloads from Amazon S3 using IRSA credentials if the model is missing.
3	Amazon S3 with prefetch and fallback	Use when you want to stage model weights to RAM for pod startup. You provide a custom `initContainer` that checks NVMe first and falls back to copying from the operator-provisioned Amazon S3 mount if the model is not cached locally.



Prerequisites

Before you begin, verify that you've:

- Set up inference capabilities on your Amazon SageMaker HyperPod clusters. For more information, see Setting up your HyperPod clusters for model deployment.
- Installed kubectl utility and configured jq in your terminal.
- Pre-populated model weights on the local NVMe storage of your target nodes (see the section called “Preload model weights to NVMe” for instructions).

Choose your deployment approach

Use the following decision flow to determine which approach is right for your use case.

```
#                 #  # create S3/FSx PVCs as a       #
# Use k8sVolume   #  # fallback when the model is    #
# field in CRD to #  # missing on a node?            #
# read from NVMe  #  ###################################
# directly.       #    YES  #                # NO
###################         #                #
                 ###################  ########################
                 # Approach 3       #  # Approach 2           #
                 #                  #  #                       #
                 # Use S3 with      #  # Use k8sVolume with a #
                 # prefetch enabled.#  # custom initContainer #
                 # Custom           #  # you create that      #
                 # initContainer    #  # checks NVMe first    #
                 # checks NVMe      #  # and downloads from   #
                 # first, falls     #  # S3 via IRSA if the   #
                 # back to S3, and  #  # model is missing.    #
                 # copies to RAM.   #  ########################
                 ####################
```

Deploy using a Kubernetes volume (no fallback)

Use this approach when you have model weights on NVMe on every node and want the simplest setup — no Amazon S3 or Amazon FSx configuration, no PV/PVC, and no initContainers.

When you set `modelSourceType: kubernetesVolume`, the operator skips PV/PVC creation entirely. No CSI driver, Amazon S3 fuse mount, or Amazon FSx mount is used. The customer-provided `model-weights` volume is used directly in the pod spec, and the worker reads model data from NVMe at `/opt/ml/model`.

> **Important**
>
> When using `modelSourceType: kubernetesVolume`, the operator derives the expected volume name from `modelVolumeMount.name` in your worker configuration. `kubernetes.volumes` must contain a volume with that same name. The operator validates this and rejects the deployment with a `KubernetesVolumeValidationFailed` condition if no matching volume is found. In the following examples, both use `model-weights`.

1. Create the `InferenceEndpointConfig` YAML file. Replace the placeholder values with your actual resource identifiers.

```
cat <<EOF> deploy_nvme_k8s_volume.yaml
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: InferenceEndpointConfig
metadata:
  name: nvme-k8s-volume
  namespace: default
spec:
  endpointName: nvme-k8s-volume
  modelName: Qwen2.5-VL-7B-Instruct
  invocationEndpoint: v1/chat/completions
  replicas: 1
  modelSourceConfig:
    modelSourceType: kubernetesVolume
  kubernetes:
    volumes:
      - name: model-weights
        hostPath:
          path: /opt/dlami/nvme/<YOUR_MODEL>
          type: Directory
  loadBalancer:
    healthCheckPath: /health
  worker:
    image: lmcache/vllm-openai:latest
    args:
      - /opt/ml/model
      - --max-model-len
      - "15000"
      - --tensor-parallel-size
      - "1"
    modelInvocationPort:
      containerPort: 8000
      name: http
    modelVolumeMount:
      name: model-weights
      mountPath: /opt/ml/model
    resources:
      limits:
        nvidia.com/gpu: "1"
      requests:
        cpu: "6"
        memory: 30Gi
        nvidia.com/gpu: "1"
    environmentVariables:
```

```
      - name: PYTHONHASHSEED
        value: "123"
      - name: VLLM_REQUEST_TIMEOUT
        value: "600"
EOF
```

> **Note**
>
> To configure KV caching and intelligent routing for improved performance, see Configure KV caching and intelligent routing.

2. Deploy the `InferenceEndpointConfig`.

```
kubectl apply -f deploy_nvme_k8s_volume.yaml
```

3. Verify the deployment status.

```
kubectl describe InferenceEndpointConfig nvme-k8s-volume -n default
```

Deploy using a Kubernetes volume with fallback

Use this approach when the model might or might not be on NVMe on a given node. A `hostPath` volume only works on nodes where the data exists — pods scheduled on other nodes would mount an empty or nonexistent path, causing the model server to fail.

In this approach, you set `modelSourceType: kubernetesVolume` and provide a custom `initContainer` that checks NVMe first and downloads from Amazon S3 using IRSA credentials if the model is missing.

Set up IRSA

Before deploying, configure IAM Roles for Service Accounts (IRSA) to give your pods credentials for downloading from Amazon S3.

1. Get the OIDC provider ID for your cluster.

```
aws eks describe-cluster --name <CLUSTER_NAME> --region <REGION> \
  --query "cluster.identity.oidc.issuer" --output text
```

2. Create an IAM trust policy. Save the following as `trust-policy.json`, replacing the placeholder values.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": {
      "Federated": "arn:aws:iam::<ACCOUNT_ID>:oidc-provider/
oidc.eks.<REGION>.amazonaws.com/id/<OIDC_ID>"
    },
    "Action": "sts:AssumeRoleWithWebIdentity",
    "Condition": {
      "StringEquals": {
        "oidc.eks.<REGION>.amazonaws.com/id/<OIDC_ID>:sub":
 "system:serviceaccount:<NAMESPACE>:<SA_NAME>",
        "oidc.eks.<REGION>.amazonaws.com/id/<OIDC_ID>:aud": "sts.amazonaws.com"
      }
    }
  }]
}
```

> **Warning**
>
> Always scope the trust policy to a specific namespace and ServiceAccount name. Never use wildcards in the subject condition (for example, `system:serviceaccount:*:*`), as this would allow any ServiceAccount in any namespace to assume the role.

3. Create the IAM role and attach a scoped Amazon S3 read policy for your model bucket.

```
aws iam create-role --role-name <ROLE_NAME> \
  --assume-role-policy-document file://trust-policy.json

aws iam put-role-policy --role-name <ROLE_NAME> \
  --policy-name S3ModelReadAccess \
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [{
      "Effect": "Allow",
      "Action": ["s3:GetObject", "s3:ListBucket"],
      "Resource": [
```

```
        "arn:aws:s3:::<YOUR_BUCKET>",
        "arn:aws:s3:::<YOUR_BUCKET>/<YOUR_MODEL_PREFIX>/*"
      ]
    }]
  }'
```

4. Create the Kubernetes service account with the IRSA annotation.

```
kubectl create sa <SA_NAME> -n <NAMESPACE>
kubectl annotate sa <SA_NAME> -n <NAMESPACE> \
  eks.amazonaws.com/role-arn=arn:aws:iam::<ACCOUNT_ID>:role/<ROLE_NAME>
```

Deploy the model

1. Create the `InferenceEndpointConfig` YAML file. Replace the placeholder values with your actual resource identifiers.

```
cat <<EOF> deploy_nvme_k8s_volume_fallback.yaml
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: InferenceEndpointConfig
metadata:
  name: nvme-k8s-volume-fallback
  namespace: default
spec:
  endpointName: nvme-k8s-volume-fallback
  modelName: Qwen2.5-VL-7B-Instruct
  invocationEndpoint: v1/chat/completions
  replicas: 1
  modelSourceConfig:
    modelSourceType: kubernetesVolume
  kubernetes:
    serviceAccountName: <YOUR_SERVICE_ACCOUNT>
    initContainers:
      - name: smart-loader
        image: public.ecr.aws/aws-cli/aws-cli:latest
        command: ["/bin/bash", "-c"]
        args:
          - |
            if [ "$(ls -A /model)" ]; then
              echo "NVMe hit — model already present ($(du -sh /model | cut -f1))"
            else
              echo "NVMe miss — downloading from S3"
```

```
              aws s3 sync s3://<YOUR_BUCKET>/<YOUR_MODEL>/ /model/
            fi
        volumeMounts:
          - name: model-weights
            mountPath: /model
    volumes:
      - name: model-weights
        hostPath:
          path: /opt/dlami/nvme/<YOUR_MODEL>
          type: DirectoryOrCreate
  loadBalancer:
    healthCheckPath: /health
  worker:
    image: lmcache/vllm-openai:latest
    args:
      - /opt/ml/model
      - --max-model-len
      - "15000"
      - --tensor-parallel-size
      - "1"
    modelInvocationPort:
      containerPort: 8000
      name: http
    modelVolumeMount:
      name: model-weights
      mountPath: /opt/ml/model
    resources:
      limits:
        nvidia.com/gpu: "1"
      requests:
        cpu: "6"
        memory: 30Gi
        nvidia.com/gpu: "1"
    environmentVariables:
      - name: PYTHONHASHSEED
        value: "123"
EOF
```

Note

To configure KV caching and intelligent routing for improved performance, see Configure KV caching and intelligent routing.

2. Deploy the `InferenceEndpointConfig`.

```
kubectl apply -f deploy_nvme_k8s_volume_fallback.yaml
```

3. Verify the deployment status.

```
kubectl describe InferenceEndpointConfig nvme-k8s-volume-fallback -n default
```

Deploy using Amazon S3 with prefetch and NVMe fallback

Use this approach when you want inference performance by staging model weights to RAM, with automatic fallback to Amazon S3 if the model isn't cached locally on NVMe.

When you set `modelSourceType: s3` with `prefetchEnabled: true`, the operator creates two volumes automatically:

- A volume named after your `modelVolumeMount.name` (typically `model-weights`) — an Amazon S3 CSI fuse mount containing your model
- `model-weights-copy` — a RAM-backed `emptyDir` where the worker reads from

You add a custom `nvme-cache` volume pointing to the node's local NVMe storage, and a custom `initContainer` that:

- If the model exists on NVMe — copies from NVMe to RAM (`model-weights-copy`), skipping the network entirely.
- If the model is missing — falls back to copying from the Amazon S3 mount (`model-weights`) to RAM (`model-weights-copy`). Optionally copies to NVMe so subsequent pod startups on the same node use the fast local path.

> **Important**
>
> Do not override `model-weights` in `kubernetes.volumes` when using this approach. The operator creates `model-weights` pointing to the Amazon S3 CSI volume. Overriding it removes the operator-provisioned volume that your initContainer needs for fallback. Use a separate volume name (for example, `nvme-cache`) for your NVMe hostPath.

Important

Do not include `model-weights-copy` in `kubernetes.volumes`. It is a reserved name created automatically by the operator. Your initContainer can reference it in `volumeMounts` but must not declare it as a volume.

1. Create the `InferenceEndpointConfig` YAML file. Replace the placeholder values with your actual resource identifiers.

```
cat <<EOF> deploy_nvme_s3_prefetch_fallback.yaml
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: InferenceEndpointConfig
metadata:
  name: nvme-s3-prefetch-fallback
  namespace: default
spec:
  endpointName: nvme-s3-prefetch-fallback
  modelName: Qwen2.5-VL-7B-Instruct
  invocationEndpoint: v1/chat/completions
  replicas: 1
  modelSourceConfig:
    modelSourceType: s3
    s3Storage:
      bucketName: <YOUR_BUCKET>
      region: <YOUR_REGION>
    prefetchEnabled: true
  kubernetes:
    serviceAccountName: <YOUR_SERVICE_ACCOUNT>
    initContainers:
      - name: smart-loader
        image: public.ecr.aws/aws-cli/aws-cli:latest
        command: ["/bin/bash", "-c"]
        args:
          - |
            # Check NVMe first, fall back to S3 mount, then copy to RAM
            if [ "$(ls -A /nvme)" ]; then
              echo "NVMe hit ($(du -sh /nvme | cut -f1))"
              echo "Copying model from NVMe to RAM..."
              cp -r /nvme/* /model/
            else
              echo "NVMe miss — copying from S3 mount to NVMe, then NVMe to RAM"
```

```
            cp -r /s3-model/* /nvme/
            cp -r /nvme/* /model/
          fi
          echo "Done. $(du -sh /model | cut -f1) in RAM."
      volumeMounts:
        - name: model-weights
          mountPath: /s3-model
        - name: nvme-cache
          mountPath: /nvme
        - name: model-weights-copy
          mountPath: /model
  volumes:
    - name: nvme-cache
      hostPath:
        path: /opt/dlami/nvme/<YOUR_MODEL>
        type: DirectoryOrCreate
loadBalancer:
  healthCheckPath: /health
worker:
  image: lmcache/vllm-openai:latest
  args:
    - /opt/ml/model
    - --max-model-len
    - "15000"
    - --tensor-parallel-size
    - "1"
  modelInvocationPort:
    containerPort: 8000
    name: http
  modelVolumeMount:
    name: model-weights
    mountPath: /opt/ml/model
  resources:
    limits:
      nvidia.com/gpu: "1"
    requests:
      cpu: "6"
      memory: 30Gi
      nvidia.com/gpu: "1"
  environmentVariables:
    - name: PYTHONHASHSEED
      value: "123"
    - name: VLLM_REQUEST_TIMEOUT
      value: "600"
```

```
EOF
```

> **Note**
>
> To configure KV caching and intelligent routing for improved performance, see Configure KV caching and intelligent routing.

2. Deploy the `InferenceEndpointConfig`.

```
kubectl apply -f deploy_nvme_s3_prefetch_fallback.yaml
```

3. Verify the deployment status.

```
kubectl describe InferenceEndpointConfig nvme-s3-prefetch-fallback -n default
```

Understanding model-weights and model-weights-copy with prefetch

When using prefetch, the operator creates two model-related volumes:

- A volume named after your `modelVolumeMount.name` (typically `model-weights`) — an Amazon S3 CSI fuse mount containing your model
- `model-weights-copy` — a RAM-backed emptyDir where the worker actually reads from

In your `InferenceEndpointConfig`, you define:

```
modelVolumeMount:
    name: model-weights
    mountPath: /opt/ml/model
```

While you reference `model-weights`, when `prefetchEnabled: true`, it is actually `model-weights-copy` that gets mounted at `/opt/ml/model` in the worker container. When using a custom initContainer, ensure that you copy the data into the volume called `model-weights-copy` — that is where the worker expects to find it.

When `prefetchEnabled: false`, there is only one volume (named after your `modelVolumeMount.name`) and it is mounted directly at `/opt/ml/model`.

Configure a custom service account

You can assign a custom Kubernetes ServiceAccount to your inference endpoint pods using the `spec.kubernetes.serviceAccountName` field in the `InferenceEndpointConfig`. This is useful for providing Amazon credentials via IRSA (IAM Roles for Service Accounts) to your worker containers or init containers — for example, to download model weights from Amazon S3 in a fallback scenario.

> **Important**
>
> Custom service account support is disabled by default and must be explicitly enabled by a cluster administrator before use. See the section called “Enable custom service accounts” for instructions.

If you do not specify a ServiceAccount, the namespace's default ServiceAccount is used.

Enable custom service accounts

Custom service account support is disabled by default. A cluster administrator must enable it in the operator's Helm configuration before users can reference custom ServiceAccounts in their `InferenceEndpointConfig`.

- Update the operator Helm values to enable the feature. If you deployed the operator via Helm, upgrade with the flag:

```
helm upgrade hyperpod-inference-operator <CHART_PATH> \
  --set enableCustomServiceAccounts=true \
  --reuse-values
```

- If you deployed the operator as an Amazon EKS add-on, update the add-on configuration to include `enableCustomServiceAccounts: true` in the advanced configuration settings.
- Verify the operator pod has the environment variable set:

```
kubectl get deployment hyperpod-inference-controller-manager \
  -n hyperpod-inference-system \
  -o jsonpath='{.spec.template.spec.containers[0].env}' | jq '.[] |
 select(.name=="ENABLE_CUSTOM_SERVICE_ACCOUNTS")'
```

  You should see:

```
{
  "name": "ENABLE_CUSTOM_SERVICE_ACCOUNTS",
  "value": "true"
}
```

Important

If this feature is not enabled, any `InferenceEndpointConfig` that specifies `kubernetes.serviceAccountName` is rejected with a `DeploymentFailed` status and the message: `kubernetes.serviceAccountName is not enabled. Requires addon configuration (enableCustomServiceAccounts: true)`.

Label the service account

Before you can reference a custom ServiceAccount, a cluster administrator must label it as user-assignable:

```
kubectl label serviceaccount <your-service-account> \
  sagemaker.amazonaws.com/user-assignable=true \
  -n <namespace>
```

Only ServiceAccounts with this label can be referenced by inference endpoints. This is a security control to prevent unauthorized privilege escalation.

Specify the service account in your configuration

Add the `serviceAccountName` field under `spec.kubernetes` in your `InferenceEndpointConfig`:

```
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: InferenceEndpointConfig
metadata:
  name: my-inference-endpoint
  namespace: my-namespace
spec:
  kubernetes:
    serviceAccountName: my-inference-sa
```

```
  # ... rest of your config
```

Validation rules

The operator validates the `serviceAccountName` field on both create and update operations. Your deployment will be rejected with a `DeploymentFailed` status if any of the following conditions are met:

- The ServiceAccount does not exist in the namespace — `serviceAccountName "X" not found in namespace "Y"`
- The ServiceAccount is missing the required label — `serviceAccountName "X" is not labeled as user-assignable (requires label sagemaker.amazonaws.com/user-assignable=true)`
- The ServiceAccount is the operator's system ServiceAccount — `serviceAccountName must not reference the operator's service account`

Note

All containers in the inference pod (worker, init containers, and sidecars) inherit the permissions of the specified ServiceAccount. If the ServiceAccount is annotated with `eks.amazonaws.com/role-arn`, the pod receives temporary Amazon credentials for that IAM role. Cluster administrators should only label ServiceAccounts as user-assignable after reviewing the associated RBAC roles and IAM permissions.

Note

If a ServiceAccount is deleted while an `InferenceEndpointConfig` is already running, existing pods continue to run with their current credentials until they are restarted. However, new pod creation (for example, during scaling or rescheduling) will fail because the ServiceAccount no longer exists. The operator validates the ServiceAccount when the deployment is first created and when the IEC spec is updated — it does not continuously monitor the ServiceAccount. Updating the IEC spec after the SA is deleted will result in a `DeploymentFailed` status.

Security best practices for custom service accounts

When you use a custom ServiceAccount with inference endpoints, the HyperPod inference operator creates Deployments on your behalf. All containers in the inference pod — including the worker, init containers, and sidecars — inherit the permissions of the specified ServiceAccount. Follow these best practices to secure your cluster.

Lock down RBAC permissions

- Create a dedicated ServiceAccount for each inference workload. Do not reuse ServiceAccounts across unrelated workloads.
- Bind only the minimum RBAC permissions required. For example, if your init container only needs to read from Amazon S3, the ServiceAccount should not have permissions to list or modify Kubernetes resources.

```
# Example: minimal Role for an inference workload that only needs S3 access via IRSA
# No Kubernetes API permissions needed — IRSA provides AWS credentials directly
apiVersion: v1
kind: ServiceAccount
metadata:
  name: my-inference-sa
  namespace: my-namespace
  labels:
    sagemaker.amazonaws.com/user-assignable: "true"
  annotations:
    eks.amazonaws.com/role-arn: arn:aws:iam::<ACCOUNT_ID>:role/<SCOPED_ROLE_NAME>
```

- Avoid granting cluster-wide permissions (ClusterRoleBindings) to ServiceAccounts used by inference pods.

Scope IRSA IAM roles

- When annotating a ServiceAccount with `eks.amazonaws.com/role-arn`, ensure the IAM role follows least-privilege principles.
- Scope Amazon S3 permissions to the specific bucket and prefix containing your model weights.

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
```

```
    "Action": ["s3:GetObject", "s3:ListBucket"],
    "Resource": [
      "arn:aws:s3:::<YOUR_BUCKET>",
      "arn:aws:s3:::<YOUR_BUCKET>/<YOUR_MODEL_PREFIX>/*"
    ]
  }]
}
```

- Do not use broad managed policies such as `AmazonS3FullAccess` in production. Use `AmazonS3ReadOnlyAccess` or a custom policy scoped to your model bucket.

Protect the user-assignable label

- Only cluster administrators should add or remove the `sagemaker.amazonaws.com/user-assignable=true` label. Use Kubernetes RBAC to restrict who can modify ServiceAccount labels in your namespace.
- Review the RBAC roles and IAM permissions associated with a ServiceAccount before labeling it as user-assignable.
- Periodically audit which ServiceAccounts carry the `user-assignable` label.

```
kubectl get serviceaccounts -n <NAMESPACE> -l sagemaker.amazonaws.com/user-
assignable=true
```

- Ensure non-admin roles do not include `patch`, `update`, or `create` verbs on ServiceAccount resources. The operator validates the `user-assignable` label at deployment time, but does not prevent unauthorized users from adding the label to a ServiceAccount. Restricting who can modify ServiceAccounts via RBAC is the primary control for protecting this label. Non-admin users should only have `get` and `list` access:

```
# Example: RBAC Role for non-admin users — read-only access to ServiceAccounts
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: sa-read-only
  namespace: <NAMESPACE>
rules:
  - apiGroups: [""]
    resources: ["serviceaccounts"]
    verbs: ["get", "list"]
```

Important

The HyperPod inference operator acts as an intermediary that creates Deployments on behalf of users. Unlike standard Kubernetes workloads where the caller directly creates pods, the operator assigns the specified ServiceAccount to pods it creates. This means that any permissions granted to a user-assignable ServiceAccount are effectively available to anyone who can create an `InferenceEndpointConfig` in that namespace. Ensure that namespace-level RBAC controls who can create and update `InferenceEndpointConfig` resources.

Preload model weights to NVMe

If you need to pre-populate NVMe on specific nodes before deploying, you can use a one-off pod to sync from Amazon S3.

Note

This approach targets a specific node via nodeName and does not work with autoscaling. For autoscaling scenarios, use the Kubernetes volume with fallback or Amazon S3 with prefetch approaches, which handle missing models automatically via initContainer fallback logic.

1. Create the preload pod YAML file. Replace the placeholder values with your actual resource identifiers.

```
cat <<EOF> nvme-s3-copy.yaml
apiVersion: v1
kind: Pod
metadata:
  name: nvme-s3-copy
  namespace: default
spec:
  nodeName: <TARGET_NODE>
  restartPolicy: Never
  containers:
    - name: s3-copy
      image: public.ecr.aws/aws-cli/aws-cli:latest
      command: ["/bin/bash", "-c"]
```

```
      args:
        - |
          echo "=== Starting S3 sync to NVMe ==="
          aws s3 sync s3://<YOUR_BUCKET>/<YOUR_MODEL>/ /nvme/<YOUR_MODEL>/ --region
 <YOUR_REGION>
          echo "=== Sync complete ==="
          ls -la /nvme/<YOUR_MODEL>/
          du -sh /nvme/<YOUR_MODEL>/
          echo "=== Done ==="
      volumeMounts:
        - name: nvme-storage
          mountPath: /nvme
  serviceAccountName: default
  volumes:
    - name: nvme-storage
      hostPath:
        path: /opt/dlami/nvme
        type: Directory
EOF
```

2. Apply the pod and monitor the sync progress.

```
kubectl apply -f nvme-s3-copy.yaml
kubectl get pod nvme-s3-copy -w
kubectl logs nvme-s3-copy -f
```

3. Clean up the pod after the sync completes.

```
kubectl delete pod nvme-s3-copy
```

Reserved volume names

The operator manages several internal volumes that cannot be overridden via `kubernetes.volumes`. Using any of these names results in a `KubernetesVolumeValidationFailed` condition.

Reserved volume names

#	Name	Purpose
1	`shm`	Shared memory (`/dev/shm`) for inter-process communication
2	`model-weights-copy`	RAM-backed emptyDir used when `prefetchEnabled: true`
3	`parallel-copy-configmap`	ConfigMap for parallel copy script (prefetch)
4	`lmcache-config`	LMCache configuration volume
5	`gated-model-downloader-configmap`	ConfigMap for gated model download script

Things to remember

- **Do not use reserved volume names.** The operator manages several internal volumes (see the section called "Reserved volume names"). Using any of these names in `kubernetes.volumes` results in a `KubernetesVolumeValidationFailed` condition.
- **Volume names must match.** The operator derives the volume name from `modelVolumeMount.name`. When using `modelSourceType: kubernetesVolume`, `kubernetes.volumes` must contain a volume with that same name.
- **Mount volumes to the correct location in your initContainer.** Ensure that any volume you create is mounted to the correct path in your initContainer.
- **No custom service account is needed for S3/FSx.** If you are unable to create custom service accounts or prefer not to, you can use `modelSourceType: s3` or `fsx`. The operator provisions S3/FSx volumes automatically. You can still add custom `initContainers` and override volumes on top of the operator-managed storage.
- **IRSA credentials are injected into all containers.** When you set `kubernetes.serviceAccountName` to a service account with an IRSA annotation, Amazon EKS injects Amazon credentials (`aws-iam-token` volume, `AWS_ROLE_ARN`, `AWS_WEB_IDENTITY_TOKEN_FILE`) into all containers, including your custom initContainers.

- **Do not set `modelLocation` when using `kubernetesVolume`.** The volume path is controlled by `kubernetes.volumes`. Setting `modelLocation` when `modelSourceType` is `kubernetesVolume` results in a validation error.
- **Understand how `model-weights` vs `model-weights-copy` works with prefetch.** When `prefetchEnabled: true`, the operator creates two model-related volumes:
  - `model-weights` — the source volume (from Amazon S3/Amazon FSx PVC or your override)
  - `model-weights-copy` — a RAM-backed emptyDir where the worker actually reads from
- While you reference `model-weights` in your config, when `prefetchEnabled: true`, it is actually `model-weights-copy` that gets mounted at `/opt/ml/model` in the worker container. When using a custom initContainer, ensure that you copy the data into the volume called `model-weights-copy` — that is where the worker expects to find it. When `prefetchEnabled: false`, there is only one volume (named after your `modelVolumeMount.name`) and it is mounted directly at `/opt/ml/model`.

Troubleshooting

Use these debugging commands if your deployment isn't working as expected.

- Check the `InferenceEndpointConfig` status to see the high-level deployment state and any configuration issues.

```
kubectl describe InferenceEndpointConfig <ENDPOINT_NAME> -n <NAMESPACE>
```

- Check the Kubernetes deployment status.

```
kubectl describe deployment <ENDPOINT_NAME> -n <NAMESPACE>
```

- Check the status of all Kubernetes objects in your namespace.

```
kubectl get pods,svc,deployment,InferenceEndpointConfig,sagemakerendpointregistration
 -n <NAMESPACE>
```

- Check initContainer logs if the model loading step fails.

```
kubectl logs <POD_NAME> -c smart-loader -n <NAMESPACE>
```

- If the deployment fails with "not found in namespace", verify the ServiceAccount exists:

```
kubectl get serviceaccount <name> -n <namespace>
```

- If the deployment fails with "not labeled as user-assignable", ask your cluster administrator to add the required label:

```
kubectl label serviceaccount <name> sagemaker.amazonaws.com/user-assignable=true -n
 <namespace>
```

- If the deployment fails with "must not reference the operator's service account", create a separate ServiceAccount for your workload. You cannot use the HyperPod inference operator's own ServiceAccount.

Custom certificates and Route 53 DNS management for HyperPod Inference

The following steps show you how to use your own ACM certificates for HyperPod inference endpoints and optionally configure the operator to manage Route 53 DNS records for your custom domain.

With custom certificates, you provide an ACM certificate ARN and the operator attaches it to the Application Load Balancer (ALB), monitors its health, and supports automatic renewal detection. The operator supports publicly trusted ACM certificates, Amazon Private CA certificates, and certificates imported from external CAs.

Custom certificates can be used on their own or combined with Route 53 DNS management. Route 53 DNS management requires a custom certificate and uses the domain name from your certificate configuration to create and manage DNS records.

Prerequisites

Before you begin, verify that you've:

- Set up inference capabilities on your Amazon SageMaker HyperPod clusters. For more information, see Setting up your HyperPod clusters for model deployment.
- Installed kubectl in your terminal.
- Provisioned or imported a TLS certificate in ACM in the same Amazon Region as your HyperPod cluster. The certificate must be in the **Issued** state and must include a certificate chain (intermediate and root CA). Self-signed certificates imported to ACM are not supported as custom certificates because they lack a certificate chain.

- (For Route 53 DNS management) Created a Route 53 hosted zone for your domain. Public hosted zones are recommended. Private hosted zones work for record creation, but the operator verifies DNS resolution using the pod's DNS resolver, which relies on the VPC DNS resolver. For private hosted zones, the VPC must have DNS resolution and DNS hostnames enabled, and the private hosted zone must be associated with the cluster's VPC.

Configure IAM permissions

The inference operator's execution role requires additional permissions for custom certificates and Route 53 DNS management. Add the following policies to your HyperPod Inference execution role.

ACM and Amazon S3 permissions for custom certificates

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ACMCustomCertificateAccess",
            "Effect": "Allow",
            "Action": [
                "acm:DescribeCertificate",
                "acm:GetCertificate"
            ],
            "Resource": "arn:aws:acm:<region>:<account-id>:certificate/*"
        },
        {
            "Sid": "S3CertificateUpload",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:PutObjectTagging"
            ],
            "Resource": "arn:aws:s3:::<tls-certificate-bucket>/*",
            "Condition": {
                "StringEquals": {
                    "s3:RequestObjectTag/CreatedBy": "HyperPodInference"
                }
            }
        }
    ]
}
```

> **Note**
>
> If your Amazon S3 bucket name starts with `hyperpod-tls`, the Amazon S3 permissions are already included in the `AmazonSageMakerHyperPodInferenceAccess` managed policy and you only need to add the ACM statement.

Route 53 permissions for DNS management

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Route53DNSManagement",
            "Effect": "Allow",
            "Action": [
                "route53:GetHostedZone",
                "route53:ListResourceRecordSets",
                "route53:ChangeResourceRecordSets"
            ],
            "Resource": "arn:aws:route53:::hostedzone/<hosted-zone-id>"
        }
    ]
}
```

Replace `<region>`, `<account-id>`, `<tls-certificate-bucket>`, and `<hosted-zone-id>` with your actual values. You can scope the ACM resource ARN to specific certificates for tighter security.

Configure a custom certificate

To use a custom certificate, add the `customCertificateConfig` section to your `tlsConfig` in the `InferenceEndpointConfig` or `JumpStartModel` spec. The `tlsConfig` and `dnsConfig` fields are identical in both CRDs.

The following fields are available in `customCertificateConfig` and `tlsConfig`:

`tlsConfig.customCertificateConfig.acmArn` (Required, String)

The ARN of your ACM certificate. Must be in the **Issued** state.

`tlsConfig.customCertificateConfig.domainName` (Required, String)

The domain name to use from the certificate.

- Must be a specific domain, not a wildcard. For wildcard certificates (for example, `*.example.com`), specify the specific subdomain (for example, `api.example.com`).
- Must be lowercase.
- Must match one of the domain names listed in the certificate.

`tlsConfig.tlsCertificateOutputS3Uri` (Conditional, String)

Amazon S3 URI where the operator uploads the public certificate. Required unless the operator was installed with the `TLS_CERTIFICATE_OUTPUT_S3URI` environment variable configured. If you're unsure whether this was set, specify it explicitly.

The following is an example YAML file for creating an endpoint with a custom certificate.

```
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: InferenceEndpointConfig
metadata:
  name: my-model
  namespace: my-namespace
spec:
  modelName: my-llm
  instanceType: ml.g5.24xlarge
  invocationEndpoint: v1/chat/completions
  replicas: 2
  modelSourceConfig:
    modelSourceType: s3
    s3Storage:
      bucketName: my-model-bucket
      region: us-west-2
    modelLocation: models/my-llm
  tlsConfig:
    customCertificateConfig:
      acmArn: arn:aws:acm:us-west-2:123456789012:certificate/abc12345-1234-1234-1234-
abc123456789
      domainName: api.example.com
    tlsCertificateOutputS3Uri: s3://my-tls-bucket
  worker:
    image: my-inference-image:latest
    modelInvocationPort:
```

```
      containerPort: 8000
      name: http
    modelVolumeMount:
      name: model-weights
      mountPath: /opt/ml/model
    resources:
      limits:
        nvidia.com/gpu: "4"
      requests:
        cpu: "6"
        memory: 30Gi
        nvidia.com/gpu: "4"
```

You can add `customCertificateConfig` to a deployment that is already running. The operator detects the change on the next reconciliation, validates the certificate, attaches it to the ALB, and uploads the public certificate to Amazon S3. No downtime or redeployment is required.

> **Important**
>
> If you remove the `customCertificateConfig` section from a running deployment, the operator falls back to generating a new self-signed certificate. This replaces your CA-signed certificate on the ALB.

Configure Route 53 DNS management

Route 53 DNS management requires a custom certificate to be configured and uses the domain name from `tlsConfig.customCertificateConfig.domainName`. If you have not configured a custom certificate, see Configure a custom certificate first.

To enable Route 53 DNS management, add the `dnsConfig` section to your spec:

```
spec:
  tlsConfig:
    customCertificateConfig:
      acmArn: arn:aws:acm:us-west-2:123456789012:certificate/abc12345-1234-1234-1234-
abc123456789
      domainName: api.example.com
    tlsCertificateOutputS3Uri: s3://my-tls-bucket
  dnsConfig:
    hostedZoneId: Z1234567890ABC
```

The dnsConfig section can be added at the same time as customCertificateConfig, or added later to an existing deployment. The operator creates the DNS records on the next reconciliation without restarting your pods.

When you deploy with dnsConfig, the operator:

1. Validates the hosted zone exists and that your domain belongs to the hosted zone (for example, api.example.com requires a hosted zone for example.com).
2. Checks for existing A records at the target domain to prevent accidental overwrites.
3. Creates an **A record** (alias) pointing your domain to the ALB, and a **TXT record** with an ownership marker (hyperpod-inference/owner=<namespace>/<name>) to prevent conflicts between endpoints. Do not modify or delete the TXT record manually.
4. Polls DNS resolution every 30 seconds until the domain resolves, then marks the status as Active. If the record doesn't resolve within 10 minutes, the status transitions to Error.

> **Note**
>
> Route 53 DNS management is non-blocking. Errors in DNS record creation or propagation do not prevent your inference endpoint from reaching the Ready state. The endpoint remains accessible through the ALB's default hostname. Check the dnsStatus section in the resource status for DNS-specific errors.

Use a custom certificate without Route 53 DNS management

Route 53 DNS management is optional. If you want to manage your own DNS records, omit the dnsConfig section and configure your domain manually.

To find the ALB hostname for your deployment, the ingress name depends on whether intelligent routing is enabled.

Without intelligent routing: The ingress is named alb-<deployment-name> in your namespace.

```
kubectl get ingress alb-<deployment-name> -n <namespace> \
  -o jsonpath='{.status.loadBalancer.ingress[0].hostname}'
```

With intelligent routing: The ingress is named alb-<deployment-name>-<namespace> in the hyperpod-inference-system namespace.

```
kubectl get ingress alb-<deployment-name>-<namespace> -n hyperpod-inference-system \
  -o jsonpath='{.status.loadBalancer.ingress[0].hostname}'
```

Create a DNS record in your DNS provider pointing your domain to this ALB hostname:

- **Route 53** — Create an **A record** with **Alias** enabled, pointing to the ALB.
- **Other DNS providers** — Create a **CNAME record** pointing your domain to the ALB DNS name. CNAME records cannot be used at the root domain (for example, `example.com`); use a subdomain like `api.example.com`.

> **Note**
>
> If the ALB is recreated (for example, after deleting and redeploying the endpoint), the ALB hostname changes. You must update your DNS record manually. Route 53 DNS management handles this automatically.

Verify the status of your deployment

Check the custom certificate status

```
kubectl describe InferenceEndpointConfig my-model -n my-namespace
```

Look for the `tlsCertificate` section in the status:

```
Status:
  Tls Certificate:
    Certificate ARN:    arn:aws:acm:us-west-2:123456789012:certificate/abc12345-...
    Certificate Health: Valid
    Certificate Domain Names:
      api.example.com
    Last Cert Expiry Time: 2027-04-23T00:00:00Z
```

Certificate health values:

- **Valid** — Certificate is more than 60 days from expiration.
- **Expiring** — Certificate expires within 60 days. A Kubernetes warning event (`CertificateExpiring`) is emitted.

- **Expired** — Certificate has expired. A Kubernetes warning event (`CertificateExpired`) is emitted.

The operator checks certificate expiration every 24 hours. When it detects that a certificate has been renewed in ACM (the `NotAfter` date changes), it automatically re-uploads the public certificate to Amazon S3 and emits a `CertificateRenewed` event.

Check the DNS status

Look for the `dnsStatus` section:

```
Status:
  Dns Status:
    Managed By Operator: true
    Record Name:         api.example.com
    Hosted Zone Id:      Z1234567890ABC
    Dns Health:          Active
    Message:             DNS record resolves successfully
```

DNS health values:

- **Active** — DNS record resolves successfully. Your custom domain is ready to use.
- **Pending** — DNS records have been created in Route 53 but haven't propagated yet. The operator rechecks every 30 seconds.
- **Error** — DNS record creation or propagation failed. Check the `Message` field for details.

Test the deployed endpoint

If you configured Route 53 DNS management, invoke your endpoint using your custom domain after the DNS status shows `Active`. If you configured only a custom certificate without DNS management, use the ALB hostname from the ingress (see Use a custom certificate without Route 53 DNS management).

```
curl -X POST https://api.example.com/v1/chat/completions \
  -H "Content-Type: application/json" \
  -d '{"model": "my-llm", "messages": [{"role": "user", "content": "Hello"}]}'
```

> **Note**
>
> To invoke through the SageMaker AI endpoint, set `endpointName` in your `InferenceEndpointConfig` or `sageMakerEndpoint.name` in your `JumpStartModel` spec. If `endpointName` is not set, no SageMaker AI endpoint is created and only direct ALB invocation is available.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name my-model \
  --content-type "application/json" \
  --body '{"model": "my-llm", "messages": [{"role": "user", "content": "Hello"}]}' \
  --region us-west-2 \
  --cli-binary-format raw-in-base64-out \
  /dev/stdout
```

Manage your custom certificates and DNS records

Changing the domain or hosted zone

You can update the `domainName` (in `customCertificateConfig`) or `hostedZoneId` (in `dnsConfig`) on a running deployment. Changing the domain name triggers both certificate re-validation and DNS cutover — the new domain must be valid in your ACM certificate (as a SAN or wildcard match).

The operator performs a safe cutover:

1. Creates new DNS records in the new zone or for the new domain.
2. Verifies the new records resolve.
3. Deletes the old DNS records only after the new records are confirmed active.

During the transition, both old and new domains resolve to the ALB. The TXT ownership record has a TTL of 300 seconds (5 minutes), so DNS clients may cache the old record for up to 5 minutes after cleanup.

Cleanup

When you delete the `InferenceEndpointConfig` or remove the `dnsConfig` section, the operator automatically deletes the Route 53 A and TXT records it created. The operator only deletes records that it owns (verified by the ownership TXT record).

Troubleshooting

Use these debugging steps if your custom certificate or DNS configuration isn't working as expected.

- **Deployment fails with Amazon S3 access error.** Verify the Amazon S3 bucket specified in `tlsCertificateOutputS3Uri` exists and is in the same Region. Verify the operator's execution role has `s3:PutObject` and `s3:PutObjectTagging` permissions on the bucket. The operator validates Amazon S3 write access by uploading a zero-byte test object during initial deployment.
- **Certificate validation fails.** Verify the ACM certificate is in the `ISSUED` state: `aws acm describe-certificate --certificate-arn <arn> --region <region>`. Verify the `domainName` matches a domain or SAN in the certificate. For wildcard certificates (`*.example.com`), use a specific subdomain like `api.example.com`.
- **DNS record creation fails.** Verify the hosted zone ID is correct and the operator's execution role has Route 53 permissions. Verify the domain belongs to the hosted zone (for example, `api.example.com` requires a hosted zone for `example.com`). If you see an NS delegation conflict, use the hosted zone ID of the delegated zone instead. If you see a record conflict, another endpoint or external process owns the A record at that domain.
- **DNS record shows Pending for extended time.** Verify the hosted zone's NS records are properly delegated from the parent domain registrar. The operator uses the pod's DNS resolver (typically CoreDNS), which may cache results. After 10 minutes without resolution, the status transitions to `Error`.
- **Certificate expiration warnings.** Renew or replace the certificate in ACM. For ACM-issued certificates, ACM handles renewal automatically. For imported certificates, import a new certificate. The operator detects renewal automatically and re-uploads the public certificate to Amazon S3.

Configure request limits for your HyperPod inference model deployment

You can configure request limiting on your Amazon SageMaker HyperPod inference model deployments to control the number of concurrent requests each pod accepts. When the limit is

reached, excess requests receive a configurable HTTP error response, enabling fail-fast behavior and allowing the load balancer to redirect traffic to other pods.

Request limiting is enforced by the nginx sidecar proxy that runs alongside your model container. This requires metrics to be enabled on your deployment.

Prerequisites

Before configuring request limits, verify that:

- Metrics are enabled on your deployment (`metrics.enabled: true`). The nginx sidecar proxy that enforces request limits is only created when metrics is enabled.

Configure request limits in your deployment YAML

Add the `requestLimits` section under `worker` in your `InferenceEndpointConfig` YAML. The following example limits each pod to 10 concurrent requests with a queue of 5, returning HTTP 503 when limits are exceeded.

```
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: InferenceEndpointConfig
metadata:
  name: my-model
  namespace: ns-team-a
spec:
  modelName: my-model-name
  instanceType: ml.g5.8xlarge
  invocationEndpoint: invocations
  modelSourceConfig:
    modelSourceType: s3

      containerPort: 8080
      name: http
    modelVolumeMount:
      mountPath: /opt/ml/model
      name: model-weights
```

```
    resources:
      limits:
        nvidia.com/gpu: "1"
      requests:
        cpu: "4"
        memory: "32Gi"
        nvidia.com/gpu: "1"
    requestLimits:
      maxConcurrentRequests: 10
      maxQueueSize: 5
      overflowStatusCode: 503
  metrics:
    enabled: true
  tlsConfig:
    tlsCertificateOutputS3Uri: "s3://my-tls-bucket/certs"
```

Explanation of fields

`maxConcurrentRequests` (Optional, Integer)

Maximum number of concurrent requests the nginx sidecar proxy accepts per pod. When the limit is reached, new requests are either queued (if `maxQueueSize` is configured) or immediately rejected with the overflow status code. Minimum: 1. If not set or set to 0, no concurrency limit is enforced.

`maxQueueSize` (Optional, Integer)

Maximum number of requests to queue when the concurrent request limit is reached. Queued requests wait until an in-flight request completes. When the queue is full, new requests receive the overflow status code response. Minimum: 0. If not set or set to 0, no queuing is applied — requests are rejected immediately when the concurrent request limit is reached.

`overflowStatusCode` (Optional, Integer)

HTTP status code returned when request limits are exceeded. Must be between 400 and 599. Default: 429 (Too Many Requests). Common values:

- `429` — Too Many Requests (default). Standard HTTP status for rate limiting.
- `503` — Service Unavailable. Useful when you want the load balancer to retry on a different pod.

How request limiting works

When an inference request arrives at the nginx sidecar proxy:

1. If the number of active requests is below `maxConcurrentRequests`, the request is forwarded to the model container.
2. If the limit is reached and `maxQueueSize` is greater than 0, the request is queued and waits (up to 60 seconds) for an active slot to become available.
3. If the queue is full (or no queue is configured), the request is immediately rejected with the configured `overflowStatusCode` and a JSON error response:

```
{
  "error": "Too many concurrent requests",
  "max_concurrent": 10,
  "max_queue_size": 5,
  "current": 10
}
```

Examples

Strict concurrency limit without queuing

To reject excess requests immediately without queuing:

```
requestLimits:
  maxConcurrentRequests: 5
  overflowStatusCode: 429
```

Concurrency limit with queuing

To allow a small queue before rejecting:

```
requestLimits:
  maxConcurrentRequests: 10
  maxQueueSize: 5
  overflowStatusCode: 503
```

In this configuration, up to 10 requests are processed concurrently. When the 11th through 15th requests arrive, they are queued and wait for an active slot. The 16th request and beyond receive HTTP 503.

Autoscaling policies for your HyperPod inference model deployment

This following information provides practical examples and configurations for implementing autoscaling policies on Amazon SageMaker HyperPod inference model deployments.

You'll learn how to configure automatic scaling using the built-in `autoScalingSpec` in your deployment YAML files, as well as how to create standalone KEDA `ScaledObject` configurations for advanced scaling scenarios. The examples cover scaling triggers based on CloudWatch metrics, Amazon SQS queue lengths, Prometheus queries, and resource utilization metrics like CPU and memory.

Using autoScalingSpec in deployment YAML

Amazon SageMaker HyperPod inference operator provides built-in autoscaling capabilities for model deployments using metrics from CloudWatch and Amazon Managed Prometheus (AMP). The following deployment YAML example includes an `autoScalingSpec` section that defines the configuration values for scaling your model deployment.

```
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: JumpStartModel
metadata:
  name: deepseek-sample624
  namespace: ns-team-a
spec:
  sageMakerEndpoint:
    name: deepsek7bsme624
  model:
    modelHubName: SageMakerPublicHub
    modelId: deepseek-llm-r1-distill-qwen-1-5b
    modelVersion: 2.0.4
  server:
    instanceType: ml.g5.8xlarge
  metrics:
    enabled: true
  environmentVariables:
    - name: SAMPLE_ENV_VAR
      value: "sample_value"
  maxDeployTimeInSeconds: 1800
  tlsConfig:
    tlsCertificateOutputS3Uri: "s3://{USER}-tls-bucket-{REGION}/certificates"
  autoScalingSpec:
    minReplicaCount: 0
```

```
    maxReplicaCount: 5
    pollingInterval: 15
    initialCooldownPeriod: 60
    cooldownPeriod: 120
    scaleDownStabilizationTime: 60
    scaleUpStabilizationTime: 0
    cloudWatchTrigger:
        name: "SageMaker-Invocations"
        namespace: "AWS/SageMaker"
        useCachedMetrics: false
        metricName: "Invocations"
        targetValue: 10.5
        activationTargetValue: 5.0
        minValue: 0.0
        metricCollectionStartTime: 300
        metricCollectionPeriod: 30
        metricStat: "Sum"
        metricType: "Average"
        dimensions:
          - name: "EndpointName"
            value: "deepsek7bsme624"
          - name: "VariantName"
            value: "AllTraffic"
    prometheusTrigger:
        name: "Prometheus-Trigger"
        useCachedMetrics: false
        serverAddress: http://<prometheus-host>:9090
        query: sum(rate(http_requests_total{deployment="my-deployment"}[2m]))
        targetValue: 10.0
        activationTargetValue: 5.0
        namespace: "namespace"
        customHeaders: "X-Client-Id=cid"
        metricType: "Value"
```

Explanation of fields used in deployment YAML

`minReplicaCount` (Optional, Integer)

Specifies the minimum number of model deployment replicas to maintain in the cluster. During scale-down events, the deployment scales down to this minimum number of pods. Must be greater than or equal to 0. Default: 1.

`maxReplicaCount` (Optional, Integer)

Specifies the maximum number of model deployment replicas to maintain in the cluster. Must be greater than or equal to `minReplicaCount`. During scale-up events, the deployment scales up to this maximum number of pods. Default: 5.

`pollingInterval` (Optional, Integer)

The time interval in seconds for querying metrics. Minimum: 0. Default: 30 seconds.

`cooldownPeriod` (Optional, Integer)

The time interval in seconds to wait before scaling down from 1 to 0 pods during a scale-down event. Only applies when `minReplicaCount` is set to 0. Minimum: 0. Default: 300 seconds.

`initialCooldownPeriod` (Optional, Integer)

The time interval in seconds to wait before scaling down from 1 to 0 pods during initial deployment. Only applies when `minReplicaCount` is set to 0. Minimum: 0. Default: 300 seconds.

`scaleDownStabilizationTime` (Optional, Integer)

The stabilization time window in seconds after a scale-down trigger activates before scaling down occurs. Minimum: 0. Default: 300 seconds.

`scaleUpStabilizationTime` (Optional, Integer)

The stabilization time window in seconds after a scale-up trigger activates before scaling up occurs. Minimum: 0. Default: 0 seconds.

`cloudWatchTrigger`

The trigger configuration for CloudWatch metrics used in autoscaling decisions. The following fields are available in `cloudWatchTrigger`:

- `name` (Optional, String) - Name for the CloudWatch trigger. If not provided, uses the default format: <model-deployment-name>-scaled-object-cloudwatch-trigger.
- `useCachedMetrics` (Optional, Boolean) - Determines whether to cache metrics queried by KEDA. KEDA queries metrics using the pollingInterval, while the Horizontal Pod Autoscaler (HPA) requests metrics from KEDA every 15 seconds. When set to true, queried metrics are cached and used to serve HPA requests. Default: true.
- `namespace` (Required, String) - The CloudWatch namespace for the metric to query.
- `metricName` (Required, String) - The name of the CloudWatch metric.

- `dimensions` (Optional, List) - The list of dimensions for the metric. Each dimension includes a name (dimension name - String) and value (dimension value - String).
- `targetValue` (Required, Float) - The target value for the CloudWatch metric used in autoscaling decisions.
- `activationTargetValue` (Optional, Float) - The target value for the CloudWatch metric used when scaling from 0 to 1 pod. Only applies when `minReplicaCount` is set to 0. Default: 0.
- `minValue` (Optional, Float) - The value to use when the CloudWatch query returns no data. Default: 0.
- `metricCollectionStartTime` (Optional, Integer) - The start time for the metric query, calculated as T-metricCollectionStartTime. Must be greater than or equal to metricCollectionPeriod. Default: 300 seconds.
- `metricCollectionPeriod` (Optional, Integer) - The duration for the metric query in seconds. Must be a CloudWatch-supported value (1, 5, 10, 30, or a multiple of 60). Default: 300 seconds.
- `metricStat` (Optional, String) - The statistic type for the CloudWatch query. Default: `Average`.
- `metricType` (Optional, String) - Defines how the metric is used for scaling calculations. Default: `Average`. Allowed values: `Average`, `Value`.
  - **Average**: Desired replicas = ceil (Metric Value) / (targetValue)
  - **Value**: Desired replicas = (current replicas) × ceil (Metric Value) / (targetValue)

`prometheusTrigger`

The trigger configuration for Amazon Managed Prometheus (AMP) metrics used in autoscaling decisions. The following fields are available in `prometheusTrigger`:

- `name` (Optional, String) - Name for the CloudWatch trigger. If not provided, uses the default format: <model-deployment-name>-scaled-object-cloudwatch-trigger.
- `useCachedMetrics` (Optional, Boolean) - Determines whether to cache metrics queried by KEDA. KEDA queries metrics using the pollingInterval, while the Horizontal Pod Autoscaler (HPA) requests metrics from KEDA every 15 seconds. When set to true, queried metrics are cached and used to serve HPA requests. Default: true.
- `serverAddress` (Required, String) - The address of the AMP server. Must use the format: <https://aps-workspaces.<region>.amazonaws.com/workspaces/<workspace_id>
- `query` (Required, String) - The PromQL query used for the metric. Must return a scalar value.

- `targetValue` (Required, Float) - The target value for the CloudWatch metric used in autoscaling decisions.
- `activationTargetValue` (Optional, Float) - The target value for the CloudWatch metric used when scaling from 0 to 1 pod. Only applies when `minReplicaCount` is set to 0. Default: 0.
- `namespace` (Optional, String) - The namespace to use for namespaced queries. Default: empty string ("").
- `customHeaders` (Optional, String) - Custom headers to include when querying the Prometheus endpoint. Default: empty string ("").
- `metricType` (Optional, String) - Defines how the metric is used for scaling calculations. Default: `Average`. Allowed values: `Average`, `Value`.
  - **Average**: Desired replicas = ceil (Metric Value) / (targetValue)
  - **Value**: Desired replicas = (current replicas) × ceil (Metric Value) / (targetValue)

Using KEDA ScaledObject yaml definitions through kubectl

In addition to configuring autoscaling through the autoScalingSpec section in your deployment YAML, you can create and apply standalone KEDA `ScaledObject` YAML definitions using kubectl.

This approach provides greater flexibility for complex scaling scenarios and allows you to manage autoscaling policies independently from your model deployments. KEDA `ScaledObject` configurations support a wide range of scaling triggers including CloudWatch metrics, Amazon SQS queue lengths, Prometheus queries, and resource-based metrics like CPU and memory utilization. You can apply these configurations to existing model deployments by referencing the deployment name in the scaleTargetRef section of the ScaledObject specification.

> **Note**
>
> Ensure the keda operator role provided during the HyperPod Inference operator installation has adequate permissions to query the metrics defined in the scaled object triggers.

CloudWatch metrics

The following KEDA yaml policy uses CloudWatch metrics as a trigger to perform autoscaling on a kubernetes deployment. The policy queries the number of invocations for a Sagemaker endpoint

and scales the number of deployment pods. The complete list of parameters supported by KEDA for `aws-cloudwatch` trigger can be found at https://keda.sh/docs/2.17/scalers/aws-cloudwatch/.

```
apiVersion: keda.sh/v1alpha1
kind: ScaledObject
metadata:
  name: invocations-scaledobject # name of the scaled object that will be created by
 this
  namespace: ns-team-a # namespace that this scaled object targets
spec:
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: $DEPLOYMENT_NAME # name of the model deployment
  minReplicaCount: 1 # minimum number of pods to be maintained
  maxReplicaCount: 4 # maximum number of pods to scale to
  pollingInterval: 10
  triggers:
  - type: aws-cloudwatch
    metadata:
      namespace: AWS/SageMaker
      metricName: Invocations
      targetMetricValue: "1"
      minMetricValue: "1"
      awsRegion: "us-west-2"
      dimensionName: EndpointName;VariantName
      dimensionValue: $ENDPOINT_NAME;$VARIANT_NAME
      metricStatPeriod: "30" # seconds
      metricStat: "Sum"
      identityOwner: operator
```

Amazon SQS metrics

The following KEDA yaml policy uses Amazon SQS metrics as a trigger to perform autoscaling on a kubernetes deployment. The policy queries the number of invocations for a Sagemaker endpoint and scales the number of deployment pods. The complete list of parameters supported by KEDA for `aws-cloudwatch` trigger can be found at https://keda.sh/docs/2.17/scalers/aws-sqs/.

```
apiVersion: keda.sh/v1alpha1
kind: ScaledObject
metadata:
```

```
  name: invocations-scaledobject # name of the scaled object that will be created by
 this
  namespace: ns-team-a # namespace that this scaled object targets
spec:
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: $DEPLOYMENT_NAME # name of the model deployment
  minReplicaCount: 1 # minimum number of pods to be maintained
  maxReplicaCount: 4 # maximum number of pods to scale to
  pollingInterval: 10
  triggers:
  - type: aws-sqs-queue
    metadata:
      queueURL: https://sqs.eu-west-1.amazonaws.com/account_id/QueueName
      queueLength: "5"  # Default: "5"
      awsRegion: "us-west-1"
      scaleOnInFlight: true
      identityOwner: operator
```

Prometheus metrics

The following KEDA yaml policy uses Prometheus metrics as a trigger to perform autoscaling on a kubernetes deployment. The policy queries the number of invocations for a Sagemaker endpoint and scales the number of deployment pods. The complete list of parameters supported by KEDA for `aws-cloudwatch` trigger can be found at https://keda.sh/docs/2.17/scalers/prometheus/.

```
apiVersion: keda.sh/v1alpha1
kind: ScaledObject
metadata:
  name: invocations-scaledobject # name of the scaled object that will be created by
 this
  namespace: ns-team-a # namespace that this scaled object targets
spec:
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: $DEPLOYMENT_NAME # name of the model deployment
  minReplicaCount: 1 # minimum number of pods to be maintained
  maxReplicaCount: 4 # maximum number of pods to scale to
  pollingInterval: 10
  triggers:
  - type: prometheus
```

```
    metadata:
      serverAddress: http://<prometheus-host>:9090
      query: avg(rate(http_requests_total{deployment="$DEPLOYMENT_NAME"}[2m])) # Note:
 query must return a vector/scalar single element response
      threshold: '100.50'
      namespace: example-namespace  # for namespaced queries, eg. Thanos
      customHeaders: X-Client-Id=cid,X-Tenant-Id=tid,X-Organization-Id=oid #
 Optional. Custom headers to include in query. In case of auth header, use the custom
 authentication or relevant authModes.
      unsafeSsl: "false" #  Default is `false`, Used for skipping certificate check
 when having self-signed certs for Prometheus endpoint
      timeout: 1000 # Custom timeout for the HTTP client used in this scaler
      identityOwner: operator
```

CPU metrics

The following KEDA yaml policy uses cpu metric as a trigger to perform autoscaling on a kubernetes deployment. The policy queries the number of invocations for a Sagemaker endpoint and scales the number of deployment pods. The complete list of parameters supported by KEDA for `aws-cloudwatch` trigger can be found at https://keda.sh/docs/2.17/scalers/prometheus/.

```
apiVersion: keda.sh/v1alpha1
kind: ScaledObject
metadata:
  name: invocations-scaledobject # name of the scaled object that will be created by
 this
  namespace: ns-team-a # namespace that this scaled object targets
spec:
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: $DEPLOYMENT_NAME # name of the model deployment
  minReplicaCount: 1 # minimum number of pods to be maintained
  maxReplicaCount: 4 # maximum number of pods to scale to
  pollingInterval: 10
  triggers:
  - type: cpu
    metricType: Utilization # Allowed types are 'Utilization' or 'AverageValue'
    metadata:
        value: "60"
        containerName: "" # Optional. You can use this to target a specific container
```

Memory metrics

The following KEDA yaml policy uses Prometheus metrics query as a trigger to perform autoscaling on a kubernetes deployment. The policy queries the number of invocations for a Sagemaker endpoint and scales the number of deployment pods. The complete list of parameters supported by KEDA for `aws-cloudwatch` trigger can be found at https://keda.sh/docs/2.17/scalers/prometheus/.

```
apiVersion: keda.sh/v1alpha1
kind: ScaledObject
metadata:
  name: invocations-scaledobject # name of the scaled object that will be created by
 this
  namespace: ns-team-a # namespace that this scaled object targets
spec:
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: $DEPLOYMENT_NAME # name of the model deployment
  minReplicaCount: 1 # minimum number of pods to be maintained
  maxReplicaCount: 4 # maximum number of pods to scale to
  pollingInterval: 10
  triggers:
  - type: memory
    metricType: Utilization # Allowed types are 'Utilization' or 'AverageValue'
    metadata:
        value: "60"
        containerName: "" # Optional. You can use this to target a specific container
 in a pod
```

Sample Prometheus policy for scaling down to 0 pods

The following KEDA yaml policy uses prometheus metrics query as a trigger to perform autoscaling on a kubernetes deployment. This policy uses a `minReplicaCount` of 0 which enables KEDA to scale the deployment down to 0 pods. When `minReplicaCount` is set to 0, you need to provide an activation criteria to bring up the first pod, after the pods scale down to 0. For the Prometheus trigger, this value is provided by `activationThreshold`. For the SQS queue, it comes from `activationQueueLength`.

Note

While using `minReplicaCount` of 0, make sure the activation does not depend on a metric that is being generated by the pods. When the pods scale down to 0, that metric will never be generated and the pods will not scale up again.

```
apiVersion: keda.sh/v1alpha1
kind: ScaledObject
metadata:
  name: invocations-scaledobject # name of the scaled object that will be created by
 this
  namespace: ns-team-a # namespace that this scaled object targets
spec:
  scaleTargetRef:
    apiVersion: apps/v1
    kind: Deployment
    name: $DEPLOYMENT_NAME # name of the model deployment
  minReplicaCount: 0 # minimum number of pods to be maintained
  maxReplicaCount: 4 # maximum number of pods to scale to
  pollingInterval: 10
  cooldownPeriod:  30
  initialCooldownPeriod:  180 # time before scaling down the pods after initial
 deployment
  triggers:
  - type: prometheus
    metadata:
      serverAddress: http://<prometheus-host>:9090
      query: sum(rate(http_requests_total{deployment="my-deployment"}[2m])) # Note:
 query must return a vector/scalar single element response
      threshold: '100.50'
      activationThreshold: '5.5' # Required if minReplicaCount is 0 for initial scaling
      namespace: example-namespace
      timeout: 1000
      identityOwner: operator
```

Note

The CPU and Memory triggers can scale to 0 only when you define at least one additional scaler which is not CPU or Memory (eg. SQS + CPU, or Prometheus + CPU).

Implementing inference observability on HyperPod clusters

Amazon SageMaker HyperPod provides comprehensive inference observability capabilities that enable data scientists and machine learning engineers to monitor and optimize their deployed models. This solution is enabled through SageMaker HyperPod Observability and automatically collects performance metrics for inference workloads, delivering production-ready monitoring through integrated Prometheus and Grafana dashboards.

With metrics enabled by default, the platform captures essential model performance data including invocation latency, concurrent requests, error rates, and token-level metrics, while providing standard Prometheus endpoints for customers who prefer to implement custom observability solutions.

> **Note**
>
> This topic contains a deep dive in to implementing inference observability on HyperPod clusters. For a more general reference, see Cluster and task observability.

This guide provides step-by-step instructions for implementing and using inference observability on your HyperPod clusters. You'll learn how to configure metrics in your deployment YAML files, access monitoring dashboards based on your role (administrator, data scientist, or machine learning engineer), integrate with custom observability solutions using Prometheus endpoints, and troubleshoot common monitoring issues.

Supported inference metrics

Invocation metrics

These metrics capture model inference request and response data, providing universal visibility regardless of your model type or serving framework. When inference metrics are enabled, these metrics are calculated at invocation time and exported to your monitoring infrastructure.

- `model_invocations_total` - Total number of invocation requests to the model
- `model_errors_total` - Total number of errors during model invocation
- `model_concurrent_requests` - Active concurrent model requests
- `model_latency_milliseconds` - Model invocation latency in milliseconds
- `model_ttfb_milliseconds` - Model time to first byte latency in milliseconds

Model container metrics

These metrics provide insights into the internal operations of your model containers, including token processing, queue management, and framework-specific performance indicators. The metrics available depend on your model serving framework:

- TGI container metrics
- LMI container metrics

Metric dimensions

All inference metrics include comprehensive labels that enable detailed filtering and analysis across your deployments:

- **Cluster Identity:**
  - `cluster_id` - The unique ID of the HyperPod cluster
  - `cluster_name` - The name of the HyperPod cluster
- **Resource Identity:**
  - `resource_name` - Deployment name (For example, "jumpstart-model-deployment")
  - `resource_type` - Type of deployment (jumpstart, inference-endpoint)
  - `namespace` - Kubernetes namespace for multi-tenancy
- **Model Characteristics:**
  - `model_name` - Specific model identifier (For example, "llama-2-7b-chat")
  - `model_version` - Model version for A/B testing and rollbacks
  - `model_container_type` - Serving framework (TGI, LMI, -)
- **Infrastructure Context:**
  - `pod_name` - Individual pod identifier for debugging
  - `node_name` - Kubernetes node for resource correlation
  - `instance_type` - EC2 instance type for cost analysis
- **Operational Context:**
  - `metric_source` - Collection point (reverse-proxy, model-container)
  - `task_type` - Workload classification (inference)

Configure metrics in deployment YAML

Amazon SageMaker HyperPod enables inference metrics by default for all model deployments, providing immediate observability without additional configuration. You can customize metrics behavior by modifying the deployment YAML configuration to enable or disable metrics collection based on your specific requirements.

Deploy a model from JumpStart

Use the following YAML configuration to deploy a JuJumpStartmpStart model with metrics enabled:

```
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: JumpStartModel
metadata:
  name:mistral-model
  namespace: ns-team-a
spec:
  model:
    modelId: "huggingface-llm-mistral-7b-instruct"
    modelVersion: "3.19.0"
  metrics:
    enabled:true # Default: true (can be set to false to disable)
  replicas: 2
  sageMakerEndpoint:
    name: "mistral-model-sm-endpoint"
  server:
    instanceType: "ml.g5.12xlarge"
    executionRole: "arn:aws:iam::123456789:role/SagemakerRole"
  tlsConfig:
    tlsCertificateOutputS3Uri: s3://hyperpod/mistral-model/certs/
```

Deploy custom and fine-tuned models from Amazon S3 or Amazon FSx

Configure custom inference endpoints with detailed metrics settings using the following YAML:

```
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: JumpStartModel
metadata:
  name:mistral-model
  namespace: ns-team-a
spec:
  model:
```

```
    modelId: "huggingface-llm-mistral-7b-instruct"
    modelVersion: "3.19.0"
  metrics:
    enabled:true # Default: true (can be set to false to disable)
  replicas: 2
  sageMakerEndpoint:
    name: "mistral-model-sm-endpoint"
  server:
    instanceType: "ml.g5.12xlarge"
    executionRole: "arn:aws:iam::123456789:role/SagemakerRole"
  tlsConfig:
    tlsCertificateOutputS3Uri: s3://hyperpod/mistral-model/certs/

Deploy a custom inference endpoint

Configure custom inference endpoints with detailed metrics settings using the following
 YAML:

apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: InferenceEndpointConfig
metadata:
  name: inferenceendpoint-deepseeks
  namespace: ns-team-a
spec:
  modelName: deepseeks
  modelVersion: 1.0.1
  metrics:
    enabled: true # Default: true (can be set to false to disable)
    metricsScrapeIntervalSeconds: 30 # Optional: if overriding the default 15s
    modelMetricsConfig:
        port: 8000 # Optional: if overriding, it defaults to the
 WorkerConfig.ModelInvocationPort.ContainerPort within the InferenceEndpointConfig spec
 8080
        path: "/custom-metrics" # Optional: if overriding the default "/metrics"
  endpointName: deepseek-sm-endpoint
  instanceType: ml.g5.12xlarge
  modelSourceConfig:
    modelSourceType: s3
    s3Storage:
      bucketName: model-weights
      region: us-west-2
    modelLocation: deepseek
    prefetchEnabled: true
  invocationEndpoint: invocations
```

```
  worker:
    resources:
      limits:
        nvidia.com/gpu: 1
      requests:
        nvidia.com/gpu: 1
        cpu: 25600m
        memory: 102Gi
    image: 763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:0.32.0-lmi14.0.0-
cu124
    modelInvocationPort:
      containerPort: 8080
      name: http
    modelVolumeMount:
      name: model-weights
      mountPath: /opt/ml/model
    environmentVariables: ...
  tlsConfig:
    tlsCertificateOutputS3Uri: s3://hyperpod/inferenceendpoint-deepseeks4/certs/
```

Note

To disable metrics for specific deployments, set `metrics.enabled: false` in your YAML configuration.

Monitor and troubleshoot inference workloads by role

Amazon SageMaker HyperPod provides comprehensive observability capabilities that support different user workflows, from initial cluster setup to advanced performance troubleshooting. Use the following guidance based on your role and monitoring requirements.

HyperPod admin

Your responsibility: Enable observability infrastructure and ensure system health across the entire cluster.

What you need to know:

- Cluster-wide observability provides infrastructure metrics for all workloads
- One-click setup deploys monitoring stack with pre-configured dashboards

- Infrastructure metrics are separate from model-specific inference metrics

What you need to do:

1. Navigate to the HyperPod console.
2. Select your cluster.
3. Go to the HyperPod cluster details page you just created. You will see a new option to install the HyperPod observability add-on.
4. Click on the **Quick install** option. After 1-2 minutes all the steps will be completed and you will see the Grafana dashboard and Prometheus workspace details.

This single action automatically deploys the EKS Add-on, configures observability operators, and provisions pre-built dashboards in Grafana.

Data scientist

Your responsibility: Deploy models efficiently and monitor their basic performance.

What you need to know:

- Metrics are automatically enabled when you deploy models
- Grafana dashboards provide immediate visibility into model performance
- You can filter dashboards to focus on your specific deployments

What you need to do:

1. Deploy your model using your preferred method:
   a. Amazon SageMaker Studio UI
   b. HyperPod CLI commands
   c. Python SDK in notebooks
   d. kubectl with YAML configurations
2. Access your model metrics:
   a. Open Amazon SageMaker Studio
   b. Navigate to HyperPod Cluster and open Grafana Dashboard
   c. Select Inference Dashboard

   d. Apply filters to view your specific model deployment
3. Monitor key performance indicators:
   a. Track model latency and throughput
   b. Monitor error rates and availability
   c. Review resource utilization trends

After this is complete, you'll have immediate visibility into your model's performance without additional configuration, enabling quick identification of deployment issues or performance changes.

Machine learning engineer (MLE)

Your responsibility: Maintain production model performance and resolve complex performance issues.

What you need to know:

- Advanced metrics include model container details like queue depths and token metrics
- Correlation analysis across multiple metric types reveals root causes
- Auto-scaling configurations directly impact performance during traffic spikes

Hypothetical scenario: A customer's chat model experiences intermittent slow responses. Users are complaining about 5-10 second delays. The MLE can use inference observability for systematic performance investigation.

What you need to do:

1. Examine the Grafana dashboard to understand the scope and severity of the performance issue:
   a. High latency alert active since 09:30
   b. P99 latency: 8.2s (normal: 2.1s)
   c. Affected time window: 09:30-10:15 (45 minutes)
2. Correlate multiple metrics to understand the system behavior during the incident:
   a. Concurrent requests: Spiked to 45 (normal: 15-20)
   b. Pod scaling: KEDA scaled 2→5 pods during incident
   c. GPU utilization: Remained normal (85-90%)

   d. Memory usage: Normal (24GB/32GB)

3. Examine the distributed system behavior since the infrastructure metrics appear normal:
   a. Node-level view: All pods concentrated on same node (poor distribution)
   b. Model container metrics: TGI queue depth shows 127 requests (normal: 5-10)

```
Available in Grafana dashboard under "Model Container Metrics" panel
        Metric: tgi_queue_size{resource_name="customer-chat-llama"}
        Current value: 127 requests queued (indicates backlog)
```

4. Identify interconnected configuration issues:
   a. KEDA scaling policy: Too slow (30s polling interval)
   b. Scaling timeline: Scaling response lagged behind traffic spike by 45+ seconds
5. Implement targeted fixes based on the analysis:
   a. Updated KEDA polling interval: 30s → 15s
   b. Increased maxReplicas in scaling configuration
   c. Adjusted scaling thresholds to scale earlier (15 vs 20 concurrent requests)

You can systematically diagnose complex performance issues using comprehensive metrics, implement targeted fixes, and establish preventive measures to maintain consistent production model performance.

Implement your own observability integration

Amazon SageMaker HyperPod exposes inference metrics through industry-standard Prometheus endpoints, enabling integration with your existing observability infrastructure. Use this approach when you prefer to implement custom monitoring solutions or integrate with third-party observability platforms instead of using the built-in Grafana and Prometheus stack.

Access inference metrics endpoints

What you need to know:

- Inference metrics are automatically exposed on standardized Prometheus endpoints
- Metrics are available regardless of your model type or serving framework
- Standard Prometheus scraping practices apply for data collection

Inference metrics endpoint configuration:

- **Port:** 9113
- **Path:** /metrics
- **Full endpoint:** http://pod-ip:9113/metrics

Available inference metrics:

- `model_invocations_total` - Total number of invocation requests to the model
- `model_errors_total` - Total number of errors during model invocation
- `model_concurrent_requests` - Active concurrent requests per model
- `model_latency_milliseconds` - Model invocation latency in milliseconds
- `model_ttfb_milliseconds` - Model time to first byte latency in milliseconds

Access model container metrics

What you need to know:

- Model containers expose additional metrics specific to their serving framework
- These metrics provide internal container insights like token processing and queue depths
- Endpoint configuration varies by model container type

For JumpStart model deployments using Text Generation Inference (TGI) containers:

- **Port:** 8080 (model container port)
- **Path:** /metrics
- **Documentation:** https://huggingface.co/docs/text-generation-inference/en/reference/metrics

For JumpStart model deployments using Large Model Inference (LMI) containers:

- **Port:** 8080 (model container port)
- **Path:** /server/metrics
- **Documentation:** https://github.com/deepjavalibrary/djl-serving/blob/master/prometheus/README.md

For custom inference endpoints (BYOD):

- **Port:** Customer-configured (default 8080 Defaults to the WorkerConfig.ModelInvocationPort.ContainerPort within the InferenceEndpointConfig spec.)
- **Path:** Customer-configured (default /metrics)

Implement custom observability integration

With a custom observability integration, you're responsible for:

1. **Metrics Scraping:** Implement Prometheus-compatible scraping from the endpoints described previously
2. **Data Export:** Configure export to your chosen observability platform
3. **Alerting:** Set up alerting rules based on your operational requirements
4. **Dashboards:** Create visualization dashboards for your monitoring needs

Troubleshoot inference observability issues

The dashboard shows no data

If the Grafana dashboard is empty and all panels show "No data," perform the following steps to investigate:

1. Verify Administrator has inference observability installed:
   a. Navigate to HyperPod Console > Select cluster > Check if "Observability" status shows "Enabled"
   b. Verify Grafana workspace link is accessible from cluster overview
   c. Confirm Amazon Managed Prometheus workspace is configured and receiving data
2. Verify HyperPod Observabilty is enabled:

```
hyp observability view
```

3. Verify model metrics are enabled:

```
kubectl get jumpstartmodel -n <namespace> customer-chat-llama -o
 jsonpath='{.status.metricsStatus}' # Expected: enabled: true, state:Enabled
```

```
kubectl get jumpstartmodel -n <namespace> customer-chat-llama -o
 jsonpath='{.status.metricsStatus}' # Expected: enabled: true, state:Enabled
```

4. Check the metrics endpoint:

```
kubectl port-forward pod/customer-chat-llama-xxx 9113:9113
curl localhost:9113/metrics | grep model_invocations_total# Expected:
 model_invocations_total{...} metrics
```

5. Check the logs:

```
# Model Container
kubectl logs customer-chat-llama-xxx -c customer-chat-llama# Look for: OOM errors,
 CUDA errors, model loading failures

# Proxy/SideCar
kubectl logs customer-chat-llama-xxx -c sidecar-reverse-proxy# Look for: DNS
 resolution issues, upstream connection failures

# Metrics Exporter Sidecar
kubectl logs customer-chat-llama-xxx -c otel-collector# Look for: Metrics collection
 issues, export failures
```

Other common issues

Issue	Solution	Action
Inference observability is not installed	Install inference observability through the console	"Enable Observability" in HyperPod console
Metrics disabled in model	Update model configuration	Add `metrics: {enabled: true}` to model spec
AMP workspace not configure d	Fix data source connection	Verify AMP workspace ID in Grafana data sources
Network connectivity	Check security groups/NACLs	Ensure pods can reach AMP endpoints

Task governance for model deployment on HyperPod

This section covers how to optimize your shared Amazon SageMaker HyperPod EKS clusters for real-time inference workloads. You'll learn to configure Kueue's task governance features—including quota management, priority scheduling, and resource sharing policies—to ensure your inference workloads get the GPU resources they need during traffic spikes while maintaining fair allocation across your teams' training, evaluation, and testing activities. For more general information on task governance, see SageMaker HyperPod task governance .

How inference workload management works

To effectively manage real-time inference traffic spikes in shared HyperPod EKS clusters, implement the following task governance strategies using Kueue's existing capabilities.

Priority class configuration

Define dedicated priority classes for inference workloads with high weights (such as 100) to ensure inference pods are admitted and scheduled before other task types. This configuration enables inference workloads to preempt lower-priority jobs during cluster load, which is critical for maintaining low-latency requirements during traffic surges.

Quota sizing and allocation

Reserve sufficient GPU resources in your team's `ClusterQueue` to handle expected inference spikes. During periods of low inference traffic, unused quota resources can be temporarily allocated to other teams' tasks. When inference demand increases, these borrowed resources can be reclaimed to prioritize pending inference pods. For more information, see Cluster Queue.

Resource Sharing Strategies

Choose between two quota sharing approaches based on your requirements:

1. **Strict Resource Control:** Disable quota lending and borrowing to guarantee reserved GPU capacity is always available for your workloads. This approach requires sizing quotas large enough to independently handle peak demand and may result in idle nodes during low-traffic periods.
2. **Flexible Resource Sharing:** Enable quota borrowing to use idle resources from other teams when needed. Borrowed pods are marked as preemptible and may be evicted if the lending team reclaims capacity.

Intra-Team Preemption

Enable intra-team preemption when running mixed workloads (evaluation, training, and inference) under the same quota. This allows Kueue to preempt lower-priority jobs within your team to accommodate high-priority inference pods, ensuring real-time inference can run without depending on external quota borrowing. For more information, see Preemption.

Sample inference workload setup

The following example shows how Kueue manages GPU resources in a shared Amazon SageMaker HyperPod cluster.

Cluster configuration and policy setup

Your cluster has the following configuration:

- **Team A**: 10 P4 GPU quota
- **Team B**: 20 P4 GPU quota
- **Static provisioning**: No autoscaling
- **Total capacity**: 30 P4 GPUs

The shared GPU pool uses this priority policy:

1. **Real-time inference**: Priority 100
2. **Training**: Priority 75
3. **Evaluation**: Priority 50

Kueue enforces team quotas and priority classes, with preemption and quota borrowing enabled.

Initial state: Normal cluster utilization

In normal operations:

- Team A runs training and evaluation jobs on all 10 P4 GPUs
- Team B runs real-time inference (10 P4s) and evaluation (10 P4s) within its 20 GPU quota
- The cluster is fully utilized with all jobs admitted and running

Inference spike: Team B requires additional GPUs

When Team B experiences a traffic spike, additional inference pods require 5 more P4 GPUs. Kueue detects that the new pods are:

- Within Team B's namespace
- Priority 100 (real-time inference)
- Pending admission due to quota constraints

Kueue's response process chooses between two options:

Option 1: Quota borrowing - If Team A uses only 6 of its 10 P4s, Kueue can admit Team B's pods using the idle 4 P4s. However, these borrowed resources are preemptible—if Team A submits jobs to reach its full quota, Kueue evicts Team B's borrowed inference pods.

Option 2: Self-preemption (Recommended) - Team B runs low-priority evaluation jobs (priority 50). When high-priority inference pods are waiting, Kueue preempts the evaluation jobs within Team B's quota and admits the inference pods. This approach provides safe resource allocation with no external eviction risk.

Kueue follows a three-step process to allocate resources:

1. **Quota check**

   Question: Does Team B have unused quota?

   - Yes → Admit the pods
   - No → Proceed to Step 2

2. **Self-preemption within Team B**

   Question: Can lower-priority Team B jobs be preempted?

   - Yes → Preempt evaluation jobs (priority 50), free 5 P4s, and admit inference pods
   - No → Proceed to Step 3

   This approach keeps workloads within Team B's guaranteed quota, avoiding external eviction risks.

3. **Borrowing from other teams**

   Question: Is there idle, borrowable quota from other teams?

   - Yes → Admit using borrowed quota (marked as preemptible)

- No → Pod remains in `NotAdmitted` state

Configuring task governance for inference workloads

To integrate your inference workloads with Kueue, add task governance labels to your `InferenceEndpointConfig` or `JumpStartModel` CRD. These labels determine which LocalQueue receives the workload for quota management and define the scheduling priority used in preemption decisions. The following sections cover prerequisites, resource scoping, label configuration, and verification steps.

Prerequisites

Before configuring task governance for inference workloads, ensure the following resources exist in your HyperPod cluster:

- **Kueue** is installed and running on your cluster
- A **ClusterQueue** exists with GPU quota allocated to your team
- A **LocalQueue** exists in the namespace where you plan to deploy your inference endpoint
- One or more **PriorityClass** resources are defined for workload types (such as inference, training, evaluation)

To verify these resources are available, run the following commands:

```
# Verify Kueue is installed
kubectl get crd | grep kueue

# List available PriorityClasses
kubectl get priorityclass

# List ClusterQueues
kubectl get clusterqueue

# List LocalQueues in your namespace
kubectl get localqueue -n <your-namespace>
```

Understanding resource scoping

Task governance resources have different scopes that affect how you configure your inference deployment labels.

The `kueue.x-k8s.io/queue-name` label must reference a LocalQueue that exists in the same namespace as your `InferenceEndpointConfig` or `JumpStartModel`. If no matching LocalQueue is found in that namespace, the workload will not be admitted by Kueue.

ClusterQueue, ResourceFlavor, and PriorityClass are cluster-scoped and accessible from any namespace.

To verify resource scoping on your cluster:

```
kubectl api-resources | grep kueue
```

Adding task governance labels

To enable task governance for your inference deployment, add the following labels to the `metadata` section of your `InferenceEndpointConfig` or `JumpStartModel` CRD:

```
metadata:
  name: <your-deployment-name>
  namespace: <your-namespace>
  labels:
    kueue.x-k8s.io/queue-name: <your-localqueue-name>
    kueue.x-k8s.io/priority-class: <your-priority-class>
```

Label descriptions:

- `kueue.x-k8s.io/queue-name` — Routes the workload to your team's LocalQueue for quota tracking. Must match a LocalQueue name in the same namespace as the workload.
- `kueue.x-k8s.io/priority-class` — Sets the scheduling priority for preemption decisions. References a cluster-scoped PriorityClass by name.

Verifying task governance configuration

After applying your `InferenceEndpointConfig` or `JumpStartModel` with task governance labels, verify that Kueue admitted the workload and pods are being scheduled correctly.

To verify task governance is working

1. Check workload admission status:

   ```
   kubectl get workloads -n <namespace>
   ```

A successfully admitted workload shows `True` in the ADMITTED column and lists the ClusterQueue that reserved resources in the RESERVED IN column.

2. Check pod status:

```
kubectl get pods -n <namespace>
```

After admission, pods gradually transition through initialization stages until they reach `Running` state.

3. Check quota consumption:

```
kubectl get clusterqueue <clusterqueue-name> -o yaml
```

Review the `status` section to confirm resource consumption is being tracked.

4. Check LocalQueue pending workloads:

```
kubectl get localqueue -n <namespace>
```

The PENDING WORKLOADS column shows how many workloads are waiting for admission.

5. View Kueue admission events:

```
kubectl describe workload <workload-name> -n <namespace>
```

Review the Events section for admission decisions and any errors.

If pods remain in `Pending` state, determine whether the issue is at the Kueue admission level (workload shows `Admitted: False`) or the Kubernetes scheduler level (workload admitted but pod unschedulable).

Data capture for inference on HyperPod

Amazon SageMaker HyperPod inference data capture enables you to record inference request and response data for model monitoring, debugging, and model improvement. Inference requests flow from the SageMaker AI endpoint to the Application Load Balancer and then to the model pod. You can enable capture independently at each level, from the outermost layer (Tier 1, SageMaker AI endpoint) to the deepest layer (Tier 3, model pod):

Data capture tiers

Tier	Capture point	What is captured	Amazon S3 path
Tier 1	SageMaker AI endpoint	Input and output payloads, sampling, Amazon KMS encryption	`{s3Uri}/{hash}/sme/`
Tier 2	Application Load Balancer	Access logs (request paths, client IPs, latencies)	`{s3Uri}/{hash}/alb/`
Tier 3	Model pod	Inference input and output payloads with configurable sampling, buffering, and payload size limits. Supports Amazon KMS encryption when you provide a key. Captures data closest to the model for the deepest visibility.	`{s3Uri}/{hash}/pod/`

Tier 1 captures full payloads at the SageMaker AI Runtime API boundary and requires endpoint registration. Use Tier 1 when you need compatibility with SageMaker AI Model Monitor. Tier 3 captures full payloads at the inference container with configurable buffering, sampling, and payload limits, and works without SageMaker AI endpoint registration. Use Tier 3 when you need the deepest visibility closest to the model. Enable any combination — each tier captures at a different point in the request flow.

All tiers write to your Amazon S3 bucket. If you don't specify an `s3Uri`, data is stored in the TLS certificate bucket under a `/data-capture/` prefix by default. Within the bucket, each deployment gets a unique path based on a hash derived from the cluster ARN, namespace, CRD type, and deployment name. The same deployment always generates the same prefix, so data capture artifacts from multiple CRD submissions targeting the same deployment flow to the same Amazon S3 subfolder.

To disable data capture for a tier, set its `enabled` field to `false` or remove the tier section from your CRD. To disable all data capture, remove the `dataCapture` section entirely.

Configuring data capture

Enable data capture by adding a `dataCapture` section to your `InferenceEndpointConfig` or `JumpStartModel` CRD. The `dataCapture` block contains a single `s3Uri` (optional) and one or more tier configurations. The following example shows the overall structure with all three tiers enabled:

```
dataCapture:
  s3Uri: s3://my-capture-bucket/captures/   # Optional. Defaults to TLS bucket.
  sagemakerEndpoint:
    enabled: true
    # Tier 1 fields...
  loadBalancer:
    enabled: true
  modelPod:
    enabled: true
    # Tier 3 fields...
```

`dataCapture.s3Uri` (Optional, String)

The Amazon S3 URI where captured data is stored. If not specified, the TLS certificate bucket is used with a `/data-capture/` prefix. Maximum length: 512 characters. The bucket must be in the same account as the cluster.

Tier 1: SageMaker AI endpoint capture

Tier 1 uses SageMaker AI's native `DataCaptureConfig` to capture inference input and output payloads at the endpoint level. This is the outermost capture point and is compatible with SageMaker AI Model Monitor for automated data quality monitoring. For more information about SageMaker AI data capture, see Capture data from real-time endpoint.

```
  sagemakerEndpoint:
    enabled: true
    initialSamplingPercentage: 100
    kmsKeyId: arn:aws:kms:us-east-2:123456789012:key/my-key-id
    captureOptions:
      - captureMode: Input
```

```
        - captureMode: Output
      captureContentTypeHeader:
        jsonContentTypes:
          - application/json
```

`sagemakerEndpoint.enabled` (Required, Boolean)

Set to `true` to enable Tier 1 capture.

`sagemakerEndpoint.initialSamplingPercentage` (Optional, Integer, 0–100)

Percentage of inference requests to capture. Default: `100` (all requests are captured).

`sagemakerEndpoint.captureOptions` (Optional, List)

Specifies whether to capture the inference request payload (`Input`), the inference response payload (`Output`), or both. Each item has a `captureMode` field set to `Input` or `Output`. Default: `[Input, Output]` (both request and response are captured). Maximum: 32 items.

`sagemakerEndpoint.kmsKeyId` (Optional, String)

ARN, key ID, alias name, or alias ARN of a Amazon KMS key for encrypting captured data at rest. When specified, captured data is encrypted with this key. When omitted, data is encrypted with the default Amazon S3 bucket encryption settings. Maximum length: 2048 characters.

`sagemakerEndpoint.captureContentTypeHeader` (Optional)

Specifies how to interpret the content type of captured payloads. Supports `jsonContentTypes` and `csvContentTypes` arrays. Maximum: 10 items each.

Tier 2: Load balancer capture

Tier 2 enables ALB access logs, capturing request metadata such as client IPs, request paths, and latencies.

```
    loadBalancer:
      enabled: true
```

`loadBalancer.enabled` (Required, Boolean)

Set to `true` to enable Tier 2 capture.

> **Note**
>
> ALB access logs capture request metadata including URLs and query parameters. Use POST request bodies rather than query parameters for sensitive inputs. ALB logs do not support Amazon KMS encryption and use Amazon S3 default encryption only.

Tier 3: Model pod capture

Tier 3 captures inference input and output payloads at the model pod level, providing the deepest visibility into inference traffic. Use this tier when you need fine-grained control over buffering, payload size limits, and capture closest to the model.

```
modelPod:
  enabled: true
  initialSamplingPercentage: 100
  kmsKeyId: arn:aws:kms:us-east-2:123456789012:key/my-key-id
  captureOptions:
    - captureMode: Input
    - captureMode: Output
  bufferConfig:
    batchSize: 100
    flushIntervalSeconds: 60
  payloadConfig:
    maxPayloadSizeKB: 1024
```

`modelPod.enabled` (Required, Boolean)

Set to `true` to enable Tier 3 capture.

`modelPod.initialSamplingPercentage` (Optional, Integer, 0–100)

Percentage of inference requests to capture. Default: `100` (all requests are captured).

`modelPod.captureOptions` (Optional, List)

Specifies whether to capture the inference request payload (`Input`), the inference response payload (`Output`), or both. Each item has a `captureMode` field set to `Input` or `Output`. Default: `[Input, Output]` (both request and response are captured). Maximum: 32 items.

`modelPod.kmsKeyId` (Optional, String)

ARN, key ID, alias name, or alias ARN of a Amazon KMS key for encrypting captured data at rest. When specified, captured data is encrypted with this key. When omitted, data is encrypted with the default Amazon S3 bucket encryption settings. Maximum length: 2048 characters.

`modelPod.bufferConfig.batchSize` (Optional, Integer, 1–1000)

Number of inference requests to batch before flushing. Default: `10`.

`modelPod.bufferConfig.flushIntervalSeconds` (Optional, Integer, 10–300)

Maximum time in seconds that a batch is held before being flushed, regardless of whether the batch size has been reached. Default: `60`.

`modelPod.payloadConfig.maxPayloadSizeKB` (Optional, Integer)

Maximum payload size in KB per request. Payloads exceeding this limit are truncated. If not set, the entire payload is captured.

Update Addon

Prerequisites: Authenticate and connect to your EKS cluster

Authenticate to your Amazon account. Before connecting, collect EKS cluster name, region, and HyperPod cluster ARN:

```
CLUSTER=EKS_CLUSTER_NAME
REGION=REGION
HP_ARN=HYPERPOD_CLUSTER_ARN
```

Connect to your EKS cluster:

```
aws eks update-kubeconfig --region REGION --name EKS_CLUSTER_NAME
```

Update the addon configuration:

```
VERSION=$(aws eks describe-addon --cluster-name $CLUSTER --addon-name amazon-sagemaker-
hyperpod-inference --region $REGION --query 'addon.addonVersion' --output text)
CURRENT_CONFIG=$(aws eks describe-addon --cluster-name $CLUSTER --addon-name amazon-
sagemaker-hyperpod-inference --region $REGION --query 'addon.configurationValues' --
output text)
```

```
NEW_CONFIG=$(echo "$CURRENT_CONFIG" | jq --arg arn "$HP_ARN" '. + {hyperpodClusterArn:
 $arn}')

aws eks update-addon \
--cluster-name $CLUSTER \
--addon-name amazon-sagemaker-hyperpod-inference \
--addon-version "$VERSION" \
--configuration-values "$NEW_CONFIG" \
--resolve-conflicts OVERWRITE \
--region $REGION
```

Wait for the Addon to be active and then deploy the models

Updating permissions for existing clusters

To enable data capture on your HyperPod Inference deployments, configure the following IAM permissions.

1. **Inference Operator Execution Role**

   Add the following S3 permission:

   ```
   {
       "Sid": "DataCaptureS3Access",
       "Effect": "Allow",
       "Action": "s3:PutObject",
       "Resource": "arn:aws:s3:::hyperpod-tls*/data-capture/*",
       "Condition": {
           "StringEquals": {
               "aws:ResourceAccount": "${aws:PrincipalAccount}"
           }
       }
   }
   ```

   Add your bucket name if you want to use a custom S3 bucket.

   If you use a customer-managed KMS key, also add:

   ```
   {
       "Sid": "DataCaptureKmsAccess",
       "Effect": "Allow",
       "Action": [
           "kms:Decrypt",
   ```

```
            "kms:GenerateDataKey"
        ],
        "Resource": "arn:aws:kms:*:*:key/*",
        "Condition": {
            "StringLike": {
                "kms:ViaService": "s3.*.amazonaws.com",
                "kms:EncryptionContext:aws:s3:arn": "arn:aws:s3:::hyperpod-tls*"
            },
            "StringEquals": {
                "aws:ResourceAccount": "${aws:PrincipalAccount}"
            }
        }
}
```

2. **S3 CSI Driver Role**

   Add the following S3 permission:

```
{
    "Sid": "DataCaptureWriteAccess",
    "Effect": "Allow",
    "Action": [
        "s3:PutObject",
        "s3:AbortMultipartUpload"
    ],
    "Resource": "arn:aws:s3:::hyperpod-tls*/data-capture/*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceAccount": "${aws:PrincipalAccount}"
        }
    }
}
```

   If you use a customer-managed KMS key, also add:

```
{
    "Sid": "DataCaptureKmsAccess",
    "Effect": "Allow",
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey",
        "kms:DescribeKey"
    ],
```

```
    "Resource": "arn:aws:kms:*:*:key/*",
    "Condition": {
        "StringLike": {
            "kms:ViaService": "s3.*.amazonaws.com"
        },
        "StringEquals": {
            "aws:ResourceAccount": "${aws:PrincipalAccount}"
        }
    }
}
```

3. **S3 Bucket Policy**

   Add this bucket policy only if you enable load balancer data capture (Tier 2) to allow ALB to write access logs. Replace `$ACCOUNT_ID` with your Amazon account ID.

```
{
    "Sid": "AllowALBAccessLogDelivery",
    "Effect": "Allow",
    "Principal": {
        "Service": "logdelivery.elasticloadbalancing.amazonaws.com"
    },
    "Action": "s3:PutObject",
    "Resource": "arn:aws:s3:::hyperpod-tls*/data-capture/*",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": "$ACCOUNT_ID"
        }
    }
}
```

Best practices

- Use `initialSamplingPercentage` to control the volume of captured data. Start with a lower percentage in production and increase as needed.
- Use `payloadConfig.maxPayloadSizeKB` (Tier 3) to cap the size of captured payloads and control storage costs.
- Specify a `kmsKeyId` for Tier 1 and Tier 3 if your workload requires encryption at rest with your own Amazon KMS key.

Disaggregated Prefill and Decode for HyperPod inference

Disaggregated Prefill and Decode (DPD) separates the two phases of LLM inference, prefill and decode, onto dedicated GPU pools and transfers key-value (KV) cache between them over Elastic Fabric Adapter (EFA) using GPU-Direct Remote Direct Memory Access (RDMA).

When prefill and decode run on the same GPU (colocated), a single long-context request can stall in-flight token streams for other clients, inflating per-token latency under load. DPD removes this interference by running compute-bound prefill on one set of GPUs and memory-bandwidth-bound decode on another, producing more predictable latency under mixed traffic and letting you scale each phase independently.

The inference operator handles the orchestration, which includes provisioning the router, wiring prefill and decode pods together via LMCache and NIXL, and integrating with HyperPod observability. You can enable DPD by adding a `pdSpec` section to the same `InferenceEndpointConfig` resource you already use for inference endpoints.

When DPD helps

DPD delivers the most benefit when all of the following conditions are present:

- **Large dense models** — 70B+ parameters (for example, Llama 3.3 70B).
- **Long inputs** — 4,000+ input tokens. Inter-token latency (ITL) improvement scales with input length because longer prefills cause more decode interference when colocated.
- **Sustained concurrency** — 2+ requests per second. Without concurrent requests competing for the same GPU, there is nothing to disaggregate.
- **Moderate or long outputs** — 256+ output tokens. More output tokens means more cumulative benefit from stable per-token latency.

If your workload has short inputs, low concurrency, or uses small models, a standard colocated deployment is simpler and performs well.

Prerequisites

Before deploying inference endpoints that use Disaggregated Prefill and Decode, you need the following components set up in your local development environment:

- Amazon Command Line Interface (Amazon CLI)
- Access to your HyperPod Amazon EKS cluster via kubectl

- Hugging Face token that allows read access to the respective model checkpoint. This is not required if the model checkpoint is already located in an Amazon S3 bucket.
- A worker image that includes vLLM, LMCache, NVIDIA NIXL, and the EFA libfabric provider. The following image options are supported:
  - DLC: `public.ecr.aws/deep-learning-containers/vllm:server-hyperpod-cuda-v1.1`
  - LMCache: `lmcache/vllm-openai:v0.4.3`

  Both images include LMCache 0.4.3, vLLM 0.19.0, and NIXL 1.0.0.
- HyperPod Inference Operator **version 3.2 or later** installed. DPD is not supported on earlier versions. The operator is installed by default in newly created HyperPod Amazon EKS clusters. If you intend to use an existing cluster, follow the installation instructions in Setting up your HyperPod clusters for model deployment. Verify your version:

```
kubectl get deployment hyperpod-inference-operator-controller-manager \
  -n hyperpod-inference-system \
  -o jsonpath='{.spec.template.spec.containers[?(@.name=="manager")].image}{"\n"}'
```

> **Important**
>
> Disaggregated Prefill and Decode requires EFA-capable instances with GPU-Direct RDMA support. The following instance types are supported: `ml.p5.48xlarge`, `ml.p5e.48xlarge`, `ml.p5en.48xlarge`, `ml.p6-b200.48xlarge`, `ml.p6-b300.48xlarge`. Other instance types are not supported for DPD.

Deploy a DPD endpoint

Most `InferenceEndpointConfig` fields are shared with non-DPD endpoints and documented in Deploy foundation models and custom fine-tuned models. To enable DPD, add the following sections to your manifest.

Prefill-Decode Spec: pdSpec

Declares the prefill/decode topology and specifies arguments. Presence of this field is what makes the endpoint disaggregated: the operator creates separate Deployments for prefill and decode and wires them together via the router and LMCache PD backend.

```
pdSpec:
  prefillSpec:
    replicas: 1
    resources:
      limits:
        nvidia.com/gpu: ${GPUS_PER_NODE}
      requests:
        nvidia.com/gpu: ${GPUS_PER_NODE}
    args:
      - "--gpu-memory-utilization"
      - "0.75"
  decodingSpec:
    replicas: 1
    resources:
      limits:
        nvidia.com/gpu: ${GPUS_PER_NODE}
      requests:
        nvidia.com/gpu: ${GPUS_PER_NODE}
  routingThreshold: 4096
```

`replicas`

Scale prefill and decode independently.

`resources`

Applied to the role's pod spec. Top-level `worker.resources` is ignored for DPD pods; per-role values override.

`routingThreshold`

Token length threshold that routes requests to the disaggregated path. Requests that do not meet this threshold bypass the prefiller and go directly to the decoder.

`args`

vLLM flags specific to that role. Merged into `worker.args` at startup: flags already in `worker.args` are replaced with the per-role value; flags not present are appended.

DPD Environment Variables: `environmentVariables`

These environment variables are applied identically to both the prefiller and decoder containers; there is no per-role env-var field. For per-role behavior, use `pdSpec.{prefillSpec,decodingSpec}.args` instead.

```
environmentVariables:
  - name: PD_BUFFER_SIZE
    value: "8589934592"
  - name: LMCACHE_SAVE_DECODE_CACHE
    value: "False"
  - name: PYTHONHASHSEED
    value: "0"
```

`PD_BUFFER_SIZE` (8 GiB)

GPU buffer reserved on the decoder for incoming KV cache transfers, sized per rank. For Llama 70B at TP=8, each token's KV cache is approximately 40 KB per rank, so a 6000-token prompt occupies approximately 0.23 GB per rank and 8 GiB holds approximately 35 such in-flight transfers. When the buffer exceeds capacity, the decoder logs `Failed to allocate memory object, retrying...` and clients see latency spikes. Increase to 16/32 GiB or scale `decodingSpec.replicas` if needed.

`LMCACHE_SAVE_DECODE_CACHE: "False"`

Disables redundant L1 caching on the decoder. The prefiller is the source of truth for cache hits.

`PYTHONHASHSEED: "0"`

LMCache uses Python's built-in `hash()` to compute prompt-token cache keys. Python randomizes that hash seed per process by default, so identical prompts produce different keys on prefiller and decoder and lookups miss. Pinning the seed makes the keys agree across pods.

Configure the routing strategy

The `intelligentRoutingSpec` section sets the routing strategy the DPD router uses to select a prefiller for each request. The router is created automatically when `pdSpec` is present; this section is optional and defaults to `prefixaware`.

```
intelligentRoutingSpec:
  enabled: true
```

```
  routingStrategy: prefixaware
```

DPD can also be integrated with intelligent routing and KV caching. For more information, see Configure KV caching and intelligent routing.

With a single prefill replica, all strategies route to that replica. The choice only affects behavior when `prefillSpec.replicas > 1`:

- For a single prefill replica, use `prefixaware` (the default) to maximize KV cache hits when prompts share common prefixes such as system prompts or chat history.
- For multiple prefill replicas, use `roundrobin` to distribute load evenly across replicas and avoid hot-spotting a single prefiller.

Complete example

The following manifest deploys Llama 3.3 70B on two ml.p5.48xlarge instances (one prefiller, one decoder):

```
apiVersion: inference.sagemaker.aws.amazon.com/v1
kind: InferenceEndpointConfig
metadata:
  name: dpd-test
  namespace: default
spec:
  endpointName: dpd-test
  instanceType: ml.p5.48xlarge
  invocationEndpoint: v1/chat/completions
  modelName: Llama-3.3-70B-Instruct
  modelSourceConfig:
    modelSourceType: s3
    modelLocation: Llama-3.3-70B-Instruct
    s3Storage:
      bucketName: <YOUR_BUCKET>
      region: <YOUR_REGION>
  loadBalancer:
    healthCheckPath: /health
  metrics:
    enabled: true
  kvCacheSpec:
    enableL1Cache: true
  intelligentRoutingSpec:
```

```
    enabled: true
    routingStrategy: prefixaware
  pdSpec:
    prefillSpec:
      replicas: 1
      resources:
        requests:
          nvidia.com/gpu: "8"
        limits:
          nvidia.com/gpu: "8"
    decodingSpec:
      replicas: 1
      resources:
        requests:
          nvidia.com/gpu: "8"
        limits:
          nvidia.com/gpu: "8"
    routingThreshold: 4096
  worker:
    image: public.ecr.aws/deep-learning-containers/vllm:server-hyperpod-cuda-v1.1
    args:
      - "--model"
      - "/opt/ml/model"
      - "--host"
      - "0.0.0.0"
      - "--port"
      - "8000"
      - "--tensor-parallel-size"
      - "8"
      - "--max-model-len"
      - "16384"
      - "--gpu-memory-utilization"
      - "0.75"
    modelInvocationPort:
      name: http
      containerPort: 8000
    modelVolumeMount:
      name: model-weights
      mountPath: /opt/ml/model
    resources:
      requests:
        cpu: "96"
        memory: 1024Gi
        nvidia.com/gpu: "8"
```

```
      limits:
        cpu: "96"
        memory: 1024Gi
        nvidia.com/gpu: "8"
    environmentVariables:
      - name: HF_HOME
        value: /tmp/hf_home
      - name: PD_BUFFER_SIZE
        value: "8589934592"
      - name: LMCACHE_SAVE_DECODE_CACHE
        value: "False"
      - name: PYTHONHASHSEED
        value: "0"
```

Apply the manifest:

```
kubectl apply -f inference_endpoint_dpd_config.yaml
```

Verify the deployment

Image pull and model loading take several minutes. Monitor pod status:

```
kubectl get pods -A \
  | grep -E "prefill-|decode-|router"
```

A healthy deployment shows:

```
NAMESPACE                   NAME                                READY   STATUS
 RESTARTS   AGE
default                     prefill-dpd-test-XXXX               3/3     Running   0
         7m
default                     decode-dpd-test-XXXX                3/3     Running   0
         7m
hyperpod-inference-system   dpd-test-router-XXXX                2/2     Running   0
         7m
```

Each model pod has 3 containers (vLLM worker, Nginx reverse proxy, OpenTelemetry collector). The router pod has 2 containers (router, OpenTelemetry collector). Check the `InferenceEndpointConfig` status:

```
kubectl get inferenceendpointconfig dpd-test -n default \
```

```
  -o jsonpath='{.status.conditions[0].message}{"\n"}'
```

Expected output: `DPD prefill and decode deployments are ready`

Verify DPD roles

Confirm the prefiller reports `sender` and the decoder reports `receiver`. This is the single most discriminating startup signal — if both pods report the same role or neither prints the line, the operator did not wire DPD correctly.

```
PREFILL_POD=$(kubectl get pod -n ${NAMESPACE} \
  -l 'inference.sagemaker.aws.amazon.com/dpd-role=prefill' \
  -o jsonpath='{.items[0].metadata.name}')

DECODE_POD=$(kubectl get pod -n ${NAMESPACE} \
  -l 'inference.sagemaker.aws.amazon.com/dpd-role=decode' \
  -o jsonpath='{.items[0].metadata.name}')

kubectl logs $PREFILL_POD -n ${NAMESPACE} -c prefill-${DEPLOYMENT_NAME} \
  | grep -oE "'pd_role': '[a-z]+'" | sort -u

kubectl logs $DECODE_POD -n ${NAMESPACE} -c decode-${DEPLOYMENT_NAME} \
  | grep -oE "'pd_role': '[a-z]+'" | sort -u
```

Expected output:

```
'pd_role': 'sender'
'pd_role': 'receiver'
```

Invoke the endpoint

Once the endpoint is ready, send a short and a long prompt to exercise both routing paths, then check the logs to confirm KV transfer over EFA.

```
PREFILL_POD=$(kubectl get pod -n ${NAMESPACE} \
  -l 'inference.sagemaker.aws.amazon.com/dpd-role=prefill' \
  -o jsonpath='{.items[0].metadata.name}')

DECODE_POD=$(kubectl get pod -n ${NAMESPACE} \
  -l 'inference.sagemaker.aws.amazon.com/dpd-role=decode' \
  -o jsonpath='{.items[0].metadata.name}')
```

```
ROUTER_POD=$(kubectl get pods -n hyperpod-inference-system -o name \
  | grep -- "${DEPLOYMENT_NAME}-${NAMESPACE}-router" | head -1)

ROUTER_URL=http://${DEPLOYMENT_NAME}-${NAMESPACE}-routing-service.hyperpod-inference-
system.svc.cluster.local:443/v1/chat/completions
```

Short prompt (under threshold, direct to decoder)

Requests with fewer tokens than `routingThreshold` bypass the prefiller and go directly to the decoder:

```
kubectl run curl-short --rm -it --image=curlimages/curl --restart=Never -- \
  curl -s -k -X POST "$ROUTER_URL" \
    -H "Content-Type: application/json" \
    -d '{
      "model": "/opt/ml/model",
      "messages": [{"role": "user", "content": "What is disaggregated prefill-decode in
 one sentence?"}],
      "max_tokens": 80,
      "temperature": 0.0
    }'
```

Long prompt (exceeds threshold, DPD path)

Requests that exceed the threshold route through the prefiller for KV cache computation, then to the decoder for token generation:

```
kubectl run curl-long --rm -it --image=curlimages/curl --restart=Never -- sh -c '
LONG=""
i=0; while [ $i -lt 600 ]; do LONG="${LONG}The quick brown fox jumps over the lazy dog.
 "; i=$((i+1)); done
curl -s -k -X POST "'"$ROUTER_URL"'" \
  -H "Content-Type: application/json" \
  -d "{\"model\":\"/opt/ml/model\",\"messages\":[{\"role\":\"user\",\"content\":
\"${LONG}\"}],\"max_tokens\":30,\"temperature\":0.0}"
'
```

Verify KV transfer

After sending a long prompt, confirm the KV cache was transferred by checking decoder logs:

```
kubectl logs $DECODE_POD -n ${NAMESPACE} -c decode-${DEPLOYMENT_NAME} \
  | grep -E "Retrieved.*tokens.*throughput" | tail -2
```

Expected output (one line per TP rank):

```
[Worker_TP5] [LMCache INFO] [req_id=cmpl-...] Retrieved 6035 out of 6035 required
 tokens (from 6035 total tokens).
   size: 0.2344 gb, cost 1.3304 ms, throughput: 176.1686 GB/s
```

`Retrieved N out of N required tokens` with N > 0 confirms KV cache crossed the NIXL channel successfully. If you see `Retrieved 0 out of N`, the decoder fell back to local recomputation — see Disaggregated Prefill and Decode (DPD) deployment issues.

You can also verify the routing decision in the router logs:

```
kubectl logs $ROUTER_POD -n hyperpod-inference-system -c router-container --tail=20 \
  | grep -E "Conditional routing"
```

For the long prompt, you should see:

```
[INFO] Conditional routing: estimated_tokens=6750, threshold=4096, disaggregate=True
```

For the short prompt:

```
[INFO] Conditional routing: estimated_tokens=12, threshold=4096, disaggregate=False
```

> **Note**
>
> To invoke through a SageMaker AI AI endpoint, set `endpointName` in your `InferenceEndpointConfig`. If `endpointName` is not set, no SageMaker AI AI endpoint is created and only direct ALB invocation is available.

Observability

Enable metrics by setting `metrics.enabled: true` in your `InferenceEndpointConfig`. DPD metrics are available in the HyperPod inference dashboard. For more information, see Implementing inference observability on HyperPod clusters.

The following DPD-specific metrics are available:

DPD-specific metrics

Metric	Description
E2E TTFT	Overall time to first token (prefill + KV transfer + routing)
Prefill TTFT	Prefiller-only latency
Prefill Queue	Number of requests waiting for prefill
Decode Queue	Number of requests waiting on the decoder
Prefill Time	Time spent on prefill computation
Decode Latency	Per-token output latency (TPOT)
KV Transfer Time	Time to transfer KV cache from prefiller to decoder
DPD Routing Counts	Disaggregated vs. fallback (under-threshold) requests

Tune your DPD deployment

The following table provides a quick reference for tuning DPD based on the symptoms you observe in your metrics dashboard.

DPD tuning reference

Config	What it does	Default	When to tune
`pdSpec.routingThreshold`	Minimum input tokens to route through the prefiller. Requests under this threshold go directly to the decoder.	`4096`	The default works well for most workloads. Setting it too low increases TTFT due to unnecessary KV transfers on short prompts, while setting it too high limits TPOT improvement because fewer requests take the DPD path.

Config	What it does	Default	When to tune
`pdSpec.prefillSpec.replicas`	Number of prefill pods.	`1`	Scale up if prefill queue depth is high in order to improve prefill TTFT.
`PD_BUFFER_SIZE`	Decoder GPU buffer for incoming KV transfers (per rank). 8 GiB holds approximately 35 in-flight 6K-token transfers for 70B at TP=8.	`"8589934592"` (8 GiB)	Increase to handle more concurrent KV transfers. Decrease if you see memory issues. When increasing, you may need to lower `--gpu-memory-utilization` on the decoder to free GPU memory for the larger buffer.
`--gpu-memory-utilization`	Fraction of GPU memory vLLM uses for weights, activations, and KV cache.	`0.75`	Increase for more KV cache headroom on long inputs. Risk: prefiller OOM because prefill also needs memory for activations. Test with your actual input length distribution.
`--max-num-seqs`	Max concurrent sequences per worker batch.	16 (prefiller), 32 (decoder)	Raise for better batching under load. Lower if hitting OOM on the prefiller. Set per-role via `pdSpec.{prefillSpec,decodingSpec}.args`.
`intelligentRoutingSpec.routingStrategy`	How the router selects a prefiller when multiple replicas exist.	`prefixaware`	Use `roundrobin` to evenly distribute load across multiple prefiller replicas. Use `prefixaware` or `kvaware` with a single prefiller or when prompts share common prefixes (system prompts, chat history) to maximize cache hits.

Test with your actual workload and input length distribution.

To apply configuration changes, edit your deployment YAML and re-apply:

```
kubectl apply -f inference_endpoint_dpd_config.yaml
```

Known limitations

- DPD is recommended for dense models with 70B or more parameters. Smaller models and Mixture-of-Experts models typically do not benefit from disaggregation.
- The current release supports a single decode deployment per endpoint. Support for multiple decode deployments is planned for a future release.
- Performance is validated up to 64 concurrent requests on ml.p5.48xlarge with Llama 3.3 70B.
- To revert from a DPD deployment to a standard colocated deployment, apply a new `InferenceEndpointConfig` without `pdSpec`.

For troubleshooting DPD deployments, see Disaggregated Prefill and Decode (DPD) deployment issues.

HyperPod inference troubleshooting

This troubleshooting guide addresses common issues that can occur during Amazon SageMaker HyperPod inference deployment and operation. These problems typically involve VPC networking configuration, IAM permissions, Kubernetes resource management, and operator connectivity issues that can prevent successful model deployment or cause deployments to fail or remain in pending states.

This troubleshooting guide uses the following terminology: **Troubleshooting steps** are diagnostic procedures to identify and investigate problems, **Resolution** provides the specific actions to fix identified issues, and **Verification** confirms that the solution worked correctly.

Topics

- Inference operator installation failures through SageMaker AI console
- Inference operator installation failures through Amazon CLI
- Certificate download timeout
- Model deployment issues

- VPC ENI permission issue
- IAM trust relationship issue
- Missing NVIDIA GPU plugin error
- Inference operator fails to start
- Hugging Face Hub model deployment failures
- Disaggregated Prefill and Decode (DPD) deployment issues
- Inference Gateway troubleshooting guide

Inference operator installation failures through SageMaker AI console

Overview: When installing the inference operator through the SageMaker AI console using Quick Install or Custom Install, the underlying CloudFormation stacks may fail due to various issues. This section covers common failure scenarios and their resolutions.

Inference operator add-on installation failure through Quick or Custom install

Problem: The HyperPod cluster creation completes successfully, but the inference operator add-on installation fails.

Common causes:

- Pod capacity limits exceeded on cluster nodes. The inference operator installation requires a minimum of 13 pods. The minimum recommended instance type is `ml.c5.4xlarge`.
- IAM permission issues
- Resource quota constraints
- Network or VPC configuration problems

Symptoms and diagnosis

Symptoms:

- Inference operator add-on shows CREATE_FAILED or DEGRADED status in console
- CloudFormation stack associated with the add-on is in CREATE_FAILED state
- Installation progress stops or shows error messages

Diagnostic steps:

1. Check the inference operator add-on status:

```
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION \
    --query "addon.{Status:status,Health:health,Issues:issues}" \
    --output json
```

2. Check for pod limit issues:

```
# Check current pod count per node
kubectl get nodes -o json | jq '.items[] | {name: .metadata.name,
 allocatable: .status.allocatable.pods, capacity: .status.capacity.pods}'

# Check pods running on each node
kubectl get pods --all-namespaces -o wide | awk '{print $8}' | sort | uniq -c

# Check for pod evictions or failures
kubectl get events --all-namespaces --sort-by='.lastTimestamp' | grep -i "pod\|limit
\|quota"
```

3. Check CloudFormation stack status (if using console installation):

```
# List CloudFormation stacks related to the cluster
aws cloudformation list-stacks \
    --region $REGION \
    --query "StackSummaries[?contains(StackName, '$EKS_CLUSTER_NAME') &&
 StackStatus=='CREATE_FAILED'].
{Name:StackName,Status:StackStatus,Reason:StackStatusReason}" \
    --output table

# Get detailed stack events
aws cloudformation describe-stack-events \
    --stack-name <stack-name> \
    --region $REGION \
    --query "StackEvents[?ResourceStatus=='CREATE_FAILED']" \
    --output table
```

Resolution

To resolve the installation failure, save the current configuration, delete the failed add-on, fix the underlying issue, and then reinstall the inference operator through the SageMaker AI console (recommended) or the Amazon CLI.

Step 1: Save the current configuration

- Extract and save the add-on configuration before deletion:

```
# Save the current configuration
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION \
    --query 'addon.configurationValues' \
    --output text > addon-config-backup.json

# Verify the configuration was saved
cat addon-config-backup.json

# Pretty print for readability
cat addon-config-backup.json | jq '.'
```

Step 2: Delete the failed add-on

- Delete the inference operator add-on:

```
aws eks delete-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION

# Wait for deletion to complete
echo "Waiting for add-on deletion..."
aws eks wait addon-deleted \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION 2>/dev/null || sleep 60
```

Step 3: Fix the underlying issue

Choose the appropriate resolution based on the failure cause:

If the issue is pod limit exceeded:

```
# The inference operator requires a minimum of 13 pods.
# The minimum recommended instance type is ml.c5.4xlarge.
#
# Option 1: Add instance group with higher pod capacity
# Different instance types support different maximum pod counts
# For example: m5.large (29 pods), m5.xlarge (58 pods), m5.2xlarge (58 pods)
aws sagemaker update-cluster \
    --cluster-name $HYPERPOD_CLUSTER_NAME \
    --region $REGION \
    --instance-groups '[{"InstanceGroupName":"worker-
group-2","InstanceType":"ml.m5.xlarge","InstanceCount":2}]'

# Option 2: Scale existing node group to add more nodes
aws eks update-nodegroup-config \
    --cluster-name $EKS_CLUSTER_NAME \
    --nodegroup-name <nodegroup-name> \
    --scaling-config minSize=2,maxSize=10,desiredSize=5 \
    --region $REGION

# Option 3: Clean up unused pods
kubectl delete pods --field-selector status.phase=Failed --all-namespaces
kubectl delete pods --field-selector status.phase=Succeeded --all-namespaces
```

Step 4: Reinstall the inference operator

After fixing the underlying issue, reinstall the inference operator using one of the following methods:

- **SageMaker AI console with Custom Install (recommended):** Reuse existing IAM roles and TLS bucket from your previous installation. For steps, see Method 1: Install HyperPod Inference Add-on through SageMaker AI console (Recommended).
- **Amazon CLI with saved configuration:** Use the configuration you backed up in Step 1 to reinstall the add-on. For the full CLI installation steps, see Method 2: Installing the Inference Operator using the Amazon CLI.

```
aws eks create-addon \
```

```
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --addon-version v1.0.0-eksbuild.1 \
    --configuration-values file://addon-config-backup.json \
    --region $REGION
```

- **SageMaker AI console with Quick Install:** Creates new IAM roles, TLS bucket, and dependency add-ons automatically. For steps, see Method 1: Install HyperPod Inference Add-on through SageMaker AI console (Recommended).

Step 5: Verify successful installation

```
# Check add-on status
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION \
    --query "addon.{Status:status,Health:health}" \
    --output table

# Verify pods are running
kubectl get pods -n hyperpod-inference-system

# Check operator logs
kubectl logs -n hyperpod-inference-system deployment/hyperpod-inference-controller-
manager --tail=50
```

Cert-manager installation failed due to Kueue webhook not ready

Problem: The cert-manager add-on installation fails with a webhook error because the Task Governance (Kueue) webhook service has no available endpoints. This is a race condition that occurs when cert-manager tries to create resources before the Task Governance webhook pods are fully running. This can happen when Task Governance add-on is being installed along with the Inference operator during cluster creation.

Symptoms and diagnosis

Error message:

```
AdmissionRequestDenied
Internal error occurred: failed calling webhook "mdeployment.kb.io": failed to call
 webhook:
```

```
Post "https://kueue-webhook-service.kueue-system.svc:443/mutate-apps-v1-deployment?
timeout=10s":
no endpoints available for service "kueue-webhook-service"
```

Root cause:

- Task Governance add-on installs and registers a mutating webhook that intercepts all Deployment creations
- Cert-manager add-on tries to create Deployment resources before Task Governance webhook pods are ready
- Kubernetes admission control calls the Task Governance webhook, but it has no endpoints (pods not running yet)

Diagnostic step:

1. Check cert-manager add-on status:

```
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name cert-manager \
    --region $REGION \
    --query "addon.{Status:status,Health:health,Issues:issues}" \
    --output json
```

Resolution

Solution: Delete and reinstall cert-manager

The Task Governance webhook becomes ready within 60 seconds. Simply delete and reinstall the cert-manager add-on:

1. Delete the failed cert-manager add-on:

```
aws eks delete-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name cert-manager \
    --region $REGION
```

2. Wait 30-60 seconds for the Task Governance webhook to become ready, then reinstall the cert-manager add-on:

```
sleep 60

aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name cert-manager \
    --region $REGION
```

Inference operator installation failures through Amazon CLI

Overview: When installing the inference operator through the Amazon CLI, add-on installation may fail due to missing dependencies. This section covers common CLI installation failure scenarios and their resolutions.

Inference add-on installation failed due to missing CSI drivers

Problem: The inference operator add-on creation fails because required CSI driver dependencies are not installed on the EKS cluster.

Symptoms and diagnosis:

Error messages:

The following errors appear in the add-on creation logs or inference operator logs:

```
S3 CSI driver not installed (missing CSIDriver s3.csi.aws.com).
Please install the required CSI driver and see the troubleshooting guide for more
 information.

FSx CSI driver not installed (missing CSIDriver fsx.csi.aws.com).
Please install the required CSI driver and see the troubleshooting guide for more
 information.
```

Diagnostic steps:

1. Check if CSI drivers are installed:

```
# Check for S3 CSI driver
```

```
kubectl get csidriver s3.csi.aws.com
kubectl get pods -n kube-system | grep mountpoint

# Check for FSx CSI driver
kubectl get csidriver fsx.csi.aws.com
kubectl get pods -n kube-system | grep fsx
```

2. Check EKS add-on status:

```
# List all add-ons
aws eks list-addons --cluster-name $EKS_CLUSTER_NAME --region $REGION

# Check specific CSI driver add-ons
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name aws-mountpoint-
s3-csi-driver --region $REGION 2>/dev/null || echo "S3 CSI driver not installed"
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name aws-fsx-csi-
driver --region $REGION 2>/dev/null || echo "FSx CSI driver not installed"
```

3. Check inference operator add-on status:

```
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION \
    --query "addon.{Status:status,Health:health,Issues:issues}" \
    --output json
```

Resolution:

Step 1: Install missing S3 CSI driver

1. Create IAM role for S3 CSI driver (if not already created):

```
# Set up service account role ARN (from installation steps)
export S3_CSI_ROLE_ARN=$(aws iam get-role --role-name $S3_CSI_ROLE_NAME --query
 'Role.Arn' --output text 2>/dev/null || echo "Role not found")
echo "S3 CSI Role ARN: $S3_CSI_ROLE_ARN"
```

2. Install S3 CSI driver add-on:

```
aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
```

```
    --addon-name aws-mountpoint-s3-csi-driver \
    --addon-version v1.14.1-eksbuild.1 \
    --service-account-role-arn $S3_CSI_ROLE_ARN \
    --region $REGION
```

3. Verify S3 CSI driver installation:

```
# Wait for add-on to be active
aws eks wait addon-active --cluster-name $EKS_CLUSTER_NAME --addon-name aws-
mountpoint-s3-csi-driver --region $REGION

# Verify CSI driver is available
kubectl get csidriver s3.csi.aws.com
kubectl get pods -n kube-system | grep mountpoint
```

Step 2: Install missing FSx CSI driver

1. Create IAM role for FSx CSI driver (if not already created):

```
# Set up service account role ARN (from installation steps)
export FSX_CSI_ROLE_ARN=$(aws iam get-role --role-name $FSX_CSI_ROLE_NAME --query
 'Role.Arn' --output text 2>/dev/null || echo "Role not found")
echo "FSx CSI Role ARN: $FSX_CSI_ROLE_ARN"
```

2. Install FSx CSI driver add-on:

```
aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name aws-fsx-csi-driver \
    --addon-version v1.6.0-eksbuild.1 \
    --service-account-role-arn $FSX_CSI_ROLE_ARN \
    --region $REGION

# Wait for add-on to be active
aws eks wait addon-active --cluster-name $EKS_CLUSTER_NAME --addon-name aws-fsx-
csi-driver --region $REGION

# Verify FSx CSI driver is running
kubectl get pods -n kube-system | grep fsx
```

Step 3: Verify all dependencies

After installing the missing dependencies, verify they are running correctly before retrying the inference operator installation:

```
# Check all required add-ons are active
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name aws-mountpoint-s3-
csi-driver --region $REGION
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name aws-fsx-csi-driver
 --region $REGION
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name metrics-server --
region $REGION
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name cert-manager --
region $REGION

# Verify all pods are running
kubectl get pods -n kube-system | grep -E "(mountpoint|fsx|metrics-server)"
kubectl get pods -n cert-manager
```

Inference Custom Resource Definitions are missing during model deployment

Problem: Custom Resource Definitions (CRDs) are missing when you attempt to create model deployments. This issue occurs when you previously installed and deleted the inference add-on without cleaning up model deployments that have finalizers.

Symptoms and diagnosis:

Root cause:

If you delete the inference add-on without first removing all model deployments, custom resources with finalizers remain in the cluster. These finalizers must complete before you can delete the CRDs. The add-on deletion process doesn't wait for CRD deletion to complete, which causes the CRDs to remain in a terminating state and prevents new installations.

To diagnose this issue

1. Check whether CRDs exist.

   ```
   kubectl get crd | grep inference.sagemaker.aws.amazon.com
   ```

2. Check for stuck custom resources.

   ```
   # Check for JumpStartModel resources
   ```

```
kubectl get jumpstartmodels -A

# Check for InferenceEndpointConfig resources
kubectl get inferenceendpointconfigs -A
```

3. Inspect finalizers on stuck resources.

```
# Example for a specific JumpStartModel
kubectl get jumpstartmodels <model-name> -n <namespace> -o
 jsonpath='{.metadata.finalizers}'

# Example for a specific InferenceEndpointConfig
kubectl get inferenceendpointconfigs <config-name> -n <namespace> -o
 jsonpath='{.metadata.finalizers}'
```

Resolution:

Manually remove the finalizers from all model deployments that weren't deleted when you removed the inference add-on. Complete the following steps for each stuck custom resource.

To remove finalizers from JumpStartModel resources

1. List all JumpStartModel resources across all namespaces.

   ```
   kubectl get jumpstartmodels -A
   ```

2. For each JumpStartModel resource, remove the finalizers by patching the resource to set metadata.finalizers to an empty array.

   ```
   kubectl patch jumpstartmodels <model-name> -n <namespace> -p '{"metadata":
   {"finalizers":[]}}' --type=merge
   ```

   The following example shows how to patch a resource named kv-l1-only.

   ```
   kubectl patch jumpstartmodels kv-l1-only -n default -p '{"metadata":{"finalizers":
   []}}' --type=merge
   ```

3. Verify that the model instance is deleted.

   ```
   kubectl get jumpstartmodels -A
   ```

When all resources are cleaned up, you should see the following output.

```
Error from server (NotFound): Unable to list "inference.sagemaker.aws.amazon.com/
v1, Resource=jumpstartmodels": the server could not find the requested resource
 (get jumpstartmodels.inference.sagemaker.aws.amazon.com)
```

4. Verify that the JumpStartModel CRD is removed.

```
kubectl get crd | grep jumpstartmodels.inference.sagemaker.aws.amazon.com
```

If the CRD is successfully removed, this command returns no output.

To remove finalizers from InferenceEndpointConfig resources

1. List all InferenceEndpointConfig resources across all namespaces.

```
kubectl get inferenceendpointconfigs -A
```

2. For each InferenceEndpointConfig resource, remove the finalizers.

```
kubectl patch inferenceendpointconfigs <config-name> -n <namespace> -p
 '{"metadata":{"finalizers":[]}}' --type=merge
```

The following example shows how to patch a resource named my-inference-config.

```
kubectl patch inferenceendpointconfigs my-inference-config -n default -p
 '{"metadata":{"finalizers":[]}}' --type=merge
```

3. Verify that the config instance is deleted.

```
kubectl get inferenceendpointconfigs -A
```

When all resources are cleaned up, you should see the following output.

```
Error from server (NotFound): Unable to list "inference.sagemaker.aws.amazon.com/
v1, Resource=inferenceendpointconfigs": the server could not find the requested
 resource (get inferenceendpointconfigs.inference.sagemaker.aws.amazon.com)
```

4. Verify that the InferenceEndpointConfig CRD is removed.

```
kubectl get crd | grep inferenceendpointconfigs.inference.sagemaker.aws.amazon.com
```

If the CRD is successfully removed, this command returns no output.

To reinstall the inference add-on

After you clean up all stuck resources and verify that the CRDs are removed, reinstall the inference add-on. For more information, see Installing the Inference Operator with EKS add-on.

Verification:

1. Verify that the inference add-on is successfully installed.

```
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION \
    --query "addon.{Status:status,Health:health}" \
    --output table
```

   The Status should be ACTIVE and the Health should be HEALTHY.

2. Verify that CRDs are properly installed.

```
kubectl get crd | grep inference.sagemaker.aws.amazon.com
```

   You should see the inference-related CRDs listed in the output.

3. Test creating a new model deployment to confirm that the issue is resolved.

```
# Create a test deployment using your preferred method
kubectl apply -f <your-model-deployment.yaml>
```

Prevention:

To prevent this issue, complete the following steps before you uninstall the inference add-on.

1. Delete all model deployments.

```
# Delete all JumpStartModel resources
kubectl delete jumpstartmodels --all -A

# Delete all InferenceEndpointConfig resources
kubectl delete inferenceendpointconfigs --all -A

# Wait for all resources to be fully deleted
kubectl get jumpstartmodels -A
kubectl get inferenceendpointconfigs -A
```

2. Verify that all custom resources are deleted.
3. After you confirm that all resources are cleaned up, delete the inference add-on.

Inference add-on installation failed due to missing cert-manager

Problem: The inference operator add-on creation fails because the cert-manager EKS Add-On is not installed, resulting in missing Custom Resource Definitions (CRDs).

Symptoms and diagnosis:

Error messages:

The following errors appear in the add-on creation logs or inference operator logs:

```
Missing required CRD: certificaterequests.cert-manager.io.
The cert-manager add-on is not installed. Please install cert-manager and see the
 troubleshooting guide for more information.
```

Diagnostic steps:

1. Check if cert-manager is installed:

```
# Check for cert-manager CRDs
kubectl get crd | grep cert-manager
kubectl get pods -n cert-manager

# Check EKS add-on status
aws eks describe-addon --cluster-name $EKS_CLUSTER_NAME --addon-name cert-manager --
region $REGION 2>/dev/null || echo "Cert-manager not installed"
```

2. Check inference operator add-on status:

```
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION \
    --query "addon.{Status:status,Health:health,Issues:issues}" \
    --output json
```

Resolution:

Step 1: Install cert-manager add-on

1. Install the cert-manager EKS add-on:

```
aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name cert-manager \
    --addon-version v1.18.2-eksbuild.2 \
    --region $REGION
```

2. Verify cert-manager installation:

```
# Wait for add-on to be active
aws eks wait addon-active --cluster-name $EKS_CLUSTER_NAME --addon-name cert-
manager --region $REGION

# Verify cert-manager pods are running
kubectl get pods -n cert-manager

# Verify CRDs are installed
kubectl get crd | grep cert-manager | wc -l
# Expected: Should show multiple cert-manager CRDs
```

Step 2: Retry inference operator installation

1. After cert-manager is installed, retry the inference operator installation:

```
# Delete the failed add-on if it exists
aws eks delete-addon \
```

```
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION 2>/dev/null || echo "Add-on not found, proceeding with
 installation"

# Wait for deletion to complete
sleep 30

# Reinstall the inference operator add-on
aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --addon-version v1.0.0-eksbuild.1 \
    --configuration-values file://addon-config.json \
    --region $REGION
```

2. Monitor the installation:

```
# Check installation status
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION \
    --query "addon.{Status:status,Health:health}" \
    --output table

# Verify inference operator pods are running
kubectl get pods -n hyperpod-inference-system
```

Inference add-on installation failed due to missing ALB Controller

Problem: The inference operator add-on creation fails because the Amazon Load Balancer Controller is not installed or not properly configured for the inference add-on.

Symptoms and diagnosis:

Error messages:

The following errors appear in the add-on creation logs or inference operator logs:

```
ALB Controller not installed (missing aws-load-balancer-controller pods).
```

```
Please install the Application Load Balancer Controller and see the troubleshooting
 guide for more information.
```

Diagnostic steps:

1. Check if ALB Controller is installed:

```
# Check for ALB Controller pods
kubectl get pods -n kube-system | grep aws-load-balancer-controller
kubectl get pods -n hyperpod-inference-system | grep aws-load-balancer-controller

# Check ALB Controller service account
kubectl get serviceaccount aws-load-balancer-controller -n kube-system 2>/dev/null ||
 echo "ALB Controller service account not found"
kubectl get serviceaccount aws-load-balancer-controller -n hyperpod-inference-
system 2>/dev/null || echo "ALB Controller service account not found in inference
 namespace"
```

2. Check inference operator add-on configuration:

```
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION \
    --query "addon.
{Status:status,Health:health,ConfigurationValues:configurationValues}" \
    --output json
```

Resolution:

Choose one of the following options based on your setup:

Option 1: Let the inference add-on install ALB Controller (Recommended)

- Ensure the ALB role is created and properly configured in your add-on configuration:

```
# Verify ALB role exists
export ALB_ROLE_ARN=$(aws iam get-role --role-name alb-role --query 'Role.Arn' --
output text 2>/dev/null || echo "Role not found")
echo "ALB Role ARN: $ALB_ROLE_ARN"

# Update your addon-config.json to enable ALB
```

```
cat > addon-config.json << EOF
{
  "executionRoleArn": "$EXECUTION_ROLE_ARN",
  "tlsCertificateS3Bucket": "$BUCKET_NAME",
  "hyperpodClusterArn": "$HYPERPOD_CLUSTER_ARN",
  "alb": {
    "enabled": true,
    "serviceAccount": {
      "create": true,
      "roleArn": "$ALB_ROLE_ARN"
    }
  },
  "keda": {
    "auth": {
      "aws": {
        "irsa": {
          "roleArn": "$KEDA_ROLE_ARN"
        }
      }
    }
  }
}
EOF
```

Option 2: Use existing ALB Controller installation

- If you already have ALB Controller installed, configure the add-on to use the existing installation:

```
# Update your addon-config.json to disable ALB installation
cat > addon-config.json << EOF
{
  "executionRoleArn": "$EXECUTION_ROLE_ARN",
  "tlsCertificateS3Bucket": "$BUCKET_NAME",
  "hyperpodClusterArn": "$HYPERPOD_CLUSTER_ARN",
  "alb": {
    "enabled": false
  },
  "keda": {
    "auth": {
      "aws": {
        "irsa": {
```

```
          "roleArn": "$KEDA_ROLE_ARN"
        }
      }
    }
  }
}
EOF
```

Step 3: Retry inference operator installation

1. Reinstall the inference operator add-on with the updated configuration:

```
# Delete the failed add-on if it exists
aws eks delete-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION 2>/dev/null || echo "Add-on not found, proceeding with
 installation"

# Wait for deletion to complete
sleep 30

# Reinstall with updated configuration
aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --addon-version v1.0.0-eksbuild.1 \
    --configuration-values file://addon-config.json \
    --region $REGION
```

2. Verify ALB Controller is working:

```
# Check ALB Controller pods
kubectl get pods -n hyperpod-inference-system | grep aws-load-balancer-controller
kubectl get pods -n kube-system | grep aws-load-balancer-controller

# Check service account annotations
kubectl describe serviceaccount aws-load-balancer-controller -n hyperpod-inference-
system 2>/dev/null
kubectl describe serviceaccount aws-load-balancer-controller -n kube-system 2>/dev/
null
```

Inference add-on installation failed due to missing KEDA operator

Problem: The inference operator add-on creation fails because the KEDA (Kubernetes Event Driven Autoscaler) operator is not installed or not properly configured for the inference add-on.

Symptoms and diagnosis:

Error messages:

The following errors appear in the add-on creation logs or inference operator logs:

```
KEDA operator not installed (missing keda-operator pods).
KEDA can be installed separately in any namespace or via the Inference addon.
```

Diagnostic steps:

1. Check if KEDA operator is installed:

```
# Check for KEDA operator pods in common namespaces
kubectl get pods -n keda-system | grep keda-operator 2>/dev/null || echo "KEDA not
 found in keda-system namespace"
kubectl get pods -n kube-system | grep keda-operator 2>/dev/null || echo "KEDA not
 found in kube-system namespace"
kubectl get pods -n hyperpod-inference-system | grep keda-operator 2>/dev/null ||
 echo "KEDA not found in inference namespace"

# Check for KEDA CRDs
kubectl get crd | grep keda 2>/dev/null || echo "KEDA CRDs not found"

# Check KEDA service account
kubectl get serviceaccount keda-operator -A 2>/dev/null || echo "KEDA service account
 not found"
```

2. Check inference operator add-on configuration:

```
aws eks describe-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION \
    --query "addon.
{Status:status,Health:health,ConfigurationValues:configurationValues}" \
    --output json
```

Resolution:

Choose one of the following options based on your setup:

Option 1: Let the inference add-on install KEDA (Recommended)

- Ensure the KEDA role is created and properly configured in your add-on configuration:

```
# Verify KEDA role exists
export KEDA_ROLE_ARN=$(aws iam get-role --role-name keda-operator-role --query
 'Role.Arn' --output text 2>/dev/null || echo "Role not found")
echo "KEDA Role ARN: $KEDA_ROLE_ARN"

# Update your addon-config.json to enable KEDA
cat > addon-config.json << EOF
{
  "executionRoleArn": "$EXECUTION_ROLE_ARN",
  "tlsCertificateS3Bucket": "$BUCKET_NAME",
  "hyperpodClusterArn": "$HYPERPOD_CLUSTER_ARN",
  "alb": {
    "serviceAccount": {
      "create": true,
      "roleArn": "$ALB_ROLE_ARN"
    }
  },
  "keda": {
    "enabled": true,
    "auth": {
      "aws": {
        "irsa": {
          "roleArn": "$KEDA_ROLE_ARN"
        }
      }
    }
  }
}
EOF
```

Option 2: Use existing KEDA installation

- If you already have KEDA installed, configure the add-on to use the existing installation:

```
# Update your addon-config.json to disable KEDA installation
cat > addon-config.json << EOF
{
  "executionRoleArn": "$EXECUTION_ROLE_ARN",
  "tlsCertificateS3Bucket": "$BUCKET_NAME",
  "hyperpodClusterArn": "$HYPERPOD_CLUSTER_ARN",
  "alb": {
    "serviceAccount": {
      "create": true,
      "roleArn": "$ALB_ROLE_ARN"
    }
  },
  "keda": {
    "enabled": false
  }
}
EOF
```

Step 3: Retry inference operator installation

1. Reinstall the inference operator add-on with the updated configuration:

```
# Delete the failed add-on if it exists
aws eks delete-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --region $REGION 2>/dev/null || echo "Add-on not found, proceeding with
 installation"

# Wait for deletion to complete
sleep 30

# Reinstall with updated configuration
aws eks create-addon \
    --cluster-name $EKS_CLUSTER_NAME \
    --addon-name amazon-sagemaker-hyperpod-inference \
    --addon-version v1.0.0-eksbuild.1 \
    --configuration-values file://addon-config.json \
    --region $REGION
```

2. Verify KEDA is working:

```
# Check KEDA pods
kubectl get pods -n hyperpod-inference-system | grep keda
kubectl get pods -n kube-system | grep keda
kubectl get pods -n keda-system | grep keda 2>/dev/null

# Check KEDA CRDs
kubectl get crd | grep scaledobjects
kubectl get crd | grep scaledjobs

# Check KEDA service account annotations
kubectl describe serviceaccount keda-operator -n hyperpod-inference-system 2>/dev/
null
kubectl describe serviceaccount keda-operator -n kube-system 2>/dev/null
kubectl describe serviceaccount keda-operator -n keda-system 2>/dev/null
```

Certificate download timeout

When deploying a SageMaker AI endpoint, the creation process fails due to the inability to download the certificate authority (CA) certificate in a VPC environment. For detailed configuration steps, refer to the Admin guide.

Error message:

The following error appears in the SageMaker AI endpoint CloudWatch logs:

```
Error downloading CA certificate: Connect timeout on endpoint URL: "https://
****.s3.<REGION>.amazonaws.com/****/***.pem"
```

Root cause:

- This issue occurs when the inference operator cannot access the self-signed certificate in Amazon S3 within your VPC
- Proper configuration of the Amazon S3 VPC endpoint is essential for certificate access

Resolution:

1. If you don't have an Amazon S3 VPC endpoint:
   - Create an Amazon S3 VPC endpoint following the configuration in section 5.3 of the Admin guide.

2. If you already have an Amazon S3 VPC endpoint:
   - Ensure that the subnet route table is configured to point to the VPC endpoint (if using gateway endpoint) or that private DNS is enabled for interface endpoint.
   - Amazon S3 VPC endpoint should be similar to the configuration mentioned in section 5.3 Endpoint creation step

Model deployment issues

Overview: This section covers common issues that occur during model deployment, including pending states, failed deployments, and monitoring deployment progress.

Model deployment stuck in pending state

When deploying a model, the deployment remains in a "Pending" state for an extended period. This indicates that the inference operator is unable to initiate the model deployment in your HyperPod cluster.

Components affected:

During normal deployment, the inference operator should:

- Deploy model pod
- Create load balancer
- Create SageMaker AI endpoint

Troubleshooting steps:

1. Check the inference operator pod status:

```
kubectl get pods -n hyperpod-inference-system
```

   Expected output example:

```
NAME                                                        READY   STATUS
 RESTARTS   AGE
hyperpod-inference-operator-controller-manager-65c49967f5-894fg   1/1     Running   0
         6d13h
```

2. Review the inference operator logs and examine the operator logs for error messages:

```
kubectl logs hyperpod-inference-operator-controller-manager-5b5cdd7757-txq8f -n
 hyperpod-inference-operator-system
```

What to look for:

- Error messages in the operator logs
- Status of the operator pod
- Any deployment-related warnings or failures

> **Note**
>
> A healthy deployment should progress beyond the "Pending" state within a reasonable time. If issues persist, review the inference operator logs for specific error messages to determine the root cause.

Model deployment failed state troubleshooting

When a model deployment enters a "Failed" state, the failure could occur in one of three components:

- Model pod deployment
- Load balancer creation
- SageMaker AI endpoint creation

Troubleshooting steps:

1. Check the inference operator status:

   ```
   kubectl get pods -n hyperpod-inference-system
   ```

   Expected output:

   ```
   NAME                                                    READY   STATUS
    RESTARTS   AGE
   ```

```
hyperpod-inference-operator-controller-manager-65c49967f5-894fg   1/1     Running
 0          6d13h
```

2. Review the operator logs:

```
kubectl logs hyperpod-inference-operator-controller-manager-5b5cdd7757-txq8f -n
 hyperpod-inference-operator-system
```

What to look for:

The operator logs will indicate which component failed:

- Model pod deployment failures
- Load balancer creation issues
- SageMaker AI endpoint errors

Checking model deployment progress

To monitor the progress of your model deployment and identify potential issues, you can use kubectl commands to check the status of various components. This helps determine whether the deployment is progressing normally or has encountered problems during the model pod creation, load balancer setup, or SageMaker AI endpoint configuration phases.

Method 1: Check the JumpStart model status

```
kubectl describe jumpstartmodel.inference.sagemaker.aws.amazon.com/<model-name> -n
 <namespace>
```

Key status indicators to monitor:

1. Deployment Status
   - Look for `Status.State`: Should show `DeploymentComplete`
   - Check `Status.Deployment Status.Available Replicas`
   - Monitor `Status.Conditions` for deployment progress
2. SageMaker AI Endpoint Status
   - Check `Status.Endpoints.Sagemaker.State`: Should show `CreationCompleted`
   - Verify `Status.Endpoints.Sagemaker.Endpoint Arn`

3. TLS Certificate Status
   - View `Status.Tls Certificate` details
   - Check certificate expiration in `Last Cert Expiry Time`

Method 2: Check the inference endpoint configuration

```
kubectl describe inferenceendpointconfig.inference.sagemaker.aws.amazon.com/
<deployment_name> -n <namespace>
```

Common status states:

- `DeploymentInProgress`: Initial deployment phase
- `DeploymentComplete`: Successful deployment
- `Failed`: Deployment failed

> **Note**
>
> Monitor the Events section for any warnings or errors. Check replica count matches expected configuration. Verify all conditions show `Status: True` for a healthy deployment.

VPC ENI permission issue

SageMaker AI endpoint creation fails due to insufficient permissions for creating network interfaces in VPC.

Error message:

```
Please ensure that the execution role for variant AllTraffic has sufficient permissions
 for creating an endpoint variant within a VPC
```

Root cause:

The inference operator's execution role lacks the required Amazon EC2 permission to create network interfaces (ENI) in VPC.

Resolution:

Add the following IAM permission to the inference operator's execution role:

```
{
    "Effect": "Allow",
    "Action": [
        "ec2:CreateNetworkInterfacePermission",
        "ec2:DeleteNetworkInterfacePermission"
     ],
    "Resource": "*"
}
```

Verification:

After adding the permission:

1. Delete the failed endpoint (if exists)
2. Retry the endpoint creation
3. Monitor the deployment status for successful completion

> **Note**
>
> This permission is essential for SageMaker AI endpoints running in VPC mode. Ensure the execution role has all other necessary VPC-related permissions as well.

IAM trust relationship issue

HyperPod inference operator fails to start with an STS AssumeRoleWithWebIdentity error, indicating an IAM trust relationship configuration problem.

Error message:

```
failed to enable inference watcher for HyperPod cluster *****: operation error
 SageMaker: UpdateClusterInference,
get identity: get credentials: failed to refresh cached credentials, failed to retrieve
 credentials,
operation error STS: AssumeRoleWithWebIdentity, https response error StatusCode: 403,
 RequestID: ****,
api error AccessDenied: Not authorized to perform sts:AssumeRoleWithWebIdentity
```

Resolution:

Update the trust relationship of the inference operator's IAM execution role with the following configuration.

Replace the following placeholders:

- <ACCOUNT_ID>: Your Amazon account ID
- <REGION>: Your Amazon region
- <OIDC_ID>: Your Amazon EKS cluster's OIDC provider ID

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
            "Federated": "arn:aws:iam::<ACCOUNT_ID>:oidc-provider/
oidc.eks.<REGION>.amazonaws.com/id/<OIDC_ID>"
            },
            "Action": "sts:AssumeRoleWithWebIdentity",
            "Condition": {
                "StringLike": {
                    "oidc.eks.<REGION>.amazonaws.com/id/<OIDC_ID>:sub":
 "system:serviceaccount:<namespace>:<service-account-name>",
                    "oidc.eks.<REGION>.amazonaws.com/id/<OIDC_ID>:aud":
 "sts.amazonaws.com"
                }
            }
        },
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "sagemaker.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Verification:

After updating the trust relationship:

1. Verify the role configuration in IAM console
2. Restart the inference operator if necessary
3. Monitor operator logs for successful startup

Missing NVIDIA GPU plugin error

Model deployment fails with GPU insufficiency error despite having available GPU nodes. This occurs when the NVIDIA device plugin is not installed in the HyperPod cluster.

Error message:

```
0/15 nodes are available: 10 node(s) didn't match Pod's node affinity/selector,
5 Insufficient nvidia.com/gpu. preemption: 0/15 nodes are available:
10 Preemption is not helpful for scheduling, 5 No preemption victims found for incoming
 pod.
```

Root cause:

- Kubernetes cannot detect GPU resources without the NVIDIA device plugin
- Results in scheduling failures for GPU workloads

Resolution:

Install the NVIDIA GPU plugin by running:

```
kubectl create -f https://raw.githubusercontent.com/NVIDIA/k8s-device-plugin/refs/tags/
v0.17.1/deployments/static/nvidia-device-plugin.yml
```

Verification steps:

1. Check the plugin deployment status:

   ```
   kubectl get pods -n kube-system | grep nvidia-device-plugin
   ```

2. Verify GPU resources are now visible:

```
kubectl get nodes -o=custom-
columns=NAME:.metadata.name,GPU:.status.allocatable.nvidia\\.com/gpu
```

3. Retry model deployment

> **Note**
>
> Ensure NVIDIA drivers are installed on GPU nodes. Plugin installation is a one-time setup per cluster. May require cluster admin privileges to install.

Inference operator fails to start

Inference operator pod failed to start and is causing the following error message. This error is due to permission policy on the operator execution role not being authorized to perform `sts:AssumeRoleWithWebIdentity`. Due to this, the operator part running on the control plane is not started.

Error message:

```
Warning Unhealthy 5m46s (x22 over 49m) kubelet Startup probe failed: Get
 "http://10.1.100.59:8081/healthz": context deadline exceeded (Client.Timeout exceeded
 while awaiting headers)
```

Root cause:

- Permission policy of the inference operator execution role is not set to access authorization token for resources.

Resolution:

Set the following policy of the execution role of `EXECUTION_ROLE_ARN` for the HyperPod inference operator:

```
HyperpodInferenceAccessPolicy-ml-cluster to include all resources
```

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:PutObject",
                "s3:GetObject",
                "s3:DeleteObject"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ecr:GetAuthorizationToken"
            ],
            "Resource": "*"
        }
    ]
}
```

Verification steps:

1. Change the policy.
2. Terminate the HyperPod inference operator pod.
3. The pod will be restarted without throwing any exceptions.

Hugging Face Hub model deployment failures

Overview: When deploying models from Hugging Face Hub using the `huggingface` model source type, the deployment may fail during the model download phase. This section covers common failure scenarios and how to diagnose them using Kubernetes events and pod logs.

Diagnosing Hugging Face deployment failures

Troubleshooting steps:

1. Check the InferenceEndpointConfig status and events for error details:

```
kubectl describe inferenceendpointconfig <name> -n <namespace>
```

   Look for events with reason `HuggingFaceDownloadFailed` and the `DeploymentFailed` condition in the status, which contain specific error messages.

2. If the init container is failing (pod shows `Init:CrashLoopBackOff` or `Init:Error`), check the init container logs:

```
kubectl logs <pod-name> -c hf-model-downloader -n <namespace>
```

3. Check the pod status for init container exit codes:

```
kubectl get pod <pod-name> -n <namespace> -o
 jsonpath='{.status.initContainerStatuses[0].state}'
```

Invalid or expired Hugging Face token

Symptoms: Init container fails with `401 Unauthorized` or `Access denied` errors. The pod enters `CrashLoopBackOff`.

Root cause:

- The Hugging Face API token in the Kubernetes Secret is invalid, expired, or revoked.
- The token does not have access to the gated model.

Resolution:

1. Generate a new token at huggingface.co/settings/tokens.
2. For gated models, ensure you have accepted the model's license agreement on the Hugging Face Hub model page.
3. Update the Kubernetes Secret with the new token:

```
kubectl delete secret <secret-name> -n <namespace>
kubectl create secret generic <secret-name> \
  --from-literal=token=hf_NEW_TOKEN_HERE \
  -n <namespace>
```

4. Delete the failing pod to trigger a new download attempt:

```
kubectl delete pod -l app=<iec-name> -n <namespace>
```

Network connectivity failures

Symptoms: Init container fails with connection timeout or DNS resolution errors. The pod enters `CrashLoopBackOff`.

Root cause: The cluster nodes do not have outbound internet access to Hugging Face domains (`*.huggingface.co` and `*.hf.co`). This is common in private subnets without a NAT gateway.

Resolution:

1. Verify that your VPC has a NAT gateway configured for the private subnets where your cluster nodes run.
2. Verify that security groups allow outbound HTTPS (port 443) traffic.
3. Verify that network ACLs allow outbound traffic to the internet.
4. Test connectivity from within the cluster:

```
kubectl run test-connectivity --image=curlimages/curl --rm -it --restart=Never -- \
  curl -sI https://huggingface.co
```

> **Note**
>
> If outbound internet access is not available, consider using Amazon S3 or Amazon FSx as the model source instead. Download the model to Amazon S3 first, then deploy using the `s3` model source type.

Model not found

Symptoms: Init container fails with `Repository Not Found` or `404` errors.

Root cause:

- The `modelId` is incorrect or the model does not exist on Hugging Face Hub.

- The model is private and the token does not have access.

Resolution:

1. Verify the model ID exists by visiting `https://huggingface.co/<org>/<model>` in your browser.
2. Ensure the `modelId` in your InferenceEndpointConfig is in the correct `org/model` format (for example, `mistralai/Mistral-7B-Instruct-v0.3`).

Disaggregated Prefill and Decode (DPD) deployment issues

Overview: Common issues that can occur when deploying inference endpoints with Disaggregated Prefill and Decode (DPD). These problems typically involve pod startup, KV cache transfer, routing behavior, or resource allocation.

Pod startup issues

Problem: DPD pods fail to start or remain in a non-ready state.

Symptoms and resolution:

- **Pods stuck in `ContainerCreating` for more than 10 minutes.** Run `kubectl describe pod <pod-name>` and look for `Failed to pull image` or `MountVolume.SetUp failed`. Verify the worker image exists and the Amazon S3 bucket is accessible from the cluster.
- **Pods stuck at 2/3 Ready.** The vLLM worker is still loading the model. Llama 3.3 70B takes 5–10 minutes from a cold Amazon S3 fetch. Check progress:

  ```
  kubectl logs <pod-name> -c <prefill|decode>-<endpoint-name> | grep -i "engine\|
  loading"
  ```

  Wait for the log message indicating the engine is ready.
- **Pods restart with `EngineDeadError` or `TimeoutError`.** This indicates an operator version older than v3.2. Upgrade the inference operator before continuing.
- **All HTTP requests return 503 immediately after deploy.** Pods are still loading the model. Wait for the `InferenceEndpointConfig` status to reach `DeploymentComplete`:

  ```
  kubectl get inferenceendpointconfig <endpoint-name> -n <namespace> -w
  ```

KV cache transfer issues

Problem: KV cache transfer between prefill and decode pods fails or performs poorly.

Symptoms and resolution:

- **Decoder logs show `Retrieved 0 out of N required tokens`.** KV transfer did not occur and the decoder fell back to local recomputation. Verify that the `pd_role` is correct (prefiller must be `sender`, decoder must be `receiver`), both pods use the same worker image, and PYTHONHASHSEED is set to `"0"` on both pods.
- **Decoder logs show `Failed to allocate memory object, retrying...`** The decoder PD buffer is full under high concurrency. Either increase PD_BUFFER_SIZE (try `"17179869184"` for 16 GiB or `"34359738368"` for 32 GiB) or scale `decodingSpec.replicas`.
- **KV transfer throughput below 1 GB/s.** EFA is not being used and transfers are falling back to CPU. Verify that both pods are scheduled on EFA-capable nodes in the same Availability Zone, that nodes have EFA resources available (`kubectl describe node <node-name> | grep efa`), and that the worker image includes the EFA libfabric provider.

Routing issues

Problem: Requests are not being routed correctly between prefill and decode pods.

Symptoms and resolution:

- **All requests bypass the prefiller (even long prompts).** Check the router logs for routing decisions:

  ```
  ROUTER_POD=$(kubectl get pods -n hyperpod-inference-system -o name | grep router |
   head -1)
  kubectl logs $ROUTER_POD -n hyperpod-inference-system -c router-container --tail=50 \
    | grep "Conditional routing"
  ```

  Verify the `estimated_tokens` value exceeds your `routingThreshold`. If the token estimate is lower than expected, the router's tokenizer may be counting differently — try lowering `routingThreshold`.
- **Uneven load distribution across prefillers.** If you have multiple prefiller replicas and observe that one is overloaded while others are idle, switch the routing strategy to `roundrobin` for even

distribution. Alternatively, use `kvaware` for cache-aware distribution that accounts for the actual state of each prefiller.

Inference Gateway troubleshooting guide

Overview: The HyperPod Inference Gateway routes traffic through three layers: the Body-Based Router (BBR), the gateway with `HTTPRoute`, and the Endpoint Picker (EPP). Misconfiguration at any layer can result in failed requests, traffic reaching the wrong model, or uneven load across model-serving pods. This section covers issues with the gateway, BBR, the gateway and `HTTPRoute`, `InferencePool`, and EPP, and any issues that arise from them.

Diagnose gateway state

Use the following commands to inspect the gateway and the resources it manages.

List every `InferenceGatewayConfig` resource across namespaces:

```
kubectl get inferencegatewayconfig -A
```

Show detailed status, per-scheduler rollout state, and condition messages for a specific gateway:

```
kubectl describe inferencegatewayconfig <name> -n <namespace>
```

Check the gateway controller and Body-Based Router pods:

```
kubectl get pods -n hyperpod-inference-system
```

Check the downstream routing resources generated by the controller:

```
kubectl get httproute,inferencepool,securitypolicy -A
```

Inspect `status.conditions` and each scheduler's `rolloutState` (`Pending`, `Progressing`, `Available`, or `Degraded`). Actionable failure reasons are on the corresponding condition message.

Add-on install issues

Problem: Gateway resources are missing, or the `GatewayClass` is not accepted after installing the HyperPod Inference Amazon EKS add-on.

Symptoms and resolution: `kubectl get gatewayclass inference-gateway` returns `NotFound`, or the resource shows `ACCEPTED=False`. This indicates that the add-on is not installed or that the installation did not complete. Reinstall or update the add-on:

```
aws eks update-addon --cluster-name $CLUSTER --region $REGION \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --resolve-conflicts OVERWRITE
```

Then confirm the gateway controller is running:

```
kubectl rollout status deploy/inference-gateway-controller \
  -n hyperpod-inference-system --timeout=150s
```

InferenceGatewayConfig not becoming Ready

Problem: An `InferenceGatewayConfig` is created, but its `status.conditions` show `Accepted=False` or `Ready=False`, or the `kubectl apply` is rejected outright by validation.

Symptoms and resolution:

- **`kubectl apply` fails with `bbr must be enabled when more than one scheduler is defined`.** The Body-Based Router is required whenever more than one scheduler is defined. Set `spec.bbr.enabled` to `true`.
- **`kubectl apply` fails with `modelName must be unique across schedulers`.** Two schedulers declare the same `modelName`. Rename one so that every scheduler has a distinct `modelName`.
- **`Accepted=False`, `Reason=InvalidLoraAdapters`.** A LoRA adapter name declared under `spec.schedulers[].loraAdapters` is a duplicate across schedulers, or collides with a scheduler's `modelName`. Inspect the condition message for the offending name:

  ```
  kubectl describe inferencegatewayconfig <name> -n <namespace>
  ```

- **`Accepted=False`, `Reason=ResourceNamingViolation`.** The concatenated name `<config-name>-<scheduler-name>` exceeds the Kubernetes 63-character label limit. Shorten the config or scheduler name.
- **`Ready=False`, `Reason=GatewayNotProgrammed`.** The gateway has not yet provisioned the load balancer. Inspect the parent Gateway:

  ```
  kubectl get gateway -n hyperpod-inference-system
  ```

```
kubectl describe gateway <name> -n hyperpod-inference-system
```

- **`AdmissionBlocked=True`, `Reason=WebhookDenied`.** A cluster admission webhook is rejecting the gateway pod. The condition message names the offending webhook. Remove or correct the webhook, then restart the gateway Deployment so that the pod is recreated immediately. The Deployment name is generated, so look it up first:

  ```
  kubectl -n hyperpod-inference-system get deploy \
    -l gateway.envoyproxy.io/owning-gateway-name=<gateway-name>
  ```

  Then restart it:

  ```
  kubectl -n hyperpod-inference-system rollout restart deploy/<gateway-deployment>
  ```

Per-scheduler failures

Problem: A specific scheduler's condition (`BackendsReady`, `LoraSupported`, or `PoolReady`) indicates that the scheduler is not fully ready.

Symptoms and resolution:

- **`BackendsReady=False`, `Reason=NoModelPods` or `Reason=NoReadyModelPods`.** No pods match `spec.schedulers[].modelSelector`, or matching pods are not yet Ready. Compare labels on the model-serving pods against the scheduler's selector:

  ```
  kubectl get pods -n <namespace> --show-labels
  ```

  Deploy the model-serving pods and wait for them to become Ready before applying the `InferenceGatewayConfig`.
- **`BackendsReady=False`, `Reason=InvalidModelSelector`.** The `matchLabels` or `matchExpressions` under `modelSelector` is malformed. Correct the selector in the config.
- **`LoraSupported=False`, `Reason=ModelServerLoraDisabled`.** The model server backing this scheduler was not started with LoRA support enabled. Enable the equivalent flag on the model server (for example, `--enable-lora` for vLLM) and restart the model pods.
- **`PoolReady=False`, `Reason=NotFound` or `Reason=NotAccepted`.** The `InferencePool` or its HTTPRoute has not yet been reconciled or accepted by the gateway. Inspect both:

```
kubectl get inferencepool,httproute -n <namespace>
```

If either is still missing several minutes after the config was applied, describe the parent Gateway to check for admission errors:

```
kubectl describe gateway -n hyperpod-inference-system
```

Scheduler rolloutState is Degraded

Problem: The Endpoint Picker Deployment for a scheduler is stuck and does not become Available.

Symptoms and resolution: The `EPPReady` condition on the scheduler carries the actionable reason. Common causes include:

- The container image cannot be pulled.
- Pods are crash-looping.
- The container has a configuration error, such as an invalid environment variable, volume mount, or secret reference.
- The Deployment exceeded its progress deadline.

Use the following commands to identify the failing scheduler and inspect its Deployment:

```
# List the schedulers reporting Degraded
kubectl get inferencegatewayconfig <name> -n <namespace> \
  -o jsonpath='{range .status.schedulers[?(@.rolloutState=="Degraded")]}{.name}{"\n"}
{end}'

# Describe the scheduler's Endpoint Picker Deployment for pod events and container
 errors
kubectl describe deploy -n <namespace> \
  -l inference.sagemaker.aws.amazon.com/scheduler=<scheduler-name>
```

Stale endpoint after a model pod restart

Problem: After a model pod is deleted and a replacement pod becomes Ready, the Endpoint Picker continues to route to the deleted pod's IP address. Requests return HTTP 503 or connection refused, and the condition does not recover on its own.

Resolution: Add a readiness probe to the model pod so that Kubernetes marks the pod NotReady before its IP is removed from the pool, and only advertises the replacement pod once it is fully serving traffic. Set `port` to the scheduler's `targetPort` and `path` to your model server's health endpoint:

```
readinessProbe:
  httpGet:
    path: /health
    port: 8000
```

Workaround: If you cannot redeploy the model pod immediately, restart the scheduler's Endpoint Picker to force it to rebuild its endpoint list from the current pod set:

```
kubectl rollout restart deploy -n <namespace> \
  -l inference.sagemaker.aws.amazon.com/scheduler=<scheduler-name>
```

JWT authentication returns 401 or 403

Problem: `spec.auth.jwt` is configured and requests are rejected before reaching a model, or the gateway never becomes Ready after JWT authentication is enabled.

Symptoms and resolution:

- **HTTP 401.** The token is missing, expired, malformed, or its `iss` claim does not match the configured provider. Confirm the client sends an `Authorization: Bearer <token>` header, and decode the JWT to compare its `iss` claim against `spec.auth.jwt.provider.issuer`.
- **HTTP 403.** Signature validation failed, or the token's `aud` or `requiredClaims` do not match the provider configuration. Inspect the provider configuration and confirm the token's `aud` and every entry in `requiredClaims` match:

  ```
  kubectl get inferencegatewayconfig <name> -n <namespace> \
    -o jsonpath='{.spec.auth.jwt.provider}'
  ```

- **Gateway never becomes Ready with JWT enabled.** A generated `SecurityPolicy` is not Accepted by the gateway. Inspect the SecurityPolicy resources for the failure reason:

  ```
  kubectl get securitypolicy -A
  kubectl describe securitypolicy <name> -n <namespace>
  ```

A common cause is that `spec.auth.jwt.provider.remoteJWKS.uri` is unreachable from the gateway. Confirm the URI resolves and returns a valid JWKS document.

Metrics missing from dashboards

Problem: Endpoint Picker or Body-Based Router metrics do not appear in your monitoring dashboard.

Symptoms and resolution: Metrics collection is enabled by default, so the OpenTelemetry Collector sidecar is normally present. Confirm whether the sidecar is running on both pod types, and whether metrics were explicitly disabled.

Check the sidecar on Body-Based Router pods:

```
kubectl -n hyperpod-inference-system get pods \
  -o jsonpath='{.items[*].spec.containers[*].name}' | tr ' ' '\n' | grep otel
```

Check the sidecar on Endpoint Picker pods:

```
kubectl -n <namespace> get pods \
  -o jsonpath='{.items[*].spec.containers[*].name}' | tr ' ' '\n' | grep otel
```

Check whether metrics were explicitly disabled:

```
kubectl get inferencegatewayconfig <name> -n <namespace> \
  -o jsonpath='{.spec.observability.metrics.enabled}'
```

Empty output from the last command means the field is not set, and metrics are enabled. Only an explicit `false` disables the sidecar. If the value is `false`, set it to `true` or remove the field, and the controller injects the sidecar on the next reconciliation.

Request failures

Problem: The gateway is Ready, but inference requests fail.

Symptoms and resolution:

- **HTTP 404 for a known model.** The `model` value in the request body does not exactly match any scheduler's `modelName`, or the requested model is served through a LoRA adapter that

is not declared under `spec.schedulers[].loraAdapters`. If no scheduler matches the requested model and `spec.bbr.defaultBackend` is not set, the gateway returns 404. Verify the configured model names and adapter names:

```
kubectl get inferencegatewayconfig <name> -n <namespace> \
  -o jsonpath='{.spec.schedulers[*].modelName}'

kubectl get inferencegatewayconfig <name> -n <namespace> \
  -o jsonpath='{.spec.schedulers[*].loraAdapters}'
```

- **Requests hang and then time out.** Model-serving pods are still loading model weights, or the `InferencePool` has no Ready endpoints. Wait for the model pods to become Ready before invoking the gateway endpoint. Use the scheduler's `modelSelector` labels from your `InferenceGatewayConfig` as the selector:

```
kubectl get pods -n <namespace> -l <key>=<value>
kubectl logs <pod> -n <namespace>
```

Debugging endpoint selection

Problem: Traffic skews to a small number of model pods, or a LoRA request is routed to a pod that does not host the adapter.

Resolution: Temporarily raise the Endpoint Picker's log verbosity to inspect its scoring decisions. Set `logLevel` on the scheduler:

```
spec:
  schedulers:
    - name: <scheduler-name>
      logLevel: 4
```

Log level meanings:

- 1 - Request lifecycle events.
- 2 - Default. Warnings and admission rejections.
- 3 - Selected endpoint and per-scorer summaries.
- 4 - Per-endpoint, per-scorer scores and weighted totals.
- 5 - Protocol-level trace (verbose).

Inspect the Endpoint Picker logs:

```
kubectl logs -n <namespace> -l app=<scheduler-name>-epp -c epp --tail=200 -f
```

Return `logLevel` to its default when the investigation is complete to avoid excess log volume.

Lifecycle and cleanup

Problem: Uninstalling or upgrading the HyperPod Inference Amazon EKS add-on leaves orphaned resources in the cluster, or blocks a subsequent install.

Resolution: Always delete every `InferenceGatewayConfig` resource before uninstalling or upgrading the add-on. Uninstalling the add-on while an `InferenceGatewayConfig` is still present removes the controller that owns the resource's finalizers, which leaves those resources stuck in `Terminating`.

```
kubectl delete inferencegatewayconfig --all -A
kubectl get inferencegatewayconfig -A
```

Confirm the second command returns no rows before continuing with the add-on operation.

After reinstalling the add-on, list the resources in the gateway namespace and remove anything that no longer maps to a live `InferenceGatewayConfig`:

```
kubectl get deploy,svc,httproute,inferencepool,gateway,configmap \
  -n hyperpod-inference-system
```

ACM certificates issued by the controller are not deleted by an add-on uninstall. To remove them, filter ACM certificates in the Amazon Resource Groups Tagging API by the tag `CreatedBy=HyperPodInference` and delete the certificates you no longer need.

Collect logs

Use the following commands to retrieve logs from each gateway component:

```
# Gateway controller
kubectl logs -n hyperpod-inference-system deploy/inference-gateway-controller

# Body-Based Router (deployment name is <gateway-name>-bbr)
kubectl logs -n hyperpod-inference-system deploy/<gateway-name>-bbr -c bbr

# Endpoint Picker for a specific scheduler
```

```
kubectl logs -n <namespace> -l app=<scheduler-name>-epp -c epp
```

Model weights caching and image caching

When you scale out an inference deployment, each new pod must pull the inference server container image from a registry. It must also download model weights from remote storage (Amazon S3 or Amazon FSx) before it can serve traffic. For large language models, downloading model weights and pulling container images contribute most to cold start latency.

To eliminate these bottlenecks during scale-out, configure one or both of the following host-local caching mechanisms in Amazon SageMaker HyperPod Inference:

Model weights caching (`weightsCache`)

Pre-populates model weight files on host-local NVMe storage on each eligible node. Inference pods on the same node load weights from local storage instead of downloading them from the remote model source, eliminating redundant downloads across pods.

Image caching (`imageCache`)

Pre-pulls the inference server container image onto target nodes so that new pods start without waiting for a cold image pull.

You configure both caching mechanisms through the `modelCacheConfig` field on your `InferenceEndpointConfig` or `JumpStartModel` deployment.

You can enable weights caching and image caching independently or together. Both features work with all Amazon SageMaker HyperPod Inference model sources, including Amazon SageMaker JumpStart deployments (both open-weights and gated models) and custom models from Amazon S3 or Amazon FSx.

Prerequisites

Before you enable caching, verify the following:

Instance type with local NVMe storage

Model weights caching stores weights on host-local NVMe storage (`/opt/dlami/nvme` by default). Your instance type must provide local NVMe storage at the configured `hostPath`.

Sufficient NVMe capacity

Ensure the node has enough local storage for your model. Each deployment uses its own isolated cache directory, so multiple cached deployments on the same node each consume their own storage.

Inference operator

Your cluster must have a version of the HyperPod Inference operator that supports model caching. If the `modelCacheConfig` field is not recognized, update the inference operator add-on to the latest version.

Important

If your instance type does not have local NVMe storage at the configured `hostPath`, model weights caching does not warm the cache and inference pods fall back to downloading weights from the remote model source. Verify that your instance type provides local NVMe storage before enabling this feature.

Configure model weights caching and image caching

Add a `modelCacheConfig` block to the `spec` of your `InferenceEndpointConfig` or `JumpStartModel` resource. The following example enables both model weights caching and image caching.

```
spec:
  # ... model source, worker, and TLS configuration ...
  modelCacheConfig:
    weightsCache:
      enabled: true
      hostPath: /opt/dlami/nvme
    imageCache:
      enabled: true
```

The `modelCacheConfig` field supports the following sub-fields.

Field	Default	Description
`weightsCache.enabled`	`false`	Whether host-local model weights caching is enabled. When `true`, the operator pre-populates model weights on host-local storage and mounts them into inference pods.
`weightsCache.hostPath`	`/opt/dlami/nvme`	The host path where cached model weights are stored. Must be a non-empty absolute path of at most 255 characters.
`imageCache.enabled`	`false`	Whether container image caching is enabled. When `true`, the operator pre-pulls the inference server container image onto target nodes.

How model weights caching works

When `weightsCache.enabled` is `true`, the operator downloads model weights from the remote model source (Amazon S3 or Amazon FSx) to host-local NVMe storage on each eligible node before inference pods start serving traffic. Inference pods mount the cached weights read-only and load the model from local storage instead of downloading it from the remote source repeatedly.

The operator populates the cache on nodes that match the scheduling constraints of the inference deployment, and labels each node when its cache is warm. The inference deployment uses *preferred* node affinity on this label, so pods are scheduled onto warm nodes when available but can still schedule elsewhere.

Isolation

Each deployment uses an isolated, per-deployment cache directory under the configured `hostPath`, so multiple model deployments on the same node do not interfere with each other.

Cache miss fallback

If a pod is scheduled on a node where the cache is not yet available, the deployment falls back to loading model weights directly from the remote model source, so deployments remain functional even without a warm cache.

Node replacement

If a node is replaced (for example, after a failure), the operator must warm the cache on the new node again before pods are preferentially scheduled to it. Existing warm nodes continue serving traffic in the meantime.

Cleanup on delete

When you delete the deployment, the operator removes the cached weight files from the nodes it populated.

How image caching works

When `imageCache.enabled` is `true`, the operator pre-pulls the inference server container image onto target nodes. Because the image is already present on the node, new inference pods avoid the cold image pull that would otherwise delay pod startup. This is especially beneficial for large inference server images and for deployments that scale out frequently.

Image caching is independent of model weights caching. You can enable it on its own, or combine it with weights caching to reduce both image-pull and weight-download time during scale-out.

Verify that caching is working

Use the following checks to confirm that caching is active for your deployment.

Check node labels for a warm cache

When a node's cache is warm, the operator applies a cache-ready label to it. Model weights caching uses a label with the prefix `inference.sagemaker.aws.amazon.com/weights-cache-ready.`, and image caching uses the prefix `inference.sagemaker.aws.amazon.com/image-cache-ready.`, each suffixed with the cache configuration's UID.

```
kubectl get nodes --show-labels | grep "cache-ready"
```

No output means no nodes have warmed the cache yet.

Check pod events for the cache mount

Inspect an inference pod and confirm it mounts the host-local cache path read-only. If the hostPath volume is absent, the pod is loading weights from remote storage.

```
kubectl describe pod inference-pod-name -n namespace
```

Check operator logs

Review the inference operator logs for cache warm-up activity or errors.

```
kubectl logs -n hyperpod-inference-system deployment/hyperpod-inference-controller-
manager | grep -i "cache"
```

Troubleshooting

Symptom	Possible cause	Resolution
Pods start slowly even though caching is enabled.	The NVMe path does not exist on the instance type.	Verify that your instance type has local NVMe storage and that `hostPath` matches the actual mount point.
The cache never warms.	Insufficient disk space at the host path.	Check available capacity at `hostPath`. Large models can require substantial local storage.
No nodes are labeled as cache-ready.	The cache download failed, or the remote source is unreachable.	Check the operator logs for download errors and verify network access to Amazon S3 or Amazon FSx.
Multiple deployments cause disk pressure on a node.	Cached deployments share the same node NVMe storage.	Use separate instance groups or reduce the number of concurrent cached deployments per node.

Considerations

- Model weights caching requires instance types with local NVMe storage. EBS-only instances are not supported.
- The maximum cacheable model size is bounded by the available NVMe capacity on the instance type.
- Cache warm-up time depends on model size and network throughput to the remote model source.

KV caching and intelligent routing

Amazon SageMaker HyperPod Inference provides managed tiered key-value (KV) caching and intelligent routing to optimize inference performance for large language model (LLM) workloads. KV caching saves precomputed key-value vectors after processing previous tokens, eliminating redundant recalculations. Through a two-tier caching architecture, you can configure an L1 cache that uses CPU memory for low-latency local reuse, and an L2 cache that leverages Redis or managed tiered storage to enable scalable, node-level cache sharing.

Intelligent routing analyzes incoming requests and directs them to the inference instance most likely to have relevant cached key-value pairs. The system examines the request and routes it based on one of the following routing strategies:

- `prefixaware` — Subsequent requests with the same prompt prefix are routed to the same instance.
- `kvaware` — Incoming requests are routed to the instance with the highest KV cache hit rate.
- `session` — Requests from the same user session are routed to the same instance.
- `roundrobin` — Distributes requests evenly without considering the state of the KV cache.

Intelligent routing works with all Amazon SageMaker HyperPod Inference deployment methods, including Amazon SageMaker JumpStart deployments (both console and kubectl), NVMe local storage deployments, and deployments from Amazon S3, Amazon FSx, or Hugging Face Hub. You can enable caching and routing regardless of which deployment method you use to serve your model.

> **Note**
>
> KV caching and intelligent routing currently support only vLLM-based inference containers.

Configure KV caching and intelligent routing

1. Enable KV caching by setting `enableL1Cache` and `enableL2Cache` to `true`. Then, configure `l2CacheSpec` by setting `l2CacheBackend` to either `redis` or `tieredstorage`. If you choose `redis`, update `l2CacheLocalUrl` with the Redis cluster URL.

```
kvCacheSpec:
  enableL1Cache: true
```

```
    enableL2Cache: true
    l2CacheSpec:
      l2CacheBackend: <redis | tieredstorage>
      l2CacheLocalUrl: <Redis cluster URL if l2CacheBackend is redis >
```

> **Note**
>
> If the Redis cluster is not within the same Amazon VPC as the HyperPod cluster, encryption for the data in transit is not guaranteed.

> **Note**
>
> You do not need `l2CacheLocalUrl` if `tieredstorage` is selected.

2. Enable intelligent routing by setting `enabled` to `true` under `intelligentRoutingSpec`. You can specify which routing strategy to use under `routingStrategy`. If no routing strategy is specified, it defaults to `prefixaware`.

```
intelligentRoutingSpec:
    enabled: true
    routingStrategy: <routing strategy to use>
```

3. Enable router metrics and caching metrics by setting `enabled` to `true` under `metrics`. The `port` value needs to be the same as the `containerPort` value under `modelInvocationPort`.

```
metrics:
    enabled: true
    modelMetrics:
      port: <port value>
    ...
    modelInvocationPort:
      containerPort: <port value>
```

KV-aware routing compatibility

The compatibility matrix and version constraints in this section apply *only* to the `kvaware` routing strategy. The `kvaware` strategy directs incoming requests to the inference instance with the

highest KV cache hit rate and currently supports only vLLM-based images with the `/completions` API as the invocation endpoint.

> **Note**
>
> If you use `kvaware` routing, you must set `invocationEndpoint` to `/completions` in your deployment manifest. The `/v1/chat/completions` endpoint is not supported with `kvaware` routing. Other routing strategies (`prefixaware`, `session`, `roundrobin`) work with any invocation endpoint.

Supported images:

- vLLM Image: hub.docker.com/r/vllm/vllm-openai
- LMCache Image: hub.docker.com/r/lmcache/vllm-openai
- Amazon Deep Learning Container: gallery.ecr.aws/deep-learning-containers/vllm

Inference Operator Version	Amazon EKS Add-on Version	LMCache Image Version	vLLM Image Version
>= v3.1.3	>= v1.2.1-eksbuild.1	>= v0.4.3	>= v0.19.1
< v3.1.3	< v1.2.1-eksbuild.1	v0.3.9post2	v0.11.1

> **Note**
>
> We recommend using inference operator version v3.1.3 or above with the corresponding LMCache and vLLM versions shown in the support matrix. Newer LMCache versions support tensor parallelism, improved failure handling, and cache worker registration, which provide better robustness for KV-aware routing.

Validating KV cache aware routing

After deploying a model with KV-aware routing enabled, use the following steps to verify that routing is working correctly.

Check worker registration

Verify that workers have registered with the router by checking the router logs:

```
kubectl logs -n hyperpod-inference-system <router-pod> | grep -i "register"
```

A healthy registration shows:

```
INFO: Worker registered: lmcacheengineconfig_<hash>
```

Check cache hits in router logs

Verify that the router is using KV-aware routing to direct requests:

```
kubectl logs -n hyperpod-inference-system <router-pod> | grep -i "kvaware\|Matched
 instance\|Lookup"
```

When KV-aware routing is working correctly:

```
INFO: Routing request to lmcacheengineconfig_<hash> found by kvaware router
```

When KV-aware routing is not working (falls back to round-robin):

```
DEBUG: Matched instance url None
```

Check LMCache initialization in worker logs

Verify that LMCache initialized successfully on the worker pods:

```
kubectl logs -n <namespace> <worker-pod> | grep -i "LMCache"
```

A healthy initialization shows:

```
LMCache INFO: LMCacheManager initialized successfully
```

If LMCache failed to initialize, you will see:

```
LMCache ERROR: Failed to initialize LMCacheManager components: . System will operate in
 degraded mode (recompute).
```

Verify with Grafana metrics

With metrics enabled (`metrics.enabled: true`), the following metrics from the vLLM worker `/metrics` endpoint confirm cache hits. These metrics should show high values when KV-aware routing is working correctly:

Metric	Description
`vllm:prefix_cache_hits_total / vllm:prefix_cache_queries_total`	GPU prefix cache hit rate (computed as a ratio)
`lmcache:num_vllm_hit_tokens_total`	Number of tokens served from LMCache
`lmcache:num_lookup_hits_total / lmcache:num_lookup_tokens_total`	LMCache lookup hit rate (computed as a ratio)
`lmcache:request_cache_hit_rate`	Per-request cache hit rate (histogram)

Inference Gateway for Amazon SageMaker HyperPod Inference

The Amazon SageMaker HyperPod Inference Gateway is a Kubernetes-native, large language model (LLM)-aware routing and orchestration layer for HyperPod clusters on Amazon EKS. It inspects inference requests, reads the model name from each request, and selects a model-serving pod based on GPU load, so that traffic for multiple models is routed efficiently through a single gateway endpoint.

The gateway routes each request through three layers. The Body-Based Router (BBR), a shared component, reads the `model` field from the request body, resolves a LoRA adapter name to its base model, and sets the `X-Gateway-Model-Name` and `X-Gateway-Base-Model-Name` headers. The gateway then matches those headers to an HTTPRoute and forwards the request to the `InferencePool` for the requested model. Within that pool, the Endpoint Picker (EPP/scheduler) chooses a model-serving pod by scoring candidates on model-server metrics such as queue depth and KV cache utilization, together with prefix-cache and LoRA adapter affinity. Each entry that

you define under `spec.schedulers` runs its own Endpoint Picker, so this topic uses the terms Endpoint Picker, EPP, and scheduler interchangeably.

The Inference Gateway builds on the HyperPod Inference Operator instead of replacing it. While the operator continues to orchestrate model deployment, the gateway introduces an LLM-aware routing layer in front of the model-serving pods. The gateway does not depend on a specific model server or orchestration layer, and is delivered through the HyperPod Inference Amazon EKS add-on.

You define a gateway with the `InferenceGatewayConfig` custom resource. A single `InferenceGatewayConfig` describes one gateway: the shared Body-Based Router, TLS termination, request authentication, and one scheduler for each model the gateway serves. For the full schema, see the section called "InferenceGatewayConfig CRD reference".

> **Important**
>
> Endpoints created by the Inference Gateway have no request-level authentication or authorization by default. Unless you configure `spec.auth.jwt` on the `InferenceGatewayConfig`, the gateway accepts any request that reaches it; access is restricted only by your VPC and network controls. We strongly recommend enabling JWT authentication on every gateway. To configure authentication, see the section called "Prerequisites and deployment" and `spec.auth` under the section called "spec fields".

Prerequisites and deployment

The Inference Gateway is delivered as part of the HyperPod Inference Amazon EKS add-on. Installing the add-on makes the gateway available, so no separate installation is required. You then turn on gateway routing for a model through the `spec.inferenceGateway.enabled` field on the model's `InferenceEndpointConfig` resource. For the version in which a capability was introduced, see the section called "HyperPod Inference release notes".

Before you route traffic through the gateway, verify the following:

Deployed model-serving pods

Each scheduler routes to model-serving pods selected by a label selector. Deploy your models with the HyperPod Inference Operator, and note the labels applied to their pods so that you can reference them in the gateway configuration. To list the labels on your model pods, run the following command:

```
kubectl get pods -n NAMESPACE --show-labels
```

Model server versions

The Inference Gateway requires vLLM v0.9.2 or later and SGLang v0.3.5.post1 or later. On earlier vLLM versions, the KV cache metric is published under a different name from the one the gateway reads. Requests are still routed using the remaining signals, but KV cache utilization is ignored and no error is reported. Earlier SGLang versions do not support the `--enable-metrics` flag and the container fails to start. Start SGLang with this flag so the gateway can read the metrics it needs for routing decisions.

Add-on version

The Inference Gateway is available starting with version `v2.0.0-eksbuild.2` of the Amazon SageMaker HyperPod Inference add-on. Install or update to the latest available version of the add-on. If your cluster does not recognize the `InferenceGatewayConfig` resource, the add-on is running an earlier version that does not include the gateway.

Cluster dependencies

- cert-manager must be installed on the cluster for the auto-issue TLS path, which the gateway uses when `spec.tls` is set without an `acmArn`.
- The Amazon Load Balancer Controller must be installed for the Application Load Balancer endpoint type.
- The gateway uses the `hyperpod-inference-system` namespace.

TLS certificate

To terminate HTTPS at the gateway, either provide an existing ACM certificate ARN or let the gateway auto-issue a certificate. Auto-issue uses cert-manager and imports the certificate into ACM. This flow requires the operator execution role to have the `acm:ImportCertificate`, `acm:AddTagsToCertificate`, `acm:DescribeCertificate`, and `acm:DeleteCertificate` permissions through IRSA.

Request authentication (recommended)

We strongly recommend enabling JWT authentication on every gateway by setting `spec.auth.jwt` on the `InferenceGatewayConfig`. When `spec.auth` is omitted, the gateway has no request-level authentication and access is restricted only by your VPC and network controls. To enable JWT authentication, have the following ready before you author the `InferenceGatewayConfig`: an OIDC issuer URL, the HTTPS JWKS endpoint that publishes

the issuer's signing keys, and the audience values (or required claims) that tokens for this gateway must carry. See `spec.auth` under the section called “spec fields” for the full schema.

Set up the certificate issuer IAM role

When the gateway auto-issues a TLS certificate, cert-manager generates the certificate in the cluster and the gateway controller imports it into ACM. Because the import is an Amazon API call, the controller needs Amazon credentials. Provide them by creating an IAM role that the `inference-gateway-controller` service account in the `hyperpod-inference-system` namespace assumes through IAM roles for service accounts (IRSA).

> **Important**
>
> TLS auto-issue is enabled by default, and the gateway controller reads this role when it starts. Create the role before you install the add-on.

Set the following environment variables and retrieve the OIDC issuer for your cluster.

```
export CLUSTER=EKS_CLUSTER_NAME
export REGION=REGION
export ACCOUNT=AWS_ACCOUNT_ID
export ROLE_NAME=CERT_ISSUER_ROLE_NAME

export OIDC_ID=$(aws eks describe-cluster --name $CLUSTER --region $REGION \
  --query 'cluster.identity.oidc.issuer' --output text | sed 's|https://||')
```

Create a trust policy that allows the gateway controller service account to assume the role.

```
cat > trust-policy.json <<EOF
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Principal": {
      "Federated": "arn:aws:iam::${ACCOUNT}:oidc-provider/${OIDC_ID}"
    },
    "Action": "sts:AssumeRoleWithWebIdentity",
    "Condition": {
      "StringEquals": {
```

```
        "${OIDC_ID}:sub": "system:serviceaccount:hyperpod-inference-system:inference-
gateway-controller",
        "${OIDC_ID}:aud": "sts.amazonaws.com"
      }
    }
  }]
}
EOF
```

Create the role and attach the `AmazonSageMakerHyperPodInferenceGatewayAccess` managed policy. The policy grants the ACM permissions that the controller needs to import, tag, describe, and delete the certificates it creates.

```
aws iam create-role --role-name $ROLE_NAME --assume-role-policy-document file://trust-
policy.json
aws iam attach-role-policy --role-name $ROLE_NAME --policy-arn arn:aws:iam::aws:policy/
AmazonSageMakerHyperPodInferenceGatewayAccess
```

Provide this role ARN as `inferenceGateway.serviceAccount.roleArn` when you install the add-on.

> **Note**
>
> If the role already exists from another cluster, verify that its trust policy includes the OIDC provider for this cluster.

Install the add-on

The HyperPod Inference add-on installs both the Inference Operator and the Inference Gateway. Install it with the following command. For `inferenceGateway.serviceAccount.roleArn`, use the certificate issuer role that you created in the preceding section. Replace the remaining placeholder values with the roles and bucket for your account.

```
aws eks create-addon \
  --cluster-name $CLUSTER --region $REGION \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --addon-version v2.0.0-eksbuild.2 \
  --configuration-values '{
    "executionRoleArn": "arn:aws:iam::<ACCOUNT>:role/<EXEC_ROLE>",
    "tlsCertificateS3Bucket": "<TLS_BUCKET>",
```

```
    "inferenceOperator": { "enabled": true },
    "inferenceGateway": {
      "enabled": true,
      "serviceAccount": { "roleArn": "arn:aws:iam::<ACCOUNT>:role/
<CERT_ISSUER_ROLE_NAME>" }
    },
    "keda": { "enabled": true, "auth": { "aws": { "irsa": { "enabled": true, "roleArn":
 "arn:aws:iam::<ACCOUNT>:role/<KEDA_IRSA_ROLE>" } } } },
    "alb": { "enabled": true, "serviceAccount": { "create": true, "roleArn":
 "arn:aws:iam::<ACCOUNT>:role/<ALB_IRSA_ROLE>" } },
    "jumpstartGatedModelDownloadRoleArn": "arn:aws:iam::<ACCOUNT>:role/
<JUMPSTART_ROLE>"
  }'
```

If the add-on is already installed on the cluster, replace `create-addon` with `update-addon` and add `--resolve-conflicts OVERWRITE`. The rest of the command is unchanged. `OVERWRITE` applies the configuration values in the command over the existing add-on configuration.

Confirm that the gateway controller is running and that the gateway resources are registered.

```
kubectl rollout status deploy/inference-gateway-controller \
  -n hyperpod-inference-system --timeout=150s

kubectl get crd inferencegatewayconfigs.inference.sagemaker.aws.amazon.com

kubectl get gatewayclass inference-gateway
```

Confirm that the add-on itself is active and reports no health issues.

```
aws eks describe-addon \
  --cluster-name $CLUSTER --region $REGION \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --query 'addon.{version:addonVersion,status:status,health:health.issues}'
```

Integration with the HyperPod Inference Operator

The HyperPod Inference Operator and the Inference Gateway have distinct responsibilities. The operator owns model deployment, orchestration, and the wiring that attaches a model to the gateway. The gateway owns request routing and generates the routing resources for each scheduler. For more information about deploying models with the operator, see the section called “Deploy models on HyperPod”.

HyperPod Inference Operator

Reconciles the model custom resources `InferenceEndpointConfig` and `JumpStartModel` (group `inference.sagemaker.aws.amazon.com`, version `v1`). The operator creates the model Deployment and Service, the Application Load Balancer, KEDA autoscaling, the cert-manager certificate, and the SageMaker AI endpoint registration. When the gateway is enabled for a model, the operator also wires that model into the gateway.

Inference Gateway

Owns request routing, from the Body-Based Router through the gateway and HTTPRoute to the Endpoint Picker, and generates the downstream routing resources for each scheduler: the `InferencePool`, Endpoint Picker configuration, HTTPRoute, and `EnvoyExtensionPolicy`.

> **Note**
>
> The operator's model custom resources use version `v1`, while the gateway's `InferenceGatewayConfig` resource uses version `v1alpha1`. Both belong to the `inference.sagemaker.aws.amazon.com` group.

You attach a model to the gateway through the operator, on the model's `InferenceEndpointConfig` (or `JumpStartModel`) resource, using the `spec.inferenceGateway` field:

`spec.inferenceGateway.enabled` (Optional, Boolean)

Whether this model is attached to the gateway. Default: `false`.

`spec.inferenceGateway.name` (Optional, String)

The name of the `InferenceGatewayConfig` resource to attach to. Models that share a name and namespace share one gateway. When this field is empty, the operator generates a name of the form `inf-igw-<uuid>`.

The following snippet shows the `inferenceGateway` opt-in on an `InferenceEndpointConfig` resource.

```
apiVersion: inference.sagemaker.aws.amazon.com/v1
```

```
kind: InferenceEndpointConfig
metadata:
  name: my-model
spec:
  # ... model deployment fields ...
  inferenceGateway:
    enabled: true
    name: my-gateway        # Optional. When empty, the operator generates inf-igw-
<uuid>.
```

The operator mirrors the attachment state on the model resource under `status.inferenceGateway`, which reports a `State` of `Pending`, `Ready`, or `Failed`, and the `Name` of the attached `InferenceGatewayConfig`. You cannot set `inferenceGateway.enabled` together with `intelligentRoutingSpec.enabled` on the same model; these fields are mutually exclusive.

When the gateway is enabled for a model, the operator creates or updates a single `InferenceGatewayConfig` resource and merges an entry for the model into its `spec.schedulers` list. The operator sets the scheduler `name`, `modelName`, `targetPort`, and `modelSelector`, and defaults `scheduler` to `llm-d` when it first creates the entry. On later reconciliations, the operator preserves customer-provided values such as `scheduler`, `weights`, and `loraAdapters`. The Body-Based Router is enabled automatically when more than one scheduler is present.

The operator does not delete the `InferenceGatewayConfig` resource or the downstream routing resources. When you disable the gateway for a model or delete the model, the operator removes only that model's scheduler entry. The gateway controller owns cleanup of the routing resources.

You can author an `InferenceGatewayConfig` in two ways, and the two paths coexist on the same resource:

- Enable the gateway per model through the operator, by setting `spec.inferenceGateway.enabled` on the model's `InferenceEndpointConfig`. The operator authors and maintains the scheduler entry for the model.
- Author the `InferenceGatewayConfig` resource directly, as shown in the section called "Examples".

The gateway components and the `InferenceGatewayConfig` CRD must be installed through the HyperPod Inference Amazon EKS add-on before a model resource with the gateway enabled

can be reconciled. For operator add-on installation, see the section called "Installing the Inference Operator with EKS add-on". For deploying the model-serving pods that a scheduler routes to, see the section called "Deploy foundation models and custom fine-tuned models".

> **Note**
>
> Maintaining the health of the SageMaker HyperPod Inference Operator is a shared responsibility between Amazon and the customer. Amazon is responsible for delivering and maintaining the SageMaker HyperPod Inference Operator. Following installation, the customer is responsible for monitoring the operational health of the operator within their cluster.

InferenceGatewayConfig CRD reference

You configure the Inference Gateway with a single `InferenceGatewayConfig` custom resource. The resource is a singleton for a given gateway: it holds the shared Body-Based Router configuration and a list of per-model schedulers. The controller generates the underlying `InferencePool`, Endpoint Picker, HTTPRoute, and `EnvoyExtensionPolicy` resources for each scheduler; you author only the `InferenceGatewayConfig` resource.

InferenceGatewayConfig resource metadata

Property	Value
Kind	`InferenceGatewayConfig`
Group	`inference.sagemaker.aws.amazon.com`
Version	`v1alpha1`
Plural	`inferencegatewayconfigs`
Short name	`igwc`
Scope	Namespaced
Status subresource	`/status`

spec fields

The `spec` field of the `InferenceGatewayConfig` resource contains the shared Body-Based Router configuration, TLS settings, the required list of schedulers, and optional observability and pod-default settings.

`bbr` (Required)

Configuration for the shared Body-Based Router. Contains the following fields:

`bbr.enabled` (Required, Boolean)

Whether the Body-Based Router is enabled. The router must be enabled when more than one scheduler is configured.

`bbr.replicas` (Optional, Integer)

Number of Body-Based Router replicas. Minimum: 1. Default: 2.

`bbr.defaultBackend` (Optional)

The backend that receives requests that the router cannot match to a scheduler. Contains a `name` string and a `port` integer (default: `8000`).

`bbr.maxRequestBodyBytes` (Optional, Integer)

Maximum request body size, in bytes, that the router buffers to read the `model` field. Default and maximum: 268435456 (256 MiB).

`tls`

HTTPS termination configuration for the gateway. Contains an `acmArn` field that references an existing ACM certificate. If `tls` is set with an empty `acmArn`, the gateway auto-issues a certificate with cert-manager and imports it into ACM.

`auth` (Optional, Recommended)

Request authentication configuration. We strongly recommend enabling JWT bearer-token authentication on every gateway; when omitted, the gateway has no request-level authentication. Load balancer health check routes remain unauthenticated so that health probes can succeed without a token.

Contains `auth.jwt.provider` with the following fields:

`name` (Required, String)

Unique name for the provider.

`issuer` (Required, String)

OIDC issuer URL (`https://...`). The gateway validates the token's `iss` claim against this value.

`remoteJWKS.uri` (Required, String)

HTTPS JWKS endpoint used to verify the JWT signature.

`audiences` (Optional, List)

Accepted `aud` claim values (up to 8). At least one of `audiences` or `requiredClaims` must be set.

`requiredClaims` (Optional, List)

Claim-based authorization (up to 16 entries). Each entry has `name`, `valueType` (`String` or `StringArray`), and `values` (1–128 entries, each 1–1024 characters). When set, the gateway denies requests by default and admits only tokens whose claim values match.

`observability` (Optional)

Observability configuration. Contains `metrics.enabled`, which controls the OpenTelemetry metrics sidecar. Metrics are enabled by default.

`podDefaults` (Optional)

Default pod settings applied to both the Body-Based Router and Endpoint Picker pods. Supports `resources`, `nodeSelector`, `tolerations`, `affinity`, `labels`, `annotations`, `env`, and `envFrom`.

`schedulers` (Required, List)

A list of per-model scheduler configurations, keyed by `name`. At least one scheduler is required, and you can define up to 100. Each entry is a `SchedulerSpec`, described in the section called "SchedulerSpec fields".

SchedulerSpec fields

Each entry in `spec.schedulers` configures routing and endpoint selection for one model. A scheduler names the generated `InferencePool`, Endpoint Picker, HTTPRoute, and `EnvoyExtensionPolicy` resources.

`name` (Required, String)

The scheduler name. Used to name the generated `InferencePool`, Endpoint Picker, HTTPRoute, and `EnvoyExtensionPolicy` resources. Maximum length: 63 characters.

`modelSelector` (Required)

A Kubernetes label selector that selects the model-serving pods this scheduler routes to.

`modelName` (Required, String)

The model name matched against the `model` field in the request body and used as the HTTPRoute header match. Must be unique across schedulers. Maximum length: 253 characters.

`targetPort` (Optional, Integer)

The port on the model-serving pods that receives forwarded traffic. Range: 1–65535. Default: `8000`.

`appProtocol` (Optional, String)

The application protocol used to reach the model-serving pods. Valid values: `http`, `kubernetes.io/h2c`. Default: `http`.

`scheduler` (Optional, String)

The scheduler type, which selects the Endpoint Picker image. Valid values: `llm-d`, `epp`. Default: `llm-d`.

`engineType` (Optional, String)

The inference engine running in the model-serving pods. This value selects the set of Prometheus metric names that the Endpoint Picker scrapes. Valid values: `vllm`, `sglang`. Default: `vllm`.

`weights` (Optional)

Scoring weights the Endpoint Picker uses to rank candidate pods. All weights are non-negative integers. Mutually exclusive with `configMapRef`. Supported weights:

`queue`

Weight for pending request queue depth. Default: 2.

`kvCache`

Weight for KV cache utilization. Default: 2.

`prefix`

Weight for prefix-cache affinity. Default: 3.

`lru`

Weight for least-recently-used scoring. Valid only when `scheduler` is `llm-d`.

`loraAffinity`

Weight for LoRA adapter affinity.

`runningRequests`

Weight for the number of running requests on a pod.

`predictedLatency`

Weight for predicted request latency.

`configMapRef` (Optional)

A reference to a ConfigMap that supplies a custom Endpoint Picker configuration, as an alternative to `weights`. Contains a required `name` and a `key` (default: `default-plugins.yaml`). Mutually exclusive with `weights`.

`replicas` (Optional, Integer)

Number of Endpoint Picker replicas for this scheduler. Minimum: 1. Default: 2. When `replicas` is greater than 1, the Endpoint Picker runs in high availability with leader election.

`env` and `envFrom` (Optional)

Environment variables appended to this scheduler's Endpoint Picker container.

`loraAdapters` (Optional, List)

LoRA adapter names served behind this scheduler's model. Maximum: 50 items, each up to 253 characters.

`routeTimeout` (Optional, String)

The HTTPRoute request timeout, as a Gateway API duration (for example, `30s` or `5m`). Set to `0s` to disable the timeout.

`logLevel` (Optional, Integer)

The Endpoint Picker log verbosity. Range: 0–5.

Validation rules

The `InferenceGatewayConfig` resource enforces the following validation rules. A resource that violates any of these rules is rejected.

- The Body-Based Router must be enabled (`bbr.enabled: true`) when more than one scheduler is configured.
- `modelName` must be unique across all schedulers.
- Within a scheduler, `weights` and `configMapRef` are mutually exclusive.
- The `weights.lru` weight is valid only when the scheduler's `scheduler` type is `llm-d`.

status fields

The controller reports the observed state of the gateway in the `status` subresource.

`conditions`

Standard Kubernetes conditions describing the overall state of the gateway configuration.

`schedulers`

Per-scheduler status. Each entry contains:

`name`

The scheduler name.

`conditions`

Conditions describing the state of this scheduler.

`currentScheduler`

The scheduler type currently in effect for this entry.

`rolloutState`

The rollout state of the scheduler. One of `Pending`, `Progressing`, `Available`, or `Degraded`.

`observedGeneration`

The generation of the resource most recently reconciled by the controller.

`tls`

TLS status, reported in auto-issue mode only. Contains `acmArn`, `issuedAt`, and `dnsNames`.

Kubernetes RBAC permissions

The Inference Gateway runs as a single controller under the Kubernetes service account `inference-gateway-controller` in the `hyperpod-inference-system` namespace. The Body-Based Router, the per-scheduler Endpoint Pickers, the Gateway controller, and the `InferenceGatewayConfig` reconciler all run under this one controller. Its cluster-scoped permissions are granted by a `ClusterRole` named `sagemaker-inference-gateway-controller-supplement` and a matching `ClusterRoleBinding`. Together they supplement the service account and permissions that the bundled Gateway chart already provides. These permissions are scoped and least-privilege, and the controller does not run as cluster administrator.

The following table lists the controller's cluster-scoped permissions, grouped by purpose. In this table, *full access* means the `create`, `get`, `list`, `watch`, `update`, `patch`, and `delete` verbs.

Inference Gateway controller permissions

API group	Resources	Verbs	Purpose
`inference.sagemaker.aws.amazon.com`	`inferencegatewayconfigs`, including its `status` and `finalizers` subresources	`get`, `list`, `watch`, `update`, and `patch` for `inferencegatewayconfigs`; `get`, `update`, and `patch` for its `status`; `update` for its `finalizers`	Reconcile the `InferenceGatewayConfig` resource, write its status, and manage its finalizer.
`gateway.networking.k8s.io`	`httproutes`, `gateways`, `gatewayclasses`	Full access for `httproutes` and `gateways`; `get`, `list`, `watch`, `create`,	Program request routing through the Gateway API.

API group	Resources	Verbs	Purpose
		and patch for gatewaycl asses	
inference .networki ng.k8s.io	inference pools	Full access	Create the routing backend for each scheduler.
inference .networki ng.x-k8s.io	inference pools , inference objective s ,inference modelrewr ites	get, list, watch	Read routing intent for endpoint selection.
gateway.e nvoyproxy.io	envoyexte nsionpoli cies , envoyprox ies ,httproute filters , clienttra fficpolic ies ,securityp olicies	Full access	Configure the gateway data plane and its telemetry.

API group	Resources	Verbs	Purpose
Core ("")	configmaps, services, serviceaccounts, events, secrets, pods	Full access for configmaps, services, and serviceaccounts; create and patch for events; get, list, and watch for secrets and pods	Manage the generated workloads and read routing and serving state.
apps	deployments	Full access	Manage the Body-Based Router and Endpoint Picker deployments.
rbac.authorization.k8s.io	roles, rolebindings	Full access	Create the per-scheduler Endpoint Picker Role.
discovery.k8s.io, coordination.k8s.io	endpointslices; leases	get, list, and watch for endpointslices; get, list, watch, create, update, and patch for leases	Endpoint discovery and Endpoint Picker leader election.
networking.k8s.io	ingresses, networkpolicies	Full access	Provision the Application Load Balancer path through the Amazon Load Balancer Controller.

API group	Resources	Verbs	Purpose
`cert-manager.io`	`issuers`, `certificates` (with `get`, `list`, and `watch` on core `secrets`)	Full access	Auto-issue a TLS certificate when `spec.tls` is set without an `acmArn`.
`apiextensions.k8s.io`	`customresourcedefinitions`	`create`; and `get`, `update`, `patch`, and `delete` restricted by resource name to the specific Gateway API CRDs the gateway manages	Install the custom resource definitions the gateway depends on.

Note

The `create` verb on `customresourcedefinitions` is not restricted to specific resource names. The controller installs the Gateway API custom resource definitions it depends on by applying them at startup from its own container image, because their combined size exceeds the Amazon EKS add-on payload limit. Kubernetes does not allow the `create` verb to be restricted to named resources, so this permission is necessarily broad. All other operations on custom resource definitions—`get`, `update`, `patch`, and `delete`—are restricted to the specific custom resource definitions the gateway manages. This permission allows defining only those CRD types; it does not grant access to the data of any custom resource.

The controller also creates the following namespaced roles at runtime, depending on your gateway configuration:

- *Body-Based Router*—A namespaced `Role` that grants `get`, `list`, and `watch` on `configmaps`, which the router reads to resolve LoRA adapters. When the router runs across multiple namespaces, this is a `ClusterRole` instead.
- *Endpoint Picker*—A namespaced `Role` that grants read access to `pods`. When an Endpoint Picker runs with more than one replica, the controller also creates a leader-election `Role` for `leases` and `events`. When Prometheus metrics are enabled, the controller creates an optional `ClusterRole` that grants `create` on `tokenreviews` and `subjectaccessreviews` and read access to the `/metrics` endpoint.

> **Note**
>
> When you enable the gateway through the HyperPod Inference Operator, the operator's own controller holds permission to create and update `InferenceGatewayConfig` resources. For how the operator wires a model into the gateway, see the section called "Integration with the HyperPod Inference Operator".

Some of these permissions apply only when the corresponding feature is enabled.

Observability

The Inference Gateway emits Prometheus metrics from every gateway component. Both the Body-Based Router and each Endpoint Picker expose a standard Prometheus `/metrics` endpoint on their pods. Body-Based Router pods run in the `hyperpod-inference-system` namespace; Endpoint Picker pods run in the same namespace as the `InferenceGatewayConfig`. Metrics cover per-model request counters and durations, scheduling latency and per-plugin execution time inside the Endpoint Picker, and aggregated pool metrics such as average KV cache utilization and queue depth. Model-server pod metrics (for example, from vLLM or SGLang) are emitted by the model server itself; the Endpoint Picker scrapes them to score candidate pods.

When `spec.observability.metrics.enabled` is `true` (the default), the gateway controller injects an OpenTelemetry Collector sidecar into every Body-Based Router and Endpoint Picker pod. The sidecar forwards these metrics to the HyperPod inference observability stack, where the built-in Grafana dashboards surface them alongside model-server and cluster metrics. For setup and dashboard details, see Implementing inference observability on HyperPod clusters. Set the field to `false` to skip sidecar injection. For the field reference, see `observability` under the section called "spec fields".

To view the gateway metrics in Amazon Managed Grafana, open the *Inference Dashboards* folder and select the *Inference Gateway* dashboard. The dashboard reports gateway-wide availability, request rate, and end-to-end latency, per-scheduler throughput, latency, and errors for each model, and the rate at which the Body-Based Router resolves model names from request bodies.

Examples

The following examples show common `InferenceGatewayConfig` configurations and how to invoke the gateway.

Minimal multi-model configuration

This example routes to an llm-d scheduler with auto-issued TLS. Because `tls` is set to an empty object, the gateway auto-issues a certificate and imports it into ACM.

```
apiVersion: inference.sagemaker.aws.amazon.com/v1alpha1
kind: InferenceGatewayConfig
metadata:
  name: inference-gateway-demo
  namespace: inference-gateway
spec:
  bbr:
    enabled: true
  tls: {}                       # Auto-issue a certificate via cert-manager and import
 to ACM.
  schedulers:
    - name: llama
      modelName: "meta-llama/Llama-3.2-1B-Instruct"
      modelSelector:
        matchLabels:
          app: vllm-llama
      targetPort: 8000
      scheduler: llm-d
```

SGLang scheduler with explicit weights

This example uses the epp scheduler type with the `sglang` engine and sets explicit Endpoint Picker scoring weights.

```
spec:
  bbr:
    enabled: true
```

```
  schedulers:
    - name: qwen7b
      modelName: "Qwen/Qwen2.5-7B-Instruct"
      modelSelector:
        matchLabels:
          app: sglang-qwen7b
      targetPort: 8000
      scheduler: epp
      engineType: sglang
      logLevel: 4
      weights:
        kvCache: 2
        prefix: 3
        runningRequests: 2
```

LoRA adapter ConfigMap

The Body-Based Router discovers LoRA adapters and their base model from a ConfigMap labeled for BBR management. The router uses this mapping to resolve an adapter name in the request body to its base model.

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: deepseek-adapters
  labels:
    inference.networking.k8s.io/bbr-managed: "true"
data:
  baseModel: deepseek/vllm-deepseek-r1
  adapters: |
    - ski-resorts
    - movie-critique
```

Invoke the gateway

The gateway serves an OpenAI-compatible inference endpoint. This is the runtime invocation contract for sending inference requests through the gateway; it is not an Amazon API operation. Send requests to the gateway endpoint with the `model` field set to the `modelName` of the target scheduler. The Body-Based Router reads this field to route the request.

```
curl https://your-gateway-endpoint/v1/chat/completions \
  -H "Content-Type: application/json" \
```

```
  -d '{
    "model": "meta-llama/Llama-3.1-8B-Instruct",
    "messages": [
      {"role": "user", "content": "Hello"}
    ]
  }'
```

Amazon SageMaker HyperPod Inference release notes

This topic covers release notes that track updates, fixes, and new features for Amazon SageMaker HyperPod Inference. SageMaker HyperPod Inference enables you to deploy and scale machine learning models on your HyperPod clusters with enterprise-grade reliability. For general Amazon SageMaker HyperPod platform releases, updates, and improvements, see the section called "HyperPod release notes".

For information about SageMaker HyperPod Inference capabilities and deployment options, see the section called "Deploy models on HyperPod".

SageMaker HyperPod Inference release notes: HyperPod Inference Amazon EKS v2.1.0-eksbuild.1 and Inference Operator v3.7

Release Date: September 21, 2026

Summary

Amazon SageMaker HyperPod Inference Operator v3.7 adds pod tolerations and `priorityClassName` support for finer scheduling control, opt-in CloudWatch log publishing with configurable verbosity, and a MultiProcess (MP) mode for LMCache. It also updates the bundled Amazon FSx CSI driver.

Amazon SageMaker HyperPod Inference Operator v3.7 is available in all Amazon Regions where SageMaker HyperPod is supported.

Inference Operator

Inference Operator v3.7 includes the following features:

- **Pod Tolerations** – Add the new `tolerations` field to your `InferenceEndpointConfig` or `JumpStartModel` to schedule inference pods onto tainted nodes, such as dedicated HyperPod GPU node pools. Set the field under `spec.kubernetes.tolerations` for

`InferenceEndpointConfig`, or `spec.tolerations` for `JumpStartModel`. The field accepts the standard Kubernetes toleration structure. The operator propagates your tolerations to the managed deployment pods so they can run on nodes with matching taints.

- **PriorityClass Configuration** – Set a Kubernetes `priorityClassName` on the inference operator, ALB controller, KEDA, and Inference Gateway pods through the EKS add-on `configurationValues` or the operator Helm chart. Use this to control scheduling priority and preemption order for these pods relative to other workloads on the cluster.
- **CloudWatch Log Publishing** – Publish operator logs to Amazon CloudWatch through an opt-in FluentBit sidecar. The feature is **disabled by default**. Enable it in your deployment configuration when you want centralized log aggregation in CloudWatch.
- **Configurable Log Verbosity** – Control console and CloudWatch log verbosity with new customer-settable knobs. Raise verbosity when troubleshooting a deployment, or lower it to reduce log volume and cost in steady state. Valid log levels are `debug`, `info`, `warn`, and `error`.
- **LMCache MultiProcess (MP) Mode** – Enable MultiProcess mode for LMCache by setting `kvCacheSpec.mode`. MP mode runs a sidecar process that shares GPU memory through CUDA-IPC caching. This lets you offload KV cache data in multiple supported formats.

Dependency Updates

- **FSx CSI driver** – This release upgrades the bundled `aws-fsx-csi-driver` from 1.11.0 to 1.17.0 and realigns cert-manager to v1.18.2.

Prerequisites

To use the CloudWatch log publishing feature, your Inference Operator execution role must allow writing to CloudWatch Logs. If your execution role doesn't already include these permissions, add the following statement to the role's IAM policy:

```
{
    "Sid": "CustomerSideOperatorLogs",
    "Effect": "Allow",
    "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents"
    ],
    "Resource": "arn:aws:logs:*:*:log-group:/aws/hyperpod/*/inference-operator*"
```

```
}
```

If you installed the Inference Operator as an EKS add-on, the managed execution-role policy already includes these permissions and no action is required.

Upgrade to v3.7 or v2.1.0-eksbuild.1

EKS Add-on upgrade:

If you installed the Inference Operator as an EKS Add-on, upgrade to the latest version:

```
CLUSTER=EKS_CLUSTER_NAME
REGION=REGION

aws eks update-addon \
  --cluster-name $CLUSTER \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --addon-version v2.1.0-eksbuild.1 \
  --resolve-conflicts OVERWRITE \
  --region $REGION
```

To enable CloudWatch logging and configure log levels, add a `logging` block to the configuration you pass to `--configuration-values`. This parameter replaces the entire configuration, so include your existing keys along with the new block:

```
"logging": {
  "cloudWatch": { "enabled": true, "logLevel": "info" },
  "console": { "logLevel": "debug" }
}
```

Helm upgrade:

If you already have the Inference Operator installed by using Helm, use the following commands to upgrade:

```
helm get values -n kube-system hyperpod-inference-operator \
> current-values.yaml

cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator
```

```
helm upgrade hyperpod-inference-operator . -n kube-system \
  -f current-values.yaml --set image.tag=v3.7

# Verification
kubectl get deployment hyperpod-inference-operator-controller-manager \
  -n hyperpod-inference-system \
  -o jsonpath='{.spec.template.spec.containers[0].image}'
```

To enable CloudWatch logging and configure log levels, add the corresponding `--set` flags:

```
helm upgrade hyperpod-inference-operator . -n kube-system \
  -f current-values.yaml --set image.tag=v3.7 \
  --set logging.cloudWatch.enabled=true \
  --set logging.cloudWatch.logLevel=info \
  --set logging.console.logLevel=debug
```

SageMaker HyperPod Inference release notes: HyperPod Inference Amazon EKS v2.0.0-eksbuild.2 and Inference Operator v3.6

Release Date: September 10, 2026

Summary

The `v2.0.0-eksbuild.2` release of the HyperPod Inference Amazon EKS add-on introduces the HyperPod Inference Gateway, a Kubernetes-native, LLM-aware routing layer that distributes inference traffic across model-serving pods using request-body content and GPU-aware endpoint selection. Both the Inference Operator and the Inference Gateway ship together as part of this add-on release.

This is a major version update of the add-on, from `v1.6.0-eksbuild.1` to `v2.0.0-eksbuild.2`. The version update reflects the addition of the Inference Gateway, and the release remains backward compatible with the existing add-on features. If you do not need either component, you can disable it in the add-on configuration by setting `inferenceGateway.enabled` or `inferenceOperator.enabled` to `false`.

Inference Gateway

- **Inference Gateway** – Route inference traffic for multiple models through a single gateway endpoint using three routing layers: a Body-Based Router that reads the request `model` field, the

gateway with HTTPRoute for header-based routing, and a GPU-aware Endpoint Picker. Configure the gateway with the new `InferenceGatewayConfig` CRD, including per-model schedulers, scoring weights, LoRA adapter support, and optional TLS termination. See the section called "Inference Gateway".

Inference Operator

- **Gateway integration on `InferenceEndpointConfig` and `JumpStartModel`** – Added an optional `inferenceGateway` field to both CRDs. Set `inferenceGateway.enabled` to `true` to opt a model into a shared gateway. The operator then adds a scheduler entry for that model to an `InferenceGatewayConfig`, creating the gateway if it does not already exist. Use `inferenceGateway.name` to select the gateway. Models that specify the same name in the same namespace share one gateway, and a name that is not yet in use creates a new one. When the field is empty, the operator generates a unique name so the model gets its own gateway. The operator mirrors the gateway's readiness in `status.inferenceGateway`. For more information, see the section called "Integration with the HyperPod Inference Operator".
- **Custom pod annotations on `InferenceEndpointConfig`** – Added an optional `podTemplateAnnotations` field under `spec.kubernetes`. The operator propagates these annotations to the underlying pods, so that pod-scraping integrations such as metrics autodiscovery can read them.

Upgrade to v2.0.0-eksbuild.2 or v3.6

Configuration schema changes:

The add-on configuration schema changed in this release. `inferenceGateway` is newly added and configures the HyperPod Inference Gateway. The schema also adds `inferenceOperator`, which gives you the flexibility to turn the Inference Operator on or off independently. Both components are enabled by default, with `inferenceGateway.enabled` and `inferenceOperator.enabled` set to `true`. To disable either component, set its `enabled` field to `false` in `--configuration-values`.

EKS Add-on upgrade:

If you installed the Inference Operator as an EKS Add-on, upgrade to `v2.0.0-eksbuild.2` with the following command:

```
CLUSTER=EKS_CLUSTER_NAME
```

```
REGION=REGION
ACCOUNT=AWS_ACCOUNT_ID

aws eks update-addon \
  --cluster-name $CLUSTER --region $REGION \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --addon-version v2.0.0-eksbuild.2 \
  --resolve-conflicts OVERWRITE \
  --configuration-values '{
    "executionRoleArn": "arn:aws:iam::<ACCOUNT>:role/<EXEC_ROLE>",
    "tlsCertificateS3Bucket": "<TLS_BUCKET>",
    "inferenceOperator": { "enabled": true },
    "inferenceGateway": {
      "enabled": true,
      "serviceAccount": { "roleArn": "arn:aws:iam::<ACCOUNT>:role/<CERT_ISSUER_ROLE>" }
    },
    "keda": { "enabled": true, "auth": { "aws": { "irsa": { "enabled": true, "roleArn":
 "arn:aws:iam::<ACCOUNT>:role/<KEDA_IRSA_ROLE>" } } } },
    "alb": { "enabled": true, "serviceAccount": { "create": true, "roleArn":
 "arn:aws:iam::<ACCOUNT>:role/<ALB_IRSA_ROLE>" } },
    "jumpstartGatedModelDownloadRoleArn": "arn:aws:iam::<ACCOUNT>:role/
<JUMPSTART_ROLE>"
  }'
```

Helm upgrade:

The Inference Gateway is available only through the Amazon EKS add-on. If you manage the Inference Operator with Helm and want to continue using operator-only features, upgrade your Helm release with the following commands. We recommend migrating to the add-on to get the full capabilities of both the Inference Operator and the Inference Gateway.

```
helm get values -n kube-system hyperpod-inference-operator \
> current-values.yaml

cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator

helm upgrade hyperpod-inference-operator . -n kube-system \
  -f current-values.yaml --set image.tag=v3.6

# Verification
kubectl get deployment hyperpod-inference-operator-controller-manager \
  -n hyperpod-inference-system \
```

```
  -o jsonpath='{.spec.template.spec.containers[0].image}'
```

For migration from Helm to the Amazon EKS add-on, see the section called "Helm to EKS Add-on Migration".

SageMaker HyperPod Inference release notes: HyperPod Inference Amazon EKS v1.6.0-eksbuild.1 and Inference Operator v3.5

Release Date: September 3, 2026

Summary

Amazon SageMaker HyperPod Inference Operator v3.5 gives you direct control over where model weights are pre-cached. You can now attach your own node affinity rules to the weights cache instead of relying solely on the instance-type targeting the operator derives from your deployment. This release also adds two Prometheus metrics for inbound request volume, and includes a few security fixes.

Amazon SageMaker HyperPod Inference Operator v3.5 is available in all Amazon Regions where SageMaker HyperPod is supported.

New Features

- **Node Affinity for Model Weights Caching** – Constrain which nodes pre-cache model weights by using the new `nodeAffinity` field under `modelCacheConfig.weightsCache` on your `InferenceEndpointConfig` or `JumpStartModel`. The field accepts the standard Kubernetes node affinity structure, so you get `requiredDuringSchedulingIgnoredDuringExecution` and `preferredDuringSchedulingIgnoredDuringExecution` terms. Multiple `nodeSelectorTerms` give you OR semantics, which lets you target node pools, Availability Zones, or custom label sets in one deployment.

  The operator applies your rules in addition to the instance-type targeting it derives from `spec.instanceType` or `spec.instanceTypes`, so weights are cached only on nodes that satisfy both. Use this to pin the weights cache to a single Availability Zone or to specific HyperPod instance groups.
- **Inbound Request Tracking** – Two new Prometheus metrics give you visibility into inbound inference request volume, so you can measure total demand, track shed load, and plan autoscaling and capacity accordingly.
  - `model_requests_received_total` – Counts every request at the proxy entrypoint, before any admission control decision. This includes requests that are later shed.

- `model_requests_shed_total` – Counts requests rejected by admission control through throttling.

Upgrade to v3.5 or v1.6.0-eksbuild.1

Helm upgrade:

If you already have the Inference Operator installed by using Helm, use the following commands to upgrade:

```
helm get values -n kube-system hyperpod-inference-operator \
> current-values.yaml

cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator

helm upgrade hyperpod-inference-operator . -n kube-system \
  -f current-values.yaml --set image.tag=v3.5

# Verification
kubectl get deployment hyperpod-inference-operator-controller-manager \
  -n hyperpod-inference-system \
  -o jsonpath='{.spec.template.spec.containers[0].image}'
```

EKS Add-on upgrade:

If you installed the Inference Operator as an EKS Add-on, upgrade to the latest version:

```
CLUSTER=EKS_CLUSTER_NAME
REGION=REGION

aws eks update-addon \
  --cluster-name $CLUSTER \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --addon-version v1.6.0-eksbuild.1 \
  --resolve-conflicts OVERWRITE \
  --region $REGION
```

SageMaker HyperPod Inference release notes: HyperPod Inference Amazon EKS v1.5.0-eksbuild.1 and Inference Operator v3.4

Release Date: August 21, 2026

Summary

Amazon SageMaker HyperPod Inference Operator v3.4 makes the resource requests and limits of the managed sidecar containers configurable through the CRD. You can now size the reverse proxy, metrics collector, and data capture uploader containers to match your workload instead of relying on fixed defaults.

Amazon SageMaker HyperPod Inference Operator v3.4 is available in all Amazon Regions where SageMaker HyperPod is supported.

New Features

- **Configurable Container Resources** – Set resource requests and limits for the operator-managed sidecar containers. Use the new `metricsSidecarResources`, `metricsCollectorResources`, and `s3UploaderResources` fields on your `InferenceEndpointConfig` or `JumpStartModel`. These fields let you raise the reverse proxy memory for high-concurrency deployments, tune the metrics collector, and size the data capture uploader. When a field is set, the operator applies your values instead of the built-in defaults and preserves them across reconciliation. Each field fully replaces that container's resource block, so specify complete requests and limits.

Upgrade to v3.4 or v1.5.0-eksbuild.1

Helm upgrade:

If you already have the Inference Operator installed by using Helm, use the following commands to upgrade:

```
helm get values -n kube-system hyperpod-inference-operator \
> current-values.yaml

cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator

helm upgrade hyperpod-inference-operator . -n kube-system \
  -f current-values.yaml --set image.tag=v3.4

# Verification
kubectl get deployment hyperpod-inference-operator-controller-manager \
  -n hyperpod-inference-system \
  -o jsonpath='{.spec.template.spec.containers[0].image}'
```

EKS Add-on upgrade:

If you installed the Inference Operator as an EKS Add-on, upgrade to the latest version:

```
CLUSTER=EKS_CLUSTER_NAME
REGION=REGION

aws eks update-addon \
  --cluster-name $CLUSTER \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --addon-version v1.5.0-eksbuild.1 \
  --resolve-conflicts OVERWRITE \
  --region $REGION
```

SageMaker HyperPod Inference release notes: HyperPod Inference Amazon EKS v1.4.0-eksbuild.1 and Inference Operator v3.3

Release Date: August 4, 2026

Summary

Amazon SageMaker HyperPod Inference Operator v3.3 introduces host-local model caching. This reduces cold-start latency when you scale out an inference deployment. This release also makes the Application Load Balancer idle timeout configurable for each deployment.

Amazon SageMaker HyperPod Inference Operator v3.3 is available in all Amazon Regions where SageMaker HyperPod is supported.

New Features

- **Model Weights and Image Caching** – Cache model weights on node-local NVMe storage and pre-pull the inference server container image onto target nodes. Pods added during scale-out do not download weights from Amazon S3 or Amazon FSx. They do not wait for a cold image pull. Enable either mechanism independently or both together by using `modelCacheConfig` in your CRD. This feature requires an instance type with local NVMe storage. See the section called "Model weights and image caching".
- **Configurable ALB Idle Timeout** – Control how long the Application Load Balancer keeps an idle connection open by using `loadBalancer.idleTimeoutSeconds` on your `InferenceEndpointConfig` or `JumpStartModel`. Valid values are 1–4000 seconds, and the default is 60 seconds. Increase this value for deployments whose requests take longer than the default to return a response.

Bug Fixes

- **Missing Routing Service** – Fixed an issue where an interrupted initial reconcile could leave a deployment without the Kubernetes routing Service. This Service backs the deployment's Ingress and load balancer. Endpoints returned HTTP 503 responses while all health signals reported healthy. The operator now re-creates the routing Service when it is missing.
- **Intelligent Routing Endpoint Registration** – Fixed an issue where intelligent routing deployments used an unprefixed name for the Ingress path lookup. The lookup failed on every reconciliation, which prevented SageMaker AI endpoint registration from completing.
- **KV Cache Configuration** – Fixed an issue where the operator did not honor `enableL1Cache` or `enableL2Cache` set to `false` in `kvCacheSpec`.

Upgrade to v3.3 or v1.4.0-eksbuild.1

Helm upgrade:

If you already have the Inference Operator installed by using Helm, use the following commands to upgrade:

```
helm get values -n kube-system hyperpod-inference-operator \
> current-values.yaml

cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator

helm upgrade hyperpod-inference-operator . -n kube-system \
  -f current-values.yaml --set image.tag=v3.3

# Verification
kubectl get deployment hyperpod-inference-operator-controller-manager \
  -n hyperpod-inference-system \
  -o jsonpath='{.spec.template.spec.containers[0].image}'
```

EKS Add-on upgrade:

If you installed the Inference Operator as an EKS Add-on, upgrade to the latest version:

```
CLUSTER=EKS_CLUSTER_NAME

```

SageMaker HyperPod Inference release notes: HyperPod Inference Amazon EKS v1.3.0-eksbuild.1 and Inference Operator v3.2

Release Date: June 12, 2026

Summary

Inference Operator v3.2 enables customers to deploy long-context LLMs (such as Llama 3.3 70B) with predictable per-token latency under concurrent load. The release introduces Disaggregated Prefill and Decode (DPD), which separates the compute-bound prefill phase and the memory-bandwidth-bound decode phase onto distinct GPU pools and transfers KV cache between them over EFA with GPU-Direct RDMA. DPD reduces tail per-token latency, increases throughput, and lets you scale prefill and decode capacity independently. Besides DPD we include other bug fixes in this release.

Key Features

Disaggregated Prefill and Decode (DPD)

- Added a new pdSpec field to the `InferenceEndpointConfig` CRD that enables disaggregated inference. When pdSpec is set, the operator provisions separate prefiller and decoder pods, wires them together via the DPD router, and transfers KV cache between them using LMCache over NIXL and EFA with GPU-Direct RDMA. Example configurable fields include (more config can check user guide):
  - `routingThreshold` – Token-length threshold above which requests use the disaggregated path. Below the threshold, requests bypass the prefiller and go directly to the decoder.
  - `prefillSpec.args` and `decodingSpec.args` – Per-role vLLM flags merged into `worker.args` at startup.
  - `prefillSpec.replicas` and `decodingSpec.replicas` – Scale prefill and decode capacity independently to match your workload's input and output length distribution.
- **Prerequisite**

- To deploy DPD endpoints, your cluster nodes must support EFA with RDMA read and write, and be located within the same Availability Zone for high-bandwidth node-to-node communication.
- Recommended instance families: `ml.p5.48xlarge`, `ml.p5e.48xlarge`, `ml.p5en.48xlarge`, `ml.p6-b200.48xlarge`, `ml.p6-b300.48xlarge`.

Bug Fixes

- **Operator scheduling on x86 nodes** – The operator deployment now uses `nodeAffinity` to schedule onto amd64 Linux nodes only.
- We include other minor and security fixes.

Upgrade to v3.2 or v1.3.0-eksbuild.1

Helm upgrade:

If you already have the Inference Operator installed via Helm, use the following commands to upgrade:

```
helm get values -n kube-system hyperpod-inference-operator \
> current-values.yaml

cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator

helm upgrade hyperpod-inference-operator . -n kube-system \
  -f current-values.yaml --set image.tag=v3.2

# Verification
kubectl get deployment hyperpod-inference-operator-controller-manager \
  -n hyperpod-inference-system \
  -o jsonpath='{.spec.template.spec.containers[0].image}'
```

EKS Add-on upgrade:

If you installed the Inference Operator as an EKS Add-on, upgrade to the latest version:

```
CLUSTER=EKS_CLUSTER_NAME
REGION=REGION
```

```
aws eks update-addon \
  --cluster-name $CLUSTER \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --addon-version v1.3.0-eksbuild.1 \
  --resolve-conflicts OVERWRITE \
  --region $REGION
```

SageMaker HyperPod Inference release notes: HyperPod Inference Amazon EKS v1.2.0-eksbuild.1 and Inference Operator v3.1.2

Release Date: May 6, 2026

Summary

Inference Operator v3.1.2 introduces inference data capture for logging endpoint traffic, HuggingFace Hub integration for direct model deployment, Route 53 DNS management for custom domains, local NVMe model deployment for reduced cold-start latency, and custom service accounts with IRSA support.

New Features

- **Inference Data Capture** – Record inputs and outputs at three capture points: SageMaker AI endpoint, load balancer (ALB access logs), and model pod. Enable any combination via `dataCapture` in your CRD. See the section called "Data capture".
- **HuggingFace Model Source** – Deploy models directly from HuggingFace Hub without pre-staging to S3 or FSx. Supports gated models via `tokenSecretRef`, revision pinning via `commitSHA`, and token isolation. Compatible with vLLM, TGI, and SGLang runtimes. See the section called "Deploy models from Amazon S3, Amazon FSx, or Hugging Face Hub using kubectl".
- **Route 53 DNS Management** – Automatically create and manage DNS records for custom domains via `dnsConfig`. See the section called "Custom certificates and Route 53 DNS".
- **Local NVMe Model Deployment** – Load model weights from node-local NVMe storage via `modelSourceType: kubernetesVolume` to reduce cold-start latency. Supports fallback to S3. See the section called "Deploy models from local NVMe storage using kubectl".
- **Custom Service Accounts** – Assign custom ServiceAccounts with IRSA support to inference pods via `spec.kubernetes.serviceAccountName`.

Bug Fixes

- **Tag Propagation** – User-defined tags on `InferenceEndpointConfig` now propagate correctly to the `SageMakerEndpointRegistration` CRD and downstream SageMaker AI resources. Previously, tags were not passed during endpoint registration creation or updates.
- **Autoscaling Replica Preservation** – Fixed an issue where updating an `InferenceEndpointConfig` or `JumpStartModel` CR would reset the replica count to the spec value, overriding the current HPA/KEDA-managed replica count. The operator now preserves the active replica count during CR updates.
- **Autoscaling CRD Validation** – Fixed `prometheusTrigger.serverAddress` validation regex that incorrectly required a trailing path segment, causing 404 errors when KEDA appended `/api/v1/query` to the AMP workspace URL.
- **Certificate Rotation** – Fixed custom certificate rotation not propagating to ALB after operator pod restart.

Upgrade to v3.1.2 or v1.2.0-eksbuild.1

Helm upgrade:

If you already have the Inference Operator installed via Helm, use the following commands to upgrade:

```
helm get values -n kube-system hyperpod-inference-operator \
> current-values.yaml

cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator

helm upgrade hyperpod-inference-operator . -n kube-system \
  -f current-values.yaml --set image.tag=v3.1.2

# Verification
kubectl get deployment hyperpod-inference-operator-controller-manager \
  -n hyperpod-inference-system \
  -o jsonpath='{.spec.template.spec.containers[0].image}'
```

EKS Add-on upgrade:

If you installed the Inference Operator as an EKS Add-on, upgrade to the latest version.

First, check if `hyperpodClusterArn` is already in your add-on configuration:

```
CLUSTER=EKS_CLUSTER_NAME
REGION=REGION

aws eks describe-addon \
  --cluster-name $CLUSTER \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --region $REGION \
  --query 'addon.configurationValues' --output text | jq .
```

If `hyperpodClusterArn` is present in the output, run the following command to upgrade:

```
aws eks update-addon \
  --cluster-name $CLUSTER \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --addon-version v1.2.0-eksbuild.1 \
  --resolve-conflicts OVERWRITE \
  --region $REGION
```

If `hyperpodClusterArn` is not present, fetch the current configuration, add it, and upgrade:

```
HP_ARN=HYPERPOD_CLUSTER_ARN

CURRENT_CONFIG=$(aws eks describe-addon \
  --cluster-name $CLUSTER \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --region $REGION \
  --query 'addon.configurationValues' --output text)

# Add hyperpodClusterArn to the configuration
NEW_CONFIG=$(echo "$CURRENT_CONFIG" | jq --arg arn "$HP_ARN" \
  '. + {hyperpodClusterArn: $arn}')

aws eks update-addon \
  --cluster-name $CLUSTER \
  --addon-name amazon-sagemaker-hyperpod-inference \
  --addon-version v1.2.0-eksbuild.1 \
  --configuration-values "$NEW_CONFIG" \
  --resolve-conflicts OVERWRITE \
  --region $REGION
```

Wait for the add-on to become active before deploying models.

SageMaker HyperPod Inference release notes: Inference Operator v3.1

Release Date: April 3, 2026

Summary

Inference Operator v3.1 introduces custom Kubernetes pod configuration, custom certificate support, and per-pod request limits.

Key Features

- **Custom Kubernetes Pod Configuration** – Added a new `kubernetes` field to the `InferenceEndpointConfig` CRD that allows users to customize inference pod configurations:
  - **Custom init containers** – Run user-defined init containers before the inference server starts (for example, cache warming, GDS setup). Init containers are injected after the operator's prefetch container.
  - **Custom volumes** – Add additional volumes (`emptyDir`, `hostPath`, `configMap`, etc.) to the pod spec, which can be referenced by init containers via `volumeMounts`.
  - **Custom scheduler name** – Specify a custom Kubernetes scheduler for pod placement.
- **Custom Certificates** – Use your own ACM certificates for inference endpoints instead of operator-generated self-signed certificates, configured via `customCertificateConfig`. Supports publicly trusted ACM certificates, Amazon Private CA certificates, and certificates imported from external CAs. The operator monitors certificate health and supports automatic renewal detection.
- **Request Limits** – Control request handling per pod via the new `RequestLimits` configuration under `Worker`, with the following configurable fields:
  - `maxConcurrentRequests` – Maximum concurrent in-flight requests per pod.
  - `maxQueueSize` – Requests to queue when the concurrency limit is reached before rejecting.
  - `overflowStatusCode` – HTTP status code returned when limits are exceeded (default: 429).

For detailed information including prerequisites and upgrade instructions, see the sections below.

Prerequisites

To use the Custom Certificates feature, add the following permissions to your Inference Operator execution role:

```
{
```

```
    "Sid": "ACMCertificateAccess",
    "Effect": "Allow",
    "Action": [
        "acm:DescribeCertificate",
        "acm:GetCertificate"
    ],
    "Resource": "arn:aws:acm:*:*:certificate/*"
}
```

Upgrade to v3.1

If you already have the Inference Operator installed via Helm, use the following commands to upgrade:

```
helm get values -n kube-system hyperpod-inference-operator \
> current-values.yaml

cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator

helm upgrade hyperpod-inference-operator . -n kube-system \
  -f current-values.yaml --set image.tag=v3.1

# Verification
kubectl get deployment hyperpod-inference-operator-controller-manager \
  -n hyperpod-inference-system \
  -o jsonpath='{.spec.template.spec.containers[0].image}'
```

SageMaker HyperPod Inference release notes: Inference Operator v3.0

Release Date: February 23, 2026

Summary

Inference Operator 3.0 introduces EKS Add-on integration for simplified lifecycle management, Node Affinity support for granular scheduling control, and improved resource tagging. Existing Helm-based installations can be migrated to the EKS Add-on using the provided migration script. Update your Inference Operator execution role with new tagging permissions before upgrading.

Key Features

- **EKS Add-on Integration** – Enterprise-grade lifecycle management with simplified installation experience

- **Node Affinity** – Granular scheduling control for excluding spot instances, preferring availability zones, or targeting nodes with custom labels

For detailed information including prerequisites, upgrade instructions, and migration guidance, see the sections below.

Prerequisites

Before upgrading the Helm version to 3.0, customers should add additional tagging permissions to their Inference operator execution role. As part of improving resource tagging and security, the Inference Operator now tags ALB, S3, and ACM resources. This enhancement requires additional permissions in the Inference Operator execution role. Add the following permissions to your Inference Operator execution role:

```
{
    "Sid": "CertificateTagginPermission",
    "Effect": "Allow",
    "Action": [
        "acm:AddTagsToCertificate"
    ],
    "Resource": "arn:aws:acm:*:*:certificate/*",
},
{
    "Sid": "S3PutObjectTaggingAccess",
    "Effect": "Allow",
    "Action": [
        "s3:PutObjectTagging"
    ],
    "Resource": [
        "arn:aws:s3:::<TLS_BUCKET>/*" # Replace * with your TLS bucket
    ]
}
```

Upgrade to v3.0

If you already have the Inference Operator installed via Helm, use the following commands to upgrade:

```
helm get values -n kube-system hyperpod-inference-operator \
> current-values.yaml
```

```
cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator

helm upgrade hyperpod-inference-operator . -n kube-system \
  -f current-values.yaml --set image.tag=v3.0

# Verification
kubectl get deployment hyperpod-inference-operator-controller-manager \
  -n hyperpod-inference-system \
  -o jsonpath='{.spec.template.spec.containers[0].image}'
```

Helm to EKS Add-on Migration

If Inference operator is installed through Helm before 3.0 version, we recommend migrating to EKS Add-on to get timely updates on the new features that will be released for Inference Operator. This script migrates the SageMaker HyperPod Inference Operator from Helm-based installation to EKS Add-on installation.

Overview: The script takes a cluster name and region as parameters, retrieves the existing Helm installation configuration, and migrates to EKS Add-on deployment. It creates new IAM roles for the Inference Operator, ALB Controller, and KEDA Operator.

Before migrating the Inference Operator, the script ensures required dependencies (S3 CSI driver, FSx CSI driver, cert-manager, and metrics-server) exist. If they don't exist, it deploys them as Add-on.

After the Inference Operator Add-on migration completes, the script also migrates S3, FSx, and other dependencies (ALB, KEDA, cert-manager, metrics-server) if they were originally installed via the Inference Operator Helm chart. Use `--skip-dependencies-migration` to skip this step for S3 CSI driver, FSx CSI driver, cert-manager, and metrics-server. Note that ALB and KEDA are installed as part of the Add-on in the same namespace as Inference Operator, and will be migrated as part of the Inference Operator Add-on.

> **Important**
>
> During the migration, do not deploy new models as they will not be deployed until the migration is completed. Once the Inference Operator Add-on is in ACTIVE state, new models can be deployed. Migration time typically takes 15 to 20 minutes, and it can complete within 30 minutes if only a few models are currently deployed.

Migration Prerequisites:

- Amazon CLI configured with appropriate credentials
- kubectl configured with access to your EKS cluster
- Helm installed
- Existing Helm installation of hyperpod-inference-operator

> **Note**
>
> Endpoints that are already running will not be interrupted during the migration process. Existing endpoints will continue to serve traffic without disruption throughout the migration.

Getting the Migration Script:

```
git clone https://github.com/aws/sagemaker-hyperpod-cli.git
cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator/migration
```

Usage:

```
./helm_to_addon.sh [OPTIONS] \
  --cluster-name <cluster-name> (Required) \
  --region <region> (Required) \
  --helm-namespace kube-system (Optional) \
  --auto-approve (Optional) \
  --skip-dependencies-migration (Optional) \
  --s3-mountpoint-role-arn <s3-mountpoint-role-arn> (Optional) \
  --fsx-role-arn <fsx-role-arn> (Optional)
```

Options:

- `--cluster-name NAME` – EKS cluster name (required)
- `--region REGION` – Amazon region (required)
- `--helm-namespace NAMESPACE` – Namespace where Helm chart is installed (default: kube-system) (optional)

- `--s3-mountpoint-role-arn ARN` – S3 Mountpoint CSI driver IAM role ARN (optional)
- `--fsx-role-arn ARN` – FSx CSI driver IAM role ARN (optional)
- `--auto-approve` – Skip confirmation prompts if this flag is enabled. `step-by-step` and `auto-approve` are mutually exclusive, if `--auto-approve` is given, do not specify `--step-by-step` (optional)
- `--step-by-step` – Pause after each major step for review. This should not be mentioned if `--auto-approve` is already added (optional)
- `--skip-dependencies-migration` – Skip migration of Helm-installed dependencies to Add-on. For dependencies were NOT installed via the Inference Operator Helm chart, or if you want to manage them separately. (optional)

Examples:

Basic migration (migrates dependencies):

```
./helm_to_addon.sh \
  --cluster-name my-cluster \
  --region us-east-1
```

Auto-approve without prompts:

```
./helm_to_addon.sh \
  --cluster-name my-cluster \
  --region us-east-1 \
  --auto-approve
```

Skip dependency migration for FSx, S3 mountpoint, cert manager and Metrics server:

```
./helm_to_addon.sh \
  --cluster-name my-cluster \
  --region us-east-1 \
  --skip-dependencies-migration
```

Provide existing S3 and FSx IAM roles:

```
./helm_to_addon.sh \
  --cluster-name my-cluster \
```

```
  --region us-east-1 \
  --s3-mountpoint-role-arn arn:aws:iam::123456789012:role/s3-csi-role \
  --fsx-role-arn arn:aws:iam::123456789012:role/fsx-csi-role
```

Backup Location:

Backups are stored in `/tmp/hyperpod-migration-backup-<timestamp>/`

Backups enable safe migration and recovery:

- **Rollback on Failure** – If migration fails, the script can automatically restore your cluster to its pre-migration state using the backed up configurations
- **Audit Trail** – Provides a complete record of what existed before migration for troubleshooting and compliance
- **Configuration Reference** – Allows you to compare pre-migration and post-migration configurations
- **Manual Recovery** – If needed, you can manually inspect and restore specific resources from the backup directory

Rollback:

If migration fails, the script prompts for user confirmation before initiating rollback to restore the previous state.

SageMaker HyperPod Inference release notes: Inference Operator v2.3

What's new

This release introduces new optional fields in the Custom Resource Definitions (CRDs) to enhance deployment configuration flexibility.

Features

- **Multi Instance Types**
  - **Enhanced deployment reliability** – Supports multi-instance type configurations with automatic failover to alternative instance types when preferred options lack capacity
  - **Intelligent resource scheduling** – Uses Kubernetes node affinity to prioritize instance types while guaranteeing deployment even when preferred resources are unavailable

- **Optimized cost and performance** – Maintains your instance type preferences and prevents capacity-related failures during cluster fluctuations

Bug Fixes

Changes to the field `invocationEndpoint` in the spec of the `InferenceEndpointConfig` will now take effect:

- If the `invocationEndpoint` field is patched or updated, dependent resources, such as the `Ingress`, the Load Balancer, `SageMakerEndpointRegistration`, and SageMaker Endpoint, will be updated with normalisation.
- The value for `invocationEndpoint` provided will be stored as-is in the `InferenceEndpointConfig` spec itself. When this value is used to create a Load Balancer and — if enabled— a SageMaker Endpoint, it will be normalised to have one leading forward slash.
  - `v1/chat/completions` will be normalised to `/v1/chat/completions` for the `Ingress`, AWS Load Balancer, and SageMaker Endpoint. For the `SageMakerEndpointRegistration`, it will be displayed in its spec as `v1/chat/completions`.
  - `///invoke` will be normalised to `/invoke` for the `Ingress`, AWS Load Balancer, and SageMaker Endpoint. For the `SageMakerEndpointRegistration`, it will be displayed in its spec as `invoke`.

Installing Helm:

Follow: https://github.com/aws/sagemaker-hyperpod-cli/tree/main/helm_chart

If you are focused on only installing the inference operator, after step 1 i.e. `Set Up Your Helm Environment`, do `cd HyperPodHelmChart/charts/inference-operator`. Since you are in the inference operator chart directory itself, in the commands, wherever you see `helm_chart/HyperPodHelmChart`, replace with `.`.

Upgrade Operator to v2.3 in case already installed:

```
cd sagemaker-hyperpod-cli/helm_chart/HyperPodHelmChart/\
charts/inference-operator

helm get values -n kube-system hyperpod-inference-operator \
> current-values.yaml
```

```
helm upgrade hyperpod-inference-operator . \
  -n kube-system \
  -f current-values.yaml \
  --set image.tag=v2.3
```

SageMaker HyperPod cluster events reference

This page provides a complete reference of all structured events emitted by Amazon SageMaker HyperPod clusters. Events provide visibility into cluster, instance group, and instance-level operations including provisioning, scaling, patching, and orchestrator-specific lifecycle changes.

Cluster events are available for HyperPod clusters with `NodeProvisioningMode` set to `Continuous`. Events are accessible through the `ListClusterEvents` and `DescribeClusterEvent` APIs, the SageMaker AI console **Events** tab, and Amazon EventBridge.

Cluster event record

Each cluster event is represented as a structured record containing identification, timing, scope, severity, and operation-specific metadata. The following example shows a complete event record as delivered through the `DescribeClusterEvent` API and Amazon EventBridge:

```
{
  "version": "0",
  "id": "0bd4a141-0a02-9d8a-f977-3924c3fb259c",
  "detail-type": "SageMaker HyperPod Cluster Event",
  "source": "aws.sagemaker",
  "account": "111122223333",
  "time": "2026-06-01T17:20:25Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:sagemaker:us-west-2:111122223333:cluster/sample-cluster"
  ],
  "detail": {
    "EventDetails": {
      "EventId": "83ea0bb5-be77-45e8-a458-0a87f778a205",
      "ClusterArn": "arn:aws:sagemaker:us-west-2:111122223333:cluster/sample-cluster",
      "ClusterName": "sample-cluster",
      "InstanceGroupName": "p5Inst",
      "InstanceId": "i-0391f86fa0fe0d465",
      "ResourceType": "Instance",
      "EventTime": 1748794825350,
```

```
      "EventLevel": "Error",
      "Description": "Instance creation in Cluster sample-cluster and InstanceGroup
 p5Inst failed",
      "EventDetails": {
        "EventMetadata": {
          "Instance": {
            "FailureMessage": "We currently do not have sufficient capacity to launch
 new ml.p5.48xlarge instances. Please try again.",
            "NodeLogicalId": "df268d19-f035-4f28-9b80-b956b92ae21e"
          }
        }
      }
    }
  }
}
```

Event record fields

The `detail.EventDetails` object contains the following fields:

Field	Type	Require	Description
`EventId`	String (UUID)	Yes	Unique identifier for the event.
`ClusterArn`	String	Yes	ARN of the HyperPod cluster.
`ClusterName`	String	Yes	Name of the HyperPod cluster.
`EventTime`	Timestamp	Yes	When the event occurred (epoch milliseconds).
`ResourceType`	String	Yes	Scope of the event: `Cluster`, `InstanceGroup`, or `Instance`.
`EventLevel`	String	Yes	Severity classification: `Info`, `Warn`, or `Error`.
`Description`	String	No	Human-readable summary of the event.
`InstanceGroupName`	String	No	Instance group name (present when `ResourceType` is `InstanceGroup` or `Instance`).

Field	Type	Require	Description
`InstanceId`	String	No	EC2 instance ID (present when `ResourceType` is `Instance`).
`EventDetails`	Object	No	Additional metadata specific to the resource type and operation.

Event levels

Level	Meaning
`Info`	Operation completed successfully or is progressing normally.
`Warn`	Operation completed with a non-critical issue or a condition that may require future attention.
`Error`	Operation failed or requires immediate attention.

Resource types

ResourceType	Scope	Example events
`Cluster`	Whole-cluster operations	Cluster creation/update started, cluster operation failed
`InstanceGroup`	Instance group operations	Scaling started/completed, patching scheduled, FSx lifecycle
`Instance`	Individual instance operations	EC2 provisioning, lifecycle script execution, ENI management, termination

EventDetails metadata

Cluster events include an `EventMetadata` object within the `EventDetails` field that provides operation-specific context beyond what the event description conveys. The contents of

`EventMetadata` vary by resource type and event type. For the complete schema and supported fields, see EventMetadata in the Amazon SageMaker AI API Reference.

EventBridge envelope fields

When delivered through Amazon EventBridge, the event record is wrapped in the standard EventBridge envelope:

Field	Description
`version`	EventBridge schema version (always `"0"`).
`id`	Unique EventBridge event ID.
`detail-type`	`SageMaker HyperPod Cluster Event`
`source`	`aws.sagemaker`
`account`	Amazon account ID that owns the cluster.
`time`	ISO 8601 timestamp of the event.
`region`	Amazon Region where the cluster resides.
`resources`	Array containing the cluster ARN.
`detail`	Contains the `EventDetails` object described above.

Common events (EKS and Slurm)

The following events are emitted for all HyperPod clusters regardless of orchestrator. The **Description** column shows the value of the `Description` field in the event record as it appears in the API response and the console **Events** tab.

Cluster lifecycle

Event	Description
Cluster operation started	Cluster <cluster-name> <operation> started successfully

Event	Description
Cluster operation start failed	Failed to start Cluster <cluster-name> <operation>
Cluster operation completed	Cluster <cluster-name> <operation> completed successfully
Cluster operation failed	Cluster <cluster-name> <operation> failed

Instance group lifecycle

Event	Description
Instance group operation started	InstanceGroup <instance-group-name> <operation> started successfu lly in Cluster <cluster-name>
Instance group operation start failed	Failed to start InstanceGroup <instance-group-name> <operation> in Cluster <cluster-name>
Instance group operation completed	Instance Group <instance-group-name> <operation> in Cluster <cluster-name> completed successfully
Instance group operation failed	Instance Group <instance-group-name> <operation> in Cluster <cluster-name> failed

Instance group network configuration

Event	Description
Network configura tion found	Found Subnet <subnet-id> in AZ <availability-zone> with SecurityG roupIds <security-group-ids> for IG <instance-group-name> in Cluster <cluster-name>
Network configura tion failed	Failed to process Instance Group Network Configuration details for IG <instance-group-name> in Cluster <cluster-name>

Event	Description
Custom AMI override found	Found Custom AMI Override <ami-id> for IG <instance-group-name> in Cluster <cluster-name>
Custom AMI override failed	Failed to process Custom AMI Override details for IG <instance-group-name> in Cluster <cluster-name>
Platform network configuration used	Using HyperPod Platform provided network configuration for IG <instance-group-name> in Cluster <cluster-name>
Network configura tion determined	Instance Group network configuration successfully determined for IG <instance-group-name> in Cluster <cluster-name>

Instance creation

Event	Description
Instance operation started	Instance <operation> started successfully in Cluster <cluster-name> and IG <instance-group-name>
Instance operation start failed	Failed to start Instance <operation> in Cluster <cluster-name> and IG <instance-group-name>
Capacity reservation found	Found CapacityReservation ID <reservation-id> for Cluster <cluster-name> and IG <instance-group-name>, using reserved capacity
Capacity reservation not found	No CapacityReservation found for Cluster <cluster-name> and IG <instance-group-name>, using on-demand pool
Instance payload setup failed	Failed to process CapacityReservationDetails for Cluster <cluster-name> and IG <instance-group-name>
Customer ENI created	Successfully created Customer ENI for instance in Cluster <cluster-name> and IG <instance-group-name>
Customer ENI creation failed	Failed to create Customer ENI for instance in Cluster <cluster-name> and IG <instance-group-name>

Event	Description
EC2 instance provisioned	EC2 Instance <instance-id> successfully provisioned in Cluster <cluster-name> and IG <instance-group-name>
EC2 instance creation failed	Failed to provision EC2 Instance in Cluster <cluster-name> and IG <instance-group-name>
Lifecycle script status updated	Instance lifecycle script execution for EC2 Instance <instance-id> has <status>
Lifecycle script status update failed	Failed to update Instance lifecycle script execution status for EC2InstanceId <instance-id>
Instance creation failed with lifecycle logs	Instance lifecycle script execution for EC2 Instance <instance-id> has Failed. To view lifecycle script logs, visit log group...
Unused ENI cleanup succeeded	Successfully deleted unused Customer ENIs for EC2 Instance <instance-id> in Cluster <cluster-name> and IG <instance-group-name>
Unused ENI cleanup failed	Failed to delete unused Customer ENIs for EC2 Instance <instance-id> in Cluster <cluster-name> and IG <instance-group-name>

Instance deletion

Event	Description
EC2 instance termination in progress	Termination of EC2 Instance <instance-id> is currently in progress in Cluster <cluster-name> and IG <instance-group-name>
EC2 instance termination failed	Failed to terminate EC2 Instance <instance-id> in Cluster <cluster-name> and IG <instance-group-name>
Customer ENI deleted	Customer ENI successfully deleted for EC2 Instance <instance-id> in Cluster <cluster-name> and IG <instance-group-name>

Event	Description
Customer ENI deletion failed	Failed to delete Customer ENI for EC2 Instance <instance-id> in Cluster <cluster-name> and IG <instance-group-name>

Instance reboot

Event	Description
EC2 instance reboot in progress	Reboot of EC2 Instance <instance-id> is currently in progress on Cluster <cluster-name> and IG <instance-group-name>
EC2 instance reboot request failed	Failed to submit reboot request for EC2 Instance <instance-id> in Cluster <cluster-name> and IG <instance-group-name>

Instance operation (generic)

Event	Description
Instance operation completed	Instance <operation> <instance-id> in Cluster <cluster-name> and IG <instance-group-name> completed successfully
Instance operation failed	Instance <operation> <instance-id> in Cluster <cluster-name> and IG <instance-group-name> failed

Instance replacement

Event	Description
Instance replacement started	Instance <instance-id> is starting as part of instance replacement in Cluster <cluster-name> and IG <instance-group-name>
Instance replacement start failed	Instance <instance-id> failed to start as part of instance replacement in Cluster <cluster-name> and IG <instance-group-name>

Event	Description
Instance replacement completed	Instance <instance-id> <operation> completed successfully as part of instance replacement in Cluster <cluster-name> and IG <instance-group-name>
Instance replacement failed	Instance <instance-id> <operation> failed as part of instance replaceme nt in Cluster <cluster-name> and IG <instance-group-name>

FSx filesystem lifecycle

Event	Description
FSx creation started	FSx creation started for IG <instance-group-name> in Cluster <cluster-name>
FSx creation failed	Failed to create FSx for IG <instance-group-name> in Cluster <cluster-name>
FSx creation completed	FSx creation successfully completed for IG <instance-group-name> in Cluster <cluster-name>
FSx deletion started	FSx deletion started for IG <instance-group-name> in Cluster <cluster-name>
FSx deletion failed	Failed to delete FSx for IG <instance-group-name> in Cluster <cluster-name>
FSx deletion completed	FSx deletion successfully completed for IG <instance-group-name> in Cluster <cluster-name>
FSx update started	FSx update started for IG <instance-group-name> in Cluster <cluster-name>
FSx update failed	Failed to update FSx for IG <instance-group-name> in Cluster <cluster-name>

Event	Description
FSx update completed	FSx update successfully completed for IG <instance-group-name> in Cluster <cluster-name>

Patching (common steps)

These patching events are emitted for both EKS and Slurm clusters during `UpdateClusterSoftware` operations.

Event	Description
Instance group patching scheduled	InstanceGroup <instance-group-name> in Cluster <cluster-name> has been scheduled for UpdateClusterSoftware to latest.
Instance group patching schedule failed	Failed to schedule UpdateClusterSoftware for IG <instance-group-name> in Cluster <cluster-name>.
Instance group patching started	UpdateClusterSoftware initiated for IG <instance-group-name> in Cluster <cluster-name> using <strategy> strategy.
Instance group patching start failed	Failed to initiate UpdateClusterSoftware for IG <instance-group-name> in Cluster <cluster-name>.
Next patching batch selected	Next update batch selected for IG <instance-group-name> in Cluster <cluster-name>.
Next patching batch selection failed	Failed to select the next update batch for IG <instance-group-name> in Cluster <cluster-name>.
Failed instances queued for replacement	Failed instances in IG <instance-group-name> in Cluster <cluster-name> queued for node replacement.
Failed instance replacement queueing failed	Failed to queue instances for node replacement in IG <instance-group-name> in Cluster <cluster-name>.

Event	Description
Instance group patching completed	UpdateClusterSoftware completed successfully for IG <instance-group-name> in Cluster <cluster-name>.
Instance group patching completion failed	Failed to complete UpdateClusterSoftware for IG <instance-group-name> in Cluster <cluster-name>.
Root volume replacement started	Root volume replacement started for Instance <instance-id> in IG <instance-group-name>.
Root volume replacement failed	Failed to start root volume replacement for Instance <instance-id> in IG <instance-group-name>.
Instance patching succeeded	Instance <instance-id> in IG <instance-group-name> updated successfully.

EKS-specific events

The following events are emitted only for HyperPod clusters orchestrated with Amazon EKS.

Access entry management

Event	Description
SLR access entry operation succeeded	SLR Access Entry <operation> successful for Cluster <cluster-name>
SLR access entry operation failed	SLR Access Entry <operation> failed for Cluster <cluster-name>
EKS access entries operation succeeded	EKS Access Entries <operation> successful for Cluster <cluster-name>
EKS access entries operation failed	EKS Access Entries <operation> failed for Cluster <cluster-name>

Kubernetes configuration updates

Event	Description
Kubernetes config update succeeded	Successfully updated Kubernetes config for instance <instance-id> in Cluster <cluster-name> and IG <instance-group-name>
Kubernetes config update failed	Failed to update Kubernetes config for instance <instance-id> in Cluster <cluster-name> and IG <instance-group-name>

Karpenter autoscaling

Event	Description
Autoscaling operation succeeded	AutoScaling <operation> <status> successfully in Cluster <cluster-name>
Autoscaling operation failed	Failed to <operation> AutoScaling in Cluster <cluster-name>
Karpenter CRD installation succeeded	CustomResourceDefinition installation completed successfully in EKS Cluster <cluster-name>
Karpenter CRD installation failed	CustomResourceDefinition installation failed for EKS Cluster <cluster-name>
Karpenter SLR access policy update succeeded	<operation> access policies with AmazonSageMakerHyperPodServiceRole access entry in EKS cluster <cluster-name> successfully
Karpenter SLR access policy update failed	Failed to <operation> access policies with AmazonSageMakerHyperPodServiceRole access entry in EKS cluster <cluster-name>

Patching — EKS instance-level

Event	Description
Instance patching preparation succeeded	Instance <instance-id> in IG <instance-group-name> cordoned and pods evicted.
Instance patching skipped (PDB violation)	UpdateClusterSoftware for Instance <instance-id> in IG <instance-group-name> skipped due to PodDisruptionBudget constraint.
Instance patching preparation failed	Failed to prepare instance <instance-id> in IG <instance-group-name> for UpdateClusterSoftware.
Instance restored to schedulable state	Instance <instance-id> in IG <instance-group-name> restored to schedulable state.
Instance restore to schedulable failed	Failed to restore instance <instance-id> in IG <instance-group-name> to schedulable state.

Patching — EKS rollback

Event	Description
Bake time started	Baking period started for IG <instance-group-name> in Cluster <cluster-name>. Monitoring alarms [<alarm-names>] for <duration> seconds.
Bake time completed	Baking period completed for IG <instance-group-name> in Cluster <cluster-name>. No alarms triggered during the <duration>-second baking period.
Bake time alarm triggered	Baking period failed for IG <instance-group-name> in Cluster <cluster-name>. Alarms [<alarm-names>] entered ALARM state. Initiating auto-rollback.

Event	Description
Bake time evaluation failed	Failed to evaluate alarms during baking period for IG <instance-group-name> in Cluster <cluster-name>.
Instance group patching rollback initiated	UpdateClusterSoftware failed for IG <instance-group-name> in Cluster <cluster-name>. Initiating rollback.
Instance group patching rollback failed	Rollback failed for IG <instance-group-name> in Cluster <cluster-name>. Some instances may be in FailedMaintenance state.
Instance patching rollback initiated	Instance <instance-id> in IG <instance-group-name> failed to update. Rollback initiated.
Instance patching rollback succeeded	Instance <instance-id> in IG <instance-group-name> rolled back successfully to previous AMI.
Instance patching rollback failed	UpdateClusterSoftware rollback failed for instance <instance-id> in IG <instance-group-name>.

Slurm-specific events

The following events are emitted only for HyperPod clusters orchestrated with Slurm.

Event	Description
Provisioning parameters found	Found provisioning_parameters.json in LifeCycleScript S3 Path for controller group <instance-group-name>
Provisioning parameters not found	No provisioning_parameters.json found in LifeCycleScript S3 Path for controller group <instance-group-name>
Slurm munge key created	Successfully created and stored munge key

Event	Description
Slurm drift validation passed	Slurm configuration drift validation passed
Slurm drift detected	Slurm configuration drift detected: <drift-details>
Slurm cluster rollback completed	Cluster creation failed: controller and login nodes did not become ready within the expected time
Slurm reconfiguration succeeded	Slurm was reconfigured successfully. Slurm config updated to match desired state

EventBridge integration

HyperPod sends cluster events to Amazon EventBridge using three detail types:

Detail type	Description
`SageMaker HyperPod Cluster Event`	Operational events for provisioning, scaling, patching, and orchestrator-specific operations. Includes `EventLevel` for severity filtering.
`SageMaker HyperPod Cluster State Change`	Cluster-level status transitions (for example, Creating to InService). Includes full cluster configuration.
`SageMaker HyperPod Cluster Node Health Event`	Health monitoring events from the HyperPod Health Monitoring Agent (HMA). Includes health status, reason, repair action, and recommendation.

Event pattern examples

All HyperPod cluster events:

```
{
  "source": ["aws.sagemaker"],
```

```
  "detail-type": ["SageMaker HyperPod Cluster Event"]
}
```

Error events only (for alerting):

```
{
  "source": ["aws.sagemaker"],
  "detail-type": ["SageMaker HyperPod Cluster Event"],
  "detail": {
    "EventDetails": {
      "EventLevel": ["Error"]
    }
  }
}
```

Events for a specific cluster:

```
{
  "source": ["aws.sagemaker"],
  "detail-type": ["SageMaker HyperPod Cluster Event"],
  "resources": ["arn:aws:sagemaker:us-west-2:111122223333:cluster/my-cluster-id"]
}
```

Node health events:

```
{
  "source": ["aws.sagemaker"],
  "detail-type": ["SageMaker HyperPod Cluster Node Health Event"]
}
```

API reference

- ListClusterEvents — List events with filtering, sorting, and pagination
- DescribeClusterEvent — Get full details for a specific event
- ClusterEventSummary — Event summary data type
- ClusterEventDetail — Event detail data type

HyperPod in Studio

You can launch machine learning workloads on Amazon SageMaker HyperPod clusters and view HyperPod cluster information in Amazon SageMaker Studio. The increased visibility into cluster details and hardware metrics can help your team identify the right candidate for your pre-training or fine-tuning workloads.

A set of commands are available to help you get started when you launch Studio IDEs on a HyperPod cluster. You can work on your training scripts, use Docker containers for the training scripts, and submit jobs to the cluster, all from within the Studio IDEs. The following sections provide information on how to set this up, how to discover clusters and monitor their tasks, how to view cluster information, and how to connect to HyperPod clusters in IDEs within Studio.

Topics

- Setting up HyperPod in Studio
- HyperPod tabs in Studio
- Connecting to HyperPod clusters and submitting tasks to clusters
- Troubleshooting

Setting up HyperPod in Studio

You need to set up the clusters depending on your choice of the cluster orchestrator to access your clusters through Amazon SageMaker Studio. In the following sections, choose the setup that matches with your orchestrator.

The instructions assume that you already have your cluster set up. For information on the cluster orchestrators and how to set up, start with the HyperPod orchestrator pages:

- Orchestrating SageMaker HyperPod clusters with Slurm
- Orchestrating SageMaker HyperPod clusters with Amazon EKS

Topics

- Setting up a Slurm cluster in Studio
- Setting up an Amazon EKS cluster in Studio

Setting up a Slurm cluster in Studio

The following instructions describe how to set up a HyperPod Slurm cluster in Studio.

1. Create a domain or have one ready. For information on creating a domain, see Guide to getting set up with Amazon SageMaker AI.
2. (Optional) Create and attach a custom FSx for Lustre volume to your domain.

   a. Ensure that your FSx Lustre file system exists in the same VPC as your intended domain, and is in one of the subnets present in the domain.

   b. You can follow the instructions in Adding a custom file system to a domain.
3. (Optional) We recommend that you add tags to your clusters to ensure a more smooth workflow. For information on how to add tags, see Edit a SageMaker HyperPod cluster to update your cluster using the SageMaker AI console.

   a. Tag your FSx for Lustre file system to your Studio domain. This will help you identify the file system while launching your Studio spaces. To do so, add the following tag to your cluster to identify it with the FSx filesystem ID, `fs-id`.

      Tag Key = "`hyperpod-cluster-filesystem`", Tag Value = "`fs-id`".

   b. Tag your Amazon Managed Grafana workspace to your Studio domain. Use this tag to link to your Grafana workspace directly from your cluster in Studio. Add the following tag to your cluster to identify it with your Grafana workspace ID, `ws-id`.

      Tag Key = "`grafana-workspace`", Tag Value = "`ws-id`".
4. Add the following permission to your execution role.

   For information on SageMaker AI execution roles and how to edit them, see Understanding domain space permissions and execution roles.

   To learn how to attach policies to an IAM user or group, see Adding and removing IAM identity permissions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:TerminateSession"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",

                "sagemaker:DescribeClusterNode",
                "sagemaker:ListClusterNodes",
                "sagemaker:UpdateCluster",
                "sagemaker:UpdateClusterSoftware"
            ],
            "Resource": "arn:aws-cn:sagemaker:us-east-1:111122223333:cluster/
*"
        }
    ]
```

```
}
```

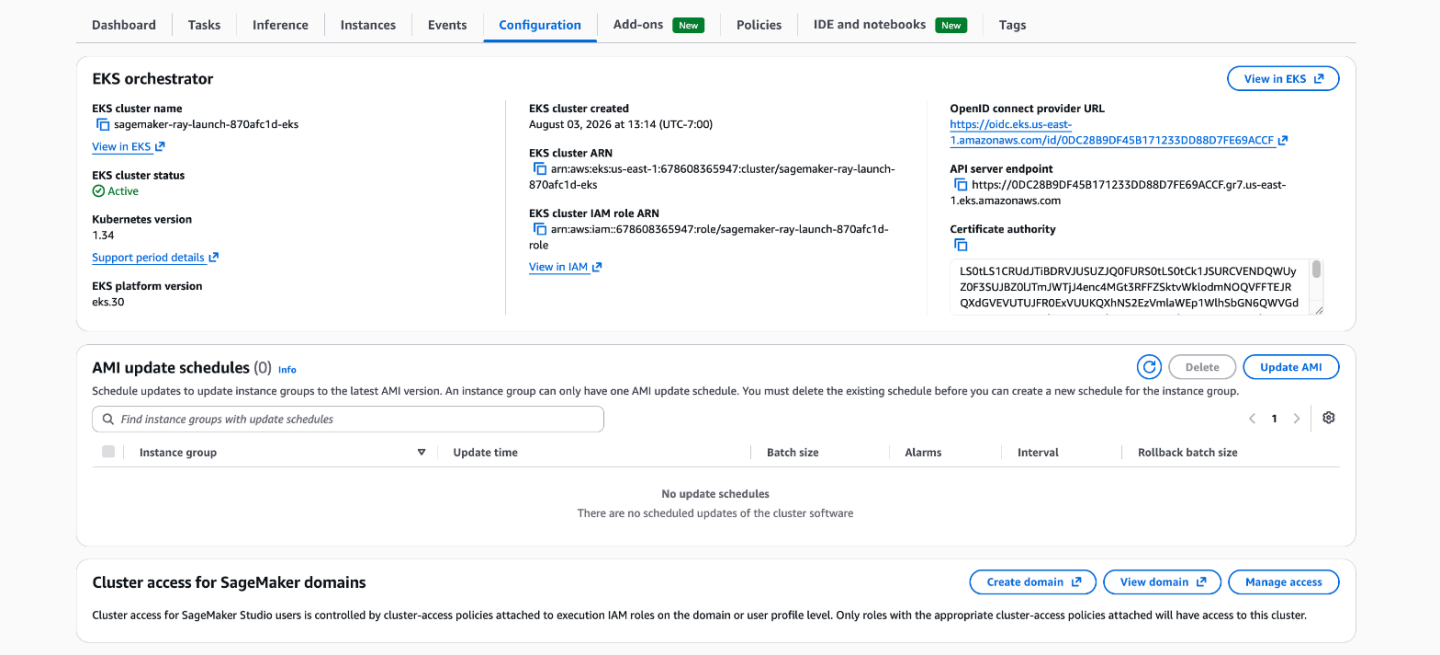
5. Add a tag to this IAM role, with Tag Key = "`SSMSessionRunAs`" and Tag Value = "`os user`". The `os user` here is the same user that you setup for the Slurm cluster. Manage access to SageMaker HyperPod clusters at an IAM role or user level by using the Run As feature in Amazon Systems Manager Agent (SSM Agent). With this feature, you can start each SSM session using the operating system (OS) user associated to the IAM role or user.

   For information on how to add tags to your execution role, see Tag IAM roles.
6. Turn on Run As support for Linux and macOS managed nodes. The Run As settings are account wide and is required for all SSM sessions to start successfully.
7. (Optional) Restrict task view in Studio for Slurm clusters. For information on viewable tasks in Studio, see Tasks.

In Amazon SageMaker Studio you can navigate to view your clusters in HyperPod clusters (under Compute).

Restrict task view in Studio for Slurm clusters

You can restrict users to view Slurm tasks that are authorized to view, without requiring manual input of namespaces or additional permissions checks. The restriction is applied based on the users' IAM role, providing a streamlined and secure user experience. The following section provides information on how to restrict task view in Studio for Slurm clusters. For information on viewable tasks in Studio, see Tasks.



All Studio users can view, manage, and interact with all Slurm cluster tasks by default. To restrict this, you can manage access to SageMaker HyperPod clusters at an IAM role or user level by using the **Run As** feature in Amazon Systems Manager Agent (SSM Agent).

You can do this by tagging IAM roles with specific identifiers, such as their username or group. When a user accesses Studio, the Session Manager uses the Run As feature to execute commands as a specific Slurm user account that matches their IAM role tags. The Slurm configuration can be set up to limit task visibility based on the user account. The Studio UI will automatically filter tasks visible to that specific user account when commands are executed through the Run As feature. Once set up, each user assuming the role with the specified identifiers will have those Slurm tasks filtered based on the Slurm configuration. For information on how to add tags to your execution role, see Tag IAM roles.

Setting up an Amazon EKS cluster in Studio

You do most of this setup from your HyperPod cluster details page in the SageMaker AI console. Open the SageMaker AI console, choose **HyperPod clusters**, choose your cluster, and then choose the **Configuration** tab. Under **Cluster access for SageMaker domains**, choose **Manage access**. This is where you create or view a domain and attach the cluster-access policies that let Studio users reach the cluster.

The following screenshot shows the **Cluster access for SageMaker domains** section on the **Configuration** tab.

The following instructions describe how to set up an Amazon EKS cluster in Studio.

1. Under the **Manage access** page, select an existing domain. Studio access to a HyperPod cluster runs through a domain, and the domain execution role is the IAM principal Studio uses to act on your cluster. For information on creating a domain, see Guide to getting set up with Amazon SageMaker AI.
2. Attach the following permissions to your execution role from the IAM console.

   For information on SageMaker AI execution roles and how to edit them, see Understanding domain space permissions and execution roles.

   To learn how to attach policies to an IAM user or group, see Adding and removing IAM identity permissions.

Before you attach the policy, replace both example ARNs with your own:

- Replace `arn:aws:sagemaker:us-east-1:111122223333:cluster/hyperpod-cluster-name` with your HyperPod cluster ARN.
- Replace `arn:aws:eks:us-east-1:111122223333:cluster/eks-cluster-name` with your Amazon EKS cluster ARN. It appears twice, in `UseEksClusterPermissions` and in `DescribeSpacesAddon`, where it carries a trailing `/*`.

These are two different resources with two different ARNs. Find the HyperPod cluster ARN in the SageMaker AI console and the Amazon EKS cluster ARN in the Amazon EKS console. If you leave the example values in place, Studio cannot describe your cluster and the **Tasks** tab does not load.

```
{
    "Version": "2012-10-17",

            "Effect": "Allow",
            "Action": "eks:DescribeAddon",
            "Resource": "arn:aws:eks:us-east-1:111122223333:cluster/eks-cluster-
name/*"
        },
        {
            "Sid": "ListClustersPermission",
            "Effect": "Allow",
            "Action": [
                "sagemaker:ListClusters"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
                "ssm:TerminateSession"
            ],
            "Resource": "*"
        }
```

```
    ]
}
```

3. Attach cluster-access policies to the execution role. The IAM policy in the previous step lets the execution role call the Amazon APIs. It does not give the role any permissions inside the Kubernetes cluster. Cluster-access policies do that, and only a role with the right ones attached reaches the cluster. Attach them from **Manage access**, on the domain or the user profile.

   Select the execution role for the domain or user profile you are granting access to, then select the policies your users need. Choose whether to scope access to a namespace or to the whole cluster, scoping to a namespace when teams share a cluster, and then save. Scoping to a namespace also restricts which tasks those users can see in Studio. For what each policy allows, how to scope access, and how to grant a custom set of permissions instead, see Restrict task view in Studio for EKS clusters.

   Granting access this way creates the Amazon EKS access entry for the execution role for you, so there is no separate step in the Amazon EKS console. For the concepts behind the access model, see Grant IAM users access to Kubernetes with EKS access entries.

4. (Optional) To ensure a more smooth experience, we recommend that you add tags to your clusters. For information on how to add tags, see Edit a SageMaker HyperPod cluster to update your cluster using the SageMaker AI console.

   Tag your Amazon Managed Grafana workspace to your Studio domain. Use this tag to link to your Grafana workspace directly from your cluster in Studio. Add the following tag to your cluster to identify it with your Grafana workspace ID, `ws-id`.

   Tag Key = “`grafana-workspace`”, Tag Value = “`ws-id`”.

Restrict task view in Studio for EKS clusters

You can restrict users’ visibility to specified Kubernetes namespaces, ensuring that users can access the resources they need while maintaining strict access controls.

There are two ways to do this. Scoping a cluster-access policy to a namespace is done entirely in the console and is the simpler option. A custom Kubernetes RBAC role gives you control over the exact verbs and resources a user gets, at the cost of managing the role yourself.

Restrict with a cluster-access policy

HyperPod provides cluster-access policies that you attach from **Manage access** on the **Configuration** tab. Attach only the policies a set of users needs, and scope the access to a namespace rather than to the whole cluster. This is the same flow as the third step above.

We recommend that you attach all of the policies to the role for the full HyperPod in Studio experience. Each policy covers a different part of the experience, so leaving one off removes the capability it grants. Attach a subset only when you intend to withhold a capability from that set of users.

Policy	What it allows
`AmazonSagemakerHyperpodTrainingPolicy`	Submit and manage training workloads. Full access to `RayCluster`, `RayJob`, and `RayCronJob`, to `HyperPodPyTorchJob`, to Kubeflow `PyTorchJob`, `MPIJob`, and `TFJob`, and to Kubernetes jobs and pods. Read access to pod logs, config maps, events, services, service accounts, resource quotas, limit ranges, deployments, stateful sets, replica sets, and Kueue local queues and workloads. Can create a `RayDashboardConnection`.
`AmazonSagemakerHyperpodInferencePolicy`	Deploy and manage inference workloads. Full access to `RayCluster` and `RayService`, to `JumpStartModel`, `InferenceEndpointConfig`, and `SageMakerEndpointRegistration`, and to pods. Read access to pod logs, config maps, events, services, service accounts, resource quotas, limit ranges, deployments, stateful sets, replica sets, horizontal pod autoscalers, ingresses, and Kueue local queues and workloads. Can create a `RayDashboardConnection`.
`AmazonSagemakerHyperpodSpacePolicy`	Use spaces for interactive development. Full access to `Workspace` resources, and read access to workspace templates, access strategies, and integration templates. Read access to pods, services, service accounts, persistent volume claims, events, resource quotas, bindings, daemon

Policy	What it allows
	sets, deployments, and replica sets. Can create a `Workspace Connection` , which is what opens a space.
`AmazonSagemakerHyperpodSpaceTemplatePolicy`	Read the shared space templates. Attach it scoped to the `jupyter-k8s-shared` namespace, where the templates live, rather than to the namespace your users work in.
`AmazonSagemakerHyperpodUserClusterPolicy`	See cluster-wide resources, which the Studio UI needs to render. Read access to namespaces and nodes, get access to custom resource definitions, read access to Kueue cluster queues, resource flavors, and workload priority classes, and permission to check the user's own access. Attach it scoped to the cluster rather than to a namespace.

Full access means get, list, watch, create, update, patch, and delete.

These are Amazon EKS cluster-access policies, not IAM managed policies. Their ARNs take the form `arn:<partition>:eks::aws:cluster-access-policy/<name>`. Attaching one through **Manage access** creates the Amazon EKS access entry for the execution role, which is what applies the policy to the role.

Restrict with a custom Kubernetes RBAC role

Use a custom role when you want to grant a custom set of permissions instead of the ones a cluster-access policy provides. The following configuration allows administrators to grant specific, limited access to data scientists for viewing tasks within the cluster. This configuration grants the following permissions:

- List and get pods
- List and get events
- Get Custom Resource Definitions (CRDs)

YAML Configuration

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
```

```
metadata:
  name: pods-events-crd-cluster-role
rules:
- apiGroups: [""]
  resources: ["pods"]
  verbs: ["get", "list"]
- apiGroups: [""]
  resources: ["events"]
  verbs: ["get", "list"]
- apiGroups: ["apiextensions.k8s.io"]
  resources: ["customresourcedefinitions"]
  verbs: ["get"]
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: pods-events-crd-cluster-role-binding
subjects:
- kind: Group
  name: pods-events-crd-cluster-level
  apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: ClusterRole
  name: pods-events-crd-cluster-role
  apiGroup: rbac.authorization.k8s.io
```

1. Save the YAML configuration to a file named `cluster-role.yaml`.
2. Apply the configuration using kubectl from the Kubernetes website:

   ```
   kubectl apply -f cluster-role.yaml
   ```

3. Verify the configuration:

   ```
   kubectl get clusterrole pods-events-crd-cluster-role
   kubectl get clusterrolebinding pods-events-crd-cluster-role-binding
   ```

4. Assign users to the `pods-events-crd-cluster-level` group through your identity provider or IAM.

HyperPod tabs in Studio

In Amazon SageMaker Studio you can navigate to one of your clusters in **HyperPod clusters** (under **Compute**) and view your list of clusters. The displayed clusters contain information like tasks, hardware metrics, settings, and metadata details. This visibility can help your team identify the right candidate for your pre-training or finetuning workloads. The following sections provide information on each type of information.

Tasks

Amazon SageMaker HyperPod provides a view of your cluster tasks. Tasks are operations or jobs that are sent to the cluster. These can be machine learning operations, like training, running experiments, or inference. The following section provides information on your HyperPod cluster tasks.

In Amazon SageMaker Studio, you can navigate to one of your clusters in **HyperPod clusters** (under **Compute**) and view the **Tasks** information on your cluster. If you are having any issues with viewing tasks, see Troubleshooting.

The task table includes:

For Slurm clusters

For Slurm clusters, the tasks currently in the Slurm job scheduler queue are shown in the table. The information shown for each task includes the task name, status, job ID, partition, run time, nodes, created by, and actions.

For a list and details about past jobs, use the `sacct` command from the Slurm documentation in JupyterLab or a Code Editor terminal. The `sacct` command shows *historical information* about jobs that have *finished* or are *complete* in the system. It provides accounting information, including job resources usage like memory and exit status.

By default, all Studio users can view, manage, and interact with all available Slurm tasks. To restrict the viewable tasks to Studio users, see Restrict task view in Studio for Slurm clusters.

For Amazon EKS clusters

For Amazon EKS clusters, kubeflow (PyTorch, MPI, TensorFlow) tasks are shown in the table. PyTorch tasks are shown by default. You can sort for PyTorch, MPI, and TensorFlow under **Task type**. The information that is shown for each task includes the task name, status, namespace, priority class, and creation time.

By default, all users can view jobs across all namespaces. To restrict the viewable Kubernetes namespaces available to Studio users, see Restrict task view in Studio for EKS clusters. If a user cannot view the tasks and is asked to provide a namespace, they need to get that information from the administrator.

Metrics

Amazon SageMaker HyperPod provides a view of your Slurm or Amazon EKS cluster utilization metrics. The following provides information on your HyperPod cluster metrics.

You will need to install the Amazon EKS add-on to view the following metrics. For more information, see Install the Amazon CloudWatch Observability EKS add-on.

In Amazon SageMaker Studio, you can navigate to one of your clusters in **HyperPod clusters** (under **Compute**) and view the **Metrics** details on your cluster. Metrics provides a comprehensive view of cluster utilization metrics, including hardware, team, and task metrics. This includes compute availability and usage, team allocation and utilization, and task run and wait time information.

Settings

Amazon SageMaker HyperPod provides a view of your cluster settings. The following provides information on your HyperPod cluster settings.

In Amazon SageMaker Studio you can navigate to one of your clusters in **HyperPod clusters** (under **Compute**) and view the **Settings** information on your cluster. The information includes the following:

- **Instances** details, including instance ID, status, instance type, and instance group
- **Instance groups** details, including instance group name, type, counts, and compute information
- **Orchestration** details, including the orchestrator, version, and certification authority
- **Cluster resiliency** details
- **Security** details, including subnets and security groups

IDE and Notebooks

Amazon SageMaker HyperPod provides a view of the development spaces running on your cluster. Spaces are self-contained environments for running JupyterLab or Code Editor IDEs directly on

your HyperPod EKS cluster. You can create, configure, start, stop, and open spaces directly from Studio.

In Amazon SageMaker Studio, navigate to one of your clusters in **HyperPod clusters** (under **Compute**) and choose the **IDE and Notebooks** tab.

Key capabilities available through Studio include:

- Create spaces with configurable compute, storage, and image settings through a guided form.
- View all spaces in a searchable table showing name, application type, status, access type, storage, GPU, and vCPU allocations.
- Start and stop spaces with a single click to manage compute costs.
- Open spaces directly in the browser (JupyterLab or Code Editor) or connect through a Remote IDE. For more information, see the section called “Remote access using SSH over SSM”.
- Delete spaces that are no longer needed.
- Select namespaces to organize spaces by team with resource quotas and governance settings.
- Apply templates for consistent space configurations across teams.

For information on creating a domain, see Guide to getting set up with Amazon SageMaker AI.

Prerequisites

- Install the HyperPod add-on on your cluster. For more information, see the section called “Install SageMaker AI Spaces Add-on”.
- Set up your cluster to be used in Studio. For more information, see Setting up an Amazon EKS cluster in Studio.
- To enable private spaces among users with the same execution role, you must ensure the `ExecutionRoleSessionNameMode` flag is set to `USER_IDENTITY`. With the HyperPod Spaces feature, the username used inside the space is automatically derived from the Studio authentication context, allowing users to have a consistent identity across Studio and HyperPod Spaces without requiring additional sign-in.

  For Studio domains configured in IAM authentication mode, the Spaces username is derived from the IAM role session name. This corresponds to the IAM session used to launch Studio, either through the Amazon Management Console or through a presigned Studio URL. For Studio domains configured in IAM Identity Center authentication mode, the Spaces username is the sanitized authenticated IAM Identity Center username.

This is set by default for new domains and can be overridden for older domains. This setting can also be overridden for each user profile. For more information, see the section called "Execution role session name mode".

How it works

Once the add-on is installed and access is configured, navigate to your HyperPod cluster in Studio and select the **IDE and Notebooks** tab to see the spaces management interface.

Creating a space

To create a new space, choose **Create space**. The creation form allows you to configure the following:

- **Namespace**: Select your team namespace with resource quotas and governance settings. This determines your available compute allocation.
- **Space settings:**
  - **Template**: Select a pre-configured template (for example, JupyterLab or Code Editor) to apply default settings.
  - **Compute**: Choose between GPU and CPU configurations with fine-grained control over GPUs, vCPUs, and memory.
  - **GPU partition**: If fractional GPU is enabled, you can choose a partition to use for your workspace.
  - **Image**: Select from available container images or custom images configured by your administrator.
  - **EBS space storage**: Configure persistent storage for your notebooks and data.
- **Task governance**: When enabled for the namespace, spaces integrate with HyperPod task governance for resource management and priority scheduling. For more information, see the section called "Task governance for Interactive Spaces on HyperPod".

Managing spaces

The spaces table provides a consolidated view of all your environments, including status and resource allocations.

From the **Actions** column, you can:

- Stop a running space to release compute resources while preserving your data on EBS storage.
- Open the space in your browser to launch the JupyterLab or Code Editor web interface.
- Connect using a Remote IDE. For more information, see the section called "Remote access using SSH over SSM".

Connecting to your space

Spaces support two connection methods:

Web UI access

Choose **Open** from the spaces table to launch the IDE directly in your browser. This opens a fully functional JupyterLab or Code Editor interface hosted on your HyperPod cluster. No local software installation is required beyond a web browser. This is ideal for quick iterations, notebook-based exploration, and collaborative work. To enable Web UI access on your cluster, see the section called "Web browser access".

Remote IDE connection

Choose **Open in Remote IDE** from the spaces table to connect your local IDE to the space running on HyperPod. This provides a secure connection without requiring you to manage SSH keys or expose port 22. You get the full power of your local development environment while running code on HyperPod cluster compute. For more information, see the section called "Remote access using SSH over SSM".

Details

Amazon SageMaker HyperPod provides a view of your cluster metadata details. The following paragraph provides information on how to get your HyperPod cluster details.

In Amazon SageMaker Studio, you can navigate to one of your clusters in **HyperPod clusters** (under **Compute**) and view the **Details** on your cluster. This includes the tags, logs, and metadata.

Connecting to HyperPod clusters and submitting tasks to clusters

You can launch machine learning workloads on HyperPod clusters within Amazon SageMaker Studio IDEs. When you launch Studio IDEs on a HyperPod cluster, a set of commands are available to help you get started. You can work on your training scripts, use Docker containers for the training scripts, and submit jobs to the cluster, all from within the Studio IDEs. The following section provides information on how to connect your cluster to Studio IDEs.

In Amazon SageMaker Studio you can navigate to one of your clusters in **HyperPod clusters** (under **Compute**) and view your list of clusters. You can connect your cluster to an IDE listed under **Actions**.

You can also choose your custom file system from the list of options. For information on how to get this set up, see Setting up HyperPod in Studio.

Alternatively, you can create a space and launch an IDE using the Amazon CLI. Use the following commands to do so. The following example creates a `Private JupyterLab` space for *`user-profile-name`* with the *`fs-id`* FSx for Lustre file system attached.

1. Create a space using the `create-space` Amazon CLI.

```
aws sagemaker create-space \
--region your-region \
--ownership-settings "OwnerUserProfileName=user-profile-name" \
--space-sharing-settings "SharingType=Private" \
--space-settings
 "AppType=JupyterLab,CustomFileSystems=[{FSxLustreFileSystem={FileSystemId=fs-
id}}]"
```

2. Create the app using the `create-app` Amazon CLI.

```
aws sagemaker create-app \
--region your-region \
--space-name space-name \
--resource-spec '{"ec2InstanceType":"'"instance-
type"'","appEnvironmentArn":"'"image-arn"'"}'
```

Once you have your applications open, you can submit tasks directly to the clusters you are connected to.

Troubleshooting

The following section lists troubleshooting solutions for HyperPod in Studio.

Topics

- Tasks tab
- Metrics tab

Tasks tab

If you get Custom Resource Definition (CRD) is not configured on the cluster while in the **Tasks** tab.

- Grant `EKSAdminViewPolicy` and `ClusterAccessRole` policies to your domain execution role.

  For information on how to add tags to your execution role, see Tag IAM roles.

  To learn how to attach policies to an IAM user or group, see Adding and removing IAM identity permissions.

If the tasks grid for Slurm metrics doesn't stop loading in the **Tasks** tab.

- Ensure that `RunAs` enabled in your Amazon Session Manager preferences and the role you are using has the `SSMSessionRunAs` tag attached.
  - To enable `RunAs`, navigate to the **Preference** tab in the Systems Manager console.
  - Turn on Run As support for Linux and macOS managed nodes

For restricted task view in Studio for EKS clusters:

- If your execution role doesn't have permissions to list namespaces for EKS clusters.
  - See Restrict task view in Studio for EKS clusters.
- If users are experiencing issues with access for EKS clusters.

  1. Verify RBAC is enabled by running the following Amazon CLI command.

     ```
     kubectl api-versions | grep rbac
     ```

     This should return rbac.authorization.k8s.io/v1.
  2. Check if the `ClusterRole` and `ClusterRoleBinding` exist by running the following commands.

     ```
     kubectl get clusterrole pods-events-crd-cluster-role
     kubectl get clusterrolebinding pods-events-crd-cluster-role-binding
     ```
  3. Verify user group membership. Ensure the user is correctly assigned to the `pods-events-crd-cluster-level` group in your identity provider or IAM.
- If user can't see any resources.

  - Verify group membership and ensure the `ClusterRoleBinding` is correctly applied.
- If users can see resources in all namespaces.
  - If namespace restriction is required, consider using `Role` and `RoleBinding` instead of `ClusterRole` and `ClusterRoleBinding`.
- If configuration appears correct, but permissions aren't applied.
  - Check if there are any `NetworkPolicies` or `PodSecurityPolicies` interfering with access.

Metrics tab

If there are no Amazon CloudWatch metrics are displayed in the **Metrics** tab.

- The `Metrics` section of HyperPod cluster details uses CloudWatch to fetch the data. In order to see the metrics in this section, you need to have enabled Cluster and task observability. Contact your administrator to configure metrics.

SageMaker HyperPod references

Find more information and references about using SageMaker HyperPod in the following topics.

Topics

- SageMaker HyperPod pricing
- SageMaker HyperPod APIs
- SageMaker HyperPod Slurm configuration
- SageMaker HyperPod DLAMI
- SageMaker HyperPod API permissions reference
- SageMaker HyperPod commands in Amazon CLI
- SageMaker HyperPod Python modules in Amazon SDK for Python (Boto3)

SageMaker HyperPod pricing

The following topics provide information about SageMaker HyperPod pricing. To find more details on price per hour for using SageMaker HyperPod instances, see also Amazon SageMaker Pricing.

Capacity requests

You can allocate on-demand or reserved compute capacity with SageMaker AI for use on SageMaker HyperPod. On-demand cluster creation allocates available capacity from the SageMaker AI on-demand capacity pool. Alternatively, you can request reserved capacity to ensure access by submitting a ticket for a quota increase. Inbound capacity requests are prioritized by SageMaker AI and you receive an estimated time for capacity allocation.

Service billing

When you provision a compute capacity on SageMaker HyperPod, you are billed for the duration of the capacity allocation. SageMaker HyperPod billing appears in your anniversary bills with a line item for the type of capacity allocation (on-demand, reserved), the instance type, and the time spent on using the instance.

To submit a ticket for a quota increase, see the section called “SageMaker HyperPod quotas”.

SageMaker HyperPod APIs

The following list is a full set of SageMaker HyperPod APIs for submitting action requests in JSON format to SageMaker AI through Amazon CLI or Amazon SDK for Python (Boto3).

- BatchDeleteClusterNodes
- CreateCluster
- DeleteCluster
- DescribeCluster
- DescribeClusterNode
- ListClusterNodes
- ListClusters
- UpdateCluster
- UpdateClusterSoftware

SageMaker HyperPod Slurm configuration

HyperPod supports two approaches for configuring Slurm on your cluster. Choose the approach that best fits your needs.

Approach	Description	Recommended For
API-driven configuration	Define Slurm configuration directly in the CreateCluster and UpdateCluster API requests	New clusters; simplified management
Legacy configuration	Use a separate `provisioning_parameters.json` file stored in Amazon S3	Existing clusters; backward compatibility

API-driven Slurm configuration (Recommended)

With API-driven configuration, you define Slurm node types, partition assignments, and filesystem mounts directly in the CreateCluster and UpdateCluster API requests. This approach provides:

- **Single source of truth** – All configuration in the API request
- **No S3 file management** – No need to create or maintain `provisioning_parameters.json`
- **Built-in validation** – API validates Slurm topology before cluster creation
- **Drift detection** – Detects unauthorized changes to `slurm.conf`
- **Per-instance-group storage** – Configure different FSx filesystems for different instance groups
- **FSx for OpenZFS support** – Mount OpenZFS filesystems in addition to FSx for Lustre

SlurmConfig (per instance group)

Add `SlurmConfig` to each instance group to define the Slurm node type and partition assignment.

```
"SlurmConfig": {
    "NodeType": "Controller | Login | Compute",
    "PartitionNames": ["string"]
}
```

Parameters:

- `NodeType` – Required. The Slurm node type for this instance group. Valid values:
  - `Controller` – Slurm controller (head) node. Runs the `slurmctld` daemon. Exactly one instance group must have this node type.

- `Login` – Login node for user access. Optional. At most one instance group can have this node type.
- `Compute` – Worker nodes that execute jobs. Can have multiple instance groups with this node type.

> **Important**
>
> `NodeType` is immutable. Once set during cluster creation, it cannot be changed. To use a different node type, create a new instance group.

- `PartitionNames` – Conditional. An array of Slurm partition names. Required for `Compute` node types; not allowed for `Controller` or `Login` node types. Currently supports a single partition name per instance group.

> **Note**
>
> All nodes are automatically added to the universal `dev` partition in addition to their specified partition.

Example:

```
{
    "InstanceGroupName": "gpu-compute",
    "InstanceType": "ml.p4d.24xlarge",
    "InstanceCount": 8,
    "SlurmConfig": {
        "NodeType": "Compute",
        "PartitionNames": ["gpu-training"]
    },
    "LifeCycleConfig": {
        "SourceS3Uri": "s3://sagemaker-bucket/lifecycle/src/",
        "OnCreate": "on_create.sh"
    },
    "ExecutionRole": "arn:aws:iam::111122223333:role/HyperPodRole"
}
```

Orchestrator.Slurm (cluster level)

Add `Orchestrator.Slurm` to the cluster configuration to specify how HyperPod manages the `slurm.conf` file.

```
"Orchestrator": {
    "Slurm": {
        "SlurmConfigStrategy": "Managed | Overwrite | Merge"
    }
}
```

Parameters:

- `SlurmConfigStrategy` – Required when `Orchestrator.Slurm` is provided. Controls how HyperPod manages the `slurm.conf` file on the controller node. Valid values:
  - `Managed` (default) – HyperPod fully controls the partition-node mappings in `slurm.conf`. Drift detection is enabled: if the current `slurm.conf` differs from the expected configuration, UpdateCluster fails with an error. Use this strategy when you want HyperPod to be the single source of truth for Slurm configuration.
  - `Overwrite` – HyperPod forces the API configuration to be applied, overwriting any manual changes to `slurm.conf`. Drift detection is disabled. Use this strategy to recover from drift or reset the cluster to a known state.
  - `Merge` – HyperPod preserves manual `slurm.conf` changes and merges them with the API configuration. Drift detection is disabled. Use this strategy if you need to make manual Slurm configuration changes that should persist across updates.

> **Note**
>
> If `Orchestrator.Slurm` is omitted from the request, the default behavior is `Managed` strategy.

> **Tip**
>
> You can change `SlurmConfigStrategy` at any time using UpdateCluster. There is no lock-in to a specific strategy.

Example:

```
{
    "ClusterName": "my-hyperpod-cluster",
    "InstanceGroups": [...],
    "Orchestrator": {
        "Slurm": {
            "SlurmConfigStrategy": "Managed"
        }
    }
}
```

SlurmConfigStrategy comparison

Strategy	Drift Detection	Manual Changes	Use Case
`Managed`	Enabled – blocks updates if drift detected	Blocked	HyperPod managed
`Overwrite`	Disabled	Overwritten	Recovery from drift; reset to known state
`Merge`	Disabled	Preserved	Advanced users with custom `slurm.conf` needs

FSx configuration via InstanceStorageConfigs

With API-driven configuration, you can configure FSx filesystems per instance group using `InstanceStorageConfigs`. This allows different instance groups to mount different filesystems.

Prerequisites:

- Your cluster must use a custom VPC (via `VpcConfig`). FSx filesystems reside in your VPC, and the platform-managed VPC cannot reach them.
- At least one instance group must have `SlurmConfig` with `NodeType: Controller`.

FsxLustreConfig

Configure FSx for Lustre filesystem mounting for an instance group.

```
"InstanceStorageConfigs": [
    {
        "FsxLustreConfig": {
            "DnsName": "string",
            "MountPath": "string",
            "MountName": "string"
        }
    }
]
```

Parameters:

- `DnsName` – Required. The DNS name of the FSx for Lustre filesystem. Example: `fs-0abc123def456789.fsx.us-west-2.amazonaws.com`
- `MountPath` – Optional. The local mount path on the instance. Default: `/fsx`
- `MountName` – Required. The mount name of the FSx for Lustre filesystem. You can find this in the Amazon FSx console or by running `aws fsx describe-file-systems`.

FsxOpenZfsConfig

Configure FSx for OpenZFS filesystem mounting for an instance group.

```
"InstanceStorageConfigs": [
    {
        "FsxOpenZfsConfig": {
            "DnsName": "string",
            "MountPath": "string"
        }
    }
]
```

Parameters:

- `DnsName` – Required. The DNS name of the FSx for OpenZFS filesystem. Example: `fs-0xyz987654321.fsx.us-west-2.amazonaws.com`
- `MountPath` – Optional. The local mount path on the instance. Default: `/home`

> **Note**
>
> Each instance group can have at most one `FsxLustreConfig` and one `FsxOpenZfsConfig`.

Example with multiple filesystems:

```
{
    "InstanceGroupName": "gpu-compute",
    "InstanceType": "ml.p4d.24xlarge",
    "InstanceCount": 4,
    "SlurmConfig": {
        "NodeType": "Compute",
        "PartitionNames": ["gpu-training"]
    },
    "InstanceStorageConfigs": [
        {
            "FsxLustreConfig": {
                "DnsName": "fs-0abc123def456789.fsx.us-west-2.amazonaws.com",
                "MountPath": "/fsx",
                "MountName": "abcdefgh"
            }
        },
        {
            "FsxOpenZfsConfig": {
                "DnsName": "fs-0xyz987654321.fsx.us-west-2.amazonaws.com",
                "MountPath": "/shared"
            }
        },
        {
            "EbsVolumeConfig": {
                "VolumeSizeInGB": 500
            }
        }
    ],
    "LifeCycleConfig": {
        "SourceS3Uri": "s3://sagemaker-bucket/lifecycle/src/",
        "OnCreate": "on_create.sh"
    },
    "ExecutionRole": "arn:aws:iam::111122223333:role/HyperPodRole"
}
```

Important

FSx configuration changes only apply during node provisioning. Existing nodes retain their original FSx configuration. To apply new FSx configuration to all nodes, scale down the instance group to 0, then scale back up.

Complete API-driven configuration example

The following example shows a complete CreateCluster request using API-driven Slurm configuration:

```
{
    "ClusterName": "ml-training-cluster",
    "InstanceGroups": [
        {
            "InstanceGroupName": "controller",
            "InstanceType": "ml.c5.xlarge",
            "InstanceCount": 1,
            "SlurmConfig": {
                "NodeType": "Controller"
            },
            "LifeCycleConfig": {
                "SourceS3Uri": "s3://sagemaker-us-west-2-111122223333/lifecycle/src/",
                "OnCreate": "on_create.sh"
            },
            "ExecutionRole": "arn:aws:iam::111122223333:role/HyperPodRole",
            "ThreadsPerCore": 2
        },
        {
            "InstanceGroupName": "login",
            "InstanceType": "ml.m5.xlarge",
            "InstanceCount": 1,
            "SlurmConfig": {
                "NodeType": "Login"
            },
            "LifeCycleConfig": {
                "SourceS3Uri": "s3://sagemaker-us-west-2-111122223333/lifecycle/src/",
                "OnCreate": "on_create.sh"
            },
            "ExecutionRole": "arn:aws:iam::111122223333:role/HyperPodRole",
            "ThreadsPerCore": 2
```

```
        },
        {
            "InstanceGroupName": "gpu-compute",
            "InstanceType": "ml.p4d.24xlarge",
            "InstanceCount": 8,
            "SlurmConfig": {
                "NodeType": "Compute",
                "PartitionNames": ["gpu-training"]
            },
            "InstanceStorageConfigs": [
                {
                    "FsxLustreConfig": {
                        "DnsName": "fs-0abc123def456789.fsx.us-west-2.amazonaws.com",
                        "MountPath": "/fsx",
                        "MountName": "abcdefgh"
                    }
                }
            ],
            "LifeCycleConfig": {
                "SourceS3Uri": "s3://sagemaker-us-west-2-111122223333/lifecycle/src/",
                "OnCreate": "on_create.sh"
            },
            "ExecutionRole": "arn:aws:iam::111122223333:role/HyperPodRole",
            "ThreadsPerCore": 2,
            "OnStartDeepHealthChecks": ["InstanceStress", "InstanceConnectivity"]
        },
        {
            "InstanceGroupName": "cpu-compute",
            "InstanceType": "ml.c5.18xlarge",
            "InstanceCount": 4,
            "SlurmConfig": {
                "NodeType": "Compute",
                "PartitionNames": ["cpu-preprocessing"]
            },
            "InstanceStorageConfigs": [
                {
                    "FsxLustreConfig": {
                        "DnsName": "fs-0abc123def456789.fsx.us-west-2.amazonaws.com",
                        "MountPath": "/fsx",
                        "MountName": "abcdefgh"
                    }
                }
            ],
            "LifeCycleConfig": {
```

```
                "SourceS3Uri": "s3://sagemaker-us-west-2-111122223333/lifecycle/src/",
                "OnCreate": "on_create.sh"
            },
            "ExecutionRole": "arn:aws:iam::111122223333:role/HyperPodRole",
            "ThreadsPerCore": 2
        }
    ],
    "Orchestrator": {
        "Slurm": {
            "SlurmConfigStrategy": "Managed"
        }
    },
    "VpcConfig": {
        "SecurityGroupIds": ["sg-0abc123def456789a"],
        "Subnets": ["subnet-0abc123def456789a", "subnet-0abc123def456789b"]
    },
    "Tags": [
        {
            "Key": "Project",
            "Value": "ML-Training"
        }
    ]
}
```

To learn more about using API-driven configuration, see the section called “Lifecycle scripts”.

Legacy configuration: provisioning_parameters.json

> **Note**
>
> The `provisioning_parameters.json` approach is the legacy method for configuring Slurm on HyperPod. For new clusters, we recommend using the API-driven configuration approach described above. The legacy approach remains fully supported for backward compatibility.

With the legacy approach, you create a Slurm configuration file named `provisioning_parameters.json` and upload it to Amazon S3 as part of your lifecycle scripts. HyperPod reads this file during cluster creation to configure Slurm nodes.

Configuration form for provisioning_parameters.json

The following code is the Slurm configuration form you should prepare to properly set up Slurm nodes on your HyperPod cluster. You should complete this form and upload it as part of a set of lifecycle scripts during cluster creation. To learn how this form should be prepared throughout HyperPod cluster creation processes, see the section called “Lifecycle scripts”.

```
// Save as provisioning_parameters.json.
{
    "version": "1.0.0",
    "workload_manager": "slurm",
    "controller_group": "string",
    "login_group": "string",
    "worker_groups": [
        {
            "instance_group_name": "string",
            "partition_name": "string"
        }
    ],
    "fsx_dns_name": "string",
    "fsx_mountname": "string"
}
```

Parameters:

- `version` – Required. This is the version of the HyperPod provisioning parameter form. Keep it to `1.0.0`.
- `workload_manager` – Required. This is for specifying which workload manager to be configured on the HyperPod cluster. Keep it to `slurm`.
- `controller_group` – Required. This is for specifying the name of the HyperPod cluster instance group you want to assign to Slurm controller (head) node.
- `login_group` – Optional. This is for specifying the name of the HyperPod cluster instance group you want to assign to Slurm login node.
- `worker_groups` – Required. This is for setting up Slurm worker (compute) nodes on the HyperPod cluster.
  - `instance_group_name` – Required. This is for specifying the name of the HyperPod instance group you want to assign to Slurm worker (compute) node.
  - `partition_name` – Required. This is for specifying the partition name to the node.

- `fsx_dns_name` – Optional. If you want to set up your Slurm nodes on the HyperPod cluster to communicate with Amazon FSx, specify the FSx DNS name.
- `fsx_mountname` – Optional. If you want to set up your Slurm nodes on the HyperPod cluster to communicate with Amazon FSx, specify the FSx mount name.

Comparison: API-driven vs. legacy configuration

Feature	API-driven (Recommended)	Legacy (provisioning_parameters.json)
Configuration location	CreateCluster API request	S3 file
FSx for Lustre	Yes – Per instance group	Yes – Cluster-wide only
FSx for OpenZFS	Yes – Per instance group	No – Not supported
Built-in validation	Yes	No
Drift detection	Yes – (Managed strategy)	No
S3 file management	Not required	Required
Lifecycle script complexity	Simplified	Full SLURM setup required

SageMaker HyperPod DLAMI

SageMaker HyperPod runs a DLAMI based on:

- Amazon Deep Learning Base GPU AMI (Ubuntu 20.04) for orchestration with Slurm.
- Amazon Linux 2 based AMI for orchestration with Amazon EKS.

The SageMaker HyperPod DLAMI is bundled with additional packages to support open source tools such as Slurm, Kubernetes, dependencies, and SageMaker HyperPod cluster software packages to support resiliency features such as cluster health check and auto-resume. To follow up with HyperPod software updates that the HyperPod service team distributes through DLAMIs, see the section called “HyperPod release notes”.

SageMaker HyperPod API permissions reference

Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.
Amazon managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

When you are setting up access control for allowing to run SageMaker HyperPod API operations and writing a permissions policy that you can attach to IAM users for cloud administrators, use the following table as a reference.

Amazon SageMaker API Operations	Required Permissions (API Actions)	Resources
CreateCluster	`sagemaker:CreateCluster`	`arn:aws:sagemaker:region:account-id:cluster/cluster-id`
DeleteCluster	`sagemaker:DeleteCluster`	`arn:aws:sagemaker:region:account-id:cluster/cluster-id`
DescribeCluster	`sagemaker:DescribeCluster`	`arn:aws:sagemaker:region:account-id:cluster/cluster-id`

DescribeClusterNode	sagemaker:DescribeClusterNode	arn:aws:sagemaker:*region*:*account-id*:cluster/*cluster-id*
ListClusterNodes	sagemaker:ListClusterNodes	arn:aws:sagemaker:*region*:*account-id*:cluster/*cluster-id*
ListClusters	sagemaker:ListClusters	arn:aws:sagemaker:*region*:*account-id*:cluster/*cluster-id*
UpdateCluster	sagemaker:UpdateCluster	arn:aws:sagemaker:*region*:*account-id*:cluster/*cluster-id*
UpdateClusterSoftware	sagemaker:UpdateClusterSoftware	arn:aws:sagemaker:*region*:*account-id*:cluster/*cluster-id*

For a complete list of permissions and resource types for SageMaker APIs, see Actions, resources, and condition keys for Amazon SageMaker AI in the *Amazon Service Authorization Reference*.

SageMaker HyperPod commands in Amazon CLI

The following are the Amazon CLI commands for SageMaker HyperPod to run the core HyperPod API operations.

- batch-delete-cluster-nodes
- create-cluster
- delete-cluster
- describe-cluster

- describe-cluster-node
- list-cluster-nodes
- list-clusters
- update-cluster
- update-cluster-software

SageMaker HyperPod Python modules in Amazon SDK for Python (Boto3)

The following are the methods of the Amazon SDK for Python (Boto3) client for SageMaker AI to run the core HyperPod API operations.

- batch_delete_cluster_nodes
- create_cluster
- delete_cluster
- describe_cluster
- describe_cluster_node
- list_cluster_nodes
- list_clusters
- update_cluster
- update_cluster_software

Amazon SageMaker HyperPod release notes

This topic covers release notes that track update, fixes, and new features for Amazon SageMaker HyperPod. If you are looking for general feature releases, updates, and improvements for Amazon SageMaker HyperPod, you might find this page helpful.

The HyperPod AMI releases are documented separately to include information of the key components including general AMI releases, versions, and dependencies. If you are looking for these information related to HyperPod AMI releases, see the section called “HyperPod AMI”.

SageMaker HyperPod release notes: April 16, 2026

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features

- **Flexible instance groups** – You can now create instance groups with multiple instance types using the new `InstanceRequirements` parameter. This enables priority-based provisioning, where HyperPod attempts to provision the highest-priority instance type first and falls back to lower-priority types if capacity is unavailable. Flexible instance groups simplify Karpenter auto-scaling configurations by reducing the number of instance groups needed. You can specify up to 20 instance types per instance group. For more information, see Flexible instance groups.

SageMaker HyperPod release notes: January 25, 2026

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features

- Released the new SageMaker HyperPod AMI for Amazon EKS 1.34. For more information, see the section called "January 25, 2026".

For more information, see Kubernetes v1.34.

SageMaker HyperPod release notes: November 07, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features

- Upgraded security patches the section called "November 07, 2025".

SageMaker HyperPod release notes: September 29, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features

- Released the new SageMaker HyperPod AMI for Amazon EKS 1.33. For more information, the section called "September 29, 2025".

Important

- The Dynamic Resource Allocation beta Kubernetes API is enabled by default in this release.
  - This API improves scheduling and monitoring workloads that require resources such as GPUs.
  - This API was developed by the open source Kubernetes community and might change in future versions of Kubernetes. Before you use the API, review the Kubernetes documentation and understand how it affects your workloads.
- HyperPod is not releasing a HyperPod Amazon Linux 2 AMI for Kubernetes 1.33. Amazon recommends that you migrate to AL2023. For more information, see Upgrade from Amazon Linux 2 to AL2023.

For more information, see Kubernetes v1.33.

SageMaker HyperPod release notes: August 4, 2025

SageMaker HyperPod releases new public AMIs for EKS orchestration. Public AMIs can be used by themselves, or they can be used to create custom AMIs. For more information about the public AMIs, see Public AMI releases. For more information about creating a custom AMI, see Custom Amazon Machine Images (AMIs) for SageMaker HyperPod clusters.

SageMaker HyperPod release notes: July 31, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features and improvements

- Released a new AMI that updates the operating system from Amazon Linux 2 to Amazon Linux 2023 for EKS clusters. Key upgrades include Linux Kernel 6.1, Python 3.10, NVIDIA Driver 560.35.03, and DNF package manager replacing YUM.

> **Important**
>
> The update from Amazon Linux 2 to AL2023 introduces significant changes that might affect compatibility with software and configurations designed for AL2. We strongly recommend testing your applications with AL2023 before fully upgrading your clusters.

For more information about the new AMI and how to upgrade your clusters, see SageMaker HyperPod AMI releases for Amazon EKS: July 31, 2025.

SageMaker HyperPod release notes: May 13, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Slurm.

New features and improvements

- Released an updated AMI that supports Ubuntu 22.04 LTS for Slurm clusters. This release includes several system and software component upgrades to provide improved performance, updated features, and enhanced security.

> **Important**
>
> The update from Ubuntu 20.04 LTS to Ubuntu 22.04 LTS introduces changes that might affect compatibility with software and configurations designed for Ubuntu 20.04.

For more information, see:

- the section called “Key updates in the Ubuntu 22.04 AMI”
- the section called “Upgrading to the Ubuntu 22.04 AMI”
- the section called “Troubleshooting upgrade failures”

SageMaker HyperPod release notes: May 1, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features

- Added usage reporting for EKS-orchestrated clusters, allowing organizations to implement transparent, usage-based cost allocation across teams, projects, or departments. This feature complements HyperPod's Task Governance functionality to ensure fair cost distribution in shared multi-tenant AI/ML environments. For more information, see Reporting Compute Usage in HyperPod.

SageMaker HyperPod release notes: April 28, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Slurm and Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features and improvements

- Upgraded NVIDIA driver from version 550.144.03 to 550.163.01. This upgrade is to address Common Vulnerabilities and Exposures (CVEs) present in the NVIDIA GPU Display Security Bulletin for April 2025.

For information about related AMI releases, see the section called "April 28, 2025" and the section called "April 28, 2025".

SageMaker HyperPod release notes: April 18, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features

- Released new SageMaker HyperPod AMI for Amazon EKS 1.32.1. For more information, see the section called "April 18, 2025".

SageMaker HyperPod release notes: April 10, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Slurm.

New features and improvements

- Added a Direct Preference Optimization (DPO) recipe tutorial for SageMaker HyperPod with Slurm orchestration. This fine-tuning tutorial provides step-by-step guidance for optimizing model alignment using the DPO method on GPU-powered SageMaker HyperPod Slurm clusters. For more information, see HyperPod Slurm cluster DPO tutorial (GPU).

SageMaker HyperPod release notes: April 03, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Slurm and Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features and improvements

- Added a Quickstart page for deploying SageMaker HyperPod clusters. The page leverages streamlined setup workflows from SageMaker HyperPod's specialized workshops and automates deployment using prebuilt Amazon CloudFormation templates. It supports infrastructure preferences like Slurm or Amazon EKS, for easy configuration and deployment of baseline clusters.
- SageMaker HyperPod now supports the following instance types for both Slurm and Amazon EKS clusters.
  - New instance types: I3en, M7i, R7i instances. For the full list of supported instances, see the `InstanceType` field in the `ClusterInstanceGroupDetails`.

SageMaker HyperPod release notes: March 16, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Slurm and Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features and improvements

- Added the following IAM condition keys for more granular access control in the `CreateCluster` and `UpdateCluster` API operations.

Condition key	Description			
sagemaker:InstanceTypes	Control access based on the specified instance types.			
sagemaker:VpcSubnets	Restrict cluster creation or updates to specific Amazon VPC subnets.			
sagemaker:VpcSecurityGroupIds	Manage access based on Amazon VPC security group IDs.			

SageMaker HyperPod release notes: February 20, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Slurm and Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features and improvements

- Added support for deleting instance groups from your SageMaker HyperPod cluster. For more information, see the section called "Delete instance groups" from EKS-orchestrated clusters and the section called "Scale down a cluster" for Slurm-orchestrated clusters.

SageMaker HyperPod release notes: February 18, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Slurm and Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features

- This release of SageMaker HyperPod incorporates a security update from the Nvidia container toolkit (from version 1.17.3 to version 1.17.4). For more information, see v1.17.4 release note.

> **Note**
>
> For all container workloads in the Nvidia container toolkit version 1.17.4, the mounting of CUDA compatibility libraries is now disabled. To ensure compatibility with multiple CUDA versions on container workflows, update your `LD_LIBRARY_PATH` to include your CUDA compatibility libraries. You can find the specific steps in ???.

For information about related AMI releases, see the section called “February 18, 2025” and the section called “February 18, 2025”.

SageMaker HyperPod release notes: February 06, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Slurm and Orchestrating SageMaker HyperPod clusters with Amazon EKS.

New features and improvements

- Enhanced SageMaker HyperPod multi-AZ support: You can specify different subnets and security groups, cutting across different Availability Zones, for individual instance groups within your cluster. For more information about SageMaker HyperPod multi-AZ support, see the section called “Setting up SageMaker HyperPod clusters across multiple AZs”.

SageMaker HyperPod release notes: January 22, 2025

AMI releases

- ???

SageMaker HyperPod release notes: January 09, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS and Orchestrating SageMaker HyperPod clusters with Slurm.

New features and improvements

- Added IPv6 support: Clusters can use IPv6 addressing when configured with IPv6-enabled VPC and subnets. For more information, see the section called “Setting up SageMaker HyperPod with a custom Amazon VPC”.

SageMaker HyperPod release notes: December 21, 2024

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS and Orchestrating SageMaker HyperPod clusters with Slurm.

New features

- SageMaker HyperPod now supports the following instance types for both Slurm and Amazon EKS clusters.
  - New instance types: C6gn, C6i, M6i, R6i.
  - New Trainium instance types: Trn1 and Trn1n.

Improvements

- Enhanced error logging visibility when Slurm interrupts jobs, and prevented unnecessary job step termination during Slurm-initiated job cancellations.
- Updated base DLAMI for p5en for both Slurm and Amazon EKS clusters.

AMI releases

- ???
- ???

SageMaker HyperPod release notes: December 13, 2024

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS and Orchestrating SageMaker HyperPod clusters with Slurm.

New feature

- SageMaker HyperPod releases a set of Amazon CloudWatch metrics to monitor the health and performance of SageMaker HyperPod Slurm clusters. These metrics are related to CPU, GPU, memory utilization, and cluster instance information such as node counts and failed nodes. This

monitoring feature is enabled by default, and the metrics can be accessed under the `/aws/sagemaker/Clusters` CloudWatch namespace. You can also set up CloudWatch alarms based on these metrics to proactively detect and address potential issues within their Slurm-based HyperPod clusters. For more information, see the section called "Slurm metrics".

AMI releases

- the section called "December 13, 2024"

SageMaker HyperPod release notes: November 24, 2024

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS and Orchestrating SageMaker HyperPod clusters with Slurm.

New features

- Added support for configuring SageMaker HyperPod clusters across multiple Availability Zones. For more information about SageMaker HyperPod multi-AZ support, see Setting up SageMaker HyperPod clusters across multiple AZs.

AMI releases

- the section called "November 24, 2024"
- the section called "November 24, 2024"

SageMaker HyperPod release notes: November 15, 2024

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS and Orchestrating SageMaker HyperPod clusters with Slurm. For more information, see and the section called "November 15, 2024".

New features and improvements

- Added support for trn1 and trn1n instance types for both Amazon EKS and Slurm orchestrated clusters.
- Improved log management for Slurm clusters:
  - Implemented log rotation: weekly or daily based on size.

- Set log retention to 3 weeks.
- Compressed logs to reduce storage impact.
- Continued uploading logs to CloudWatch for long-term retention.

> **Note**
>
> Some logs are still stored in syslogs.

- Adjusted Fluent Bit settings to prevent tracking issues with files containing long lines.

Bug fixes

- Prevented unintended truncation with Slurm controller node updates in configuration file `slurm.config`.

AMI releases

- the section called “November 15, 2024”
- the section called “November 15, 2024”

SageMaker HyperPod release notes: November 11, 2024

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS and Orchestrating SageMaker HyperPod clusters with Slurm.

New feature

- SageMaker HyperPod AMI now supports G6e instance types.

AMI releases

- the section called “November 11, 2024”
- the section called “November 11, 2024”

SageMaker HyperPod release notes: October 31, 2024

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS and Orchestrating SageMaker HyperPod clusters with Slurm.

New features

- Added scaling down SageMaker HyperPod clusters at the instance group level and instance level for both Amazon EKS and Slurm orchestrated clusters. For more information about scaling down Amazon EKS clusters, see Scaling down a SageMaker HyperPod cluster. For more information about scaling down Slurm clusters, see *Scale down a cluster* in Managing SageMaker HyperPod Slurm clusters using the Amazon CLI.
- SageMaker HyperPod now supports the P5e instance type for both Amazon EKS and Slurm orchestrated clusters.

SageMaker HyperPod release notes: October 21, 2024

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS and Orchestrating SageMaker HyperPod clusters with Slurm.

New feature

- SageMaker HyperPod now supports the P5e[n], G6, Gr6, and Trn2[n] instance types for both Slurm and Amazon EKS clusters.

AMI releases

- the section called “October 21, 2024”
- the section called “October 21, 2024”

SageMaker HyperPod release notes: September 10, 2024

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Amazon EKS and Orchestrating SageMaker HyperPod clusters with Slurm.

New features

- Added Amazon EKS support in SageMaker HyperPod. To learn more, see the section called “Amazon EKS orchestration”.

- Added support for managing SageMaker HyperPod clusters through Amazon CloudFormation and Terraform. For more information about managing HyperPod clusters through Amazon CloudFormation, see CloudFormation documentation for `AWS::SageMaker::Cluster`. To learn about managing HyperPod clusters through Terraform, see Terraform documentation for `awscc_sagemaker_cluster`.

AMI releases

- the section called “September 10, 2024”
- the section called “September 10, 2024”

SageMaker HyperPod release notes: August 20, 2024

SageMaker HyperPod releases the following for the section called “Slurm orchestration”.

New features

- Enhanced the SageMaker HyperPod auto-resume functionality, extending the resiliency capability for Slurm nodes attached with Generic RESources (GRES).

  When Generic Resources (GRES) are attached to a Slurm node, Slurm typically doesn't permit changes in the node allocation, such as replacing nodes, and thus doesn’t allow to resume a failed job. Unless explicitly forbidden, the HyperPod auto-resume functionality automatically re-queues any faulty job associated with the GRES-enabled nodes. This process involves stopping the job, placing it back into the job queue, and then restarting the job from the beginning.

Other changes

- Pre-packaged `slurmrestd` in the SageMaker HyperPod AMI.
- Changed the default values for `ResumeTimeout` and `UnkillableStepTimeout` from 60 seconds to 300 seconds in `slurm.conf` to improve system responsiveness and job handling.
- Made minor improvements on health checks for NVIDIA Data Center GPU Manager (DCGM) and The NVIDIA System Management Interface (nvidia-smi).

Bug fixes

- The HyperPod auto-resume plug-in can use idle nodes to resume a job.

SageMaker HyperPod release notes: June 20, 2024

SageMaker HyperPod releases the following for the section called "Slurm orchestration".

New features

- Added a new capability of attaching additional storage to SageMaker HyperPod cluster instances. With this capability, you can configure supplementary storage at the instance group configuration level during the cluster creation or update processes, either through the SageMaker HyperPod console or the `CreateCluster` and `UpdateCluster` APIs. The additional EBS volume is attached to each instance within a SageMaker HyperPod cluster and mounted to `/opt/sagemaker`. To learn more about implementing it in your SageMaker HyperPod cluster, see the updated documentation on the following pages.
  - the section called "Getting started"
  - the section called "Managing Slurm clusters"

  Note that you need to update the HyperPod cluster software to use this capability. After patching the HyperPod cluster software, you can utilize this capability for existing SageMaker HyperPod clusters created before June 20, 2024 by adding new instance groups. This capability is fully effective for any SageMaker HyperPod clusters created after June 20, 2024.

Upgrade steps

- Run the following command to call the UpdateClusterSoftware API to update your existing HyperPod clusters with the latest HyperPod DLAMI. To find more instructions, see the section called "Update the SageMaker HyperPod platform software of a cluster".

  > **Important**
  >
  > Back up your work before running this API. The patching process replaces the root volume with the updated AMI, which means that your previous data stored in the instance root volume will be lost. Make sure that you back up your data from the instance root volume to Amazon S3 or Amazon FSx for Lustre. For more information, see the section called "Use the backup script provided by SageMaker HyperPod".

```
aws sagemaker update-cluster-software --cluster-name your-cluster-name
```

> **Note**
>
> Note that you should run the Amazon CLI command to update your HyperPod cluster. Updating the HyperPod software through SageMaker HyperPod console UI is currently not available.

SageMaker HyperPod release notes: April 24, 2024

SageMaker HyperPod releases the following for the section called "Slurm orchestration".

Bug fixes

- Fixed a bug with the `ThreadsPerCore` parameter in the `ClusterInstanceGroupSpecification` API. With the fix, the `CreateCluster` and `UpdateCluster` APIs properly take and apply the user input through `ThreadsPerCore`. This fix is effective on HyperPod clusters created after April 24, 2024. If you had issues with this bug and want to get this fix applied to your cluster, you need to create a new cluster. Make sure that you back up and restore your work while moving to a new cluster following the instructions at the section called "Use the backup script provided by SageMaker HyperPod".

SageMaker HyperPod release notes: March 27, 2024

SageMaker HyperPod releases the following for the section called "Slurm orchestration".

HyperPod software patch

The HyperPod service team distributes software patches through the section called "SageMaker HyperPod DLAMI". See the following details about the latest HyperPod DLAMI.

- In this release of the HyperPod DLAMI, Slurm is built with REST service (`slurmestd`) with JSON, YAML, and JWT support.
- Upgraded Slurm to v23.11.3.

Improvements

- Increased auto-resume service timeout to 60 minutes.
- Improved instance replacement process to not restart the Slurm controller.

- Improved error messages from running lifecycle scripts, such as download errors and instance health check errors on instance start-up.

Bug fixes

- Fixed a bug with chrony service that caused an issue with time synchronization.
- Fixed a bug with parsing `slurm.conf`.
- Fixed an issue with NVIDIA `go-dcgm` library.

SageMaker HyperPod release notes: March 14, 2024

SageMaker HyperPod releases the following for the section called "Slurm orchestration".

Improvements

- HyperPod now properly supports passing partition names provided through `provisioning_parameters.json` and creates partitions appropriately based on provided inputs. For more information about `provisioning_parameters.json`, see the section called "Legacy configuration: provisioning_parameters.json" and the section called "Lifecycle scripts".

AMI releases

- the section called "March 14, 2024"

SageMaker HyperPod release notes: February 15, 2024

SageMaker HyperPod releases the following for the section called "Slurm orchestration".

New features

- Added a new `UpdateClusterSoftware` API for SageMaker HyperPod security patching. When security patches become available, we recommend you to update existing SageMaker HyperPod clusters in your account by running `aws sagemaker update-cluster-software --cluster-name` *`your-cluster-name`*. To follow up with future security patches, keep tracking this Amazon SageMaker HyperPod release notes page. To learn how the `UpdateClusterSoftware` API works, see the section called "Update the SageMaker HyperPod platform software of a cluster".

SageMaker HyperPod release notes: November 29, 2023

SageMaker HyperPod releases the following for the section called "Slurm orchestration".

New features

- Launched Amazon SageMaker HyperPod at Amazon re:Invent 2023.

AMI releases

- the section called "November 29, 2023"

Amazon SageMaker HyperPod AMI

Amazon SageMaker HyperPod Amazon Machine Images (AMIs) are specialized machine images for distributed machine learning workloads and high-performance computing. These AMIs enhance base images with essential components including GPU drivers and Amazon Neuron accelerator support.

Key components added to HyperPod AMIs include:

- Public AMIs with support for building custom AMIs
- Advanced orchestration tools:
  - Orchestrating SageMaker HyperPod clusters with Slurm
  - Orchestrating SageMaker HyperPod clusters with Amazon EKS
- Cluster management dependencies
- Built-in resiliency features:
  - cluster health check
  - auto-resume capabilities
- Support for HyperPod cluster management and configuration

These enhancements are built upon the following base Deep Learning AMIs (DLAMIs):

- Amazon Deep Learning Base GPU AMI (Ubuntu 20.04) for orchestration with Slurm.
- Amazon Linux 2 or Amazon Linux 2023 based AMI for orchestration with Amazon EKS.

Choose your HyperPod AMIs based on your orchestration preference:

- For Slurm orchestration, see the section called "AMI releases for Slurm".
- For Amazon EKS orchestration, see the section called "AMI releases for Amazon EKS".

For information about Amazon SageMaker HyperPod feature releases, see the section called "HyperPod release notes".

Update your AMI version in your SageMaker HyperPod cluster

Amazon SageMaker HyperPod Amazon Machine Images (AMIs) are specialized machine images for distributed machine learning workloads and high-performance computing. Each AMI comes pre-loaded with drivers, machine learning frameworks, training libraries, and performance monitoring tools. By updating the AMI version in your cluster, you can use the latest versions of these components and packages for your training jobs and workflows.

When updating the AMI version within your cluster, you have the option to process the update immediately, schedule a one-time only update, or use a cron expression to create a recurring schedule. You can also choose to update all of the instances in an instance group or just batches of instances. If you choose to update batches, you set the percentage or amount of instances that SageMaker AI should upgrade at a time. If you use this method of updating, you set an interval of how long SageMaker AI should wait in between batches.

If you choose to update in batches, you can also include a list of alarms and metrics. During the wait interval, SageMaker AI observes these metrics and if any exceed their threshold, the corresponding alarm goes into the ALARM state, and SageMaker AI rolls back the AMI update. To utilize automatic rollbacks, your IAM execution role must have the permission `cloudwatch:DescribeAlarms`.

> **Note**
>
> Updating your cluster in batches is available only for HyperPod clusters integrated with Amazon EKS. Also, if you're creating multiple schedules, we recommend that you have a time buffer in between schedules. If schedules overlap, updates might fail.

For more information about each AMI release for your HyperPod cluster, see Amazon SageMaker HyperPod AMI. For more information about general HyperPod releases, see Amazon SageMaker HyperPod release notes.

You can use the SageMaker AI API or CLI operations to update your cluster or see scheduled updates for a specific cluster. If you're using the Amazon console, follow these steps:

> **Note**
>
> Updating your AMI with the Amazon console is available only for clusters integrated with Amazon EKS. If you have a Slurm cluster, you must use the SageMaker AI API or CLI operations.

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. On the left, expand **HyperPod Clusters**, and choose **Cluster Management**.
3. Choose the cluster that you want to update, then choose **Details**, and **Update AMI**.

To create and manage update schedules programmatically, use the following API operations:

- CreateCluster – create a cluster while specifying an update schedule
- UpdateCluster – update a cluster to add an update schedule
- UpdateClusterSoftware – to update the platform software of a cluster
- DescribeCluster – see an update schedule you created for a cluster
- DescribeClusterNode and ListClusterNodes – see when the cluster was last updated.

Required permissions

Depending to how you configured your Pod Disruption Budget in your Amazon EKS cluster, HyperPod evicts pods, releases nodes, and prevents any update scheduling during the AMI update process. If any constraints within the budget are violated, HyperPod skips that node during the AMI update. For SageMaker HyperPod to correctly evict pods, you must add the necessary permissions to the HyperPod service-linked role. The following yaml file has the necessary permissions.

```
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRole
metadata:
  name: hyperpod-patching
rules:
- apiGroups: [""]
  resources: ["pods"]
```

```
  verbs: ["list"]
- apiGroups: [""]
  resources: ["pods/eviction"]
  verbs: ["create"]
---
apiVersion: rbac.authorization.k8s.io/v1
kind: ClusterRoleBinding
metadata:
  name: hyperpod-patching
subjects:
- kind: User
  name: hyperpod-service-linked-role
roleRef:
  kind: ClusterRole
  name: hyperpod-patching
  apiGroup: rbac.authorization.k8s.io
```

Use the following commands to apply the permissions.

```
git clone https://github.com/aws/sagemaker-hyperpod-cli.git

cd sagemaker-hyperpod-cli/helm_chart

helm upgrade hyperpod-dependencies HyperPodHelmChart --namespace kube-system --install
```

Cron expressions

To configure a one-time update at a certain time or a recurring schedule, use cron expressions. Cron expressions support six fields and are separated by white space. All six fields are required.

```
cron(Minutes Hours Day-of-month Month Day-of-week Year)
```

Fields	Values	Wildcards
Minutes	00 – 59	N/A
Hours	00 – 23	N/A
Day-of-month	01 – 31	?
Month	01 – 12	* /

Fields	Values	Wildcards
Day-of-week	1 – 7 or MON-SUN	? # L
Year	Current year – 2099	*

Wildcards

- The ***** (asterisk) wildcard includes all values in the field. In the `Hours` field, ***** would include every hour.
- The **/** (forward slash) wildcard specifies increments. In the `Months` field, you could enter ***/3** to specify every 3rd month.
- The **?** (question mark) wildcard specifies one or another. In the `Day-of-month` field you could enter **7**, and if you didn't care what day of the week the seventh was, you could enter **?** in the Day-of-week field.
- The **L** wildcard in the `day-of-week` or field specifies the last day of the month or week. For example, `5L` means the last Friday of the month.
- The **#** wildcard in the ay-of-week field specifies a certain instance of the specified day of the week within a month. For example, 3#2 would be the second Tuesday of the month: the 3 refers to Tuesday because it is the third day of each week, and the 2 refers to the second day of that type within the month.

You can use cron expressions for the following scenarios:

- One-time schedule that runs at a certain time and day. You can use the ? wildcard to denote that day-of-month or day-of-week don't matter.

```
cron(30 14 ? 12 MON 2024)
```

```
cron(30 14 15 12 ? 2024)
```

- A weekly schedule that runs at a certain time and day. The following example creates a schedule that runs at 12:00pm on every Monday regardless of day-of-month.

```
cron(00 12 ? * 1 *)
```

- Monthly schedule that runs every month regardless of the day-of-week. The following schedule runs at 12:30pm on the 15th of every month.

```
cron(30 12 15 * ? *)
```

- A monthly schedule that uses day-of-week.

```
cron(30 12 ? * MON *)
```

- To create a schedule that runs every Nth month, use the / wildcard. The following example creates a monthly schedule that runs every 3 months. The following two examples demonstrate how it works with day-of-week and day-of-month.

```
cron(30 12 15 */3 ? *)
```

```
cron(30 12 ? */3 MON *)
```

- A schedule that runs on a certain instance of the specified day of the week. The following example creates a schedule that runs at 12:30pm on the second Monday of every month.

```
cron(30 12 ? * 1#2 *)
```

- A schedule that runs on the last instance of the specified day of the week. The following schedule runs at 12:30pm on the last Monday of every month.

```
cron(30 12 ? * 1L *)
```

SageMaker HyperPod AMI releases for Slurm

The following release notes track the latest updates for Amazon SageMaker HyperPod AMI releases for Slurm orchestration. These HyperPod AMIs are built upon Amazon Deep Learning Base GPU AMI (Ubuntu 22.04). The HyperPod service team distributes software patches through the section called "SageMaker HyperPod DLAMI". For HyperPod AMI releases for Amazon EKS orchestration, see the section called "AMI releases for Amazon EKS". For information about Amazon SageMaker HyperPod feature releases, see the section called "HyperPod release notes".

> **Note**
>
> To update existing HyperPod clusters with the latest DLAMI, see the section called "Update the SageMaker HyperPod platform software of a cluster".

SageMaker HyperPod AMI releases for Slurm: October 19, 2026

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 25.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v25.11

- Slurm 25.11 (ARM64):
  - Linux Kernel version: 7.0.0-1014-aws
  - Glibc version: 2.39
  - OpenSSL version: 3.0.13
  - FSx Lustre Client version: 2.15.6-1fsx35
  - Containerd version: v2.4.2
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Default version: 13.2
  - CUDA version: 12.8, 12.9, 13.0, 13.2
  - EFA Installer version: 1.50.0
  - Python version: 3.12.3
  - Slurm version: 25.11.8
  - nvme-cli version: 2.8 1.8
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx35
  - nvidia-imex version: 595.91.07-1ubuntu1

- systemd version: 255
- openssh version: 9.6
- sudo version: 1.9.15
- ufw version: 0.36.2
- gcc version: 13.3.0
- cmake version: 3.28.3
- git version: 2.43.0
- make version: 4.3
- cloudwatch-agent version: 1.300074.0b1920-1
- nfs-utils version: 1:2.6.4-3ubuntu5.1
- iscsi-initiator-utils version: 2.1.9-3ubuntu5.5
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1.17-0ubuntu1
- rdma-core version: 64.0amzn0-1

- Slurm 25.11 (x86_64):
  - Linux Kernel version: 7.0.0-1014-aws
  - Glibc version: 2.39
  - OpenSSL version: 3.0.13
  - FSx Lustre Client version: 2.15.6-1fsx35
  - Containerd version: v2.4.2
  - aws Neuronx DKMS version: 2.31.7.0
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Default version: 13.2
  - CUDA version: 12.8, 12.9, 13.0, 13.2
  - EFA Installer version: 1.50.0
  - Python version: 3.12.3
  - Slurm version: 25.11.8
  - nvme-cli version: 2.8 1.8
  - stress version: 1.0.7

  - collectd version: 5.12.0.

- lustre-client version: 2.15.6-1fsx35
- systemd version: 255
- openssh version: 9.6
- sudo version: 1.9.15
- ufw version: 0.36.2
- gcc version: 13.3.0
- cmake version: 3.28.3
- make version: 4.3
- cloudwatch-agent version: 1.300074.0b1920-1
- nfs-utils version: 1:2.6.4-3ubuntu5.1
- iscsi-initiator-utils version: 2.1.9-3ubuntu5.5
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1.17-0ubuntu1
- rdma-core version: 64.0amzn0-1

SageMaker HyperPod AMI releases for Slurm: September 17, 2026

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 25.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v25.11

- Slurm 25.11 (ARM64):
  - Linux Kernel version: 6.8.0-1063-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx35
  - Containerd version: v2.3.5

- NVIDIA Driver version: 595.91.07
- NVIDIA CUDA Default version: 13.2
- CUDA version: 12.8, 12.9, 13.0, 13.2
- EFA Installer version: 1.50.0
- Python version: 3.10.12
- Slurm version: 25.11.8
- nvme-cli version: 1.16
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx35
- nvidia-imex version: 595.91.07-1ubuntu1
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- git version: 2.34.1
- make version: 4.3
- cloudwatch-agent version: 1.300072.0b1766-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 64.0amzn0-1

- Slurm 25.11 (x86_64):
  - Linux Kernel version: 6.8.0-1063-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx35
  - Containerd version: v2.3.5

- aws Neuronx DKMS version: 2.30.2.0
- NVIDIA Driver version: 595.91.07
- NVIDIA CUDA Default version: 13.2
- CUDA version: 12.8, 12.9, 13.0, 13.2
- EFA Installer version: 1.50.0
- Python version: 3.10.12
- Slurm version: 25.11.8
- nvme-cli version: 1.16
- stress version: 1.0.5
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx35
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300072.0b1766-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 64.0amzn0-1

SageMaker Hyperpod AMI releases for Slurm: September 8, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Slurm.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Slurm support

This release includes the following updates:

Default (Ubuntu 22.04, x86_64)

- Linux Kernel version: 6.8.0-1063-aws
- Glibc version: 2.35
- OpenSSL version: 3.0.2
- FSx Lustre Client version: 2.15.6-1fsx34
- Containerd version: v2.3.5
- aws Neuronx DKMS version: 2.30.2.0
- NVIDIA Driver version: 595.91.07
- NVIDIA CUDA Default version: 13.2
- NVIDIA CUDA version: 12.8, 12.9, 13.0, 13.2
- EFA Installer version: 1.47.0
- Python version: 3.10.12
- Slurm version: slurm-25.11.8
- nvme-cli version: 1.16
- stress version: 1.0.5
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx34
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300072.0b1766-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1

- lvm2 version: 2.03.11
- rdma-core version: 61.0-1

Default (Ubuntu 22.04, ARM64)

- Linux Kernel version: 6.8.0-1063-aws
- Glibc version: 2.35
- OpenSSL version: 3.0.2
- FSx Lustre Client version: 2.15.6-1fsx34
- Containerd version: v2.3.5
- NVIDIA Driver version: 595.91.07
- NVIDIA CUDA Default version: 13.2
- NVIDIA CUDA version: 12.8, 12.9, 13.0, 13.2
- EFA Installer version: 1.47.0
- Python version: 3.10.12
- Slurm version: slurm-25.11.8
- nvme-cli version: 1.16
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx34
- nvidia-imex version: 595.91.07-1ubuntu1
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300072.0b1766-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11

- rdma-core version: 61.0-1

Default (Ubuntu 24.04, x86_64)

- Linux Kernel version: 6.17.0-1020-aws
- Glibc version: 2.39
- OpenSSL version: 3.0.13
- FSx Lustre Client version: 2.15.6-1fsx32
- Containerd version: v2.3.5
- aws Neuronx DKMS version: 2.30.2.0
- NVIDIA Driver version: 595.91.07
- NVIDIA CUDA Default version: 13.2
- NVIDIA CUDA version: 12.8, 12.9, 13.0, 13.2
- EFA Installer version: 1.47.0
- Python version: 3.12.3
- Slurm version: slurm-25.11.8
- nvme-cli version: 2.8 1.8
- stress version: 1.0.7
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx32
- systemd version: 255
- openssh version: 9.6
- sudo version: 1.9.15
- ufw version: 0.36.2
- gcc version: 13.3.0
- cmake version: 3.28.3
- make version: 4.3
- cloudwatch-agent version: 1.300072.0b1766-1
- nfs-utils version: 1:2.6.4-3ubuntu5.1
- iscsi-initiator-utils version: 2.1.9-3ubuntu5.4
- lvm2 version: 2.03.16

- rdma-core version: 61.0-1

Default (Ubuntu 24.04, ARM64)

- Linux Kernel version: 6.17.0-1020-aws
- Glibc version: 2.39
- OpenSSL version: 3.0.13
- FSx Lustre Client version: 2.15.6-1fsx32
- Containerd version: v2.3.5
- NVIDIA Driver version: 595.91.07
- NVIDIA CUDA Default version: 13.2
- NVIDIA CUDA version: 12.8, 12.9, 13.0, 13.2
- EFA Installer version: 1.47.0
- Python version: 3.12.3
- Slurm version: slurm-25.11.8
- nvme-cli version: 2.8 1.8
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx32

SageMaker HyperPod AMI releases for Slurm: August 29, 2026

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 25.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v25.11

- Slurm 25.11 (ARM64):
  - Linux Kernel version: 6.17.0-1020-aws
  - Glibc version: 2.39
  - OpenSSL version: 3.0.13
  - FSx Lustre Client version: 2.15.6-1fsx32
  - Containerd version: v2.3.4
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Default version: 13.2
  - CUDA version: 12.8, 12.9, 13.0, 13.2
  - EFA Installer version: 1.47.0
  - Python version: 3.12.3
  - Slurm version: 25.11.4
  - nvme-cli version: 2.8 1.8
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx32
  - nvidia-imex version: 595.91.07-1ubuntu1
  - systemd version: 255
  - openssh version: 9.6
  - sudo version: 1.9.15
  - ufw version: 0.36.2
  - gcc version: 13.3.0

- cmake version: 3.28.3
- git version: 2.43.0
- make version: 4.3
- cloudwatch-agent version: 1.300072.0b1766-1
- nfs-utils version: 1:2.6.4-3ubuntu5.1
- iscsi-initiator-utils version: 2.1.9-3ubuntu5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1.17-0ubuntu1
- rdma-core version: 61.0-1

- Slurm 25.11 (x86_64):
  - AMI version: 2.1.0
  - Linux Kernel version: 6.8.0-1063-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx33
  - Containerd version: v2.3.4
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Default version: 13.2
  - CUDA version: 12.8, 12.9, 13.0, 13.2
  - EFA Installer version: 1.47.0
  - Python version: 3.10.12
  - Slurm version: 25.11.4
  - nvme-cli version: 1.16
  - stress version: 1.0.5
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx33
  - systemd version: 249
  - openssh version: 8.9
  - sudo version: 1.9.9

- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300072.0b1766-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

SageMaker HyperPod AMI releases for Slurm: July 30, 2026

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 25.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v25.11

- Slurm 25.11 (ARM64):
  - AMI version: 2.0.1
  - Linux Kernel version: 6.8.0-1060-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx32
  - Containerd version: v2.2.6
  - NVIDIA Driver version: 595.71.05
  - NVIDIA CUDA Default version: 13.2
  - CUDA version: 12.8, 12.9, 13.0, 13.2

- EFA Installer version: 1.47.0
- Python version: 3.10.12
- Slurm version: 25.11.4
- nvme-cli version: 1.16
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx32
- nvidia-imex version: 595.71.05-1ubuntu1
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- git version: 2.34.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.0b1529-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

- Slurm 25.11 (x86_64):
  - AMI version: 2.0.1
  - Linux Kernel version: 6.8.0-1060-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx32
  - Containerd version: v2.2.6
  - aws Neuronx DKMS version: 2.29.0.0
  - NVIDIA Driver version: 595.71.05

- NVIDIA CUDA Default version: 13.2
- CUDA version: 12.8, 12.9, 13.0, 13.2
- EFA Installer version: 1.47.0
- Python version: 3.10.12
- Slurm version: 25.11.4
- nvme-cli version: 1.16
- stress version: 1.0.5
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx32
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.0b1529-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

SageMaker HyperPod AMI releases for Slurm: July 09, 2026

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 25.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v25.11

- Slurm 25.11 (ARM64):
  - Linux Kernel version: 6.8.0-1057-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx32
  - Containerd version: v2.2.5
  - NVIDIA Driver version: 580.159.04
  - NVIDIA CUDA Default version: 13.0
  - CUDA version: 12.6, 12.8, 12.9, 13.0
  - EFA Installer version: 1.47.0
  - Python version: 3.10.12
  - Slurm version: 25.11.4
  - nvme-cli version: 1.16
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx32
  - nvidia-imex version: 580.159.04-1ubuntu1
  - systemd version: 249
  - openssh version: 8.9
  - sudo version: 1.9.9
  - ufw version: 0.36.1
  - gcc version: 11.4.0
  - cmake version: 3.22.1
  - git version: 2.34.1
  - make version: 4.3
  - cloudwatch-agent version: 1.300069.0b1529-1
  - nfs-utils version: 1:2.6.1-1ubuntu1.2
  - iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
  - lvm2 version: 2.03.11

- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

- Slurm 25.11 (x86_64):
  - Linux Kernel version: 6.8.0-1057-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx32
  - Containerd version: v2.2.5
  - aws Neuronx DKMS version: 2.29.0.0
  - NVIDIA Driver version: 580.159.04
  - NVIDIA CUDA Default version: 12.9
  - CUDA version: 12.6, 12.8, 12.9, 13.0
  - EFA Installer version: 1.47.0
  - Python version: 3.10.12
  - Slurm version: 25.11.4
  - nvme-cli version: 1.16
  - stress version: 1.0.5
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx32
  - systemd version: 249
  - openssh version: 8.9
  - sudo version: 1.9.9
  - ufw version: 0.36.1
  - gcc version: 11.4.0
  - cmake version: 3.22.1
  - make version: 4.3
  - cloudwatch-agent version: 1.300069.0b1529-1
  - nfs-utils version: 1:2.6.1-1ubuntu1.2
  - iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
  - lvm2 version: 2.03.11

- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

SageMaker HyperPod AMI releases for Slurm: June 21, 2026

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 25.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v25.11

- Slurm 25.11 (ARM64):
  - Linux Kernel version: 6.17.0-1017-aws
  - Glibc version: 2.39
  - OpenSSL version: 3.0.13
  - FSx Lustre Client version: 2.15.6-1fsx31
  - Containerd version: v2.2.5
  - NVIDIA Driver version: 595.71.05
  - NVIDIA CUDA Default version: 13.2
  - CUDA version: 12.8, 12.9, 13.0, 13.2
  - EFA Installer version: 1.47.0
  - Python version: 3.12.3
  - Slurm version: 25.11.4
  - nvme-cli version: 2.8 1.8
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx31
  - nvidia-imex version: 595.71.05-1ubuntu1
  - systemd version: 255
  - openssh version: 9.6

- sudo version: 1.9.15
- ufw version: 0.36.2
- gcc version: 13.3.0
- cmake version: 3.28.3
- git version: 2.43.0
- make version: 4.3
- cloudwatch-agent version: 1.300069.0b1529-1
- nfs-utils version: 1:2.6.4-3ubuntu5.1
- iscsi-initiator-utils version: 2.1.9-3ubuntu5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1.17-0ubuntu1
- rdma-core version: 61.0-1

- Slurm 25.11 (x86_64):
  - Linux Kernel version: 6.8.0-1057-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx31
  - Containerd version: v2.2.5
  - aws Neuronx DKMS version: 2.28.0.0
  - NVIDIA Driver version: 580.159.04
  - NVIDIA CUDA Default version: 12.9
  - CUDA version: 12.6, 12.8, 12.9, 13.0
  - EFA Installer version: 1.47.0
  - Python version: 3.10.12
  - Slurm version: 25.11.4
  - nvme-cli version: 1.16
  - stress version: 1.0.5
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx31

  - systemd version: 249

- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.0b1529-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

SageMaker HyperPod AMI releases for Slurm: May 27, 2026

Known issue: auto-resume on Slurm 25.11

Auto-resume has known issues on SageMaker HyperPod clusters running Slurm 25.11. Jobs submitted with auto-resume enabled are not guaranteed to resume on the node that is replaced after a node fault. Instead the affected jobs are requeued. A fix is under investigation.

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 25.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v25.11

- Slurm 25.11 (ARM64):

- Linux Kernel version: 6.8.0-1053-aws
- Glibc version: 2.35
- OpenSSL version: 3.0.2
- FSx Lustre Client version: 2.15.6-1fsx30
- Containerd version: v2.2.3
- NVIDIA Driver version: 580.126.09
- NVIDIA CUDA Default version: 13.0
- CUDA version: 12.6, 12.8, 12.9, 13.0
- EFA Installer version: 1.47.0
- Python version: 3.10.12
- Slurm version: 25.11.4
- nvme-cli version: 1.16
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx30
- nvidia-imex version: 580.126.09-1
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- git version: 2.34.1
- make version: 4.3
- cloudwatch-agent version: 1.300067.0b1404-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

- Slurm 25.11 (x86_64):

- Linux Kernel version: 6.8.0-1053-aws
- Glibc version: 2.35
- OpenSSL version: 3.0.2
- FSx Lustre Client version: 2.15.6-1fsx30
- Containerd version: v2.2.3
- aws Neuronx DKMS version: 2.27.4.0
- NVIDIA Driver version: 580.126.09
- NVIDIA CUDA Default version: 12.9
- CUDA version: 12.6, 12.8, 12.9, 13.0
- EFA Installer version: 1.47.0
- Python version: 3.10.12
- Slurm version: 25.11.4
- nvme-cli version: 1.16
- stress version: 1.0.5
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx30
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300067.0b1404-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

SageMaker HyperPod AMI releases for Slurm: May 07, 2026

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 24.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v24.11

- Slurm 24.11 (ARM64):
  - Linux Kernel version: 6.8.0-1053-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx29
  - Containerd version: v2.2.3
  - NVIDIA Driver version: 580.126.09
  - NVIDIA CUDA Default version: 13.0
  - CUDA version: 12.6, 12.8, 12.9, 13.0
  - EFA Installer version: 1.47.0
  - Python version: 3.10.12
  - Slurm version: 24.11.0
  - nvme-cli version: 1.16
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx29
  - nvidia-imex version: 580.126.09-1
  - systemd version: 249
  - openssh version: 8.9
  - sudo version: 1.9.9
  - ufw version: 0.36.1
  - gcc version: 11.4.0

- cmake version: 3.22.1
- git version: 2.34.1
- make version: 4.3
- cloudwatch-agent version: 1.300067.0b1404-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

- Slurm 24.11 (x86_64):
  - Linux Kernel version: 6.8.0-1053-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx29
  - Containerd version: v2.2.3
  - aws Neuronx DKMS version: 2.27.4.0
  - NVIDIA Driver version: 580.126.09
  - NVIDIA CUDA Default version: 12.9
  - CUDA version: 12.6, 12.8, 12.9, 13.0
  - EFA Installer version: 1.47.0
  - Python version: 3.10.12
  - Slurm version: 24.11.0
  - nvme-cli version: 1.16
  - stress version: 1.0.5
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx29
  - systemd version: 249
  - openssh version: 8.9
  - sudo version: 1.9.9

- ufw version: 0.36.1

- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300067.0b1404-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

SageMaker HyperPod AMI releases for Slurm: April 23, 2026

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 24.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v24.11

- Slurm 24.11 (aarch64):
  - Linux Kernel version: 6.8.0-1052-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx28
  - Containerd version: v2.2.3
  - NVIDIA Driver version: 580.126.09
  - NVIDIA CUDA Default version: 13.0
  - CUDA version: 12.6, 12.8, 12.9, 13.0
  - EFA Installer version: 1.47.0
  - Python version: 3.10.12

- Slurm version: 24.11.0
- nvme-cli version: 1.16
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx28
- nvidia-imex version: 580.126.09-1
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- git version: 2.34.1
- make version: 4.3
- cloudwatch-agent version: 1.300066.1b1374-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 61.0-1

- Slurm 24.11 (x86_64):
  - Linux Kernel version: 6.8.0-1052-aws
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx28
  - Containerd version: v2.2.3
  - aws Neuronx DKMS version: 2.27.4.0
  - NVIDIA Driver version: 580.126.09
  - NVIDIA CUDA Default version: 12.9
  - CUDA version: 12.6, 12.8, 12.9, 13.0

  - EFA Installer version: 1.47.0

- Python version: 3.10.12
- Slurm version: 24.11.0
- nvme-cli version: 1.16
- stress version: 1.0.5
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx28
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300066.1b1374-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2

SageMaker HyperPod AMI releases for Slurm: February 12, 2026

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 24.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v24.11

- Slurm 24.11 (ARM64):
  - Linux Kernel version: 6.8
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx25
  - Runc version: 1.3.4
  - Containerd version: containerd containerd.io v2.2.1
  - NVIDIA Driver version: 580.126.09
  - CUDA version: 12.6, 12.8, 12.9, 13.0
  - EFA Installer version: 1.45.1
  - Python version: 3.10.12

- Slurm version: 24.11.0
- nvme-cli version: 1.16
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx25
- nvidia-imex version: 580.126.09-1
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- git version: 2.34.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.0b1337-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 60.0-1

- Slurm 24.11 (x86_64):
  - Linux Kernel version: 6.8
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx25
  - Runc version: 1.3.4
  - Containerd version: containerd containerd.io v2.2.1
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.126.09
  - CUDA version: 12.6, 12.8, 12.9, 13.0

  - EFA Installer version: 1.45.0

- Python version: 3.10.12
- Slurm version: 24.11.0
- nvme-cli version: 1.16
- stress version: 1.0.5
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx25
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.0b1337-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 60.0-1

SageMaker HyperPod AMI releases for Slurm: January 25, 2026

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 24.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v24.11

- Slurm 24.11 (ARM64):

- Linux Kernel version: 6.8
- Glibc version: 2.35
- OpenSSL version: 3.0.2
- FSx Lustre Client version: 2.15.6-1fsx25
- Runc version: 1.3.4
- Containerd version: containerd containerd.io v2.2.1
- NVIDIA Driver version: 580.126.09
- CUDA version: 12.6, 12.8, 12.9, 13.0
- EFA Installer version: 2.3.1amzn3.0
- Python version: 3.10.12
- Slurm version: 24.11.0
- nvme-cli version: 1.16
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx25
- nvidia-imex version: 580.126.09-1
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- git version: 2.34.1
- make version: 4.3
- cloudwatch-agent version: 1.300063.0b1323-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 60.0-1

- Slurm 24.11 (x86_64):

- Linux Kernel version: 6.8
- Glibc version: 2.35
- OpenSSL version: 3.0.2
- FSx Lustre Client version: 2.15.6-1fsx25
- Runc version: 1.3.4
- Containerd version: containerd containerd.io v2.2.1
- aws Neuronx DKMS version: 2.25.4.0
- NVIDIA Driver version: 580.126.09
- CUDA version: 12.6, 12.8, 12.9, 13.0
- EFA Installer version: 2.3.1amzn2.0
- Python version: 3.10.12
- Slurm version: 24.11.0
- nvme-cli version: 1.16
- stress version: 1.0.5
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx25
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300063.0b1323-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 60.0-1

SageMaker HyperPod AMI releases for Slurm: December 29, 2025

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 24.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm v24.11

- Slurm 24.11 (ARM64):
  - Linux Kernel version: 6.8
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx25
  - Runc version: 1.3.4
  - Containerd version: containerd containerd.io v2.2.1
  - NVIDIA Driver version: 580.105.08
  - CUDA version: 12.6, 12.8, 12.9, 13.0
  - EFA Installer version: 2.3.1amzn3.0
  - Python version: 3.10.12
  - Slurm version: 24.11.0
  - nvme-cli version: 1.16
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx25
  - nvidia-imex version: 580.105.08-1
  - systemd version: 249
  - openssh version: 8.9
  - sudo version: 1.9.9
  - ufw version: 0.36.1
  - gcc version: 11.4.0

- cmake version: 3.22.1
- git version: 2.34.1
- make version: 4.3
- cloudwatch-agent version: 1.300062.0b1304-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 60.0-1

- Slurm 24.11 (x86_64):
  - Linux Kernel version: 6.8
  - Glibc version: 2.35
  - OpenSSL version: 3.0.2
  - FSx Lustre Client version: 2.15.6-1fsx25
  - Runc version: 1.3.4
  - Containerd version: containerd containerd.io v2.2.1
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.105.08
  - CUDA version: 12.6, 12.8, 12.9, 13.0
  - EFA Installer version: 2.3.1amzn2.0
  - Python version: 3.10.12
  - Slurm version: 24.11.0
  - nvme-cli version: 1.16
  - stress version: 1.0.5
  - collectd version: 5.12.0.
  - lustre-client version: 2.15.6-1fsx25
  - systemd version: 249
  - openssh version: 8.9
  - sudo version: 1.9.9

  - ufw version: 0.36.1

- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300062.0b1304-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 60.0-1

SageMaker HyperPod AMI releases for Slurm: November 22, 2025

AMI general updates

- Released updates for SageMaker HyperPod AMI for Slurm versions 24.11.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Slurm support

This release includes the following updates:

Slurm (arm64)

- Linux Kernel version: 6.8
- Glibc version: 2.35
- OpenSSL version: 3.0.2
- FSx Lustre Client version: 2.15.6-1fsx21
- Runc version: 1.3.3
- Containerd version: containerd containerd.io v2.1.5
- NVIDIA Driver version: 580.95.05
- CUDA version: 12.6, 12.8, 12.9, 13.0
- EFA Installer version: 2.1.0amzn5.0
- Python version: 3.10.12

- Slurm version: 24.11.0
- nvme-cli version: 1.16
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx21
- nvidia-imex version: 580.95.05-1
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- git version: 2.34.1
- make version: 4.3
- cloudwatch-agent version: 1.300062.0b1304-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 58.amzn0-1

Slurm (x86_64)

- Linux Kernel version: 6.8
- Glibc version: 2.35
- OpenSSL version: 3.0.2
- FSx Lustre Client version: 2.15.6-1fsx21
- Runc version: 1.3.3
- Containerd version: containerd containerd.io v2.1.5
- aws Neuronx DKMS version: 2.24.7.0
- NVIDIA Driver version: 580.95.05

- CUDA version: 12.6, 12.8, 12.9, 13.0
- EFA Installer version: 2.3.1amzn1.0
- Python version: 3.10.12
- Slurm version: 24.11.0
- nvme-cli version: 1.16
- stress version: 1.0.5
- collectd version: 5.12.0.
- lustre-client version: 2.15.6-1fsx21
- systemd version: 249
- openssh version: 8.9
- sudo version: 1.9.9
- ufw version: 0.36.1
- gcc version: 11.4.0
- cmake version: 3.22.1
- make version: 4.3
- cloudwatch-agent version: 1.300062.0b1304-1
- nfs-utils version: 1:2.6.1-1ubuntu1.2
- iscsi-initiator-utils version: 2.1.5-1ubuntu1.1
- lvm2 version: 2.03.11
- ec2-instance-connect version: 1.1.14-0ubuntu1.1
- rdma-core version: 59.amzn0-1

SageMaker HyperPod release notes: November 07, 2025

The AMI includes the following:

- Supported Amazon Web Services service: Amazon EC2
- Operating System: Ubuntu 22.04
- Compute Architecture: ARM64
- Updated packages: NVIDIA Driver: 580.95.05
- CUDA Versions: cuda-12.6, cuda-12.8, cuda-12.9, cuda-13.0

- Security fixes: Runc Security patch

SageMaker HyperPod release notes: September 29, 2025

The AMI includes the following:

- Supported Amazon Web Services service: Amazon EC2
- Operating System: Ubuntu 22.04
- Compute Architecture: ARM64
- Updated packages: NVIDIA Driver: 570.172.08
- Security fixes

SageMaker HyperPod release notes: August 12, 2025

The AMI includes the following:

- Supported Amazon Web Services service: Amazon EC2
- Operating System: Ubuntu 22.04
- Compute Architecture: ARM64
- Latest available version is installed for the following packages:
  - Linux Kernel: 6.8
  - FSx Lustre
  - Docker
  - Amazon CLI v2 at `/usr/bin/aws`
  - NVIDIA DCGM
  - Nvidia container toolkit:
    - Version command: `nvidia-container-cli -V`
  - Nvidia-docker2:
    - Version command: `nvidia-docker version`
  - Nvidia-IMEX: v570.172.08-1
- NVIDIA Driver: 570.158.01
- NVIDIA CUDA 12.4, 12.5, 12.6, 12.8 stack:
  - CUDA, NCCL and cuDDN installation directories: `/usr/local/cuda-xx.x/`

    - Example: `/usr/local/cuda-12.8/`, `/usr/local/cuda-12.8/`
  - Compiled NCCL Version:
    - For CUDA directory of 12.4, compiled NCCL Version 2.22.3+CUDA12.4
    - For CUDA directory of 12.5, compiled NCCL Version 2.22.3+CUDA12.5
    - For CUDA directory of 12.6, compiled NCCL Version 2.24.3+CUDA12.6
    - For CUDA directory of 12.8, compiled NCCL Version 2.27.5+CUDA12.8
  - Default CUDA: 12.8
    - PATH `/usr/local/cuda` points to CUDA 12.8
    - Updated below env vars:
      - `LD_LIBRARY_PATH` to have `/usr/local/cuda-12.8/lib:/usr/local/cuda-12.8/lib64:/usr/local/cuda-12.8:/usr/local/cuda-12.8/targets/sbsa-linux/lib:/usr/local/cuda-12.8/nvvm/lib64:/usr/local/cuda-12.8/extras/CUPTI/lib64`
      - `PATH` to have `/usr/local/cuda-12.8/bin/:/usr/local/cuda-12.8/include/`
      - For any different CUDA version, please update `LD_LIBRARY_PATH` accordingly.
- EFA installer: 1.42.0
- Nvidia GDRCopy: 2.5.1
- Amazon OFI NCCL plugin comes with EFA installer
  - Paths `/opt/amazon/ofi-nccl/lib/aarch64-linux-gnu` and `/opt/amazon/ofi-nccl/efa` are added to `LD_LIBRARY_PATH`.
- Amazon CLI v2 at `/usr/local/bin/aws2` and Amazon CLI v1 at `/usr/bin/aws`
- EBS volume type: gp3
- Python: `/usr/bin/python3.10`

SageMaker HyperPod release notes: May 27, 2025

SageMaker HyperPod releases the following for Orchestrating SageMaker HyperPod clusters with Slurm.

New features and improvements

- Updated base AMI to `Deep Learning Base OSS Nvidia Driver GPU AMI (Ubuntu 22.04) 20250523` with the following key components:

- NVIDIA Driver: 570.133.20
- CUDA: 12.8 (default), with support for CUDA 12.4-12.6
- NCCL Version: 2.26.5
- EFA Installer: 1.40.0
- Amazon OFI NCCL: 1.14.2-aws

- Updated Neuron SDK packages:
  - aws-neuronx-collectives: 2.25.65.0-9858ac9a1 (from 2.24.59.0-838c7fc8b)
  - aws-neuronx-dkms: 2.21.37.0 (from 2.20.28.0)
  - aws-neuronx-runtime-lib: 2.25.57.0-166c7a468 (from 2.24.53.0-f239092cc)
  - aws-neuronx-tools: 2.23.9.0 (from 2.22.61.0)

Important notes

- NVIDIA Container Toolkit 1.17.4 now has disabled mounting of CUDA compatible libraries.
- Updated EFA configuration from 1.37 to 1.38, and EFA now includes the Amazon OFI NCCL plugin, which is located in the `/opt/amazon/ofi-nccl` directory instead of the original `/opt/aws-ofi-nccl/` path. (Released on February 18, 2025)
- Kernel version is pinned for stability and driver compatibility.

SageMaker HyperPod AMI releases for Slurm: May 13, 2025

Amazon SageMaker HyperPod released an updated AMI that supports Ubuntu 22.04 LTS for Slurm clusters. Amazon regularly updates AMIs to ensure you have access to the most current software stack. Upgrading to the latest AMI provides enhanced security through comprehensive package updates, improved performance and stability for your workloads, and compatibility with new instance types and latest kernel features.

> **Important**
>
> The update from Ubuntu 20.04 LTS to Ubuntu 22.04 LTS introduces changes that might affect compatibility with software and configurations designed for Ubuntu 20.04.

In this release note, you will see:

- Key updates in the Ubuntu 22.04 AMI

- Upgrading to the Ubuntu 22.04 AMI
- Troubleshooting upgrade failures

Key updates in the Ubuntu 22.04 AMI

The following table lists the component versions of the Ubuntu 22.04 AMI compared to the previous AMI.

Component versions of the Ubuntu 22.04 AMI compared to the previous AMI

Component	Previous version	Updated version		
Ubuntu OS	20.04 LTS	22.04 LTS		
Slurm	24.11	24.11 (unchanged)		
Python	3.8 (default)	3.10 (default)		
Elastic Fabric Adapter (EFA) on Amazon FSx	Not supported	Supported		
Linux kernel	5.15	6.8		
GNU C Library (glibc)	2.31	2.35		
GNU Compiler Collection (GCC)	9.4.0	11.4.0		
libc6	≤ 2.31	≥ 2.35 supported		
Network File System (NFS)	1:1.3.4	1:2.6.1		

> **Note**
>
> Although the Slurm version (24.11) remains unchanged, the underlying OS and library updates in this AMI may affect your system behavior and workload compatibility. You must test your workloads before upgrading production clusters.

Upgrading to the Ubuntu 22.04 AMI

Before upgrading your cluster to the Ubuntu 22.04 AMI, complete these preparation steps and review the upgrade requirements. To troubleshoot upgrade failures, see the section called "Troubleshooting upgrade failures".

Review Python compatibility

The Ubuntu 22.04 AMI uses Python 3.10 as the default version, upgraded from Python 3.8. Although Python 3.10 maintains compatibility with most Python 3.8 code, you should test your existing workloads before upgrading. If your workloads require Python 3.8, you can install it using the following command in your lifecycle script:

```
yum install python-3.8
```

Before upgrading your cluster, make sure to do the following:

1. Test your code compatibility with Python 3.10.
2. Verify your lifecycle scripts work in the new environment.
3. Check that all dependencies are compatible with the new Python version.
4. If you created your HyperPod cluster by copying the default lifecycle script from GitHub, add the following command to your `setup_mariadb_accounting.sh` file before upgrading to Ubuntu 22. For the complete script, see setup_mariadb_accounting.sh on GitHub.

   ```
   apt-get -y -o DPkg::Lock::Timeout=120 update && apt-get -y -o DPkg::Lock::Timeout=120
    install apg
   ```

Upgrade your Slurm cluster

You can upgrade your Slurm cluster to use the new AMI in two ways:

1. Create a new cluster using the `CreateCluster` API.
2. Update an existing cluster's software using the `UpdateClusterSoftware` API.

Validated configurations

Amazon has tested a wide range of distributed training workloads and infrastructure features on G5, G6, G6e, P4d, P5, and Trn1 instances, including:

- Distributed training with PyTorch (e.g., FSDP, NeMo, LLaMA, MNIST).
- Accelerator testing across instance types with Nvidia (P/G series) and Amazon Neuron (Trn1).
- Resiliency features that include auto-resume and deep health checks.

Cluster downtime and availability

During the upgrade process, the cluster will be unavailable. To minimize disruption, do the following:

- Test the upgrade process on smaller clusters.
- Create checkpoints before the upgrade, then restart training workloads from existing checkpoints after the upgrade completes.

Troubleshooting upgrade failures

When an upgrade fails, first determine if the failure is related to lifecycle scripts. These scripts commonly fail due to syntax errors, missing dependencies, or incorrect configurations.

To investigate failures related to lifecycle scripts, check CloudWatch logs. All SageMaker HyperPod events and logs are stored under the log group: `/aws/sagemaker/Clusters/[ClusterName]/[ClusterID]`. Look specifically at the log stream `LifecycleConfig/[instance-group-name]/[instance-id]`, which provides detailed information about any errors during script execution.

If the upgrade failure is unrelated to lifecycle scripts, collect relevant information including the cluster ARN, error logs, and timestamps, then contact Amazon support for further assistance.

SageMaker HyperPod AMI releases for Slurm: May 07, 2025

Amazon SageMaker HyperPod for Slurm released a major OS version upgrade to Ubuntu 22.04 (from the earlier Ubuntu 20.04). Check DLAMI Ubuntu 22.04 (release notes) for more information: `Deep Learning Base OSS Nvidia Driver GPU AMI (Ubuntu 22.04) 20250503`.

Key package upgrades:

- Ubuntu 22.04 LTS (from 20.04)
- Python Version:
  - Python 3.10 is now the default Python version in the Slurm AMI Ubuntu 22.04
  - This upgrade provide access to the latest features, performance improvements and bug fixes introduced in Python 3.10
- Support for EFA on FSx
- New Linux Kernel version 6.8 (updated from 5.15)
- Glibc version: 2.35 (updated from 2.31)
- GCC version: 11.4.0 (updated from 9.4.0)
- Newer libc6 version support (from libc6 version <= 2.31)
- NFS version: 1:2.6.1 (updated from 1:1.3.4)

SageMaker HyperPod AMI releases for Slurm: April 28, 2025

Improvements for Slurm

- Upgraded NVIDIA driver from version 550.144.03 to 550.163.01. This upgrade is to address Common Vulnerabilities and Exposures (CVEs) present in the NVIDIA GPU Display Security Bulletin for April 2025.

Amazon SageMaker HyperPod DLAMI for Slurm support

Installed the latest version of Amazon Neuron SDK

- **aws-neuronx-collectives:** 2.24.59.0-838c7fc8b
- **aws-neuronx-dkms:** 2.20.28.0
- **aws-neuronx-runtime-lib:** 2.24.53.0-f239092cc

- **aws-neuronx-tools/unknown:** 2.22.61.0

SageMaker HyperPod AMI releases for Slurm: February 18, 2025

Improvements for Slurm

- Upgraded Slurm version to 24.11.
- Upgraded Elastic Fabric Adapter (EFA) version from 1.37.0 to 1.38.0.
- The EFA now includes the Amazon OFI NCCL plugin. You can find this plugin in the `/opt/amazon/ofi-nccl` directory, rather than the original `/opt/aws-ofi-nccl/` location. If you need to update your `LD_LIBRARY_PATH` environment variable, make sure to modify the path to point to the new `/opt/amazon/ofi-nccl` location for the OFI NCCL plugin.
- Removed the emacs package from these DLAMIs. You can install emacs from GNU emac.

Amazon SageMaker HyperPod DLAMI for Slurm support

Installed the latest version of Amazon Neuron SDK 2.19

- **aws-neuronx-collectives/unknown:** 2.23.135.0-3e70920f2 amd64
- **aws-neuronx-dkms/unknown:** 2.19.64.0 amd64
- **aws-neuronx-runtime-lib/unknown:** 2.23.112.0-9b5179492 amd64
- **aws-neuronx-tools/unknown:** 2.20.204.0 amd64

SageMaker HyperPod AMI releases for Slurm: December 21, 2024

SageMaker HyperPod DLAMI for Slurm support

Deep Learning Slurm AMI

- **NVIDIA driver:** 550.127.05
- **EFA driver:** 2.13.0-1
- Installed the latest version of Amazon Neuron SDK
  - **aws-neuronx-collectives:** 2.22.33.0
  - **aws-neuronx-dkms:** 2.18.20.0
  - **aws-neuronx-oci-hook:** 2.5.8.0

- **aws-neuronx-runtime-lib:** 2.22.19.0
- **aws-neuronx-tools:** 2.19.0.0

SageMaker HyperPod AMI releases for Slurm: November 24, 2024

AMI general updates

- Released in `MEL` (Melbourne) Region.
- Updated SageMaker HyperPod base DLAMI to the following versions:
  - Slurm: 2024-11-22.

SageMaker HyperPod AMI releases for Slurm: November 15, 2024

AMI general updates

- Installed latest `libnvidia-nscq-xxx` package.

SageMaker HyperPod DLAMI for Slurm support

Deep Learning Slurm AMI

- **NVIDIA driver:** 550.127.05
- **EFA driver:** 2.13.0-1
- Installed the latest version of Amazon Neuron SDK
  - **aws-neuronx-collectives:** v2.22.33.0-d2128d1aa
  - **aws-neuronx-dkms:** v2.17.17.0
  - **aws-neuronx-oci-hook:** v2.4.4.0
  - **aws-neuronx-runtime-lib:** v2.21.41.0
  - **aws-neuronx-tools:** v2.18.3.0

SageMaker HyperPod AMI releases for Slurm: November 11, 2024

AMI general updates

- Updated SageMaker HyperPod base DLAMI to the following version:
  - Slurm: 2024-10-23.

SageMaker HyperPod AMI releases for Slurm: October 21, 2024

AMI general updates

- Updated SageMaker HyperPod base DLAMI to the following versions:
  - Slurm: 2024-09-27.

SageMaker HyperPod AMI releases for Slurm: September 10, 2024

SageMaker HyperPod DLAMI for Slurm support

Deep Learning Slurm AMI

- Installed the NVIDIA driver v550.90.07
- Installed the EFA driver v2.10
- Installed the latest version of Amazon Neuron SDK
  - **aws-neuronx-collectives:** v2.21.46.0
  - **aws-neuronx-dkms:** v2.17.17.0
  - **aws-neuronx-oci-hook:** v2.4.4.0
  - **aws-neuronx-runtime-lib:** v2.21.41.0
  - **aws-neuronx-tools:** v2.18.3.0

SageMaker HyperPod AMI releases for Slurm: March 14, 2024

HyperPod DLAMI for Slurm software patch

- Upgraded Slurm to v23.11.1
- Added OpenPMIx v4.2.6 for enabling Slurm with PMIx.
- Built upon the Amazon Deep Learning Base GPU AMI (Ubuntu 20.04) released on 2023-10-26
- A complete list of pre-installed packages in this HyperPod DLAMI in addition to the base AMI
  - Slurm: v23.11.1
  - OpenPMIx : v4.2.6
  - Munge: v0.5.15
  - `aws-neuronx-dkms`: v2.*
  - `aws-neuronx-collectives`: v2.*

- `aws-neuronx-runtime-lib`: v2.*
- `aws-neuronx-tools`: v2.*
- SageMaker HyperPod software packages to support features such as cluster health check and auto-resume

Upgrade steps

- Run the following command to call the UpdateClusterSoftware API to update your existing HyperPod clusters with the latest HyperPod DLAMI. To find more instructions, see the section called "Update the SageMaker HyperPod platform software of a cluster".

> **Important**
>
> Back up your work before running this API. The patching process replaces the root volume with the updated AMI, which means that your previous data stored in the instance root volume will be lost. Make sure that you back up your data from the instance root volume to Amazon S3 or Amazon FSx for Lustre. For more information, see the section called "Use the backup script provided by SageMaker HyperPod".

```
aws sagemaker update-cluster-software --cluster-name your-cluster-name
```

> **Note**
>
> Note that you should run the Amazon CLI command to update your HyperPod cluster. Updating the HyperPod software through SageMaker HyperPod console UI is currently not available.

SageMaker HyperPod AMI release for Slurm: November 29, 2023

HyperPod DLAMI for Slurm software patch

The HyperPod service team distributes software patches through the section called "SageMaker HyperPod DLAMI". See the following details about the latest HyperPod DLAMI.

- Built upon the Amazon Deep Learning Base GPU AMI (Ubuntu 20.04) released on 2023-10-18

- A complete list of pre-installed packages in this HyperPod DLAMI in addition to the base AMI
  - Slurm: v23.02.3
  - Munge: v0.5.15
  - `aws-neuronx-dkms`: v2.*
  - `aws-neuronx-collectives`: v2.*
  - `aws-neuronx-runtime-lib`: v2.*
  - `aws-neuronx-tools`: v2.*
  - SageMaker HyperPod software packages to support features such as cluster health check and auto-resume

SageMaker HyperPod AMI releases for Amazon EKS

The following release notes track the latest updates for Amazon SageMaker HyperPod AMI releases for Amazon EKS orchestration. Each release note includes a summarized list of packages pre-installed or pre-configured in the SageMaker HyperPod DLAMIs for Amazon EKS support. Each DLAMI is built on AL2023 and supports a specific Kubernetes version. For HyperPod DLAMI releases for Slurm orchestration, see the section called "AMI releases for Slurm". For information about Amazon SageMaker HyperPod feature releases, see the section called "HyperPod release notes".

> **Note**
>
> EKS workloads run inside containers that bundle their own CUDA toolkit, so the maximum supported version determines which containerized CUDA versions are compatible with the host driver.
>
> - **Maximum Supported CUDA Version** — The highest CUDA version the installed NVIDIA driver can support. Your containerized workloads can use any CUDA version up to the maximum supported version.
> - **NVIDIA CUDA Toolkit** — The CUDA toolkit version installed on the host.

SageMaker Hyperpod AMI releases for Amazon EKS: October 16, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.31, 1.32, 1.33, 1.34, 1.35, 1.36.

- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.31

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.111-136.204.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.8
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.4.3
  - Containerd version: 2.3.5+unknown
  - aws SSM Agent version: 3.3.5390.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - Maximum Supported CUDA Version version: 13.2
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.50.0
  - ENA Driver version: 2.17.4g
  - Python version: 3.9.25
  - Kubernetes version: v1.31.13-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.5
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.4.0
  - lustre-client version: 2.15.6
  - systemd version: 252

- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300071.0
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 64.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.111-136.204.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.8
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.4.3
  - Containerd version: 2.3.5+unknown
  - aws SSM Agent version: 3.3.5390.0
  - NVIDIA Driver version: 595.91.07
  - Maximum Supported CUDA Version version: 13.2
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.50.0
  - ENA Driver version: 2.17.4g
  - Python version: 3.9.25
  - Kubernetes version: v1.31.13-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.5
  - nvme-cli version: 2.13 1.13

- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- nvidia-imex version: 595.91.07
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300071.0
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 64.0

Kubernetes v1.32

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.111-136.204.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.8
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.4.3
  - Containerd version: 2.3.5+unknown
  - aws SSM Agent version: 3.3.5538.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07

- Maximum Supported CUDA Version version: 13.2
- NVIDIA CUDA Toolkit version: 13.2
- EFA Installer version: 1.50.0
- ENA Driver version: 2.17.4g
- Python version: 3.9.25
- Kubernetes version: v1.32.9-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.5
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300071.0
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 64.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.111-136.204.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.8

- FSx Lustre Client version: 2.15.6
- Runc version: 1.4.3
- Containerd version: 2.3.5+unknown
- aws SSM Agent version: 3.3.5538.0
- NVIDIA Driver version: 595.91.07
- Maximum Supported CUDA Version version: 13.2
- NVIDIA CUDA Toolkit version: 13.2
- EFA Installer version: 1.50.0
- ENA Driver version: 2.17.4g
- Python version: 3.9.25
- Kubernetes version: v1.32.9-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.5
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- nvidia-imex version: 595.91.07
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300071.0
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16

- ec2-instance-connect version: 1.1

- aws-cfn-bootstrap version: 2.0
- rdma-core version: 64.0

Kubernetes v1.33

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.111-136.204.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.8
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.4.3
  - Containerd version: 2.3.5+unknown
  - aws SSM Agent version: 3.3.5538.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 580.178.04
  - Maximum Supported CUDA Version version: 13.0
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.49.0
  - ENA Driver version: 2.17.4g
  - Python version: 3.9.25
  - Kubernetes version: v1.33.5-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.5
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.4.0
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 9.9
  - sudo version: 1.9.15

- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300071.0
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.111-136.204.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.8
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.4.3
  - Containerd version: 2.3.5+unknown
  - aws SSM Agent version: 3.3.5538.0
  - NVIDIA Driver version: 580.178.04
  - Maximum Supported CUDA Version version: 13.0
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.49.0
  - ENA Driver version: 2.17.4g
  - Python version: 3.9.25
  - Kubernetes version: v1.33.5-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.5
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7

  - collectd version: 5.12.0.

- acl version: 2.4.0
- lustre-client version: 2.15.6
- nvidia-imex version: 580.178.04
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300071.0
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

Kubernetes v1.34

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.111-136.204.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.8
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.4.3
  - Containerd version: 2.3.5+unknown
  - aws SSM Agent version: 3.3.5538.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - Maximum Supported CUDA Version version: 13.2
  - NVIDIA CUDA Toolkit version: 13.2

- EFA Installer version: 1.50.0
- ENA Driver version: 2.17.4g
- Python version: 3.9.25
- Kubernetes version: v1.34.2-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.5
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300071.0
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 64.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.111-136.204.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.8
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.4.3

- Containerd version: 2.3.5+unknown
- aws SSM Agent version: 3.3.5538.0
- NVIDIA Driver version: 595.91.07
- Maximum Supported CUDA Version version: 13.2
- NVIDIA CUDA Toolkit version: 13.2
- EFA Installer version: 1.50.0
- ENA Driver version: 2.17.4g
- Python version: 3.9.25
- Kubernetes version: v1.34.2-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.5
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- nvidia-imex version: 595.91.07
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300071.0
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0

- rdma-core version: 64.0

Kubernetes v1.35

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.111-136.204.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.8
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.4.3
  - Containerd version: 2.3.5+unknown
  - aws SSM Agent version: 3.3.5538.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - Maximum Supported CUDA Version version: 13.2
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.50.0
  - ENA Driver version: 2.17.4g
  - Python version: 3.9.25
  - Kubernetes version: v1.35.2-eks-f69f56f
  - iptables-services version: 1.8.8
  - nginx version: 1.30.5
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.4.0
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 9.9
  - sudo version: 1.9.15

SageMaker Hyperpod AMI releases for Amazon EKS: September 17, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.30, 1.31, 1.32, 1.33, 1.34, 1.35, 1.36.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.30

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.103-127.188.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.5226.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.50.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: v1.30.14-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.4
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.4.0
  - lustre-client version: 2.15.6
  - systemd version: 252

- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 64.0

Kubernetes v1.31

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.103-127.188.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.5226.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.50.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: v1.31.13-eks-ecaa3a6
  - iptables-services version: 1.8.8

- nginx version: 1.30.4
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 64.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.103-127.188.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.5226.0
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Toolkit version: 13.2

  - EFA Installer version: 1.50.0

- ENA Driver version: 2.17.2g
- Python version: 3.9.25
- Kubernetes version: v1.31.13-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.4
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- nvidia-imex version: 595.91.07
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 64.0

Kubernetes v1.32

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.103-127.188.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7

- FSx Lustre Client version: 2.15.6
- Runc version: 1.3.5
- Containerd version: 2.2.5+unknown
- aws SSM Agent version: 3.3.5226.0
- aws Neuronx DKMS version: 2.30.2.0
- NVIDIA Driver version: 595.91.07
- NVIDIA CUDA Toolkit version: 13.2
- EFA Installer version: 1.50.0
- ENA Driver version: 2.17.2g
- Python version: 3.9.25
- Kubernetes version: v1.32.9-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.4
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0

- rdma-core version: 64.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.103-127.188.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.5226.0
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.50.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: v1.32.9-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.4
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.4.0
  - lustre-client version: 2.15.6

- aws-cfn-bootstrap version: 2.0
- rdma-core version: 64.0

SageMaker Hyperpod AMI releases for Amazon EKS: September 8, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.30, 1.31, 1.32, 1.33, 1.34, 1.35, 1.36.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.30

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.49.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: Kubernetes v1.30.14-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.4
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.4.0
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 9.9
  - sudo version: 1.9.15
  - gcc version: 11.5.0

- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

Kubernetes v1.31

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.49.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: Kubernetes v1.31.13-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.4
  - nvme-cli version: 2.13.1.13

  - stress version: 1.0.7

- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.4624.0
  - NVIDIA Driver version: 595.91.07
  - Maximum Supported CUDA Version version: 13.2
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.49.0
  - ENA Driver version: 2.17.2g

  - Python version: 3.9.25

- Kubernetes version: Kubernetes v1.31.13-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.4
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- nvidia-imex version: 595.91.07
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

Kubernetes v1.32

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5

- Containerd version: 2.2.5+unknown
- aws SSM Agent version: 3.3.4624.0
- aws Neuronx DKMS version: 2.30.2.0
- NVIDIA Driver version: 595.91.07
- NVIDIA CUDA Toolkit version: 13.2
- EFA Installer version: 1.49.0
- ENA Driver version: 2.17.2g
- Python version: 3.9.25
- Kubernetes version: Kubernetes v1.32.9-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.4
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

- AL2023 (ARM64):

- Linux Kernel version: 6.12.100-125.179.amzn2023.aarch64
- Glibc version: 2.34
- OpenSSL version: 3.5.7
- FSx Lustre Client version: 2.15.6
- Runc version: 1.3.5
- Containerd version: 2.2.5+unknown
- aws SSM Agent version: 3.3.4624.0
- NVIDIA Driver version: 595.91.07
- Maximum Supported CUDA Version version: 13.2
- NVIDIA CUDA Toolkit version: 13.2
- EFA Installer version: 1.49.0
- ENA Driver version: 2.17.2g
- Python version: 3.9.25
- Kubernetes version: Kubernetes v1.32.9-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.4
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- nvidia-imex version: 595.91.07
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3

- cloudwatch-agent version: 1.300069.1

- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

Kubernetes v1.33

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 580.178.04
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.49.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: Kubernetes v1.33.5-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.4
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.4.0
  - lustre-client version: 2.15.6
  - systemd version: 252

- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.95-124.187.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.4+unknown
  - aws SSM Agent version: 3.3.4624.0
  - NVIDIA Driver version: 595.91.07
  - Maximum Supported CUDA Version version: 13.2
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.47.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: Kubernetes v1.33.5-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.4
  - nvme-cli version: 2.13 1.13

- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- nvidia-imex version: 595.91.07
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

Kubernetes v1.34

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07

- NVIDIA CUDA Toolkit version: 13.2
- EFA Installer version: 1.49.0
- ENA Driver version: 2.17.2g
- Python version: 3.9.25
- Kubernetes version: Kubernetes v1.34.2-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.4
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6

- Runc version: 1.3.5
- Containerd version: 2.2.5+unknown
- aws SSM Agent version: 3.3.4624.0
- NVIDIA Driver version: 595.91.07
- Maximum Supported CUDA Version version: 13.2
- NVIDIA CUDA Toolkit version: 13.2
- EFA Installer version: 1.49.0
- ENA Driver version: 2.17.2g
- Python version: 3.9.25
- Kubernetes version: Kubernetes v1.34.2-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.4
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- nvidia-imex version: 595.91.07
- systemd version: 252

- aws-cfn-bootstrap version: 2.0

- rdma-core version: 63.0

Kubernetes v1.35

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.49.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: Kubernetes v1.35.2-eks-f69f56f
  - iptables-services version: 1.8.8
  - nginx version: 1.30.4
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.4.0
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 9.9
  - sudo version: 1.9.15
  - gcc version: 11.5.0
  - cmake version: 3.22.2

- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.4624.0
  - NVIDIA Driver version: 595.91.07
  - Maximum Supported CUDA Version version: 13.2
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.49.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: Kubernetes v1.35.2-eks-f69f56f
  - iptables-services version: 1.8.8
  - nginx version: 1.30.4
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.4.0
  - lustre-client version: 2.15.6

- nvidia-imex version: 595.91.07
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

Kubernetes v1.36

- AL2023 (x86_64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.49.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25

- Kubernetes version: Kubernetes v1.36.2-eks-7d6f6ec
- iptables-services version: 1.8.8
- nginx version: 1.30.4
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.4.0
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 9.9
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300069.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 63.0

- AL2023 (ARM64):
  - Linux Kernel version: 6.12.100-125.179.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7

SageMaker Hyperpod AMI releases for Amazon EKS: August 29, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.30, 1.31, 1.32, 1.33, 1.34, 1.35, 1.36.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.30

- AL2023 (x86_64):
  - AMI version: 2.1.0
  - Linux Kernel version: 6.12.100-125.179.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.7
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.5+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.30.2.0
  - NVIDIA Driver version: 595.91.07
  - Maximum Supported CUDA Version version: 13.2
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.49.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: v1.30.14-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.4

SageMaker Hyperpod AMI releases for Amazon EKS: July 30, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.30, 1.31, 1.32, 1.33, 1.34, 1.35, 1.36.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.30

- AL2023 (x86_64):
  - AMI version: 2.0.2
  - Linux Kernel version: 6.12.94-123.180.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.4+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.29.0.0
  - NVIDIA Driver version: 595.71.05
  - Maximum Supported CUDA Version version: 13.2
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.47.0
  - ENA Driver version: 2.17.2g
  - Python version: 3.9.25
  - Kubernetes version: v1.30.14-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.3
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.3.1
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 8.7
  - sudo version: 1.9.15
  - gcc version: 11.5.0
  - cmake version: 3.22.2

- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300067.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

Kubernetes v1.31

- AL2023 (x86_64):
  - AMI version: 2.0.2
  - Linux Kernel version: 6.12.94-123.180.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.4+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.29.0.0
  - NVIDIA Driver version: 595.71.05
  - Maximum Supported CUDA Version version: 13.2
  - NVIDIA CUDA Toolkit version: 13.2
  - EFA Installer version: 1.47.0

SageMaker Hyperpod AMI releases for Amazon EKS: July 06, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.30, 1.31, 1.32, 1.33, 1.34, 1.35.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.30

- AL2023 (x86_64):
  - AMI version: 1.4.0
  - Linux Kernel version: 6.12.92-122.168.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.4+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.28.0.0
  - NVIDIA Driver version: 580.159.04
  - Maximum Supported CUDA Version version: 13.0

- NVIDIA CUDA Toolkit version: 12.8
- EFA Installer version: 1.47.0
- ENA Driver version: 2.17.1g
- Python version: 3.9.25
- Kubernetes version: v1.30.14-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.2
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300067.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

Kubernetes v1.31

- AL2023 (x86_64):
- AMI version: 1.4.0

- Linux Kernel version: 6.12.92-122.168.amzn2023.x86_64

- Glibc version: 2.34
- OpenSSL version: 3.5.5
- FSx Lustre Client version: 2.15.6
- Runc version: 1.3.5
- Containerd version: 2.2.4+unknown
- aws SSM Agent version: 3.3.4624.0
- aws Neuronx DKMS version: 2.28.0.0
- NVIDIA Driver version: 580.159.04
- Maximum Supported CUDA Version version: 13.0
- NVIDIA CUDA Toolkit version: 12.8
- EFA Installer version: 1.47.0
- ENA Driver version: 2.17.1g
- Python version: 3.9.25
- Kubernetes version: v1.31.13-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.30.2
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300067.1
- nfs-utils version: 2.5.4

- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

- AL2023 (ARM64):
  - AMI version: 1.4.0
  - Linux Kernel version: 6.12.92-122.168.amzn2023.aarch64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.4+unknown
  - aws SSM Agent version: 3.3.4624.0
  - NVIDIA Driver version: 580.159.04
  - Maximum Supported CUDA Version version: 13.0
  - NVIDIA CUDA Toolkit version: 12.8
  - EFA Installer version: 1.47.0
  - ENA Driver version: 2.17.1g
  - Python version: 3.9.25
  - Kubernetes version: v1.31.13-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.2
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.3.1
  - lustre-client version: 2.15.6
  - nvidia-imex version: 580.159.04
  - systemd version: 252
  - openssh version: 8.7

- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300067.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

Kubernetes v1.32

- AL2023 (x86_64):
  - AMI version: 1.4.0
  - Linux Kernel version: 6.12.92-122.168.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.5
  - Containerd version: 2.2.4+unknown
  - aws SSM Agent version: 3.3.4624.0
  - aws Neuronx DKMS version: 2.28.0.0
  - NVIDIA Driver version: 580.159.04
  - Maximum Supported CUDA Version version: 13.0

SageMaker Hyperpod AMI releases for Amazon EKS: June 19, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, 1.33, 1.34, 1.35.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - AMI version: 1.0.1
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64

- Glibc version: 2.26
- OpenSSL version: 1.0.2k-fips
- FSx Lustre Client version: 2.12.8
- Docker version: Docker version 25.0.14, build 0bab007
- Runc version: 1.3.4
- Containerd version: 1.7.29
- aws CLI v2 version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
- aws SSM Agent version: 3.3.3598.0
- aws Neuronx DKMS version: 2.26.5.0
- NVIDIA Driver version: 570.211.01
- Maximum Supported CUDA Version version: 12.8
- NVIDIA CUDA Toolkit version: 12.2
- EFA Installer version: 1.45.0
- ENA Driver version: 2.16.1g
- Python version: 3.7.16
- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1

- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300066.2
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.2.1
  - Linux Kernel version: 6.1.170-213.321.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: 1.7.27
  - aws SSM Agent version: 3.3.4108.0
  - aws Neuronx DKMS version: 2.27.4.0
  - NVIDIA Driver version: 580.150
  - Maximum Supported CUDA Version version: 13.0
  - NVIDIA CUDA Toolkit version: 12.8
  - EFA Installer version: 1.47.0
  - ENA Driver version: 2.16.1g
  - Python version: 3.9.25
  - Kubernetes version: v1.28.15-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.0
  - nvme-cli version: 2.13.1.13

  - stress version: 1.0.7

- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

Kubernetes v1.29

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - AMI version: 1.0.1
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws CLI v2 version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60

- aws SSM Agent version: 3.3.3598.0
- aws Neuronx DKMS version: 2.26.5.0
- NVIDIA Driver version: 570.211.01
- Maximum Supported CUDA Version version: 12.8
- NVIDIA CUDA Toolkit version: 12.2
- EFA Installer version: 1.45.0
- ENA Driver version: 2.16.1g
- Python version: 3.7.16
- Kubernetes version: v1.29.15-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300066.2
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1

- aws-cfn-bootstrap version: 2.0

- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.2.1
  - Linux Kernel version: 6.1.170-213.321.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws SSM Agent version: 3.3.4108.0
  - aws Neuronx DKMS version: 2.27.4.0
  - NVIDIA Driver version: 580.150
  - Maximum Supported CUDA Version version: 13.0
  - NVIDIA CUDA Toolkit version: 12.8
  - EFA Installer version: 1.47.0
  - ENA Driver version: 2.16.1g
  - Python version: 3.9.25
  - Kubernetes version: v1.29.15-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.30.0
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.3.1
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 8.7
  - sudo version: 1.9.15
  - gcc version: 11.5.0

  - cmake version: 3.22.2

- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

Kubernetes v1.30

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - AMI version: 1.0.1
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws CLI v2 version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
  - aws SSM Agent version: 3.3.3598.0
  - aws Neuronx DKMS version: 2.26.5.0
  - NVIDIA Driver version: 570.211.01
  - Maximum Supported CUDA Version version: 12.8
  - NVIDIA CUDA Toolkit version: 12.2
  - EFA Installer version: 1.45.0
  - ENA Driver version: 2.16.1g
  - Python version: 3.7.16

- Kubernetes version: v1.30.14-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300066.2
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

Kubernetes v1.31

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - AMI version: 1.0.1
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
  - Glibc version: 2.26

- OpenSSL version: 1.0.2k-fips
- FSx Lustre Client version: 2.12.8
- Docker version: Docker version 25.0.14, build 0bab007
- Runc version: 1.3.4
- Containerd version: 1.7.29
- aws CLI v2 version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
- aws SSM Agent version: 3.3.3598.0
- aws Neuronx DKMS version: 2.26.5.0
- NVIDIA Driver version: 570.211.01
- Maximum Supported CUDA Version version: 12.8

SageMaker Hyperpod AMI releases for Amazon EKS: May 27, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, 1.33, 1.34, 1.35.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws CLI version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
  - aws SSM Agent version: 3.3.3598.0
  - aws Neuronx DKMS version: 2.26.5.0
  - NVIDIA Driver version: 570.211.01
  - Maximum Supported CUDA Version version: 12.8
  - NVIDIA CUDA Toolkit version: 12.2
  - EFA Installer version: 1.45.0
  - ENA Driver version: 2.16.1g

- Python version: 3.7.16
- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.1.2
  - Linux Kernel version: 6.1.170-210.320.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5

  - FSx Lustre Client version: 2.15.6

- Runc version: 1.3.4
- Containerd version: 1.7.27
- aws SSM Agent version: 3.3.4108.0
- aws Neuronx DKMS version: 2.27.4.0
- NVIDIA Driver version: 580.126.09
- Maximum Supported CUDA Version version: 13.0
- NVIDIA CUDA Toolkit version: 12.8
- EFA Installer version: 1.47.0
- ENA Driver version: 2.16.1g
- Python version: 3.9.25
- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.28.3
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0

- rdma-core version: 61.0

Kubernetes v1.29

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws CLI version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
  - aws SSM Agent version: 3.3.3598.0
  - aws Neuronx DKMS version: 2.26.5.0
  - NVIDIA Driver version: 570.211.01
  - Maximum Supported CUDA Version version: 12.8
  - NVIDIA CUDA Toolkit version: 12.2
  - EFA Installer version: 1.45.0
  - ENA Driver version: 2.16.1g
  - Python version: 3.7.16
  - Kubernetes version: v1.29.15-eks-ecaa3a6
  - iptables-services version: 1.8.4
  - nginx version: 1.20.1
  - nvme-cli version: 1.11.1
  - epel-release version: 7
  - stress version: 1.0.4

SageMaker Hyperpod AMI releases for Amazon EKS: May 07, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, 1.33, 1.34, 1.35.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws CLI version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
  - aws SSM Agent version: 3.3.3598.0
  - aws Neuronx DKMS version: 2.26.5.0
  - NVIDIA Driver version: 570.211.01
  - Maximum Supported CUDA Version version: 12.8
  - NVIDIA CUDA Toolkit version: 12.2
  - EFA Installer version: 1.45.0
  - ENA Driver version: 2.16.1g
  - Python version: 3.7.16
  - Kubernetes version: v1.28.15-eks-ecaa3a6
  - iptables-services version: 1.8.4
  - nginx version: 1.20.1
  - nvme-cli version: 1.11.1

- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.1.1
  - Linux Kernel version: 6.1.168-203.330.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: 1.7.27
  - aws SSM Agent version: 3.3.4108.0
  - aws Neuronx DKMS version: 2.27.4.0
  - NVIDIA Driver version: 580.126.09

- Maximum Supported CUDA Version version: 13.0
- NVIDIA CUDA Toolkit version: 12.8
- EFA Installer version: 1.47.0
- ENA Driver version: 2.16.1g
- Python version: 3.9.25
- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.28.3
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

Kubernetes v1.29

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**

- AL2 (x86_64):

- Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
- Glibc version: 2.26
- OpenSSL version: 1.0.2k-fips
- FSx Lustre Client version: 2.12.8
- Docker version: Docker version 25.0.14, build 0bab007
- Runc version: 1.3.4
- Containerd version: 1.7.29
- aws CLI version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
- aws SSM Agent version: 3.3.3598.0
- aws Neuronx DKMS version: 2.26.5.0
- NVIDIA Driver version: 570.211.01
- Maximum Supported CUDA Version version: 12.8
- NVIDIA CUDA Toolkit version: 12.2
- EFA Installer version: 1.45.0
- ENA Driver version: 2.16.1g
- Python version: 3.7.16
- Kubernetes version: v1.29.15-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23

- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.1.1
  - Linux Kernel version: 6.1.168-203.330.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws SSM Agent version: 3.3.4108.0
  - aws Neuronx DKMS version: 2.27.4.0
  - NVIDIA Driver version: 580.126.09
  - Maximum Supported CUDA Version version: 13.0
  - NVIDIA CUDA Toolkit version: 12.8
  - EFA Installer version: 1.47.0
  - ENA Driver version: 2.16.1g
  - Python version: 3.9.25
  - Kubernetes version: v1.29.15-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.28.3
  - nvme-cli version: 2.13 1.13

- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

Kubernetes v1.30

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws CLI version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60

- aws SSM Agent version: 3.3.3598.0
- aws Neuronx DKMS version: 2.26.5.0
- NVIDIA Driver version: 570.211.01
- Maximum Supported CUDA Version version: 12.8
- NVIDIA CUDA Toolkit version: 12.2
- EFA Installer version: 1.45.0
- ENA Driver version: 2.16.1g
- Python version: 3.7.16
- Kubernetes version: v1.30.14-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4

SageMaker Hyperpod AMI releases for Amazon EKS: April 23, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, 1.33, 1.34, 1.35.
- Base DLAMI release note is available here.

This release includes the following updates:

Kubernetes v1.28

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws CLI v2 version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
  - aws SSM Agent version: 3.3.3598.0
  - aws Neuronx DKMS version: 2.26.5.0
  - NVIDIA Driver version: 570.211.01
  - Maximum Supported CUDA Version: 12.8
  - NVIDIA CUDA Toolkit version: 12.2
  - EFA Installer version: 1.45.0
  - ENA Driver version: 2.16.1g
  - Python version: 3.7.16
  - Kubernetes version: v1.28.15-eks-ecaa3a6
  - iptables-services version: 1.8.4
  - nginx version: 1.20.1
  - nvme-cli version: 1.11.1
  - epel-release version: 7
  - stress version: 1.0.4
  - collectd version: 5.8.1
  - acl version: 2.2.51
  - rsyslog version: 8.24.0

- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.1.0
  - Linux Kernel version: 6.1.166-197.305.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: 1.7.27
  - aws SSM Agent version: 3.3.4108.0
  - aws Neuronx DKMS version: 2.27.4.0
  - NVIDIA Driver version: 580.126.09
  - Maximum Supported CUDA Version: 13.0
  - NVIDIA CUDA Toolkit version: 12.8
  - EFA Installer version: 1.47.0
  - ENA Driver version: 2.16.1g
  - Python version: 3.9.25

- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.28.3
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

Kubernetes v1.29

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007

- Runc version: 1.3.4
- Containerd version: 1.7.29
- aws CLI v2 version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
- aws SSM Agent version: 3.3.3598.0
- aws Neuronx DKMS version: 2.26.5.0
- NVIDIA Driver version: 570.211.01
- Maximum Supported CUDA Version: 12.8
- NVIDIA CUDA Toolkit version: 12.2
- EFA Installer version: 1.45.0
- ENA Driver version: 2.16.1g
- Python version: 3.7.16
- Kubernetes version: v1.29.15-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.2

- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.1.0
  - Linux Kernel version: 6.1.166-197.305.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.5.5
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws SSM Agent version: 3.3.4108.0
  - aws Neuronx DKMS version: 2.27.4.0
  - NVIDIA Driver version: 580.126.09
  - Maximum Supported CUDA Version: 13.0
  - NVIDIA CUDA Toolkit version: 12.8
  - EFA Installer version: 1.47.0
  - ENA Driver version: 2.16.1g
  - Python version: 3.9.25
  - Kubernetes version: v1.29.15-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.28.3
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.3.1
  - lustre-client version: 2.15.6
  - systemd version: 252

- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 61.0

Kubernetes v1.30

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: 1.7.29
  - aws CLI v2 version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
  - aws SSM Agent version: 3.3.3598.0
  - aws Neuronx DKMS version: 2.26.5.0
  - NVIDIA Driver version: 570.211.01
  - Maximum Supported CUDA Version: 12.8
  - NVIDIA CUDA Toolkit version: 12.2

- EFA Installer version: 1.45.0
- ENA Driver version: 2.16.1g
- Python version: 3.7.16
- Kubernetes version: v1.30.14-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.2
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.1.0
  - Linux Kernel version: 6.1.166-197.305.amzn2023.x86_64
  - Glibc version: 2.34

- OpenSSL version: 3.5.5

SageMaker Hyperpod AMI releases for Amazon EKS: March 30, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, 1.33, 1.34.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):

- Linux Kernel version: 5.10.248-247.988.amzn2.x86_64
- Glibc version: 2.26
- OpenSSL version: 1.0.2k-fips
- FSx Lustre Client version: 2.12.8
- Docker version: Docker version 25.0.14, build 0bab007
- Runc version: 1.3.4
- Containerd version: 1.7.29
- aws CLI v2 version: aws-cli/1.44.50 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.60
- aws SSM Agent version: 3.3.3598.0
- aws Neuronx DKMS version: 2.26.5.0
- NVIDIA Driver version: 570.211.01
- Maximum Supported CUDA Version: 12.8
- NVIDIA CUDA Toolkit version: 12.2
- EFA Installer version: 1.45.0
- ENA Driver version: 2.16.1g
- Python version: 3.7.16
- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23

- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.3
  - Linux Kernel version: 6.1.163-186.299.amzn2023.x86_64
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: 1.7.27
  - aws SSM Agent version: 3.3.3598.0
  - aws Neuronx DKMS version: 2.26.10.0
  - NVIDIA Driver version: 580.126.09
  - Maximum Supported CUDA Version: 13.0
  - NVIDIA CUDA Toolkit version: 12.8
  - EFA Installer version: 1.45.0
  - ENA Driver version: 2.16.1g
  - Python version: 3.9.25
  - Kubernetes version: v1.28.15-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.28.2

  - nvme-cli version: 2.13 1.13

- stress version: 1.0.7

- aws-cfn-bootstrap version: 2.0
- rdma-core version: 58.

SageMaker Hyperpod AMI releases for Amazon EKS: March 01, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, 1.33, 1.34.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws CLI v2 version: aws-cli/1.44.44 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.54
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 570.211.01
  - CUDA version: 12.2
  - ENA Driver version: 2.16.1g
  - EFA Installer version: 1.45.0
  - Python version: 3.7.16
  - Kubernetes version: v1.28.15-eks-ecaa3a6
  - iptables-services version: 1.8.4
  - nginx version: 1.20.1
  - nvme-cli version: 1.11.1
  - epel-release version: 7
  - stress version: 1.0.4

- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.2
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.27
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.126.09
  - CUDA version: 12.8
  - ENA Driver version: 2.16.1g
  - EFA Installer version: 1.45.0

- Python version: 3.9.25
- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.28.2
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

Kubernetes v1.29

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8

- Docker version: Docker version 25.0.14, build 0bab007
- Runc version: 1.3.4
- Containerd version: containerd github.com/containerd/containerd 1.7.29
- aws CLI v2 version: aws-cli/1.44.44 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.54
- aws Neuronx DKMS version: 2.25.4.0
- NVIDIA Driver version: 570.211.01
- CUDA version: 12.2
- ENA Driver version: 2.16.1g
- EFA Installer version: 1.45.0
- Python version: 3.7.16
- Kubernetes version: v1.29.15-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.1
- nfs-utils version: 1.3.0

- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.2
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.126.09
  - CUDA version: 12.8
  - ENA Driver version: 2.16.1g
  - EFA Installer version: 1.45.0
  - Python version: 3.9.25
  - Kubernetes version: v1.29.15-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.28.2
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.3.1
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 8.7
  - sudo version: 1.9.15
  - gcc version: 11.5.0

- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

Kubernetes v1.30

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws CLI v2 version: aws-cli/1.44.44 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.54
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 570.211.01
  - CUDA version: 12.2
  - ENA Driver version: 2.16.1g
  - EFA Installer version: 1.45.0
  - Python version: 3.7.16
  - Kubernetes version: v1.30.14-eks-ecaa3a6
  - iptables-services version: 1.8.4

- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.2
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29

  - aws Neuronx DKMS version: 2.25.4.0

- NVIDIA Driver version: 580.126.09
- CUDA version: 12.8
- ENA Driver version: 2.16.1g
- EFA Installer version: 1.45.0
- Python version: 3.9.25
- Kubernetes version: v1.30.14-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.28.2
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300064.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

Kubernetes v1.31

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**

- AL2 (x86_64):

- Linux Kernel version: 5.10
- Glibc version: 2.26
- OpenSSL version: 1.0.2k-fips
- FSx Lustre Client version: 2.12.8
- Docker version: Docker version 25.0.14, build 0bab007
- Runc version: 1.3.4
- Containerd version: containerd github.com/containerd/containerd 1.7.29
- aws CLI v2 version: aws-cli/1.44.44 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.54
- aws Neuronx DKMS version: 2.25.4.0
- NVIDIA Driver version: 570.211.01
- CUDA version: 12.2
- ENA Driver version: 2.16.1g
- EFA Installer version: 1.45.0
- Python version: 3.7.16
- Kubernetes version: v1.31.13-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2

- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.2
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd/v2 2.1.5
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.126.09
  - CUDA version: 12.8
  - ENA Driver version: 2.16.1g
  - EFA Installer version: 1.45.0
  - Python version: 3.9.25

- make version: 4.3
- cloudwatch-agent version: 1.300064.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 58.

Kubernetes v1.32

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29

- aws CLI v2 version: aws-cli/1.44.46 Python/3.10.17 Linux/5.10.248-247.988.amzn2.x86_64 botocore/1.42.56
- aws Neuronx DKMS version: 2.25.4.0
- NVIDIA Driver version: 570.211.01
- CUDA version: 12.2
- ENA Driver version: 2.16.1g
- EFA Installer version: 1.45.0
- Python version: 3.7.16
- Kubernetes version: v1.32.9-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300064.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0

- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.2
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd/v2 2.1.5

SageMaker Hyperpod AMI releases for Amazon EKS: February 12, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, 1.33, 1.34.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws CLI v2 version: aws-cli/1.44.31 Python/3.10.17 Linux/5.10.247-246.989.amzn2.x86_64 botocore/1.42.41
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 570.211.01
  - CUDA version: 12.2

- ENA Driver version: 2.15.0g
- EFA Installer version: 1.45.0
- Python version: 3.7.16
- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300062.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.1
  - Linux Kernel version: 6.1
  - Glibc version: 2.34

- OpenSSL version: 3.2.2
- FSx Lustre Client version: 2.15.6
- Runc version: 1.3.4
- Containerd version: containerd github.com/containerd/containerd 1.7.27
- aws Neuronx DKMS version: 2.25.4.0
- NVIDIA Driver version: 580.126.09
- CUDA version: 12.8
- ENA Driver version: 2.15.0g
- EFA Installer version: 1.45.0
- Python version: 3.9.25
- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.28.1
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300062.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1

- aws-cfn-bootstrap version: 2.0

- rdma-core version: 60.0

Kubernetes v1.29

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws CLI v2 version: aws-cli/1.44.31 Python/3.10.17 Linux/5.10.247-246.989.amzn2.x86_64 botocore/1.42.41
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 570.211.01
  - CUDA version: 12.2
  - ENA Driver version: 2.15.0g
  - EFA Installer version: 1.45.0
  - Python version: 3.7.16
  - Kubernetes version: v1.29.15-eks-ecaa3a6
  - iptables-services version: 1.8.4
  - nginx version: 1.20.1
  - nvme-cli version: 1.11.1
  - epel-release version: 7
  - stress version: 1.0.4
  - collectd version: 5.8.1
  - acl version: 2.2.51
  - rsyslog version: 8.24.0
  - lustre-client version: 2.12.8

- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300062.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.1
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.126.09
  - CUDA version: 12.8
  - ENA Driver version: 2.15.0g
  - EFA Installer version: 1.45.0
  - Python version: 3.9.25
  - Kubernetes version: v1.29.15-eks-ecaa3a6
  - iptables-services version: 1.8.8

  - nginx version: 1.28.1

- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300062.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

Kubernetes v1.30

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29

- aws CLI v2 version: aws-cli/1.44.31 Python/3.10.17 Linux/5.10.247-246.989.amzn2.x86_64 botocore/1.42.41
- aws Neuronx DKMS version: 2.25.4.0

SageMaker Hyperpod AMI releases for Amazon EKS: January 25, 2026

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, 1.33, 1.34.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26

- OpenSSL version: 1.0.2k-fips
- FSx Lustre Client version: 2.12.8
- Docker version: Docker version 25.0.14, build 0bab007
- Runc version: 1.3.4
- Containerd version: containerd github.com/containerd/containerd 1.7.29
- aws CLI v2 version: aws-cli/1.44.21 Python/3.10.17 Linux/5.10.247-246.989.amzn2.x86_64 botocore/1.42.31
- aws Neuronx DKMS version: 2.25.4.0
- NVIDIA Driver version: 570.211.01
- CUDA version: 12.2
- ENA Driver version: 2.15.0g
- Python version: 3.7.16
- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82

- cloudwatch-agent version: 1.300062.1

- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.0
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.27
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.126.09
  - CUDA version: 12.8
  - ENA Driver version: 2.15.0g
  - Python version: 3.9.25
  - Kubernetes version: v1.28.15-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.28.0
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.3.1
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 8.7
  - sudo version: 1.9.15

  - gcc version: 11.5.0

- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300062.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

Kubernetes v1.29

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.14, build 0bab007
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws CLI v2 version: aws-cli/1.44.21 Python/3.10.17 Linux/5.10.247-246.989.amzn2.x86_64 botocore/1.42.31
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 570.211.01
  - CUDA version: 12.2
  - ENA Driver version: 2.15.0g
  - Python version: 3.7.16
  - Kubernetes version: v1.29.15-eks-ecaa3a6
  - iptables-services version: 1.8.4
  - nginx version: 1.20.1

- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300062.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.0
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.126.09

- CUDA version: 12.8
- ENA Driver version: 2.15.0g
- Python version: 3.9.25
- Kubernetes version: v1.29.15-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.28.0
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300062.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

Kubernetes v1.30

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
- Linux Kernel version: 5.10
- Glibc version: 2.26

- OpenSSL version: 1.0.2k-fips
- FSx Lustre Client version: 2.12.8
- Docker version: Docker version 25.0.14, build 0bab007
- Runc version: 1.3.4
- Containerd version: containerd github.com/containerd/containerd 1.7.29
- aws CLI v2 version: aws-cli/1.44.21 Python/3.10.17 Linux/5.10.247-246.989.amzn2.x86_64 botocore/1.42.31
- aws Neuronx DKMS version: 2.25.4.0
- NVIDIA Driver version: 570.211.01
- CUDA version: 12.2
- ENA Driver version: 2.15.0g
- Python version: 3.7.16
- Kubernetes version: v1.30.14-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82

- cloudwatch-agent version: 1.300062.1

- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - AMI version: 1.0.0
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.4
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.126.09
  - CUDA version: 12.8
  - ENA Driver version: 2.15.0g
  - Python version: 3.9.25
  - Kubernetes version: v1.30.14-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.28.0
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.3.1
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 8.7
  - sudo version: 1.9.15

  - gcc version: 11.5.0

- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300062.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16

- cloudwatch-agent version: 1.300062.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 58.

SageMaker Hyperpod AMI releases for Amazon EKS: December 29, 2025

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, 1.33.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.13, build 0bab007
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.29

- aws CLI v2 version: aws-cli/1.44.4 Python/3.10.17 Linux/5.10.245-245.983.amzn2.x86_64 botocore/1.42.14
- aws Neuronx DKMS version: 2.25.4.0
- NVIDIA Driver version: 570.195.03
- CUDA version: 12.2
- ENA Driver version: 2.15.0g
- Python version: 3.7.16
- Kubernetes version: v1.28.15-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300060.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.27
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.105.08
  - CUDA version: 12.8
  - ENA Driver version: 2.15.0g
  - Python version: 3.9.25
  - Kubernetes version: v1.28.15-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.28.0
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.3.1
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 8.7
  - sudo version: 1.9.15
  - gcc version: 11.5.0
  - cmake version: 3.22.2
  - git version: 2.50.1
  - make version: 4.3
  - cloudwatch-agent version: 1.300060.1
  - nfs-utils version: 2.5.4

  - lvm2 version: 2.03.16

- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

Kubernetes v1.29

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.13, build 0bab007
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws CLI v2 version: aws-cli/1.44.4 Python/3.10.17 Linux/5.10.245-245.983.amzn2.x86_64 botocore/1.42.14
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 570.195.03
  - CUDA version: 12.2
  - ENA Driver version: 2.15.0g
  - Python version: 3.7.16
  - Kubernetes version: v1.29.15-eks-ecaa3a6
  - iptables-services version: 1.8.4
  - nginx version: 1.20.1
  - nvme-cli version: 1.11.1
  - epel-release version: 7
  - stress version: 1.0.4
  - collectd version: 5.8.1
  - acl version: 2.2.51
  - rsyslog version: 8.24.0

- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300060.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 580.105.08
  - CUDA version: 12.8
  - ENA Driver version: 2.15.0g
  - Python version: 3.9.25
  - Kubernetes version: v1.29.15-eks-ecaa3a6
  - iptables-services version: 1.8.8
  - nginx version: 1.28.0
  - nvme-cli version: 2.13 1.13

- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300060.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

Kubernetes v1.30

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.13, build 0bab007
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws CLI v2 version: aws-cli/1.44.4 Python/3.10.17 Linux/5.10.245-245.983.amzn2.x86_64 botocore/1.42.14

- aws Neuronx DKMS version: 2.25.4.0
- NVIDIA Driver version: 570.195.03
- CUDA version: 12.2
- ENA Driver version: 2.15.0g
- Python version: 3.7.16
- Kubernetes version: v1.30.14-eks-ecaa3a6
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300060.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 60.0

- AL2023 (x86_64):
  - Linux Kernel version: 6.1

- Glibc version: 2.34
- OpenSSL version: 3.2.2
- FSx Lustre Client version: 2.15.6
- Runc version: 1.3.3
- Containerd version: containerd github.com/containerd/containerd 1.7.29
- aws Neuronx DKMS version: 2.25.4.0
- NVIDIA Driver version: 580.105.08
- CUDA version: 12.8
- ENA Driver version: 2.15.0g
- Python version: 3.9.25
- Kubernetes version: v1.30.14-eks-ecaa3a6
- iptables-services version: 1.8.8
- nginx version: 1.28.0
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300060.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1

- aws-cfn-bootstrap version: 2.0

- rdma-core version: 60.0

Kubernetes v1.31

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.13, build 0bab007
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.29
  - aws CLI v2 version: aws-cli/1.44.4 Python/3.10.17 Linux/5.10.245-245.983.amzn2.x86_64 botocore/1.42.14
  - aws Neuronx DKMS version: 2.25.4.0
  - NVIDIA Driver version: 570.195.03
  - CUDA version: 12.2
  - ENA Driver version: 2.15.0g
  - Python version: 3.7.16
  - Kubernetes version: v1.31.13-eks-ecaa3a6
  - iptables-services version: 1.8.4
  - nginx version: 1.20.1
  - nvme-cli version: 1.11.1
  - epel-release version: 7
  - stress version: 1.0.4
  - collectd version: 5.8.1
  - acl version: 2.2.51
  - rsyslog version: 8.24.0
  - lustre-client version: 2.12.8
  - systemd version: 219

- openssh version: 7.4
- sudo version: 1.8.23

- rdma-core version: 58.

SageMaker Hyperpod AMI releases for Amazon EKS: November 22, 2025

AMI general updates

- Released updates for SageMaker Hyperpod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, 1.33.
- Base DLAMI release note is available here.

SageMaker Hyperpod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips

- FSx Lustre Client version: 2.12.8
- Docker version: Docker version 25.0.13, build 0bab007
- Runc version: 1.3.3
- Containerd version: containerd github.com/containerd/containerd 1.7.27
- aws CLI v2 version: aws-cli/1.42.71 Python/3.10.17 Linux/5.10.245-241.978.amzn2.x86_64 botocore/1.40.71
- aws Neuronx DKMS version: 2.24.7.0
- NVIDIA Driver version: 570.195.03
- CUDA version: 12.2
- ENA Driver version: 2.15.0g
- Python version: 3.7.16
- Kubernetes version: v1.28.15-eks-473151a
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300060.1
- nfs-utils version: 1.3.0

- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 59.

- AL2023 (x86_64):
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.27
  - aws Neuronx DKMS version: 2.24.7.0
  - NVIDIA Driver version: 580.95.05
  - CUDA version: 12.8
  - ENA Driver version: 2.15.0g
  - Python version: 3.9.24
  - Kubernetes version: v1.28.15-eks-473151a
  - iptables-services version: 1.8.8
  - nginx version: 1.28.0
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.3.1
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 8.7
  - sudo version: 1.9.15
  - gcc version: 11.5.0
  - cmake version: 3.22.2
  - git version: 2.50.1

- make version: 4.3
- cloudwatch-agent version: 1.300060.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 59.

Kubernetes v1.29

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.13, build 0bab007
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.27
  - aws CLI v2 version: aws-cli/1.42.71 Python/3.10.17 Linux/5.10.245-241.978.amzn2.x86_64 botocore/1.40.71
  - aws Neuronx DKMS version: 2.24.7.0
  - NVIDIA Driver version: 570.195.03
  - CUDA version: 12.2
  - ENA Driver version: 2.15.0g
  - Python version: 3.7.16
  - Kubernetes version: v1.29.15-eks-473151a
  - iptables-services version: 1.8.4
  - nginx version: 1.20.1
  - nvme-cli version: 1.11.1
  - epel-release version: 7

- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300060.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 59.

- AL2023 (x86_64):
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.27
  - aws Neuronx DKMS version: 2.24.7.0
  - NVIDIA Driver version: 580.95.05
  - CUDA version: 12.8
  - ENA Driver version: 2.15.0g
  - Python version: 3.9.24

- Kubernetes version: v1.29.15-eks-473151a
- iptables-services version: 1.8.8
- nginx version: 1.28.0
- nvme-cli version: 2.13 1.13
- stress version: 1.0.7
- collectd version: 5.12.0.
- acl version: 2.3.1
- lustre-client version: 2.15.6
- systemd version: 252
- openssh version: 8.7
- sudo version: 1.9.15
- gcc version: 11.5.0
- cmake version: 3.22.2
- git version: 2.50.1
- make version: 4.3
- cloudwatch-agent version: 1.300060.1
- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 59.

Kubernetes v1.30

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.13, build 0bab007

- Runc version: 1.3.2
- Containerd version: containerd github.com/containerd/containerd 1.7.27
- aws CLI v2 version: aws-cli/1.42.69 Python/3.10.17 Linux/5.10.245-241.976.amzn2.x86_64 botocore/1.40.69
- aws Neuronx DKMS version: 2.24.7.0
- NVIDIA Driver version: 570.195.03
- CUDA version: 12.2
- ENA Driver version: 2.15.0g
- Python version: 3.7.16
- Kubernetes version: v1.30.11-eks-473151a
- iptables-services version: 1.8.4
- nginx version: 1.20.1
- nvme-cli version: 1.11.1
- epel-release version: 7
- stress version: 1.0.4
- collectd version: 5.8.1
- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23
- gcc version: 7.3.1
- cmake version: 2.8.12.2
- git version: 2.47.3
- make version: 3.82
- cloudwatch-agent version: 1.300060.1
- nfs-utils version: 1.3.0
- lvm2 version: 2.02.187
- ec2-instance-connect version: 1.1

- aws-cfn-bootstrap version: 2.0
- rdma-core version: 58.

- AL2023 (x86_64):
  - Linux Kernel version: 6.1
  - Glibc version: 2.34
  - OpenSSL version: 3.2.2
  - FSx Lustre Client version: 2.15.6
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.27
  - aws Neuronx DKMS version: 2.24.7.0
  - NVIDIA Driver version: 580.95.05
  - CUDA version: 12.8
  - ENA Driver version: 2.15.0g
  - Python version: 3.9.24
  - Kubernetes version: v1.30.11-eks-473151a
  - iptables-services version: 1.8.8
  - nginx version: 1.28.0
  - nvme-cli version: 2.13 1.13
  - stress version: 1.0.7
  - collectd version: 5.12.0.
  - acl version: 2.3.1
  - lustre-client version: 2.15.6
  - systemd version: 252
  - openssh version: 8.7
  - sudo version: 1.9.15
  - gcc version: 11.5.0
  - cmake version: 3.22.2
  - git version: 2.50.1
  - make version: 4.3

  - cloudwatch-agent version: 1.300060.1

- nfs-utils version: 2.5.4
- lvm2 version: 2.03.16
- ec2-instance-connect version: 1.1
- aws-cfn-bootstrap version: 2.0
- rdma-core version: 59.

Kubernetes v1.31

- **AL2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - Linux Kernel version: 5.10
  - Glibc version: 2.26
  - OpenSSL version: 1.0.2k-fips
  - FSx Lustre Client version: 2.12.8
  - Docker version: Docker version 25.0.13, build 0bab007
  - Runc version: 1.3.3
  - Containerd version: containerd github.com/containerd/containerd 1.7.27
  - aws CLI v2 version: aws-cli/1.42.71 Python/3.10.17 Linux/5.10.245-241.978.amzn2.x86_64 botocore/1.40.71
  - aws Neuronx DKMS version: 2.24.7.0
  - NVIDIA Driver version: 570.195.03
  - CUDA version: 12.2
  - ENA Driver version: 2.15.0g
  - Python version: 3.7.16
  - Kubernetes version: v1.31.7-eks-473151a
  - iptables-services version: 1.8.4
  - nginx version: 1.20.1
  - nvme-cli version: 1.11.1
  - epel-release version: 7
  - stress version: 1.0.4
  - collectd version: 5.8.1

- acl version: 2.2.51
- rsyslog version: 8.24.0
- lustre-client version: 2.12.8
- systemd version: 219
- openssh version: 7.4
- sudo version: 1.8.23

SageMaker HyperPod AMI releases for Amazon EKS: November 07, 2025

AMI general updates

- Released updates for SageMaker HyperPod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, and 1.33.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):

    - NVIDIA driver version: 570.195.03
    - CUDA version: 12.8
    - Kubernetes version: 1.28.15
- AL2023 (x86_64):
    - NVIDIA driver version: 580.95.05
    - CUDA version: 13.0
    - Kubernetes version: 1.28.15
- Package updates include boto3, botocore, pip, regex, psutil, and nvidia container toolkit components.
- Added package: annotated-doc 0.0.3

Kubernetes v1.29

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
    - NVIDIA driver version: 570.195.03
    - CUDA version: 12.8
    - Kubernetes version: 1.29.15
- AL2023 (x86_64):
    - NVIDIA driver version: 580.95.05
    - CUDA version: 13.0
    - Kubernetes version: 1.29.15
- Package updates include kernel updates, glibc updates, and various system libraries.
- Added package: annotated-doc 0.0.3

Kubernetes v1.30

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
    - NVIDIA driver version: 570.195.03
    - CUDA version: 12.8
    - Kubernetes version: 1.30.11

- AL2023 (x86_64):
  - NVIDIA driver version: 580.95.05
  - CUDA version: 13.0
  - Kubernetes version: 1.30.11
- Package updates include kernel livepatch updates and system library updates.
- Added package: annotated-doc 0.0.3

Kubernetes v1.31

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - NVIDIA driver version: 570.195.03
  - CUDA version: 12.8
  - Kubernetes version: 1.31.7
- AL2023 (x86_64):
  - NVIDIA driver version: 580.95.05
  - CUDA version: 13.0
  - Kubernetes version: 1.31.13
- AL2023 (arm):
  - NVIDIA driver version: 580.95.05
  - CUDA version: 13.0
  - Kubernetes version: 1.31.13
  - Kernel version: 6.12.46-66.121.amzn2023.aarch64
- Package updates include extensive system library updates, kernel updates, and boost library updates.
- Added packages: apr-util-lmdb, kernel-livepatch-6.1.156-177.286

Kubernetes v1.32

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - NVIDIA driver version: 570.195.03

    - CUDA version: 12.8
    - Kubernetes version: 1.32.3
    - Amazon IAM Authenticator version: v0.6.29
- AL2023 (x86_64):
    - NVIDIA driver version: 580.95.05
    - CUDA version: 13.0
    - Kubernetes version: 1.32.9
- AL2023 (arm):
    - NVIDIA driver version: 580.95.05
    - CUDA version: 13.0
    - Kubernetes version: 1.32.9
    - Kernel version: 6.12.46-66.121.amzn2023.aarch64
- Package updates include kernel livepatch updates and system library updates.
- Added package: annotated-doc 0.0.3

Kubernetes v1.33

- AL2023 (x86_64):
    - NVIDIA driver version: 580.95.05
    - CUDA version: 13.0
    - Kubernetes version: 1.33.5
    - Kernel version: 6.1.155-176.282.amzn2023.x86_64
- AL2023 (arm):
    - NVIDIA driver version: 580.95.05
    - CUDA version: 13.0
    - Kubernetes version: 1.33.5
    - Kernel version: 6.12.46-66.121.amzn2023.aarch64
- Package updates include extensive system library updates, kernel updates, and boost library updates.
- Added packages: apr-util-lmdb, kernel-livepatch updates

Note

runc version has been upgraded to 1.3.2 Security bulletin

SageMaker HyperPod AMI releases for Amazon EKS: October 29, 2025

AMI general updates

- Released updates for SageMaker HyperPod AMI for Amazon EKS versions 1.28, 1.29, 1.30, 1.31, 1.32, and 1.33.
- Base DLAMI release note is available here.

SageMaker HyperPod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - NVIDIA driver version: 570.195.03
  - CUDA version: 12.8
  - Kubernetes version: 1.28.15
- AL2023 (x86_64):
  - NVIDIA driver version: 580.95.05
  - CUDA version: 13.0
  - Kubernetes version: 1.28.15
- Package updates include boto3, botocore, pip, regex, psutil, and nvidia container toolkit components.
- Added package: annotated-doc 0.0.3

Kubernetes v1.29

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):

    - NVIDIA driver version: 570.195.03
    - CUDA version: 12.8
    - Kubernetes version: 1.29.15
- AL2023 (x86_64):
    - NVIDIA driver version: 580.95.05
    - CUDA version: 13.0
    - Kubernetes version: 1.29.15
- Package updates include kernel updates, glibc updates, and various system libraries.
- Added package: annotated-doc 0.0.3

Kubernetes v1.30

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
    - NVIDIA driver version: 570.195.03
    - CUDA version: 12.8
    - Kubernetes version: 1.30.11
- AL2023 (x86_64):
    - NVIDIA driver version: 580.95.05
    - CUDA version: 13.0
    - Kubernetes version: 1.30.11
- Package updates include kernel livepatch updates and system library updates.
- Added package: annotated-doc 0.0.3

Kubernetes v1.31

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
    - NVIDIA driver version: 570.195.03
    - CUDA version: 12.8
    - Kubernetes version: 1.31.7
- AL2023 (x86_64):

  - NVIDIA driver version: 580.95.05
  - CUDA version: 13.0
  - Kubernetes version: 1.31.13
- AL2023 (arm):
  - NVIDIA driver version: 580.95.05
  - CUDA version: 13.0
  - Kubernetes version: 1.31.13
  - Kernel version: 6.12.46-66.121.amzn2023.aarch64
- Package updates include extensive system library updates, kernel updates, and boost library updates.
- Added packages: apr-util-lmdb, kernel-livepatch-6.1.156-177.286

Kubernetes v1.32

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- AL2 (x86_64):
  - NVIDIA driver version: 570.195.03
  - CUDA version: 12.8
  - Kubernetes version: 1.32.3
- AL2023 (x86_64):
  - NVIDIA driver version: 580.95.05
  - CUDA version: 13.0
  - Kubernetes version: 1.32.9
- AL2023 (arm):
  - NVIDIA driver version: 580.95.05
  - CUDA version: 13.0
  - Kubernetes version: 1.32.9
  - Kernel version: 6.12.46-66.121.amzn2023.aarch64
- Package updates include kernel livepatch updates and system library updates.
- Added package: annotated-doc 0.0.3

Kubernetes v1.33

- AL2023 (x86_64):
  - NVIDIA driver version: 580.95.05
  - CUDA version: 13.0
  - Kubernetes version: 1.33.5
  - Kernel version: 6.1.155-176.282.amzn2023.x86_64
- AL2023 (arm):
  - NVIDIA driver version: 580.95.05
  - CUDA version: 13.0
  - Kubernetes version: 1.33.5
  - Kernel version: 6.12.46-66.121.amzn2023.aarch64
- Package updates include extensive system library updates, kernel updates, and boost library updates.
- Added packages: apr-util-lmdb, kernel-livepatch updates

SageMaker HyperPod AMI releases for Amazon EKS: October 22, 2025

AL2x86

> **Note**
>
> Amazon Linux 2 is now deprecated. The Kubernetes AMI is based on AL2023.

Base DLAMI release note is available here.

- EKS versions 1.28 - 1.32
- This release contains CVE patches for affected NVIDIA Driver packages found in the Nvidia October Security Bulletin.
- NVIDIA SMI

```
NVIDIA-SMI 570.195.03
Driver Version: 570.195.03
CUDA Version: 12.8
```

- Major versions

package name	version
framework_version	70
gdr_copy	2.4.1
supported_ec2_instances	G4dn, G5, G6, Gr6, G6e, P4d, P4de, P5, P5e, P5en
efa_version	1.43.3
ebs_volume_type	gp3
nvidia_driver	570.195.03
python_location	/usr/bin/python3.10
nvidia_cuda_stack	/usr/local/cuda-12.1,/usr/local/cuda-12.2,/usr/local/cuda-12.3,/usr/local/cuda-12.4
ssm_agent_version	3.3.3050.0
kernel_version	5.10.244-240.965.amzn2.x86_64
nvidia_container_toolkit_version	1.17.8
ofi_nccl_version	1.16.3
operating_system	Amazon Linux 2
default_cuda	/usr/local/cuda-12.1/
compute_architecture	x86_64

- Added packages: No packages were added in this release.
- Updated packages

package name	previous version	new version
boto3	1.40.46	1.40.49
botocore	1.40.46	1.40.49
fastapi	0.118.0	0.118.2
filelock	3.19.1	3.20.0
importlib_metadata	8.7.0	8.0.0
jaraco.context	6.0.1	5.3.0
jaraco.functools	4.3.0	4.0.1
matplotlib	3.10.6	3.10.7
packaging	25	24.2
platformdirs	4.4.0	4.5.0
propcache	0.4.0	0.4.1
rich	14.1.0	14.2.0
tomli	2.2.1	2.3.0
types-python-dateutil	2.9.0.20250822	2.9.0.20251008
virtualenv	20.34.0	20.35.1
websocket-client	1.8.0	1.9.0

- Removed packages: No packages were removed in this release.

AL2023x86

Base DLAMI release note is available here.

- EKS versions 1.28 - 1.32. No release for EKS version 1.33.

- This release contains CVE patches for affected NVIDIA Driver packages found in the Nvidia October Security Bulletin.
- NVIDIA SMI

```
NVIDIA-SMI 580.95.05
Driver Version: 580.95.05
CUDA Version: 13.0
```

- Major versions

package name	version

SageMaker HyperPod AMI releases for Amazon EKS: September 29, 2025

AMI general updates

- Released the new SageMaker HyperPod AMI for Amazon EKS 1.33. For more information, see SageMaker HyperPod AMI releases for Amazon EKS: September 29, 2025.

> **Important**
>
> - The Dynamic Resource Allocation beta Kubernetes API is enabled by default in this release.
>   - This API improves scheduling and monitoring workloads that require resources such as GPUs.
>   - This API was developed by the open source Kubernetes community and might change in future versions of Kubernetes. Before you use the API, review the Kubernetes documentation and understand how it affects your workloads.
> - HyperPod is not releasing a HyperPod Amazon Linux 2 AMI for Kubernetes 1.33. Amazon recommends that you migrate to AL2023. For more information, see Upgrade from Amazon Linux 2 to AL2023.

For more information, see Kubernetes v1.33.

SageMaker HyperPod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- NVIDIA SMI:
  - NVIDIA driver version: 570.172.08
  - CUDA version: 12.8
- Packages:
  - Languages and core libraries:
    - GCC: 11.5.0-5.amzn2023.0.5
    - GCC 14: 14.2.1-7.amzn2023.0.1

- Java: 17.0.16+8-1.amzn2023.1
- Perl: 5.32.1-477.amzn2023.0.7
- Python: 3.9.23-1.amzn2023.0.3
- Go: 3.2.0-37.amzn2023
- Rust: 1.89.0-1.amzn2023.0.2

- Core Libraries:
  - GlibC: 2.34-196.amzn2023.0.1
  - OpenSSL: 3.2.2-1.amzn2023.0.1
  - Zlib: 1.2.11-33.amzn2023.0.5
  - XZ Utils: 5.2.5-9.amzn2023.0.2
  - Util-linux: 2.37.4-1.amzn2023.0.4
- Neuron:
  - aws-neuronx-dkms: 2.23.9.0-dkms
  - aws-neuronx-tools: 2.25.145.0-1
- EFA:
  - efa driver: 2.17.2-1.amzn2023
  - efa config: 1.18-1.amzn2023
  - efa nv peermem: 1.2.2-1.amzn2023
  - efa profile: 1.7-1.amzn2023
- kernel:
  - kernel: 6.1.148-173.267.amzn2023
  - kernel development: 6.1.148-173.267.amzn2023
  - kernel headers: 6.1.148-173.267.amzn2023
  - kernel tools: 6.1.148-173.267.amzn2023
  - kernel modules extra: 6.1.148-173.267.amzn2023
  - kernel livepatch: 1.0-0.amzn2023
- Nvidia:
  - nvidia container toolkit: 1.17.8-1
  - nvidia container toolkit base: 1.17.8-1
  - libnvidia-container: 1.17.8-1 (with tools)

- nvidia fabric manager: 570.172.08-1
- libnvidia-nscq: 570.172.08-1

Kubernetes v1.29

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- NVIDIA SMI:
  - NVIDIA driver version: 570.172.08
  - CUDA version: 12.8
- Packages:
  - Languages and core libraries:
    - GCC: 11.5.0-5.amzn2023.0.5
    - GCC 14: 14.2.1-7.amzn2023.0.1
    - Java: 17.0.16+8-1.amzn2023.1
    - Perl: 5.32.1-477.amzn2023.0.7
    - Python: 3.9.23-1.amzn2023.0.3
    - Go: 3.2.0-37.amzn2023
    - Rust: 1.89.0-1.amzn2023.0.2
  - Core Libraries:
    - GlibC: 2.34-196.amzn2023.0.1
    - OpenSSL: 3.2.2-1.amzn2023.0.1
    - Zlib: 1.2.11-33.amzn2023.0.5
    - XZ Utils: 5.2.5-9.amzn2023.0.2
    - Util-linux: 2.37.4-1.amzn2023.0.4
  - Neuron:
    - aws-neuronx-dkms: 2.23.9.0-dkms
    - aws-neuronx-tools: 2.25.145.0-1
  - EFA:
    - efa driver: 2.17.2-1.amzn2023
    - efa config: 1.18-1.amzn2023
    - efa nv peermem: 1.2.2-1.amzn2023

    - efa profile: 1.7-1.amzn2023
  - kernel:
    - kernel: 6.1.148-173.267.amzn2023
    - kernel development: 6.1.148-173.267.amzn2023
    - kernel headers: 6.1.148-173.267.amzn2023
    - kernel tools: 6.1.148-173.267.amzn2023
    - kernel modules extra: 6.1.148-173.267.amzn2023
    - kernel livepatch: 1.0-0.amzn2023
  - Nvidia:
    - nvidia container toolkit: 1.17.8-1
    - nvidia container toolkit base: 1.17.8-1
    - libnvidia-container: 1.17.8-1 (with tools)
    - nvidia fabric manager: 570.172.08-1
    - libnvidia-nscq: 570.172.08-1

Kubernetes v1.30

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- NVIDIA SMI:
  - NVIDIA driver version: 570.172.08
  - CUDA version: 12.8
- Packages:
  - Languages and core libraries:
    - GCC: 11.5.0-5.amzn2023.0.5
    - GCC 14: 14.2.1-7.amzn2023.0.1
    - Java: 17.0.16+8-1.amzn2023.1
    - Perl: 5.32.1-477.amzn2023.0.7
    - Python: 3.9.23-1.amzn2023.0.3
    - Go: 3.2.0-37.amzn2023
    - Rust: 1.89.0-1.amzn2023.0.2
  - Core Libraries:

    - GlibC: 2.34-196.amzn2023.0.1
    - OpenSSL: 3.2.2-1.amzn2023.0.1
    - Zlib: 1.2.11-33.amzn2023.0.5
    - XZ Utils: 5.2.5-9.amzn2023.0.2
    - Util-linux: 2.37.4-1.amzn2023.0.4
  - Neuron:
    - aws-neuronx-dkms: 2.23.9.0-dkms
    - aws-neuronx-tools: 2.25.145.0-1
  - EFA:
    - efa driver: 2.17.2-1.amzn2023
    - efa config: 1.18-1.amzn2023
    - efa nv peermem: 1.2.2-1.amzn2023
    - efa profile: 1.7-1.amzn2023
  - kernel:
    - kernel: 6.1.148-173.267.amzn2023
    - kernel development: 6.1.148-173.267.amzn2023
    - kernel headers: 6.1.148-173.267.amzn2023
    - kernel tools: 6.1.148-173.267.amzn2023
    - kernel modules extra: 6.1.148-173.267.amzn2023
    - kernel livepatch: 1.0-0.amzn2023
  - Nvidia:
    - nvidia container toolkit: 1.17.8-1
    - nvidia container toolkit base: 1.17.8-1
    - libnvidia-container: 1.17.8-1 (with tools)
    - nvidia fabric manager: 570.172.08-1
    - libnvidia-nscq: 570.172.08-1

Kubernetes v1.31

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
  - NVIDIA SMI:

- NVIDIA driver version: 570.172.08
- CUDA version: 12.8

- Packages:
  - Languages and core libraries:
    - GCC: 11.5.0-5.amzn2023.0.5
    - GCC 14: 14.2.1-7.amzn2023.0.1
    - Java: 17.0.16+8-1.amzn2023.1
    - Perl: 5.32.1-477.amzn2023.0.7
    - Python: 3.9.23-1.amzn2023.0.3
    - Go: 3.2.0-37.amzn2023
    - Rust: 1.89.0-1.amzn2023.0.2
  - Core Libraries:
    - GlibC: 2.34-196.amzn2023.0.1
    - OpenSSL: 3.2.2-1.amzn2023.0.1
    - Zlib: 1.2.11-33.amzn2023.0.5
    - XZ Utils: 5.2.5-9.amzn2023.0.2
    - Util-linux: 2.37.4-1.amzn2023.0.4
  - Neuron:
    - aws-neuronx-dkms: 2.23.9.0-dkms
    - aws-neuronx-tools: 2.25.145.0-1
  - EFA:
    - efa driver: 2.17.2-1.amzn2023
    - efa config: 1.18-1.amzn2023
    - efa nv peermem: 1.2.2-1.amzn2023
    - efa profile: 1.7-1.amzn2023
  - kernel:
    - kernel: 6.1.148-173.267.amzn2023
    - kernel development: 6.1.148-173.267.amzn2023
    - kernel headers: 6.1.148-173.267.amzn2023
    - kernel tools: 6.1.148-173.267.amzn2023

    - kernel modules extra: 6.1.148-173.267.amzn2023
    - kernel livepatch: 1.0-0.amzn2023
  - Nvidia:
    - nvidia container toolkit: 1.17.8-1
    - nvidia container toolkit base: 1.17.8-1
    - libnvidia-container: 1.17.8-1 (with tools)
    - nvidia fabric manager: 570.172.08-1
    - libnvidia-nscq: 570.172.08-1

Kubernetes v1.32

- **Amazon Linux 2 is now deprecated. Kubernetes AMI is based on AL2023.**
- NVIDIA SMI:
  - NVIDIA driver version: 570.172.08
  - CUDA version: 12.8
- Packages:
  - Languages and core libraries:
    - GCC: 11.5.0-5.amzn2023.0.5
    - GCC 14: 14.2.1-7.amzn2023.0.1
    - Java: 17.0.16+8-1.amzn2023.1
    - Perl: 5.32.1-477.amzn2023.0.7
    - Python: 3.9.23-1.amzn2023.0.3
    - Go: 3.2.0-37.amzn2023
    - Rust: 1.89.0-1.amzn2023.0.2
  - Core Libraries:
    - GlibC: 2.34-196.amzn2023.0.1
    - OpenSSL: 3.2.2-1.amzn2023.0.1
    - Zlib: 1.2.11-33.amzn2023.0.5
    - XZ Utils: 5.2.5-9.amzn2023.0.2
    - Util-linux: 2.37.4-1.amzn2023.0.4

  - Neuron:

- aws-neuronx-dkms: 2.23.9.0-dkms
- aws-neuronx-tools: 2.25.145.0-1

- EFA:
  - efa driver: 2.17.2-1.amzn2023
  - efa config: 1.18-1.amzn2023
  - efa nv peermem: 1.2.2-1.amzn2023
  - efa profile: 1.7-1.amzn2023
- kernel:
  - kernel: 6.1.148-173.267.amzn2023
  - kernel development: 6.1.148-173.267.amzn2023
  - kernel headers: 6.1.148-173.267.amzn2023
  - kernel tools: 6.1.148-173.267.amzn2023
  - kernel modules extra: 6.1.148-173.267.amzn2023
  - kernel livepatch: 1.0-0.amzn2023
- Nvidia:
  - nvidia container toolkit: 1.17.8-1
  - nvidia container toolkit base: 1.17.8-1
  - libnvidia-container: 1.17.8-1 (with tools)
  - nvidia fabric manager: 570.172.08-1
  - libnvidia-nscq: 570.172.08-1

Kubernetes v1.33

The following table contains information about components within this AMI release and the corresponding versions.

component	AL2023_x86	AL2023_arm64
EKS	v1.33.4	v1.33.4
amazon-ssm-agent	3.3.2299.0-1.amzn2023	3.3.2299.0-1.amzn2023
aws-neuronx-dkms	2.23.9.0-dkms	N/A

component	AL2023_x86	AL2023_arm64
containerd	1.7.27-1.eks.amzn2023.0.4	1.7.27-1.eks.amzn2023.0.4
efa	2.17.2-1.amzn2023	2.17.2-1.amzn2023
ena	2.14.1g	2.14.1g
kernel	6.12.40-64.114.amzn2023	N/A
kernel6.12	N/A	6.12.40-64.114.amzn2023
kmod-nvidia-latest-dkms	570.172.08-1.amzn2023	570.172.08-1.el9
nvidia-container-toolkit	1.17.8-1	1.17.8-1
runc	1.2.6-1.amzn2023.0.1	1.2.6-1.amzn2023.0.1

SageMaker HyperPod AMI releases for Amazon EKS: August 25, 2025

SageMaker HyperPod DLAMI for Amazon EKS support

This release includes the following updates:

Kubernetes v1.28

NVIDIA SMI:

- Nvidia Driver Version: 570.172.08
- CUDA Version: 12.8

Added Packages:

- kernel-livepatch-5.10.240-238.955.x86_64 1.0-0.amzn2 amzn2extra-kernel-5.10

Updated Packages:

- gdk-pixbuf2.x86_64: 2.36.12-3.amzn2 → 2.36.12-3.amzn2.0.2
- kernel.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2

- kernel-devel.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2
- kernel-headers.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2
- kernel-tools.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2
- libgs.x86_64: 9.54.0-9.amzn2.0.11 → 9.54.0-9.amzn2.0.12
- microcode_ctl.x86_64: 2:2.1-47.amzn2.4.24 → 2:2.1-47.amzn2.4.25
- pam.x86_64: 1.1.8-23.amzn2.0.2 → 1.1.8-23.amzn2.0.4

Removed Packages:

- kernel-livepatch-5.10.239-236.958.x86_64 1.0-0.amzn2 amzn2extra-kernel-5.10

Repository Changed:

- libnvidia-container-tools.x86_64: cuda-rhel8-x86_64 → nvidia-container-toolkit
- libnvidia-container1.x86_64: cuda-rhel8-x86_64 → nvidia-container-toolkit
- nvidia-container-toolkit.x86_64: cuda-rhel8-x86_64 → nvidia-container-toolkit
- nvidia-container-toolkit-base.x86_64: cuda-rhel8-x86_64 → nvidia-container-toolkit

Kubernetes v1.29

NVIDIA SMI:

- Nvidia Driver Version: 570.172.08
- CUDA Version: 12.8

Added Packages:

- kernel-livepatch-5.10.240-238.955.x86_64 1.0-0.amzn2 amzn2extra-kernel-5.10

Updated Packages:

- gdk-pixbuf2.x86_64: 2.36.12-3.amzn2 → 2.36.12-3.amzn2.0.2
- kernel.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2
- kernel-devel.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2
- kernel-headers.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2

- kernel-tools.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2
- libgs.x86_64: 9.54.0-9.amzn2.0.11 → 9.54.0-9.amzn2.0.12
- microcode_ctl.x86_64: 2:2.1-47.amzn2.4.24 → 2:2.1-47.amzn2.4.25
- pam.x86_64: 1.1.8-23.amzn2.0.2 → 1.1.8-23.amzn2.0.4

Removed Packages:

- kernel-livepatch-5.10.239-236.958.x86_64 1.0-0.amzn2 amzn2extra-kernel-5.10

Repository Changed:

- libnvidia-container-tools.x86_64: cuda-rhel8-x86_64 → nvidia-container-toolkit
- libnvidia-container1.x86_64: cuda-rhel8-x86_64 → nvidia-container-toolkit
- nvidia-container-toolkit.x86_64: cuda-rhel8-x86_64 → nvidia-container-toolkit
- nvidia-container-toolkit-base.x86_64: cuda-rhel8-x86_64 → nvidia-container-toolkit

Kubernetes v1.30

NVIDIA SMI:

- Nvidia Driver Version: 570.172.08
- CUDA Version: 12.8

Added Packages:

- kernel-livepatch-5.10.240-238.955.x86_64 1.0-0.amzn2 amzn2extra-kernel-5.10

Updated Packages:

- aws-neuronx-dkms.noarch: 2.22.2.0-dkms → 2.23.9.0-dkms
- efa.x86_64: 2.15.3-1.amzn2 → 2.17.2-1.amzn2
- efa-nv-peermem.x86_64: 1.2.1-1.amzn2 → 1.2.2-1.amzn2
- gdk-pixbuf2.x86_64: 2.36.12-3.amzn2 → 2.36.12-3.amzn2.0.2
- ibacm.x86_64: 57.amzn1-1.amzn2.0.2 → 58.amzn0-1.amzn2.0.2
- infiniband-diags.x86_64: 57.amzn1-1.amzn2.0.2 → 58.amzn0-1.amzn2.0.2

- kernel.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2
- kernel-devel.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2
- kernel-headers.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2
- kernel-tools.x86_64: 5.10.239-236.958.amzn2 → 5.10.240-238.955.amzn2
- libfabric-aws.x86_64: 2.1.0amzn3.0-1.amzn2 → 2.1.0amzn5.0-1.amzn2
- libfabric-aws-devel.x86_64: 2.1.0amzn3.0-1.amzn2 → 2.1.0amzn5.0-1.amzn2
- libgs.x86_64: 9.54.0-9.amzn2.0.11 → 9.54.0-9.amzn2.0.12
- libibumad.x86_64: 57.amzn1-1.amzn2.0.2 → 58.amzn0-1.amzn2.0.2
- libibverbs.x86_64: 57.amzn1-1.amzn2.0.2 → 58.amzn0-1.amzn2.0.2
- libibverbs-core.x86_64: 57.amzn1-1.amzn2.0.2 → 58.amzn0-1.amzn2.0.2
- libibverbs-utils.x86_64: 57.amzn1-1.amzn2.0.2 → 58.amzn0-1.amzn2.0.2
- libnccl-ofi.x86_64: 1.15.0-1.amzn2 → 1.16.2-1.amzn2
- librdmacm.x86_64: 57.amzn1-1.amzn2.0.2 → 58.amzn0-1.amzn2.0.2
- librdmacm-utils.x86_64: 57.amzn1-1.amzn2.0.2 → 58.amzn0-1.amzn2.0.2

SageMaker HyperPod AMI releases for Amazon EKS: August 12, 2025

The AMI includes the following:

- Supported Amazon Service: Amazon EC2
- Operating System: Amazon Linux 2023
- Compute Architecture: ARM64
- Latest available version is installed for the following packages:
  - Linux Kernel: 6.12
  - FSx Lustre
  - Docker
  - Amazon CLI v2 at `/usr/bin/aws`
  - NVIDIA DCGM
  - Nvidia container toolkit:
    - Version command: `nvidia-container-cli -V`
  - Nvidia-docker2:
    - Version command: `nvidia-docker version`
  - Nvidia-IMEX: v570.172.08-1
- NVIDIA Driver: 570.158.01
- NVIDIA CUDA 12.4, 12.5, 12.6, 12.8 stack:
  - CUDA, NCCL and cuDDN installation directories: `/usr/local/cuda-xx.x/`
    - Example: `/usr/local/cuda-12.8/`, `/usr/local/cuda-12.8/`
  - Compiled NCCL Version:

    - For CUDA directory of 12.4, compiled NCCL Version 2.22.3+CUDA12.4
    - For CUDA directory of 12.5, compiled NCCL Version 2.22.3+CUDA12.5
    - For CUDA directory of 12.6, compiled NCCL Version 2.24.3+CUDA12.6
    - For CUDA directory of 12.8, compiled NCCL Version 2.27.5+CUDA12.8
  - Default CUDA: 12.8
    - PATH `/usr/local/cuda` points to CUDA 12.8
    - Updated below env vars:
      - `LD_LIBRARY_PATH` to have `/usr/local/cuda-12.8/lib:/usr/local/cuda-12.8/lib64:/usr/local/cuda-12.8:/usr/local/cuda-12.8/targets/sbsa-linux/lib:/usr/local/cuda-12.8/nvvm/lib64:/usr/local/cuda-12.8/extras/CUPTI/lib64`
      - `PATH` to have `/usr/local/cuda-12.8/bin/:/usr/local/cuda-12.8/include/`
      - For any different CUDA version, please update `LD_LIBRARY_PATH` accordingly.
- EFA installer: 1.42.0
- Nvidia GDRCopy: 2.5.1
- Amazon OFI NCCL plugin comes with EFA installer
  - Paths `/opt/amazon/ofi-nccl/lib` and `/opt/amazon/ofi-nccl/efa` are added to `LD_LIBRARY_PATH`.
- Amazon CLI v2 at `/usr/local/bin/aws`
- EBS volume type: gp3
- Python: `/usr/bin/python3.9`

SageMaker HyperPod AMI releases for Amazon EKS: August 6, 2025

SageMaker HyperPod DLAMI for Amazon EKS support

The AMIs include the following updates:

K8s v1.28

- **Neuron packages:**
  - **aws-neuronx-collectives:** 2.27.34.0_ec8cd5e8b-1
  - **aws-neuronx-dkms:** 2.23.9.0-dkms
  - **aws-neuronx-runtime-lib:** 2.27.23.0_8deec4dbf-1

- **aws-neuronx-k8-plugin:** 2.27.7.0-1
- **aws-neuronx-k8-scheduler:** 2.27.7.0-1
- **aws-neuronx-tools:** 2.25.145.0-1

K8s v1.29

- **Neuron packages:**
  - **aws-neuronx-collectives:** 2.27.34.0_ec8cd5e8b-1
  - **aws-neuronx-dkms:** 2.23.9.0-dkms
  - **aws-neuronx-runtime-lib:** 2.27.23.0_8deec4dbf-1
  - **aws-neuronx-k8-plugin:** 2.27.7.0-1
  - **aws-neuronx-k8-scheduler:** 2.27.7.0-1
  - **aws-neuronx-tools:** 2.25.145.0-1

K8s v1.30

- **Neuron packages:**
  - **aws-neuronx-collectives:** 2.27.34.0_ec8cd5e8b-1
  - **aws-neuronx-dkms:** 2.23.9.0-dkms
  - **aws-neuronx-runtime-lib:** 2.27.23.0_8deec4dbf-1
  - **aws-neuronx-k8-plugin:** 2.27.7.0-1
  - **aws-neuronx-k8-scheduler:** 2.27.7.0-1
  - **aws-neuronx-tools:** 2.25.145.0-1

K8s v1.31

- **Neuron packages:**
  - **aws-neuronx-collectives:** 2.27.34.0_ec8cd5e8b-1
  - **aws-neuronx-dkms:** 2.23.9.0-dkms
  - **aws-neuronx-runtime-lib:** 2.27.23.0_8deec4dbf-1
  - **aws-neuronx-k8-plugin:** 2.27.7.0-1
  - **aws-neuronx-k8-scheduler:** 2.27.7.0-1

- **aws-neuronx-tools:** 2.25.145.0-1

K8s v1.32

- **Neuron packages:**
  - **aws-neuronx-collectives:** 2.27.34.0_ec8cd5e8b-1
  - **aws-neuronx-dkms:** 2.23.9.0-dkms
  - **aws-neuronx-runtime-lib:** 2.27.23.0_8deec4dbf-1
  - **aws-neuronx-k8-plugin:** 2.27.7.0-1
  - **aws-neuronx-k8-scheduler:** 2.27.7.0-1
  - **aws-neuronx-tools:** 2.25.145.0-1

> **Important**
>
> - Deep Learning Base OSS Nvidia Driver AMI (Amazon Linux 2) Version 70.3
> - Deep Learning Base Proprietary Nvidia Driver AMI (Amazon Linux 2) Version 68.4
> - Latest CUDA 12.8 support
> - Upgraded Nvidia Driver to from 570.158.01 to 570.172.08 to fix CVE's present in the Nvidia Security Bulletin for July

SageMaker HyperPod AMI releases for Amazon EKS: July 31, 2025

Amazon SageMaker HyperPod now supports a new AMI for Amazon EKS clusters that updates the base operating system to Amazon Linux 2023. This release provides several improvements from Amazon Linux 2 (AL2). HyperPod releases new AMIs regularly, and we recommend that you run all of your HyperPod clusters on the latest and most secure versions of AMIs to address vulnerabilities and phase out outdated software and libraries.

Key upgrades

- **Operating System**: Amazon Linux 2023 (updated from Amazon Linux 2, or AL2)
- **Package Manager**: DNF is the default package management tool, replacing YUM used in AL2
- **Networking Service**: `systemd-networkd` manages network interfaces, replacing ISC `dhclient` used in AL2

- **Linux Kernel**: Version 6.1, updated from the kernel used in AL2
- **Glibc**: Version 2.34, updated from the version in AL2
- **GCC**: Version 11.5.0, updated from the version in AL2
- **NFS**: Version 1:2.6.1, updated from version 1:1.3.4 in AL2
- **NVIDIA Driver**: Version 570.172.08, a newer driver version
- **Python**: Version 3.9, replacing Python 2.7 used in AL2
- **NVME**: Version 1.11.1, a newer version of the NVMe driver

Before you upgrade

There are a few important things to know before upgrading. With AL2023, several packages have been added, upgraded or removed compared to AL2. We strongly recommend that you test your applications with AL2023 before upgrading your clusters. For a comprehensive list of all package changes in AL2023, see Package changes in Amazon Linux 2023.

The following are some of the significant changes between AL2 and AL2023:

- **Python 3.10**: The most significant update, apart from the operating system, is the Python version upgrade. After upgrading, clusters have Python 3.10 as default. While some Python 3.8 distributed training workloads might be compatible with Python 3.10, we strongly recommend that you test your specific workloads separately. If migration to Python 3.10 proves challenging but you still want to upgrade your cluster for other new features, you can install an older Python version by using the command `yum install python-xx.x` with lifecycle scripts before running any workloads. Ensure you test both your existing lifecycle scripts and application code for compatibility.
- **NVIDIA runtime enforcement**: AL2023 strictly enforces the NVIDIA container runtime requirements, causing containers with hard-coded NVIDIA environment variables (such as `NVIDIA_VISIBLE_DEVICES: "all"`) to fail on CPU-only nodes (whereas AL2 ignored these settings when no GPU drivers are present). You can override the enforcement by setting `NVIDIA_VISIBLE_DEVICES: "void"` in your pod specification or by using CPU-only images.
- **cgroup v2**: AL2023 features the next generation of unified control group hierarchy (cgroup v2). cgroup v2 is used for container runtimes and is also used by `systemd`. While AL2023 still includes code that can make the system run using cgroup v1, this isn't a recommended configuration.
- **Amazon VPC CNI and `eksctl` versions**: AL2023 also requires your Amazon VPC CNI version to be 1.16.2 or greater and your `eksctl` version to be 0.176.0 or greater.

- **EFA on FSx for Lustre**: You can now use EFA on FSx for Lustre, which enables you to achieve application performance comparable to on-premises AI/ML or HPC (high performance computing) clusters, while benefiting from the scalability, flexibility and elasticity of cloud computing.

Additionally, upgrading to AL2023 requires at minimum version `1.0.643.0_1.0.192.0` of Health Monitoring Agent. Complete the following procedure to update the Health Monitoring Agent:

1. If you use HyperPod lifecycle scripts from the GitHub repository awsome-distributed-training, make sure to pull the latest version. Earlier versions are not compatible with AL2023. The new lifecycle script ensures that `containerd` uses the additional mounted storage for pulling in container images in AL2023.
2. Pull in the latest version of the HyperPod CLI git repository.
3. Update dependencies with the following command: `helm dependencies update helm_chart/HyperPodHelmChart`
4. As mentioned on the step 4 in the README of HyperPodHelmChart, run the following command to upgrade the version of dependencies running on the cluster: `helm upgrade dependencies helm_chart/HyperPodHelmChart -namespace kube-system`

Workloads that have been tested on upgraded EKS clusters

The following are some use cases where the upgrade has been tested:

- **Backwards compatibility**: Popular distributed training jobs involving PyTorch should be backwards compatible on the new AMI. However, since your workloads may depend on specific Python or Linux libraries, we recommend first testing on a smaller scale or subset of nodes before upgrading your larger clusters.
- **Accelerator testing**: Jobs across various instance types, utilizing both NVIDIA accelerators (for the P and G instance families) and Amazon Neuron accelerators (for Trn instances) have been tested.

How to upgrade your AMI and associated workloads

You can upgrade to the new AMI using one of the following methods:

- Use the create-cluster API to create a new cluster with the latest AMI.

- Use the update-cluster-software API to upgrade your existing cluster. Note that this option re-runs any lifecycle scripts.

The cluster is unavailable during the update process. We recommend planning for this downtime and restarting the training workload from an existing checkpoint after the upgrade completes. As a best practice, we recommend that you perform testing on a smaller cluster before upgrading your larger clusters.

If the update command fails, first identify the cause of the failure. For lifecycle script failures, make the necessary corrections to your scripts and retry. For any other issues that cannot be resolved, contact Amazon Web Services Support.

Troubleshooting

Use the following section to help with troubleshooting any issues you encounter when upgrading to AL2023.

How do I fix errors such as "`nvml error: driver not loaded: unknown`" on CPU-only cluster nodes?

If containers that worked on CPU AL2 Amazon EKS nodes now fail on AL2023, your container image may have hard-coded NVIDIA environment variables. You can check for hard-coded environment variables with the following command:

```
docker inspect image:tag | grep -i nvidia
```

AL2023 strictly enforces these requirements whereas AL2 was more lenient on CPU-only nodes. One solution is to override the AL2023 enforcement by setting certain NVIDIA environment variables in your Amazon EKS pod specification, as shown in the following example:

```
yaml
containers:
- name: your-container
image: your-image:tag
env:
- name: NVIDIA_VISIBLE_DEVICES
value: "void"
- name: NVIDIA_DRIVER_CAPABILITIES
value: ""
```

Another alternative is to use CPU-only container images (such as `pytorch/pytorch:latest-cpu`) or build custom images without NVIDIA dependencies.

SageMaker HyperPod AMI releases for Amazon EKS: July 15, 2025

SageMaker HyperPod DLAMI for Amazon EKS support

The AMIs include the following updates:

K8s v1.28

- **Latest NVIDIA Driver:** 550.163.01
- **Default CUDA:** 12.4
- **EFA Installer:** 1.38.0
- **Neuron packages:**
  - **aws-neuronx-dkms.noarch:** 2.22.2.0-dkms
  - **aws-neuronx-oci-hook.x86_64:** 2.4.4.0-1
  - **aws-neuronx-tools.x86_64:** 2.18.3.0-1
  - **aws-neuron-dkms.noarch:** 2.3.26.0-dkms
  - **aws-neuron-k8-plugin.x86_64:** 1.9.3.0-1
  - **aws-neuron-k8-scheduler.x86_64:** 1.9.3.0-1
  - **aws-neuron-runtime.x86_64:** 1.6.24.0-1
  - **aws-neuron-runtime-base.x86_64:** 1.6.21.0-1
  - **aws-neuron-tools.x86_64:** 2.1.4.0-1
  - **aws-neuronx-collectives.x86_64:** 2.26.43.0_47cc904ea-1
  - **aws-neuronx-gpsimd-customop.x86_64:** 0.2.3.0-1
  - **aws-neuronx-gpsimd-customop-lib.x86_64:** 0.16.2.0-1
  - **aws-neuronx-gpsimd-tools.x86_64:** 0.16.1.0_0a6506a47-1
  - **aws-neuronx-k8-plugin.x86_64:** 2.26.26.0-1
  - **aws-neuronx-k8-scheduler.x86_64:** 2.26.26.0-1
  - **aws-neuronx-runtime-lib.x86_64:** 2.26.42.0_2ff3b5c7d-1

SageMaker HyperPod AMI releases for Amazon EKS: June 09, 2025

SageMaker HyperPod DLAMI for Amazon EKS support

Neuron SDK Updates

- **aws-neuronx-dkms.noarch:** 2.21.37.0 (from 2.20.74.0)

SageMaker HyperPod AMI releases for Amazon EKS: May 22, 2025

AMI general updates

SageMaker HyperPod DLAMI for Amazon EKS support

Deep Learning Base AMI AL2

- **Latest NVIDIA Driver:** 550.163.01
- **CUDA Stack updates:**
  - **Default CUDA:** 12.1
  - **NCCL Version:** 2.22.3
- **EFA Installer:** 1.38.0
- **Amazon OFI NCCL:** 1.13.2
- **Linux Kernel:** 5.10
- **GDRCopy:** 2.4

Important

- **NVIDIA Container Toolkit 1.17.4 update:** CUDA compat libraries mounting is now disabled
- **EFA Updates from 1.37 to 1.38:**
  - Amazon OFI NCCL plugin now located in /opt/amazon/ofi-nccl
  - Previous location /opt/aws-ofi-nccl/ is deprecated

Neuron SDK Updates

- **aws-neuronx-dkms.noarch:** 2.20.74.0 (from 2.20.28.0)
- **aws-neuronx-collectives.x86_64:** 2.25.65.0_9858ac9a1-1 (from 2.24.59.0_838c7fc8b-1)
- **aws-neuronx-runtime-lib.x86_64:** 2.25.57.0_166c7a468-1 (from 2.24.53.0_f239092cc-1)
- **aws-neuronx-tools.x86_64:** 2.23.9.0 (from 2.22.61.0)
- **aws-neuronx-gpsimd-customop-lib.x86_64:** 0.15.12.0 (from 0.14.12.0)
- **aws-neuronx-gpsimd-tools.x86_64:** 0.15.1.0_5d31b6a3f (from 0.14.6.0_241eb69f4)
- **aws-neuronx-k8-plugin.x86_64:** 2.25.24.0 (from 2.24.23.0)
- **aws-neuronx-k8-scheduler.x86_64:** 2.25.24.0 (from 2.24.23.0)

Support notes:

- AMI components including CUDA versions may be removed or changed based on framework support policy
- Kernel version is pinned for compatibility. Users should avoid updates unless required for security patches
- For EC2 instances with multiple network cards, please refer to EFA configuration guide for proper setup

SageMaker HyperPod AMI releases for Amazon EKS: May 07, 2025

Installed the latest version of Amazon Neuron SDK

- **tensorflow-model-server-neuron.x86_64** 2.8.0.2.3.0.0-0 neuron

SageMaker HyperPod AMI releases for Amazon EKS: April 28, 2025

Improvements for K8s

- Upgraded NVIDIA driver from version 550.144.03 to 550.163.01. This upgrade is to address Common Vulnerabilities and Exposures (CVEs) present in the NVIDIA GPU Display Security Bulletin for April 2025.

SageMaker HyperPod DLAMI for Amazon EKS support

Installed the latest version of Amazon Neuron SDK

- **aws-neuronx-dkms.noarch:** 2.20.28.0-dkms
- **aws-neuronx-oci-hook.x86_64:** 2.4.4.0-1
- **aws-neuronx-tools.x86_64:** 2.18.3.0-1
- **aws-neuron-dkms.noarch:** 2.3.26.0-dkms
- **aws-neuron-k8-plugin.x86_64:** 1.9.3.0-1
- **aws-neuron-k8-scheduler.x86_64:** 1.9.3.0-1
- **aws-neuron-runtime.x86_64:** 1.6.24.0-1
- **aws-neuron-runtime-base.x86_64:** 1.6.21.0-1
- **aws-neuron-tools.x86_64:** 2.1.4.0-1
- **aws-neuronx-collectives.x86_64:** 2.24.59.0_838c7fc8b-1
- **aws-neuronx-gpsimd-customop.x86_64:** 0.2.3.0-1
- **aws-neuronx-gpsimd-customop-lib.x86_64:** 0.14.12.0-1
- **aws-neuronx-gpsimd-tools.x86_64:** 0.14.6.0_241eb69f4-1
- **aws-neuronx-k8-plugin.x86_64:** 2.24.23.0-1
- **aws-neuronx-k8-scheduler.x86_64:** 2.24.23.0-1
- **aws-neuronx-runtime-lib.x86_64:** 2.24.53.0_f239092cc-1
- **aws-neuronx-tools.x86_64:** 2.22.61.0-1
- **tensorflow-model-server-neuronx.x86_64:** 2.10.1.2.12.2.0-0

SageMaker HyperPod AMI releases for Amazon EKS: April 18, 2025

AMI general updates

- New SageMaker HyperPod AMI for Amazon EKS 1.32.1.

SageMaker HyperPod DLAMI for Amazon EKS support

The AMIs include the following:

Deep Learning EKS AMI 1.32.1

- **Amazon EKS Components**
  - Kubernetes Version: 1.32.1
  - Containerd Version: 1.7.27
  - Runc Version: 1.1.14
  - Amazon IAM Authenticator: 0.6.29
- **Amazon SSM Agent:** 3.3.1611.0
- **Linux Kernel:** 5.10.235
- **OSS Nvidia driver:** 550.163.01
- **NVIDIA CUDA:** 12.4
- **EFA Installer:** 1.38.0
- **GDRCopy:** 2.4.1-1
- **Nvidia container toolkit:** 1.17.6
- **Amazon OFI NCCL:** 1.13.2
- **aws-neuronx-tools:** 2.18.3.0
- **aws-neuronx-runtime-lib:** 2.24.53.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.20.28.0
- **aws-neuronx-collectives:** 2.24.59.0

SageMaker HyperPod AMI releases for Amazon EKS: February 18, 2025

Improvements for K8s

- Upgraded Nvidia container toolkit from version 1.17.3 to version 1.17.4.
- Fixed the issue where customers were unable to connect to nodes after a reboot.
- Upgraded Elastic Fabric Adapter (EFA) version from 1.37.0 to 1.38.0.

- The EFA now includes the Amazon OFI NCCL plugin, which is located in the `/opt/amazon/ofi-nccl` directory instead of the original `/opt/aws-ofi-nccl/` path. If you need to update your `LD_LIBRARY_PATH` environment variable, make sure to modify the path to point to the new `/opt/amazon/ofi-nccl` location for the OFI NCCL plugin.
- Removed the emacs package from these DLAMIs. You can install emacs from GNU emac.

SageMaker HyperPod DLAMI for Amazon EKS support

Installed the latest version of neuron SDK

- **aws-neuronx-dkms.noarch:** 2.19.64.0-dkms @neuron
- **aws-neuronx-oci-hook.x86_64:** 2.4.4.0-1 @neuron
- **aws-neuronx-tools.x86_64:** 2.18.3.0-1 @neuron
- **aws-neuronx-collectives.x86_64:** 2.23.135.0_3e70920f2-1 neuron
- **aws-neuronx-gpsimd-customop.x86_64:** 0.2.3.0-1 neuron
- **aws-neuronx-gpsimd-customop-lib.x86_64**
- **aws-neuronx-gpsimd-tools.x86_64:** 0.13.2.0_94ba34927-1 neuron
- **aws-neuronx-k8-plugin.x86_64:** 2.23.45.0-1 neuron
- **aws-neuronx-k8-scheduler.x86_64:** 2.23.45.0-1 neuron
- **aws-neuronx-runtime-lib.x86_64:** 2.23.112.0_9b5179492-1 neuron
- **aws-neuronx-tools.x86_64:** 2.20.204.0-1 neuron
- **tensorflow-model-server-neuronx.x86_64**

SageMaker HyperPod AMI releases for Amazon EKS: January 22, 2025

AMI general updates

- New SageMaker HyperPod AMI for Amazon EKS 1.31.2.

SageMaker HyperPod DLAMI for Amazon EKS support

The AMIs include the following:

Deep Learning EKS AMI 1.31

- **Amazon EKS Components**

  - Kubernetes Version: 1.31.2
  - Containerd Version: 1.7.23
  - Runc Version: 1.1.14
  - Amazon IAM Authenticator: 0.6.26
- **Amazon SSM Agent:** 3.3.987
- **Linux Kernel:** 5.10.230
- **OSS Nvidia driver:** 550.127.05
- **NVIDIA CUDA:** 12.4
- **EFA Installer:** 1.37.0
- **GDRCopy:** 2.4.1-1
- **Nvidia container toolkit:** 1.17.3
- **Amazon OFI NCCL:** 1.13.0
- **aws-neuronx-tools:** 2.18.3
- **aws-neuronx-runtime-lib:** 2.23.112.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.18.20.0
- **aws-neuronx-collectives:** 2.23.133.0

SageMaker HyperPod AMI releases for Amazon EKS: December 21, 2024

SageMaker HyperPod DLAMI for Amazon EKS support

The AMIs include the following:

K8s v1.28

- **Amazon EKS Components**
  - Kubernetes Version: 1.28.15
  - Containerd Version: 1.7.23
  - Runc Version: 1.1.14
  - Amazon IAM Authenticator: 0.6.26
- **Amazon SSM Agent:** 3.3.987
- **Linux Kernel:** 5.10.228

- **OSS NVIDIA driver:** 550.127.05
- **NVIDIA CUDA:** 12.4
- **EFA Installer:** 1.37.0
- **GDRCopy:** 2.4
- **NVIDIA container toolkit:** 1.17.3
- **Amazon OFI NCCL:** 1.13.0
- **aws-neuronx-tools:** 2.18.3.0-1
- **aws-neuronx-runtime-lib:** 2.23.112.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.18.20.0
- **aws-neuronx-collectives:** 2.23.135.0

K8s v1.29

- **Amazon EKS Components**
  - Kubernetes Version: 1.29.10
  - Containerd Version: 1.7.23
  - Runc Version: 1.1.14
  - Amazon IAM Authenticator: 0.6.26
- **Amazon SSM Agent:** 3.3.987
- **Linux Kernel:** 5.15.0
- **OSS Nvidia driver:** 550.127.05
- **NVIDIA CUDA:** 12.4
- **EFA Installer:** 1.37.0
- **GDRCopy:** 2.4
- **Nvidia container toolkit:** 1.17.3
- **Amazon OFI NCCL:** 1.13.0
- **aws-neuronx-tools:** 2.18.3.0-1
- **aws-neuronx-runtime-lib:** 2.23.112.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.18.20.0

- **aws-neuronx-collectives:** 2.23.135.0

K8s v1.30

- **Amazon EKS Components**
  - Kubernetes Version: 1.30.6
  - Containerd Version: 1.7.23
  - Runc Version: 1.1.14
  - Amazon IAM Authenticator: 0.6.26
- **Amazon SSM Agent:** 3.3.987.0
- **Linux Kernel:** 5.10.228
- **OSS Nvidia driver:** 550.127.05
- **NVIDIA CUDA:** 12.4
- **EFA Installer:** 1.37.0
- **GDRCopy:** 2.4
- **Nvidia container toolkit:** 1.17.3
- **Amazon OFI NCCL:** 1.13.0
- **aws-neuronx-tools:** 2.18.3.0-1
- **aws-neuronx-runtime-lib:** 2.23.112.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.18.20.0
- **aws-neuronx-collectives:** 2.23.135.0

SageMaker HyperPod AMI releases for Amazon EKS: December 13, 2024

SageMaker HyperPod DLAMI for Amazon EKS upgrade

- Updated SSM Agent to version `3.3.1311.0`.

SageMaker HyperPod AMI releases for Amazon EKS: November 24, 2024

AMI general updates

- Released in `MEL` (Melbourne) Region.

- Updated SageMaker HyperPod base DLAMI to the following versions:
  - Kubernetes: 2024-11-01.

SageMaker HyperPod AMI releases for Amazon EKS: November 15, 2024

SageMaker HyperPod DLAMI for Amazon EKS support

The AMIs include the following:

Deep Learning EKS AMI 1.28

- **Amazon EKS Components**
  - Kubernetes Version: 1.28.15
  - Containerd Version: 1.7.23
  - Runc Version: 1.1.14
  - Amazon IAM Authenticator: 0.6.26
- **Amazon SSM Agent:** 3.3.987
- **Linux Kernel:** 5.10.228
- **OSS NVIDIA driver:** 550.127.05
- **NVIDIA CUDA:** 12.4
- **EFA Installer:** 1.34.0
- **GDRCopy:** 2.4
- **NVIDIA container toolkit:** 1.17.3
- **Amazon OFI NCCL:** 1.11.0
- **aws-neuronx-tools:** 2.18.3.0-1
- **aws-neuronx-runtime-lib:** 2.22.19.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.18.20.0
- **aws-neuronx-collectives:** 2.22.33.0

Deep Learning EKS AMI 1.29

- **Amazon EKS Components**

  - Kubernetes Version: 1.29.10
  - Containerd Version: 1.7.23
  - Runc Version: 1.1.14
  - Amazon IAM Authenticator: 0.6.26
- **Amazon SSM Agent:** 3.3.987
- **Linux Kernel:** 5.10.228
- **OSS Nvidia driver:** 550.127.05
- **NVIDIA CUDA:** 12.4
- **EFA Installer:** 1.34.0
- **GDRCopy:** 2.4
- **Nvidia container toolkit:** 1.17.3
- **Amazon OFI NCCL:** 1.11.0
- **aws-neuronx-tools:** 2.18.3.0-1
- **aws-neuronx-runtime-lib:** 2.22.19.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.18.20.0
- **aws-neuronx-collectives:** 2.22.33.0

Deep Learning EKS AMI 1.30

- **Amazon EKS Components**
  - Kubernetes Version: 1.30.6
  - Containerd Version: 1.7.23
  - Runc Version: 1.1.14
  - Amazon IAM Authenticator: 0.6.26
- **Amazon SSM Agent:** 3.3.987
- **Linux Kernel:** 5.10.228
- **OSS Nvidia driver:** 550.127.05
- **NVIDIA CUDA:** 12.4
- **EFA Installer:** 1.34.0
- **GDRCopy:** 2.4

- **Nvidia container toolkit:** 1.17.3
- **Amazon OFI NCCL:** 1.11.0
- **aws-neuronx-tools:** 2.18.3.0-1
- **aws-neuronx-runtime-lib:** 2.22.19.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.18.20.0
- **aws-neuronx-collectives:** 2.22.33.0

SageMaker HyperPod AMI releases for Amazon EKS: November 11, 2024

AMI general updates

- Updated SageMaker HyperPod DLAMI with Amazon EKS versions 1.28.13, 1.29.8, 1.30.4.

SageMaker HyperPod AMI releases for Amazon EKS: October 21, 2024

AMI general updates

- Updated SageMaker HyperPod base DLAMI to the following versions:
  - Amazon EKS: 1.28.11, 1.29.6, 1.30.2.

SageMaker HyperPod AMI releases for Amazon EKS: September 10, 2024

SageMaker HyperPod DLAMI for Amazon EKS support

The AMIs include the following:

Deep Learning EKS AMI 1.28

- **Amazon EKS Components**
  - Kubernetes Version: 1.28.11
  - Containerd Version: 1.7.20
  - Runc Version: 1.1.11
  - Amazon IAM Authenticator: 0.6.21
- **Amazon SSM Agent:** 3.3.380
- **Linux Kernel:** 5.10.223

- **OSS NVIDIA driver:** 535.183.01
- **NVIDIA CUDA:** 12.2
- **EFA Installer:** 1.32.0
- **GDRCopy:** 2.4
- **NVIDIA container toolkit:** 1.16.1
- **Amazon OFI NCCL:** 1.9.1
- **aws-neuronx-tools:** 2.18.3.0-1
- **aws-neuronx-runtime-lib:** 2.21.41.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.17.17.0
- **aws-neuronx-collectives:** 2.21.46.0

Deep Learning EKS AMI 1.29

- **Amazon EKS Components**
  - Kubernetes Version: 1.29.6
  - Containerd Version: 1.7.20
  - Runc Version: 1.1.11
  - Amazon IAM Authenticator: 0.6.21
- **Amazon SSM Agent:** 3.3.380
- **Linux Kernel:** 5.10.223
- **OSS Nvidia driver:** 535.183.01
- **NVIDIA CUDA:** 12.2
- **EFA Installer:** 1.32.0
- **GDRCopy:** 2.4
- **Nvidia container toolkit:** 1.16.1
- **Amazon OFI NCCL:** 1.9.1
- **aws-neuronx-tools:** 2.18.3.0-1
- **aws-neuronx-runtime-lib:** 2.21.41.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.17.17.0

- **aws-neuronx-collectives:** 2.21.46.0

Deep Learning EKS AMI 1.30

- **Amazon EKS Components**
  - Kubernetes Version: 1.30.2
  - Containerd Version: 1.7.20
  - Runc Version: 1.1.11
  - Amazon IAM Authenticator: 0.6.21
- **Amazon SSM Agent:** 3.3.380
- **Linux Kernel:** 5.10.223
- **OSS Nvidia driver:** 535.183.01
- **NVIDIA CUDA:** 12.2
- **EFA Installer:** 1.32.0
- **GDRCopy:** 2.4
- **Nvidia container toolkit:** 1.16.1
- **Amazon OFI NCCL:** 1.9.1
- **aws-neuronx-tools:** 2.18.3.0-1
- **aws-neuronx-runtime-lib:** 2.21.41.0
- **aws-neuronx-oci-hook:** 2.4.4.0-1
- **aws-neuronx-dkms:** 2.17.17.0
- **aws-neuronx-collectives:** 2.21.46.0

Public AMI releases

The following release notes track the latest updates for Amazon SageMaker HyperPod public AMI releases for Amazon EKS orchestration. Each release note includes a summarized list of packages pre-installed or pre-configured in the SageMaker HyperPod DLAMIs for Amazon EKS support. Each DLAMI is built on AL2023 and supports a specific Kubernetes version. For information about Amazon SageMaker HyperPod feature releases, see the section called “HyperPod release notes”.

This page is regularly updated to provide comprehensive AMI lifecycle management information including security vulnerabilities, deprecation announcements, and patching recommendations.

As part of a commitment to maintaining secure and up-to-date infrastructure, SageMaker AI continuously monitors all HyperPod public AMIs for critical vulnerabilities using automated scanning workflows. When critical security issues are identified, AMIs are systematically deprecated with appropriate migration guidance. Regular updates include Common Vulnerabilites and Exposures (CVE) remediation status, compliance findings, and recommended actions to ensure that you can maintain secure HyperPod environments while minimizing operational disruption during AMI transitions.

SageMaker HyperPod public AMI releases: August 04, 2025

Amazon SageMaker HyperPod now supports new public AMIs for Amazon EKS clusters. The AMIs include the following:

K8s v1.32

AMI Name: HyperPod EKS 1.32 x86_64 AMI Amazon Linux 2 2025080407

- **Amazon EKS Components**
  - Kubernetes Version: 1.32.3
  - Containerd Version: 1.7.23
  - Runc Version: 1.2.6
  - Amazon IAM Authenticator: 0.6.29
- **Amazon SSM Agent:** 3.3.2299.0
- **Linux Kernel:** 5.10.238-234.956.amzn2.x86_64
- **OSS NVIDIA driver:** 550.163.01

Amazon SageMaker HyperPod AMI automatic patching

Amazon SageMaker HyperPod can automatically apply security-only AMI patches to your clusters without disrupting running workloads. Auto-patching is an opt-in capability that you configure for each instance group, allowing HyperPod to keep your nodes on a secure, up-to-date AMI version on a predictable cadence while respecting active training jobs.

Overview

Keeping clusters patched is operationally expensive, even with full AMI visibility and manual update tools. Workloads that run for days or weeks cannot easily be interrupted to apply a security patch, and manual patching requires coordination, maintenance windows, and careful sequencing. This friction commonly causes updates to be deferred.

Auto-patching on HyperPod addresses this by applying patch-level AMI updates automatically and in a workload-aware manner:

- **Opt-in, per instance group** – You enable auto-patching by adding an `AutoPatchConfig` to an instance group on CreateCluster or UpdateCluster. Different instance groups in the same cluster can use different patching strategies.
- **Workload-aware** – HyperPod applies patches only as nodes become idle, so it does not interrupt running workloads.
- **Patch-only** – Auto-patching applies only patch-level updates within your currently selected AMI line (for example, 1.2.3 → 1.2.4), following semantic versioning. It never crosses a minor or major version boundary, which preserves backward compatibility between critical AI/ML software

components such as NVIDIA drivers, CUDA, and EFA with your existing training and inference containers.

- **Predictable schedule** – When a new patch AMI is released, HyperPod sets a fixed patch date 21 days out. You can move it earlier or defer it up to 60 days.
- **Built-in visibility** – You receive Amazon Health (PHD) notifications when a patch AMI is available, and on completion or failure. Live patch progress is shown on the cluster details page in the console.

The result is that security patches land on a predictable cadence without workload disruption.

Prerequisites

- **AMI versioning** – Auto-patching requires that your cluster has a tracked AMI version. Clusters created on or after January 1, 2026 have AMI versioning; clusters created before that date are not eligible for auto-patching.
- **HyperPod EKS clusters** – Auto-patching is available only for HyperPod Amazon EKS clusters.

Enabling auto-patching

You enable auto-patching for each instance group through an `AutoPatchConfig`. You can set it when you create a cluster (CreateCluster) or update an existing one (UpdateCluster). You configure auto-patching through the API.

Create an `update_cluster.json` file for your cluster.

```
{
    "ClusterName": "name-of-cluster-to-update",
    "InstanceGroups": [{
        "AutoPatchConfig": {
            "PatchingStrategy": "WhenIdle"
        },
        "InstanceGroupName": "string",
        "InstanceType": "string",
        "InstanceCount": number,
        "ExecutionRole": "string",
        "ThreadsPerCore": number,
        "InstanceStorageConfigs": [{
            "EbsVolumeConfig": {
                "VolumeSizeInGB": number
```

```
            }
        }],
        "OverrideVpcConfig": {
            "SecurityGroupIds": ["string"],
            "Subnets": ["string"]
        }
    }]
}
```

Run the following `update-cluster` command to submit the request.

```
aws sagemaker update-cluster \
    --cli-input-json file://complete/path/to/update_cluster.json
```

Set `PatchingStrategy` to one of:

- `"WhenIdle"` – ideal for training workloads; patches each node as it goes idle.
- `"WhenAllIdle"` – ideal for training workloads; patches the whole instance group atomically once it is fully idle.

Disabling auto-patching

To disable auto-patching, run the `update-cluster` command without the `AutoPatchConfig` object. This stops all future automated AMI patch upgrades for the instance group.

Viewing and updating the auto-patching schedule

You can view and adjust the auto-patching schedule for an instance group at any time through the API.

You can view the current `PatchingStrategy` by calling the `describe-cluster` API.

```
# View
aws sagemaker describe-cluster --cluster-name $HP_CLUSTER_NAME --query
 'InstanceGroups[0].AutoPatchConfig'

# Expected Output: { "PatchingStrategy": "WhenIdle" }
```

By default, HyperPod sets the patch date to be 21 days after a security patch AMI is released. You can use UpdateCluster to change this schedule. `NextPatchDate` is a UTC timestamp in ISO

8601 format and must fall within 60 days of the patch AMI release. To patch sooner, set an earlier timestamp; to defer, set a later one (up to the maximum).

Add the `PatchSchedule` to the `AutoPatchConfig` object in the `update_cluster.json` file above, then call the `update-cluster` CLI command.

```
"AutoPatchConfig": {
    "PatchingStrategy": "WhenIdle",
    "PatchSchedule": {
        "NextPatchDate": "2026-07-15T00:00:00Z"
    }
}
```

Patching strategies

When you enable auto-patching on an instance group, you choose a patching strategy. HyperPod currently supports two strategies, both designed for training workloads.

Strategy	How it works	Best for	Caveat
`WhenIdle`	HyperPod cordons all nodes in the instance group, then patches each node individually as it becomes idle.	Training workloads where you want opportunistic, disruptio n-less patching node by node.	Long-running workloads can leave some nodes unpatched and cordoned for an extended period. The instance group might temporarily run a mix of AMI versions.
`WhenAllIdle`	HyperPod cordons all nodes, then patches the entire instance group atomically once every node is idle.	Training workloads where you want all nodes on a consistent AMI version after a single, atomic patch.	If the instance group does not fully drain, the patch fails and is retried on the next cycle.

In both strategies, HyperPod cordons nodes first so that no new workload is scheduled onto a node that is waiting to be patched. HyperPod patches a node only after it is idle, so it never forcibly interrupts active workloads. No new pods are assigned to already cordoned nodes for 24 hours until the node is successfully patched. Nodes stay cordoned for up to 24 hours, and then HyperPod

uncordons them whether or not patching succeeded. During auto-patching, HyperPod modifies the following node attributes when cordoning and uncordoning nodes.

- Label `sagemaker.amazonaws.com/cordoned-by: AutoPatching` – added when the node is cordoned, removed when it is uncordoned.
- Node spec `spec.unschedulable: true` – set when the node is cordoned, cleared when it is uncordoned.

Separately, HyperPod adds the following label when it detects that a node is idle.

- Label `sagemaker.amazonaws.com/idle: true`

Choosing a strategy

- Use `WhenIdle` when you want patches to make progress as soon as individual nodes free up and you can tolerate temporary AMI version skew across the instance group. If some nodes stay busy for a long time, you can manually upgrade the remaining nodes to converge faster, or uncordon them.
- Use `WhenAllIdle` when AMI version consistency across the instance group matters more than patch speed, and you expect the group to drain fully within a few hours. If the group does not drain, you can trigger a manual patch later or wait for the next auto-patch cycle.

Patch schedule

HyperPod manages the patch schedule for you through the `NextPatchDate` field:

- When a new patch AMI becomes available for your selected AMI line, HyperPod automatically sets `NextPatchDate` to a fixed 21 days from the release.
- You can pull the date in to patch sooner, or push it back up to a maximum of 60 days from the patch AMI release, using UpdateCluster.
- If you do not want the upcoming patch, you can opt out of auto-patching for that instance group.

Amazon Health notifications

Throughout the auto-patching process, HyperPod sends Amazon Health (Personal Health Dashboard) notifications so you always know what is happening:

- When a new AMI is available for patching.
- On patch start, partial-completion, full-completion, and failures.

AMI support policy

Auto-patching applies security patches within the support window defined for your AMI version. For the full HyperPod AMI support policy, see Amazon SageMaker HyperPod AMI support policy.

Frequently asked questions

Will auto-patching trigger an Amazon EKS version upgrade, or a major/minor AMI upgrade at end of life?

No. Auto-patching only applies patch-level updates within your currently selected AMI line (for example, 1.2.1 → 1.2.2). Amazon EKS control-plane upgrades and major/minor AMI version bumps remain explicit, customer-initiated operations – even when an AMI version approaches end of support. HyperPod surfaces end-of-support signals through `ImageVersionStatus` and Amazon Health notifications well ahead of the support window closing. However, it never crosses a minor or major boundary on your behalf.

What does a node being idle mean?

On HyperPod Amazon EKS, a node is considered idle when it has no active workload pods running on it. Because HyperPod cordons nodes before patching, no new workloads are scheduled onto a node after it is queued for a patch, so after your workload pods complete and drain, the node becomes idle and HyperPod patches it. `WhenIdle` evaluates idleness per node; `WhenAllIdle` waits until every node in the instance group is idle at the same time.

The following namespaces are excluded when evaluating node idleness – pods running in them are not counted when determining whether a node is idle:

- `kube-system`
- `kube-public`
- `kube-node-lease`
- `aws-hyperpod`
- `hyperpod-inference-system`
- `kueue-system`

- amazon-cloudwatch
- amazon-network-flow-monitor
- aws-secrets-manager
- cert-manager
- external-dns
- fluent-bit
- hyperpod-observability
- keda
- kube-state-metrics
- kubeflow
- prometheus-node-exporter
- jupyter-k8s-system

In addition, the following pods are excluded when evaluating node idleness – they are not counted when determining whether a node is idle:

- **DaemonSet pods** – infrastructure pods managed by a DaemonSet that run on every node.
- **Static pods** – pods owned by the node itself.
- **Completed pods** – pods that have finished execution (in the `Succeeded` or `Failed` phase).
- **Terminating pods** – pods that are in the process of being deleted.

What happens if my nodes never go idle?

With the `WhenIdle` patching strategy, nodes that remain busy stay cordoned and unpatched until they become idle, up to a maximum of 24 hours. If some nodes can't be patched because of running workloads, the instance group can end up with a mix of AMI versions across its nodes. To converge faster, you can manually upgrade the remaining nodes by calling the `UpdateClusterSoftware` API. With the `WhenAllIdle` strategy, if all nodes in an instance group don't fully drain within 24 hours, the patch fails and is retried on the next auto-patch cycle. This ensures that all nodes end up on a consistent AMI version. However, if you have workloads that run longer than 24 hours, the patch fails under this strategy.

What should I do if my instance group is partially patched?

If your cluster's instance group is only partially patched – that is, not all nodes are using the same AMI version – you receive an Amazon Personal Health Dashboard (PHD) notification. To bring the instance group to a consistent AMI version, call the UpdateClusterSoftware API with the `ImageReleaseVersion` you want to apply. Only the nodes that are not already on the desired AMI version are upgraded.

How do I know a patch is happening?

You receive Amazon Health (PHD) notifications when a patch AMI becomes available, and on patch start, completion, and failure. Live progress is also shown on the cluster details page in the console. Notifications are delivered via Amazon Health / Personal Health Dashboard (PHD). They go to the Amazon account that owns the cluster. Routing is per-account and whoever has access to the Health Dashboard in that account sees them. To route to a specific channel, you can use EventBridge rules on Amazon Health events to forward to Amazon SNS, Lambda, or PagerDuty.

Can I select a particular AMI version for patching?

No, you cannot select a target AMI version for patching. The system automatically patches to the next available patch-level version in the same major.minor line. For example, if a node is on 1.1.1, it auto-patches only to 1.1.2 (a patch release), never to 1.2.0 (a minor release). However, you can specify the major.minor branch using the `ImageReleaseVersion` field in the UpdateClusterSoftware API or during cluster creation/updates. After you select a major.minor line, auto-patching keeps your nodes on patch releases within that same major.minor line for as long as it remains supported. For more information about the AMI version support policy, see Amazon SageMaker HyperPod AMI support policy.

Can I roll back a patch?

Automatic rollback is not supported. If you need to revert to a previous AMI version, you must roll back manually by calling the UpdateClusterSoftware API with the `ImageReleaseVersion` of the AMI version you want to restore.

Amazon SageMaker HyperPod AMI support policy

Amazon SageMaker HyperPod provides pre-built Amazon Machine Images (AMIs) optimized for distributed training and inference workloads. This page details the support policy for HyperPod AMI releases.

Scope

This support policy applies to the following HyperPod AMI components:

- EFA (Elastic Fabric Adapter)
- NVIDIA Driver
- NCCL (aws-ofi-nccl)
- CUDA
- OS Kernel

The policy defines the window during which HyperPod will ship security patches for a given AMI version.

Support policy

The following table outlines the release schedule for HyperPod AMI versions and their planned support timelines. Amazon provides ongoing security patches for supported AMI versions. In some cases, an AMI version might need to be designated end of support earlier than originally planned if:

a. security issues cannot be addressed while maintaining semantic versioning guidelines,

b. any of the core dependencies (for example, NVIDIA driver, CUDA, OS kernel) reach end-of-life, or

c. upstream vendors discontinue support for a bundled component.

Version	Description	Support window
Major	HyperPod AMI major version releases involve upgrading core components (EFA, NVIDIA driver, NCCL, CUDA, OS kernel) to new major versions. These releases might introduce breaking changes, such as NVIDIA driver changes from 570.x to 580.x, that require workload validation. Major versions are denoted by the first number in the version string (for example, 1.0, 2.0, 3.0).	12 months
Minor	HyperPod AMI minor version releases include upgrading core components to newer compatible minor versions within the same major version. Minor versions are denoted by the second number in the version string (for example, 1.1, 1.2, 2.1).	6 months

Version	Description	Support window
Patch	HyperPod AMI patch version releases include security fixes and bug fixes for the supported components. Patch releases do not change the major or minor versions of any bundled component. Patch versions are denoted by the third number in the version string (for example, 1.1.1, 1.2.1, 2.1.3).	Until a new patch version is released

Vulnerability management

Amazon continuously monitors supported HyperPod AMI versions for security vulnerabilities affecting the in-scope components (EFA, NVIDIA driver, NCCL, CUDA, OS kernel). When vulnerabilities are detected and a fix is available that satisfies the semantic versioning constraints for the given AMI version, Amazon will release a patch update to remediate the issue.

HyperPod EKS

HyperPod EKS AMIs are versioned independently of the Kubernetes version they ship with. A given AMI version (for example, 1.1.2) is built for each supported Kubernetes minor version (for example, 1.33, 1.34, 1.35), with identical core component versions across the Kubernetes lines.

Major versions support policy

AMI version	Supported until
1.x.x	January 2027

AMI version list

The following table lists the supported HyperPod EKS AMI versions, the Kubernetes minor versions they ship with, and their planned end of support dates. When creating or updating clusters, we recommend that you choose supported AMI versions from the following table. The **Supported package versions** column lists the in-scope components covered by this support policy; for the full list of bundled packages in each release, see the Amazon SageMaker HyperPod AMI release notes for Amazon EKS in the section called “AMI releases for Amazon EKS”.

AMI version	Latest patch	Supported EKS versions	Supported package versions	First released
1.3.x	1.3.0	1.30, 1.31, 1.32, 1.33, 1.34, 1.35	• NVIDIA Driver: 580.167.08 • CUDA Toolkit: 12.8 • EFA Installer: 1.47.0 • OS Kernel: 6.1.x	June 29, 2026
1.2.x	1.2.0	1.30, 1.31, 1.32, 1.33, 1.34, 1.35	• NVIDIA Driver: 580.159.04 • CUDA Toolkit: 12.8 • EFA Installer: 1.47.0 • OS Kernel: 6.1.x	June 26, 2026
1.1.x	1.1.6	1.30, 1.31, 1.32, 1.33, 1.34, 1.35	• NVIDIA Driver: 580.126.09 • CUDA Toolkit: 12.8 • EFA Installer: 1.47.0 • OS Kernel: 6.1.x	April 23, 2026
1.0.x	1.0.3	1.30, 1.31, 1.32, 1.33, 1.34	• NVIDIA Driver: 580.150 • CUDA Toolkit: 12.8 • EFA Installer: 1.47.0 • OS Kernel: 6.1.x	January 25, 2026

Frequently asked questions

Can I still use an older AMI after it is no longer supported?

Older AMIs remain available on existing HyperPod clusters after they reach end of support. However, you cannot create a new cluster using an end-of-support AMI. We strongly recommend upgrading to a supported AMI version, which continues to receive security patches. You are responsible for managing any vulnerabilities that might arise from running an AMI version no longer supported by Amazon.

What happens when a new patch version is released?

When a new patch version is released, the previous patch version within the same minor version reaches end of support. If auto-patching is enabled, HyperPod applies patch updates automatically without disrupting running workloads.

How will I be notified about new AMI versions or end-of-support dates?

Amazon will notify customers through Personal Health Dashboard (PHD) notifications and the HyperPod console when AMI updates are available or when their current AMI version is approaching end of support.

Does this policy apply to custom AMIs?

No. This support policy applies only to Amazon-vended HyperPod AMIs. If you use a custom AMI, you are responsible for maintaining and patching all components. For more information about custom AMIs, see Custom Amazon Machine Images (AMIs) for SageMaker HyperPod clusters.

Generative AI in SageMaker notebook environments

Jupyter AI is an open-source extension of JupyterLab integrating generative AI capabilities into Jupyter notebooks. Through the Jupyter AI chat interface and magic commands, users experiment with code generated from natural language instructions, explain existing code, ask questions about their local files, generate entire notebooks, and more. The extension connects Jupyter notebooks with large language models (LLMs) that users can use to generate text, code, or images, and to ask questions about their own data. Jupyter AI supports generative model providers such as AI21, Anthropic, Amazon (JumpStart and Amazon Bedrock), Cohere, and OpenAI.

You can also use Amazon Q Developer as an out of the box solution. Instead of having to manually set up a connection to a model, you can start using Amazon Q Developer with minimal configuration. When you enable Amazon Q Developer, it becomes the default solution provider within Jupyter AI. For more information about using Amazon Q Developer, see SageMaker JupyterLab.

The extension's package is included in Amazon SageMaker Distribution version 1.2 and onwards. Amazon SageMaker Distribution is a Docker environment for data science and scientific computing used as the default image of JupyterLab notebook instances. Users of different IPython environments can install Jupyter AI manually.

In this section, we provide an overview of Jupyter AI capabilities and demonstrate how to configure models provided by JumpStart or Amazon Bedrock from JupyterLab or Studio Classic notebooks.

For more in-depth information on the Jupyter AI project, refer to its documentation. Alternatively, you can refer to the blog post *Generative AI in Jupyter* for an overview and examples of key Jupyter AI capabilities.

Before using Jupyter AI and interacting with your LLMs, make sure that you satisfy the following prerequisites:

- For models hosted by Amazon, you should have the ARN of your SageMaker AI endpoint or have access to Amazon Bedrock. For other model providers, you should have the API key used to authenticate and authorize requests to your model. Jupyter AI supports a wide range of model providers and language models, refer to the list of its supported models to stay updated on the latest available models. For information on how to deploy a model in JumpStart, see Deploy a Model in the JumpStart documentation. You need to request access to Amazon Bedrock to use it as your model provider.
- Ensure that Jupyter AI libraries are present in your environment. If not, install the required package by following the instructions in Jupyter AI installation.
- Familiarize yourself with the capabilities of Jupyter AI in Access Jupyter AI Features.
- Configure the target models you wish to use by following the instructions in Configure your model provider.

After completing the prerequisite steps, you can proceed to Use Jupyter AI in JupyterLab or Studio Classic.

Topics

- Jupyter AI installation
- Access Jupyter AI Features
- Configure your model provider
- Use Jupyter AI in JupyterLab or Studio Classic

Jupyter AI installation

To use Jupyter AI, you must first install the Jupyter AI package. For Amazon SageMaker AI Distribution users, we recommend selecting the SageMaker Distribution image version 1.2 or later. No further installation is necessary. Users of JupyterLab in Studio can choose the version of their Amazon SageMaker Distribution when creating a space.

For users of other IPython environments, the version of the recommended Jupyter AI package depends on the version of JupyterLab they are using.

The Jupyter AI distribution consists of two packages.

- `jupyter_ai`: This package provides a JupyterLab extension and a native chat user interface (UI). It acts as a conversational assistant using the large language model of your choice.
- `jupyter_ai_magics`: This package provides the IPython `%%ai` and `%ai` magic commands with which you can invoke a large language model (LLM) from your notebook cells.

> **Note**
>
> Installing `jupyter_ai` also installs `jupyter_ai_magics`. However, you can install `jupyter_ai_magics` independently without JupyterLab or `jupyter_ai`. The magic commands `%%ai` and `%ai` work in any IPython kernel environment. If you only install `jupyter_ai_magics`, you can't use the chat UI.

For users of JupyterLab 3, in particular Studio Classic users, we recommend installing `jupyter-ai` version 1.5.x or any later 1.x version. However, we highly recommend using Jupyter AI with JupyterLab 4. The `jupyter-ai` version compatible with JupyterLab 3 may not allow users to set additional model parameters such as temperature, top-k and top-p sampling, max tokens or max length, or user acceptance license agreements.

For users of JupyterLab 4 environments that do not use SageMaker Distribution, we recommend installing `jupyter-ai` version 2.5.x or any later 2.x version.

See the installation instructions in the *Installation* section of Jupyter AI documentation.

Access Jupyter AI Features

You can access Jupyter AI capabilities through two distinct methods: using the chat UI or using magic commands within notebooks.

From the chat user interface AI assistant

The chat interface connects you with Jupyternaut, a conversational agent that uses the language model of your choice.

After launching a JupyterLab application installed with Jupyter AI, you can access the chat interface by choosing the chat icon () in the left navigation panel. First-time users are prompted to configure their model. See Configure your model provider in the chat UI for configuration instructions.

Using the chat UI, you can:

- **Answer questions**: For instance, you can ask Jupyternaut to create a Python function that adds CSV files to an Amazon S3 bucket. Subsequently, you can refine your answer with a follow-up question, such as adding a parameter to the function to choose the path where the files are written.
- **Interact with files in JupyterLab**: You can include a portion of your notebook in your prompt by selecting it. Then, you can either replace it with the model's suggested answer or manually copy the answer to your clipboard.
- **Generate entire notebooks** from prompts: By starting your prompt with `/generate`, you trigger a notebook generation process in the background without interrupting your use of Jupyternaut. A message containing the link to the new file is displayed upon completion of the process.
- **Learn from and ask questions about local files**: Using the `/learn` command, you can teach an embedding model of your choice about local files and then ask questions about those files using the `/ask` command. Jupyter AI stores the embedded content in a local FAISS vector database, then uses retrieval-augmented generation (RAG) to provide answers based on what it has learned. To erase all previously learned information from your embedding model, use `/learn -d`.

> **Note**
>
> Amazon Q developer doesn't have the capability to generate notebooks from scratch.

For a complete list of features and detailed instructions on their usage, see the Jupyter AI chat interface documentation. To learn about how to configure access to a model in Jupyternaut, see Configure your model provider in the chat UI.

From notebook cells

Using `%%ai` and `%ai` magic commands, you can interact with the language model of your choice from your notebook cells or any IPython command line interface. The `%%ai` command applies your instructions to the entire cell, whereas `%ai` apply them to the specific line.

The following example illustrates an `%%ai` magic command invoking an Anthropic Claude model to output an HTML file containing the image of a white square with black borders.

```
%%ai anthropic:claude-v1.2 -f html
Create a square using SVG with a black border and white fill.
```

To learn about the syntax of each command, use `%ai help`. To list the providers and models supported by the extension, run `%ai list`.

For a complete list of features and detailed instructions on their usage, see the Jupyter AI magic commands documentation. In particular, you can customize the output format of your model using the `-f` or `--format` parameter, allow variable interpolation in prompts, including special `In` and `Out` variables, and more.

To learn about how to configure the access to a model, see Configure your model provider in a notebook.

Configure your model provider

> **Note**
>
> In this section, we assume that the language and embedding models that you plan to use are already deployed. For models provided by Amazon, you should already have the ARN of your SageMaker AI endpoint or access to Amazon Bedrock. For other model providers, you should have the API key used to authenticate and authorize requests to your model. Jupyter AI supports a wide range of model providers and language models, refer to the list of its supported models to stay updated on the latest available models. For information on how to deploy a model provided by JumpStart, see Deploy a Model in the JumpStart documentation. You need to request access to Amazon Bedrock to use it as your model provider.

The configuration of Jupyter AI varies depending on whether you are using the chat UI or magic commands.

Configure your model provider in the chat UI

> **Note**
>
> You can configure several LLMs and embedding models following the same instructions. However, you must configure at least one **Language model**.

To configure your chat UI

1. In JupyterLab, access the chat interface by choosing the chat icon ( ) in the left navigation panel.
2. Choose the configuration icon ( ) in the top right corner of the left pane. This opens the Jupyter AI configuration panel.
3. Fill out the fields related to your service provider.

   - **For models provided by JumpStart or Amazon Bedrock**
     - In the **language model** dropdown list, select `sagemaker-endpoint` for models deployed with JumpStart or `bedrock` for models managed by Amazon Bedrock.
     - The parameters differ based on whether your model is deployed on SageMaker AI or Amazon Bedrock.
       - For models deployed with JumpStart:
         - Enter the name of your endpoint in **Endpoint name**, and then the Amazon Web Services Region in which your model is deployed in **Region name**. To retrieve the ARN of the SageMaker AI endpoints, navigate to https://console.amazonaws.cn/sagemaker/ and then choose **Inference** and **Endpoints** in the left menu.
         - Paste the JSON of the **Request schema** tailored to your model, and the corresponding **Response path** for parsing the model's output.

> **Note**
>
> You can find the request and response format of various of JumpStart foundation models in the following example notebooks. Each notebook is named after the model it demonstrates.

  - For models managed by Amazon Bedrock: Add the Amazon profile storing your Amazon credentials on your system (optional), and then the Amazon Web Services Region in which your model is deployed in **Region name**.
- (Optional) Select an embedding model to which you have access. Embedding models are used to capture additional information from local documents, enabling the text generation model to respond to questions within the context of those documents.
- Choose **Save Changes** and navigate to the left arrow icon (←) in the top left corner of the left pane. This opens the Jupyter AI chat UI. You can start interacting with your model.

- **For models hosted by third-party providers**
  - In the **language model** dropdown list, select your provider ID. You can find the details of each provider, including their ID, in Jupyter AI list of model providers.
  - (Optional) Select an embedding model to which you have access. Embedding models are used to capture additional information from local documents, enabling the text generation model to respond to questions within the context of those documents.
  - Insert your models' API keys.
  - Choose **Save Changes** and navigate to the left arrow icon (←) in the top left corner of the left pane. This opens the Jupyter AI chat UI. You can start interacting with your model.

The following snapshot is an illustration of the chat UI configuration panel set to invoke a Flan-t5-small model provided by JumpStart and deployed in SageMaker AI.

Language model
Language model
SageMaker endpoint :: *
Endpoint name
hf-text2text-flan-t5-small
Specify an endpoint name as the model ID. In addition, you must specify a region name, request schema, and response path. For more information, see the documentation about SageMaker endpoints deployment and about using magic commands with SageMaker endpoints.
Region name (required)
us-west-2
Request schema (required)
{"inputs":"<prompt>"}
Response path (required)

API Keys
Input
When writing a message, press Enter to:
Send the message
Start a new line (use Shift+Enter to send)
Save Changes

Pass extra model parameters and custom parameters to your request

Your model may need extra parameters, like a customized attribute for user agreement approval or adjustments to other model parameters such as temperature or response length. We recommend configuring these settings as a start up option of your JupyterLab application using a Lifecycle Configuration. For information on how to create a Lifecycle Configuration and attach it to your domain, or to a user profile from the SageMaker AI console, see Create and associate a lifecycle configuration. You can choose your LCC script when creating a space for your JupyterLab application.

Use the following JSON schema to configure your extra parameters:

```
{
  "AiExtension": {
    "model_parameters": {
      "<provider_id>:<model_id>": { Dictionary of model parameters which is unpacked
 and passed as-is to the provider.}
    }
  }
}
```

The following script is an example of a JSON configuration file that you can use when creating a JupyterLab application LCC to set the maximum length of an AI21 Labs Jurassic-2 model deployed on Amazon Bedrock. Increasing the length of the model's generated response can prevent the systematic truncation of your model's response.

```
#!/bin/bash
set -eux

mkdir -p /home/sagemaker-user/.jupyter

json='{"AiExtension": {"model_parameters": {"bedrock:ai21.j2-mid-v1": {"model_kwargs":
 {"maxTokens": 200}}}}}'
# equivalent to %%ai bedrock:ai21.j2-mid-v1 -m {"model_kwargs":{"maxTokens":200}}

# File path
file_path="/home/sagemaker-user/.jupyter/jupyter_jupyter_ai_config.json"

#jupyter --paths
```

```
# Write JSON to file
echo "$json" > "$file_path"

# Confirmation message
echo "JSON written to $file_path"

restart-jupyter-server

# Waiting for 30 seconds to make sure the Jupyter Server is up and running
sleep 30
```

The following script is an example of a JSON configuration file for creating a JupyterLab application LCC used to set additional model parameters for an Anthropic Claude model deployed on Amazon Bedrock.

```
#!/bin/bash
set -eux

mkdir -p /home/sagemaker-user/.jupyter

json='{"AiExtension": {"model_parameters": {"bedrock:anthropic.claude-v2":
{"model_kwargs":{"temperature":0.1,"top_p":0.5,"top_k":25
0,"max_tokens_to_sample":2}}}}}'
# equivalent to %%ai bedrock:anthropic.claude-v2 -m {"model_kwargs":
{"temperature":0.1,"top_p":0.5,"top_k":250,"max_tokens_to_sample":2000}}

# File path
file_path="/home/sagemaker-user/.jupyter/jupyter_jupyter_ai_config.json"

#jupyter --paths

# Write JSON to file
echo "$json" > "$file_path"

# Confirmation message
echo "JSON written to $file_path"

restart-jupyter-server

# Waiting for 30 seconds to make sure the Jupyter Server is up and running
sleep 30
```

Once you have attached your LCC to your domain, or user profile, add your LCC to your space when launching your JupyterLab application. To ensure that your configuration file is updated by the LCC, run `more ~/.jupyter/jupyter_jupyter_ai_config.json` in a terminal. The content of the file should correspond to the content of the JSON file passed to the LCC.

Configure your model provider in a notebook

To invoke a model via Jupyter AI within JupyterLab or Studio Classic notebooks using the `%%ai` and `%ai` magic commands

1. Install the client libraries specific to your model provider in your notebook environment. For example, when using OpenAI models, you need to install the `openai` client library. You can find the list of the client libraries required per provider in the *Python package(s)* column of the Jupyter AI Model providers list.

   > **Note**
   >
   > For models hosted by Amazon, `boto3` is already installed in the SageMaker AI Distribution image used by JupyterLab, or any Data Science image used with Studio Classic.

2. - **For models hosted by Amazon**

     Ensure that your execution role has the permission to invoke your SageMaker AI endpoint for models provided by JumpStart or that you have access to Amazon Bedrock.

   - **For models hosted by third-party providers**

     Export your provider's API key in your notebook environment using environment variables. You can use the following magic command. Replace the `provider_API_key` in the command by the environment variable found in the *Environment variable* column of the Jupyter AI Model providers list for your provider.

     ```
     %env provider_API_key=your_API_key
     ```

Use Jupyter AI in JupyterLab or Studio Classic

You can use Jupyter AI in JupyterLab or Studio Classic by invoking language models from either the chat UI or from notebook cells. The following sections give information about the steps needed to complete this.

Use language models from the chat UI

Compose your message in the chat UI text box to start interacting with your model. To clear the message history, use the `/clear` command.

> **Note**
>
> Clearing the message history does not erase the chat context with the model provider.

Use language models from notebook cells

Before using the `%%ai` and `%ai` commands to invoke a language model, load the IPython extension by running the following command in a JupyterLab or Studio Classic notebook cell.

```
%load_ext jupyter_ai_magics
```

- **For models hosted by Amazon:**
  - To invoke a model deployed in SageMaker AI, pass the string `sagemaker-endpoint:`*`endpoint-name`* to the `%%ai` magic command with the required parameters below, then add your prompt in the following lines.

    The following table lists the required and optional parameters when invoking models hosted by SageMaker AI or Amazon Bedrock.

Parameter Name	Parameter	Short Version	Description
Request schema	`--request-schema`	`-q`	**Required**: The JSON object the endpoint expects, with the prompt being substituted

Parameter Name	Parameter	Short Version	Description
			into any value that matches the string literal `<prompt>`.
Region name	`--region-name`	`-n`	**Required**: The Amazon Web Services Region where the model is deployed.
Response path	`--response-path`	`-p`	**Required**: A JSONPath string used to extract the language model's output from the JSON response of the endpoint.

Parameter Name	Parameter	Short Version	Description
Extra model parameters	`--model-parameters`	`-m`	**Optional**: A JSON value specifying additional parameters to be passed to the model. The accepted value is parsed into a dictionary, unpacked, and directly passed to the provider class. This is useful when the endpoint or the model requires custom parameters. For example, in Llama 2 models when accepting the End User License Agreement (EULA) is necessary, you can pass the EULA acceptance to the endpoint using `-m {"endpoint_kwargs":{"CustomAttributes":"accept_eula=true"}}` . Alternatively, you can use the `-m` parameter to pass extra model

Parameter Name	Parameter	Short Version	Description
			parameters, such as setting the maximum number of tokens for a model's generated response. For example, when working with an AI21 Labs Jurassic model: `-m {"model_kwargs":{"maxTokens":256}} .`
Output format	`--format`	`-f`	**Optional**: The IPython display used to render the output. It can be any of the following values `[code|html|image|json|markdown|math|md|text]`, provided that the invoked model supports the specified format.

The following command invokes a Llama 2 7B model hosted by SageMaker AI.

```
%%ai sagemaker-endpoint:jumpstart-dft-meta-textgeneration-llama-2-7b -q
 {"inputs":"<prompt>","parameters":
{"max_new_tokens":64,"top_p":0.9,"temperature":0.6,"return_full_text":false}}
```

```
 -n us-east-2 -p [0].generation -m {"endpoint_kwargs":
{"CustomAttributes":"accept_eula=true"}} -f text
Translate English to French:
sea otter => loutre de mer
peppermint => menthe poivrée
plush girafe => girafe peluche
cheese =>
```

The following example invokes a Flan-t5-small model hosted by SageMaker AI.

```
%%ai sagemaker-endpoint:hf-text2text-flan-t5-small --request-
schema={"inputs":"<prompt>","parameters":{"num_return_sequences":4}} --region-
name=us-west-2 --response-path=[0]["generated_text"] -f text
What is the atomic number of Hydrogen?
```

- To invoke a model deployed in Amazon Bedrock, pass the string `bedrock:`*`model-name`* to the `%%ai` magic command with any optional parameter defined in the list of parameters for invoking models hosted by JumpStart or Amazon Bedrock, then add your prompt in the following lines.

  The following example invokes an AI21 Labs Jurassic-2 model hosted by Amazon Bedrock.

  ```
  %%ai bedrock:ai21.j2-mid-v1 -m {"model_kwargs":{"maxTokens":256}} -f code
  Write a function in python implementing a bubbble sort.
  ```

- **For models hosted by third-party providers**

  To invoke a model hosted by third-party providers, pass the string *`provider-id`*`:`*`model-name`* to the `%%ai` magic command with an optional `Output format`, then add your prompt in the following lines. You can find the details of each provider, including their ID, in the Jupyter AI list of model providers.

  The following command asks an Anthropic Claude model to output an HTML file containing the image of a white square with black borders.

  ```
  %%ai anthropic:claude-v1.2 -f html
  Create a square using SVG with a black border and white fill.
  ```

Amazon Q Developer

Amazon Q Developer is a generative AI conversational assistant that helps you write better code. Amazon Q Developer is available in the following IDEs within Amazon SageMaker Studio:

- JupyterLab
- Code Editor, based on Code-OSS, Visual Studio Code - Open Source

Use the following sections to set up Amazon Q Developer and use it within your environment.

Topics

- Set up Amazon Q Developer for your users
- Use Amazon Q to Expedite Your Machine Learning Workflows
- Customize Amazon Q Developer in Amazon SageMaker Studio applications

Set up Amazon Q Developer for your users

Amazon Q Developer is a generative AI conversational assistant. You can set up Amazon Q Developer within a new domain or an existing domain. Use the following information to set up Amazon Q Developer.

With Amazon Q Developer, your users can:

- Receive step-by-step guidance on using SageMaker AI features independently or in combination with other Amazon services.
- Get sample code to get started on your ML tasks such as data preparation, training, inference, and MLOps.
- Receive troubleshooting assistance to debug and resolve errors encountered while running code.

> **Note**
>
> Amazon Q Developer in Studio doesn't use user content to improve the service, regardless of whether you use the Free-tier or Pro-tier subscription. For IDE-level telemetry sharing, Amazon Q might track your users' usage, such as the number of questions asked and whether recommendations were accepted or rejected. This telemetry data doesn't include

personally identifiable information such as the users' IP address. For more information on data protection and instructions for opting out, see Opt out of data sharing in the IDE.

You can set up Amazon Q Developer with either a Pro or Free tier subscription. The Pro tier is a paid subscription service with higher usage limits and other features. For more information about the differences between the tiers, see Understanding tiers of service for Amazon Q Developer.

For information about subscribing to Amazon Q Developer Pro, see Subscribing to Amazon Q Developer Pro.

Set up instructions for Amazon Q Developer Free Tier:

To set up Amazon Q Developer Free Tier, use the following procedure:

To set up Amazon Q Developer Free Tier

1. Add the following policy to the IAM role that you've used to create your JupyterLab or Code Editor space:

   JSON

```
{
 "Version":"2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "q:SendMessage"
   ],
   "Resource": [
    "*"
   ]
  },
  {
   "Sid": "AmazonQDeveloperPermissions",
   "Effect": "Allow",
   "Action": [
    "codewhisperer:GenerateRecommendations"
   ],
   "Resource": "*"
```

```
  }
 ]
}
```

2. Navigate to Amazon SageMaker Studio.
3. Open your JupyterLab or Code Editor space.
4. Navigate to the **Launcher** and choose **Terminal**.
5. In JupyterLab, do the following:

   a. Specify `restart-jupyter-server`.

   b. Restart your browser and navigate back to Amazon SageMaker Studio.

Set up instructions for Amazon Q Developer Pro tier:

> ⚠ **Prerequisites**
>
> To set up Amazon Q Pro, you must have:
>
> - An Amazon SageMaker AI domain set up for your organization with IAM Identity Center configured as the means of access.
> - An Amazon Q Developer Pro subscription.

If you're updating a domain that you've already set up for your organization, you need to update it to use Amazon Q Developer. You can use either the Amazon Web Services Management Console or the Amazon Command Line Interface to update a domain.

You must use the ARN of your Amazon Q Developer profile. You can find the Q Profile ARN on the Q Developer Settings page.

You can use the following Amazon Command Line Interface command to update your domain:

```
aws --region Amazon Web Services Region sagemaker update-domain --domain-id domain-id
 --domain-settings-for-update "AmazonQSettings={Status=ENABLED,QProfileArn=Q-Profile-
ARN}"
```

You can also use the following procedure to update the domain within the Amazon Web Services Management Console.

1. Navigate to the Amazon SageMaker AI console.
2. Choose domains.
3. Select **App Configurations**.
4. For **Amazon Q Developer for SageMaker AI Applications**, choose **Edit**.
5. Select **Enable Amazon Q Developer on this domain**.
6. Provide the Q Profile ARN.
7. Choose **Submit**.

You must use the ARN of your Amazon Q Developer profile. You can find the ARN of the Q Profile on the **Amazon Q account details** page of the Amazon Q Developer console.

The **Set up for organizations** is an advanced setup for the Amazon SageMaker AI domain that lets you use IAM Identity Center. For information about how you can set up the domain and information about setting up IAM Identity Center, see Use custom setup for Amazon SageMaker AI.

When setting up Amazon Q Developer in a new domain, you can either use the Amazon Web Services Management Console or the following Amazon Command Line Interface command from your local machine:

```
aws --region Amazon Web Services Region sagemaker create-domain --domain-
id domain-id --domain-name "example-domain-name" --vpc-id example-vpc-id
 --subnet-ids example-subnet-ids --auth-mode SSO --default-user-settings
 "ExecutionRole=arn:aws:iam::111122223333:role/IAM-role",--domain-settings
 "AmazonQSettings={status=ENABLED,qProfileArn=Q-profile-ARN" --query example-domain-
ARN--output text
```

You can use the following Amazon CLI command to disable Amazon Q Developer:

```
aws --region Amazon Web Services Region sagemaker update-domain --domain-id domain-id
 --domain-settings-for-update "AmazonQSettings={Status=DISABLED,QProfileArn=Q-Profile-
ARN}"
```

We recommend using the latest version of the Amazon Command Line Interface. For information about updating the Amazon CLI, see Install or update to the latest version of the Amazon Command Line Interface.

If you need to establish a connection between Amazon Q Developer and your VPC, see Creating an interface VPC endpoint for Amazon Q .

Note

Amazon Q Developer has the following limitations:

- It doesn't support shared spaces.
- Amazon Q Developer detects whether a code suggestion might be too similar to publicly available code. The reference tracker can flag suggestions with repository URLs and licenses, or filter them out. This allows you to review the referenced code and its usage before you adopt it. All references are logged for you to review later to ensure that your code flow is not disturbed and that you can keep coding without interruption.

  For more information about code references, see Using code references - Amazon Q Developer and AI Coding Assistant - Amazon Q Developer FAQs.
- Amazon Q processes all user interaction data within the US East (N. Virginia) Amazon Web Services Region. For more information about how Amazon Q processes data and the Amazon Web Services Regions it supports, see Supported Regions for Amazon Q Developer.
- Amazon Q only works within Amazon SageMaker Studio. It is not supported within Amazon SageMaker Studio Classic.
- On JupyterLab, Amazon Q works within SageMaker AI Distribution Images version 2.0 and above. On Code Editor, Amazon Q works within SageMaker AI Distribution Images version 2.2.1 and above.
- Amazon Q Developer in JupyterLab works within the Jupyter AI extension. You can't use other 3P models within the extension while you're using Amazon Q.

Amazon Q customizations in Amazon SageMaker AI

If you use Amazon Q Developer Pro, you have the option to create *customizations*. With customizations, Amazon Q Developer provides suggestions based on your company's codebase. If you create customizations in Amazon Q Developer, they become available for you to use in JupyterLab and Code Editor in Amazon SageMaker Studio. For more information about setting up customizations, see Customizing suggestions in the *Amazon Q Developer User Guide*.

Use Amazon Q to Expedite Your Machine Learning Workflows

Amazon Q Developer is your AI-powered companion for machine learning development. With Amazon Q Developer, you can:

- Receive step-by-step guidance on using SageMaker AI features independently or in combination with other Amazon services.
- Get sample code to get started on your ML tasks such as data preparation, training, inference, and MLOps.

To use Amazon Q Developer, choose the **Q** from the left-hand navigation of your JupyterLab or Code Editor environment.

If you don't see the **Q** icon, your administrator needs to set it up for you. For more information about setting up Amazon Q Developer, see Set up Amazon Q Developer for your users.

Amazon Q automatically provides suggestions to help you write your code. You can also ask for suggestions through the chat interface.

Customize Amazon Q Developer in Amazon SageMaker Studio applications

You can customize Amazon Q Developer in the JupyterLab and Code Editor applications in Amazon SageMaker Studio. When you customize Q Developer, it provides suggestions and answers based on examples from your codebase. If you use Amazon Q Developer Pro, you can load any customizations that you've created with that service.

Customize in JupyterLab

In JupyterLab, you can load any customizations that you've created with Amazon Q Developer Pro. Or, in your JupyterLab space, you can customize Q Developer locally with files that you upload to the space.

To use customizations that you've created in Amazon Q Developer Pro

When you load a customization, Q Developer provides suggestions based on the codebase that you used to create the customization. Also, when you use the chat in the **Amazon Q** panel, you interact with your customization.

For more information about setting up customizations, see Customizing suggestions in the *Amazon Q Developer User Guide*.

To load your customization

Open your JupyterLab space and complete the following steps.

1. In the status bar at the bottom of JupyterLab, choose **Amazon Q**. A menu opens.
2. In the menu, choose **Other Features**. The **Amazon Q Features** tab opens in the main work area.
3. In the **Amazon Q Features** tab, under **Select Customization**, choose your Q Developer customization.
4. Interact with your customization in either of the following ways:
    - Create a notebook, and write code in it. As you do, Q Developer automatically provides tailored inline suggestions based on your customization.
    - Chat with Q Developer in the **Amazon Q** panel by following these steps:
        a. In the left sidebar in JupyterLab, choose the **Jupyter AI Chat** icon. The **Amazon Q** panel opens.
        b. Use the **Ask Amazon Q** chat box to interact with your customization.

To customize Amazon Q Developer with files in your JupyterLab space

In JupyterLab, you can customize Q Developer with files that you upload to your space. Then, in the chat in the **Amazon Q** panel, you can use a command to ask Q Developer about those files.

When you customize Q Developer with files in your space, the customization exists only in your space. You can't load the customization elsewhere, such as in other spaces or in the Amazon Q Developer console.

You can customize Q Developer with files in JupyterLab if you use either Amazon Q Developer Pro or Amazon Q Developer at the Free tier.

To customize with your files

Open your JupyterLab space and complete the following steps.

1. Check whether your space is configured with the required embedding model. You can customize Q Developer in JupyterLab only if you use the default embedding model, which is **CodeSage :: codesage-small**. To check, do the following:

   a. In the left sidebar in JupyterLab, choose the **Jupyter AI Chat** icon. The **Amazon Q** panel opens.

   b. Choose the settings icon in the upper-right corner of the panel.

   c. For **Embedding model**, if necessary, choose **CodeSage :: codesage-small**, and choose **Save Changes**.

   d. In the upper-right corner of the panel, choose the back icon.

2. To upload files that you want to customize Q Developer with, in the **File Browser** panel, choose the **Upload Files** icon.

3. After you upload your files, in the **Ask Amazon Q** chat box, type `/learn` *`file path/`*. Replace *file path/* with the path to your files in your JupyterLab space. When Amazon Q finishes processing your files, it confirms with a chat message in the Amazon Q panel.

4. To ask Q Developer a question about your files, type `/ask` in the chat box, and follow the command with your question. Amazon Q generates an answer based on your files, and it responds in the chat.

For more information about the `/learn` and `/ask` commands, such as their options and supported arguments, see Learning about local data in the Jupyter AI user documentation. That page explains how to use the commands with the Jupyternaut AI chatbot. JupyterLab in Amazon SageMaker Studio supports the same command syntax.

Customize in Code Editor

If you've created a customization in Amazon Q Developer Pro, you can load it in Code Editor. Then, when Q Developer provides suggestions for your code, it bases them on the codebase that you used to create the customization. Also, when you use the chat in the **Amazon Q: Chat** panel, you interact with your customization.

To use customizations that you've created in Amazon Q Developer Pro

Open your Code Editor space and complete the following steps.

1. In the Code Editor menu, choose **View**, and choose **Command Pallette**.
2. In the command pallet, begin typing **`>Amazon Q: Select Customization`**, and choose that option in the filtered list of commands when it appears. The command pallet shows your Q Developer customizations.
3. Choose your customization.
4. Interact with your customization in either of the following ways:
   - Create a Python file or a Jupyter notebook, and write code in it. As you do, Q Developer automatically provides tailored inline suggestions based on your customization.
   - Chat with Q Developer in the **Amazon Q** panel by following these steps:
     a. In the left sidebar in Code Editor, choose the **Amazon Q** icon. The **Amazon Q: Chat** panel opens.
     b. Use the chat box to interact with your customization.

For more information about the capabilities of Q Developer, see Using Amazon Q Developer in the IDE in the *Amazon Q Developer User Guide*.

Amazon SageMaker Partner AI Apps overview

With Amazon SageMaker Partner AI Apps, users get access to generative AI and machine learning (ML) development applications built, published, and distributed by industry-leading application providers. Partner AI Apps are certified to run on SageMaker AI. With Partner AI Apps, users can accelerate and improve how they build solutions based on foundation models (FM) and classic ML models without compromising the security of their sensitive data. The data stays completely within their trusted security configuration and is never shared with a third party.

How it works

Partner AI Apps are full application stacks that include an Amazon Elastic Kubernetes Service cluster and an array of accompanying services that can include Application Load Balancer, Amazon Relational Database Service, Amazon Simple Storage Service buckets, Amazon Simple Queue Service queues, and Redis caches.

These service applications can be shared across all users in a SageMaker AI domain and are provisioned by an admin. After provisioning the application by purchasing a subscription through the Amazon Web Services Marketplace, the admin can give users in the SageMaker AI domain permissions to access the Partner AI App directly from Amazon SageMaker Studio, Amazon SageMaker Unified Studio (preview), or using a pre-signed URL. For information about launching an application from Studio, see Launch Amazon SageMaker Studio.

Partner AI Apps offers the following benefits for administrators and users.

- Administrators use the SageMaker AI console to browse, discover, select, and provision the Partner AI Apps for use by their data science and ML teams. After the Partner AI Apps are deployed, SageMaker AI runs them on service-managed Amazon Web Services accounts. This significantly reduces the operational overhead associated with building and operating these applications, and contributes to the security and privacy of customer data.
- Data scientists and ML developers can access Partner AI Apps from within their ML development environment in Amazon SageMaker Studio or Amazon SageMaker Unified Studio (preview). They can use the Partner AI Apps to analyze their data, experiments, and models created on SageMaker AI. This minimizes context switching and helps accelerate building foundation models and bringing new generative AI capabilities to market.

Integration with Amazon Web Services services

Partner AI Apps uses the existing Amazon Identity and Access Management (IAM) configuration for authorization and authentication. As a result, users don't need to provide separate credentials to access each Partner AI App from Amazon SageMaker Studio. For more information about authorization and authentication with Partner AI Apps, see Set up Partner AI Apps.

Partner AI Apps also integrates with Amazon CloudWatch to provide operational monitoring and management. Customers can also browse Partner AI Apps, and get details about them, such as features, customer experience, and pricing, from the Amazon Web Services Management Console. For information about Amazon CloudWatch, see How Amazon CloudWatch works.

Partner AI applications such as Deepchecks support integration with Amazon Bedrock to enable LLM-based evaluation features such as "LLM as a judge" evaluations and automated annotation capabilities. When Amazon Bedrock integration is enabled, the Partner AI App uses your customer-managed Amazon Bedrock account to access foundation models, ensuring that your data remains within your trusted security configuration. For more information about configuring Amazon Bedrock integration, see Configure Amazon Bedrock integration.

Supported types

Partner AI Apps support the following types:

- Comet
- Deepchecks
- Fiddler
- Lakera Guard

When the admin launches a Partner AI App, they must select the configuration of the instance cluster that the Partner AI App is launched with. This configuration is known as the Partner AI App's tier. A Partner AI App's tier can be one of the following values:

- `small`
- `medium`
- `large`

The following sections give information about each of the Partner AI App types, and details about the Partner AI App's tier values.

Comet overview

Comet provides an end-to-end model evaluation platform for AI developers, with LLM evaluations, experiment tracking, and production monitoring.

We recommend the following Partner AI App tiers based on the workload:

- `small` – Recommended for up to 5 users and 20 running jobs.
- `medium` – Recommended for up to 50 users and 100 running jobs.
- `large` – Recommended for up to 500 users and more than 100 running jobs.

> **Note**
>
> SageMaker AI does not support viewing the Comet UI as part of the output of a Jupyter notebook.

Deepchecks overview

AI application developers and stakeholders can use Deepchecks to continuously validate LLM-based applications including characteristics, performance metrics, and potential pitfalls throughout the entire lifecycle from pre-deployment and internal experimentation to production.

We recommend the following Partner AI App tiers based on the speed desired for the workload:

- `small` – Processes 200 tokens per second.
- `medium` – Processes 500 tokens per second.
- `large` – Processes 1300 tokens per second.

Fiddler overview

The Fiddler AI Observability Platform facilitates validating, monitoring, and analyzing ML models in production, including tabular, deep learning, computer vision, and natural language processing models.

We recommend the following Partner AI App tiers based on the speed desired for the workload:

- `small` – Processing 10MM events across 5 models, 100 features, and 20 iterations takes about 53 minutes.
- `medium` – Processing 10MM events across 5 models, 100 features, and 20 iterations takes about 23 minutes.
- `large` – Processing 10MM events across 5 models, 100 features, and 100 iterations takes about 27 minutes.

Lakera Guard overview

Lakera Guard is a low-latency AI application firewall to secure generative AI applications from gen AI-specific threats.

We recommend the following Partner AI App tiers based on the workload:

- `small` – Recommended for up to 20 Robotic Process Automations (RPAs).
- `medium` – Recommended for up to 100 RPAs.
- `large` – Recommended for up to 200 RPAs.

Set up Partner AI Apps

The following topics describe the permissions needed to start using Amazon SageMaker Partner AI Apps. The permissions required are split into two parts, depending on the user permissions level:

- **Administrative permissions** – Permissions for administrators setting up data scientist and machine learning (ML) developer environments.
  - Amazon Web Services Marketplace
  - Partner AI Apps management
  - Amazon License Manager
- **User permissions** – Permissions for data scientists and machine learning developers.
  - User authorization
  - Identity propagation
  - SDK access

Prerequisites

Admins can complete the following prerequisites to set up Partner AI Apps.

- (Optional) Onboard to a SageMaker AI domain. Partner AI Apps can be accessed directly from a SageMaker AI domain. For more information, see Amazon SageMaker AI domain overview.
  - If using Partner AI Apps in a SageMaker AI domain in VPC-only mode, admins must create an endpoint with the following format to connect to the Partner AI Apps. For more information about using Studio in VPC-only mode, see Connect Amazon SageMaker Studio in a VPC to External Resources.

    ```
    aws.sagemaker.region.partner-app
    ```
- (Optional) If admins are interacting with the domain using the Amazon CLI, they must also complete the following prerequisites.

  1. Update the Amazon CLI by following the steps in Installing the current Amazon CLI Version.

2. From the local machine, run `aws configure` and provide Amazon credentials. For information about Amazon credentials, see Understanding and getting your Amazon credentials.

Administrative permissions

The administrator must add the following permissions to enable Partner AI Apps in SageMaker AI.

- Permission to complete Amazon Web Services Marketplace subscription for Partner AI Apps
- Set up Partner AI App execution role

Amazon Web Services Marketplace subscription for Partner AI Apps

Admins must complete the following steps to add permissions for Amazon Web Services Marketplace. For information about using Amazon Web Services Marketplace, see Getting started as a buyer using Amazon Web Services Marketplace.

1. Grant permissions for Amazon Web Services Marketplace. Partner AI Apps administrators require these permissions to purchase subscriptions to Partner AI Apps from Amazon Web Services Marketplace. To get access to Amazon Web Services Marketplace, admins must attach the `AWSMarketplaceManageSubscriptions` managed policy to the IAM role that they're using to access the SageMaker AI console and purchase the app. For details about the `AWSMarketplaceManageSubscriptions` managed policy, see Amazon managed policies for Amazon Web Services Marketplace buyers. For information about attaching managed policies, see Adding and removing IAM identity permissions.
2. Grant permissions for SageMaker AI to run operations on the admins behalf using other Amazon Web Services services. Admins must grant SageMaker AI permissions to use these services and the resources that they act upon. The following policy definition demonstrates how to grant the required Partner AI Apps permissions. These permissions are needed in addition to the existing permissions for the admin role. For more information, see How to use SageMaker AI execution roles.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
```

```
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:CreatePartnerApp",
                "sagemaker:DeletePartnerApp",
                "sagemaker:UpdatePartnerApp",
                "sagemaker:DescribePartnerApp",
                "sagemaker:ListPartnerApps",
                "sagemaker:CreatePartnerAppPresignedUrl",
                "sagemaker:CreatePartnerApp",
                "sagemaker:AddTags",
                "sagemaker:ListTags",
                "sagemaker:DeleteTags"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:PassRole"
            ],
            "Resource": "arn:aws-cn:iam::*:role/*",
            "Condition": {
                "StringEquals": {
                     "iam:PassedToService": "sagemaker.amazonaws.com"
                 }
            }
        }
    ]
}
```

Set up Partner AI App execution role

1. Partner AI Apps require an execution role to interact with resources in the Amazon Web Services account. Admins can create this execution role using the Amazon CLI. The Partner AI App uses this role to complete actions related to Partner AI App functionality.

```
aws iam create-role --role-name PartnerAiAppExecutionRole --assume-role-policy-
document '{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "sagemaker.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}'
```

2. Create the Amazon License Manager service-linked role by following the steps in Create a service-linked role for License Manager.
3. Grant permissions for the Partner AI App to access License Manager using the Amazon CLI. These permissions are required to access the licenses for Partner AI App. This allows the Partner AI App to verify access to the Partner AI App license.

```
aws iam put-role-policy --role-name PartnerAiAppExecutionRole --policy-name
 LicenseManagerPolicy --policy-document '{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "license-manager:CheckoutLicense",
      "license-manager:CheckInLicense",
      "license-manager:ExtendLicenseConsumption",
      "license-manager:GetLicense",
      "license-manager:GetLicenseUsage"
    ],
    "Resource": "*"
  }
}'
```

4. If the Partner AI App requires access to an Amazon S3 bucket, then add Amazon S3 permissions to the execution role. For more information, see Required permissions for Amazon S3 API operations.

Configure Amazon Bedrock integration

Partner AI applications such as Deepchecks support integration with Amazon Bedrock to enable LLM-based evaluation features. When configuring a Partner AI App with Amazon Bedrock support,

administrators can specify which foundation models and inference profiles are available for use within the application. If you need to increase the quota limit for your Amazon Bedrock models, see Request an increase for Amazon Bedrock quotas.

1. Ensure the Partner AI App execution role has the required Amazon Bedrock permissions. Add the following permissions to enable Amazon Bedrock model access:

```
aws iam put-role-policy --role-name PartnerAiAppExecutionRole --policy-name
 BedrockInferencePolicy --policy-document '{
    "Version": "2012-10-17",
    "Statement": {
      "Effect": "Allow",
      "Action": [
        "bedrock:InvokeModel",
        "bedrock:GetFoundationModel",
        "bedrock:GetInferenceProfile"
      ],
      "Resource": "*"
    }
  }'
```

2. Identify the Amazon Bedrock models that your organization wants to make available to the Partner AI App. You can view available models in your region using the Amazon Bedrock console. For information about model availability across regions, see Model support by Amazon Web Services Region.
3. (Optional) Create customer-managed inference profiles for cost tracking and model management. Inference profiles allow you to track Amazon Bedrock usage specifically for the Partner AI App and can enable cross-region inference when models are not available in your current region. For more information, see Using inference profiles in Amazon Bedrock.
4. When creating or updating the Partner AI App, specify the allowed models and inference profiles using the `CreatePartnerApp` or `UpdatePartnerApp` API. The Partner AI App will only be able to access the models and inference profiles that you explicitly configure.

> **Important**
>
> Amazon Bedrock usage through Partner AI Apps is billed directly to your Amazon Web Services account using your existing Amazon Bedrock pricing. The Partner AI App infrastructure costs are separate from Amazon Bedrock model inference costs.

Deepchecks Amazon Bedrock integration

Deepchecks supports Amazon Bedrock integration for LLM-based evaluation capabilities, including:

- *LLM as a judge evaluations* - Use foundation models to automatically evaluate model outputs for quality, relevance, and other criteria
- *Automated annotation* - Generate labels and annotations for datasets using foundation models
- *Content analysis* - Analyze text data for bias, toxicity, and other quality metrics using LLM capabilities

For detailed information about Deepchecks Amazon Bedrock features and configuration, see the Deepchecks documentation within the application.

User permissions

After admins have completed the administrative permissions settings, they must make sure that users have the permissions needed to access the Partner AI Apps.

1. Grant permissions for SageMaker AI to run operations on your behalf using other Amazon Web Services services. Admins must grant SageMaker AI permissions to use these services and the resources that they act upon. Admins grant SageMaker AI these permissions using an IAM execution role. For more information about IAM roles, see IAM roles. The following policy definition demonstrates how to grant the required Partner AI Apps permissions. This policy can be added to the execution role of the user profile. For more information, see How to use SageMaker AI execution roles.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:DescribePartnerApp",
                "sagemaker:ListPartnerApps",
                "sagemaker:CreatePartnerAppPresignedUrl"
            ],
            "Resource": "arn:aws-cn:sagemaker:*:*:partner-app/app-*"
```

```
        }
    ]
}
```

2. (Optional) If launching Partner AI Apps from Studio, add the `sts:TagSession` trust policy to the role used to launch Studio or the Partner AI Apps directly as follows. This makes sure that the identity can be propagated properly.

```
{
    "Effect": "Allow",
    "Principal": {
        "Service": "sagemaker.amazonaws.com"
    },
    "Action": [
                "sts:AssumeRole",
                "sts:TagSession"
            ]
}
```

3. (Optional) If using the SDK of a Partner AI App to access functionality in SageMaker AI, add the following `CallPartnerAppApi` permission to the role used to run the SDK code. If running the SDK code from Studio, add the permission to the Studio execution role. If running the code from anywhere other than Studio, add the permission to the IAM role used with the notebook. This gives the user access the Partner AI App functionality from the Partner AI App's SDK.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Statement1",
            "Effect": "Allow",
            "Action": [
                "sagemaker:CallPartnerAppApi"
            ],
            "Resource": [
                "arn:aws-cn:sagemaker:us-east-1:111122223333:partner-app/app"
            ]
        }
```

```
    ]
}
```

Manage user authorization and authentication

To provide access to Partner AI Apps to members of their team, admins must make sure that the identity of their users is propagated to the Partner AI Apps. This propagation makes sure users can properly access the Partner AI Apps' UI and perform authorized Partner AI App actions.

Partner AI Apps support the following identity sources:

- Amazon IAM Identity Center
- External identity providers (IdPs)
- IAM Session-based identity

The following sections gives information about the identity sources that Partner AI Apps support, as well as important details related to that identity source.

IAM Identity Center

If a user is authenticated into Studio using IAM Identity Center and launches an application from Studio, the IAM Identity Center `UserName` is automatically propagated as the user identity for a Partner AI App. This is not the case if the user launches the Partner AI App directly using the `CreatePartnerAppPresignedUrl` API.

External identity providers (IdPs)

If using SAML for Amazon Web Services account federation, admins have two options to carry over the IdP identity as the user identity for a Partner AI App. For information about setting up Amazon Web Services account federation, see How to Configure SAML 2.0 for Amazon Web Services account Federation.

- **Principal Tag** – Admins can configure the IdP-specific IAM Identity Center application to pass identity information from the landing session using the Amazon session `PrincipalTag` with the following `Name` attribute. When using SAML, the landing role session uses an IAM role. To use the `PrincipalTag`, admins must add the `sts:TagSession` permission to this landing role, as well as the Studio execution role. For more information about `PrincipalTag`, see Configure SAML assertions for the authentication response.

```
https://aws.amazon.com/SAML/Attributes/PrincipalTag:SageMakerPartnerAppUser
```

- **Landing session name** – Admins can propagate the landing session name as the identity for the Partner AI App. To do this, they must set the `EnableIamSessionBasedIdentity` opt-in flag for each Partner AI App. For more information, see `EnableIamSessionBasedIdentity`.

IAM session-based identity

> **Important**
>
> We do not recommend using this method for production accounts. For production accounts, use an identity provider for increased security.

SageMaker AI supports the following options for identity propagation when using an IAM session-based identity. All of the options, except using a session tag with Amazon STS, require setting the `EnableIamSessionBasedIdentity` opt-in flag for each application. For more information, see `EnableIamSessionBasedIdentity`.

When propagating identities, SageMaker AI verifies whether an Amazon STS Session tag is being used. If one is not used, then SageMaker AI propagates the IAM username or Amazon STS session name.

- **Amazon STS Session tag** – Admins can set a `SageMakerPartnerAppUser` session tag for the launcher IAM session. When admins launch a Partner AI App using the SageMaker AI console or the Amazon CLI, the `SageMakerPartnerAppUser` session tag is automatically passed as the user identity for the Partner AI App. The following example shows how to set the `SageMakerPartnerAppUser` session tag using the Amazon CLI. The value of the key is added as a principal tag.

  ```
  aws sts assume-role \
      --role-arn arn:aws:iam::account:role/iam-role-used-to-launch-partner-ai-app \
      --role-session-name session_name \
      --tags Key=SageMakerPartnerAppUser,Value=user-name
  ```

  When giving users access to a Partner AI App using `CreatePartnerAppPresignedUrl`, we recommend verifying the value for the `SageMakerPartnerAppUser` key. This helps to prevent

unintended access to Partner AI App resources. The following trust policy verifies that the session tag exactly matches the associated IAM user. Admins can use any principal tag for this purpose. It should be configured on the role that is launching Studio or the Partner AI App.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "RoleTrustPolicyRequireUsernameForSessionName",
            "Effect": "Allow",
            "Action": [
                "sts:AssumeRole",
                "sts:TagSession"
            ],
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:root"
            },
            "Condition": {
                "StringLike": {
                    "aws:RequestTag/SageMakerPartnerAppUser": "prefix
${aws:username}"
                }
            }
        }
    ]
}
```

- **Authenticated IAM user** – The username of the user is automatically propagated as the Partner AI App user.
- **Amazon STS session name** – If no `SageMakerPartnerAppUser` session tag is configured when using Amazon STS, SageMaker AI returns an error when users launch a Partner AI App. To avoid this error, admins must set the `EnableIamSessionBasedIdentity` opt-in flag for each Partner AI App. For more information, see `EnableIamSessionBasedIdentity`.

  When the `EnableIamSessionBasedIdentity` opt-in flag is enabled, use the IAM role trust policy to make sure that the IAM session name is or contains the IAM username. This makes sure that users don't gain access by impersonating other users. The following trust policy verifies that the session name exactly matches the associated IAM user. Admins can use any principal tag for this purpose. It should be configured on the role that is launching Studio or the Partner AI App.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "RoleTrustPolicyRequireUsernameForSessionName",
            "Effect": "Allow",
            "Action": "sts:AssumeRole",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:root"
            },
            "Condition": {
                "StringEquals": {
                    "sts:RoleSessionName": "${aws:username}"
                }
            }
        }
    ]
}
```

Admins must also add the `sts:TagSession` trust policy to the role that is launching Studio or the Partner AI App. This makes sure that the identity can be propagated properly.

```
{
    "Effect": "Allow",
    "Principal": {
        "Service": "sagemaker.amazonaws.com"
    },
    "Action": [
                "sts:AssumeRole",
                "sts:TagSession"
            ]
}
```

After setting the credentials, admins can give their users access to Studio or the Partner AI App from the Amazon CLI using either the `CreatePresignedDomainUrl` or `CreatePartnerAppPresignedUrl` API calls, respectively.

Users can also then launch Studio from the SageMaker AI console, and launch Partner AI Apps from Studio.

`EnableIamSessionBasedIdentity`

`EnableIamSessionBasedIdentity` is an opt-in flag. When the `EnableIamSessionBasedIdentity` flag is set, SageMaker AI passes IAM session information as the Partner AI App user identity. For more information about Amazon STS sessions, see Use temporary credentials with Amazon resources.

Access control

To control access to Partner AI Apps, use an IAM policy attached to the user profile's execution role. To launch a Partner AI App directly from Studio or using the Amazon CLI, the user profile's execution role must have a policy that gives permissions for the `CreatePartnerAppPresignedUrl` API. Remove this permission from the user profile's execution role to make sure they can't launch Partner AI Apps.

Root admin users

The Comet and Fiddler Partner AI Apps require at least one root admin user. Root admin users have permissions to add both normal and admin users and manage resources. The usernames provided as root admin users must be consistent with the usernames from the identity source.

While root admin users are persisted in SageMaker AI, normal admin users are not and exist only within the Partner AI App until the Partner AI App is terminated.

Admins can update root admin users using the `UpdatePartnerApp` API call. When root admin users are updated, the updated list of root admin users is passed to the Partner AI App. The Partner AI App makes sure that all usernames in the list are granted root admin privileges. If a root admin user is removed from the list, the user still retains normal admin permissions until either:

- The user is removed from the application.
- Another admin user revokes admin permissions for the user.

> **Note**
>
> Fiddler doesn't support updating admin users. Only Comet supports updates to root admin users.

To delete a root admin user, you must first update the list of root admin users using the `UpdatePartnerApp` API. Then, remove or revoke the admin permissions through the Partner AI App's UI.

If you remove a root admin user from the Partner AI App's UI without updating the list of root admin users with the `UpdatePartnerApp` API, the change is temporary. When SageMaker AI sends the next Partner AI App update request, SageMaker AI sends the root admin list that still includes the user to the Partner AI App. This overrides the deletion completed from the Partner AI App UI.

Partner AI App provisioning

After admins have set up the required permissions, they can explore and provision Amazon SageMaker Partner AI Apps for users in the domain.

Admins can view all of the available Partner AI Apps, as well as the Partner AI Apps that they have provisioned from the Amazon SageMaker AI console. From the **Partner AI Apps** page, admins can view details about the pricing model for each Partner AI App and make them available to users. Admins can make them available by navigating to the Amazon Web Services Marketplace to subscribe to that Partner AI App.

Admins can provision new apps from the Partner AI Apps page. They can also view the Partner AI Apps that they have already provisioned from the **My Apps** tab.

> **Note**
>
> Applications that admins provision can be accessed by all users that admins give proper permissions to in an Amazon Web Services account. Partner AI Apps are not restricted to a specific domain or user.

Status

When admins view a Partner AI App that they have provisioned, they can also see the status of their application with one of the following values.

- **Deployed** – The application is ready for use. Admins can update the application configuration and delete the application.

- **Error** – There was an issue with the application deployment. Admins can troubleshoot and configure the application again to deploy it.
- **Not deployed** – The application has been subscribed to, but not deployed. Admins can configure the application to deploy it.

Options

When admins configure an application, they can decide the following options:

- **App name** – A unique name for the application.
- **App maintenance schedule** – Partner AI Apps undergo maintenance on a weekly basis. With this option, admins choose both the day of the week and the time that this maintenance happens.
- **STS identity propagation** – Use this option to pass the Amazon Security Token Service (Amazon STS) launcher IAM session name as the Partner AI App user identity. For more information, see Set up Partner AI Apps.
- **Admin management** – Some Partner AI Apps support adding up to five admins that have full rights to manage the Partner AI App functionality. This only applies to Comet and Fiddler. For more information, see Set up Partner AI Apps.
- **Execution role** – The role that the Partner AI App uses to access resources and perform actions. For more information, see Set up Partner AI Apps.
- **App version** – The version of the Partner AI App that admins want to use.
- **Tier selection** – The infrastructure deployment tier for the Partner AI App. The tier size impacts the speed and capabilities of the application. For more information, see Set up Partner AI Apps.
- **Lakera S3 bucket policy** – This is only required by the Lakera-guard app to access an Amazon S3 bucket.

Set up the Amazon SageMaker Partner AI Apps SDKs

The following topic outlines the process needed to install and use the application-specific SDKs with Amazon SageMaker Partner AI Apps. To install and use SDKs for applications, you must specify environment variables specific to Partner AI Apps, so the application's SDK can pick up environment variables and trigger authorization. The following sections give information about the steps needed to complete this for each of the supported application types.

Comet

Comet offers two products:

- Opik is an source LLM evaluation framework.
- Comet's ML platform can be used to track, compare, explain, and optimize models across the complete ML lifecycle.

Comet supports the use of two different SDKs based on the product that you are interacting with. Complete the following procedure to install and use the Comet or Opik SDKs. For more information about the Comet SDK, see Quickstart. For more information about the Opik SDK, see Open source LLM evaluation framework.

1. Launch the environment that you are using the Comet or Opik SDKs with Partner AI Apps in. For information about launching a JupyterLab application, see Create a space. For information about launching a Code Editor, based on Code-OSS, Visual Studio Code - Open Source application, see Launch a Code Editor application in Studio.
2. Launch a Jupyter notebook or Code Editor space.
3. From the development environment, install the compatible Comet, Opik, and SageMaker Python SDK versions. To be compatible:
   - The SageMaker Python SDK version must be at least `2.237.0`.
   - The Comet SDK version must be the latest version.
   - The Opik SDK version must match the version used by your Opik application. Verify the Opik version used in the Opik web application UI. The exception to this is that the Opik SDK version must be at least `1.2.0` when the Opik application version is `1.1.5`.

> **Note**
>
> SageMaker JupyterLab comes with SageMaker Python SDK installed. However, you may need to upgrade the SageMaker Python SDK if the version is lower than `2.237.0`.

```
%pip install sagemaker>=2.237.0 comet_ml

##or
```

```
%pip install sagemaker>=2.237.0 opik=<compatible-version>
```

4. Set the following environment variables for the application resource ARN. These environment variables are used to communicate with the Comet and Opik SDKs. To retrieve these values, navigate to the details page for the application in Amazon SageMaker Studio.

```
os.environ['AWS_PARTNER_APP_AUTH'] = 'true'
os.environ['AWS_PARTNER_APP_ARN'] = '<partner-app-ARN>'
```

5. For the Comet application, the SDK URL is automatically included as part of the API key set in the following step. You may instead set the `COMET_URL_OVERRIDE` environment variable to manually override the SDK URL.

```
os.environ['COMET_URL_OVERRIDE'] = '<comet-url>'
```

6. For the Opik application, the SDK URL is automatically included as part of the API key set in the following step. You may instead set the `OPIK_URL_OVERRIDE` environment variable to manually override the SDK URL. To get the Opik workspace name, see the Opik application and navigate to the user's workspace.

```
os.environ['OPIK_URL_OVERRIDE'] = '<opik-url>'
os.environ['OPIK_WORKSPACE'] = '<workspace-name>'
```

7. Set the environment variable that identifies the API key for Comet or Opik. This is used to verify the connection from SageMaker to the application when the Comet and Opik SDKs are used. This API key is application-specific and is not managed by SageMaker. To get this key, you must log into the application and retrieve the API key. The Opik API key is the same as the Comet API key.

```
os.environ['COMET_API_KEY'] = '<API-key>'
os.environ["OPIK_API_KEY"] = os.environ["COMET_API_KEY"]
```

Fiddler

Complete the following procedure to install and use the Fiddler Python Client. For information about the Fiddler Python Client, see About Client 3.x.

1. Launch the notebook environment that you are using the Fiddler Python Client with Partner AI Apps in. For information about launching a JupyterLab application, see Create a space. For information about launching a Code Editor, based on Code-OSS, Visual Studio Code - Open Source application, see Launch a Code Editor application in Studio.
2. Launch a Jupyter notebook or Code Editor space.
3. From the development environnment, install the Fiddler Python Client and SageMaker Python SDK versions. To be compatible:

   - The SageMaker Python SDK version must be at least `2.237.0`.
   - The Fiddler Python Client version must be compatible with the version of Fiddler used in the application. After verifying the Fiddler version from the UI, see the Fiddler Compatibility Matrix for the compatible Fiddler Python Client version.

   > **Note**
   >
   > SageMaker JupyterLab comes with SageMaker Python SDK installed. However, you may need to upgrade the SageMaker Python SDK if the version is lower than `2.237.0`.

   ```
   %pip install sagemaker>=2.237.0 fiddler-client=<compatible-version>
   ```

4. Set the following environment variables for the application resource ARN and the SDK URL. These environment variables are used to communicate with the Fiddler Python Client. To retrieve these values, navigate to the details page for the Fiddler application in Amazon SageMaker Studio.

   ```
   os.environ['AWS_PARTNER_APP_AUTH'] = 'true'
   os.environ['AWS_PARTNER_APP_ARN'] = '<partner-app-ARN>'
   os.environ['AWS_PARTNER_APP_URL'] = '<partner-app-URL>'
   ```

5. Set the environment variable that identifies the API key for the Fiddler application. This is used to verify the connection from SageMaker to the Fiddler application when the Fiddler Python Client is used. This API key is application-specific and is not managed by SageMaker. To get this key, you must log into the Fiddler application and retrieve the API key.

   ```
   os.environ['FIDDLER_KEY'] = '<API-key>'
   ```

Deepchecks

Complete the following procedure to install and use Deepchecks Python SDK.

1. Launch the notebook environment that you are using the Deepchecks Python SDK with Partner AI Apps in. For information about launching a JupyterLab application, see Create a space. For information about launching a Code Editor, based on Code-OSS, Visual Studio Code - Open Source application, see Launch a Code Editor application in Studio.
2. Launch a Jupyter notebook or Code Editor space.
3. From the development environment, install the compatible Deepchecks Python SDK and SageMaker Python SDK versions. Partner AI Apps is running version `0.21.15` of Deepchecks. To be compatible:

   - The SageMaker Python SDK version must be at least `2.237.0`.
   - The Deepchecks Python SDK must use the minor version `0.21`.

   > **Note**
   >
   > SageMaker JupyterLab comes with SageMaker Python SDK installed. However, you may need to upgrade the SageMaker Python SDK if the version is lower than `2.237.0`.

   ```
   %pip install sagemaker>=2.237.0 deepchecks-llm-client>=0.21,<0.22
   ```

4. Set the following environment variables for the application resource ARN and the SDK URL. These environment variables are used to communicate with the Deepchecks Python SDK. To retrieve these values, navigate to the details page for the application in Amazon SageMaker Studio.

   ```
   os.environ['AWS_PARTNER_APP_AUTH'] = 'true'
   os.environ['AWS_PARTNER_APP_ARN'] = '<partner-app-ARN>'
   os.environ['AWS_PARTNER_APP_URL'] = '<partner-app-URL>'
   ```

5. Set the environment variable that identifies the API key for the Deepchecks application. This is used to verify the connection from SageMaker to the Deepchecks application when the Deepchecks Python SDK is used. This API key is application-specific and is not managed by SageMaker. To get this key, see Setup: Python SDK Installation & API Key Retrieval.

```
os.environ['DEEPCHECKS_API_KEY'] = '<API-key>'
```

Lakera

Lakera does not offer an SDK. Instead, you can interact with the Lakera Guard API through HTTP requests to the available endpoints in any programming language. For more information, see Lakera Guard API.

To use the SageMaker Python SDK with Lakera, complete the following steps:

1. Launch the environment that you are using Partner AI Apps in. For information about launching a JupyterLab application, see Create a space. For information about launching a Code Editor, based on Code-OSS, Visual Studio Code - Open Source application, see Launch a Code Editor application in Studio.
2. Launch a Jupyter notebook or Code Editor space.
3. From the development environment, install the compatible SageMaker Python SDK version. The SageMaker Python SDK version must be at least `2.237.0`

   > **Note**
   >
   > SageMaker JupyterLab comes with SageMaker Python SDK installed. However, you may need to upgrade the SageMaker Python SDK if the version is lower than `2.237.0`.

   ```
   %pip install sagemaker>=2.237.0
   ```

4. Set the following environment variables for the application resource ARN and the SDK URL. To retrieve these values, navigate to the details page for the application in Amazon SageMaker Studio.

   ```
   os.environ['AWS_PARTNER_APP_ARN'] = '<partner-app-ARN>'
   os.environ['AWS_PARTNER_APP_URL'] = '<partner-app-URL>'
   ```

Partner AI Apps in Studio

After the admin has added the required permissions and authorized users, users can view the Amazon SageMaker Partner AI App in Amazon SageMaker Studio. From Studio, users can launch apps that have been approved for use by their administrator.

Browsing and selecting

To browse the available Partner AI Apps, users must navigate to Studio. For information about launching Studio, see Launch Amazon SageMaker Studio.

After users have launched Studio, they can view all of the available Partner AI Apps by selecting the **Partner AI Apps** section in the left navigation. The **Partner AI Apps** page lists all of the Partner AI Apps, and gives information about whether the Partner AI Apps have been deployed by the admin. If the desired Partner AI Apps haven't been deployed, users can reach out to the admin to request that they deploy the Partner AI Apps for use in the SageMaker AI domain.

If the application has been deployed, users can open the Partner AI App UI to start using it or view details of the Partner AI App.

When users view the details of the application, they see the value of the following.

- ARN – This is the resource ARN of the Partner AI App.
- SDK URL – This is the URL of the Partner AI App that the Partner AI App SDK uses to support app-specific tasks such as logging model experiment tracking data from a JupyterLab notebook in Studio.

Users can use these values to write code that uses the Partner AI App SDK for app-specific tasks.

Each Partner AI App's details page includes a sample notebook. To get started, users can launch the sample notebook in a JupyterLab space in the Studio environment.

Use Amazon KMS Permissions for Amazon SageMaker Partner AI Apps

You can protect your data at rest using encryption for Amazon SageMaker Partner AI Apps. By default, it uses server-side encryption with a SageMaker owned key. SageMaker also supports an option for server-side encryption with a customer managed KMS key.

Server-side encryption with SageMaker managed keys (Default)

Partner AI Apps encrypt all your data at rest using an Amazon managed key by default.

Server-side encryption with customer managed KMS keys (Optional)

Partner AI Apps support the use of a symmetric customer managed key that you create, own, and manage to replace the existing Amazon owned encryption. Because you have full control of this layer of encryption, you can perform such tasks as:

- Establishing and maintaining key policies
- Establishing and maintaining IAM policies and grants
- Enabling and disabling key policies
- Rotating key cryptographic material
- Adding tags
- Creating key aliases
- Scheduling keys for deletion

For more information, see Customer managed keys in the *Amazon Key Management Service Developer Guide*.

How Partner AI Apps use grants in Amazon KMS

Partner AI Apps require a grant to use your customer managed key. When you create an application encrypted with a customer managed key, Partner AI Apps creates a grant on your behalf by sending a CreateGrant request to Amazon KMS. Grants in Amazon KMS are used to give Partner AI Apps access to a KMS key in a customer account.

You can revoke access to the grant, or remove the service's access to the customer managed key at any time. If you do, Partner AI App won't be able to access any of the data encrypted by the customer managed key, which affects operations that are dependent on that data. The application will not operate properly and will become irrecoverable.

Create a customer managed key

You can create a symmetric customer managed key by using the Amazon Web Services Management Console or the Amazon KMS APIs.

To create a symmetric customer managed key

Follow the steps for Creating symmetric encryption KMS keys in the *Amazon Key Management Service Developer Guide*.

Key policy

Key policies control access to your customer managed key. Every customer managed key must have exactly one key policy, which contains statements that determine who can use the key and how they can use it. When you create your customer managed key, you can specify a key policy. For more information, see Determining access to Amazon KMS keys in the *Amazon Key Management Service Developer Guide*.

To use your customer managed key with your Partner AI App resources, the following API operations must be permitted in the key policy. The principal for these operations depends on whether the role is used to create or use the application.

- Creating the application:
  - `kms:CreateGrant`
  - `kms:DescribeKey`
- Using the application:
  - `kms:Decrypt`
  - `kms:GenerateDataKey`

The following are policy statement examples you can add for Partner AI Apps based on whether the persona is an administrator or user. For more information about specifying permissions in a policy, see Amazon KMS permissions in the *Amazon Key Management Service Developer Guide*. For more information about troubleshooting, see Troubleshooting key access in the *Amazon Key Management Service Developer Guide*.

Administrator

The following policy statement is used for the administrator who is creating Partner AI Apps.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "example-key-policy",
    "Statement": [
        {
            "Sid": "Allow use of the key",
            "Effect": "Allow",
```

```
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:role/<admin-role>"
            },
            "Action": [
                "kms:CreateGrant",
                "kms:DescribeKey"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": "sagemaker.us-east-1.amazonaws.com"
                }
            }
        }
    ]
}
```

User

The following policy statement is for the user of the Partner AI Apps.

JSON

```
{
  "Version":"2012-10-17",
  "Id":"example-key-policy",
  "Statement":[
    {
      "Effect":"Allow",
      "Principal":{
        "AWS":"arn:aws-cn:iam::111122223333:role/user-role"
      },
      "Action":[
        "kms:Decrypt",
        "kms:GenerateDataKey"
      ],
      "Resource":"*",
      "Condition":{
        "StringEquals":{
          "kms:ViaService":"sagemaker.us-east-1.amazonaws.com"
        }
      }
```

```
    }
  ]
}
```

Setting up cross-account sharing for Amazon SageMaker AI partner AI apps

Amazon SageMaker AI integrates with Amazon Resource Access Manager (Amazon RAM) to enable resource sharing. Amazon RAM is a service that enables you to share some Amazon SageMaker AI resources with other Amazon Web Services accounts or through Amazon Organizations. With Amazon RAM, you share resources that you own by creating a *resource share*. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be specific Amazon Web Services accounts inside or outside of its organization in Amazon Organizations.

For more information about Amazon RAM, see the *Amazon RAM User Guide*.

This topic explains how to share resources that you own, and how to use resources that are shared with you.

Contents

- Prerequisites for sharing an Amazon SageMaker Partner AI App
- Sharing an Amazon SageMaker Partner AI App
- Accepting resource share invitations
- Identifying a shared Amazon SageMaker Partner AI App
- Responsibilities and permissions for shared Amazon SageMaker Partner AI Apps

Prerequisites for sharing an Amazon SageMaker Partner AI App

- To share an Amazon SageMaker Partner AI App, you must own it in your Amazon Web Services account. This means that the resource must be allocated or provisioned in your account. You cannot share an Amazon SageMaker Partner AI App that has been shared with you.
- To share an Amazon SageMaker Partner AI App with your organization or an organizational unit in Amazon Organizations, you must enable sharing with Amazon Organizations. For more information, see Enable Sharing with Amazon Organizations in the *Amazon RAM User Guide*.

Sharing an Amazon SageMaker Partner AI App

To share an Amazon SageMaker Partner AI App, you must add it to a resource share. A resource share is an Amazon RAM resource that lets you share your resources across Amazon Web Services accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. When you share an Amazon SageMaker Partner AI App using the Amazon SageMaker AI console, you add it to an existing resource share. To add the Amazon SageMaker Partner AI App to a new resource share, you must first create the resource share by using the Amazon RAM console.

You can share an Amazon SageMaker Partner AI App that you own using the Amazon SageMaker AI console, Amazon RAM console, or the Amazon CLI.

To share an Amazon SageMaker Partner AI App that you own using the Amazon SageMaker AI console

1. Sign in to the Amazon Web Services Management Console and open the Amazon RAM console at https://console.amazonaws.cn/ram/home.
2. In the main pane, choose **Create a resource share**.
3. Enter a name for the resource share that you want to create.
4. In the **Resources** section, for **Resource type** select **SageMaker AI Partner Apps**. The partner apps that you can share appear in the table.
5. Select the partner apps that you want to share.
6. Optionally specify tags, and then choose **Next**.
7. Specify the Amazon Web Services accounts with which you want to share your partner apps.
8. Review your resource share configuration and choose **Create resource share**. It might take the service a few minutes to finish creating the resource share.

To share an Amazon SageMaker Partner AI App that you own using the Amazon RAM console

See Creating a Resource Share in the *Amazon RAM User Guide*.

To share an Amazon SageMaker Partner AI App that you own using the Amazon CLI

Use the create-resource-share command.

Accepting resource share invitations

When a resource owner sets up a resource share, each consumer Amazon Web Services account receives an invitation to join the resource share. The consumer Amazon Web Services accounts must accept the invitation to gain access to any shared resources.

For more information on accepting a resource share invitation through Amazon RAM, see Using shared Amazon resources in the *Amazon Resource Access Manager User Guide*.

Identifying a shared Amazon SageMaker Partner AI App

Owners and consumers can identify shared Amazon SageMaker Partner AI Apps using the Amazon SageMaker AI console and Amazon CLI.

To identify a shared Amazon SageMaker Partner AI App by using the Amazon SageMaker AI console

See the section called “Partner AI Apps in Studio”.

To identify a shared Amazon SageMaker Partner AI App by using the Amazon CLI

Use the list-partner-apps command. The command returns the Amazon SageMaker Partner AI Apps that you own and Amazon SageMaker Partner AI Apps that are shared with you. `OwnerId` shows the Amazon Web Services account ID of the Amazon SageMaker Partner AI App owner.

Responsibilities and permissions for shared Amazon SageMaker Partner AI Apps

The account with which an Amazon SageMaker Partner AI App is shared needs to have the following Amazon Identity and Access Management policy.

JSON

```
{
  "Version":"2012-10-17",
  "Statement" : [
    {
      "Sid" : "AmazonSageMakerPartnerListAppsPermission",
      "Effect" : "Allow",
      "Action" : "sagemaker:ListPartnerApps",
      "Resource" : "*"
    },
```

```
    {
      "Sid" : "AmazonSageMakerPartnerAppsPermission",
      "Effect" : "Allow",
      "Action" : [
        "sagemaker:CreatePartnerAppPresignedUrl",
        "sagemaker:DescribePartnerApp",
        "sagemaker:CallPartnerAppApi"
      ],
      "Condition" : {
        "StringEquals" : {
          "aws:ResourceAccount" : [
                        "App-owner Amazon Web Services account-1", "App-owner
 Amazon Web Services account-2"]
        }
      },
      "Resource" : "arn:aws-cn:sagemaker:*:*:partner-app/*"
    }
  ]
}
```

Data labeling with a human-in-the-loop

These features are not available in the China Regions.

To train a machine learning model, you need a large, high-quality, labeled dataset. You can label your data using Amazon SageMaker Ground Truth. Choose from one of the Ground Truth built-in task types or create your own custom labeling workflow. To improve the accuracy of your data labels and reduce the total cost of labeling your data, use Ground Truth enhanced data labeling features like automated data labeling and annotation consolidation.

Topics

Training data labeling using humans with Amazon SageMaker Ground Truth

This feature is not available in the China Regions.

Note

Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

To train a machine learning model, you need a large, high-quality, labeled dataset. Ground Truth helps you build high-quality training datasets for your machine learning models. With Ground Truth, you can use workers from a vendor company that you choose or from an internal, private

workforce along with machine learning to enable you to create a labeled dataset. You can use the labeled dataset output from Ground Truth to train your own models. You can also use the output as a training dataset for an Amazon SageMaker AI model.

Depending on your ML application, you can choose from one of the Ground Truth built-in task types to have workers generate specific types of labels for your data. You can also build a custom labeling workflow to provide your own UI and tools to workers labeling your data. To learn more about the Ground Truth built in task types, see Built-in Task Types. To learn how to create a custom labeling workflow, see Custom labeling workflows.

In order to automate labeling your training dataset, you can optionally use *automated data labeling*, a Ground Truth process that uses machine learning to decide which data needs to be labeled by humans. Automated data labeling may reduce the labeling time and manual effort required. For more information, see Automate data labeling. To create a custom labeling workflow, see Custom labeling workflows.

Use either pre-built or custom tools to assign the labeling tasks for your training dataset. A *labeling UI template* is a webpage that Ground Truth uses to present tasks and instructions to your workers. The SageMaker AI console provides built-in templates for labeling data. You can use these templates to get started , or you can build your own tasks and instructions by using our HTML 2.0 components. For more information, see Custom labeling workflows.

Use the workforce of your choice to label your dataset. You can choose your workforce from:

- A private workforce that you create from your employees or contractors for handling data within your organization.
- A vendor company that you can find in the Amazon Web Services Marketplace that specializes in data labeling services.

For more information, see Workforces.

You store your datasets in Amazon S3 buckets. The buckets contain three things: The data to be labeled, an input manifest file that Ground Truth uses to read the data files, and an output manifest file. The output file contains the results of the labeling job. For more information, see Use input and output data.

Events from your labeling jobs appear in Amazon CloudWatch under the `/aws/sagemaker/LabelingJobs` group. CloudWatch uses the labeling job name as the name for the log stream.

Are You a First-time User of Ground Truth?

If you are a first-time user of Ground Truth, we recommend that you do the following:

1. **Read Getting started: Create a bounding box labeling job with Ground Truth**—This section walks you through setting up your first Ground Truth labeling job.
2. **Explore other topics**—Depending on your needs, do the following:
   - **Explore built-in task types**— Use built-in task types to streamline the process of creating a labeling job. See Built-in Task Types to learn more about Ground Truth built-in task types.
   - **Manage your labeling workforce**—Create new work teams and manage your existing workforce. For more information, see Workforces.
   - **Learn about streaming labeling jobs**— Create a streaming labeling job and send new dataset objects to workers in real time using a perpetually running labeling job. Workers continuously receive new data objects to label as long as the labeling job is active and new objects are being sent to it. To learn more, see Ground Truth streaming labeling jobs.
3. **To learn more about available operations to automate Ground Truth operations, see the SageMaker AI service API reference.**

Getting started: Create a bounding box labeling job with Ground Truth

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

To get started using Amazon SageMaker Ground Truth, follow the instructions in the following sections. The sections here explain how to use the console to create a bounding box labeling job, assign a private workforce, and send the labeling job to your workforce. You can also learn how to monitor the progress of a labeling job.

This video shows you how to setup and use Amazon SageMaker Ground Truth. (Length: 9:37)

If you want to create a custom labeling workflow, see Custom labeling workflows for instructions.

Before you create a labeling job, you must upload your dataset to an Amazon S3 bucket. For more information, see Use input and output data.

Topics

- Before You Begin
- Create a Labeling Job
- Select Workers
- Configure the Bounding Box Tool
- Monitoring Your Labeling Job

Before You Begin

Before you begin using the SageMaker AI console to create a labeling job, you must set up the dataset for use. Do this:

1. Save two images at publicly available HTTP URLs. The images are used when creating instructions for completing a labeling task. The images should have an aspect ratio of around 2:1. For this exercise, the content of the images is not important.
2. Create an Amazon S3 bucket to hold the input and output files. The bucket must be in the same Region where you are running Ground Truth. Make a note of the bucket name because you use it during step 2.

   Ground Truth requires all S3 buckets that contain labeling job input image data have a CORS policy attached. To learn more about this change, see CORS Requirement for Input Image Data.
3. You can create an IAM role or let SageMaker AI create a role with the AmazonSageMakerFullAccess IAM policy. Refer to Creating IAM roles and assign the following permissions policy to the user that is creating the labeling job:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "sagemakergroundtruth",
            "Effect": "Allow",
```

```
            "Action": [
                "cognito-idp:CreateGroup",
                "cognito-idp:CreateUserPool",
                "cognito-idp:CreateUserPoolDomain",
                "cognito-idp:AdminCreateUser",
                "cognito-idp:CreateUserPoolClient",
                "cognito-idp:AdminAddUserToGroup",
                "cognito-idp:DescribeUserPoolClient",
                "cognito-idp:DescribeUserPool",
                "cognito-idp:UpdateUserPool"
            ],
            "Resource": "*"
        }
    ]
}
```

Create a Labeling Job

In this step you use the console to create a labeling job. You tell Amazon SageMaker Ground Truth the Amazon S3 bucket where the manifest file is stored and configure the parameters for the job. For more information about storing data in an Amazon S3 bucket, see Use input and output data.

To create a labeling job

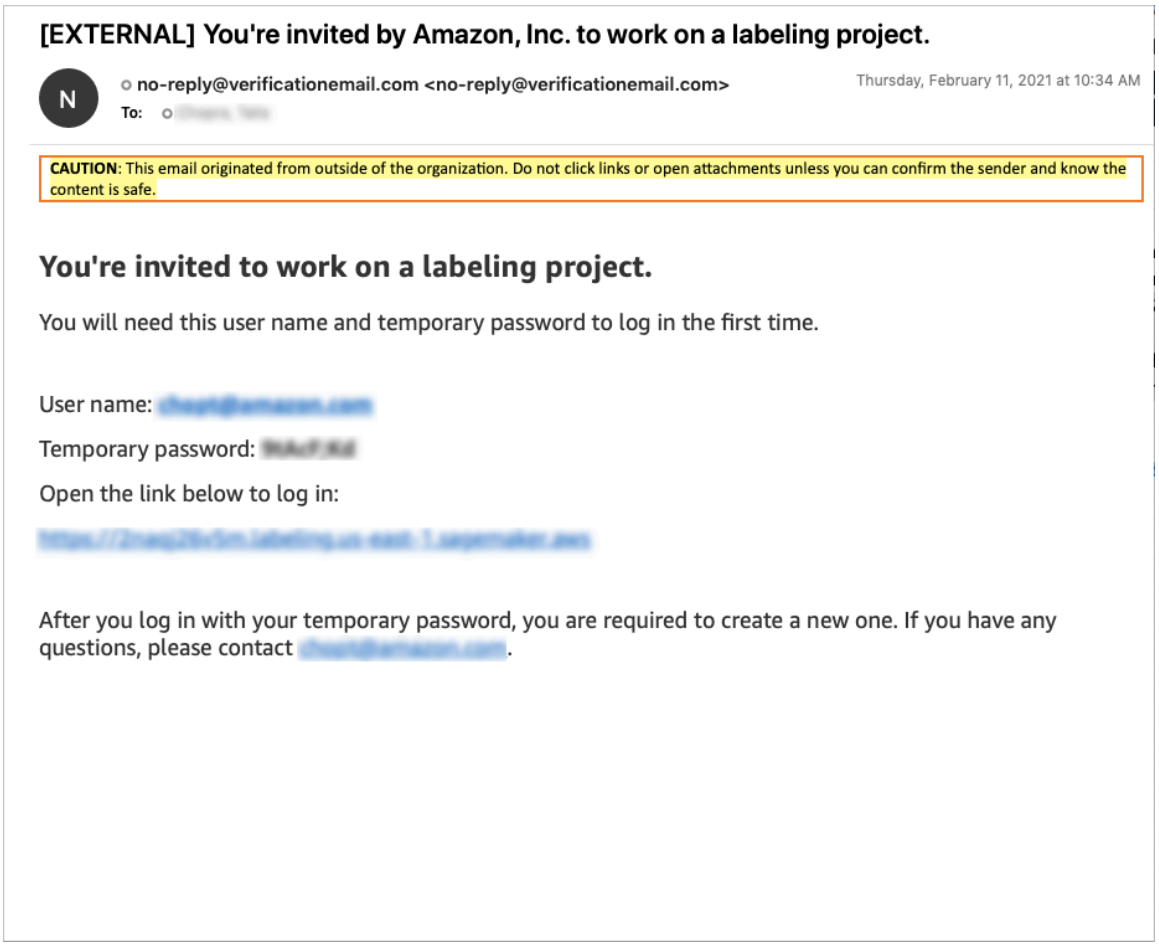
1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. From the left navigation, choose **Labeling jobs**.
3. Choose **Create labeling job** to start the job creation process.
4. In the **Job overview** section, provide the following information:

   - **Job name** – Give the labeling job a name that describes the job. This name is shown in your job list. The name must be unique in your account in an Amazon Region.
   - **Label attribute name** – Leave this unchecked as the default value is the best option for this introductory job.
   - **Input data setup** – Select **Automated data setup**. This option allows you to automatically connect to your input data in S3.
   - **S3 location for input datasets** – Enter the S3 location where you added the images in step 1.
   - **S3 location for output datasets** – The location where your output data is written in S3.

- **Data type** – Use the drop down menu to select **Image**. Ground Truth will use all images found in the S3 location for input datasets as input for your labeling job.
- **IAM role** – Create or choose an IAM role with the AmazonSageMakerFullAccess IAM policy attached.

5. In the **Task type** section, for the **Task category** field, choose **Image**.
6. In the **Task selection** choose **Bounding box**.
7. Choose **Next** to move on to configuring your labeling job.

Select Workers



In this step you choose a workforce for labeling your dataset. It is recommended that you create a private workforce to test Amazon SageMaker Ground Truth. Use email addresses to invite the members of your workforce. If you create a private workforce in this step you won't be able to import your Amazon Cognito user pool later. If you want to create a private workforce using an Amazon Cognito user pool, see Manage a Private Workforce (Amazon Cognito).

> **Tip**
>
> If a private workforce doesn't meet your needs, you can also use a vendor-managed workforce. For more information about workforce options for Ground Truth, see Workforces.

To create a private workforce:

1. In the **Workers** section, choose **Private**.
2. If this is your first time using a private workforce, in the **Email addresses** field, enter up to 100 email addresses. The addresses must be separated by a comma. You should include your own email address so that you are part of the workforce and can see data object labeling tasks.
3. In the **Organization name** field, enter the name of your organization. This information is used to customize the email sent to invite a person to your private workforce. You can change the organization name after the user pool is created through the console.
4. In the **Contact email** field enter an email address that members of the workforce use to report problems with the task.

If you add yourself to the private workforce, you will receive an email that looks similar to the following. **Amazon, Inc.** is replaced by the organization you enter in step 3 of the preceding procedure. Select the link in the email to log in using the temporary password provided. If prompted, change your password. When you successfully log in, you see the worker portal where your labeling tasks appear.

[EXTERNAL] You're invited by Amazon, Inc. to work on a labeling project.

Thursday, February 11, 2021 at 10:34 AM

To:

CAUTION: This email originated from outside of the organization. Do not click links or open attachments unless you can confirm the sender and know the content is safe.

You're invited to work on a labeling project.

You will need this user name and temporary password to log in the first time.

User name:

Temporary password:

Open the link below to log in:

After you log in with your temporary password, you are required to create a new one. If you have any questions, please contact .

> **Tip**
>
> You can find the link to your private workforce's worker portal in the **Labeling workforces** section of the Ground Truth area of the SageMaker AI console. To see the link, select the **Private** tab. The link is under the **Labeling portal sign-in URL** header in **Private workforce summary**.

Configure the Bounding Box Tool

Finally you configure the bounding box tool to give instructions to your workers. You can configure a task title that describes the task and provides high-level instructions for the workers. You can provide both quick instructions and full instructions. Quick instructions are displayed next to the image to be labeled. Full instructions contain detailed instructions for completing the task. In this example, you only provide quick instructions. You can see an example of full instructions by choosing **Full instructions** at the bottom of the section.

To configure the bounding box tool

1. In the **Task description** field type in brief instructions for the task. For example:

   ```
   Draw a box around any objects in the image.
   ```

   Replace *objects* with the name of an object that appears in your images.
2. In the **Labels** field, type a category name for the objects that the worker should draw a bounding box around. For example, if you are asking the worker to draw boxes around football players, you could use "Football Player" in this field.
3. The **Short instructions** section enables you to create instructions that are displayed on the page with the image that your workers are labeling. We suggest that you include an example of a correctly drawn bounding box and an example of an incorrectly drawn box. To create your own instructions, use these steps:

   a. Select the text between **GOOD EXAMPLE** and the image placeholder. Replace it with the following text:

      ```
      Draw the box around the object with a small border.
      ```

   b. Select the first image placeholder and delete it.

   c. Choose the image button and then enter the HTTPS URL of one of the images that you created in step 1. It is also possible to embed images directly in the short instructions section, however this section has a quota of 100 kilobytes (including text). If your images and text exceed 100 kilobytes, you receive an error.

   d. Select the text between **BAD EXAMPLE** and the image placeholder. Replace it with the following text:

      ```
      Don't make the bounding box too large or cut into the object.
      ```

   e. Select the second image placeholder and delete it.

   f. Choose the image button and then enter the HTTPS URL of the other image that you created in step 1.

4. Select **Preview** to preview the worker UI. The preview opens in a new tab, and so if your browser blocks pop ups you may need to manually enable the tab to open. When you add one or more annotations to the preview and then select **Submit** you can see a preview of the output data your annotation would created.
5. After you have configured and verified your instructions, select **Create** to create the labeling job.

If you used a private workforce, you can navigate to the worker portal that you logged into in Select Workers of this tutorial to see your labeling tasks. The tasks may take a few minutes to appear.

Now that you've created a labeling job, you can monitor it, or stop it.

Monitoring Your Labeling Job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

After you create your labeling job, you see a list of all the jobs that you have created. You can use this list to monitor that status of your labeling jobs. The list has the following fields:

- **Name** – The name that you assigned the job when you created it.
- **Status** – The completion status of the job. The status can be one of Complete, Failed, In progress, or Stopped.
- **Labeled objects/total** – Shows the total number of objects in the labeling job and how many of them have been labeled.
- **Creation time** – The date and time that you created the job.

You can also clone, chain, or stop a job. Select a job and then select one of the following from the **Actions** menu:

- **Clone** – Creates a new labeling job with the configuration copied from the selected job. You can clone a job when you want to change to the job and run it again. For example, you can clone a job that was sent to a private workforce so that you can send it to a vendor workforce instead. Or you can clone a job to rerun it against a new dataset stored in the same location as the original job.
- **Chain** – Creates a new labeling job that can build upon the data and models (if any) of a stopped, failed, or completed job. For more information about the use cases and how to use it, see Chaining labeling jobs.
- **Stop** – Stops a running job. You cannot restart a stopped job. You can clone a job to start over or chain the job to continue from where it left off. Labels for any already labeled objects are written to the output file location. For more information, see Labeling job output data.

Label Images

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use Ground Truth to label images. Select one of the following built in task types to learn more about that task type. Each page includes instructions to help you create a labeling job using that task type.

> **Tip**
>
> To learn more about supported file types and input data quotas, see Input data.

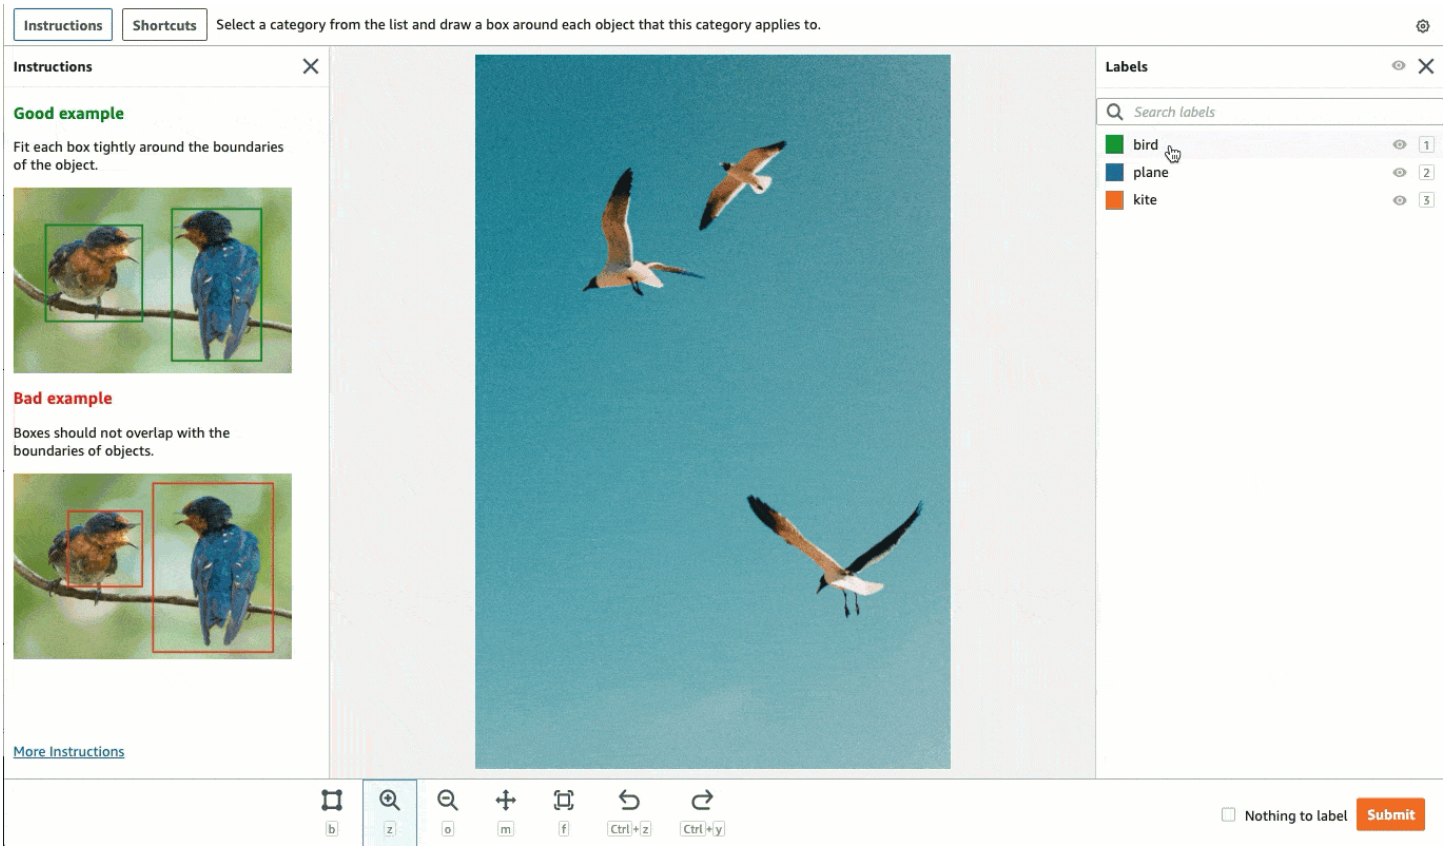
Topics

- Classify image objects using a bounding box
- Identify image contents using semantic segmentation
- Create an image classification job (Single Label)
- Create an image classification job (Multi-label)

- Image Label Verification

Classify image objects using a bounding box

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.



The images used to train a machine learning model often contain more than one object. To classify and localize one or more objects within images, use the Amazon SageMaker Ground Truth bounding box labeling job task type. In this context, localization means the pixel-location of the bounding box. You create a bounding box labeling job using the Ground Truth section of the Amazon SageMaker AI console or the `CreateLabelingJob` operation.

> **Important**
>
> For this task type, if you create your own manifest file, use `"source-ref"` to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input data.

Creating a Bounding Box Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) to learn how to create a bounding box labeling job in the SageMaker AI console. In Step 10, choose **Image** from the **Task category** drop down menu, and choose **Bounding box** as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and up to 50 labels that workers can choose from.

Create a Bounding Box Labeling Job (API)

To create a bounding box labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-BoundingBox`. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn .
- Annotation-consolidation Lambda functions for this task type end with `ACS-BoundingBox`. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```
response = client.create_labeling_job(
    LabelingJobName='example-bounding-box-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-
BoundingBox',
        'TaskKeywords': [
            'Bounding Box',
        ],
        'TaskTitle': 'Bounding Box task',
        'TaskDescription': 'Draw bounding boxes around objects in an image',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
```

```
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-
east-1:432418664414:function:ACS-BoundingBox'
          }
        },
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Provide a Template for Bounding Box Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and `header`. Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

Bounding Box Output Data

Once you have created a bounding box labeling job, your output data will be located in the Amazon S3 bucket specified in the `S3OutputPath` parameter when using the API or in the **Output dataset location** field of the **Job overview** section of the console.

For example, the output manifest file of a successfully completed single-class bounding box task will contain the following:

```
[
  {
    "boundingBox": {
      "boundingBoxes": [
        {
          "height": 2832,
          "label": "bird",
          "left": 681,
          "top": 599,
          "width": 1364
        }
      ],
      "inputImageProperties": {
        "height": 3726,
        "width": 2662
```

```
      }
    }
  }
]
```

The `boundingBoxes` parameter identifies the location of the bounding box drawn around an object identified as a "bird" relative to the top-left corner of the image which is taken to be the (0,0) pixel-coordinate. In the previous example, **`left`** and **`top`** identify the location of the pixel in the top-left corner of the bounding box relative to the top-left corner of the image. The dimensions of the bounding box are identified with **`height`** and **`width`**. The `inputImageProperties` parameter gives the pixel-dimensions of the original input image.

When you use the bounding box task type, you can create single- and multi-class bounding box labeling jobs. The output manifest file of a successfully completed multi-class bounding box will contain the following:

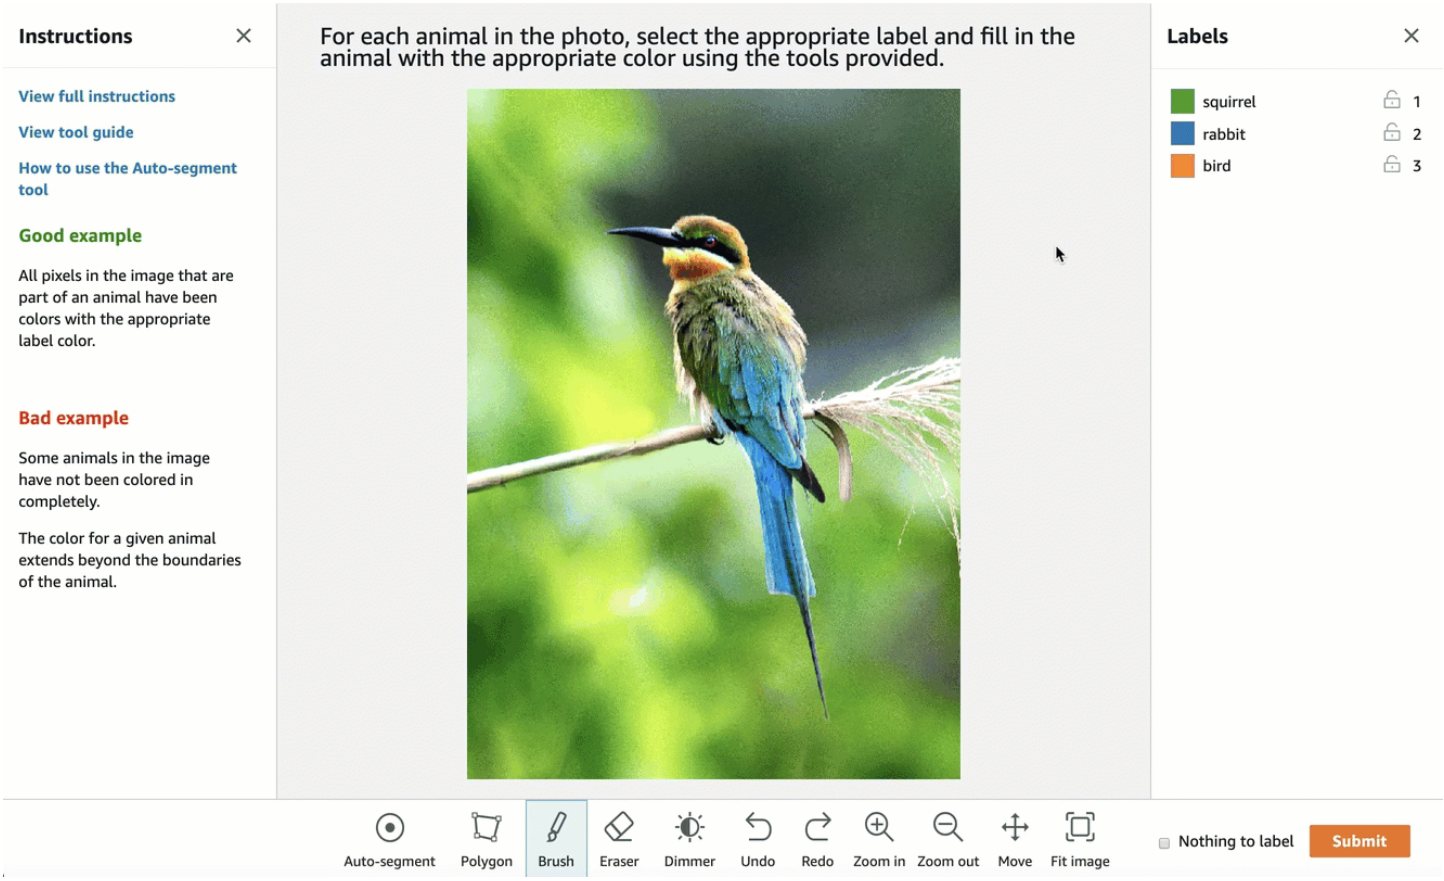
```
[
  {
    "boundingBox": {
      "boundingBoxes": [
        {
          "height": 938,
          "label": "squirrel",
          "left": 316,
          "top": 218,
          "width": 785
        },
        {
          "height": 825,
          "label": "rabbit",
          "left": 1930,
          "top": 2265,
          "width": 540
        },
        {
          "height": 1174,
          "label": "bird",
          "left": 748,
          "top": 2113,
          "width": 927
        },
        {
```

```
          "height": 893,
          "label": "bird",
          "left": 1333,
          "top": 847,
          "width": 736
        }
      ],
      "inputImageProperties": {
        "height": 3726,
        "width": 2662
      }
    }
  }
]
```

To learn more about the output manifest file that results from a bounding box labeling job, see Bounding box job output.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Labeling job output data.

Identify image contents using semantic segmentation



To identify the contents of an image at the pixel level, use an Amazon SageMaker Ground Truth semantic segmentation labeling task. When assigned a semantic segmentation labeling job, workers classify pixels in the image into a set of predefined labels or classes. Ground Truth supports single and multi-class semantic segmentation labeling jobs. You create a semantic segmentation labeling job using the Ground Truth section of the Amazon SageMaker AI console or the `CreateLabelingJob` operation.

> **Important**
>
> For this task type, if you create your own manifest file, use `"source-ref"` to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input data.

Creating a Semantic Segmentation Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) to learn how to create a semantic segmentation labeling job in the SageMaker AI console. In Step 10, choose **Image** from the **Task category** drop down menu, and choose **Semantic segmentation** as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.

Create a Semantic Segmentation Labeling Job (API)

To create a semantic segmentation labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-SemanticSegmentation`. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn .
- Annotation-consolidation Lambda functions for this task type end with `ACS-SemanticSegmentation`. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```
response = client.create_labeling_job(
    LabelingJobName='example-semantic-segmentation-labeling-job,
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
```

```
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-
SemanticSegmentation,
        'TaskKeywords': [
            'Semantic Segmentation',
        ],
        'TaskTitle': 'Semantic segmentation task',
        'TaskDescription': 'For each category provided, segment out each relevant
 object using the color associated with that category',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-
east-1:432418664414:function:ACS-SemanticSegmentation'
        },
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Provide a Template for Semantic Segmentation Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and `header`.

Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

Semantic Segmentation Output Data

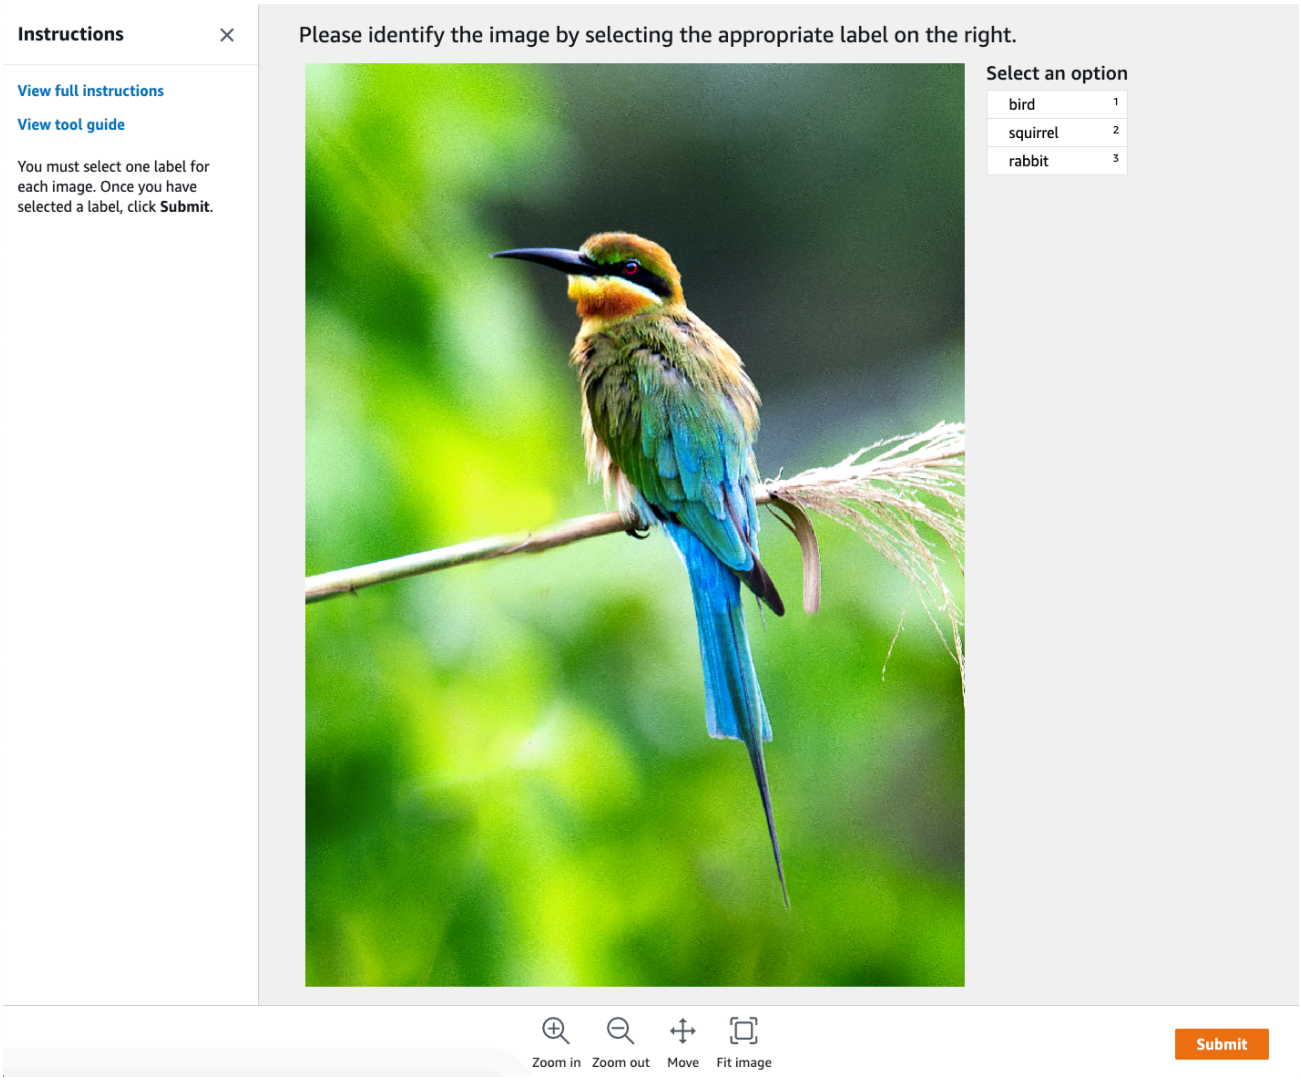
Once you have created a semantic segmentation labeling job, your output data will be located in the Amazon S3 bucket specified in the `S3OutputPath` parameter when using the API or in the **Output dataset location** field of the **Job overview** section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Labeling job output data.

To see an example of an output manifest file for a semantic segmentation labeling job, see 3D point cloud semantic segmentation output.

Create an image classification job (Single Label)

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.



Use an Amazon SageMaker Ground Truth image classification labeling task when you need workers to classify images using predefined labels that you specify. Workers are shown images and are asked to choose one label for each image. You can create an image classification labeling job using the Ground Truth section of the Amazon SageMaker AI console or the `CreateLabelingJob` operation.

> **Important**
>
> For this task type, if you create your own manifest file, use `"source-ref"` to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input data.

Create an Image Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) to learn how to create a image classification labeling job in the SageMaker AI console. In Step 10, choose **Image** from the **Task category** drop down menu, and choose **Image Classification (Single Label)** as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.

Create an Image Classification Labeling Job (API)

To create an image classification labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-ImageMultiClass`. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn .

- Annotation-consolidation Lambda functions for this task type end with `ACS-ImageMultiClass`. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```
response = client.create_labeling_job(
    LabelingJobName='example-image-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-
ImageMultiClass,
        'TaskKeywords': [
            Image classification',
```

```
        ],
        'TaskTitle': 'Image classification task',
        'TaskDescription': 'Carefully inspect the image and classify it by selecting
 one label from the categories provided.',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-
east-1:432418664414:function:ACS-ImageMultiClass'
        },
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Provide a Template for Image Classification Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and `header`.

Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

Image Classification Output Data

Once you have created an image classification labeling job, your output data will be located in the Amazon S3 bucket specified in the `S3OutputPath` parameter when using the API or in the **Output dataset location** field of the **Job overview** section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Labeling job output data.

To see an example of an output manifest file from an image classification labeling job, see Classification job output.

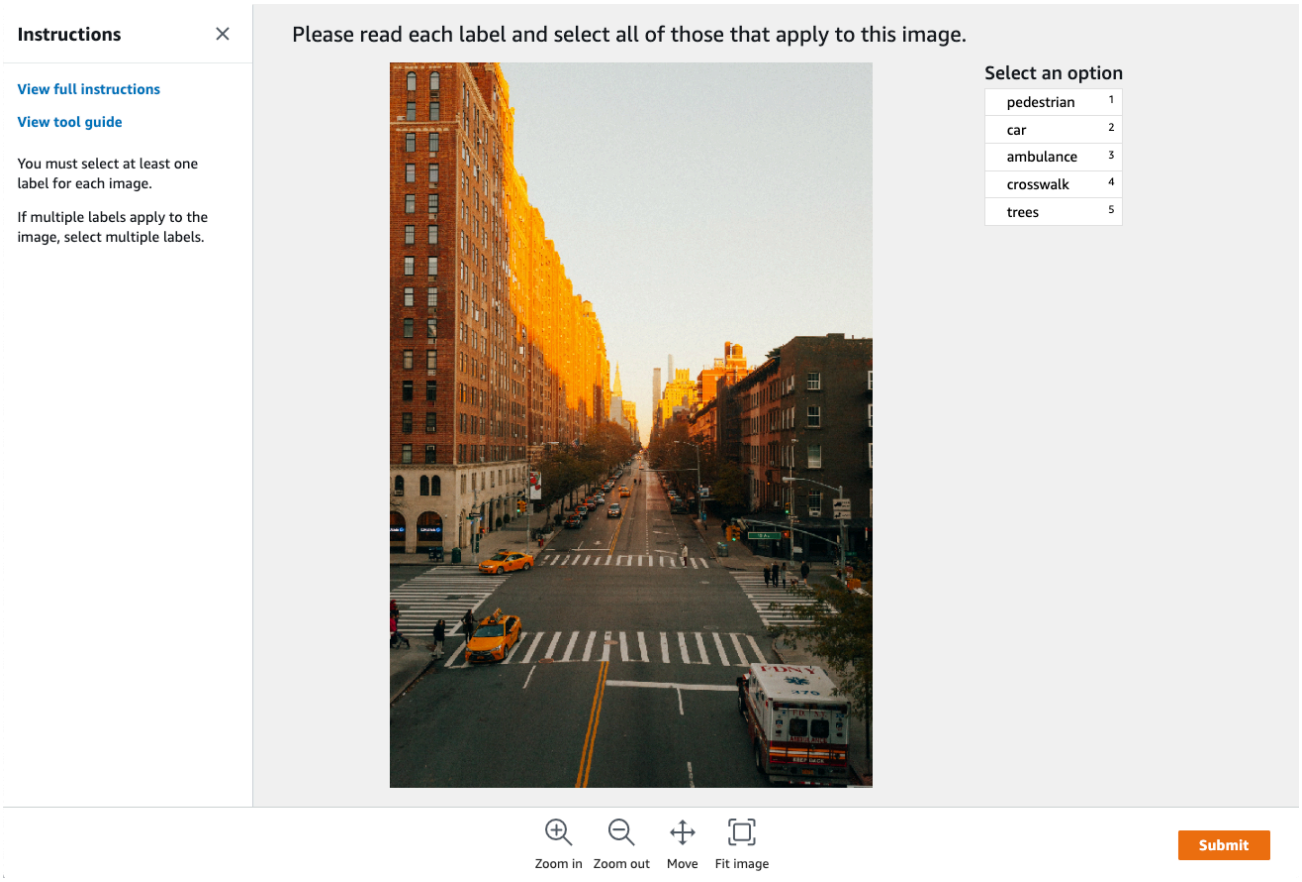
Create an image classification job (Multi-label)

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use an Amazon SageMaker Ground Truth multi-label image classification labeling task when you need workers to classify multiple objects in an image. For example, the following image features a dog and a cat. You can use multi-label image classification to associate the labels "dog" and "cat" with this image. The following page gives information about creating an image classification job.

When working on a multi-label image classification task, workers should choose all applicable labels, but must choose at least one. When creating a job using this task type, you can provide up to 50 label-categories.

When creating a labeling job in the console, Ground Truth doesn't provide a "none" category for when none of the labels applies to an image. To provide this option to workers, include a label similar to "none" or "other" when you create a multi-label image classification job.



To restrict workers to choosing a single label for each image, use the Create an image classification job (Single Label) task type.

> **Important**
>
> For this task type, if you create your own manifest file, use `"source-ref"` to identify the location of each image file in Amazon S3 that you want labeled. For more information, see Input data.

Create a Multi-Label Image Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) to learn how to create a multi-label image classification labeling job in the SageMaker AI console. In Step 10, choose **Image** from the **Task category** drop down menu, and choose **Image Classification (Multi-label)** as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create a labeling job in the console, you specify instructions to help workers complete the job and labels that workers can choose from.

Create a Multi-Label Image Classification Labeling Job (API)

To create a multi-label image classification labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-ImageMultiClassMultiLabel`. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn .
- Annotation-consolidation Lambda functions for this task type end with `ACS-ImageMultiClassMultiLabel`. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```
response = client.create_labeling_job(
    LabelingJobName='example-multi-label-image-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
```

```
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-
ImageMultiClassMultiLabel',
        'TaskKeywords': [
            'Image Classification',
        ],
        'TaskTitle': 'Multi-label image classification task',
        'TaskDescription': 'Select all labels that apply to the images shown',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-
east-1:432418664414:function:ACS-ImageMultiClassMultiLabel'
        },
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Provide a Template for Multi-label Image Classification

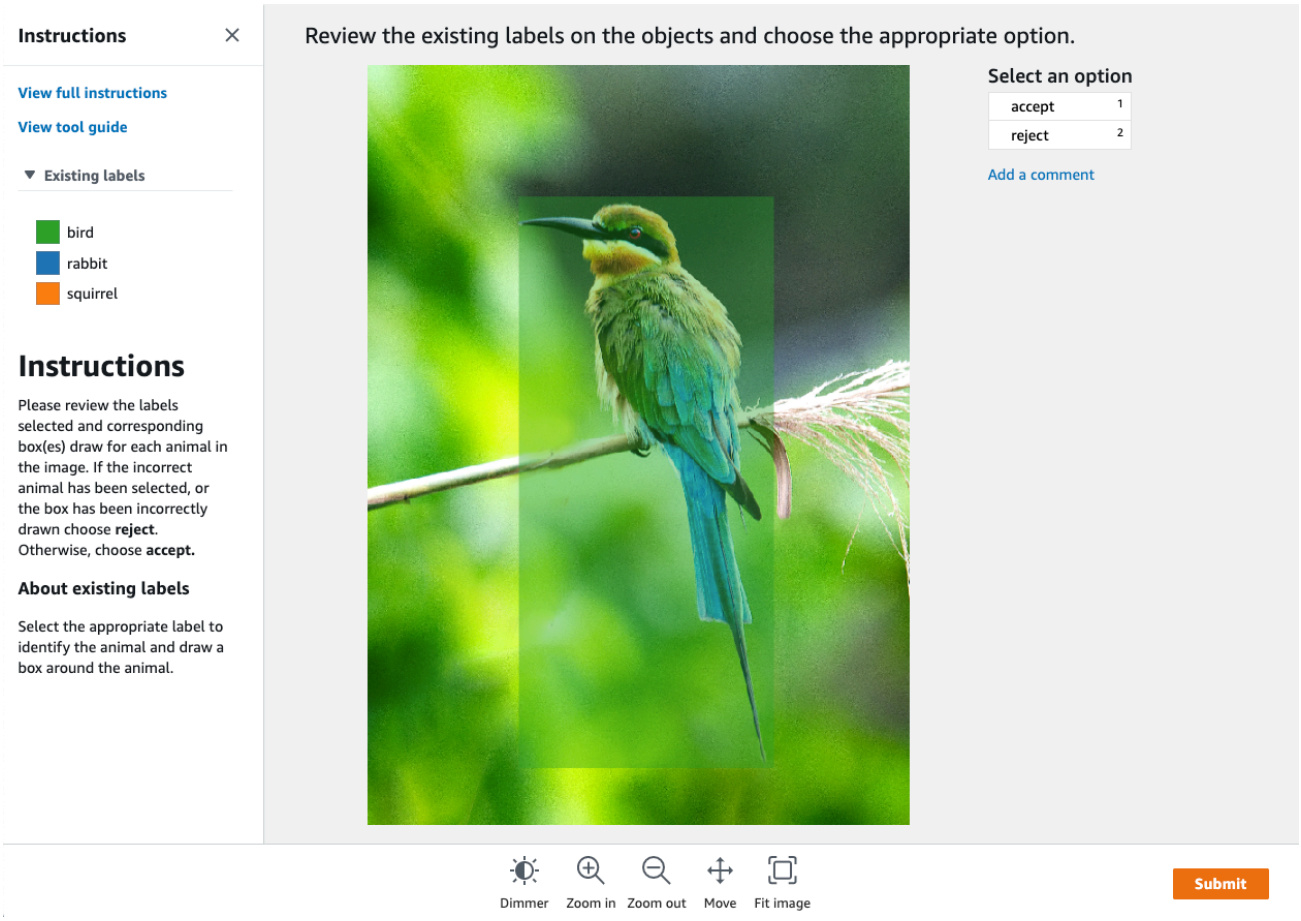
If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and `header`.

Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

Multi-label Image Classification Output Data

Once you have created a multi-label image classification labeling job, your output data will be located in the Amazon S3 bucket specified in the `S3OutputPath` parameter when using the API or in the **Output dataset location** field of the **Job overview** section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Labeling job output data.



To see an example of output manifest files for multi-label image classification labeling job, see Multi-label classification job output.

Image Label Verification

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Building a highly accurate training dataset for your machine learning (ML) algorithm is an iterative process. Typically, you review and continuously adjust your labels until you are satisfied that they accurately represent the ground truth, or what is directly observable in the real world. You can use an Amazon SageMaker Ground Truth image label verification task to direct workers to review a dataset's labels and improve label accuracy. Workers can indicate if the existing labels are correct or rate label quality. They can also add comments to explain their reasoning. Amazon SageMaker Ground Truth supports label verification for Classify image objects using a bounding box and Identify image contents using semantic segmentation labels. You create an image label verification labeling job using the Ground Truth section of the Amazon SageMaker AI console or the CreateLabelingJob operation.

Ground Truth provides a worker console similar to the following for labeling tasks. When you create the labeling job with the console, you can modify the images and content that are shown. To learn how to create a labeling job using the Ground Truth console, see Create a Labeling Job (Console).

You can create a label verification labeling job using the SageMaker AI console or API. To learn how to create a labeling job using the Ground Truth API operation `CreateLabelingJob`, see Create a Labeling Job (API).

Text labeling with Ground Truth

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use Ground Truth to label text. Ground Truth supports labeling text for named entity recognition, single label text classification, and multi-label text classification. The following topics give information about these built-in task types, as well as instructions to help you create a labeling job using that task type.

> **Tip**
>
> To learn more about supported file types and input data quotas, see Input data.

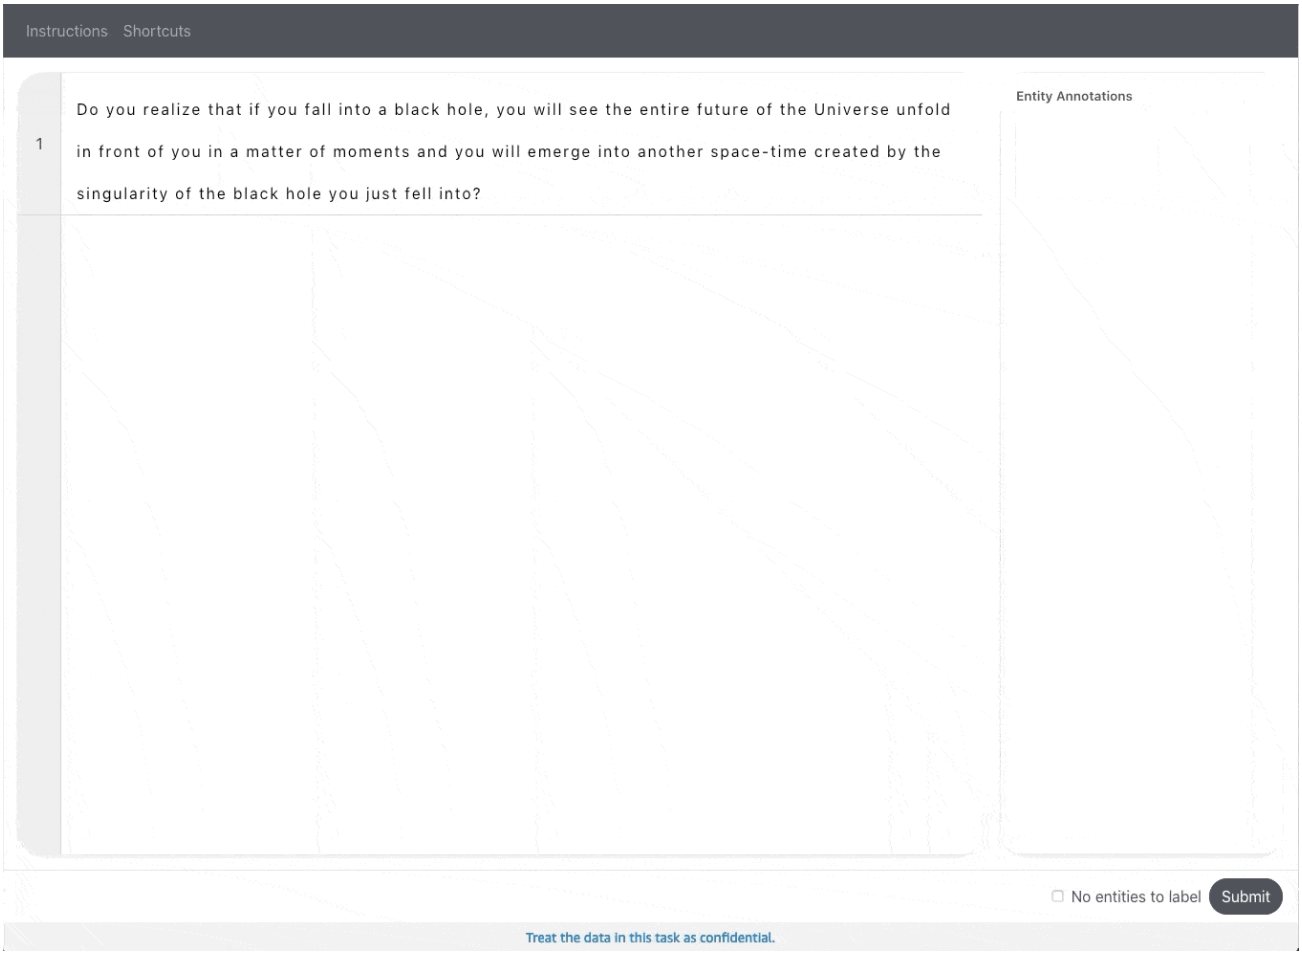
Topics

- Extract text information using named entity recognition
- Categorize text with text classification (Single Label)
- Categorize text with text classification (Multi-label)

Extract text information using named entity recognition

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

To extract information from unstructured text and classify it into predefined categories, use an Amazon SageMaker Ground Truth named entity recognition (NER) labeling task. Traditionally, NER involves sifting through text data to locate noun phrases, called *named entities*, and categorizing each with a label, such as "person," "organization," or "brand." You can broaden this task to label longer spans of text and categorize those sequences with predefined labels that you specify. You can create a named entity recognition labeling job using the Ground Truth section of the Amazon SageMaker AI console or the `CreateLabelingJob` operation.



When tasked with a named entity recognition labeling job, workers apply your labels to specific words or phrases within a larger text block. They choose a label, then apply it by using the cursor to highlight the part of the text to which the label applies. The Ground Truth named entity recognition tool supports overlapping annotations, in-context label selection, and multi-label selection for a single highlight. Also, workers can use their keyboards to quickly select labels.

> **Important**
>
> If you manually create an input manifest file, use `"source"` to identify the text that you want labeled. For more information, see Input data.

Create a Named Entity Recognition Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) to learn how to create a named entity recognition labeling job in the SageMaker AI console. In Step 10, choose **Text** from the **Task category** drop down menu, and choose **Named entity recognition** as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.

Create a Named Entity Recognition Labeling Job (API)

To create a named entity recognition labeling job, using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-NamedEntityRecognition`. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn .
- Annotation-consolidation Lambda functions for this task type end with `ACS-NamedEntityRecognition`. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.
- You must provide the following ARN for `HumanTaskUiArn`:

  ```
  arn:aws:sagemaker:aws-region:394669845002:human-task-ui/NamedEntityRecognition
  ```

  Replace *aws-region* with the Amazon Web Services Region you use to create the labeling job. For example, use `us-west-1` if you create a labeling job in US West (N. California).
- Provide worker instructions in the label category configuration file using the `instructions` parameter. You can use a string, or HTML markup language in the `shortInstruction` and `fullInstruction` fields. For more details, see Provide Worker Instructions in a Label Category Configuration File.

  ```
  "instructions": {"shortInstruction":"<h1>Add header</h1><p>Add Instructions</p>",
   "fullInstruction":"<p>Add additional instructions.</p>"}
  ```

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```
response = client.create_labeling_job(
    LabelingJobName='example-ner-labeling-job',
    LabelAttributeName='label',
    InputConfig={
```

```
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'HumanTaskUiArn': 'arn:aws:sagemaker:us-east-1:394669845002:human-task-ui/
NamedEntityRecognition'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-
NamedEntityRecognition',
        'TaskKeywords': [
            'Named entity Recognition',
        ],
        'TaskTitle': 'Named entity Recognition task',
        'TaskDescription': 'Apply the labels provided to specific words or phrases
 within the larger text block.',
        'NumberOfHumanWorkersPerDataObject': 1,
        'TaskTimeLimitInSeconds': 28800,
        'TaskAvailabilityLifetimeInSeconds': 864000,
        'MaxConcurrentTaskCount': 1000,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-
east-1:432418664414:function:ACS-NamedEntityRecognition'
        },
    Tags=[
```

```
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Provide Worker Instructions in a Label Category Configuration File

You must provide worker instructions in the label category configuration file you identify with the `LabelCategoryConfigS3Uri` parameter in `CreateLabelingJob`. You can use these instructions to provide details about the task you want workers to perform and help them use the tool efficiently.

You provide short and long instructions using `shortInstruction` and `fullInstruction` in the `instructions` parameter, respectively. To learn more about these instruction types, see Create instruction pages.

The following is an example of a label category configuration file with instructions that can be used for a named entity recognition labeling job.

```
{
  "document-version": "2018-11-28",
  "labels": [
    {
      "label": "label1",
      "shortDisplayName": "L1"
    },
    {
      "label": "label2",
      "shortDisplayName": "L2"
    },
    {
      "label": "label3",
      "shortDisplayName": "L3"
    },
    {
      "label": "label4",
      "shortDisplayName": "L4"
    },
    {
      "label": "label5",
```

```
      "shortDisplayName": "L5"
    }
  ],
  "instructions": {
    "shortInstruction": "<p>Enter description of the labels that workers have
                        to choose from</p><br><p>Add examples to help workers
 understand the label</p>",
    "fullInstruction": "<ol>
                        <li><strong>Read</strong> the text carefully.</li>
                        <li><strong>Highlight</strong> words, phrases, or sections of
 the text.</li>
                        <li><strong>Choose</strong> the label that best matches what
 you have highlighted.</li>
                        <li>To <strong>change</strong> a label, choose highlighted text
 and select a new label.</li>
                        <li>To <strong>remove</strong> a label from highlighted text,
 choose the X next to the
                        abbreviated label name on the highlighted text.</li>
                        <li>You can select all of a previously highlighted text, but
 not a portion of it.</li>
                        </ol>"
  }
}
```

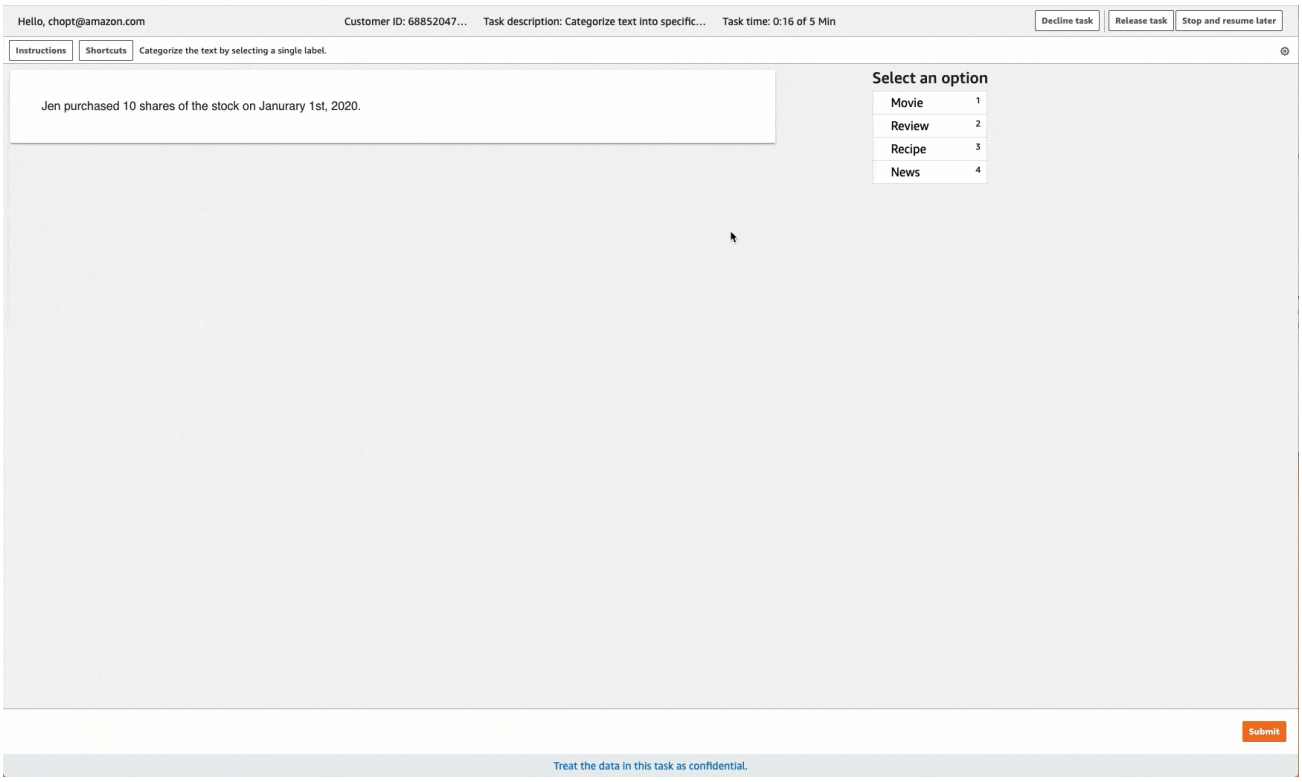
Named Entity Recognition Output Data

Once you have created a named entity recognition labeling job, your output data will be located in the Amazon S3 bucket specified in the `S3OutputPath` parameter when using the API or in the **Output dataset location** field of the **Job overview** section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Labeling job output data.

Categorize text with text classification (Single Label)

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.



To categorize articles and text into predefined categories, use text classification. For example, you can use text classification to identify the sentiment conveyed in a review or the emotion underlying a section of text. Use Amazon SageMaker Ground Truth text classification to have workers sort text into categories that you define. You create a text classification labeling job using the Ground Truth section of the Amazon SageMaker AI console or the `CreateLabelingJob` operation.

> **Important**
>
> If you manually create an input manifest file, use `"source"` to identify the text that you want labeled. For more information, see Input data.

Create a Text Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) to learn how to create a text classification labeling job in the SageMaker AI console. In Step 10, choose **Text** from the **Task category** drop down menu, and choose **Text Classification (Single Label)** as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.

Create a Text Classification Labeling Job (API)

To create a text classification labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-TextMultiClass`. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn .
- Annotation-consolidation Lambda functions for this task type end with `ACS-TextMultiClass`. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```
response = client.create_labeling_job(
    LabelingJobName='example-text-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
```

```
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-
TextMultiClass,
        'TaskKeywords': [
            Text classification',
        ],
        'TaskTitle': Text classification task',
        'TaskDescription': 'Carefully read and classify this text using the categories
 provided.',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-
east-1:432418664414:function:ACS-TextMultiClass'
        },
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Provide a Template for Text Classification Labeling Jobs

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and `header`.

Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

Text Classification Output Data

Once you have created a text classification labeling job, your output data will be located in the Amazon S3 bucket specified in the `S3OutputPath` parameter when using the API or in the **Output dataset location** field of the **Job overview** section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Labeling job output data.

To see an example of an output manifest files from a text classification labeling job, see Classification job output.

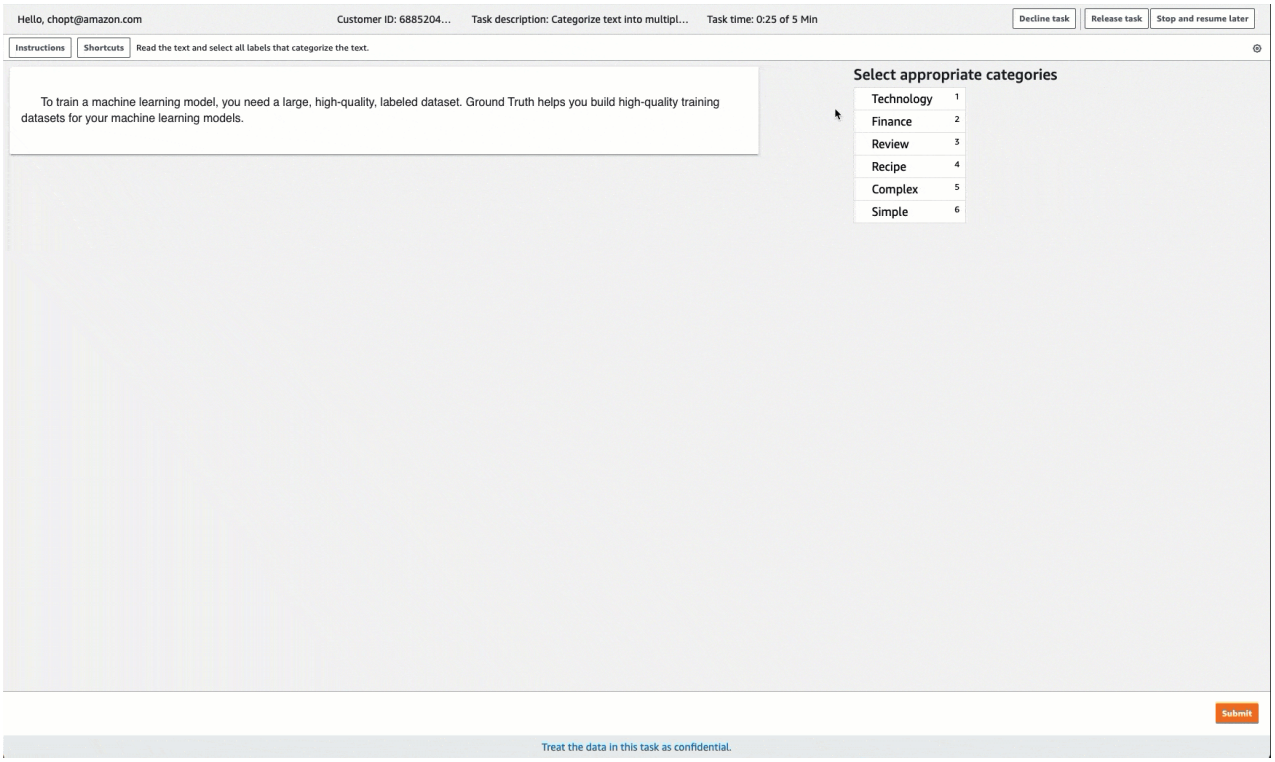
Categorize text with text classification (Multi-label)

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

To categorize articles and text into multiple predefined categories, use the multi-label text classification task type. For example, you can use this task type to identify more than one emotion conveyed in text. The following sections give information about how to create a multi-label text classification task from the console and API.

When working on a multi-label text classification task, workers should choose all applicable labels, but must choose at least one. When creating a job using this task type, you can provide up to 50 label categories.

Amazon SageMaker Ground Truth doesn't provide a "none" category for when none of the labels applies. To provide this option to workers, include a label similar to "none" or "other" when you create a multi-label text classification job.



To restrict workers to choosing a single label for each document or text selection, use the Categorize text with text classification (Single Label) task type.

> **Important**
>
> If you manually create an input manifest file, use `"source"` to identify the text that you want labeled. For more information, see Input data.

Create a Multi-Label Text Classification Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) to learn how to create a multi-label text classification labeling job in the Amazon SageMaker AI console. In Step 10, choose **Text** from the **Task category** drop down menu, and choose **Text Classification (Multi-label)** as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create the labeling job with the console, you specify instructions to help workers complete the job and labels that workers can choose from.

Create a Multi-Label Text Classification Labeling Job (API)

To create a multi-label text classification labeling job, use the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) and do the following while you configure your request:

- Pre-annotation Lambda functions for this task type end with `PRE-TextMultiClassMultiLabel`. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn .
- Annotation-consolidation Lambda functions for this task type end with `ACS-TextMultiClassMultiLabel`. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region. All parameters in red should be replaced with your specifications and resources.

```
response = client.create_labeling_job(
    LabelingJobName='example-multi-label-text-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
```

```
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/custom-worker-task-template.html'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda::function:PRE-
TextMultiClassMultiLabel,
        'TaskKeywords': [
            'Text Classification',
        ],
        'TaskTitle': 'Multi-label text classification task',
        'TaskDescription': 'Select all labels that apply to the text shown',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-
east-1:432418664414:function:ACS-TextMultiClassMultiLabel'
        },
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Create a Template for Multi-label Text Classification

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template. Only modify the `short-instructions`, `full-instructions`, and `header`.

Upload this template to S3, and provide the S3 URI for this file in `UiTemplateS3Uri`.

To learn how to create a custom template, see Custom labeling workflows.

Multi-label Text Classification Output Data

Once you have created a multi-label text classification labeling job, your output data will be located in the Amazon S3 bucket specified in the `S3OutputPath` parameter when using the API or in the **Output dataset location** field of the **Job overview** section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Labeling job output data.

To see an example of output manifest files for multi-label text classification labeling job, see Multi-label classification job output.

Videos and video frame labeling

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use Ground Truth to classify videos and annotate video frames (still images extracted from videos) using one of the three built-in video task types. These task types streamline the process of creating video and video frame labeling jobs using the Amazon SageMaker AI console, API, and language-specific SDKs.

- Video clip classification – Enable workers to classify videos into categories you specify. For example, you can use this task type to have workers categorize videos into topics like sports, comedy, music, and education. To learn more, see Classify videos.
- Video frame labeling jobs – Enable workers to annotate video frames extracted from a video using bounding boxes, polylines, polygons or keypoint annotation tools. Ground Truth offers two built-in task types to label video frames:
  - *Video frame object detection*: Enable workers to identify and locate objects in video frames.
  - *Video frame object tracking*: Enable workers to track the movement of objects across video frames.
  - *Video frame adjustment jobs*: Have workers adjust labels, label category attributes, and frame attributes from a previous video frame object detection or object tracking labeling job.
  - *Video frame verification jobs*: Have workers verify labels, label category attributes, and frame attributes from a previous video frame object detection or object tracking labeling job.

  If you have video files, you can use the Ground Truth automatic frame extraction tool to extract video frames from your videos. To learn more, see Video Frame Input Data.

> **Tip**
>
> To learn more about supported file types and input data quotas, see Input data.

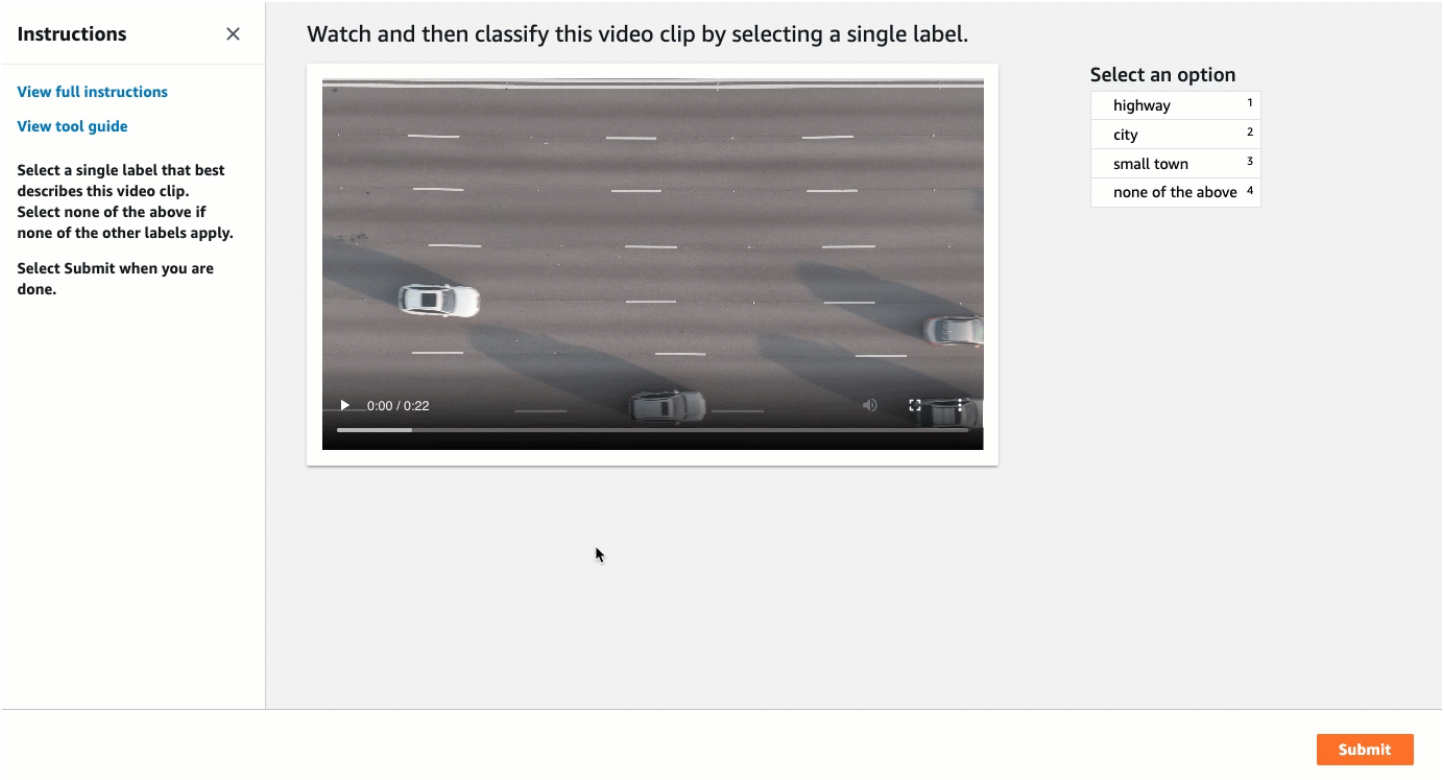
Topics

- Classify videos
- Video frames
- Worker Instructions

Classify videos

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use an Amazon SageMaker Ground Truth video classification labeling task when you need workers to classify videos using predefined labels that you specify. Workers are shown videos and are asked to choose one label for each video. You create a video classification labeling job using the Ground Truth section of the Amazon SageMaker AI console or the CreateLabelingJob operation.



Your video files must be encoded in a format that is supported by the browser used by the work team that labels your data. It is recommended that you verify that all video file formats in your input manifest file display correctly using the worker UI preview. You can communicate supported browsers to your workers using worker instructions. To see supported file formats, see Supported data formats.

> **Important**
>
> For this task type, if you create your own manifest file, use `"source-ref"` to identify the location of each video file in Amazon S3 that you want labeled. For more information, see Input data.

Create a Video Classification Labeling Job (Console)

You can follow the instructions in Create a Labeling Job (Console) to learn how to create a video classification labeling job in the SageMaker AI console. In step 10, choose **Video** from the **Task category** dropdown list, and choose **Video Classification** as the task type.

Ground Truth provides a worker UI similar to the following for labeling tasks. When you create a labeling job in the console, you specify instructions to help workers complete the job and labels from which workers can choose.

Create a Video Classification Labeling Job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Follow the instructions on Create a Labeling Job (API) and do the following while you configure your request:

- Use a pre-annotation Lambda function that ends with `PRE-VideoClassification`. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn .

- Use an annotation-consolidation Lambda function that ends with `ACS-VideoClassification`. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region.

```
response = client.create_labeling_job(
    LabelingJobName='example-video-classification-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/path/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:region:*:workteam/private-crowd/*',
        'UiConfig': {
            'UiTemplateS3Uri': 's3://bucket/path/worker-task-template.html'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-
VideoClassification',
        'TaskKeywords': [
            'Video Classification',
        ],
```

```
        'TaskTitle': 'Video classification task',
        'TaskDescription': 'Select a label to classify this video',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-
east-1:432418664414:function:ACS-VideoClassification'
        },
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Provide a Template for Video Classification

If you create a labeling job using the API, you must supply a worker task template in `UiTemplateS3Uri`. Copy and modify the following template by modifying the `short-instructions`, `full-instructions`, and `header`. Upload this template to Amazon S3, and provide the Amazon S3 URI to this file in `UiTemplateS3Uri`.

Video Classification Output Data

Once you have created a video classification labeling job, your output data is located in the Amazon S3 bucket specified in the `S3OutputPath` parameter when using the API or in the **Output dataset location** field of the **Job overview** section of the console.

To learn more about the output manifest file generated by Ground Truth and the file structure the Ground Truth uses to store your output data, see Labeling job output data.

To see an example of output manifest files for video classification labeling jobs, see Classification job output.

Video frames

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use Ground Truth built-in video frame task types to have workers annotate video frames using bounding boxes, polylines, polygons or keypoints. A *video frame* is a sequence of images that have been extracted from a video.

If you do not have video frames, you can provide video files (MP4 files) and use the Ground Truth automated frame extraction tool to extract video frames. To learn more, see Provide Video Files.

You can use the following built-in video task types to create video frame labeling jobs using the Amazon SageMaker AI console, API, and language-specific SDKs.

- **Video frame object detection** – Use this task type when you want workers to identify and locate objects in sequences of video frames. You provide a list of categories, and workers can select one category at a time and annotate objects which the category applies to in all frames. For example, you can use this task to ask workers to identify and localize various objects in a scene, such as cars, bikes, and pedestrians.
- **Video frame object tracking** – Use this task type when you want workers to track the movement of instances of objects across sequences of video frames. When a worker adds an annotation to a single frame, that annotation is associated with a unique instance ID. The worker adds annotations associated with the same ID in all other frames to identify the same object or person. For example, a worker can track the movement of a vehicle across a sequences of video frames by drawing bounding boxes associated with the same ID around the vehicle in each frame that it appears.

Use the following topics to learn more about these built-in task types and to how to create a labeling job using each task type. See Task types to learn more about the annotations tools (bounding boxes, polylines, polygons and keypoints) available for these task types.

Before you create a labeling job, we recommend that you review Video frame labeling job reference.

Topics

- Identify objects using video frame object detection
- Track objects in video frames using video frame object tracking
- Video frame labeling job reference

Identify objects using video frame object detection

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use the video frame object detection task type to have workers identify and locate objects in a sequence of video frames (images extracted from a video) using bounding boxes, polylines, polygons or keypoint *annotation tools*. The tool you choose defines the video frame task type you create. For example, you can use a bounding box video frame object detection task type workers to identify and localize various objects in a series of video frames, such as cars, bikes, and pedestrians. You can create a video frame object detection labeling job using the Amazon SageMaker AI Ground Truth console, the SageMaker API, and language-specific Amazon SDKs. To learn more, see Create a Video Frame Object Detection Labeling Job and select your preferred method. See Task types to learn more about the annotations tools you can choose from when you create a labeling job.

Ground Truth provides a worker UI and tools to complete your labeling job tasks: Preview the Worker UI.

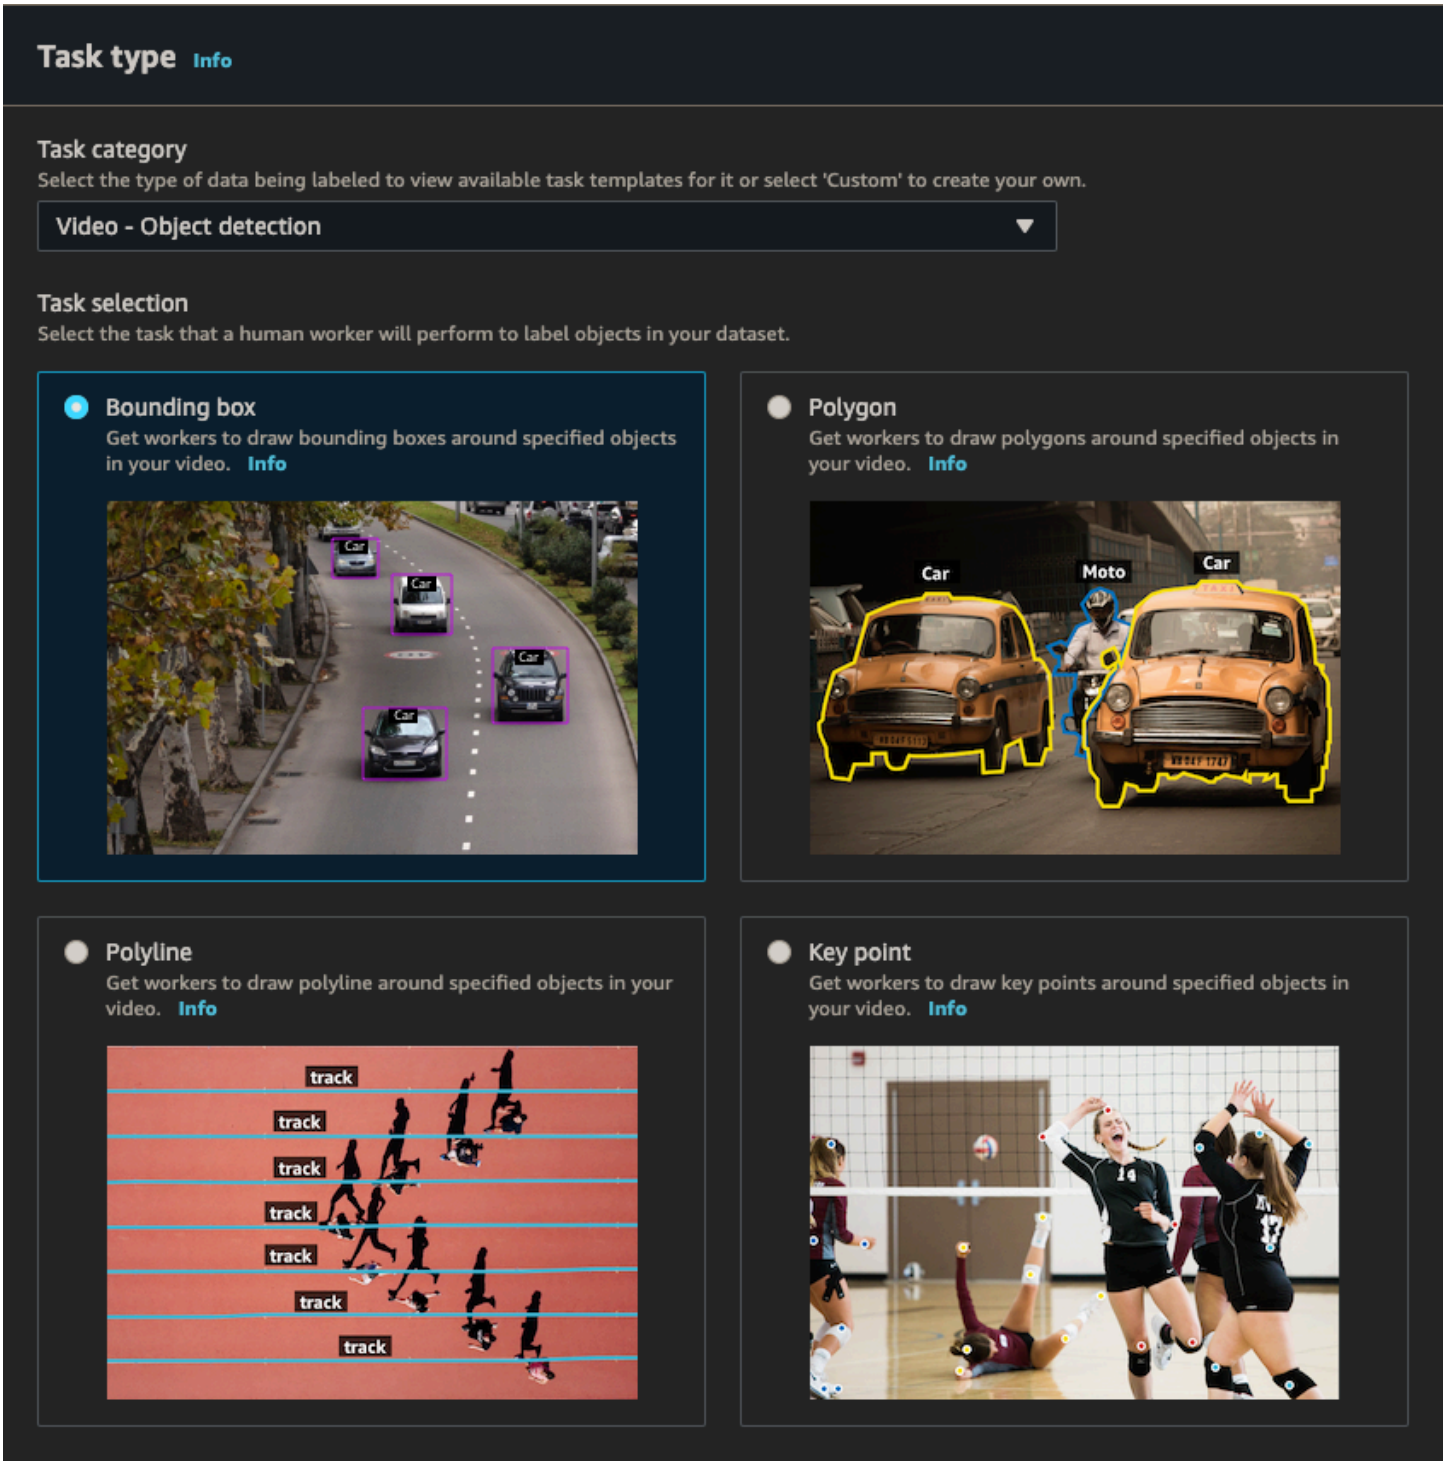
You can create a job to adjust annotations created in a video object detection labeling job using the video object detection adjustment task type. To learn more, see Create Video Frame Object Detection Adjustment or Verification Labeling Job.

Preview the Worker UI

Ground Truth provides workers with a web user interface (UI) to complete your video frame object detection annotation tasks. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, we recommend that you create a labeling job through the console using a small input dataset to preview the worker UI and ensure your video frames, labels, and label attributes appear as expected.

The UI provides workers with the following assistive labeling tools to complete your object detection tasks:

- For all tasks, workers can use the **Copy to next** and **Copy to all** features to copy an annotation to the next frame or to all subsequent frames respectively.
- For tasks that include the bounding box tools, workers can use a **Predict next** feature to draw a bounding box in a single frame, and then have Ground Truth predict the location of boxes with the same label in all other frames. Workers can then make adjustments to correct predicted box locations.



Create a Video Frame Object Detection Labeling Job

You can create a video frame object detection labeling job using the SageMaker AI console or the `CreateLabelingJob` API operation.

This section assumes that you have reviewed the Video frame labeling job reference and have chosen the type of input data and the input dataset connection you are using.

Create a Labeling Job (Console)

You can follow the instructions in Create a Labeling Job (Console) to learn how to create a video frame object tracking job in the SageMaker AI console. In step 10, choose **Video - Object detection** from the **Task category** dropdown list. Select the task type you want by selecting one of the cards in **Task selection**.

Create a Labeling Job (API)

You create an object detection labeling job using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Create a Labeling Job (API) provides an overview of the `CreateLabelingJob` operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for `HumanTaskUiArn`. Use `arn:aws:sagemaker:<region>:394669845002:human-task-ui/VideoObjectDetection`. Replace *<region>* with the Amazon Region in which you are creating the labeling job.

  Do not include an entry for the `UiTemplateS3Uri` parameter.
- Your `LabelAttributeName` must end in `-ref`. For example, *video-od-labels*`-ref`.
- Your input manifest file must be a video frame sequence manifest file. You can create this manifest file using the SageMaker AI console, or create it manually and upload it to Amazon S3. For more information, see Input Data Setup.
- You can only use private or vendor work teams to create video frame object detection labeling jobs.
- You specify your labels, label category and frame attributes, the task type, and worker instructions in a label category configuration file. Specify the task type (bounding boxes, polylines, polygons or keypoint) using `annotationType` in your label category configuration file. For more information, see Labeling category configuration file with label category and frame attributes reference to learn how to create this file.
- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the Amazon Region you use to create your labeling job.
  - To find the pre-annotation Lambda ARN, refer to `PreHumanTaskLambdaArn`. Use the Region in which you are creating your labeling job to find the correct ARN that ends with `PRE-VideoObjectDetection`.
  - To find the post-annotation Lambda ARN, refer to `AnnotationConsolidationLambdaArn`. Use the Region in which you are creating your labeling job to find the correct ARN that ends with `ACS-VideoObjectDetection`.
- The number of workers specified in `NumberOfHumanWorkersPerDataObject` must be 1.
- Automated data labeling is not supported for video frame labeling jobs. Do not specify values for parameters in `LabelingJobAlgorithmsConfig`.
- Video frame object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in `TaskTimeLimitInSeconds` (up to 7 days, or 604,800 seconds).

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region.

```
response = client.create_labeling_job(
    LabelingJobName='example-video-od-labeling-job,
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://amzn-s3-demo-bucket/path/video-frame-sequence-
input-manifest.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://amzn-s3-demo-bucket/prefix/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/prefix/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:us-east-1:*:workteam/private-crowd/*',
        'UiConfig': {
            'HumanTaskUiArn: 'arn:aws:sagemaker:us-east-1:394669845002:human-task-ui/
VideoObjectDetection'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-
VideoObjectDetection',
        'TaskKeywords': [
            'Video Frame Object Detection',
        ],
        'TaskTitle': 'Video frame object detection task',
        'TaskDescription': 'Classify and identify the location of objects and people in
 video frames',
```

```
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-
east-1:432418664414:function:ACS-VideoObjectDetection'
        },
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Create Video Frame Object Detection Adjustment or Verification Labeling Job

You can create an adjustment and verification labeling job using the Ground Truth console or `CreateLabelingJob` API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Label verification and adjustment.

Output Data Format

When you create a video frame object detection labeling job, tasks are sent to workers. When these workers complete their tasks, labels are written to the Amazon S3 output location you specified when you created the labeling job. To learn about the video frame object detection output data format, see Video frame object detection output. If you are a new user of Ground Truth, see Labeling job output data to learn more about the Ground Truth output data format.

Track objects in video frames using video frame object tracking

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use the video frame object tracking task type to have workers track the movement of objects in a sequence of video frames (images extracted from a video) using bounding boxes,

polylines, polygons or keypoint *annotation tools*. The tool you choose defines the video frame task type you create. For example, you can use a bounding box video frame object tracking task type to ask workers to track the movement of objects, such as cars, bikes, and pedestrians by drawing boxes around them.

You provide a list of categories, and each annotation that a worker adds to a video frame is identified as an *instance* of that category using an instance ID. For example, if you provide the label category car, the first car that a worker annotates will have the instance ID car:1. The second car the worker annotates will have the instance ID car:2. To track an object's movement, the worker adds annotations associated with the same instance ID around to object in all frames.

You can create a video frame object tracking labeling job using the Amazon SageMaker AI Ground Truth console, the SageMaker API, and language-specific Amazon SDKs. To learn more, see Create a Video Frame Object Detection Labeling Job and select your preferred method. See Task types to learn more about the annotations tools you can choose from when you create a labeling job.

Ground Truth provides a worker UI and tools to complete your labeling job tasks: Preview the Worker UI.

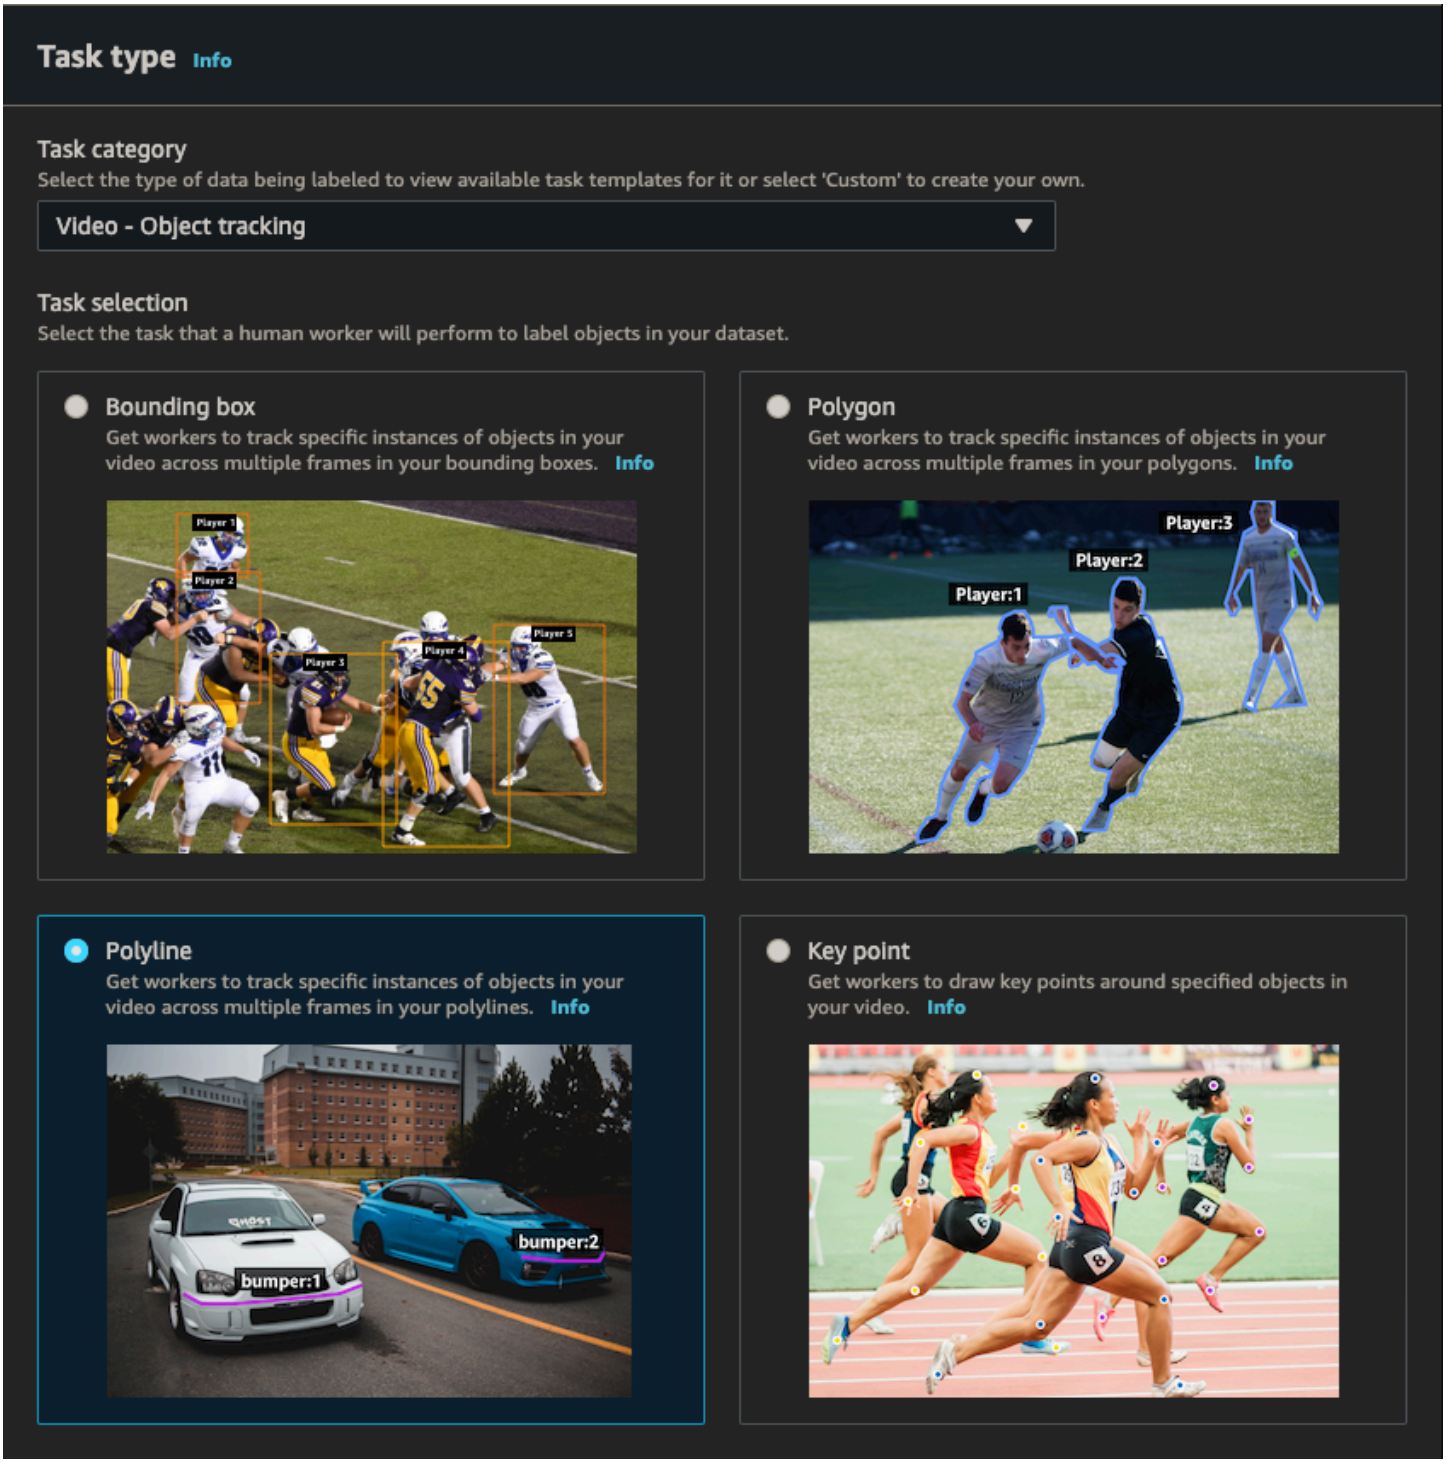
You can create a job to adjust annotations created in a video object detection labeling job using the video object detection adjustment task type. To learn more, see Create Video Frame Object Detection Adjustment or Verification Labeling Job.

Preview the Worker UI

Ground Truth provides workers with a web user interface (UI) to complete your video frame object tracking annotation tasks. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, we recommend that you create a labeling job through the console using a small input dataset to preview the worker UI and ensure your video frames, labels, and label attributes appear as expected.

The UI provides workers with the following assistive labeling tools to complete your object tracking tasks:

- For all tasks, workers can use the **Copy to next** and **Copy to all** features to copy an annotation with the same unique ID to the next frame or to all subsequent frames respectively.
- For tasks that include the bounding box tools, workers can use a **Predict next** feature to draw a bounding box in a single frame, and then have Ground Truth predict the location of boxes with the same unique ID in all other frames. Workers can then make adjustments to correct predicted box locations.



Create a Video Frame Object Tracking Labeling Job

You can create a video frame object tracking labeling job using the SageMaker AI console or the `CreateLabelingJob` API operation.

This section assumes that you have reviewed the Video frame labeling job reference and have chosen the type of input data and the input dataset connection you are using.

Create a Labeling Job (Console)

You can follow the instructions in Create a Labeling Job (Console) to learn how to create a video frame object tracking job in the SageMaker AI console. In step 10, choose **Video - Object tracking** from the **Task category** dropdown list. Select the task type you want by selecting one of the cards in **Task selection**.

Create a Labeling Job (API)

You create an object tracking labeling job using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Create a Labeling Job (API) provides an overview of the `CreateLabelingJob` operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for `HumanTaskUiArn`. Use `arn:aws:sagemaker:<region>:394669845002:human-task-ui/VideoObjectTracking`. Replace *<region>* with the Amazon Region in which you are creating the labeling job.

  Do not include an entry for the `UiTemplateS3Uri` parameter.
- Your `LabelAttributeName` must end in `-ref`. For example, *ot-labels*`-ref`.
- Your input manifest file must be a video frame sequence manifest file. You can create this manifest file using the SageMaker AI console, or create it manually and upload it to Amazon S3. For more information, see Input Data Setup. If you create a streaming labeling job, the input manifest file is optional.
- You can only use private or vendor work teams to create video frame object detection labeling jobs.
- You specify your labels, label category and frame attributes, the task type, and worker instructions in a label category configuration file. Specify the task type (bounding boxes, polylines, polygons or keypoint) using `annotationType` in your label category configuration file. For more information, see Labeling category configuration file with label category and frame attributes reference to learn how to create this file.
- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the Amazon Region you use to create your labeling job.
  - To find the pre-annotation Lambda ARN, refer to `PreHumanTaskLambdaArn`. Use the Region in which you are creating your labeling job to find the correct ARN that ends with `PRE-VideoObjectTracking`.
  - To find the post-annotation Lambda ARN, refer to `AnnotationConsolidationLambdaArn`. Use the Region in which you are creating your labeling job to find the correct ARN that ends with `ACS-VideoObjectTracking`.
- The number of workers specified in `NumberOfHumanWorkersPerDataObject` must be 1.
- Automated data labeling is not supported for video frame labeling jobs. Do not specify values for parameters in `LabelingJobAlgorithmsConfig`.

- Video frame object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in `TaskTimeLimitInSeconds` (up to 7 days, or 604,800 seconds).

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job in the US East (N. Virginia) Region.

```
response = client.create_labeling_job(
    LabelingJobName='example-video-ot-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://amzn-s3-demo-bucket/path/video-frame-sequence-
input-manifest.json'
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://amzn-s3-demo-bucket/prefix/file-to-store-output-data',
        'KmsKeyId': 'string'
    },
    RoleArn='arn:aws:iam::*:role/*',
    LabelCategoryConfigS3Uri='s3://bucket/prefix/label-categories.json',
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': 'arn:aws:sagemaker:us-east-1:*:workteam/private-crowd/*',
        'UiConfig': {
            'HumanTaskUiArn: 'arn:aws:sagemaker:us-east-1:394669845002:human-task-ui/
VideoObjectTracking'
        },
        'PreHumanTaskLambdaArn': 'arn:aws:lambda:us-east-1:432418664414:function:PRE-
VideoObjectTracking',
        'TaskKeywords': [
```

```
            'Video Frame Object Tracking',
        ],
        'TaskTitle': 'Video frame object tracking task',
        'TaskDescription': Tracking the location of objects and people across video
 frames',
        'NumberOfHumanWorkersPerDataObject': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'MaxConcurrentTaskCount': 123,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': 'arn:aws:lambda:us-
east-1:432418664414:function:ACS-VideoObjectTracking'
        },
    Tags=[
        {
            'Key': 'string',
            'Value': 'string'
        },
    ]
)
```

Create a Video Frame Object Tracking Adjustment or Verification Labeling Job

You can create an adjustment and verification labeling job using the Ground Truth console or `CreateLabelingJob` API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Label verification and adjustment.

Output Data Format

When you create a video frame object tracking labeling job, tasks are sent to workers. When these workers complete their tasks, labels are written to the Amazon S3 output location you specified when you created the labeling job. To learn about the video frame object tracking output data format, see Video frame object tracking output. If you are a new user of Ground Truth, see Labeling job output data to learn more about the Ground Truth output data format.

Video frame labeling job reference

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use this page to learn about the object detection and object tracking video frame labeling jobs. The information on this page applies to both of these built-in task types.

The video frame labeling job is unique because of the following:

- You can either provide data objects that are ready to be annotated (video frames), or you can provide video files and have Ground Truth automatically extract video frames.
- Workers have the ability to save work as they go.
- Ground Truth provides a worker UI, as well as assistive and basic labeling tools, to help workers complete your tasks. You do not need to provide a worker task template.

Use the following topics to learn more about video frame labeling jobs.

Topics

- Input data
- Job completion times
- Task types
- Workforces
- Worker user interface (UI)
- Video frame job permission requirements

Input data

The video frame labeling job uses *sequences* of video frames. A single sequence is a series of images that have been extracted from a single video. You can either provide your own sequences of video frames, or have Ground Truth automatically extract video frame sequences from your video files. To learn more, see Provide Video Files.

Ground Truth uses sequence files to identify all images in a single sequence. All of the sequences that you want to include in a single labeling job are identified in an input manifest file. Each sequence is used to create a single worker task. You can automatically create sequence files and an input manifest file using Ground Truth automatic data setup. To learn more, see Set up Automated Video Frame Input Data.

To learn how to manually create sequence files and an input manifest file, see Create a Video Frame Input Manifest File.

Job completion times

Video and video frame labeling jobs can take workers hours to complete. You can set the total amount of time that workers can work on each task when you create a labeling job. The maximum time you can set for workers to work on tasks is 7 days. The default value is 3 days.

We strongly recommend that you create tasks that workers can complete within 12 hours. Workers must keep the worker UI open while working on a task. They can save work as they go and Ground Truth saves their work every 15 minutes.

When using the SageMaker AI `CreateLabelingJob` API operation, set the total time a task is available to workers in the `TaskTimeLimitInSeconds` parameter of `HumanTaskConfig`.

When you create a labeling job in the console, you can specify this time limit when you select your workforce type and your work team.

Task types

When you create a video object tracking or video object detection labeling job, you specify the type of annotation that you want workers to create while working on your labeling task. The annotation type determines the type of output data Ground Truth returns and defines the *task type* for your labeling job.

If you are creating a labeling job using the API operation `CreateLabelingJob`, you specify the task type using the label category configuration file parameter `annotationType`. To learn more, see Labeling category configuration file with label category and frame attributes reference.

The following task types are available for both video object tracking or video object detection labeling jobs:

- **Bounding box** – Workers are provided with tools to create bounding box annotations. A bounding box is a box that a worker draws around an objects to identify the pixel-location and label of that object in the frame.
- **Polyline** – Workers are provided with tools to create polyline annotations. A polyline is defined by the series of ordered x, y coordinates. Each point added to the polyline is connected to the previous point by a line. The polyline does not have to be closed (the start point and end point do not have to be the same) and there are no restrictions on the angles formed between lines.
- **Polygon** – Workers are provided with tools to create polygon annotations. A polygon is a closed shape defined by a series of ordered x, y coordinates. Each point added to the polygon is connected to the previous point by a line and there are no restrictions on the angles formed between lines. Two lines (sides) of the polygon cannot cross. The start and end point of a polygon must be the same.
- **Keypoint** – Workers are provided with tools to create keypoint annotations. A keypoint is a single point associated with an x, y coordinate in the video frame.

Workforces

When you create a video frame labeling job, you need to specify a work team to complete your annotation tasks. You can choose a work team from a private workforce of your own workers, or from a vendor workforce that you select in the Amazon Web Services Marketplace.

To learn more about vendor workforces, see Subscribe to vendor workforces.

To learn how to create and manage a private workforce, see Private workforce.

Worker user interface (UI)

Ground Truth provides a worker user interface (UI), tools, and assistive labeling features to help workers complete your video labeling tasks. You can preview the worker UI when you create a labeling job in the console.

When you create a labeling job using the API operation `CreateLabelingJob`, you must provide an ARN provided by Ground Truth in the parameter `HumanTaskUiArn` to specify the worker UI for your task type. You can use `HumanTaskUiArn` with the SageMaker AI `RenderUiTemplate` API operation to preview the worker UI.

You provide worker instructions, labels, and optionally, attributes that workers can use to provide more information about labels and video frames. These attributes are referred to as label category attributes and frame attributes respectively. They are all displayed in the worker UI.

Label category and frame attributes

When you create a video object tracking or video object detection labeling job, you can add one or more *label category attributes* and *frame attributes*:

- **Label category attribute** – A list of options (strings), a free form text box, or a numeric field associated with one or more labels. It is used by workers to provide metadata about a label.
- **Frame attribute** – A list of options (strings), a free form text box, or a numeric field that appears on each video frame a worker is sent to annotate. It is used by workers to provide metadata about video frames.

Additionally, you can use label and frame attributes to have workers verify labels in a video frame label verification job.

Use the following sections to learn more about these attributes. To learn how to add label category and frame attributes to a labeling job, use the **Create Labeling Job** sections on the task type page of your choice.

Frame level attributes

Add frame attributes to give workers the ability to provide more information about individual video frames. Each frame attribute you add appears on all frames.

For example, you can add a number-frame attribute to have workers identify the number of objects they see in a particular frame.

In another example, you may want to provide a free-form text box to give workers the ability to provide an answer to a question.

When you create a label verification job, you can add one or more frame attributes to ask workers to provide feedback on all labels in a video frame.

Worker instructions

You can provide worker instructions to help your workers complete your video frame labeling tasks. You might want to cover the following topics when writing your instructions:

- Best practices and things to avoid when annotating objects.
- The label category attributes provided (for object detection and object tracking tasks) and how to use them.

- How to save time while labeling by using keyboard shortcuts.

You can add your worker instructions using the SageMaker AI console while creating a labeling job. If you create a labeling job using the API operation `CreateLabelingJob`, you specify worker instructions in your label category configuration file.

In addition to your instructions, Ground Truth provides a link to help workers navigate and use the worker portal. View these instructions by selecting the task type on Worker Instructions.

Declining tasks

Workers are able to decline tasks.

Workers decline a task if the instructions are not clear, input data is not displaying correctly, or if they encounter some other issue with the task. If the number of workers per dataset object (`NumberOfHumanWorkersPerDataObject`) decline the task, the data object is marked as expired and will not be sent to additional workers.

Video frame job permission requirements

When you create a video frame labeling job, in addition to the permission requirements found in Assign IAM Permissions to Use Ground Truth, you must add a CORS policy to your S3 bucket that contains your input manifest file.

CORS permission policy for your S3 bucket

When you create a video frame labeling job, you specify buckets in S3 where your input data and manifest file are located and where your output data will be stored. These buckets may be the same. You must attach the following Cross-origin resource sharing (CORS) policy to your input and output buckets. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

JSON

```
[
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
```

```
            "GET",
            "HEAD",
            "PUT"
        ],
        "AllowedOrigins": [
            "*"
        ],
        "ExposeHeaders": [
            "Access-Control-Allow-Origin"
        ],
        "MaxAgeSeconds": 3000
    }
]
```

XML

```
<?xml version="1.0" encoding="UTF-8"?>
<CORSConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
<CORSRule>
    <AllowedOrigin>*</AllowedOrigin>
    <AllowedMethod>GET</AllowedMethod>
    <AllowedMethod>HEAD</AllowedMethod>
    <AllowedMethod>PUT</AllowedMethod>
    <MaxAgeSeconds>3000</MaxAgeSeconds>
    <ExposeHeader>Access-Control-Allow-Origin</ExposeHeader>
    <AllowedHeader>*</AllowedHeader>
</CORSRule>
</CORSConfiguration>
```

To learn how to add a CORS policy to an S3 bucket, see How do I add cross-domain resource sharing with CORS? in the Amazon Simple Storage Service User Guide.

Worker Instructions

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

This topic provides an overview of the Ground Truth worker portal and the tools available to complete your video frame labeling task. First, select the type of task you are working on from **Topics**.

> **Important**
>
> It is recommended that you complete your task using a Google Chrome or Firefox web browser.

For adjustment jobs, select the original labeling job task type that produced the labels you are adjusting. Review and adjust the labels in your task as needed.

Topics

- Navigate the UI
- Bulk Edit Label and Frame Attributes
- Tool Guide
- Icons Guide
- Shortcuts
- Understand Release, Stop and Resume, and Decline Task Options

- Video Frame Object Detection Tasks

Navigate the UI

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can navigate between video frames using the navigation bar in the bottom-left corner of your UI.

Use the play button to automatically move through the entire sequence of frames.

Use the next frame and previous frame buttons to move forward or back one frame at a time. You can also input a frame number to navigate to that frame.

You can zoom in to and out of all video frames. Once you have zoomed into a video frame, you can move around in that frame using the move icon. When you set a new view in a single video frame by zooming and moving within that frame, all video frames are set to the same view. You can reset all video frames to their original view using the fit screen icon. For additional view options, see Icons Guide.

When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task. Additionally, select **More instructions** and review these instructions.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate video frames and use the tools provided.
- **Help** – Use this option to refer back to this documentation.

Bulk Edit Label and Frame Attributes

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can bulk edit label attributes and frame attributes (attributes).

When you bulk edit an attribute, you specify one or more ranges of frames that you want to apply the edit to. The attribute you select is edited in all frames in that range, including the start and end frames you specify. When you bulk edit label attributes, the range you specify *must* contain the label that the label attribute is attached to. If you specify frames that do not contain this label, you will receive an error.

To bulk edit an attribute you *must* specify the desired value for the attribute first. For example, if you want to change an attribute from *Yes* to *No*, you must select *No*, and then perform the bulk edit.

You can also specify a new value for an attribute that has not been filled in and then use the bulk edit feature to fill in that value in multiple frames. To do this, select the desired value for the attribute and complete the following procedure.

To bulk edit a label or attribute:

1. Use your mouse to right click the attribute you want to bulk edit.
2. Specify the range of frames you want to apply the bulk edit to using a dash (-) in the text box. For example, if you want to apply the edit to frames one through ten, enter `1-10`. If you want to apply the edit to frames two to five, eight to ten and twenty enter `2-5,8-10,20`.
3. Select **Confirm**.

If you get an error message, verify that you entered a valid range and that the label associated with the label attribute you are editing (if applicable) exists in all frames specified.

You can quickly add a label to all previous or subsequent frames using the **Duplicate to previous frames** and **Duplicate to next frames** options in the **Label** menu at the top of your screen.

Tool Guide

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Your task will include one or more tools. The tool provided dictates the type of annotations you will create to identify and track objects. Use the following table to learn more about each tool provided.

Tool	Icon	Action	Description
Bounding box		Add a bounding box annotation.	Choose this icon to add a bounding box.

Tool	Icon	Action	Description
			Each bounding box you add is associate d with the category you choose from the Label category drop down menu. Select the bounding box or its associated label to adjust it.
Predict next		Predict bounding boxes in the next frame.	Select a bounding box, and then choose this icon to predict the location of that box in the next frame. You can select the icon multiple times in a row to automatically detect the location of box in multiple frames. For example, select this icon 5 times to predict the location of a bounding box in the next 5 frames.

Tool	Icon	Action	Description
Keypoint		Add a keypoint annotation.	Choose this icon to add a keypoint. Click on an object the image to place the keypoint at that location. Each keypoint you add is associated with the category you choose from the Label category drop down menu. Select a keypoint or its associated label to adjust it.

Tool	Icon	Action	Description
Polyline		Add a polyline annotation.	Choose this icon to add a polyline. To add a polyline, continuously click around the object of interest to add new points. To stop drawing a polyline, select the last point that you placed a second time (this point will be green), or press **Enter** on your keyboard. Each point added to the polyline is connected to the previous point by a line. The polyline does not have to be closed (the start point and end point do not have to be the same) and there are no restrictions on the angles formed between lines. Each polyline you add is associated with the category you choose from the Label category drop down menu. Select

Tool	Icon	Action	Description
			the polyline or its associated label to adjust it.

Tool	Icon	Action	Description
Polygon		Add a polygon annotation.	Choose this icon to add a polygon. To add a polygon, continuously click around the object of interest to add new points. To stop drawing the polygon, select the start point (this point will be green). A polygon is a closed shape defined by a series of points that you place. Each point added to the polygon is connected to the previous point by a line and there are no restrictions on the angles formed between lines. The start and end point must be the same. Each polygon you add is associated with the category you choose from the Label category drop down menu. Select the polygon or its associated label to adjust it.

Tool	Icon	Action	Description
Copy to Next		Copy annotations to the next frame.	If one or more annotations are selected in the current frame, those annotations are copied to the next frame. If no annotations are selected, all annotations in the current frame will be copied to the next frame.
Copy to All		Copy annotations to all subsequent frames.	If one or more annotations are selected in the current frame, those annotations are copied to all subsequent frames. If no annotations are selected, all annotations in the current frame will be copied to all subsequent frames.

Icons Guide

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use this table to learn about the icons you see in your UI. You can automatically select some of these icons using the keyboard shortcuts found in the **Shortcuts** menu.

Icon	Action	Description
	brightness	Choose this icon to adjust the brightness of all video frames.
	contrast	Choose this icon to adjust the contrast of all video frames.
	zoom in	Choose this icon to zoom into all of the video frames.
	zoom out	Choose this icon to zoom out of all of the video frames.
	move screen	After you've zoomed into a video frame, choose this icon to move around in that video frame. You can move around the video frame using your mouse by clicking and dragging the frame in the direction you want it to move. This will change the view in all view frames.
	fit screen	Reset all video frames to their original position.
	undo	Undo an action. You can use this icon to remove a bounding box that you just added, or to undo an adjustment you made to a bounding box.

Icon	Action	Description
	redo	Redo an action that was undone using the undo icon.
	delete label	Delete a label. This will delete the bounding box associated with the label in a single frame.
	show or hide label	Select this icon to show a label that has been hidden. If this icon has a slash through it, select it to hide the label.
	edit label	Select this icon to open the **Edit instance** menu. Use this menu to edit a label category, ID, and to add or edit label attributes.

Shortcuts

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

The keyboard shortcuts listed in the **Shortcuts** menu can help you quickly select icons, undo and redo annotations, and use tools to add and edit annotations. For example, once you add a bounding box, you can use **P** to quickly predict the location of that box in subsequent frames.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands.

Understand Release, Stop and Resume, and Decline Task Options

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as unclear video frame images or an issue with the UI. If you decline a task, you will not be able to return to the task.
- **Release Task**: Use this option to release a task and allow others to work on it. When you release a task, you loose all work done on that task and other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.
- **Stop and resume later**: You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and resume later**. When you select this button and then select **Confirm**, you are returned to the worker portal, and the task status is **Stopped**. You can select the same task to resume work on it.

  Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks much be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.

Saving Your Work and Submitting

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You should periodically save your work using the **Save** button. Ground Truth will automatically save your work ever 15 minutes.

When you open a task, you must complete your work on it before pressing **Submit**.

Video Frame Object Tracking Tasks

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

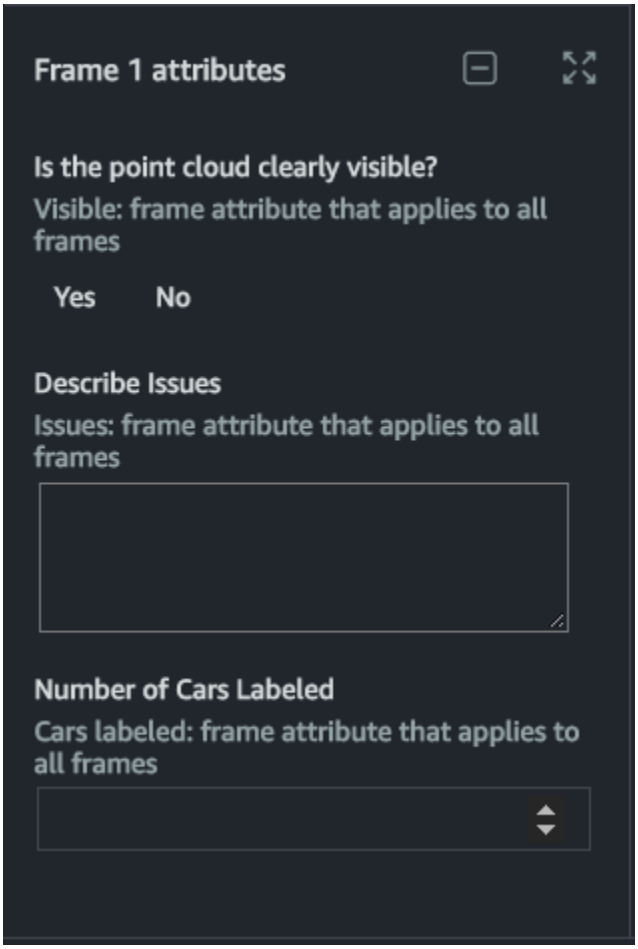
Video frame object tracking tasks require you to track the movement of objects across video frames. A video frame is a still image from a video scene. You can use the worker UI to navigate between video frames and use the tools provided to identify unique objects and track their movement from one from to the next. Use the following topics to learn how to navigate your worker UI, use the tools provided, and complete your task.

It is recommended that you complete your task using a Google Chrome or Firefox web browser.

> **Important**
>
> If you see annotations have already been added to one or more video frames when you open your task, adjust those annotations and add additional annotations as needed.

Topics

- Your Task



Your Task

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you work on a video frame object tracking task, you need to select a category from the **Label category** menu on the right side of your worker portal to start annotating. After you've chosen a category, use the tools provided to annotate the objects that the category applies to. This annotation will be associated with a unique label ID that should only be used for that object. Use this same label ID to create additional annotations for the same object in all of the video frames that it appears in. Refer to Tool Guide to learn more about the tools provided.

After you've added a label, you may see a downward pointing arrow next to the label in the **Labels** menu. Select this arrow and then select one option for each label attribute you see to provide more information about that label.

You may see frame attributes under the **Labels** menu. These attributes will appear on each frame in your task. Use these attribute prompts to enter additional information about each frame.

After you've added a label, you can quickly add and edit a label category attribute value by using the downward pointing arrow next to the label in the **Labels** menu. If you select the pencil icon next to the label in the **Labels** menu, the **Edit instance** menu will appear. You can edit the label ID, label category, and label category attributes using this menu.

To edit an annotation, select the label of the annotation that you want to edit in the **Labels** menu or select the annotation in the frame. When you edit or delete an annotation, the action will only modify the annotation in a single frame.

If you are working on a task that includes a bounding box tool, use the predict next icon to predict the location of all bounding boxes that you have drawn in a frame in the next frame. If you select a single box and then select the predict next icon, only that box will be predicted in the next frame. If you have not added any boxes to the current frame, you will receive an error. You must add at least one box to the frame before using this feature.

After you've used the predict next icon, review the location of each box in the next frame and make adjustments to the box location and size if necessary.

For all other tools, you can use the **Copy to next** and **Copy to all** tools to copy your annotations to the next or all frames respectively.

Video Frame Object Detection Tasks

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

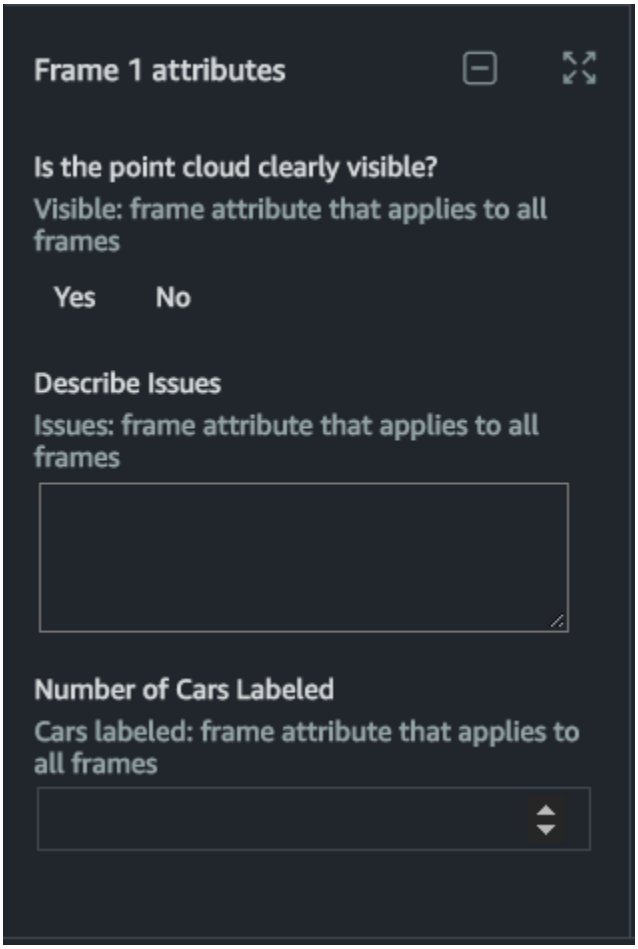
Video frame object detection tasks required you to classify and identify the location of objects in video frames using annotations. A video frame is a still image from a video scene. You can use the worker UI to navigate between video frames and create annotations to identify objects of interest. Use the following topics to learn how to navigate your worker UI, use the tools provided, and complete your task.

It is recommended that you complete your task using a Google Chrome web browser.

> **Important**
>
> If you see annotations have already been added to one or more video frames when you open your task, adjust those annotations and add additional annotations as needed.

Topics

- Your Task



Your Task

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you work on a video frame object detection task, you need to select a category from the **Label category** menu on the right side of your worker portal to start annotating. After you've chosen a category, draw annotations around objects that this category applies to. To learn more about the tools you see in your worker UI, refer to the Tool Guide.

After you've added a label, you may see a downward pointing arrow next to the label in the **Labels** menu. Select this arrow and then select one option for each label attribute you see to provide more information about that label.

You may see frame attributes under the **Labels** menu. These attributes will appear on each frame in your task. Use these attribute prompts to enter additional information about each frame.

To edit an annotation, select the label of the annotation that you want to edit in the **Labels** menu or select the annotation in the frame. When you edit or delete an annotation, the action will only modify the annotation in a single frame.

If you are working on a task that includes a bounding box tool, use the predict next icon to predict the location of all bounding boxes that you have drawn in a frame in the next frame. If you select a

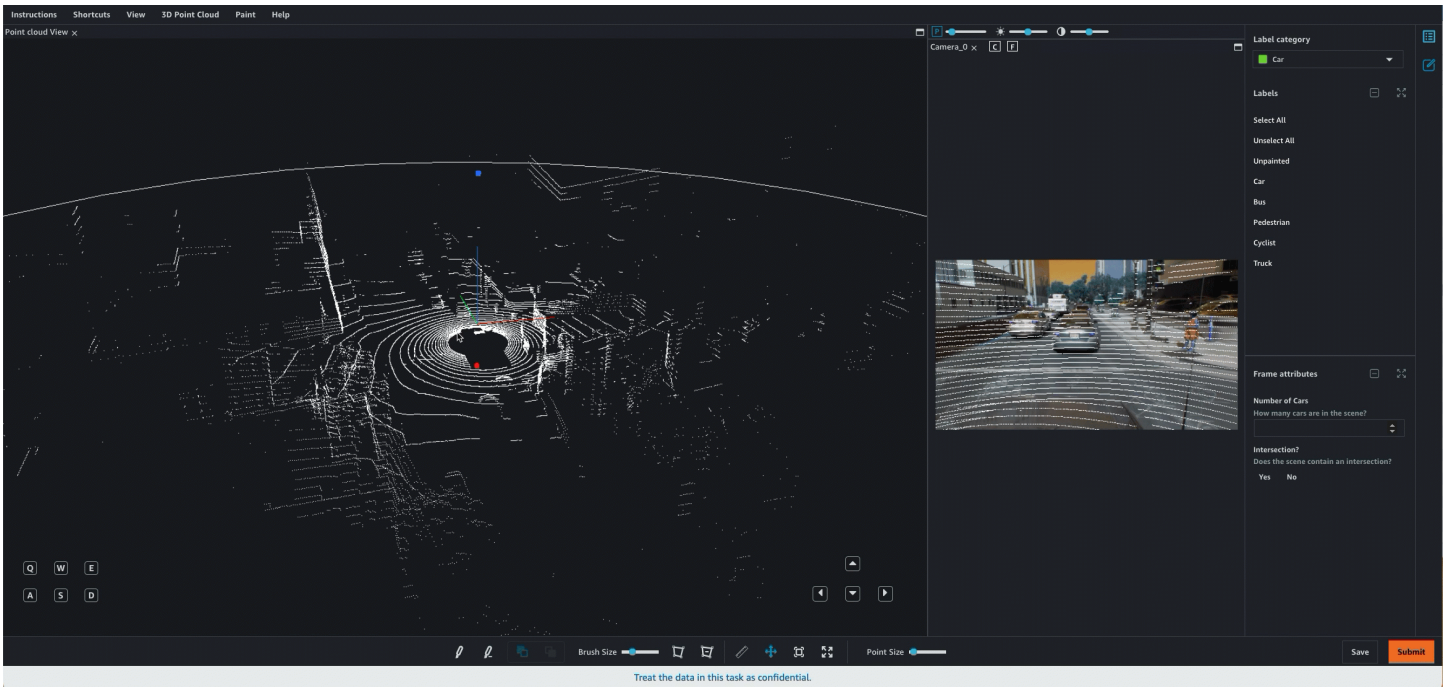
single box and then select the predict next icon, only that box will be predicted in the next frame. If you have not added any boxes to the current frame, you will receive an error. You must add at least one box to the frame before using this feature.

> **Note**
>
> The predict next feature will not overwrite manually created annotations. It will only add annotations. If you use predict next and as a result have more than one bounding box around a single object, delete all but one box. Each object should only be identified with a single box.

After you've used the predict next icon, review the location of each box in the next frame and make adjustments to the box location and size if necessary.

For all other tools, you can use the **Copy to next** and **Copy to all** tools to copy your annotations to the next or all frames respectively.

Use Ground Truth to Label 3D Point Clouds



> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Create a 3D point cloud labeling job to have workers label objects in 3D point clouds generated from 3D sensors like Light Detection and Ranging (LiDAR) sensors and depth cameras, or generated from 3D reconstruction by stitching images captured by an agent like a drone.

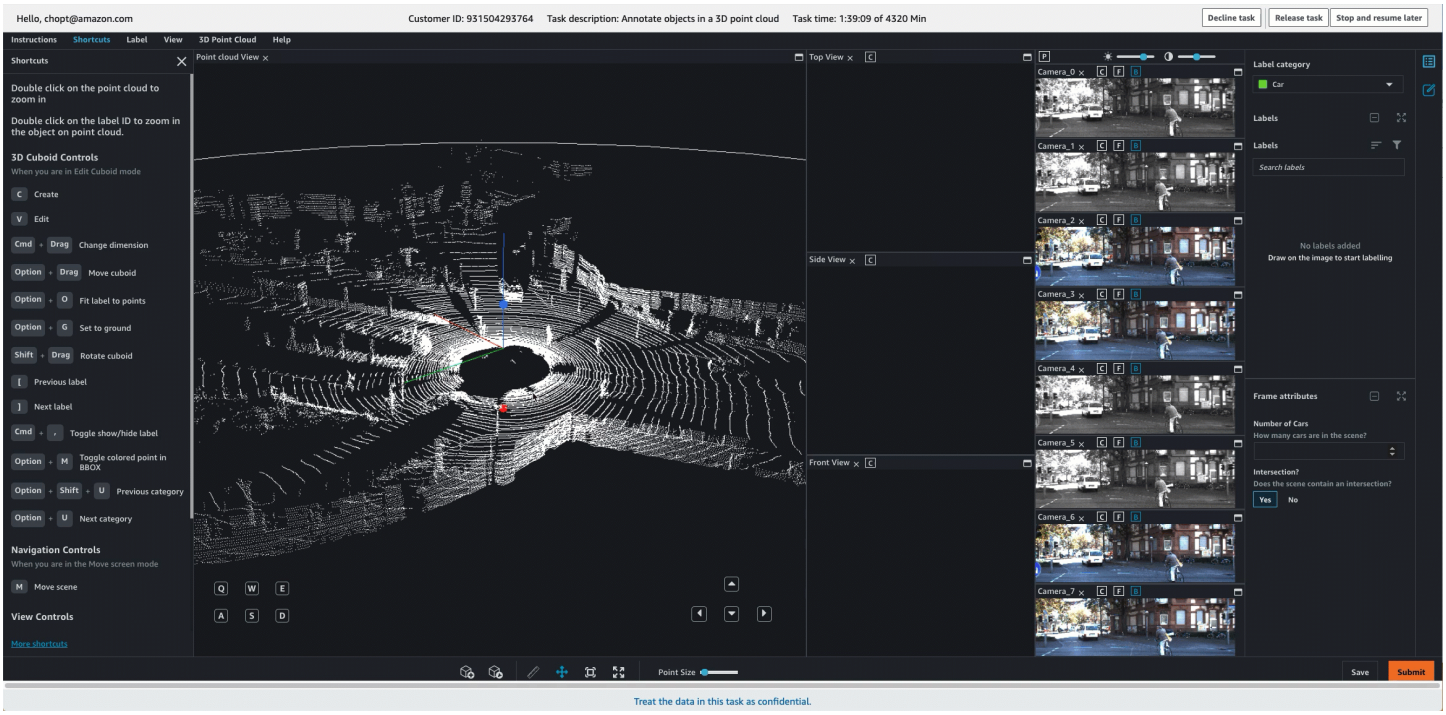
3D Point Clouds

Point clouds are made up of three-dimensional (3D) visual data that consists of points. Each point is described using three coordinates, typically `x`, `y`, and `z`. To add color or variations in point intensity to the point cloud, points may be described with additional attributes, such as `i` for intensity or values for the red (`r`), green (`g`), and blue (`b`) 8-bit color channels. When you create a Ground Truth 3D point cloud labeling job, you can provide point cloud and, optionally, sensor fusion data.

The following image shows a single, 3D point cloud scene rendered by Ground Truth and displayed in the semantic segmentation worker UI.

LiDAR

A Light Detection and Ranging (LiDAR) sensor is a common type of sensor used to collect measurements that are used to generate point cloud data. LiDAR is a remote sensing method that uses light in the form of a pulsed laser to measure the distances of objects from the sensor. You can provide 3D point cloud data generated from a LiDAR sensor for a Ground Truth 3D point cloud labeling job using the raw data formats described in Accepted Raw 3D Data Formats.



Sensor Fusion

Ground Truth 3D point cloud labeling jobs include a sensor fusion feature that supports video camera sensor fusion for all task types. Some sensors come with multiple LiDAR devices and video cameras that capture images and associate them with a LiDAR frame. To help annotators visually complete your tasks with high confidence, you can use the Ground Truth sensor fusion feature to project annotations (labels) from a 3D point cloud to 2D camera images and vice versa using 3D scanner (such as LiDAR) extrinsic matrix and camera extrinsic and intrinsic matrices. To learn more, see Sensor Fusion.

Label 3D Point Clouds

Ground Truth provides a user interface (UI) and tools that workers use to label or *annotate* 3D point clouds. When you use the object detection or semantic segmentation task types, workers can annotate a single point cloud frame. When you use object tracking, workers annotate a sequence of frames. You can use object tracking to track object movement across all frames in a sequence.

The following demonstrates how a worker would use the Ground Truth worker portal and tools to annotate a 3D point cloud for an object detection task. For similar visual examples of other task types, see 3D Point Cloud Task types.

Assistive Labeling Tools for Point Cloud Annotation

Ground Truth offers assistive labeling tools to help workers complete your point cloud annotation tasks faster and with more accuracy. For details about assistive labeling tools that are included in the worker UI for each task type, select a task type and refer to the **View the Worker Task Interface** section of that page.

Next Steps

You can create six types of tasks when you use Ground Truth 3D point cloud labeling jobs. Use the topics in 3D Point Cloud Task types to learn more about these *task types* and to learn how to create a labeling job using the task type of your choice.

The 3D point cloud labeling job is different from other Ground Truth labeling modalities. Before creating a labeling job, we recommend that you read 3D point cloud labeling jobs overview. Additionally, review input data quotas in 3D Point Cloud and Video Frame Labeling Job Quotas.

3D Point Cloud Task types

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use Ground Truth 3D point cloud labeling modality for a variety of use cases. The following list briefly describes each 3D point cloud task type. For additional details and instructions on how to create a labeling job using a specific task type, select the task type name to see its task type page.

- 3D point cloud object detection – Use this task type when you want workers to locate and classify objects in a 3D point cloud by adding and fitting 3D cuboids around objects.
- 3D point cloud object tracking – Use this task type when you want workers to add and fit 3D cuboids around objects to track their movement across a sequence of 3D point cloud frames. For example, you can use this task type to ask workers to track the movement of vehicles across multiple point cloud frames.

- 3D point cloud semantic segmentation – Use this task type when you want workers to create a point-level semantic segmentation mask by painting objects in a 3D point cloud using different colors where each color is assigned to one of the classes you specify.
- 3D point cloud adjustment task types – Each of the task types above has an associated *adjustment* task type that you can use to audit and adjust annotations generated from a 3D point cloud labeling job. Refer to the task type page of the associated type to learn how to create an adjustment labeling job for that task.

Classify objects in a 3D point cloud with object detection

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

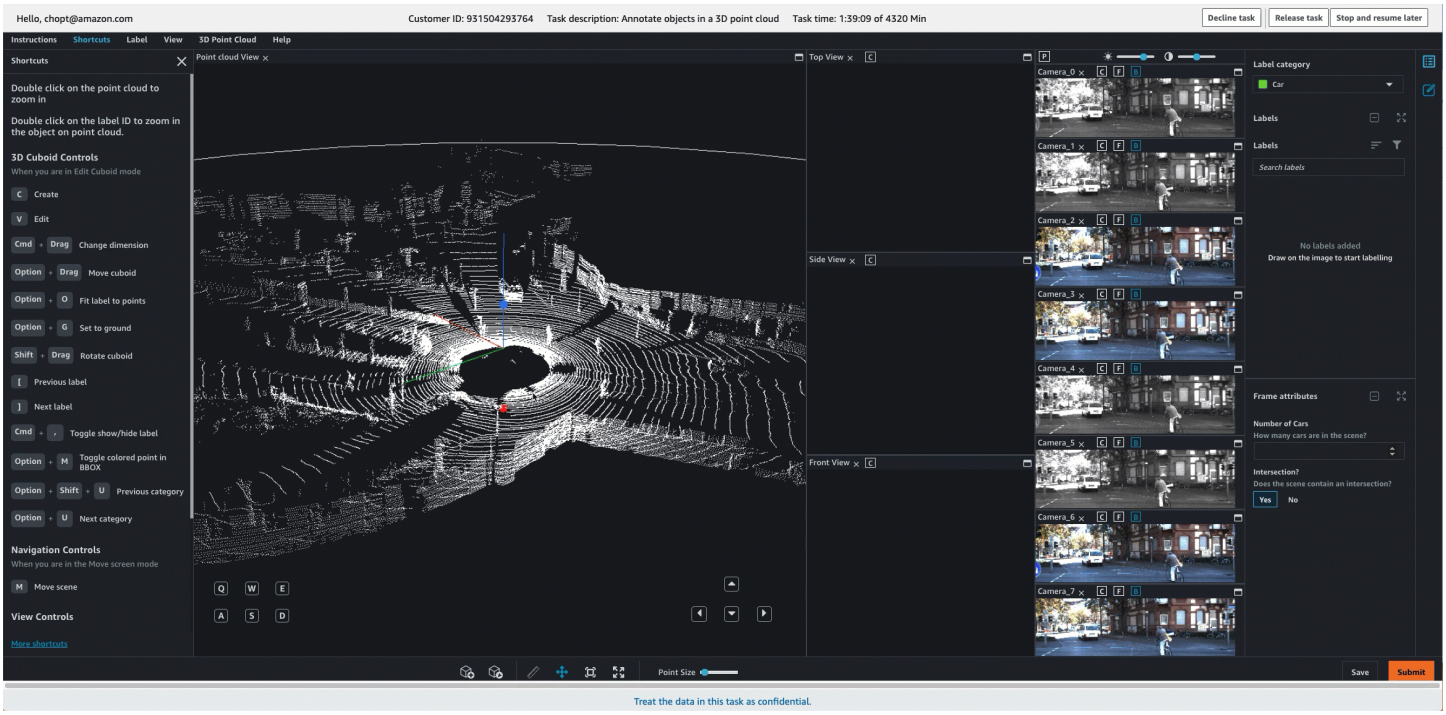
Use this task type when you want workers to classify objects in a 3D point cloud by drawing 3D cuboids around objects. For example, you can use this task type to ask workers to identify different types of objects in a point cloud, such as cars, bikes, and pedestrians. The following page gives important information about the labeling job, as well as steps to create one.

For this task type, the *data object* that workers label is a single point cloud frame. Ground Truth renders a 3D point cloud using point cloud data you provide. You can also provide camera data to give workers more visual information about scenes in the frame, and to help workers draw 3D cuboids around objects.

Ground Truth providers workers with tools to annotate objects with 9 degrees of movement (x,y,z,rx,ry,rz,l,w,h) in three dimensions in both 3D scene and projected side views (top, side, and back). If you provide sensor fusion information (like camera data), when a worker adds a cuboid to identify an object in the 3D point cloud, the cuboid shows up and can be modified in the 2D images. After a cuboid has been added, all edits made to that cuboid in the 2D or 3D scene are projected into the other view.

You can create a job to adjust annotations created in a 3D point cloud object detection labeling job using the 3D point cloud object detection adjustment task type.

If you are a new user of the Ground Truth 3D point cloud labeling modality, we recommend you review 3D point cloud labeling jobs overview. This labeling modality is different from other Ground Truth task types, and this page provides an overview of important details you should be aware of when creating a 3D point cloud labeling job.



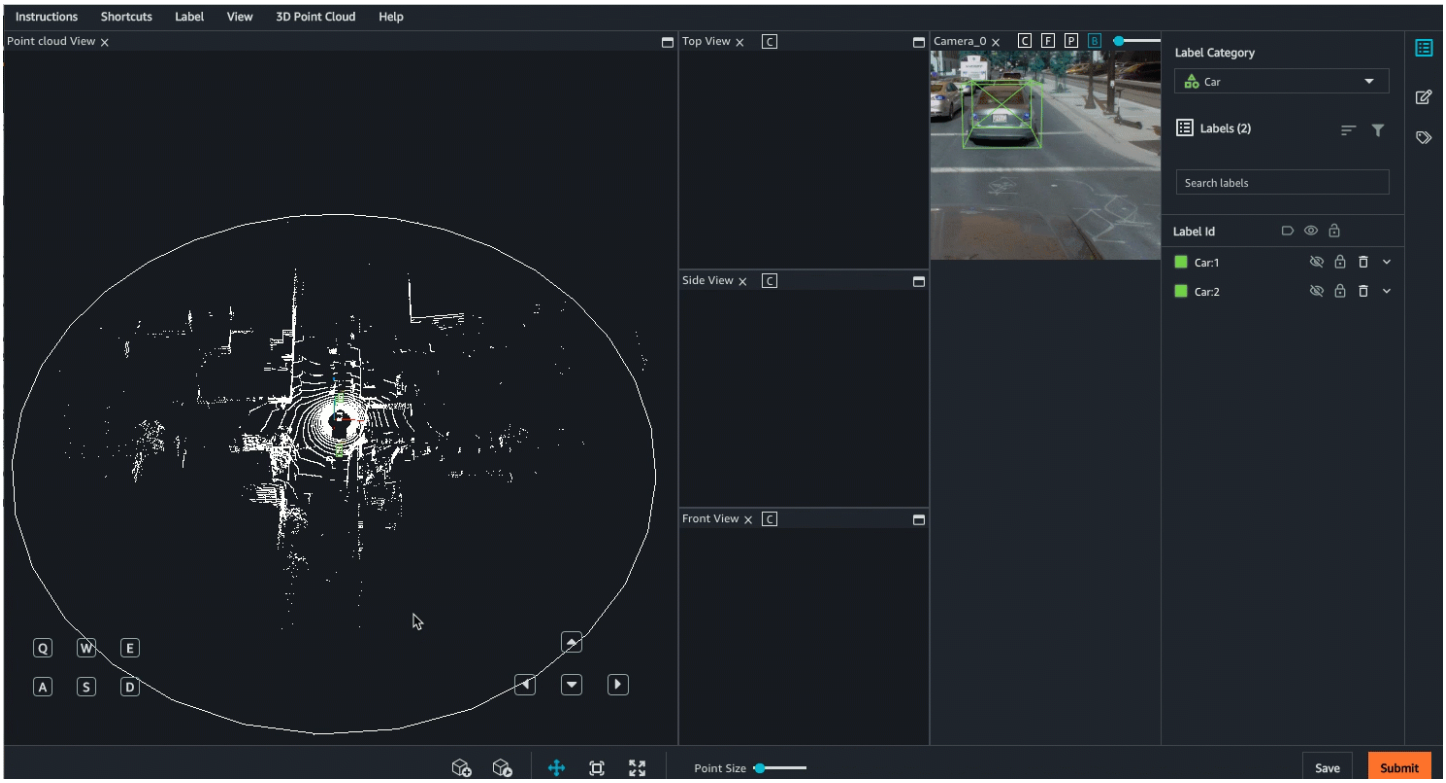
Topics

- View the Worker Task Interface
- Create a 3D Point Cloud Object Detection Labeling Job
- Create a 3D Point Cloud Object Detection Adjustment or Verification Labeling Job
- Output Data Format

View the Worker Task Interface

Ground Truth provides workers with a web portal and tools to complete your 3D point cloud object detection annotation tasks. When you create the labeling job, you provide the Amazon Resource Name (ARN) for a pre-built Ground Truth worker UI in the `HumanTaskUiArn` parameter. When you create a labeling job using this task type in the console, this worker UI is automatically used. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new user, it is recommended that you create a labeling job using the console to ensure your label attributes, point cloud frames, and if applicable, images, appear as expected.

The following is a GIF of the 3D point cloud object detection worker task interface. If you provide camera data for sensor fusion in the world coordinate system, images are matched up with scenes in the point cloud frame. These images appear in the worker portal as shown in the following GIF.



Worker can navigate in the 3D scene using their keyboard and mouse. They can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once a worker places a cuboid in the 3D scene, a side-view will appear with the three projected side views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.

Additional view options and features are available in the **View** menu in the worker UI. See the worker instruction page for a comprehensive overview of the Worker UI.

Assistive Labeling Tools

Ground Truth helps workers annotate 3D point clouds faster and more accurately using machine learning and computer vision powered assistive labeling tools for 3D point cloud object tracking tasks. The following assistive labeling tools are available for this task type:

- **Snapping** – Workers can add a cuboid around an object and use a keyboard shortcut or menu option to have Ground Truth's autofit tool snap the cuboid tightly around the object.
- **Set to ground** – After a worker adds a cuboid to the 3D scene, the worker can automatically snap the cuboid to the ground. For example, the worker can use this feature to snap a cuboid to the road or sidewalk in the scene.
- **Multi-view labeling** – After a worker adds a 3D cuboid to the 3D scene, a side panel displays front, side, and top perspectives to help the worker adjust the cuboid tightly around the object. In all of these views, the cuboid includes an arrow that indicates the orientation, or heading of the object. When the worker adjusts the cuboid, the adjustment will appear in real time on all of the views (that is, 3D, top, side, and front).

- **Sensor fusion** – If you provide data for sensor fusion, workers can adjust annotations in the 3D scenes and in 2D images, and the annotations will be projected into the other view in real time. Additionally, workers will have the option to view the direction the camera is facing and the camera frustum.
- **View options** – Enables workers to easily hide or view cuboids, label text, a ground mesh, and additional point attributes like color or intensity. Workers can also choose between perspective and orthogonal projections.

Create a 3D Point Cloud Object Detection Labeling Job

You can create a 3D point cloud labeling job using the SageMaker AI console or API operation, `CreateLabelingJob`. To create a labeling job for this task type you need the following:

- A single-frame input manifest file. To learn how to create this type of manifest file, see Create a Point Cloud Frame Input Manifest File. If you are a new user of Ground Truth 3D point cloud labeling modalities, you may also want to review Accepted Raw 3D Data Formats.
- A work team from a private or vendor workforce. To learn how to create workforces and work teams, see Workforces.

Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth.

Use one of the following sections to learn how to create a labeling job using the console or an API.

Create a Labeling Job (Console)

You can follow the instructions Create a Labeling Job (Console) in order to learn how to create a 3D point cloud object detection labeling job in the SageMaker AI console. While you are creating your labeling job, be aware of the following:

- Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File.
- Optionally, you can provide label category and frame attributes. Workers can assign one or more of these attributes to annotations to provide more information about that object. For example, you might want to use the attribute *occluded* to have workers identify when an object is partially obstructed.
- Automated data labeling and annotation consolidation are not supported for 3D point cloud labeling tasks.

- 3D point cloud object detection labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs when you select your work team (up to 7 days, or 604800 seconds).

Create a Labeling Job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Create a Labeling Job (API), provides an overview of the `CreateLabelingJob` operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for `HumanTaskUiArn`. Use `arn:aws:sagemaker:<region>:394669845002:human-task-ui/PointCloudObjectDetection`. Replace *<region>* with the Amazon Region you are creating the labeling job in.

  There should not be an entry for the `UiTemplateS3Uri` parameter.
- Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File.
- You specify your labels, label category and frame attributes, and worker instructions in a label category configuration file. To learn how to create this file, see Labeling category configuration file with label category and frame attributes reference.
- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the Amazon Region you use to create your labeling job.
  - To find the pre-annotation Lambda ARN, refer to `PreHumanTaskLambdaArn`. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be `arn:aws:lambda:us-east-1:432418664414:function:PRE-3DPointCloudObjectDetection`.
  - To find the post-annotation Lambda ARN, refer to `AnnotationConsolidationLambdaArn`. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be `arn:aws:lambda:us-east-1:432418664414:function:ACS-3DPointCloudObjectDetection`.

- The number of workers specified in `NumberOfHumanWorkersPerDataObject` must be 1.
- Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in `LabelingJobAlgorithmsConfig`.
- 3D point cloud object detection labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in `TaskTimeLimitInSeconds` (up to 7 days, or 604,800 seconds).

Create a 3D Point Cloud Object Detection Adjustment or Verification Labeling Job

You can create an adjustment or verification labeling job using the Ground Truth console or `CreateLabelingJob` API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Label verification and adjustment.

When you create an adjustment labeling job, your input data to the labeling job can include labels, and yaw, pitch, and roll measurements from a previous labeling job or external source. In the adjustment job, pitch, and roll will be visualized in the worker UI, but cannot be modified. Yaw is adjustable.

Ground Truth uses Tait-Bryan angles with the following intrinsic rotations to visualize yaw, pitch and roll in the worker UI. First, rotation is applied to the vehicle according to the z-axis (yaw). Next, the rotated vehicle is rotated according to the intrinsic y'-axis (pitch). Finally, the vehicle is rotated according to the intrinsic x''-axis (roll).

Output Data Format

When you create a 3D point cloud object detection labeling job, tasks are sent to workers. When these workers complete their tasks, labels are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (LabelingJobStatus) is `Completed`.

If you are a new user of Ground Truth, see Labeling job output data to learn more about the Ground Truth output data format. To learn about the 3D point cloud object detection output data format, see 3D point cloud object detection output.

Understand the 3D point cloud object tracking task type

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use this task type when you want workers to add and fit 3D cuboids around objects to track their movement across 3D point cloud frames. For example, you can use this task type to ask workers to track the movement of vehicles across multiple point cloud frames.

For this task type, the data object that workers label is a sequence of point cloud frames. A *sequence* is defined as a temporal series of point cloud frames. Ground Truth renders a series of 3D point cloud visualizations using a sequence you provide and workers can switch between these 3D point cloud frames in the worker task interface.

Ground Truth provides workers with tools to annotate objects with 9 degrees of rotation (x,y,z,rx,ry,rz,l,w,h) in three dimensions in both 3D scene and projected side views (top, side, and back). When a worker draws a cuboid around an object, that cuboid is given a unique ID, for example `Car:1` for one car in the sequence and `Car:2` for another. Workers use that ID to label the same object in multiple frames.

You can also provide camera data to give workers more visual information about scenes in the frame, and to help workers draw 3D cuboids around objects. When a worker adds a 3D cuboid to identify an object in either the 2D image or the 3D point cloud, and the cuboid shows up in the other view.

You can adjust annotations created in a 3D point cloud object detection labeling job using the 3D point cloud object tracking adjustment task type.

If you are a new user of the Ground Truth 3D point cloud labeling modality, we recommend you review 3D point cloud labeling jobs overview. This labeling modality is different from other Ground Truth task types, and this page provides an overview of important details you should be aware of when creating a 3D point cloud labeling job.

The following topics explain how to create a 3D point cloud object tracking job, show what the worker task interface looks like (what workers see when they work on this task), and provide an

overview of the output data you get when workers complete their tasks. The final topic provides useful information for creating object tracking adjustment or verification labeling jobs.

Topics

- Create a 3D point cloud object tracking labeling job
- View the worker task interface for a 3D point cloud object tracking task

- Information for creating a 3D point cloud object tracking adjustment or verification labeling job

Create a 3D point cloud object tracking labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can create a 3D point cloud labeling job using the SageMaker AI console or API operation, `CreateLabelingJob`. To create a labeling job for this task type you need the following:

- A sequence input manifest file. To learn how to create this type of manifest file, see Create a Point Cloud Sequence Input Manifest. If you are a new user of Ground Truth 3D point cloud labeling modalities, we recommend that you review Accepted Raw 3D Data Formats.
- A work team from a private or vendor workforce. To learn how to create workforces and work teams, see Workforces.

Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth.

To learn how to create a labeling job using the console or an API, see the following sections.

Create a labeling job (console)

You can follow the instructions Create a Labeling Job (Console) in order to learn how to create a 3D point cloud object tracking labeling job in the SageMaker AI console. While you are creating your labeling job, be aware of the following:

- Your input manifest file must be a sequence manifest file. For more information, see Create a Point Cloud Sequence Input Manifest.
- Optionally, you can provide label category attributes. Workers can assign one or more of these attributes to annotations to provide more information about that object. For example, you might want to use the attribute *occluded* to have workers identify when an object is partially obstructed.
- Automated data labeling and annotation consolidation are not supported for 3D point cloud labeling tasks.
- 3D point cloud object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs when you select your work team (up to 7 days, or 604800 seconds).

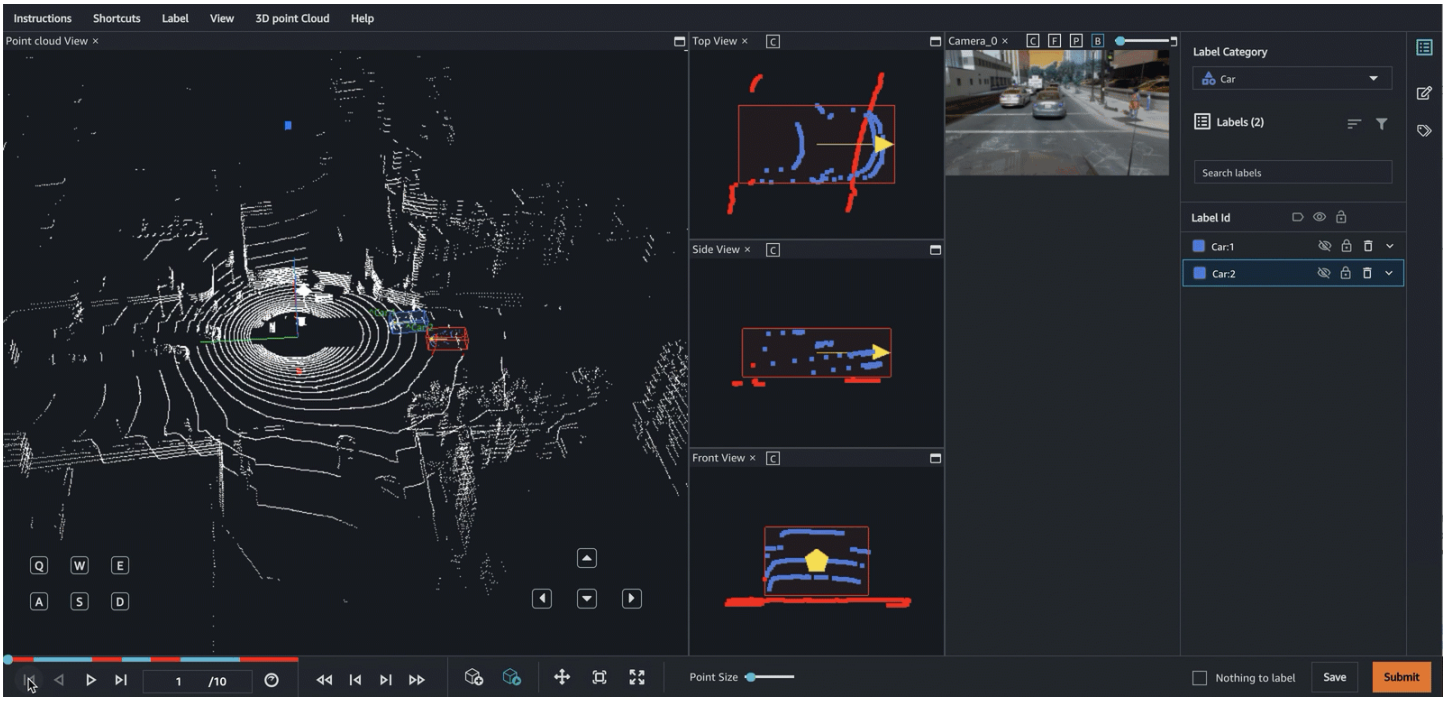
Create a labeling job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Create a Labeling Job (API) provides an overview of the `CreateLabelingJob` operation. Follow these instructions and do the following while you configure your request:

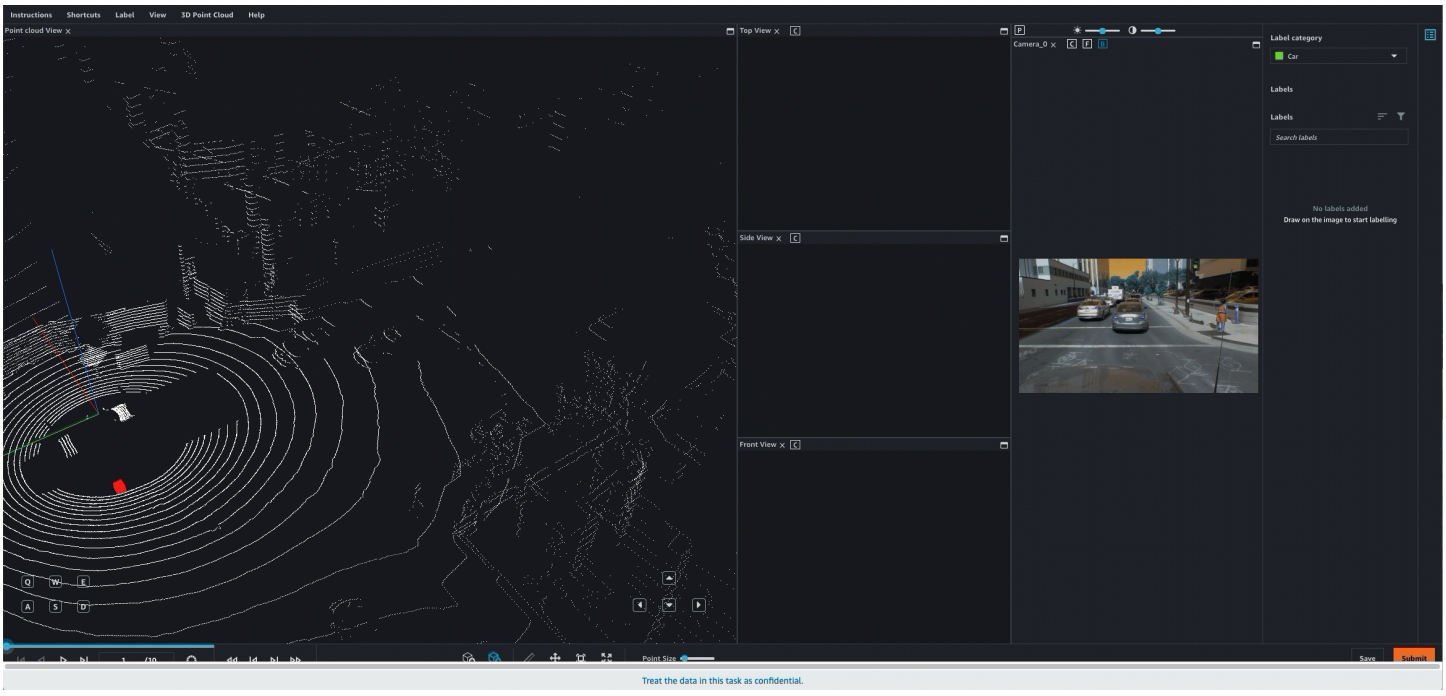
- You must enter an ARN for `HumanTaskUiArn`. Use `arn:aws:sagemaker:<region>:394669845002:human-task-ui/PointCloudObjectTracking`. Replace *<region>* with the Amazon Region you are creating the labeling job in.

  There should not be an entry for the `UiTemplateS3Uri` parameter.
- Your `LabelAttributeName` must end in `-ref`. For example, *ot-labels*`-ref`.
- Your input manifest file must be a point cloud frame sequence manifest file. For more information, see Create a Point Cloud Sequence Input Manifest.
- You specify your labels, label category and frame attributes, and worker instructions in a label category configuration file. For more information, see Labeling category configuration file with label category and frame attributes reference to learn how to create this file.



- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the Amazon Region you use to create your labeling job.
  - To find the pre-annotation Lambda ARN, refer to `PreHumanTaskLambdaArn`. Use the Region you are creating your labeling job in to find the correct ARN that ends with `PRE-3DPointCloudObjectTracking`.
  - To find the post-annotation Lambda ARN, refer to `AnnotationConsolidationLambdaArn`. Use the Region you are creating your labeling job in to find the correct ARN that ends with `ACS-3DPointCloudObjectTracking`.
- The number of workers specified in `NumberOfHumanWorkersPerDataObject` should be 1.
- Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in `LabelingJobAlgorithmsConfig`.
- 3D point cloud object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in `TaskTimeLimitInSeconds` (up to 7 days, or 604,800 seconds).

View the worker task interface for a 3D point cloud object tracking task

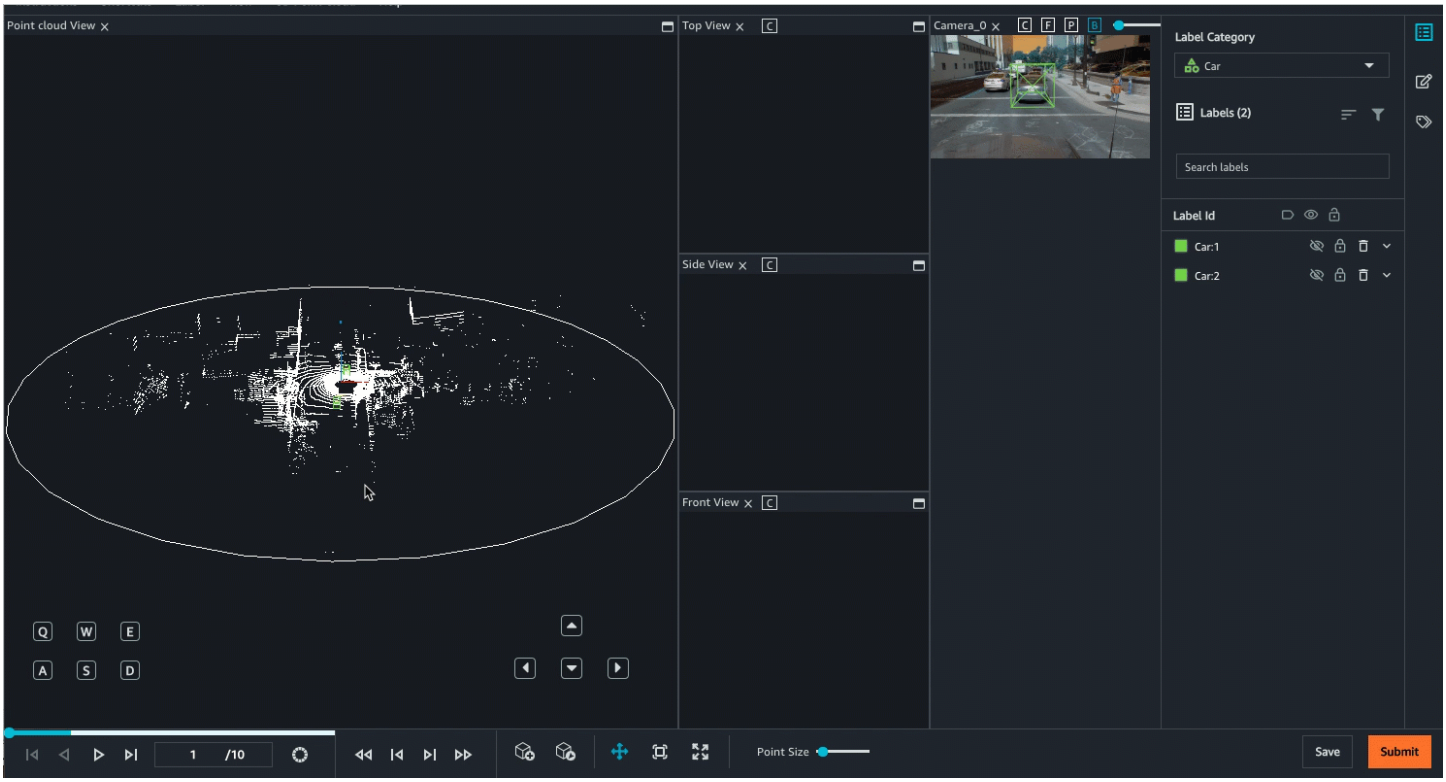


> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Ground Truth provides workers with a web portal and tools to complete your 3D point cloud object tracking annotation tasks. When you create the labeling job, you provide the Amazon Resource Name (ARN) for a pre-built Ground Truth UI in the `HumanTaskUiArn` parameter. When you create a labeling job using this task type in the console, this UI is automatically used. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new use, it is recommended that you create a labeling job using the console to ensure your label attributes, point cloud frames, and if applicable, images, appear as expected.

The following is a GIF of the 3D point cloud object tracking worker task interface and demonstrates how the worker can navigate the point cloud frames in the sequence. The annotating tools are a part of the worker task interface. They are not available for the preview interface.

Once workers add a single cuboid, that cuboid is replicated in all frames of the sequence with the same ID. Once workers adjust the cuboid in another frame, Ground Truth will interpolate the movement of that object and adjust all cuboids between the manually adjusted frames. The following GIF demonstrates this interpolation feature. In the navigation bar on the bottom-left, red-areas indicate manually adjusted frames.



If you provide camera data for sensor fusion, images are matched up with scenes in point cloud frames. These images appear in the worker portal as shown in the following GIF.

Worker can navigate in the 3D scene using their keyboard and mouse. They can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once a worker places a cuboids in the 3D scene, a side-view will appear with the three projected side views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.

Additional view options and features are available. See the worker instruction page for a comprehensive overview of the Worker UI.

Worker tools

Workers can navigate through the 3D point cloud by zooming in and out, and moving in all directions around the cloud using the mouse and keyboard shortcuts. If workers click on a point in the point cloud, the UI will automatically zoom into that area. Workers can use various tools to draw 3D cuboid around objects. For more information, see **Assistive Labeling Tools**.

After workers have placed a 3D cuboid in the point cloud, they can adjust these cuboids to fit tightly around cars using a variety of views: directly in the 3D cuboid, in a side-view featuring three zoomed-in perspectives of the point cloud around the box, and if you include images for sensor fusion, directly in the 2D image.

View options that enable workers to easily hide or view label text, a ground mesh, and additional point attributes. Workers can also choose between perspective and orthogonal projections.

Assistive Labeling Tools

Ground Truth helps workers annotate 3D point clouds faster and more accurately using UX, machine learning and computer vision powered assistive labeling tools for 3D point cloud object tracking tasks. The following assistive labeling tools are available for this task type:

- **Label autofill** – When a worker adds a cuboid to a frame, a cuboid with the same dimensions and orientation is automatically added to all frames in the sequence.
- **Label interpolation** – After a worker has labeled a single object in two frames, Ground Truth uses those annotations to interpolate the movement of that object between those two frames. Label interpolation can be turned on and off.
- **Bulk label and attribute management** – Workers can add, delete, and rename annotations, label category attributes, and frame attributes in bulk.
  - Workers can manually delete annotations for a given object before or after a frame. For example, a worker can delete all labels for an object after frame 10 if that object is no longer located in the scene after that frame.
  - If a worker accidentally bulk deletes all annotations for a object, they can add them back. For example, if a worker deletes all annotations for an object before frame 100, they can bulk add them to those frames.
  - Workers can rename a label in one frame and all 3D cuboids assigned that label are updated with the new name across all frames.
  - Workers can use bulk editing to add or edit label category attributes and frame attributes in multiple frames.

- **Snapping** – Workers can add a cuboid around an object and use a keyboard shortcut or menu option to have Ground Truth's autofit tool snap the cuboid tightly around the object's boundaries.
- **Fit to ground** – After a worker adds a cuboid to the 3D scene, the worker can automatically snap the cuboid to the ground. For example, the worker can use this feature to snap a cuboid to the road or sidewalk in the scene.
- **Multi-view labeling** – After a worker adds a 3D cuboid to the 3D scene, a side -panel displays front and two side perspectives to help the worker adjust the cuboid tightly around the object. Workers can annotation the 3D point cloud, the side panel and the adjustments appear in the other views in real time.
- **Sensor fusion** – If you provide data for sensor fusion, workers can adjust annotations in the 3D scenes and in 2D images, and the annotations will be projected into the other view in real time.
- **Auto-merge cuboids** – Workers can automatically merge two cuboids across all frames if they determine that cuboids with different labels actually represent a single object.
- **View options** – Enables workers to easily hide or view label text, a ground mesh, and additional point attributes like color or intensity. Workers can also choose between perspective and orthogonal projections.

Output data for a 3D point cloud object tracking labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you create a 3D point cloud object tracking labeling job, tasks are sent to workers. When these workers complete their tasks, their annotations are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (LabelingJobStatus) is `Completed`.

If you are a new user of Ground Truth, see Labeling job output data to learn more about the Ground Truth output data format. To learn about the 3D point cloud object tracking output data format, see 3D point cloud object tracking output.

Information for creating a 3D point cloud object tracking adjustment or verification labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can create an adjustment and verification labeling job using the Ground Truth console or `CreateLabelingJob` API. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Label verification and adjustment.

When you create an adjustment labeling job, your input data to the labeling job can include labels, and yaw, pitch, and roll measurements from a previous labeling job or external source. In the adjustment job, pitch, and roll will be visualized in the worker UI, but cannot be modified. Yaw is adjustable.

Ground Truth uses Tait-Bryan angles with the following intrinsic rotations to visualize yaw, pitch and roll in the worker UI. First, rotation is applied to the vehicle according to the z-axis (yaw). Next, the rotated vehicle is rotated according to the intrinsic y'-axis (pitch). Finally, the vehicle is rotated according to the intrinsic x''-axis (roll).

Understand the 3D point cloud semantic segmentation task type

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Semantic segmentation involves classifying individual points of a 3D point cloud into pre-specified categories. Use this task type when you want workers to create a point-level semantic segmentation mask for 3D point clouds. For example, if you specify the classes `car`, `pedestrian`, and `bike`, workers select one class at a time, and color all of the points that this class applies to the same color in the point cloud.

For this task type, the data object that workers label is a single point cloud frame. Ground Truth generates a 3D point cloud visualization using point cloud data you provide. You can also provide camera data to give workers more visual information about scenes in the frame, and to help workers paint objects. When a worker paints an object in either the 2D image or the 3D point cloud, the paint shows up in the other view.

You can also adjust or verify annotations created in a 3D point cloud object detection labeling job using the 3D point cloud semantic segmentation adjustment or labeling task type. To learn more about adjustment and verification labeling jobs, and to learn how create one, see Label verification and adjustment.

If you are a new user of the Ground Truth 3D point cloud labeling modality, we recommend you review 3D point cloud labeling jobs overview. This labeling modality is different from other Ground Truth task types, and this topic provides an overview of important details you should be aware of when creating a 3D point cloud labeling job.

The following topics explain how to create a 3D point cloud semantic segmentation job, show what the worker task interface looks like (what workers see when they work on this task), and provide an overview of the output data you get when workers complete their tasks.

Topics

- Create a 3D point cloud semantic segmentation labeling job
- View the worker task interface for a 3D point cloud semantic segmentation job
- Output data for a 3D point cloud semantic segmentation job

Create a 3D point cloud semantic segmentation labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can create a 3D point cloud labeling job using the SageMaker AI console or API operation, `CreateLabelingJob`. To create a labeling job for this task type you need the following:

- A single-frame input manifest file. To learn how to create this type of manifest file, see Create a Point Cloud Frame Input Manifest File. If you are a new user of Ground Truth 3D point cloud labeling modalities, we recommend that you review Accepted Raw 3D Data Formats.
- A work team from a private or vendor workforce. To learn how to create workforces and work teams, see Workforces.
- A label category configuration file. For more information, see Labeling category configuration file with label category and frame attributes reference.

Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth.

Use one of the following sections to learn how to create a labeling job using the console or an API.

Create a labeling job (console)

You can follow the instructions Create a Labeling Job (Console) in order to learn how to create a 3D point cloud semantic segmentation labeling job in the SageMaker AI console. While you are creating your labeling job, be aware of the following:

- Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File.
- Automated data labeling and annotation consolidation are not supported for 3D point cloud labeling tasks.
- 3D point cloud semantic segmentation labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs when you select your work team (up to 7 days, or 604800 seconds).

Create a labeling job (API)

This section covers details you need to know when you create a labeling job using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

The page, Create a Labeling Job (API), provides an overview of the `CreateLabelingJob` operation. Follow these instructions and do the following while you configure your request:

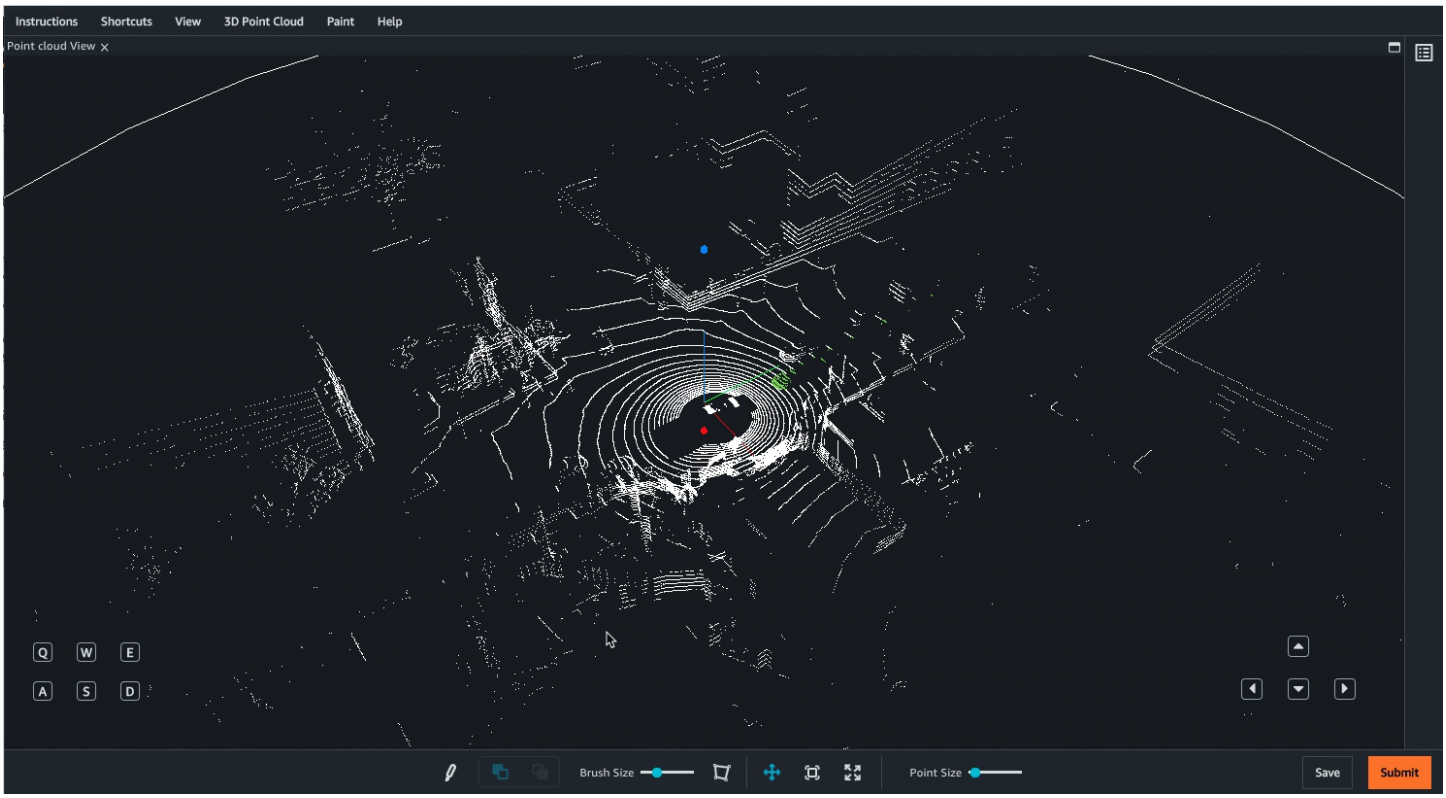
- You must enter an ARN for `HumanTaskUiArn`. Use `arn:aws:sagemaker:<region>:394669845002:human-task-ui/PointCloudSemanticSegmentation`. Replace *<region>* with the Amazon Region you are creating the labeling job in.

  There should not be an entry for the `UiTemplateS3Uri` parameter.
- Your `LabelAttributeName` must end in `-ref`. For example, *ss-labels*`-ref`.
- Your input manifest file must be a single-frame manifest file. For more information, see Create a Point Cloud Frame Input Manifest File.
- You specify your labels and worker instructions in a label category configuration file. See Labeling category configuration file with label category and frame attributes reference to learn how to create this file.
- You need to provide a pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the Amazon Region you use to create your labeling job.
  - To find the pre-annotation Lambda ARN, refer to `PreHumanTaskLambdaArn`. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be `arn:aws:lambda:us-east-1:432418664414:function:PRE-3DPointCloudSemanticSegmentation`.
  - To find the post-annotation Lambda ARN, refer to `AnnotationConsolidationLambdaArn`. Use the Region you are creating your labeling job in to find the correct ARN. For example, if you are creating your labeling job in us-east-1, the ARN will be `arn:aws:lambda:us-east-1:432418664414:function:ACS-3DPointCloudSemanticSegmentation`.
- The number of workers specified in `NumberOfHumanWorkersPerDataObject` should be 1.
- Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in `LabelingJobAlgorithmsConfig`.
- 3D point cloud semantic segmentation labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in `TaskTimeLimitInSeconds` (up to 7 days, or 604800 seconds).

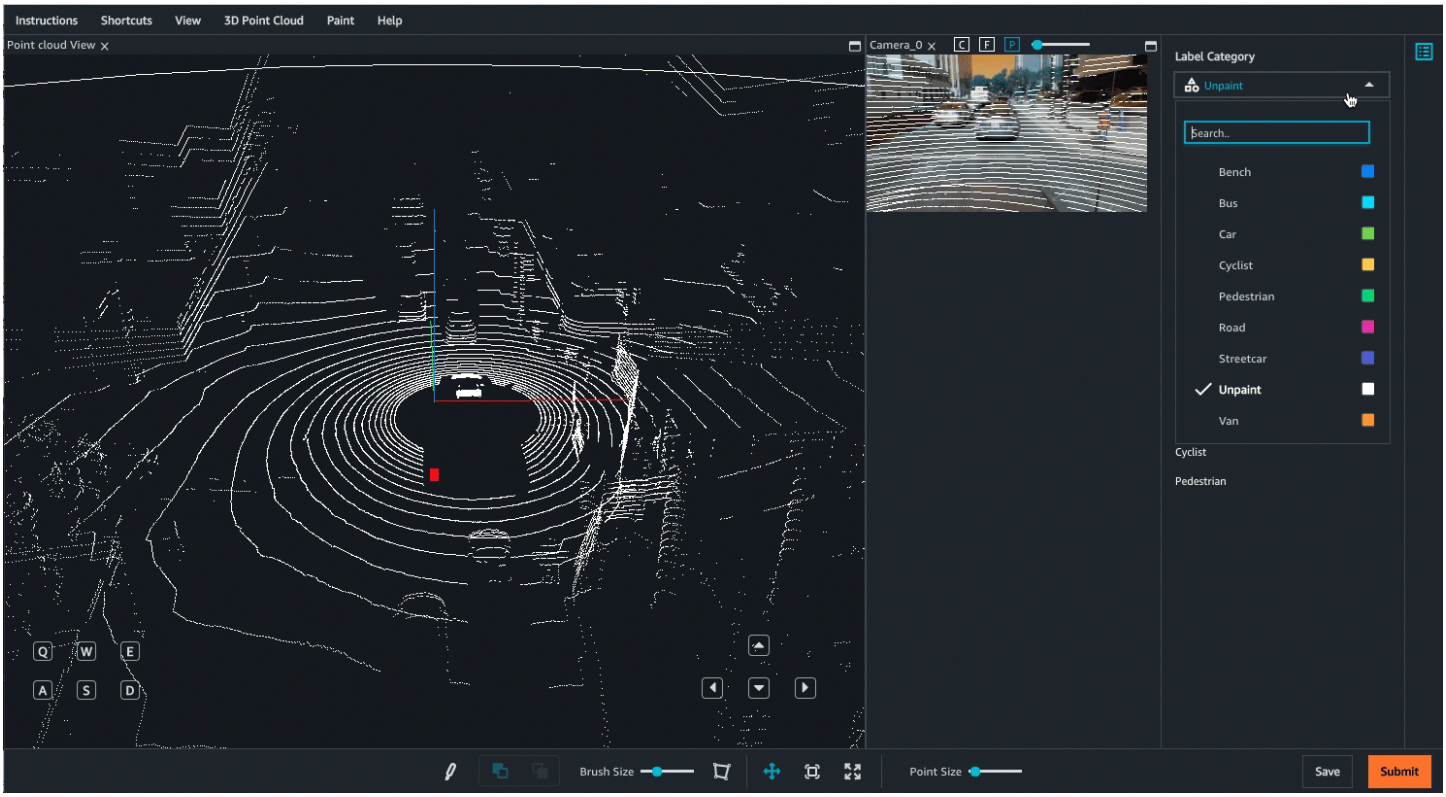
View the worker task interface for a 3D point cloud semantic segmentation job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Ground Truth provides workers with a web portal and tools to complete your 3D point cloud semantic segmentation annotation tasks. When you create the labeling job, you provide the Amazon Resource Name (ARN) for a pre-built Ground Truth UI in the `HumanTaskUiArn` parameter. When you create a labeling job using this task type in the console, this UI is automatically used. You can preview and interact with the worker UI when you create a labeling job in the console. If you are a new use, it is recommended that you create a labeling job using the console to ensure your label attributes, point cloud frames, and if applicable, images, appear as expected.



The following is a GIF of the 3D point cloud semantic segmentation worker task interface. If you provide camera data for sensor fusion, images are matched with scenes in the point cloud frame. Workers can paint objects in either the 3D point cloud or the 2D image, and the paint appears in the corresponding location in the other medium. These images appear in the worker portal as shown in the following GIF.



Worker can navigate in the 3D scene using their keyboard and mouse. They can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

The following video demonstrates movements around the 3D point cloud. Workers can hide and re-expand all side views and menus. In this GIF, the side-views and menus have been collapsed.

The following GIF demonstrates how a worker can label multiple objects quickly, refine painted objects using the Unpaint option and then view only points that have been painted.

Additional view options and features are available. See the worker instruction page for a comprehensive overview of the Worker UI.

Worker Tools

Workers can navigate through the 3D point cloud by zooming in and out, and moving in all directions around the cloud using the mouse and keyboard shortcuts. When you create a semantic segmentation job, workers have the following tools available to them:

- A paint brush to paint and unpaint objects. Workers paint objects by selecting a label category and then painting in the 3D point cloud. Workers unpaint objects by selecting the Unpaint option from the label category menu and using the paint brush to erase paint.
- A polygon tool that workers can use to select and paint an area in the point cloud.
- A background paint tool, which enables workers to paint behind objects they have already annotated without altering the original annotations. For example, workers might use this tool to paint the road after painting all of the cars on the road.
- View options that enable workers to easily hide or view label text, a ground mesh, and additional point attributes like color or intensity. Workers can also choose between perspective and orthogonal projections.

Output data for a 3D point cloud semantic segmentation job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you create a 3D point cloud semantic segmentation labeling job, tasks are sent to workers. When these workers complete their tasks, their annotations are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (LabelingJobStatus) is `Completed`.

If you are a new user of Ground Truth, see Labeling job output data to learn more about the Ground Truth output data format. To learn about the 3D point cloud object detection output data format, see 3D point cloud semantic segmentation output.

Understand the 3D-2D point cloud object tracking task type

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use this task type when you want workers to link 3D point cloud annotations with 2D images annotations and also link 2D image annotations among various cameras. Currently, Ground Truth supports cuboids for annotation in a 3D point cloud and bounding boxes for annotation in 2D videos. For example, you can use this task type to ask workers to link the movement of a vehicle in 3D point cloud with its 2D video. Using 3D-2D linking, you can easily correlate point cloud data (like the distance of a cuboid) to video data (bounding box) for up to 8 cameras.

Ground Truth provides workers with tools to annotate cuboids in a 3D point cloud and bounding boxes in up to 8 cameras using the same annotation UI. Workers can also link various bounding boxes for the same object across different cameras. For example, a bounding box in camera1 can be linked to a bounding box in camera2. This lets you to correlate an object across multiple cameras using a unique ID.

> **Note**
>
> Currently, SageMaker AI does not support creating a 3D-2D linking job using the console. To create a 3D-2D linking job using the SageMaker API, see Create a labeling job (API).

The following topics explain how to create a 3D-2D point cloud object tracking labeling job, show what the worker task interface looks like (what workers see when they work on this task), and provide an overview of the output data you get when workers complete their tasks.

Topics

- Create a 3D-2D point cloud object tracking labeling job
- View the worker task interface for a 3D-2D object tracking labeling job
- Output data for a 3D-2D object tracking labeling job

Create a 3D-2D point cloud object tracking labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can create a 3D-2D point cloud labeling job using the SageMaker API operation, `CreateLabelingJob`. To create a labeling job for this task type you need the following:

- A work team from a private or vendor workforce. To learn how to create workforces and work teams, see Workforces.
- Add a CORS policy to an S3 bucket that contains input data in the Amazon S3 console. To set the required CORS headers on the S3 bucket that contains your input images in the S3 console, follow the directions detailed in CORS Permission Requirement.
- Additionally, make sure that you have reviewed and satisfied the Assign IAM Permissions to Use Ground Truth.

To learn how to create a labeling job using the API, see the following sections.

Create a labeling job (API)

This section covers details you need to know when you create a 3D-2D object tracking labeling job using the SageMaker API operation `CreateLabelingJob`. This API defines this operation for all Amazon SDKs. To see a list of language-specific SDKs supported for this operation, review the **See Also** section of `CreateLabelingJob`.

Create a Labeling Job (API) provides an overview of the `CreateLabelingJob` operation. Follow these instructions and do the following while you configure your request:

- You must enter an ARN for `HumanTaskUiArn`. Use `arn:aws:sagemaker:<region>:394669845002:human-task-ui/PointCloudObjectTracking`. Replace *<region>* with the Amazon Region you are creating the labeling job in.

  There should not be an entry for the `UiTemplateS3Uri` parameter.
- Your `LabelAttributeName` must end in `-ref`. For example, *ot-labels*`-ref`.
- Your input manifest file must be a point cloud frame sequence manifest file. For more information, see Create a Point Cloud Sequence Input Manifest. You also need to provide a label category configuration file as mentioned above.
- You need to provide pre-defined ARNs for the pre-annotation and post-annotation (ACS) Lambda functions. These ARNs are specific to the Amazon Region you use to create your labeling job.
  - To find the pre-annotation Lambda ARN, refer to `PreHumanTaskLambdaArn`. Use the Region you are creating your labeling job in to find the correct ARN that ends with `PRE-3DPointCloudObjectTracking`.
  - To find the post-annotation Lambda ARN, refer to `AnnotationConsolidationLambdaArn`. Use the Region you are creating your labeling job in to find the correct ARN that ends with `ACS-3DPointCloudObjectTracking`.
- The number of workers specified in `NumberOfHumanWorkersPerDataObject` should be 1.
- Automated data labeling is not supported for 3D point cloud labeling jobs. You should not specify values for parameters in `LabelingJobAlgorithmsConfig`.
- 3D-2D object tracking labeling jobs can take multiple hours to complete. You can specify a longer time limit for these labeling jobs in `TaskTimeLimitInSeconds` (up to 7 days, or 604,800 seconds).

> **Note**
>
> After you have successfully created a 3D-2D object tracking job, it shows up on the console under labeling jobs. The task type for the job is displayed as **Point Cloud Object Tracking**.

Input data format

You can create a 3D-2D object tracking job using the SageMaker API operation, `CreateLabelingJob`. To create a labeling job for this task type you need the following:

- A sequence input manifest file. To learn how to create this type of manifest file, see Create a Point Cloud Sequence Input Manifest. If you are a new user of Ground Truth 3D point cloud labeling modalities, we recommend that you review Accepted Raw 3D Data Formats.
- You specify your labels, label category and frame attributes, and worker instructions in a label category configuration file. For more information, see Create a Labeling Category Configuration File with Label Category and Frame Attributes to learn how to create this file. The following is an example showing a label category configuration file for creating a 3D-2D object tracking job.

```
{
    "document-version": "2020-03-01",
    "categoryGlobalAttributes": [
        {
            "name": "Occlusion",
            "description": "global attribute that applies to all label categories",
            "type": "string",
            "enum":[
                "Partial",
                "Full"
            ]
        }
    ],
    "labels":[

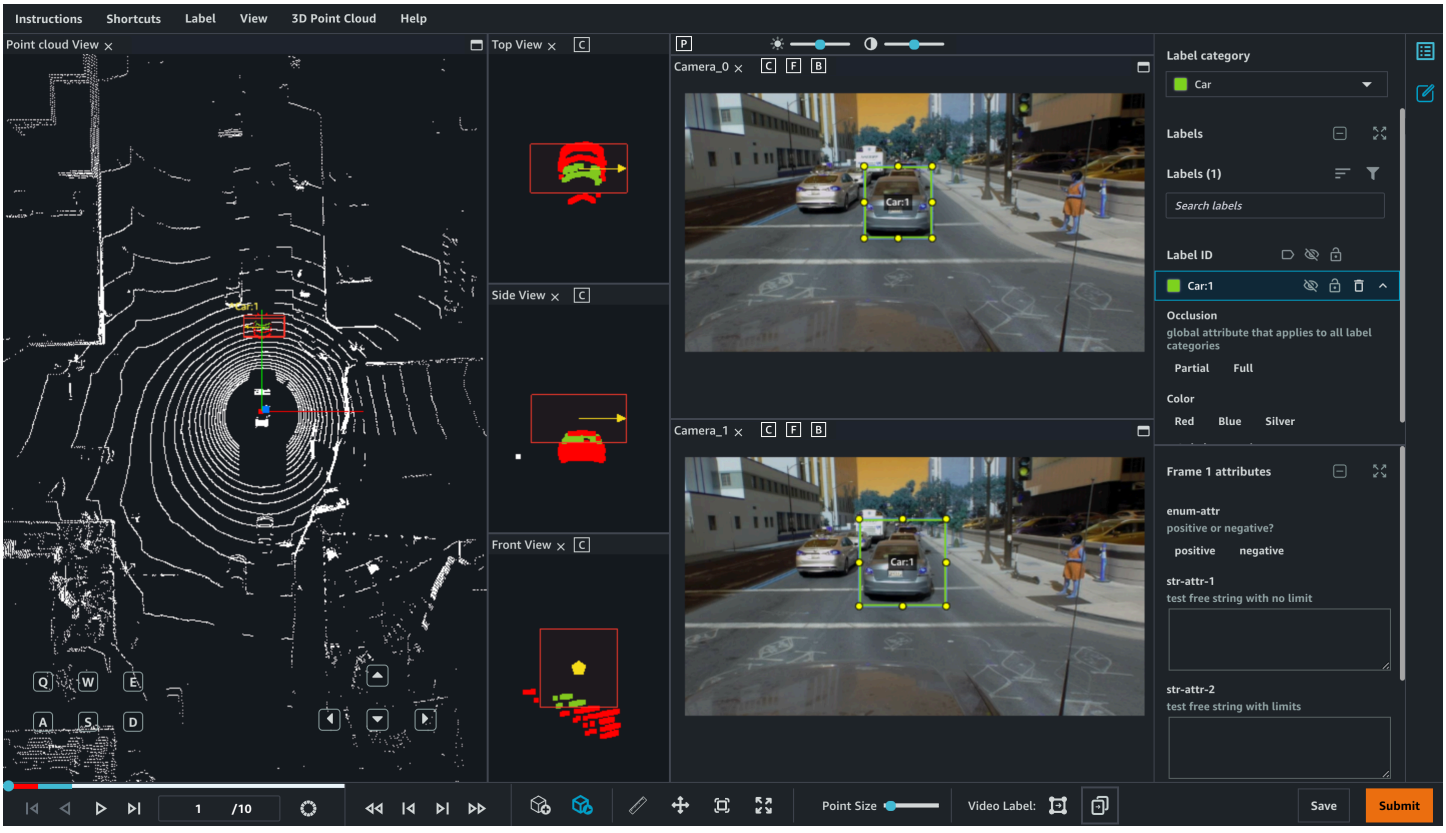
            "label": "Car",
            "attributes": [
                {
                    "name": "Type",
                    "type": "string",
                    "enum": [
                        "SUV",
```

```
                        "Sedan"
                    ]
                }
            ]
        },
        {
            "label": "Bus",
            "attributes": [
                {
                    "name": "Size",
                    "type": "string",
                    "enum": [
                        "Large",
                        "Medium",
                        "Small"
                    ]
                }
            ]
        }
    ],
    "instructions": {
        "shortIntroduction": "Draw a tight cuboid around objects after you select a
 category.",
        "fullIntroduction": "<p>Use this area to add more detailed worker
 instructions.</p>"
    },
    "annotationType": [
        {
            "type": "BoundingBox"
        },
        {
            "type": "Cuboid"
        }
    ]
}
```

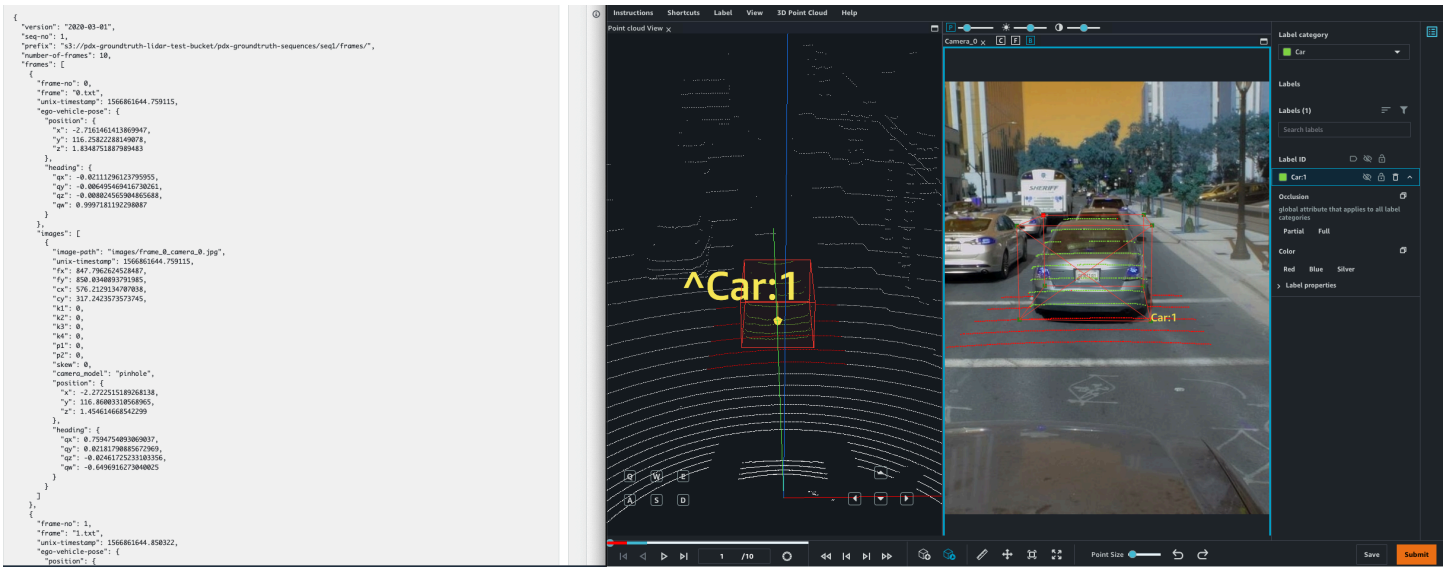


Note

You need to provide `BoundingBox` and `Cuboid` as annotationType in the label category configuration file to create a 3D-2D object tracking job.

View the worker task interface for a 3D-2D object tracking labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.



Ground Truth provides workers with a web portal and tools to complete your 3D-2D object tracking annotation tasks. When you create the labeling job, you provide the Amazon Resource Name (ARN) for a pre-built Ground Truth UI in the `HumanTaskUiArn` parameter. To use the UI when you create a labeling job for this task type using the API, you need to provide the `HumanTaskUiArn`. You can preview and interact with the worker UI when you create a labeling job through the API. The annotating tools are a part of the worker task interface. They are not available for the preview interface. The following image demonstrates the worker task interface used for the 3D-2D point cloud object tracking annotation task.

When interpolation is enabled by default. After a worker adds a single cuboid, that cuboid is replicated in all frames of the sequence with the same ID. If the worker adjusts the cuboid in

another frame, Ground Truth interpolates the movement of that object and adjust all cuboids between the manually adjusted frames. Additionally, using the camera view section, a cuboid can be shown with a projection (using to B button for "toggle labels" in the camera view) that provides the worker with a reference from the camera images. The accuracy of the cuboid to image projection is based on accuracy of calibrations captured in the extrinsic and intrinsinc data.

If you provide camera data for sensor fusion, images are matched up with scenes in point cloud frames. Note that the camera data should be time synchronized with the point cloud data to ensure an accurate depiction of point cloud to imagery over each frame in the sequence as shown in the following image.

The manifest file holds the extrinsic and intrinsic data and the pose to allow the cuboid projection on the camera image to be shown by using the **P button**.

Worker can navigate in the 3D scene using their keyboard and mouse. They can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once a worker places a cuboids in the 3D scene, a side-view appears with the three projected side views: top, side, and front. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The worker should first select the cuboid to draw a corresponding bounding box on any of the camera views. This links the cuboid and the bounding box with a common name and unique ID.

The worker can also first draw a bounding box, select it and draw the corresponding cuboid to link them.

Additional view options and features are available. See the worker instruction page for a comprehensive overview of the Worker UI.

Worker tools

Workers can navigate through the 3D point cloud by zooming in and out, and moving in all directions around the cloud using the mouse and keyboard shortcuts. If workers click on a point in the point cloud, the UI automatically zooms into that area. Workers can use various tools to draw 3D cuboid around objects. For more information, see **Assistive Labeling Tools** in the following discussion.

After workers have placed a 3D cuboid in the point cloud, they can adjust these cuboids to fit tightly around cars using a variety of views: directly in the 3D point cloud, in a side-view featuring three zoomed-in perspectives of the point cloud around the box, and if you include images for sensor fusion, directly in the 2D image.

Additional view options enable workers to easily hide or view label text, a ground mesh, and additional point attributes. Workers can also choose between perspective and orthogonal projections.

Assistive Labeling Tools

Ground Truth helps workers annotate 3D point clouds faster and more accurately using UX, machine learning and computer vision powered assistive labeling tools for 3D point cloud object tracking tasks. The following assistive labeling tools are available for this task type:

- **Label autofill** – When a worker adds a cuboid to a frame, a cuboid with the same dimensions, orientation and xyz position is automatically added to all frames in the sequence.
- **Label interpolation** – After a worker has labeled a single object in two frames, Ground Truth uses those annotations to interpolate the movement of that object between all the frames. Label interpolation can be turned on and off. It is on by default. For example, if a worker working with 5 frames adds a cuboid in frame 2, it is copied to all the 5 frames. If the worker then makes adjustments in frame 4, frame 2 and 4 now act as two points, through which a line is fit. The cuboid is then interpolated in frames 1,3 and 5.

- **Bulk label and attribute management** – Workers can add, delete, and rename annotations, label category attributes, and frame attributes in bulk.
  - Workers can manually delete annotations for a given object before and after a frame, or in all frames. For example, a worker can delete all labels for an object after frame 10 if that object is no longer located in the scene after that frame.
  - If a worker accidentally bulk deletes all annotations for a object, they can add them back. For example, if a worker deletes all annotations for an object before frame 100, they can bulk add them to those frames.
  - Workers can rename a label in one frame and all 3D cuboids assigned that label are updated with the new name across all frames.
  - Workers can use bulk editing to add or edit label category attributes and frame attributes in multiple frames.
- **Snapping** – Workers can add a cuboid around an object and use a keyboard shortcut or menu option to have Ground Truth's autofit tool snap the cuboid tightly around the object's boundaries.
- **Fit to ground** – After a worker adds a cuboid to the 3D scene, the worker can automatically snap the cuboid to the ground. For example, the worker can use this feature to snap a cuboid to the road or sidewalk in the scene.
- **Multi-view labeling** – After a worker adds a 3D cuboid to the 3D scene, a side-panel displays front and two side perspectives to help the worker adjust the cuboid tightly around the object. Workers can annotation the 3D point cloud, the side panel and the adjustments appear in the other views in real time.
- **Sensor fusion** – If you provide data for sensor fusion, workers can adjust annotations in the 3D scenes and in 2D images, and the annotations are projected into the other view in real time. To learn more about the data for sensor fusion, see Understand Coordinate Systems and Sensor Fusion.
- **Auto-merge cuboids** – Workers can automatically merge two cuboids across all frames if they determine that cuboids with different labels actually represent a single object.
- **View options** – Enables workers to easily hide or view label text, a ground mesh, and additional point attributes like color or intensity. Workers can also choose between perspective and orthogonal projections.

Output data for a 3D-2D object tracking labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you create a 3D-2D object tracking labeling job, tasks are sent to workers. When these workers complete their tasks, their annotations are written to the Amazon S3 bucket you specified when you created the labeling job. The output data format determines what you see in your Amazon S3 bucket when your labeling job status (LabelingJobStatus) is `Completed`.

If you are a new user of Ground Truth, see Labeling job output data to learn more about the Ground Truth output data format. To learn about the 3D-2D point cloud object tracking output data format, see 3D-2D object tracking point cloud object tracking output.

3D point cloud labeling jobs overview

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

This topic provides an overview of the unique features of a Ground Truth 3D point cloud labeling job. You can use the 3D point cloud labeling jobs to have workers label objects in a 3D point cloud generated from a 3D sensors like LiDAR and depth cameras or generated from 3D reconstruction by stitching images captured by an agent like a drone.

Job pre-processing time

When you create a 3D point cloud labeling job, you need to provide an input manifest file. The input manifest file can be:

- A *frame input manifest file* that has a single point cloud frame on each line.

- A *sequence input manifest file* that has a single sequence on each line. A sequence is defined as a temporal series of point cloud frames.

For both types of manifest files, *job pre-processing time* (that is, the time before Ground Truth starts sending tasks to your workers) depends on the total number and size of point cloud frames you provide in your input manifest file. For frame input manifest files, this is the number of lines in your manifest file. For sequence manifest files, this is the number of frames in each sequence multiplied by the total number of sequences, or lines, in your manifest file.

Additionally, the number of points per point cloud and the number of fused sensor data objects (like images) factor into job pre-processing times. On average, Ground Truth can pre-process 200 point cloud frames in approximately 5 minutes. If you create a 3D point cloud labeling job with a large number of point cloud frames, you might experience longer job pre-processing times. For example, if you create a sequence input manifest file with 4 point cloud sequences, and each sequence contains 200 point clouds, Ground Truth pre-processes 800 point clouds and so your job pre-processing time might be around 20 minutes. During this time, your labeling job status is `InProgress`.

While your 3D point cloud labeling job is pre-processing, you receive CloudWatch messages notifying you of the status of your job. To identify these messages, search for `3D_POINT_CLOUD_PROCESSING_STATUS` in your labeling job logs.

For **frame input manifest files**, your CloudWatch logs will have a message similar to the following:

```
{
    "labeling-job-name": "example-point-cloud-labeling-job",
    "event-name": "3D_POINT_CLOUD_PROCESSING_STATUS",
    "event-log-message": "datasetObjectId from: 0 to 10, status: IN_PROGRESS"
}
```

The event log message, `datasetObjectId from: 0 to 10, status: IN_PROGRESS` identifies the number of frames from your input manifest that have been processed. You receive a new message every time a frame has been processed. For example, after a single frame has processed, you receive another message that says `datasetObjectId from: 1 to 10, status: IN_PROGRESS`.

For **sequence input manifest files**, your CloudWatch logs will have a message similar to the following:

```
{
    "labeling-job-name": "example-point-cloud-labeling-job",
    "event-name": "3D_POINT_CLOUD_PROCESSING_STATUS",
    "event-log-message": "datasetObjectId: 0, status: IN_PROGRESS"
}
```

The event log message, `datasetObjectId from: 0, status: IN_PROGRESS` identifies the number of sequences from your input manifest that have been processed. You receive a new message every time a sequence has been processed. For example, after a single sequence has processed, you receive a message that says `datasetObjectId from: 1, status: IN_PROGRESS` as the next sequence begins processing.

Job completion times

3D point cloud labeling jobs can take workers hours to complete. You can set the total amount of time that workers can work on each task when you create a labeling job. The maximum time you can set for workers to work on tasks is 7 days. The default value is 3 days.

It is strongly recommended that you create tasks that workers can complete within 12 hours. Workers must keep the worker UI open while working on a task. They can save work as they go and Ground Truth will save their work every 15 minutes.

When using the SageMaker AI `CreateLabelingJob` API operation, set the total time a task is available to workers in the `TaskTimeLimitInSeconds` parameter of `HumanTaskConfig`.

When you create a labeling job in the console, you can specify this time limit when you select your workforce type and your work team.

Workforces

When you create a 3D point cloud labeling job, you need to specify a work team that will complete your point cloud annotation tasks. You can choose a work team from a private workforce of your own workers, or from a vendor workforce that you select in the Amazon Web Services Marketplace.

To learn more about vendor workforce, see Subscribe to vendor workforces.

To learn how to create and manage a private workforce, see Private workforce.

Worker user interface (UI)

Ground Truth provides a worker user interface (UI), tools, and assistive labeling features to help workers complete your 3D point cloud labeling tasks.

You can preview the worker UI when you create a labeling job in the console.

When you create a labeling job using the API operation `CreateLabelingJob`, you must provide an ARN provided by Ground Truth in the parameter `HumanTaskUiArn` to specify the worker UI for your task type. You can use `HumanTaskUiArn` with the SageMaker AI `RenderUiTemplate` API operation to preview the worker UI.

You provide worker instructions, labels, and optionally, label category attributes that are displayed in the worker UI.

Label category attributes

When you create a 3D point cloud object tracking or object detection labeling job, you can add one or more *label category attributes*. You can add *frame attributes* to all 3D point cloud task types:

- **Label category attribute** – A list of options (strings), a free form text box, or a numeric field associated with one or more labels. It is used by workers to to provide metadata about a label.
- **Frame attribute** – A list of options (strings), a free form text box, or a numeric field that appears on each point cloud frame a worker is sent to annotate. It is used by workers to provide metadata about frames.

Additionally, you can use label and frame attributes to have workers verify labels in a 3D point cloud label verification job.

Use the following sections to learn more about these attributes. To learn how to add label category and frame attributes to a labeling job, use the **Create Labeling Job** section on the task type page of your choice.

Label category attributes

Add label category attributes to labels to give workers the ability to provide more information about the annotations they create. A label category attribute is added to an individual label, or to all labels. When a label category attribute is applied to all labels it is referred to as a *global label category attribute*.

For example, if you add the label category *car*, you might also want to capture additional data about your labeled cars, such as if they are occluded or the size of the car. You can capture this metadata using label category attributes. In this example, if you added the attribute *occluded* to the car label category, you can assign *partial*, *completely*, *no* to the *occluded* attribute and enable workers to select one of these options.

When you create a label verification job, you add labels category attributes to each label you want workers to verify.

Frame attributes

Add frame attributes to give workers the ability to provide more information about individual point cloud frames. You can specify up to 10 frame attributes, and these attributes will appear on all frames.

For example, you can add a frame attribute that allows workers to enter a number. You may want to use this attribute to have workers identify the number of objects they see in a particular frame.

In another example, you may want to provide a free-form text box to give workers the ability to provide a free form answer to a question.

When you create a label verification job, you can add one or more frame attributes to ask workers to provide feedback on all labels in a point cloud frame.

Worker instructions

You can provide worker instructions to help your workers complete your point cloud labeling tasks. You might want to use these instructions to do the following:

- Best practices and things to avoid when annotating objects.
- Explanation of the label category attributes provided (for object detection and object tracking tasks), and how to use them.
- Advice on how to save time while labeling by using keyboard shortcuts.

You can add your worker instructions using the SageMaker AI console while creating a labeling job. If you create a labeling job using the API operation `CreateLabelingJob`, you specify worker instructions in your label category configuration file.

In addition to your instructions, Ground Truth provides a link to help workers navigate and use the worker portal. View these instructions by selecting the task type on Worker instructions.

Declining tasks

Workers are able to decline tasks.

Workers decline a task if the instructions are not clear, input data is not displaying correctly, or if they encounter some other issue with the task. If the number of workers per dataset object

([NumberOfHumanWorkersPerDataObject]) decline the task, the data object is marked as expired and will not be sent to additional workers.

3D point cloud labeling job permission requirements

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you create a 3D point cloud labeling job, in addition to the permission requirements found in Assign IAM Permissions to Use Ground Truth, you must add a CORS policy to your S3 bucket that contains your input manifest file.

Add a CORS permission policy to S3 bucket

When you create a 3D point cloud labeling job, you specify buckets in S3 where your input data and manifest file are located and where your output data will be stored. These buckets may be the same. You must attach the following Cross-origin resource sharing (CORS) policy to your input and output buckets. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

JSON

```
[
        {
            "AllowedHeaders": [
                "*"
            ],
            "AllowedMethods": [
                "GET",
                "HEAD",
                "PUT"
            ],
            "AllowedOrigins": [
                "*"
            ],
            "ExposeHeaders": [
                "Access-Control-Allow-Origin"
```

```
            ],
            "MaxAgeSeconds": 3000
        }
    ]
```

XML

```
<?xml version="1.0" encoding="UTF-8"?>
    <CORSConfiguration xmlns="http://s3.amazonaws.com/doc/2006-03-01/">
    <CORSRule>
        <AllowedOrigin>*</AllowedOrigin>
        <AllowedMethod>GET</AllowedMethod>
        <AllowedMethod>HEAD</AllowedMethod>
        <AllowedMethod>PUT</AllowedMethod>
        <MaxAgeSeconds>3000</MaxAgeSeconds>
        <ExposeHeader>Access-Control-Allow-Origin</ExposeHeader>
        <AllowedHeader>*</AllowedHeader>
    </CORSRule>
    </CORSConfiguration>
```

To learn how to add a CORS policy to an S3 bucket, see How do I add cross-domain resource sharing with CORS? in the Amazon Simple Storage Service User Guide.

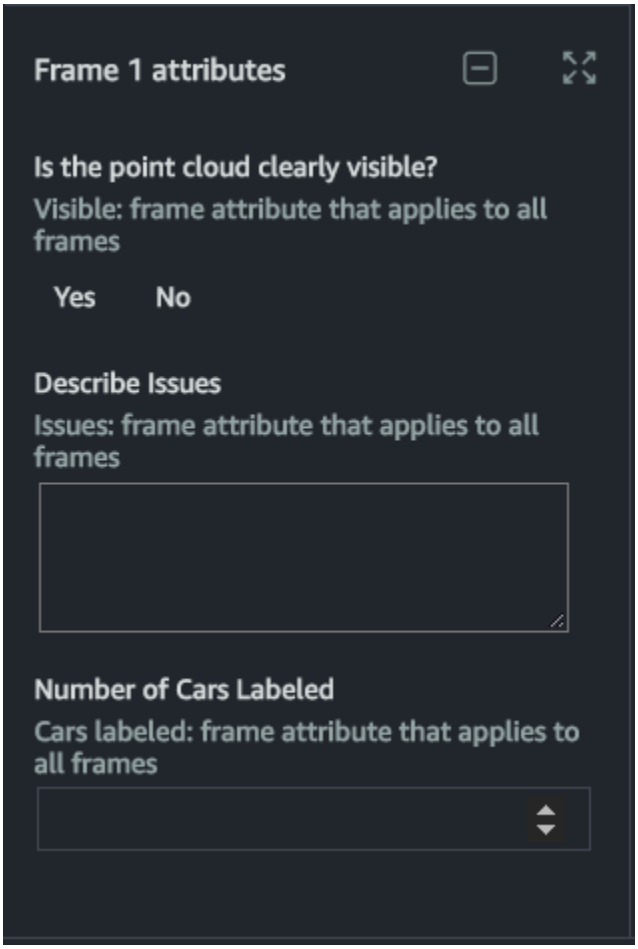
- Saving Your Work and Submitting

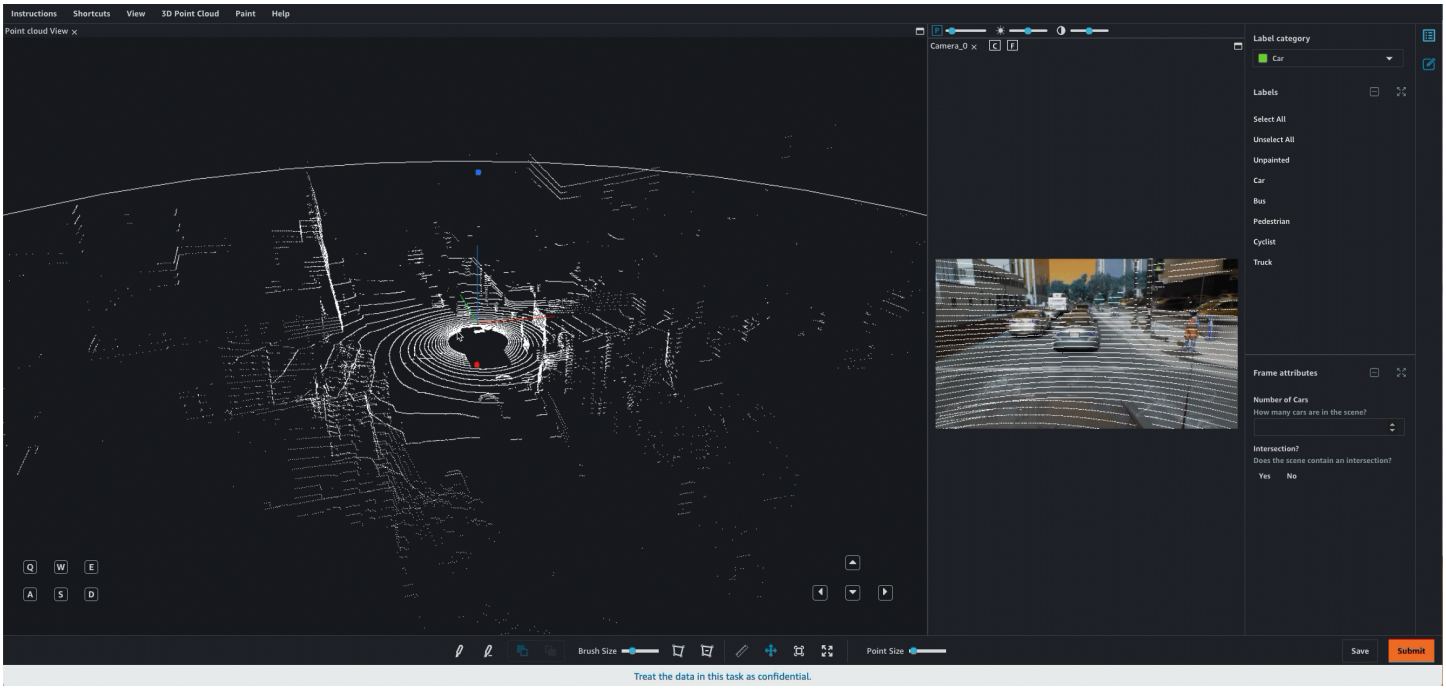


Your Task

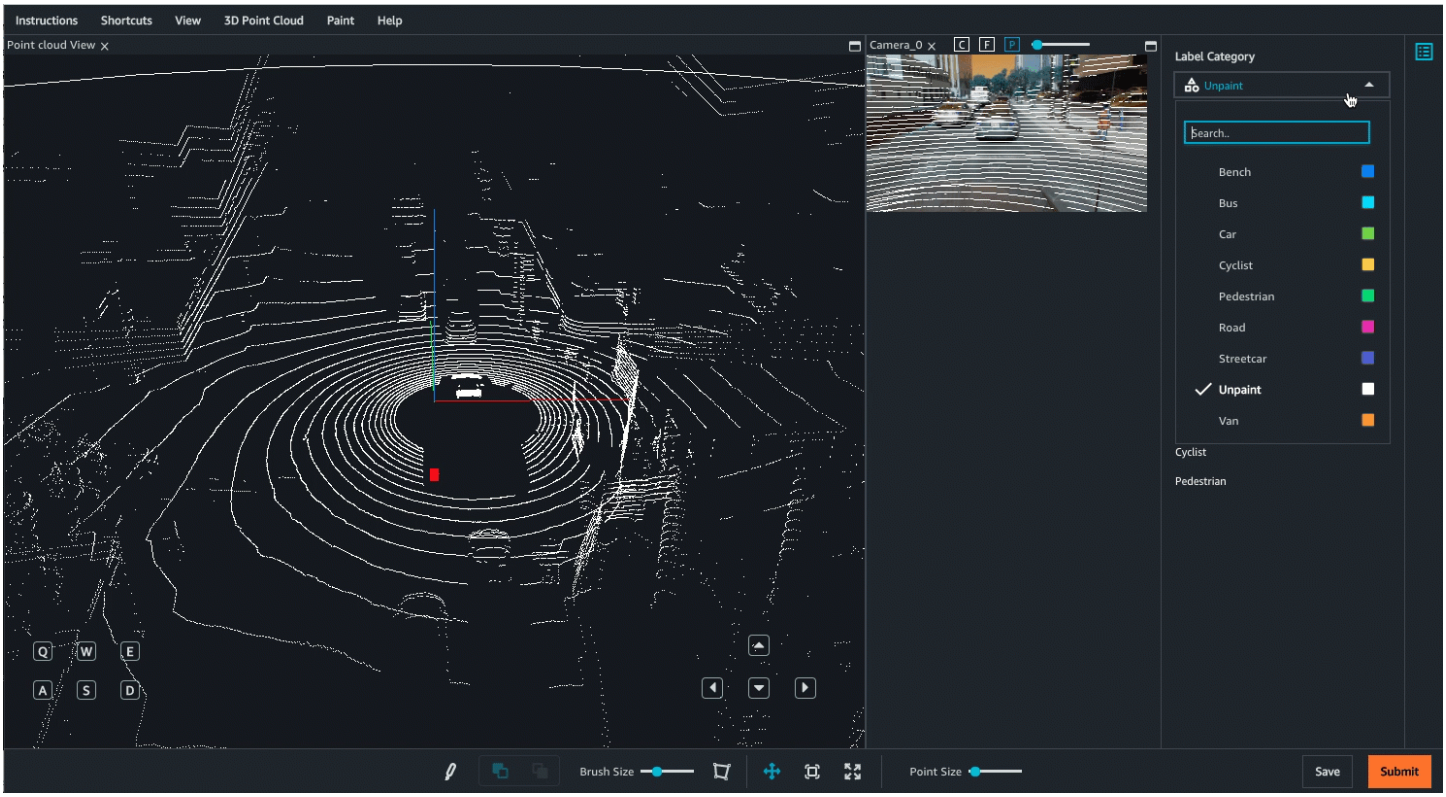
When you work on a 3D point cloud semantic segmentation task, you need to select a category from the **Annotations** menu on the right side of your worker portal using the drop down menu **Label Categories**. After you've selected a category, use the paint brush and polygon tools to paint

each object in the 3D point cloud that this category applies to. For example, if you select the category **Car**, you would use these tools to paint all of the cars in the point cloud. The following video demonstrates how to use the paint brush tool to paint an object.

If you see one or more images in your worker portal, you can paint in the images or paint in the 3D point cloud and the paint will show up in the other medium.



You may see frame attributes under the **Labels** menu. Use these attribute prompts to enter additional information about the point cloud.

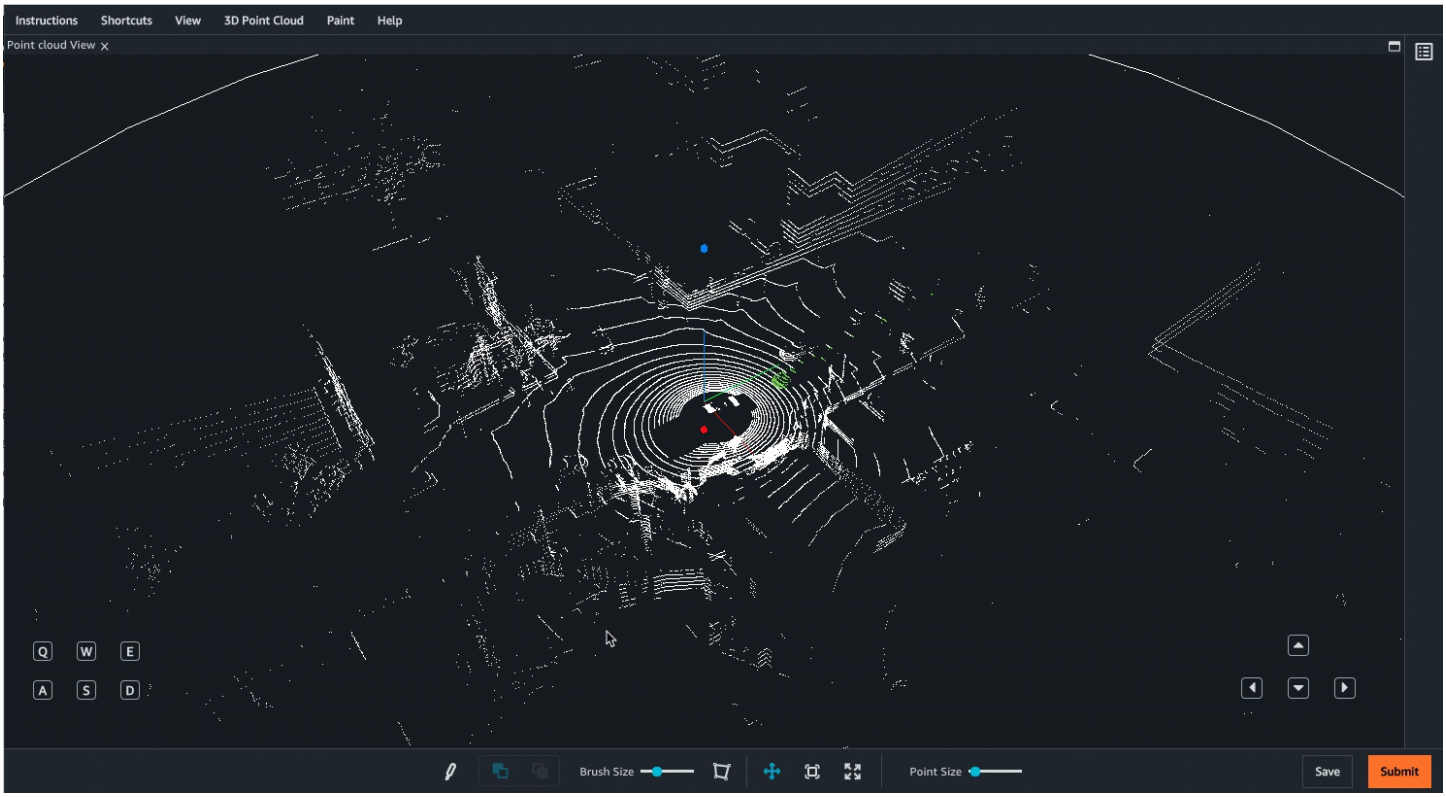


Important

If you see that objects have already been painted when you open the task, adjust those annotations.

The following video includes an image that can be annotated. You may not see an image in your task.

After you've painted one or more objects using a label category, you can select that category from the Label Category menu on the right to only view points painted for that category.



Navigate the UI

You can navigate in the 3D scene using their keyboard and mouse. You can:

- Double click on specific objects in the point cloud to zoom into them.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

The following video demonstrates movements around the 3D point cloud and in the side-view. You can hide and re-expand all side views using the full screen icon. In this GIF, the side-views and menus have been collapsed.

When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate the point cloud and use the annotation tools provided.
- **View** – Use this menu to toggle different view options on and off. For example, you can use this menu to add a ground mesh to the point cloud, and to choose the projection of the point cloud.

- **3D Point Cloud** – Use this menu to add additional attributes to the points in the point cloud, such as color, and pixel intensity. Note that some or all of these options may not be available.
- **Paint** – Use this menu to modify the functionality of the paint brush.

When you open a task, the move scene icon is on, and you can move around the point cloud using your mouse and the navigation buttons in the point cloud area of the screen. To return to the original view you see when you first opened the task, choose the reset scene icon.

After you select the paint icon, you can add paint to the point cloud and images (if included). You must select the move scene icon again to move to another area in the 3D point cloud or image.

To collapse all panels on the right and make the 3D point cloud full screen, select the full screen icon.

For the camera images and side-panels, you have the following view options:

- **C** – View the camera angle on point cloud view.
- **F** – View the frustum, or field of view, of the camera used to capture that image on point cloud view.
- **P** – View the point cloud overlaid on the image.

Icon Guide

Use this table to learn about the icons available in your worker task portal.

Icon	Name	Description
	brush	Choose this icon to turn on the brush tool. To use with this tool, choose and move over the objects that you want to paint with your mouse. After you choose it, everything you paint be associated with the category you chose.
	polygon	Choose this icon to use the polygon paint tool. Use this tool to draw polygons around objects that you want to paint. After you choose it, everything you draw a polygon around will be associated with the category you have chosen.

Icon	Name	Description
	reset scene	Choose this icon to reset the view of the point cloud, side panels, and if applicable, all images to their original position when the task was first opened.
	move scene	Choose this icon to move the scene. By default, this icon will be selected when you first start a task.
	full screen	Choose this icon to make the 3D point cloud visualiza tion full screen, and to collapse all side panels.

Icon	Name	Description
	ruler	Use this icon to measure distances, in meters, in the point cloud. You may want to use this tool if your instructions ask you to annotate all objects in a given distance from the center of the cuboid or the object used to capture data. When you select this icon, you can place the starting point (first marker) anywhere in the point cloud by selecting it with your mouse. The tool will automatically use interpolation to place a marker on the closest point within threshold distance to the location you select, otherwise the marker will be placed on ground. If you place a starting point by mistake, you can use the Escape key to revert marker placement. After you place the first marker, you see a dotted line and a dynamic label that indicates the distance you have moved away from the first marker. Click somewhere else on the point cloud to place a second marker. When you place the second marker, the dotted line becomes solid, and the distance is set. After you set a distance, you can edit it by selecting either marker. You can delete a ruler by selecting anywhere on the ruler and using the Delete key on your keyboard.

Shortcuts

The shortcuts listed in the **Shortcuts** menu can help you navigate the 3D point cloud and use the paint tool.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands.

Release, Stop and Resume, and Decline Tasks

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as an issue with the 3D point cloud, images or the UI. If you decline a task, you will not be able to return to the task.
- **Release Task**: If you release a task, you loose all work done on that task. When the task is released, other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.
- **Stop and resume later**: You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and resume later**. When you select this button and then select **Confirm**, you are returned to the worker portal, and the task status is **Stopped**. You can select the same task to resume work on it.

  Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks much be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.

Saving Your Work and Submitting

You should periodically save your work. Ground Truth will automatically save your work ever 15 minutes.

When you open a task, you must complete your work on it before pressing **Submit**.

3D point cloud object detection

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use this page to familiarize yourself with the user interface and tools available to complete your 3D point cloud object detection task.

Topics

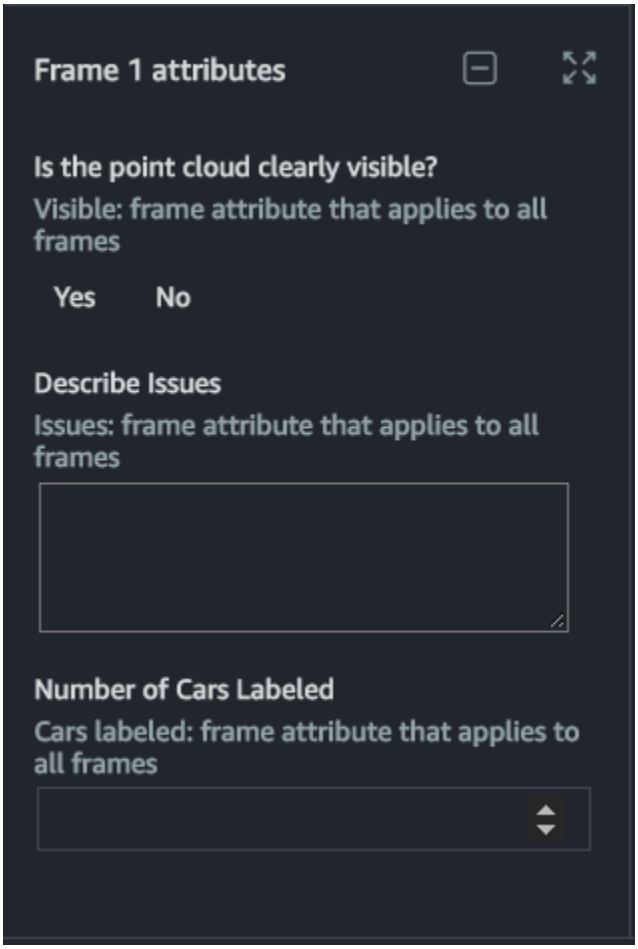
- Saving Your Work and Submitting

Your Task

When you work on a 3D point cloud object detection task, you need to select a category from the **Annotations** menu on the right side of your worker portal using the **Label Categories** menu. After you've chosen a category, use the add cuboid and fit cuboid tools to fit a cuboid around objects in the 3D point cloud that this category applies to. After you place a cuboid, you can modify its dimensions, location, and orientation directly in the point cloud, and the three panels shown on the right.

If you see one or more images in your worker portal, you can also modify cuboids in the images or in the 3D point cloud and the edits will show up in the other medium.

If you see cuboids have already been added to the 3D point cloud when you open your task, adjust those cuboids and add additional cuboids as needed.



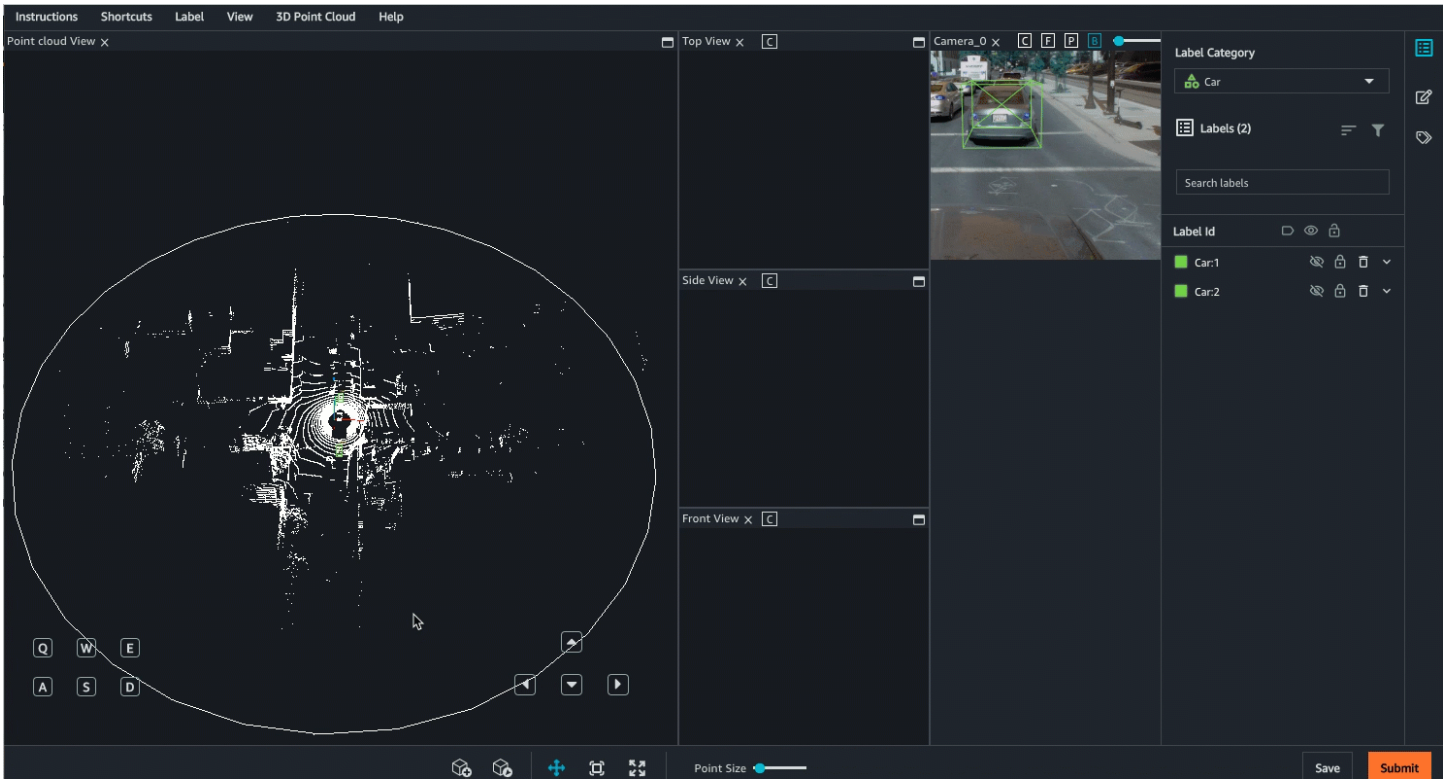
To edit a cuboid, including moving, re-orienting, and changing cuboid dimensions, you must use shortcut keys. You can see a full list of shortcut keys in the **Shortcuts** menu in your UI. The

following are important key-combinations that you should become familiar with before starting your labeling task.

Mac Command	Windows Command	Action
Cmd + Drag	Ctrl + Drag	Modify the dimensions of the cuboid.
Option + Drag	Alt + Drag	Move the cuboid.
Shift + Drag	Shift + Drag	Rotate the cuboid.
Option + O	Alt + O	Fit the cuboid tightly around the points it has been drawn around. Before using the option, make sure the cuboid fully-surrounds the object of interest.
Option + G	Alt + G	Set the cuboid to the ground.

Individual labels may have one or more label attributes. If a label has a label attribute associated with it, it will appear when you select the downward pointing arrow next to the label from the **Label Id** menu. Fill in required values for all label attributes.

You may see frame attributes under the **Labels** menu. Use these attribute prompts to enter additional information about each frame.



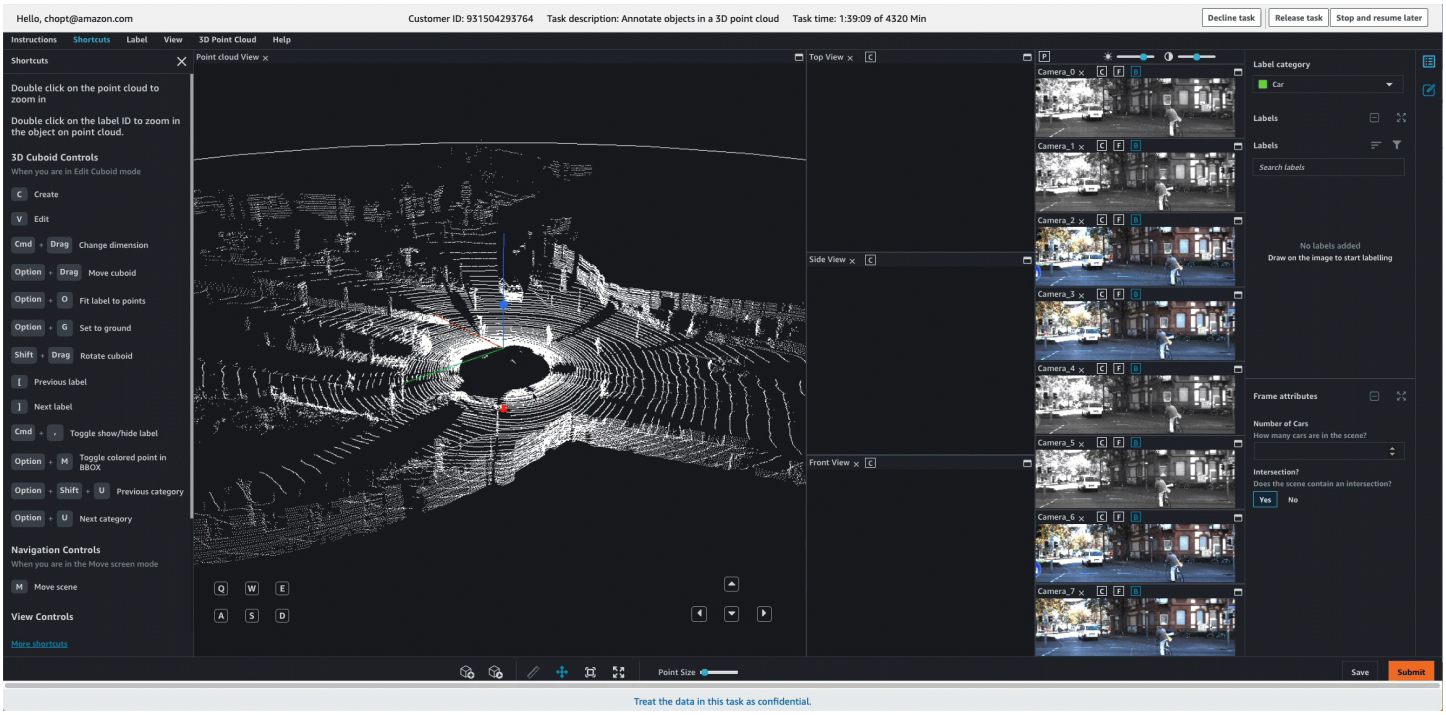
Navigate the UI

You can navigate in the 3D scene using your keyboard and mouse. You can:

- Double click on specific objects in the point cloud to zoom into them.
- You can use the [and] keys on your keyboard to zoom into and move from one label to the next. If no label is selected, when you select [or], the UI will zoom into the first label in the **Lable Id** list.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.
- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once you place a cuboids in the 3D scene, a side-view will appear with three projected views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.

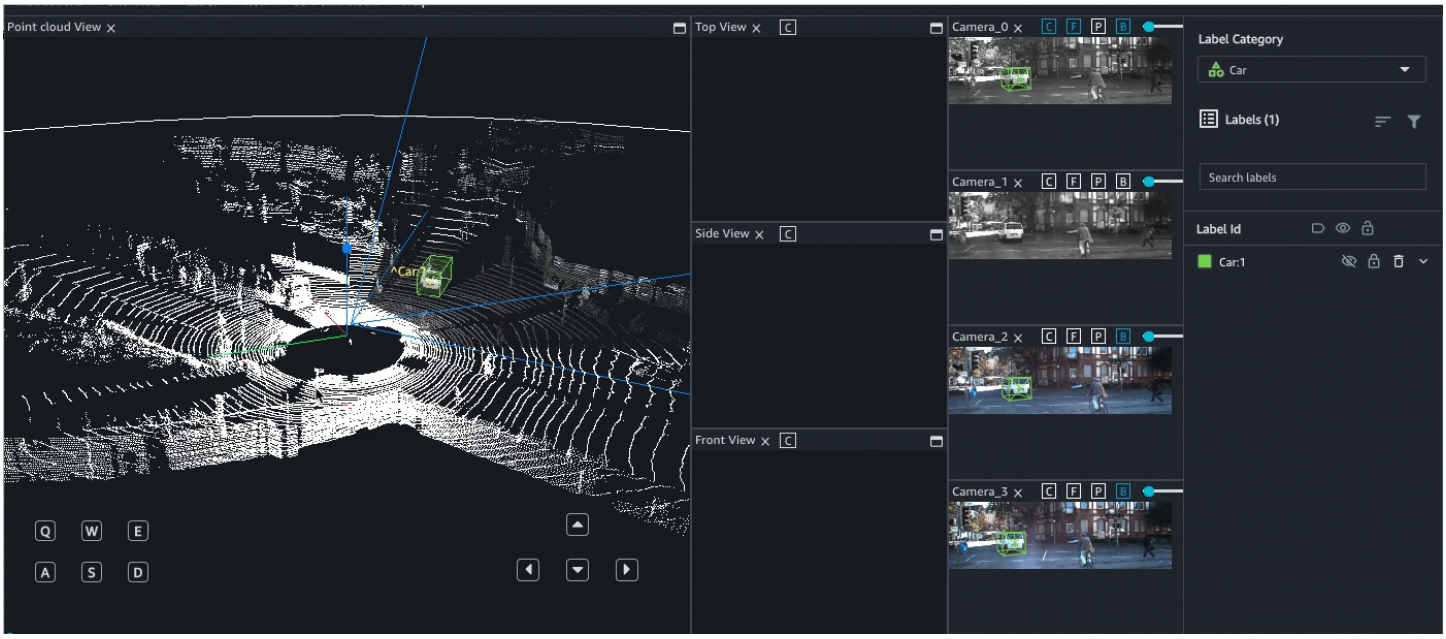


When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate the point cloud and use the annotation tools provided.
- **Label** – Use this menu to modify a cuboid. First, select a cuboid, and then choose an option from this menu. This menu includes assistive labeling tools like setting a cuboid to the ground and automatically fitting the cuboid to the object's boundaries.
- **View** – Use this menu to toggle different view options on and off. For example, you can use this menu to add a ground mesh to the point cloud, and to choose the projection of the point cloud.
- **3D Point Cloud** – Use this menu to add additional attributes to the points in the point cloud, such as color, and pixel intensity. Note that these options may not be available.

When you open a task, the move scene icon is on, and you can move around the point cloud using your mouse and the navigation buttons in the point cloud area of the screen. To return to the original view you see when you first opened the task, choose the reset scene icon. Resetting the view will not modify your annotations.

After you select the add cuboid icon, you can add cuboids to the 3D point cloud visualization. Once you've added a cuboid, you can adjust it in the three views (top, side, and front) and in the images (if included).



You must choose the move scene icon again to move to another area in the 3D point cloud or image.

To collapse all panels on the right and make the 3D point cloud full-screen, choose the full screen icon.

If camera images are included, you may have the following view options:

- **C** – View the camera angle on point cloud view.
- **F** – View the frustum, or field of view, of the camera used to capture that image on point cloud view.
- **P** – View the point cloud overlaid on the image.
- **B** – View cuboids in the image.

The following video demonstrates how to use these view options. The **F** option is used to view the field of view of the camera (the gray area), the **C** options shows the direction the camera is facing and angle of the camera (blue lines), and the **B** option is used to view the cuboid.

Icon Guide

Use this table to learn about the icons you see in your worker task portal.

Icon	Name	Description
	add cuboid	Choose this icon to add a cuboid. Each cuboid you add is associated with the category you chose.
	edit cuboid	Choose this icon to edit a cuboid. After you have added a cuboid, you can edit its dimensions, location, and orientation. After a cuboid is added, it automatically switches to edit cuboid mode.
	ruler	Use this icon to measure distances, in meters, in the point cloud. You may want to use this tool if your instructions ask you to annotate all objects in a given distance from the center of the cuboid or the object used to capture data. When you select this icon, you can place the starting point (first marker) anywhere in the point cloud by selecting it with your mouse. The tool will automatically

Icon	Name	Description
		use interpolation to place a marker on the closest point within threshold distance to the location you select, otherwise the marker will be placed on ground. If you place a starting point by mistake, you can use the Escape key to revert marker placement. After you place the first marker, you see a dotted line and a dynamic label that indicates the distance you have moved away from the first marker. Click somewhere else on the point cloud to place a second marker. When you place the second marker, the dotted line becomes solid, and the distance is set. After you set a distance, you can edit it by selecting either marker. You can delete a ruler by selecting anywhere on the ruler and using the Delete key on your keyboard.
	reset scene	Choose this icon to reset the view of the point cloud, side panels, and if applicable, all images to their original position when the task was first opened.
	move scene	Choose this icon to move the scene. By default, this icon is chosen when you first start a task.
	full screen	Choose this icon to make the 3D point cloud visualiza tion full screen, and to collapse all side panels.
	show labels	Show labels in the 3D point cloud visualization, and if applicable, in images.
	hide labels	Hide labels in the 3D point cloud visualization, and if applicable, in images.

Icon	Name	Description
	delete labels	Delete a label.

Shortcuts

The shortcuts listed in the **Shortcuts** menu can help you navigate the 3D point cloud and use tools to add and edit cuboids.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands. You need to use some of the 3D cuboid controls to edit your cuboid.

Release, Stop and Resume, and Decline Tasks

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as an issue with the 3D point cloud, images or the UI. If you decline a task, you will not be able to return to the task.
- **Release Task**: If you release a task, you loose all work done on that task. When the task is released, other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.
- **Stop and resume later**: You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and resume later**. When you select this button and then select **Confirm**, you are returned to the worker portal, and the task status is **Stopped**. You can select the same task to resume work on it.

  Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks much be completed by. If you do not return to and complete this task within that time

limit, it will expire and your work will not be submitted. Contact your administrator for more information.

Saving Your Work and Submitting

You should periodically save your work. Ground Truth will automatically save your work ever 15 minutes.

When you open a task, you must complete your work on it before pressing **Submit**.

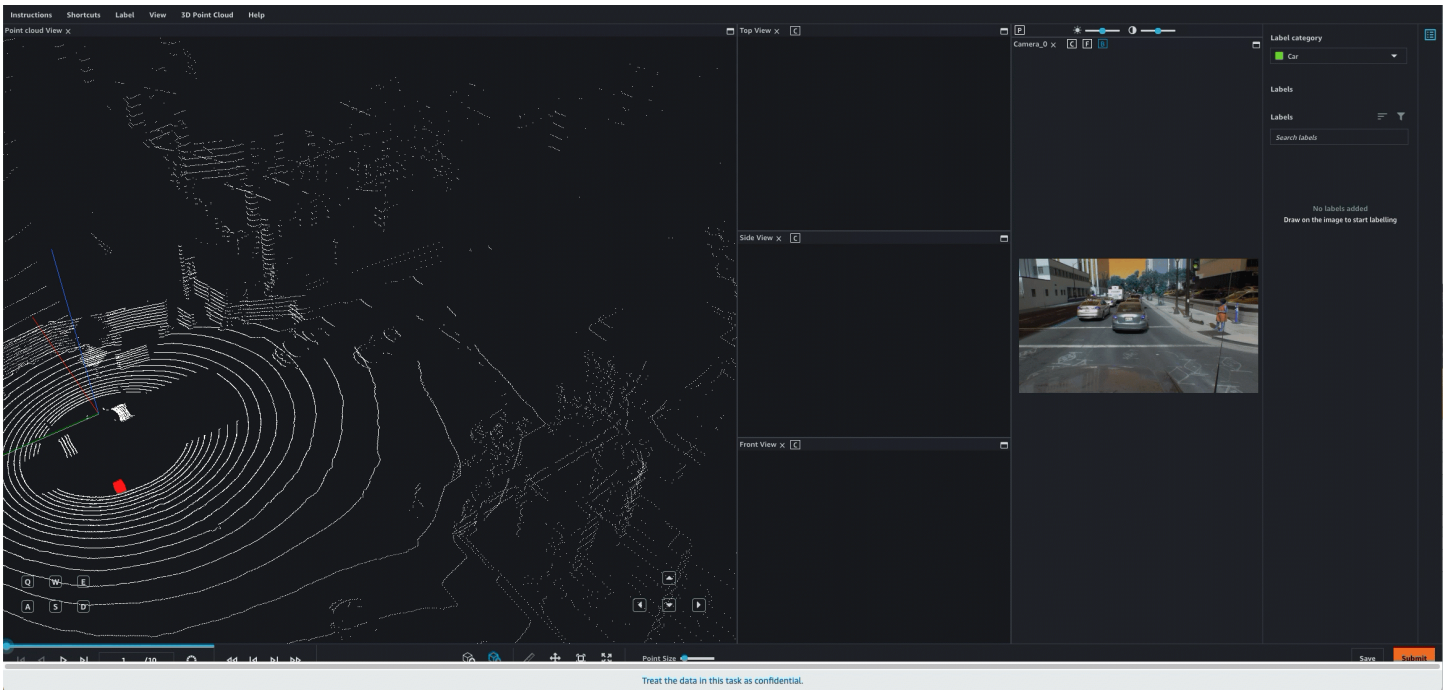
- Bulk Edit Label Category and Frame Attributes
- Icon Guide
- Shortcuts
- Release, Stop and Resume, and Decline Tasks
- Saving Your Work and Submitting

Your Task

When you work on a 3D point cloud object tracking task, you need to select a category from the **Annotations** menu on the right side of your worker portal using the **Label Categories** menu. After you've selected a category, use the add cuboid and fit cuboid tools to fit a cuboid around objects

in the 3D point cloud that this category applies to. After you place a cuboid, you can modify its location, dimensions, and orientation directly in the point cloud, and the three panels shown on the right. If you see one or more images in your worker portal, you can also modify cuboids in the images or in the 3D point cloud and the edits will show up in the other medium.

> **Important**
>
> If you see cuboids have already been added to the 3D point cloud frames when you open your task, adjust those cuboids and add additional cuboids as needed.



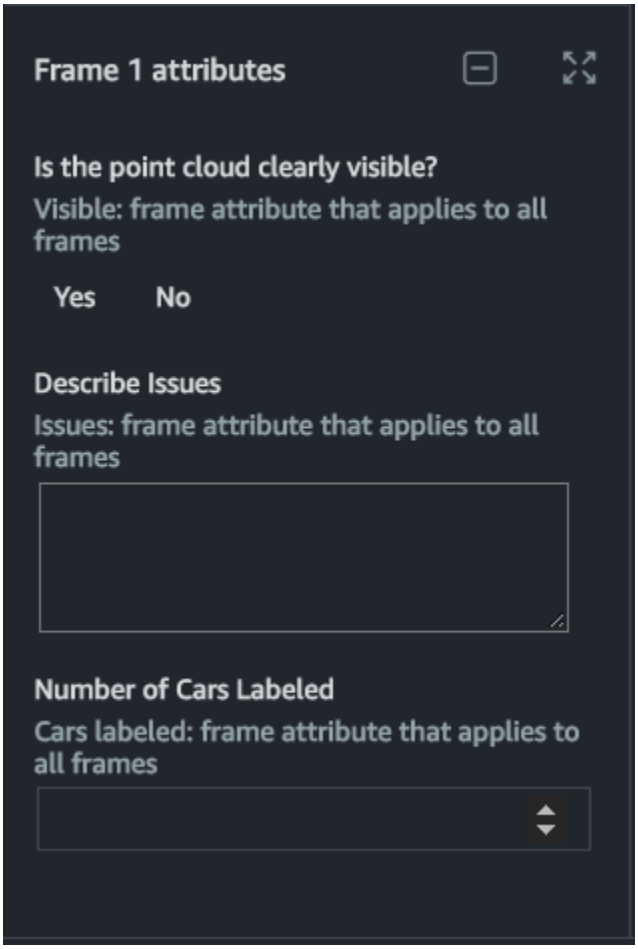
To edit a cuboid, including moving, re-orienting, and changing cuboid dimensions, you must use shortcut keys. You can see a full list of shortcut keys in the **Shortcuts** menu in your UI. The following are important key-combinations that you should become familiar with before starting your labeling task.

Mac Command	Windows Command	Action
Cmd + Drag	Ctrl + Drag	Modify the dimensions of the cuboid.
Option + Drag	Alt + Drag	Move the cuboid.
Shift + Drag	Shift + Drag	Rotate the cuboid.
Option + O	Alt + O	Fit the cuboid tightly around the points it has been drawn around. Before using the option, make sure the cuboid fully-surrounds the object of interest.
Option + G	Alt + G	Set the cuboid to the ground.

When you open your task, two frames will be loaded. If your task includes more than two frames, you need to use the navigation bar in the lower-left corner, or the load frames icon to load additional frames. You should annotate and adjust labels in all frames before submitting.

After you fit a cuboid tightly around the boundaries of an object, navigate to another frame using the navigation bar in the lower-left corner of the UI. If that same object has moved to a new location, add another cuboid and fit it tightly around the boundaries of the object. Each time you manually add a cuboid, you see the frame sequence bar in the lower-left corner of the screen turn red where that frame is located temporally in the sequence.

Your UI automatically infers the location of that object in all other frames after you've placed a cuboid. This is called *interpolation*. You can see the movement of that object, and the inferred and manually created cuboids using the arrows. Adjust inferred cuboids as needed. The following video demonstrates how to navigate between frames. The following video shows how, if you add a cuboid in one frame, and then adjust it in another, your UI will automatically infer the location of the cuboid in all of the frames in-between.



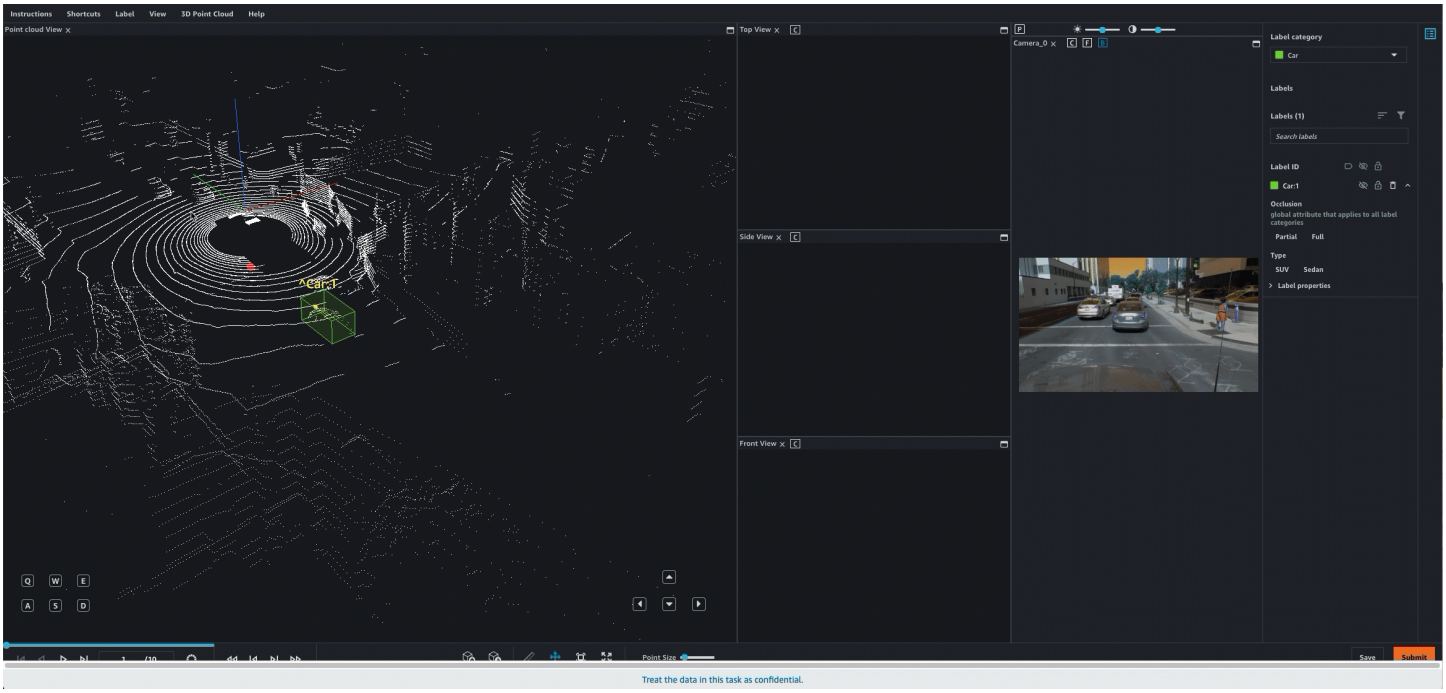
Tip

You can turn off the automatic cuboid interpolation across frames using the 3D Point Cloud menu item. Select **3D Point Cloud** from the top-menu, and then select **Interpolate Cuboids Across Frames**. This will uncheck this option and stop cuboid interpolation. You can reselect this item to turn cuboid interpolation back on.
Turning cuboid interpolation off will not impact cuboids that have already been interpolated across frames.

Individual labels may have one or more label attributes. If a label has a label attribute associated with it, it will appear when you select the downward pointing arrow next to the label from the **Label Id** menu. Fill in required values for all label attributes.

You may see frame attributes under the **Label Id** menu. These attributes will appear on each frame in your task. Use these attribute prompts to enter additional information about each frame.

Navigate the UI



You can navigate in the 3D scene using your keyboard and mouse. You can:

- Double click on specific objects in the point cloud to zoom into them.
- You can use the [and] keys on your keyboard to zoom into and move from one label to the next. If no label is selected, when you select [or], the UI will zoom into the first label in the **Label Id** list.
- Use a mouse-scroller or trackpad to zoom in and out of the point cloud.

- Use both keyboard arrow keys and Q, E, A, and D keys to move Up, Down, Left, Right. Use keyboard keys W and S to zoom in and out.

Once you place a cuboids in the 3D scene, a side-view will appear with three projected views: top, side, and back. These side-views show points in and around the placed cuboid and help workers refine cuboid boundaries in that area. Workers can zoom in and out of each of those side-views using their mouse.

The following video demonstrates movements around the 3D point cloud and in the side-view.

When you are in the worker UI, you see the following menus:

- **Instructions** – Review these instructions before starting your task.
- **Shortcuts** – Use this menu to view keyboard shortcuts that you can use to navigate the point cloud and use the annotation tools provided.
- **Label** – Use this menu to modify a cuboid. First, select a cuboid, and then choose an option from this menu. This menu includes assistive labeling tools like setting a cuboid to the ground and automatically fitting the cuboid to the object's boundaries.
- **View** – Use this menu to toggle different view options on and off. For example, you can use this menu to add a ground mesh to the point cloud, and to choose the projection of the point cloud.
- **3D Point Cloud** – Use this menu to add additional attributes to the points in the point cloud, such as color, and pixel intensity. Note that these options may not be available.

When you open a task, the move scene icon is on, and you can move around the point cloud using your mouse and the navigation buttons in the point cloud area of the screen. To return to the original view you see when you first opened the task, choose the reset scene icon.

After you select the add cuboid icon, you can add cuboids to the point cloud and images (if included). You must select the move scene icon again to move to another area in the 3D point cloud or image.

To collapse all panels on the right and make the 3D point cloud full-screen, choose the full screen icon.

If camera images are included, you may have the following view options:

- **C** – View the camera angle on point cloud view.
- **F** – View the frustum, or field of view, of the camera used to capture that image on point cloud view.
- **P** – View the point cloud overlaid on the image.
- **B** – View cuboids in the image.

The following video demonstrates how to use these view options. The **F** option is used to view the field of view of the camera (the gray area), the **C** options shows the direction the camera is facing and angle of the camera (blue lines), and the **B** option is used to view the cuboid.

Delete Cuboids

You can select a cuboid or label ID and:

- Delete an individual cuboid in the current frame you are viewing.
- Delete all cuboids with that label ID before or after the frame you are viewing.
- Delete all cuboids with that label ID in all frames.

A common use-case for cuboid deletion is if the object leaves the scene.

You can use one or more of these options to delete both manually placed and interpolated cuboids with the same label ID.

- To delete all cuboids before or after the frame you are currently on, select the cuboid, select the **Label** menu item at the top of the UI and then select one of **Delete in previous frames** or **Delete in next frames**. Use the Shortcuts menu to see the shortcut keys you can use for these options.
- To delete a label in all frames, select **Delete in all frames** from the **Labels** menu, or use the shortcut **Shift + Delete** on your keyboard.
- To delete an individual cuboid from a single frame, select the cuboid and either select the trashcan icon (🗑) next to that label ID in the **Label ID** sidebar on the right or use the Delete key on your keyboard to delete that cuboid.

If you have manually placed more than one cuboid with the same label in different frames, when you delete one of the manually placed cuboids, all interpolated cuboids adjust. This adjustment happens because the UI uses manually placed cuboids as anchor points when calculating the location of interpolated cuboid. When you remove one of these anchor points, the UI must recalculate the position of interpolated cuboids.

If you delete a cuboid from a frame, but later decide that you want to get it back, you can use the **Duplicate to previous frames** or **Duplicate to next frames** options in the **Label** menu to copy the cuboid into all the previous or all of the following frames, respectively.

Bulk Edit Label Category and Frame Attributes

You can bulk edit label attributes and frame attributes.

When you bulk edit an attribute, you specify one or more ranges of frames that you want to apply the edit to. The attribute you select is edited in all frames in that range, including the start and end

frames you specify. When you bulk edit label attributes, the range you specify *must* contain the label that the label attribute is attached to. If you specify frames that do not contain this label, you will receive an error.

To bulk edit an attribute you *must* specify the desired value for the attribute first. For example, if you want to change an attribute from *Yes* to *No*, you must select *No*, and then perform the bulk edit.

You can also specify a new value for an attribute that has not been filled in and then use the bulk edit feature to fill in that value in multiple frames. To do this, select the desired value for the attribute and complete the following procedure.

To bulk edit a label or attribute:

1. Use your mouse to right click the attribute you want to bulk edit.
2. Specify the range of frames you want to apply the bulk edit to using a dash (-) in the text box. For example, if you want to apply the edit to frames one through ten, enter `1-10`. If you want to apply the edit to frames two to five, eight to ten and twenty enter `2-5,8-10,20`.
3. Select **Confirm**.

If you get an error message, verify that you entered a valid range and that the label associated with the label attribute you are editing (if applicable) exists in all frames specified.

You can quickly add a label to all previous or subsequent frames using the **Duplicate to previous frames** and **Duplicate to next frames** options in the **Label** menu at the top of your screen.

Icon Guide

Use this table to learn about the icons you see in your worker task portal.

Icon	Name	Description
	add cuboid	Choose this icon to add a cuboid. Each cuboid you add is associated with the category you chose.
	edit cuboid	Choose this icon to edit a cuboid. After you add a cuboid, you can edit its dimensions, location, and

Icon	Name	Description
		orientation. After a cuboid is added, it automatically switches to edit cuboid mode.
	ruler	Use this icon to measure distances, in meters, in the point cloud. You may want to use this tool if your instructions ask you to annotate all objects in a given distance from the center of the cuboid or the object used to capture data. When you select this icon, you can place the starting point (first marker) anywhere in the point cloud by selecting it with your mouse. The tool will automatically use interpolation to place a marker on the closest point within threshold distance to the location you select, otherwise the marker will be placed on ground. If you place a starting point by mistake, you can use the Escape key to revert marker placement. After you place the first marker, you see a dotted line and a dynamic label that indicates the distance you have moved away from the first marker. Click somewhere else on the point cloud to place a second marker. When you place the second marker, the dotted line becomes solid, and the distance is set. After you set a distance, you can edit it by selecting either marker. You can delete a ruler by selecting anywhere on the ruler and using the Delete key on your keyboard.
	reset scene	Choose this icon to reset the view of the point cloud, side panels, and if applicable, all images to their original position when the task was first opened.
	move scene	Choose this icon to move the scene. By default, this icon is chosen when you first start a task.

Icon	Name	Description
	full screen	Choose this icon to make the 3D point cloud visualiza tion full screen and to collapse all side panels.
	load frames	Choose this icon to load additional frames.
	hide labels	Hide labels in the 3D point cloud visualization, and if applicable, in images.
	show labels	Show labels in the 3D point cloud visualization, and if applicable, in images.
	delete labels	Delete a label. This option can only be used to delete labels you have manually created or adjusted.

Shortcuts

The shortcuts listed in the **Shortcuts** menu can help you navigate the 3D point cloud and use tools to add and edit cuboids.

Before you start your task, it is recommended that you review the **Shortcuts** menu and become acquainted with these commands. You need to use some of the 3D cuboid controls to edit your cuboid.

Release, Stop and Resume, and Decline Tasks

When you open the labeling task, three buttons on the top right allow you to decline the task (**Decline task**), release it (**Release task**), and stop and resume it at a later time (**Stop and resume later**). The following list describes what happens when you select one of these options:

- **Decline task**: You should only decline a task if something is wrong with the task, such as an issue with the 3D point clouds, images or the UI. If you decline a task, you will not be able to return to the task.

- **Release Task**: Use this option to release a task and allow others to work on it. When you release a task, you loose all work done on that task and other workers on your team can pick it up. If enough workers pick up the task, you may not be able to return to it. When you select this button and then select **Confirm**, you are returned to the worker portal. If the task is still available, its status will be **Available**. If other workers pick it up, it will disappear from your portal.
- **Stop and resume later**: You can use the **Stop and resume later** button to stop working and return to the task at a later time. You should use the **Save** button to save your work before you select **Stop and resume later**. When you select this button and then select **Confirm**, you are returned to the worker portal, and the task status is **Stopped**. You can select the same task to resume work on it.

  Be aware that the person that creates your labeling tasks specifies a time limit in which all tasks much be completed by. If you do not return to and complete this task within that time limit, it will expire and your work will not be submitted. Contact your administrator for more information.

Saving Your Work and Submitting

You should periodically save your work. Ground Truth will automatically save your work ever 15 minutes.

When you open a task, you must complete your work on it before pressing **Submit**.

Label verification and adjustment

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When the labels on a dataset need to be validated, Amazon SageMaker Ground Truth provides functionality to have workers verify that labels are correct or to adjust previous labels. These types of jobs fall into two distinct categories:

- *Label verification* — Workers indicate if the existing labels are correct, or rate their quality, and can add comments to explain their reasoning. Workers will not be able to modify or adjust labels.

  If you create a 3D point cloud or video frame label adjustment or verification job, you can choose to make label category attributes (not supported for 3D point cloud semantic segmentation) and frame attributes editable by workers.
- *Label adjustment* — Workers adjust prior annotations and, if applicable, label category and frame attributes to correct them.

The following Ground Truth built-in task types support adjustment and verification labeling jobs:

- Bounding box
- Semantic segmentation
- 3D point cloud object detection, 3D point cloud object tracking, and 3D point cloud semantic segmentation
- All video frame object detection and video frame object tracking task types — bounding box, polyline, polygon and keypoint

> **Tip**
>
> For 3D point cloud and video frame labeling verification jobs, it is recommended that you add new label category attributes or frame attributes to the labeling job. Workers can use these attribute to verify individual labels or the entire frame. To learn more about label category and frame attributes, see Worker user interface (UI) for 3D point cloud and Worker user interface (UI) for video frame.

You can start a label verification and adjustment jobs using the SageMaker AI console or the API.

Cautions and considerations

To get expected behavior when creating a label verification or adjustment job, carefully verify your input data.

- If you are using image data, verify that your manifest file contains hexadecimal RGB color information.

- To save money on processing costs, filter your data to ensure you are not including unwanted objects in your labeling job input manifest.
- Add required Amazon S3 permissions to ensure your input data is processed correctly.

When you create an adjustment or verification labeling job using the Ground Truth API, you *must* use a different `LabelAttributeName` than the original labeling job.

Color information requirements for semantic segmentation jobs

To properly reproduce color information in verification or adjustment tasks, the tool requires hexadecimal RGB color information in the manifest (for example, #FFFFFF for white). When you set up a Semantic Segmentation verification or adjustment job, the tool examines the manifest to determine if this information is present. If it can't find it,Amazon SageMaker Ground Truth displays an error message and the ends job setup.

In prior iterations of the Semantic Segmentation tool, category color information wasn't output in hexadecimal RGB format to the output manifest. That feature was introduced to the output manifest at the same time the verification and adjustment workflows were introduced. Therefore, older output manifests aren't compatible with this new workflow.

Filter your data before starting the job

Amazon SageMaker Ground Truth processes all objects in your input manifest. If you have a partially labeled data set, you might want to create a custom manifest using an Amazon S3 Select query on your input manifest. Unlabeled objects individually fail, but they don't cause the job to fail, and they might incur processing costs. Filtering out objects you don't want verified reduces your costs.

If you create a verification job using the console, you can use the filtering tools provided there. If you create jobs using the API, make filtering your data part of your workflow where needed.

Topics

- Create a label verification job (console)
- Create a label adjustment job (console)
- Start a label verification or adjustment job (API)
- Label verification and adjustment data in the output manifest

Requirements to create verification and adjustment labeling jobs

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

To create a label verification or adjustment job, you must satisfy the following criteria.

- For non streaming labeling jobs: The input manifest file you use must contain the label attribute name (`LabelAttributeName`) of the labels that you want adjusted. When you chain a successfully completed labeling job, the output manifest file is used as the input manifest file for the new, chained job. To learn more about the format of the output manifest file Ground Truth produces for each task type, see Labeling job output data.

  For streaming labeling jobs: The Amazon SNS message you sent to the Amazon SNS input topic of the adjustment or verification labeling job must contain the label attribute name of the labels you want adjusted or verified. To see an example of how you can create an adjustment or verification labeling job with streaming labeling jobs, see this Jupyter Notebook example in GitHub.
- The task type of the verification or adjustment labeling job must be the same as the task type of the original job unless you are using the Image Label Verification task type to verify bounding box or semantic segmentation image labels. See the next bullet point for more details about the video frame task type requirements.
- For video frame annotation verification and adjustment jobs, you must use the same annotation task type used to create the annotations from the previous labeling job. For example, if you create a video frame object detection job to have workers draw bounding boxes around objects, and then you create a video object detection adjustment job, you must specify *bounding boxes* as the annotation task type. To learn more video frame annotation task types, see Task types.
- The task type you select for the adjustment or verification labeling job must support an audit workflow. The following Ground Truth built-in task types support adjustment and verification labeling jobs: bounding box, semantic segmentation, 3D point cloud object detection, 3D point cloud object tracking, and 3D point cloud semantic segmentation, and all video frame object detection and video frame object tracking task types — bounding box, polyline, polygon and keypoint.

Create a label verification job (console)

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use one of the following sections to create a label verification job for your task type. Bounding box and semantic segmentation labeling jobs are created by choosing the **Label verification** task type in the console. To create a verification job for 3D point cloud and video frame task types, you must choose the same task type as the original labeling job and choose to display existing labels.

Create an image label verification job (console)

Use the following procedure to create a bounding box or semantic segmentation verification job using the console. This procedure assumes that you have already created a bounding box or semantic segmentation labeling job and its status is Complete. This the labeling job that produces the labels you want verified.

To create an image label verification job:

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/ and choose **Labeling jobs**.
2. Start a new labeling job by chaining a prior job or start from scratch, specifying an input manifest that contains labeled data objects.
3. In the **Task type** pane, select **Label verification**.
4. Choose **Next**.
5. In the **Workers** section, choose the type of workforce you would like to use. For more details about your workforce options see Workforces.
6. (Optional) After you've selected your workforce, specify the **Task timeout** and **Task expiration time**.
7. In the **Existing-labels display options** pane, the system shows the available label attribute names in your manifest. Choose the label attribute name that identifies the labels that you want workers to verify. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.

8. Use the instructions areas of the tool designer to provide context about what the previous labelers were asked to do and what the current verifiers need to check.

   You can add new labels that workers choose from to verify labels. For example, you can ask workers to verify the image quality, and provide the labels *Clear* and *Blurry*. Workers will also have the option to add a comment to explain their selection.
9. Choose **See preview** to check that the tool is displaying the prior labels correctly and presents the label verification task clearly.
10. Select **Create**. This will create and start your labeling job.

Create a point cloud or video frame label verification job (console)

Use the following procedure to create a 3D point cloud or video frame verification job using the console. This procedure assumes that you have already created a labeling job using the task type that produces the types of labels you want to be verified and its status is Complete.

To create an image label verification job:

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/ and choose **Labeling jobs**.
2. Start a new labeling job by chaining a prior job or start from scratch, specifying an input manifest that contains labeled data objects.
3. In the **Task type** pane, select the same task type as the labeling job that you chained. For example, if the original labeling job was a video frame object detection keypoint labeling job, select that task type.
4. Choose **Next**.
5. In the **Workers** section, choose the type of workforce you would like to use. For more details about your workforce options see Workforces.
6. (Optional) After you've selected your workforce, specify the **Task timeout** and **Task expiration time**.
7. Toggle on the switch next to **Display existing labels**.
8. Select **Verification**.
9. For **Label attribute name**, choose the name from your manifest that corresponds to the labels that you want to display for verification. You will only see label attribute names for labels that match the task type you selected on the previous screen. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.

10. Use the instructions areas of the tool designer to provide context about what the previous labelers were asked to do and what the current verifiers need to check.

    You cannot modify or add new labels. You can remove, modify and add new label category attributes or frame attributes. It is recommended that you add new label category attributes or frame attributes to the labeling job. Workers can use these attribute to verify individual labels or the entire frame.

    By default, preexisting label category attributes and frame attributes will not be editable by workers. If you want to make a label category or frame attribute editable, select the **Allow workers to edit this attribute** check box for that attribute.

    To learn more about label category and frame attributes, see Worker user interface (UI) for 3D point cloud and Worker user interface (UI) for video frame.
11. Choose **See preview** to check that the tool is displaying the prior labels correctly and presents the label verification task clearly.
12. Select **Create**. This will create and start your labeling job.

Create a label adjustment job (console)

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use one of the following sections to create a label verification job for your task type.

Topics

- Create an image label adjustment job (console)
- Create a point cloud or video frame label adjustment job (console)

Create an image label adjustment job (console)

Use the following procedure to create a bounding box or semantic segmentation adjustment labeling job using the console. This procedure assumes that you have already created a bounding

box or semantic segmentation labeling job and its status is Complete. This the labeling job that produces the labels you want adjusted.

To create an image label adjustment job (console)

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/ and choose **Labeling jobs**.
2. Start a new labeling job by chaining a prior job or start from scratch, specifying an input manifest that contains labeled data objects.
3. Choose the same task type as the original labeling job.
4. Choose **Next**.
5. In the **Workers** section, choose the type of workforce you would like to use. For more details about your workforce options see Workforces.
6. (Optional) After you've selected your workforce, specify the **Task timeout** and **Task expiration time**.
7. Expand **Existing-labels display options** by selecting the arrow next to the title.
8. Check the box next to **I want to display existing labels from the dataset for this job**.
9. For **Label attribute name**, choose the name from your manifest that corresponds to the labels that you want to display for adjustment. You will only see label attribute names for labels that match the task type you selected on the previous screen. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.
10. Use the instructions areas of the tool designer to provide context about what the previous labelers were tasked with doing and what the current verifiers need to check and adjust.
11. Choose **See preview** to check that the tool shows the prior labels correctly and presents the task clearly.
12. Select **Create**. This will create and start your labeling job.

Create a point cloud or video frame label adjustment job (console)

Use the following procedure to create a 3D point cloud or video frame adjustment job using the console. This procedure assumes that you have already created a labeling job using the task type that produces the types of labels you want to be verified and its status is Complete.

To create a 3D point cloud or video frame label adjustment job (console)

1. Open the SageMaker AI console: https://console.amazonaws.cn/sagemaker/ and choose **Labeling jobs**.
2. Start a new labeling job by chaining a prior job or start from scratch, specifying an input manifest that contains labeled data objects.
3. Choose the same task type as the original labeling job.
4. Toggle on the switch next to **Display existing labels**.
5. Select **Adjustment**.
6. For **Label attribute name**, choose the name from your manifest that corresponds to the labels that you want to display for adjustment. You will only see label attribute names for labels that match the task type you selected on the previous screen. Ground Truth tries to detect and populate these values by analyzing the manifest, but you might need to set the correct value.
7. Use the instructions areas of the tool designer to provide context about what the previous labelers were asked to do and what the current adjusters need to check.

   You cannot remove or modify existing labels but you can add new labels. You can remove, modify and add new label category attributes or frame attributes.

   Be default, preexisting label category attributes and frame attributes will be editable by workers. If you want to make a label category or frame attribute uneditable, deselect the **Allow workers to edit this attribute** check box for that attribute.

   To learn more about label category and frame attributes, see Worker user interface (UI) for 3D point cloud and Worker user interface (UI) for video frame.
8. Choose **See preview** to check that the tool shows the prior labels correctly and presents the task clearly.
9. Select **Create**. This will create and start your labeling job.

Start a label verification or adjustment job (API)

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Start a label verification or adjustment job by chaining a successfully completed job or starting a new job from scratch using the `CreateLabelingJob` operation. The procedure is almost the same as setting up a new labeling job with `CreateLabelingJob`, with a few modifications. Use the following sections to learn what modifications are required to chain a labeling job to create an adjustment or verification labeling job.

When you create an adjustment or verification labeling job using the Ground Truth API, you *must* use a different `LabelAttributeName` than the original labeling job. The original labeling job is the job used to create the labels you want adjusted or verified.

> **Important**
>
> The label category configuration file you identify for an adjustment or verification job in `LabelCategoryConfigS3Uri` of `CreateLabelingJob` must contain the same labels used in the original labeling job. You can add new labels. For 3D point cloud and video frame jobs, you can add new label category and frame attributes to the label category configuration file.

Bounding Box and Semantic Segmentation

To create a bounding box or semantic segmentation label verification or adjustment job, use the following guidelines to specify API attributes for the `CreateLabelingJob` operation.

- Use the `LabelAttributeName` parameter to specify the output label name that you want to use for verified or adjusted labels. You must use a different `LabelAttributeName` than the one used for the original labeling job.
- If you are chaining the job, the labels from the previous labeling job to be adjusted or verified will be specified in the custom UI template. To learn how to create a custom template, see Create Custom Worker Task Templates.

  Identify the location of the UI template in the `UiTemplateS3Uri` parameter. SageMaker AI provides widgets that you can use in your custom template to display old labels. Use the `initial-value` attribute in one of the following crowd elements to extract the labels that need verification or adjustment and include them in your task template:

  - crowd-semantic-segmentation—Use this crowd element in your custom UI task template to specify semantic segmentation labels that need to be verified or adjusted.

  - crowd-bounding-box—Use this crowd element in your custom UI task template to specify bounding box labels that need to be verified or adjusted.
- The `LabelCategoryConfigS3Uri` parameter must contain the same label categories as the previous labeling job.
- Use the bounding box or semantic segmentation adjustment or verification lambda ARNs for `PreHumanTaskLambdaArn` and `AnnotationConsolidationLambdaArn`:
  - For bounding box, the adjustment labeling job lambda function ARNs end with `AdjustmentBoundingBox` and the verification lambda function ARNs end with `VerificationBoundingBox`.
  - For semantic segmentation, the adjustment labeling job lambda function ARNs end with `AdjustmentSemanticSegmentation` and the verification lambda function ARNs end with `VerificationSemanticSegmentation`.

3D point cloud and video frame

- Use the `LabelAttributeName` parameter to specify the output label name that you want to use for verified or adjusted labels. You must use a different `LabelAttributeName` than the one used for the original labeling job.
- You must use the human task UI Amazon Resource Name (ARN) (`HumanTaskUiArn`) used for the original labeling job. To see supported ARNs, see `HumanTaskUiArn`.
- In the label category configuration file, you must specify the label attribute name (`LabelAttributeName`) of the previous labeling job that you use to create the adjustment or verification labeling job in the `auditLabelAttributeName` parameter.
- You specify whether your labeling job is a *verification* or *adjustment* labeling job using the `editsAllowed` parameter in your label category configuration file identified by the `LabelCategoryConfigS3Uri` parameter.
  - For *verification* labeling jobs, you must use the `editsAllowed` parameter to specify that all labels cannot be modified. `editsAllowed` must be set to `"none"` in each entry in `labels`. Optionally, you can specify whether or not label categories attributes and frame attributes can be adjusted by workers.
  - Optionally, for *adjustment* labeling jobs, you can use the `editsAllowed` parameter to specify labels, label category attributes, and frame attributes that can or cannot be modified by workers. If you do not use this parameter, all labels, label category attributes, and frame attributes will be adjustable.

To learn more about the `editsAllowed` parameter and configuring your label category configuration file, see Label category configuration file schema.

- Use the 3D point cloud or video frame adjustment lambda ARNs for `PreHumanTaskLambdaArn` and `AnnotationConsolidationLambdaArn` for both adjustment and verification labeling jobs:
  - For 3D point clouds, the adjustment and verification labeling job lambda function ARNs end with `Adjustment3DPointCloudSemanticSegmentation`, `Adjustment3DPointCloudObjectTracking`, and `Adjustment3DPointCloudObjectDetection` for 3D point cloud semantic segmentation, object detection, and object tracking respectively.
  - For video frames, the adjustment and verification labeling job lambda function ARNs end with `AdjustmentVideoObjectDetection` and `AdjustmentVideoObjectTracking` for video frame object detection and object tracking respectively.

Ground Truth stores the output data from a label verification or adjustment job in the S3 bucket that you specified in the `S3OutputPath` parameter of the `CreateLabelingJob` operation. For more information about the output data from a label verification or adjustment labeling job, see Label verification and adjustment data in the output manifest.

Label verification and adjustment data in the output manifest

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Amazon SageMaker Ground Truth writes label verification data to the output manifest within the metadata for the label. It adds two properties to the metadata:

- A `type` property, with a value of "`groundtruth/label-verification`.
- A `worker-feedback` property, with an array of `comment` values. This property is added when the worker enters comments. If there are no comments, the field doesn't appear.

The following example output manifest shows how label verification data appears:

```
{
  "source-ref":"S3 bucket location",
  "verify-bounding-box":"1",
  "verify-bounding-box-metadata":
  {
    "class-name": "bad",
    "confidence": 0.93,
    "type": "groundtruth/label-verification",
    "job-name": "verify-bounding-boxes",
    "human-annotated": "yes",
    "creation-date": "2018-10-18T22:18:13.527256",
    "worker-feedback": [
      {"comment": "The bounding box on the bird is too wide on the right side."},
      {"comment": "The bird on the upper right is not labeled."}
    ]
  }
}
```

The worker output of adjustment tasks resembles the worker output of the original task, except that it contains the adjusted values and an `adjustment-status` property with the value of `adjusted` or `unadjusted` to indicate whether an adjustment was made.

For more examples of the output of different tasks, see Labeling job output data.

Custom labeling workflows

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

These topics help you set up a Ground Truth labeling job that uses a custom labeling template. A custom labeling template allows you to create a custom worker portal UI that workers will use to label data. Template can be created using HTML, CSS, JavaScript, Liquid template language, and Crowd HTML Elements.

Overview

If this is your first time creating a custom labeling workflow in Ground Truth, the following list is a high-level summary of the steps required.

1. *Set up your workforce* – To create a custom labeling workflow you need a workforce. This topic teaches you about configuring a workforce.
2. *Creating a custom template* – To create a custom template you must map the data from your input manifest file correctly to the variables in your template.
3. *Using optional processing Lambda functions* – To control how data from your input manifest is added to your worker template, and how worker annotations are logged in your job's output file.

This topic also has three end-to-end demos to help you better understand how to use custom labeling templates.

> **Note**
>
> The examples in the links below all include pre-annotation and post-annotation Lambda functions. These Lambda functions are optional.

- Demo template: Annotation of images with `crowd-bounding-box`
- Demo Template: Labeling Intents with `crowd-classifier`
- Build a custom data labeling workflow with Amazon SageMaker Ground Truth

Topics

- Set up your workforce
- Creating a custom worker task template
- Adding automation with Liquid
- Processing data in a custom labeling workflow with Amazon Lambda
- Demo template: Annotation of images with crowd-bounding-box
- Demo Template: Labeling Intents with crowd-classifier
- Create a custom workflow using the API

Set up your workforce

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

In this step you use the console to establish which worker type to use and make the necessary sub-selections for the worker type. It assumes you have already completed the steps up to this point in the Getting started: Create a bounding box labeling job with Ground Truth section and have chosen the **Custom labeling task** as the **Task type**.

To configure your workforce.

- Choose an option from the **Worker types**. Two types are currently available:
  - **Private** uses your employees or contractors for handling data that needs to stay within your organization.
  - **Vendor** uses third-party vendors that specialize in providing data labeling services, available through the Amazon Marketplace.

Creating a custom worker task template

Creating a custom worker task template

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

To create a custom labeling job, you need to update the worker task template, map the input data from your manifest file to the variables used in the template, and map the output data to Amazon

S3. To learn more about advanced features that use Liquid automation, see Adding automation with Liquid.

The following sections describe each of the required steps.

Worker task template

A *worker task template* is a file used by Ground Truth to customize the worker user interface (UI). You can create a worker task template using HTML, CSS, JavaScript, Liquid template language, and Crowd HTML Elements. Liquid is used to automate the template. Crowd HTML Elements are used to include common annotation tools and provide the logic to submit to Ground Truth.

Use the following topics to learn how you can create a worker task template. You can see a repository of example Ground Truth worker task templates on GitHub.

Using the base worker task template in the SageMaker AI console

You can use a template editor in the Ground Truth console to start creating a template. This editor includes a number of pre-designed base templates. It supports autofill for HTML and Crowd HTML Element code.

To access the Ground Truth custom template editor:

1. Following the instructions in Create a Labeling Job (Console).
2. Then select **Custom** for the labeling job **Task type**.
3. Choose **Next**, and then you can access the template editor and base templates in the **Custom labeling task setup** section.
4. (Optional) Select a base template from the drop-down menu under **Templates**. If you prefer to create a template from scratch, choose **Custom** from the drop down-menu for a minimal template skeleton.

Use the following section to learn how to visualize a template developed in the console locally.

Visualizing your worker task templates locally

You must use the console to test how your template processes incoming data. To test the look and feel of your template's HTML and custom elements you can use your browser.

> **Note**
>
> Variables will not be parsed. You may need to replace them with sample content while viewing your content locally.

The following example code snippet loads the necessary code to render the custom HTML elements. Use this if you want to develop your template's look and feel in your preferred editor rather than in the console.

Example

Creating a simple HTML task sample

Now that you have the base worker task template, you can use this topic to create a simple HTML-based task template.

The following is an example entry from an input manifest file.

```
{
  "source": "This train is really late.",
  "labels": [ "angry" , "sad", "happy" , "inconclusive" ],
  "header": "What emotion is the speaker feeling?"
}
```

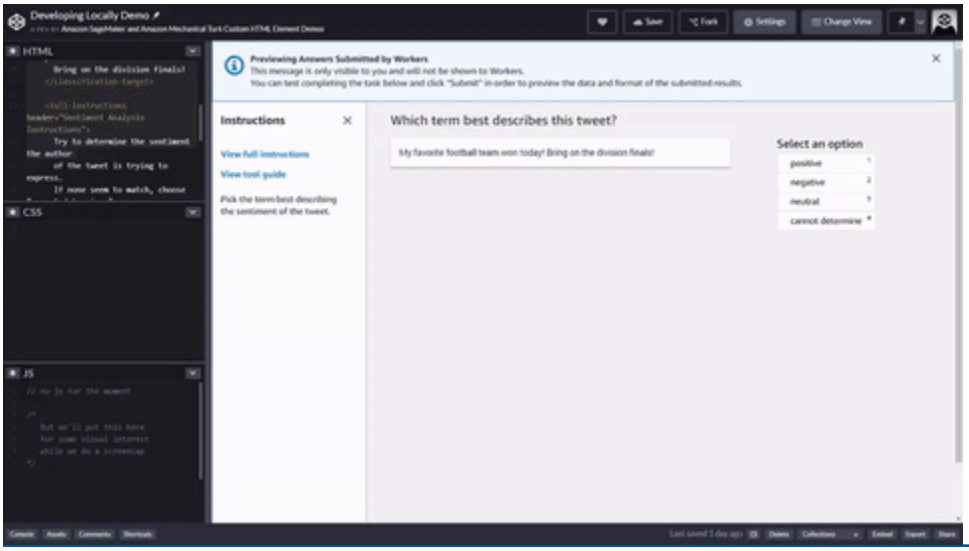
In the HTML task template we need to map the variables from input manifest file to the template. The variable from the example input manifest would be mapped using the following syntax **`task.input.source`**, **`task.input.labels`**, and **`task.input.header`**.

The following is a simple example HTML worker task template for tweet-analysis. All tasks begin and end with the `<crowd-form> </crowd-form>` elements. Like standard HTML `<form>` elements, all of your form code should go between them. Ground Truth generates the workers' tasks directly from the context specified in the template, unless you implement a pre-annotation Lambda. The `taskInput` object returned by Ground Truth or Pre-annotation Lambda is the `task.input` object in your templates.

For a simple tweet-analysis task, use the `<crowd-classifier>` element. It requires the following attributes:

- *name* - The name of your output variable. Worker annotations are saved to this variable name in your output manifest.

- *categories* - a JSON formatted array of the possible answers.
- *header* - a title for the annotation tool



The `<crowd-classifier>` element requires at least the three following child elements.

- *<classification-target>* - The text the worker will classify based on the options specified in the `categories` attribute above.
- *<full-instructions>* - Instructions that are available from the "View full instructions" link in the tool. This can be left blank, but it is recommended that you give good instructions to get better results.
- *<short-instructions>* - A more brief description of the task that appears in the tool's sidebar. This can be left blank, but it is recommended that you give good instructions to get better results.

A simple version of this tool would look like the following. The variable **`{{ task.input.source }}`** is what specifies the source data from your input manifest file. The **`{{ task.input.labels | to_json }}`** is an example of a variable filter to turn the array into a JSON representation. The `categories` attribute must be JSON.

Example of using `crowd-classifier` with the sample input manifest json

You can copy and paste the code into the editor in the Ground Truth labeling job creation workflow to preview the tool, or try out a demo of this code on CodePen.

Input data, external assets and your task template

Following sections describe the use of external assets, input data format requirements, and when to consider using pre-annotation Lambda functions.

Input data format requirements

When you create an input manifest file to use in your custom Ground Truth labeling job, you must store the data in Amazon S3. The input manifest files must also be saved in the same Amazon Web Services Region in which your custom Ground Truth labeling job is to be run. Furthermore, it can be stored in any Amazon S3 bucket that is accessible to the IAM service role that you use to run your custom labeling job in Ground Truth.

Input manifest files must use the newline-delimited JSON or JSON lines format. Each line is delimited by a standard line break, **\n** or **\r\n**. Each line must also be a valid JSON object.

Furthermore, each JSON object in the manifest file must contain one of the following keys: `source-ref` or `source`. The value of the keys are interpreted as follows:

- `source-ref` – The source of the object is the Amazon S3 object specified in the value. Use this value when the object is a binary object, such as an image.
- `source` – The source of the object is the value. Use this value when the object is a text value.

To learn more about formatting your input manifest files, see Input manifest files.

Pre-annotation Lambda function

You can optionally specify a *pre-annotation Lambda* function to manage how data from your input manifest file is handled prior to labeling. If you have specified the `isHumanAnnotationRequired` key-value pair you must us a pre-annotation Lambda function. When Ground Truth sends the pre-annotation Lambda function a JSON formatted request it uses the following schemas.

Example data object identified with the `source-ref` key-value pair

```
{
  "version": "2018-10-16",
  "labelingJobArn": arn:aws:lambda:us-west-2:555555555555:function:my-function
  "dataObject" : {
    "source-ref": s3://input-data-bucket/data-object-file-name
  }
}
```

Example data object identified with the `source` key-value pair

```
{
      "version": "2018-10-16",
      "labelingJobArn" : arn:aws:lambda:us-west-2:555555555555:function:my-function
      "dataObject" : {
        "source": Sue purchased 10 shares of the stock on April 10th, 2020
      }
    }
```

The following is the expected response from the Lambda function when `isHumanAnnotationRequired` is used.

```
{
  "taskInput": {
    "source": "This train is really late.",
    "labels": [ "angry" , "sad" , "happy" , "inconclusive" ],
    "header": "What emotion is the speaker feeling?"
  },
  "isHumanAnnotationRequired": False
}
```

Using External Assets

Amazon SageMaker Ground Truth custom templates allow external scripts and style sheets to be embedded. For example, the following code block demonstrates how you would add a style sheet located at `https://www.example.com/my-enhancement-styles.css` to your template.

Example

```
<script src="https://www.example.com/my-enhancment-script.js"></script>
<link rel="stylesheet" type="text/css" href="https://www.example.com/my-enhancement-
styles.css">
```

If you encounter errors, ensure that your originating server is sending the correct MIME type and encoding headers with the assets.

For example, the MIME and encoding types for remote scripts are: `application/javascript;CHARSET=UTF-8`.

The MIME and encoding type for remote stylesheets are: `text/css;CHARSET=UTF-8`.

Output data and your task template

The following sections describe the output data from a custom labeling job, and when to consider using a post-annotation Lambda function.

Output data

When your custom labeling job is finished, the data is saved in the Amazon S3 bucket specified when the labeling job was created. The data is saved in an `output.manifest` file.

> **Note**
>
> *`labelAttributeName`* is a placeholder variable. In your output it is either the name of your labeling job, or the label attribute name you specify when you create the labeling job.

- `source` or `source-ref` – Either the string or an S3 URI workers were asked to label.
- `labelAttributeName` – A dictionary containing consolidated label content from the post-annotation Lambda function. If a post-annotation Lambda function is not specified, this dictionary will be empty.
- `labelAttributeName-metadata` – Metadata from your custom labeling job added by Ground Truth.
- `worker-response-ref` – The S3 URI of the bucket where the data is saved. If a post-annotation Lambda function is specified this key-value pair will not present.

In this example the JSON object is formatted for readability, in the actual output file the JSON object is on a single line.

```
{
  "source" : "This train is really late.",
  "labelAttributeName" : {},
  "labelAttributeName-metadata": { # These key values pairs are added by Ground Truth
    "job_name": "test-labeling-job",
    "type": "groundTruth/custom",
    "human-annotated": "yes",
    "creation_date": "2021-03-08T23:06:49.111000",
    "worker-response-ref": "s3://amzn-s3-demo-bucket/test-labeling-job/annotations/
worker-response/iteration-1/0/2021-03-08_23:06:49.json"
  }
```

```
}
```

Using a post annotation Lambda to consolidate the results from your workers

By default Ground Truth saves worker responses unprocessed in Amazon S3. To have more fine-grained control over how responses are handled, you can specify a *post-annotation Lambda function*. For example, a post-annotation Lambda function could be used to consolidate annotation if multiple workers have labeled the same data object. To learn more about creating post-annotation Lambda functions, see Post-annotation Lambda.

If you want to use a post-annotation Lambda function, it must be specified as part of the `AnnotationConsolidationConfig` in a `CreateLabelingJob` request.

To learn more about how annotation consolidation works, see Annotation consolidation.

Adding automation with Liquid

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Our custom template system uses Liquid for automation. It is an open source inline markup language. In Liquid, the text between single curly braces and percent symbols is an instruction or *tag* that performs an operation like control flow or iteration. Text between double curly braces is a variable or *object* that outputs its value.

The most common use of Liquid will be to parse the data coming from your input manifest file, and pull out the relevant variables to create the task. Ground Truth automatically generates the tasks unless a pre-annotation Lambda is specified. The `taskInput` object returned by Ground Truth or your Pre-annotation Lambda is the `task.input` object in your templates.

The properties in your input manifest are passed into your template as the `event.dataObject`.

Example manifest data object

```
{
  "source": "This is a sample text for classification",
```

```
  "labels": [ "angry" , "sad" , "happy" , "inconclusive" ],
  "header": "What emotion is the speaker feeling?"
}
```

Example sample HTML using variables

```
<crowd-classifier
  name='tweetFeeling'
  categories='{{ task.input.labels | to_json }}'
  header='{{ task.input.header }}' >
<classification-target>
  {{ task.input.source }}
</classification-target>
```

Note the addition of `| to_json` to the `labels` property above. That is a filter that turns the input manifest array into a JSON representation of the array. Variable filters are explained in the next section.

The following list includes two types of Liquid tags that you may find useful to automate template input data processing. If you select one of the following tag-types, you will be redirected to the Liquid documentation.

- Control flow: Includes programming logic operators like `if/else`, `unless`, and `case/when`.
- Iteration: Enables you to run blocks of code repeatedly using statements like for loops.

  For an example of an HTML template that uses Liquid elements to create a for loop, see translation-review-and-correction.liquid.html in GitHub.

For more information and documentation, visit the Liquid homepage.

Variable filters

In addition to the standard Liquid filters and actions, Ground Truth offers a few additional filters. Filters are applied by placing a pipe (|) character after the variable name, then specifying a filter name. Filters can be chained in the form of:

Example

```
{{ <content> | <filter> | <filter> }}
```

Autoescape and explicit escape

By default, inputs will be HTML escaped to prevent confusion between your variable text and HTML. You can explicitly add the `escape` filter to make it more obvious to someone reading the source of your template that the escaping is being done.

escape_once

`escape_once` ensures that if you've already escaped your code, it doesn't get re-escaped on top of that. For example, so that & doesn't become &.

skip_autoescape

`skip_autoescape` is useful when your content is meant to be used as HTML. For example, you might have a few paragraphs of text and some images in the full instructions for a bounding box.

> **Use `skip_autoescape` sparingly**
>
> The best practice in templates is to avoid passing in functional code or markup with `skip_autoescape` unless you are absolutely sure you have strict control over what's being passed. If you're passing user input, you could be opening your workers up to a Cross Site Scripting attack.

to_json

`to_json` will encode what you feed it to JSON (JavaScript Object Notation). If you feed it an object, it will serialize it.

grant_read_access

`grant_read_access` takes an S3 URI and encodes it into an HTTPS URL with a short-lived access token for that resource. This makes it possible to display to workers the photo, audio, or video objects stored in S3 buckets that are not otherwise publicly accessible.

s3_presign

The `s3_presign` filter works the same way as the `grant_read_access` filter. `s3_presign` takes an Amazon S3 URI and encodes it into an HTTPS URL with a short-lived access token for that

resource. This makes it possible to display photo, audio, or video objects stored in S3 buckets that are not otherwise publicly accessible to workers.

Example of the variable filters

Input

```
auto-escape: {{ "Have you read 'James & the Giant Peach'?" }}
explicit escape: {{ "Have you read 'James & the Giant Peach'?" | escape }}
explicit escape_once: {{ "Have you read 'James &amp; the Giant Peach'?" |
 escape_once }}
skip_autoescape: {{ "Have you read 'James & the Giant Peach'?" | skip_autoescape }}
to_json: {{ jsObject | to_json }}
grant_read_access: {{ "s3://amzn-s3-demo-bucket/myphoto.png" | grant_read_access }}
s3_presign: {{ "s3://amzn-s3-demo-bucket/myphoto.png" | s3_presign }}
```

Example

Output

```
auto-escape: Have you read &#39;James &amp; the Giant Peach&#39;?
explicit escape: Have you read &#39;James &amp; the Giant Peach&#39;?
explicit escape_once: Have you read &#39;James &amp; the Giant Peach&#39;?
skip_autoescape: Have you read 'James & the Giant Peach'?
to_json: { "point_number": 8, "coords": [ 59, 76 ] }
grant_read_access: https://s3.amazonaws.com/amzn-s3-demo-bucket/myphoto.png?<access
 token and other params>
s3_presign: https://s3.amazonaws.com/amzn-s3-demo-bucket/myphoto.png?<access token and
 other params>
```

Example of an automated classification template.

To automate the simple text classification sample, replace the tweet text with a variable.

The text classification template is below with automation added. The changes/additions are highlighted in bold.

The tweet text in the prior sample is now replaced with an object. The `entry.taskInput` object uses `source` (or another name you specify in your pre-annotation Lambda) as the property name for the text, and it is inserted directly in the HTML by virtue of being between double curly braces.

Processing data in a custom labeling workflow with Amazon Lambda

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

In this topic, you can learn how to deploy optional Amazon Lambda functions when creating a custom labeling workflow. You can specify two types of Lambda functions to use with your custom labeling workflow.

- *Pre-annotation Lambda*: This function pre-processes each data object sent to your labeling job prior to sending it to workers.
- *Post-annotation Lambda*: This function processes the results once workers submit a task. If you specify multiple workers per data object, this function may include logic to consolidate annotations.

If you are a new user of Lambda and Ground Truth, we recommend that you use the pages in this section as follows:

1. First, review Using pre-annotation and post-annotation Lambda functions.
2. Then, use the page Add required permissions to use Amazon Lambda with Ground Truth to learn about security and permission requirements to use your pre-annotation and post-annotation Lambda functions in a Ground Truth custom labeling job.
3. Next, you need to visit the Lambda console or use Lambda's APIs to create your functions. Use the section Create Lambda functions using Ground Truth templates to learn how to create Lambda functions.
4. To learn how to test your Lambda functions, see Test pre-annotation and post-annotation Lambda functions.
5. After you create pre-processing and post-processing Lambda functions, select them from the **Lambda functions** section that comes after the code editor for your custom HTML in the Ground Truth console. To learn how to use these functions in a `CreateLabelingJob` API request, see Create a Labeling Job (API).

For a custom labeling workflow tutorial that includes example pre-annotation and post-annotation Lambda functions, see Demo template: Annotation of images with `crowd-bounding-box`.

Topics

- Using pre-annotation and post-annotation Lambda functions
- Add required permissions to use Amazon Lambda with Ground Truth
- Create Lambda functions using Ground Truth templates
- Test pre-annotation and post-annotation Lambda functions

Using pre-annotation and post-annotation Lambda functions

Use these topics to learn about the syntax of the requests sent to pre-annotation and post-annotation Lambda functions, and the required response syntax that Ground Truth uses in custom labeling workflows.

Topics

- Pre-annotation Lambda
- Post-annotation Lambda

Pre-annotation Lambda

Before a labeling task is sent to the worker, a optional pre-annotation Lambda function can be invoked.

Ground Truth sends your Lambda function a JSON formatted request to provide details about the labeling job and the data object.

The following are 2 example JSON formatted requests.

Data object identified with "source-ref"

```
{
    "version": "2018-10-16",
    "labelingJobArn": <labelingJobArn>
    "dataObject" : {
        "source-ref": <s3Uri>
    }
}
```

Data object identified with "source"

```
{
    "version": "2018-10-16",
    "labelingJobArn": <labelingJobArn>
    "dataObject" : {
        "source": <string>
    }
}
```

The following list contains the pre-annotation request schemas. Each parameter is described below.

- `version` (string): This is a version number used internally by Ground Truth.
- `labelingJobArn` (string): This is the Amazon Resource Name, or ARN, of your labeling job. This ARN can be used to reference the labeling job when using Ground Truth API operations such as `DescribeLabelingJob`.
- The `dataObject` (JSON object): The key contains a single JSON line, either from your input manifest file or sent from Amazon SNS. The JSON line objects in your manifest can be up to 100 kilobytes in size and contain a variety of data. For a very basic image annotation job, the `dataObject` JSON may just contain a `source-ref` key, identifying the image to be annotated. If the data object (for example, a line of text) is included directly in the input manifest file, the data object is identified with `source`. If you create a verification or adjustment job, this line may contain label data and metadata from the previous labeling job.

The following tabbed examples show examples of a pre-annotation request. Each parameter in these example requests is explained below the tabbed table.

Data object identified with "source-ref"

```
{
    "version": "2018-10-16",
    "labelingJobArn": "arn:aws:sagemaker:us-west-2:111122223333:labeling-job/
<labeling_job_name>"
    "dataObject" : {
        "source-ref": "s3://input-data-bucket/data-object-file-name"
    }
}
```

Data object identified with "source"

```
{
    "version": "2018-10-16",
    "labelingJobArn": "arn:aws:sagemaker:<aws_region>:111122223333:labeling-job/
<labeling_job_name>"
    "dataObject" : {
        "source": "Sue purchased 10 shares of the stock on April 10th, 2020"
    }
}
```

In return, Ground Truth requires a response formatted like the following:

Example of expected return data

```
{
    "taskInput": <json object>,
    "isHumanAnnotationRequired": <boolean> # Optional
}
```

In the previous example, the `<json object>` needs to contain *all* the data your custom worker task template needs. If you're doing a bounding box task where the instructions stay the same all the time, it may just be the HTTP(S) or Amazon S3 resource for your image file. If it's a sentiment analysis task and different objects may have different choices, it is the object reference as a string and the choices as an array of strings.

Implications of `isHumanAnnotationRequired`

This value is optional because it defaults to `true`. The primary use case for explicitly setting it is when you want to exclude this data object from being labeled by human workers.

If you have a mix of objects in your manifest, with some requiring human annotation and some not needing it, you can include a `isHumanAnnotationRequired` value in each data object. You can add logic to your pre-annotation Lambda to dynamically determine if an object requires annotation, and set this boolean value accordingly.

Examples of pre-annotation Lambda functions

The following basic pre-annotation Lambda function accesses the JSON object in `dataObject` from the initial request, and returns it in the `taskInput` parameter.

```
import json

def lambda_handler(event, context):
    return {
        "taskInput":  event['dataObject']
    }
```

Assuming the input manifest file uses `"source-ref"` to identify data objects, the worker task template used in the same labeling job as this pre-annotation Lambda must include a Liquid element like the following to ingest `dataObject`:

```
{{ task.input.source-ref | grant_read_access }}
```

If the input manifest file used `source` to identify the data object, the work task template can ingest `dataObject` with the following:

```
{{ task.input.source }}
```

The following pre-annotation Lambda example includes logic to identify the key used in `dataObject`, and to point to that data object using `taskObject` in the Lambda's return statement.

```
import json

def lambda_handler(event, context):

    # Event received
    print("Received event: " + json.dumps(event, indent=2))

    # Get source if specified
    source = event['dataObject']['source'] if "source" in event['dataObject'] else None

    # Get source-ref if specified
    source_ref = event['dataObject']['source-ref'] if "source-ref" in
 event['dataObject'] else None
```

```
    # if source field present, take that otherwise take source-ref
    task_object = source if source is not None else source_ref

    # Build response object
    output = {
        "taskInput": {
            "taskObject": task_object
        },
        "humanAnnotationRequired": "true"
    }

    print(output)
    # If neither source nor source-ref specified, mark the annotation failed
    if task_object is None:
        print(" Failed to pre-process {} !".format(event["labelingJobArn"]))
        output["humanAnnotationRequired"] = "false"

    return output
```

Post-annotation Lambda

When all workers have annotated the data object or when `TaskAvailabilityLifetimeInSeconds` has been reached, whichever comes first, Ground Truth sends those annotations to your post-annotation Lambda. This Lambda is generally used for Annotation consolidation.

> **Note**
>
> To see an example of a post-consolidation Lambda function, see annotation_consolidation_lambda.py in the aws-sagemaker-ground-truth-recipe GitHub repository.

The following code block contains the post-annotation request schema. Each parameter is described in the following bulleted list.

```
{
    "version": "2018-10-16",
    "labelingJobArn": <string>,
    "labelCategories": [<string>],
```

```
    "labelAttributeName": <string>,
    "roleArn" : <string>,
    "payload": {
        "s3Uri": <string>
    }
}
```

- `version` (string): A version number used internally by Ground Truth.
- `labelingJobArn` (string): The Amazon Resource Name, or ARN, of your labeling job. This ARN can be used to reference the labeling job when using Ground Truth API operations such as `DescribeLabelingJob`.
- `labelCategories` (list of strings): Includes the label categories and other attributes you either specified in the console, or that you include in the label category configuration file.
- `labelAttributeName` (string): Either the name of your labeling job, or the label attribute name you specify when you create the labeling job.
- `roleArn` (string): The Amazon Resource Name (ARN) of the IAM execution role you specify when you create the labeling job.
- `payload` (JSON object): A JSON that includes an `s3Uri` key, which identifies the location of the annotation data for that data object in Amazon S3. The second code block below shows an example of this annotation file.

The following code block contains an example of a post-annotation request. Each parameter in this example request is explained below the code block.

Example of an post-annotation Lambda request

```
{
    "version": "2018-10-16",
    "labelingJobArn": "arn:aws:sagemaker:us-west-2:111122223333:labeling-job/labeling-
job-name",
    "labelCategories": ["Ex Category1","Ex Category2", "Ex Category3"],
    "labelAttributeName": "labeling-job-attribute-name",
    "roleArn" : "arn:aws:iam::111122223333:role/role-name",
    "payload": {
        "s3Uri": "s3://amzn-s3-demo-bucket/annotations.json"
    }
}
```

> **Note**
>
> If no worker works on the data object and `TaskAvailabilityLifetimeInSeconds` has been reached, the data object is marked as failed and not included as part of post-annotation Lambda invocation.

The following code block contains the payload schema. This is the file that is indicated by the `s3Uri` parameter in the post-annotation Lambda request `payload` JSON object. For example, if the previous code block is the post-annotation Lambda request, the following annotation file is located at `s3://amzn-s3-demo-bucket/annotations.json`.

Each parameter is described in the following bulleted list.

Example of an annotation file

```
[
    {
        "datasetObjectId": <string>,
        "dataObject": {
            "s3Uri": <string>,
            "content": <string>
        },
        "annotations": [{
            "workerId": <string>,
            "annotationData": {
                "content": <string>,
                "s3Uri": <string>
            }
       }]
    }
]
```

- `datasetObjectId` (string): Identifies a unique ID that Ground Truth assigns to each data object you send to the labeling job.
- `dataObject` (JSON object): The data object that was labeled. If the data object is included in the input manifest file and identified using the `source` key (for example, a string), `dataObject` includes a `content` key, which identifies the data object. Otherwise, the location of the data object (for example, a link or S3 URI) is identified with `s3Uri`.

- `annotations` (list of JSON objects): This list contains a single JSON object for each annotation submitted by workers for that `dataObject`. A single JSON object contains a unique `workerId` that can be used to identify the worker that submitted that annotation. The `annotationData` key contains one of the following:
  - `content` (string): Contains the annotation data.
  - `s3Uri` (string): Contains an S3 URI that identifies the location of the annotation data.

The following table contains examples of the content that you may find in payload for different types of annotation.

Named Entity Recognition Payload

```
[
    {
      "datasetObjectId": "1",
      "dataObject": {
        "content": "Sift 3 cups of flour into the bowl."
      },
      "annotations": [
        {
          "workerId": "private.us-west-2.ef7294f850a3d9d1",
          "annotationData": {
            "content": "{\"crowd-entity-annotation\":{\"entities\":[{\"endOffset
\":4,\"label\":\"verb\",\"startOffset\":0},{\"endOffset\":6,\"label\":\"number
\",\"startOffset\":5},{\"endOffset\":20,\"label\":\"object\",\"startOffset\":15},
{\"endOffset\":34,\"label\":\"object\",\"startOffset\":30}]}}"
          }
        }
      ]
    }
]
```

Semantic Segmentation Payload

```
[
    {
      "datasetObjectId": "2",
      "dataObject": {
        "s3Uri": "s3://amzn-s3-demo-bucket/gt-input-data/images/bird3.jpg"
      },
      "annotations": [
```

```
        {
          "workerId": "private.us-west-2.ab1234c5678a919d0",
          "annotationData": {
            "content": "{\"crowd-semantic-segmentation\":{\"inputImageProperties\":
{\"height\":2000,\"width\":3020},\"labelMappings\":{\"Bird\":{\"color\":\"#2ca02c
\"}},\"labeledImage\":{\"pngImageData\":\"iVBOR...\"}}}"
          }
        }
      ]
    }
  ]
```

Bounding Box Payload

```
[
    {
      "datasetObjectId": "0",
      "dataObject": {
        "s3Uri": "s3://amzn-s3-demo-bucket/gt-input-data/images/bird1.jpg"
      },
      "annotations": [
        {
          "workerId": "private.us-west-2.ab1234c5678a919d0",
          "annotationData": {
            "content": "{\"boundingBox\":{\"boundingBoxes\":[{\"height\":2052,
\"label\":\"Bird\",\"left\":583,\"top\":302,\"width\":1375}],\"inputImageProperties
\":{\"height\":2497,\"width\":3745}}}"
          }
        }
      ]
    }
 ]
```

Your post-annotation Lambda function may contain logic similar to the following to loop through and access all annotations contained in the request. For a full example, see annotation_consolidation_lambda.py in the aws-sagemaker-ground-truth-recipe GitHub repository. In this GitHub example, you must add your own annotation consolidation logic.

```
for i in range(len(annotations)):
    worker_id = annotations[i]["workerId"]
    annotation_content = annotations[i]['annotationData'].get('content')
```

```
    annotation_s3_uri = annotations[i]['annotationData'].get('s3uri')
    annotation = annotation_content if annotation_s3_uri is None else
s3_client.get_object_from_s3(
        annotation_s3_uri)
    annotation_from_single_worker = json.loads(annotation)

    print("{} Received Annotations from worker [{}] is [{}]"
            .format(log_prefix, worker_id, annotation_from_single_worker))
```

Tip

When you run consolidation algorithms on the data, you can use an Amazon database service to store results, or you can pass the processed results back to Ground Truth. The data you return to Ground Truth is stored in consolidated annotation manifests in the S3 bucket specified for output during the configuration of the labeling job.

In return, Ground Truth requires a response formatted like the following:

Example of expected return data

```
[
   {
        "datasetObjectId": <string>,
        "consolidatedAnnotation": {
            "content": {
                "<labelattributename>": {
                    # ... label content
                }
            }
        }
    },
   {
        "datasetObjectId": <string>,
        "consolidatedAnnotation": {
            "content": {
                "<labelattributename>": {
                    # ... label content
                }
            }
        }
    }
```

```
    .
    .
    .
]
```

At this point, all the data you're sending to your S3 bucket, other than the `datasetObjectId`, is in the `content` object.

When you return annotations in `content`, this results in an entry in your job's output manifest like the following:

Example of label format in output manifest

```
{  "source-ref"/"source" : "<s3uri or content>",
   "<labelAttributeName>": {
        # ... label content from you
    },
   "<labelAttributeName>-metadata": { # This will be added by Ground Truth
        "job_name": <labelingJobName>,
        "type": "groundTruth/custom",
        "human-annotated": "yes",
        "creation_date": <date> # Timestamp of when received from Post-labeling Lambda
    }
}
```

Because of the potentially complex nature of a custom template and the data it collects, Ground Truth does not offer further processing of the data.

Add required permissions to use Amazon Lambda with Ground Truth

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You may need to configure some or all the following to create and use Amazon Lambda with Ground Truth.

- You need to grant an IAM role or user (collectively, an IAM entity) permission to create the pre-annotation and post-annotation Lambda functions using Amazon Lambda, and to choose them when creating the labeling job.
- The IAM execution role specified when the labeling job is configured needs permission to invoke the pre-annotation and post-annotation Lambda functions.
- The post-annotation Lambda functions may need permission to access Amazon S3.

Use the following sections to learn how to create the IAM entities and grant permissions described above.

Topics

- Grant Permission to Create and Select an Amazon Lambda Function
- Grant IAM Execution Role Permission to Invoke Amazon Lambda Functions
- Grant Post-Annotation Lambda Permissions to Access Annotation

Grant Permission to Create and Select an Amazon Lambda Function

If you do not require granular permissions to develop pre-annotation and post-annotation Lambda functions, you can attach the Amazon managed policy `AWSLambda_FullAccess` to a user or role. This policy grants broad permissions to use all Lambda features, as well as permission to perform actions in other Amazon services with which Lambda interacts.

To create a more granular policy for security-sensitive use cases, refer to the documentation Identity-based IAM policies for Lambda in the to Amazon Lambda Developer Guide to learn how to create an IAM policy that fits your use case.

Policies to Use the Lambda Console

If you want to grant an IAM entity permission to use the Lambda console, see Using the Lambda console in the Amazon Lambda Developer Guide.

Additionally, if you want the user to be able to access and deploy the Ground Truth starter pre-annotation and post-annotation functions using the Amazon Serverless Application Repository in the Lambda console, you must specify the *<aws-region>* where you want to deploy the functions (this should be the same Amazon Region used to create the labeling job), and add the following policy to the IAM role.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "serverlessrepo:ListApplicationVersions",
                "serverlessrepo:GetApplication",
                "serverlessrepo:CreateCloudFormationTemplate"
            ],
            "Resource": "arn:aws-cn:serverlessrepo:us-
east-1:838997950401:applications/aws-sagemaker-ground-truth-recipe"
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": "serverlessrepo:SearchApplications",
            "Resource": "*"
        }
    ]
}
```

Policies to See Lambda Functions in the Ground Truth Console

To grant an IAM entity permission to view Lambda functions in the Ground Truth console when the user is creating a custom labeling job, the entity must have the permissions described in Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console, including the permissions described in the section Custom Labeling Workflow Permissions.

Grant IAM Execution Role Permission to Invoke Amazon Lambda Functions

If you add the IAM managed policy AmazonSageMakerGroundTruthExecution to the IAM execution role used to create the labeling job, this role has permission to list and invoke Lambda functions with one of the following strings in the function name: `GtRecipe`, `SageMaker`, `Sagemaker`, `sagemaker`, or `LabelingFunction`.

If the pre-annotation or post-annotation Lambda function names do not include one of the terms in the preceding paragraph, or if you require more granular permission than those in the

`AmazonSageMakerGroundTruthExecution` managed policy, you can add a policy similar to the following to give the execution role permission to invoke pre-annotation and post-annotation functions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "lambda:InvokeFunction",
            "Resource": [
                "arn:aws-cn:lambda:us-east-1:111122223333:function:<pre-
annotation-lambda-name>",
                "arn:aws-cn:lambda:us-east-1:111122223333:function:<post-
annotation-lambda-name>"
            ]
        }
    ]
}
```

Grant Post-Annotation Lambda Permissions to Access Annotation

As described in Post-annotation Lambda, the post-annotation Lambda request includes the location of the annotation data in Amazon S3. This location is identified by the `s3Uri` string in the `payload` object. To process the annotations as they come in, even for a simple pass through function, you need to assign the necessary permissions to the post-annotation Lambda execution role to read files from the Amazon S3.

There are many ways that you can configure your Lambda to access annotation data in Amazon S3. Two common ways are:

- Allow the Lambda execution role to assume the SageMaker AI execution role identified in `roleArn` in the post-annotation Lambda request. This SageMaker AI execution role is the one used to create the labeling job, and has access to the Amazon S3 output bucket where the annotation data is stored.
- Grant the Lambda execution role permission to access the Amazon S3 output bucket directly.

Use the following sections to learn how to configure these options.

Grant Lambda Permission to Assume SageMaker AI Execution Role

To allow a Lambda function to assume a SageMaker AI execution role, you must attach a policy to the Lambda function's execution role, and modify the trust relationship of the SageMaker AI execution role to allow Lambda to assume it.

1. Attach the following IAM policy to your Lambda function's execution role to assume the SageMaker AI execution role identified in `Resource`. Replace *222222222222* with an Amazon account ID. Replace *sm-execution-role* with the name of the assumed role.

   JSON

   ```
   {
       "Version":"2012-10-17",
       "Statement": {
           "Effect": "Allow",
           "Action": "sts:AssumeRole",
           "Resource": "arn:aws-cn:iam::222222222222:role/sm-execution-role"
       }
   }
   ```

2. Modify the trust policy of the SageMaker AI execution role to include the following `Statement`. Replace *222222222222* with an Amazon account ID. Replace *my-lambda-execution-role* with the name of the assumed role.

   JSON

   ```
   {
       "Version":"2012-10-17",
       "Statement": [
           {
               "Effect": "Allow",
               "Principal": {
                   "AWS": "arn:aws-cn:iam::222222222222:role/my-lambda-execution-
   role"
               },
               "Action": "sts:AssumeRole"
           }
       ]
   }
   ```

Grant Lambda Execution Role Permission to Access S3

You can add a policy similar to the following to the post-annotation Lambda function execution role to give it S3 read permissions. Replace *amzn-s3-demo-bucket* with the name of the output bucket you specify when you create a labeling job.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": "arn:aws-cn:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

To add S3 read permissions to a Lambda execution role in the Lambda console, use the following procedure.

Add S3 read permissions to post-annotation Lambda:

1. Open the **Functions** page in the Lambda console.
2. Choose the name of the post-annotation function.
3. Choose **Configuration** and then choose **Permissions**.
4. Select the **Role name** and the summary page for that role opens in the IAM console in a new tab.
5. Select **Attach policies**.
6. Do one of the following:

   - Search for and select **`AmazonS3ReadOnlyAccess`** to give the function permission to read all buckets and objects in the account.

- If you require more granular permissions, select **Create policy** and use the policy example in the preceding section to create a policy. Note that you must navigate back to the execution role summary page after you create the policy.

7. If you used the `AmazonS3ReadOnlyAccess` managed policy, select **Attach policy**.

   If you created a new policy, navigate back to the Lambda execution role summary page and attach the policy you just created.

Create Lambda functions using Ground Truth templates

You can create a Lambda function using the Lambda console, the Amazon CLI, or an Amazon SDK in a supported programming language of your choice. Use the Amazon Lambda Developer Guide to learn more about each of these options:

- To learn how to create a Lambda function using the console, see Create a Lambda function with the console.
- To learn how to create a Lambda function using the Amazon CLI, see Using Amazon Lambda with the Amazon Command Line Interface.
- Select the relevant section in the table of contents to learn more about working with Lambda in the language of your choice. For example, select Working with Python to learn more about using Lambda with the Amazon SDK for Python (Boto3).

Ground Truth provides pre-annotation and post-annotation templates through an Amazon Serverless Application Repository (SAR) *recipe*. Use the following procedure to select the Ground Truth recipe in the Lambda console.

Use the Ground Truth SAR recipe to create pre-annotation and post-annotation Lambda functions:

1. Open the **Functions** page on the Lambda console.
2. Select **Create function**.
3. Select **Browse serverless app repository**.
4. In the search text box, enter **aws-sagemaker-ground-truth-recipe** and select that app.
5. Select **Deploy**. The app may take a couple of minutes to deploy.

Once the app deploys, two functions appear in the **Functions** section of the Lambda console: `serverlessrepo-aws-sagema-GtRecipePreHumanTaskFunc-<id>` and `serverlessrepo-aws-sagema-GtRecipeAnnotationConsol-<id>`.

6. Select one of these functions and add your custom logic in the **Code** section.
7. When you are finished making changes, select **Deploy** to deploy them.

Test pre-annotation and post-annotation Lambda functions

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can test your pre-annotation and post annotation Lambda functions in the Lambda console. If you are a new user of Lambda, you can learn how to test, or *invoke*, your Lambda functions in the console using the Create a Lambda function tutorial with the console in the Amazon Lambda Developer Guide. You can use the sections on this page to learn how to test the Ground Truth pre-annotation and post-annotation templates provided through an Amazon Serverless Application Repository (SAR).

Topics

- Prerequisites
- Test the Pre-annotation Lambda Function
- Test the Post-Annotation Lambda Function

Prerequisites

You must do the following to use the tests described on this page.

- You need access to the Lambda console, and you need permission to create and invoke Lambda functions. To learn how to set up these permissions, see Grant Permission to Create and Select an Amazon Lambda Function.
- If you have not deployed the Ground Truth SAR recipe, use the procedure in Create Lambda functions using Ground Truth templates to do so.

- To test the post-annotation Lambda function, you must have a data file in Amazon S3 with sample annotation data. For a simple test, you can copy and paste the following code into a file and save it as `sample-annotations.json` and upload this file to Amazon S3. Note the S3 URI of this file—you need this information to configure the post-annotation Lambda test.

```
[{"datasetObjectId":"0","dataObject":{"content":"To train a machine learning model,
 you need a large, high-quality, labeled dataset. Ground Truth helps you build
 high-quality training datasets for your machine learning models."},"annotations":
[{"workerId":"private.us-west-2.0123456789","annotationData":{"content":"{\"crowd-
entity-annotation\":{\"entities\":[{\"endOffset\":8,\"label\":\"verb\",\"startOffset
\":3},{\"endOffset\":27,\"label\":\"adjective\",\"startOffset\":11},{\"endOffset
\":33,\"label\":\"object\",\"startOffset\":28},{\"endOffset\":51,\"label\":
\"adjective\",\"startOffset\":46},{\"endOffset\":65,\"label\":\"adjective\",
\"startOffset\":53},{\"endOffset\":74,\"label\":\"adjective\",\"startOffset\":67},
{\"endOffset\":82,\"label\":\"adjective\",\"startOffset\":75},{\"endOffset\":102,
\"label\":\"verb\",\"startOffset\":97},{\"endOffset\":112,\"label\":\"verb\",
\"startOffset\":107},{\"endOffset\":125,\"label\":\"adjective\",\"startOffset
\":113},{\"endOffset\":134,\"label\":\"adjective\",\"startOffset\":126},{\"endOffset
\":143,\"label\":\"object\",\"startOffset\":135},{\"endOffset\":169,\"label
\":\"adjective\",\"startOffset\":153},{\"endOffset\":176,\"label\":\"object\",
\"startOffset\":170}]}}"}}]},{"datasetObjectId":"1","dataObject":{"content":"Sift
 3 cups of flour into the bowl."},"annotations":[{"workerId":"private.us-
west-2.0123456789","annotationData":{"content":"{\"crowd-entity-annotation\":
{\"entities\":[{\"endOffset\":4,\"label\":\"verb\",\"startOffset\":0},{\"endOffset
\":6,\"label\":\"number\",\"startOffset\":5},{\"endOffset\":20,\"label\":\"object
\",\"startOffset\":15},{\"endOffset\":34,\"label\":\"object\",\"startOffset
\":30}]}}"}}]},{"datasetObjectId":"2","dataObject":{"content":"Jen purchased 10
 shares of the stock on Janurary 1st, 2020."},"annotations":[{"workerId":"private.us-
west-2.0123456789","annotationData":{"content":"{\"crowd-entity-annotation
\":{\"entities\":[{\"endOffset\":3,\"label\":\"person\",\"startOffset\":0},
{\"endOffset\":13,\"label\":\"verb\",\"startOffset\":4},{\"endOffset\":16,\"label
\":\"number\",\"startOffset\":14},{\"endOffset\":58,\"label\":\"date\",\"startOffset
\":40}]}}"}}]},{"datasetObjectId":"3","dataObject":{"content":"The narrative
 was interesting, however the character development was weak."},"annotations":
[{"workerId":"private.us-west-2.0123456789","annotationData":{"content":"{\"crowd-
entity-annotation\":{\"entities\":[{\"endOffset\":29,\"label\":\"adjective\",
\"startOffset\":18},{\"endOffset\":73,\"label\":\"adjective\",\"startOffset
\":69}]}}"}}]}]
```

- You must use the directions in Grant Post-Annotation Lambda Permissions to Access Annotation to give your post-annotation Lambda function's execution role permission to assume the SageMaker AI execution role you use to create the labeling job. The post-annotation Lambda

function uses the SageMaker AI execution role to access the annotation data file, `sample-annotations.json`, in S3.

Test the Pre-annotation Lambda Function

Use the following procedure to test the pre-annotation Lambda function created when you deployed the Ground Truth Amazon Serverless Application Repository (SAR) recipe.

Test the Ground Truth SAR recipe pre-annotation Lambda function

1. Open the **Functions** page in the Lambda console.
2. Select the pre-annotation function that was deployed from the Ground Truth SAR recipe. The name of this function is similar to `serverlessrepo-aws-sagema-GtRecipePreHumanTaskFunc-<id>`.
3. In the **Code source** section, select the arrow next to **Test**.
4. Select **Configure test event**.
5. Keep the **Create new test event** option selected.
6. Under **Event template**, select **SageMaker Ground Truth PreHumanTask**.
7. Give your test an **Event name**.
8. Select **Create**.
9. Select the arrow next to **Test** again and you should see that the test you created is selected, which is indicated with a dot by the event name. If it is not selected, select it.
10. Select **Test** to run the test.

After you run the test, you can see the **Execution results**. In the **Function logs**, you should see a response similar to the following:

```
START RequestId: cd117d38-8365-4e1a-bffb-0dcd631a878f Version: $LATEST
Received event: {
  "version": "2018-10-16",
  "labelingJobArn": "arn:aws:sagemaker:us-east-2:123456789012:labeling-job/example-job",
  "dataObject": {
    "source-ref": "s3://sagemakerexample/object_to_annotate.jpg"
  }
```

```
}
{'taskInput': {'taskObject': 's3://sagemakerexample/object_to_annotate.jpg'},
 'isHumanAnnotationRequired': 'true'}
END RequestId: cd117d38-8365-4e1a-bffb-0dcd631a878f
REPORT RequestId: cd117d38-8365-4e1a-bffb-0dcd631a878f Duration: 0.42 ms Billed
 Duration: 1 ms Memory Size: 128 MB Max Memory Used: 43 MB
```

In this response, we can see the Lambda function's output matches the required pre-annotation response syntax:

```
{'taskInput': {'taskObject': 's3://sagemakerexample/object_to_annotate.jpg'},
 'isHumanAnnotationRequired': 'true'}
```

Test the Post-Annotation Lambda Function

Use the following procedure to test the post-annotation Lambda function created when you deployed the Ground Truth Amazon Serverless Application Repository (SAR) recipe.

Test the Ground Truth SAR recipe post-annotation Lambda

1. Open the **Functions** page in the Lambda console.
2. Select the post-annotation function that was deployed from the Ground Truth SAR recipe. The name of this function is similar to `serverlessrepo-aws-sagema-GtRecipeAnnotationConsol-<id>`.
3. In the **Code source** section, select the arrow next to **Test**.
4. Select **Configure test event**.
5. Keep the **Create new test event** option selected.
6. Under **Event template**, select **SageMaker Ground Truth AnnotationConsolidation**.
7. Give your test an **Event name**.
8. Modify the template code provided as follows:

   - Replace the Amazon Resource Name (ARN) in `roleArn` with the ARN of the SageMaker AI execution role you used to create the labeling job.
   - Replace the S3 URI in `s3Uri` with the URI of the `sample-annotations.json` file you added to Amazon S3.

   After you make these modifications, your test should look similar to the following:

```
{
  "version": "2018-10-16",
  "labelingJobArn": "arn:aws:sagemaker:us-east-2:123456789012:labeling-job/example-
job",
  "labelAttributeName": "example-attribute",
  "roleArn": "arn:aws:iam::222222222222:role/sm-execution-role",
  "payload": {
    "s3Uri": "s3://your-bucket/sample-annotations.json"
  }
}
```

9. Select **Create**.
10. Select the arrow next to **Test** again and you should see that the test you created is selected, which is indicated with a dot by the event name. If it is not selected, select it.
11. Select the **Test** to run the test.

After you run the test, you should see a `-- Consolidated Output --` section in the **Function Logs**, which contains a list of all annotations included in `sample-annotations.json`.

Demo template: Annotation of images with `crowd-bounding-box`

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you chose to use a custom template as your task type in the Amazon SageMaker Ground Truth console, you reach the **Custom labeling task panel**. There you can choose from multiple base templates. The templates represent some of the most common tasks and provide a sample to work from as you create your customized labeling task's template. If you are not using the console, or as an additional recourse, see Amazon SageMaker AI Ground Truth Sample Task UIs for a repository of demo templates for a variety of labeling job task types.

This demonstration works with the **BoundingBox** template. The demonstration also works with the Amazon Lambda functions needed for processing your data before and after the task. In the

Github repository above, to find templates that work with Amazon Lambda functions, look for `{{ task.input.<property name> }}` in the template.

Topics

- Starter Bounding Box custom template
- Your own Bounding Box custom template
- Your manifest file
- Your pre-annotation Lambda function
- Your post-annotation Lambda function
- The output of your labeling job

Starter Bounding Box custom template

This is the starter bounding box template that is provided.

The custom templates use the Liquid template language, and each of the items between double curly braces is a variable. The pre-annotation Amazon Lambda function should provide an object named `taskInput` and that object's properties can be accessed as `{{ task.input.<property name> }}` in your template.

Your own Bounding Box custom template

As an example, assume you have a large collection of animal photos in which you know the kind of animal in an image from a prior image-classification job. Now you want to have a bounding box drawn around it.

In the starter sample, there are three variables: `taskObject`, `header`, and `labels`.

Each of these would be represented in different parts of the bounding box.

- `taskObject` is an HTTP(S) URL or S3 URI for the photo to be annotated. The added `| grant_read_access` is a filter that will convert an S3 URI to an HTTPS URL with short-lived access to that resource. If you're using an HTTP(S) URL, it's not needed.
- `header` is the text above the photo to be labeled, something like "Draw a box around the bird in the photo."
- `labels` is an array, represented as `['item1', 'item2', ...]`. These are labels that can be assigned by the worker to the different boxes they draw. You can have one or many.

Each of the variable names come from the JSON object in the response from your pre-annotation Lambda, The names above are merely suggested, Use whatever variable names make sense to you and will promote code readability among your team.

> **Only use variables when necessary**
>
> If a field will not change, you can remove that variable from the template and replace it with that text, otherwise you have to repeat that text as a value in each object in your manifest or code it into your pre-annotation Lambda function.

Example: Final Customized Bounding Box Template

To keep things simple, this template will have one variable, one label, and very basic instructions. Assuming your manifest has an "animal" property in each data object, that value can be re-used in two parts of the template.

Note the re-use of `{{ task.input.animal }}` throughout the template. If your manifest had all of the animal names beginning with a capital letter, you could use `{{ task.input.animal | downcase }}`, incorporating one of Liquid's built-in filters in sentences where it needed to be presented lowercase.

Your manifest file

Your manifest file should provide the variable values you're using in your template. You can do some transformation of your manifest data in your pre-annotation Lambda, but if you don't need to, you maintain a lower risk of errors and your Lambda will run faster. Here's a sample manifest file for the template.

```
{"source-ref": "<S3 image URI>", "animal": "horse"}
{"source-ref": "<S3 image URI>", "animal" : "bird"}
{"source-ref": "<S3 image URI>", "animal" : "dog"}
{"source-ref": "<S3 image URI>", "animal" : "cat"}
```

Your pre-annotation Lambda function

As part of the job set-up, provide the ARN of an Amazon Lambda function that can be called to process your manifest entries and pass them to the template engine.

Naming your Lambda function

The best practice in naming your function is to use one of the following four strings as part of the function name: `SageMaker`, `Sagemaker`, `sagemaker`, or `LabelingFunction`. This applies to both your pre-annotation and post-annotation functions.

When you're using the console, if you have Amazon Lambda functions that are owned by your account, a drop-down list of functions meeting the naming requirements will be provided to choose one.

In this very basic example, you're just passing through the information from the manifest without doing any additional processing on it. This sample pre-annotation function is written for Python 3.7.

```
import json

def lambda_handler(event, context):
    return {
        "taskInput": event['dataObject']
    }
```

The JSON object from your manifest will be provided as a child of the `event` object. The properties inside the `taskInput` object will be available as variables to your template, so simply setting the value of `taskInput` to `event['dataObject']` will pass all the values from your manifest object to your template without having to copy them individually. If you wish to send more values to the template, you can add them to the `taskInput` object.

Your post-annotation Lambda function

As part of the job set-up, provide the ARN of an Amazon Lambda function that can be called to process the form data when a worker completes a task. This can be as simple or complex as you want. If you want to do answer consolidation and scoring as it comes in, you can apply the scoring and/or consolidation algorithms of your choice. If you want to store the raw data for offline processing, that is an option.

Provide permissions to your post-annotation Lambda

The annotation data will be in a file designated by the `s3Uri` string in the `payload` object. To process the annotations as they come in, even for a simple pass through function, you need to assign `S3ReadOnly` access to your Lambda so it can read the annotation files. In the Console page for creating your Lambda, scroll to the **Execution role** panel. Select **Create a new role from one or more templates**. Give the role a name. From the **Policy templates** drop-down, choose **Amazon S3 object read-only permissions**. Save the Lambda and the role will be saved and selected.

The following sample is in Python 2.7.

```
import json
import boto3
from urlparse import urlparse

def lambda_handler(event, context):
    consolidated_labels = []

    parsed_url = urlparse(event['payload']['s3Uri']);
    s3 = boto3.client('s3')
    textFile = s3.get_object(Bucket = parsed_url.netloc, Key = parsed_url.path[1:])
    filecont = textFile['Body'].read()
    annotations = json.loads(filecont);

    for dataset in annotations:
        for annotation in dataset['annotations']:
            new_annotation = json.loads(annotation['annotationData']['content'])
            label = {
                'datasetObjectId': dataset['datasetObjectId'],
                'consolidatedAnnotation' : {
                'content': {
                    event['labelAttributeName']: {
                        'workerId': annotation['workerId'],
                        'boxesInfo': new_annotation,
                        'imageSource': dataset['dataObject']
                        }
                    }
                }
            }
            consolidated_labels.append(label)
```

```
    return consolidated_labels
```

The post-annotation Lambda will often receive batches of task results in the event object. That batch will be the `payload` object the Lambda should iterate through. What you send back will be an object meeting the API contract.

The output of your labeling job

You'll find the output of the job in a folder named after your labeling job in the target S3 bucket you specified. It will be in a sub folder named `manifests`.

For a bounding box task, the output you find in the output manifest will look a bit like the demo below. The example has been cleaned up for printing. The actual output will be a single line per record.

Example: JSON in your output manifest

```
{
  "source-ref":"<URL>",
  "<label attribute name>":
    {
       "workerId":"<URL>",
       "imageSource":"<image URL>",
       "boxesInfo":"{\"boundingBox\":{\"boundingBoxes\":[{\"height\":878, \"label\":
\"bird\", \"left\":208, \"top\":6, \"width\":809}], \"inputImageProperties\":{\"height
\":924, \"width\":1280}}}"},
  "<label attribute name>-metadata":
    {
      "type":"groundTruth/custom",
      "job_name":"<Labeling job name>",
      "human-annotated":"yes"
    },
  "animal" : "bird"
}
```

Note how the additional `animal` attribute from your original manifest is passed to the output manifest on the same level as the `source-ref` and labeling data. Any properties from your input manifest, whether they were used in your template or not, will be passed to the output manifest.

Demo Template: Labeling Intents with `crowd-classifier`

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

If you choose a custom template, you'll reach the **Custom labeling task panel**. There you can select from multiple starter templates that represent some of the more common tasks. The templates provide a starting point to work from in building your customized labeling task's template.

In this demonstration, you work with the **Intent Detection** template, which uses the `crowd-classifier` element, and the Amazon Lambda functions needed for processing your data before and after the task.

Topics

- Starter Intent Detection custom template
- Your Intent Detection custom template
- Your pre-annotation Lambda function
- Your post-annotation Lambda function
- Your labeling job output

Starter Intent Detection custom template

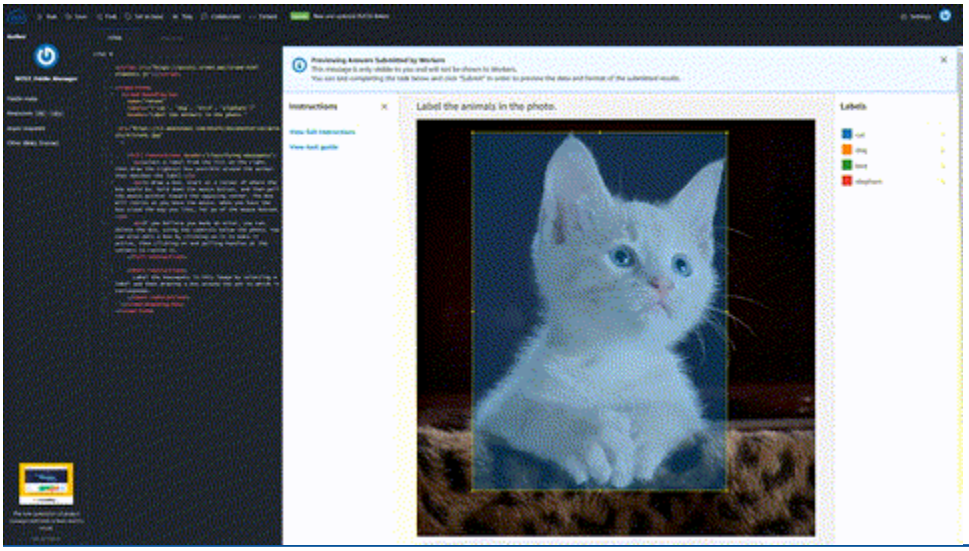
This is the intent detection template that is provided as a starting point.

The custom templates use the Liquid template language, and each of the items between double curly braces is a variable. The pre-annotation Amazon Lambda function should provide an object named `taskInput` and that object's properties can be accessed as `{{ task.input.<property name> }}` in your template.

Your Intent Detection custom template

In the starter template, there are two variables: the `task.input.labels` property in the `crowd-classifier` element opening tag and the `task.input.utterance` in the `classification-target` region's content.

Unless you need to offer different sets of labels with different utterances, avoiding a variable and just using text will save processing time and creates less possibility of error. The template used in this demonstration will remove that variable, but variables and filters like `to_json` are explained in more detail in the `crowd-bounding-box` demonstration article.



Styling Your Elements

Two parts of these custom elements that sometimes get overlooked are the `<full-instructions>` and `<short-instructions>` regions. Good instructions generate good results.

In the elements that include these regions, the `<short-instructions>` appear automatically in the "Instructions" pane on the left of the worker's screen. The `<full-instructions>` are linked from the "View full instructions" link near the top of that pane. Clicking the link opens a modal pane with more detailed instructions.

You can not only use HTML, CSS, and JavaScript in these sections, you are encouraged to if you believe you can provide a strong set of instructions and examples that will help workers complete your tasks with better speed and accuracy.

Example Try out a sample with JSFiddle

Try out an example <crowd-classifier> task. The example is rendered by JSFiddle, therefore all the template variables are replaced with hard-coded values. Click the "View full instructions" link to see a set of examples with extended CSS styling. You can fork the project to experiment with your own changes to the CSS, adding sample images, or adding extended JavaScript functionality.

Example: Final Customized Intent Detection Template

This uses the example <crowd-classifier> task, but with a variable for the <classification-target>. If you are trying to keep a consistent CSS design among a series of different labeling jobs, you can include an external stylesheet using a <link rel...> element the same way you'd do in any other HTML document.

Example: Your manifest file

If you are preparing your manifest file manually for a text-classification task like this, have your data formatted in the following manner.

```
{"source": "Roses are red"}
{"source": "Violets are Blue"}
{"source": "Ground Truth is the best"}
{"source": "And so are you"}
```

This differs from the manifest file used for the "Demo template: Annotation of images with crowd-bounding-box" demonstration in that source-ref was used as the property name instead of source. The use of source-ref designates S3 URIs for images or other files that must be converted to HTTP. Otherwise, source should be used like it is with the text strings above.

Your pre-annotation Lambda function

As part of the job set-up, provide the ARN of an Amazon Lambda that can be called to process your manifest entries and pass them to the template engine.

This Lambda function is required to have one of the following four strings as part of the function name: SageMaker, Sagemaker, sagemaker, or LabelingFunction.

This applies to both your pre-annotation and post-annotation Lambdas.

When you're using the console, if you have Lambdas that are owned by your account, a drop-down list of functions meeting the naming requirements will be provided to choose one.

In this very basic sample, where you have only one variable, it's primarily a pass-through function. Here's a sample pre-labeling Lambda using Python 3.7.

```
import json

def lambda_handler(event, context):
    return {
        "taskInput":  event['dataObject']
    }
```

The `dataObject` property of the `event` contains the properties from a data object in your manifest.

In this demonstration, which is a simple pass through, you just pass that straight through as the `taskInput` value. If you add properties with those values to the `event['dataObject']` object, they will be available to your HTML template as Liquid variables with the format `{{ task.input.<property name> }}`.

Your post-annotation Lambda function

As part of the job set up, provide the ARN of an Lambda function that can be called to process the form data when a worker completes a task. This can be as simple or complex as you want. If you want to do answer-consolidation and scoring as data comes in, you can apply the scoring or consolidation algorithms of your choice. If you want to store the raw data for offline processing, that is an option.

Set permissions for your post-annotation Lambda function

The annotation data will be in a file designated by the `s3Uri` string in the `payload` object. To process the annotations as they come in, even for a simple pass through function, you need to assign `S3ReadOnly` access to your Lambda so it can read the annotation files.
In the Console page for creating your Lambda, scroll to the **Execution role** panel. Select **Create a new role from one or more templates**. Give the role a name. From the **Policy templates** drop-down, choose **Amazon S3 object read-only permissions**. Save the Lambda and the role will be saved and selected.

The following sample is for Python 3.7.

```
import json
import boto3
from urllib.parse import urlparse
```

```
def lambda_handler(event, context):
    consolidated_labels = []

    parsed_url = urlparse(event['payload']['s3Uri']);
    s3 = boto3.client('s3')
    textFile = s3.get_object(Bucket = parsed_url.netloc, Key = parsed_url.path[1:])
    filecont = textFile['Body'].read()
    annotations = json.loads(filecont);

    for dataset in annotations:
        for annotation in dataset['annotations']:
            new_annotation = json.loads(annotation['annotationData']['content'])
            label = {
                'datasetObjectId': dataset['datasetObjectId'],
                'consolidatedAnnotation' : {
                'content': {
                    event['labelAttributeName']: {
                        'workerId': annotation['workerId'],
                        'result': new_annotation,
                        'labeledContent': dataset['dataObject']
                        }
                    }
                }
            }
            consolidated_labels.append(label)

    return consolidated_labels
```

Your labeling job output

The post-annotation Lambda will often receive batches of task results in the event object. That batch will be the `payload` object the Lambda should iterate through.

You'll find the output of the job in a folder named after your labeling job in the target S3 bucket you specified. It will be in a sub folder named `manifests`.

For an intent detection task, the output in the output manifest will look a bit like the demo below. The example has been cleaned up and spaced out to be easier for humans to read. The actual output will be more compressed for machine reading.

Example: JSON in your output manifest

```
[
```

```
{
  "datasetObjectId":"<Number representing item's place in the manifest>",
   "consolidatedAnnotation":
   {
     "content":
     {
       "<name of labeling job>":
       {
         "workerId":"private.us-east-1.XXXXXXXXXXXXXXXXXXXXX",
         "result":
         {
           "intent":
           {
               "label":"<label chosen by worker>"
           }
         },
         "labeledContent":
         {
           "content":"<text content that was labeled>"
         }
       }
     }
   }
 },
"datasetObjectId":"<Number representing item's place in the manifest>",
   "consolidatedAnnotation":
   {
     "content":
     {
       "<name of labeling job>":
       {
         "workerId":"private.us-east-1.6UDLPKQZHYWJQSCA4MBJBB7FWE",
         "result":
         {
           "intent":
           {
               "label": "<label chosen by worker>"
           }
         },
         "labeledContent":
         {
           "content": "<text content that was labeled>"
         }
       }
```

```
        }
      }
    },
      ...
      ...
      ...
]
```

This should help you create and use your own custom template.

Create a custom workflow using the API

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you have created your custom UI template (Step 2) and processing Lambda functions (Step 3), you should place the template in an Amazon S3 bucket with a file name format of: `<FileName>.liquid.html`. Use the `CreateLabelingJob` action to configure your task. You'll use the location of a custom template (Creating a custom worker task template) stored in a *`<filename>`*`.liquid.html` file on S3 as the value for the `UiTemplateS3Uri` field in the `UiConfig` object within the `HumanTaskConfig` object.

For the Amazon Lambda tasks described in Processing data in a custom labeling workflow with Amazon Lambda, the post-annotation task's ARN will be used as the value for the `AnnotationConsolidationLambdaArn` field, and the pre-annotation task will be used as the value for the `PreHumanTaskLambdaArn`.

Create a Labeling Job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can create a labeling job in the Amazon SageMaker AI console and by using an Amazon SDK in your preferred language to run `CreateLabelingJob`. After a labeling job has been created, you can track worker metrics (for private workforces) and your labeling job status using CloudWatch.

Before you create a labeling job it is recommended that you review the following pages, as applicable:

- You can specify your input data using an automatic data setup in the console, or an input manifest file in either the console or when using `CreateLabelingJob` API. For automated data setup, see Automate data setup for labeling jobs. To learn how to create an input manifest file, see Input manifest files.
- Review labeling job input data quotas: Input Data Quotas.

After you have chosen your task type, use the topics on this page to learn how to create a labeling job.

If you are a new Ground Truth user, we recommend that you start by walking through the demo in Getting started: Create a bounding box labeling job with Ground Truth.

> **Important**
>
> Ground Truth requires all S3 buckets that contain labeling job input image data to have a CORS policy attached. To learn more, see CORS Requirement for Input Image Data.

Topics

- Built-in Task Types
- Create instruction pages
- Create a Labeling Job (Console)
- Create a Labeling Job (API)
- Create a streaming labeling job
- Labeling category configuration file with label category and frame attributes reference

Built-in Task Types

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Amazon SageMaker Ground Truth has several built-in task types. Ground Truth provides a worker task template for built-in task types. Additionally, some built in task types support Automate data labeling. The following topics describe each built-in task type and demo the worker task templates that are provided by Ground Truth in the console. To learn how to create a labeling job in the console using one of these task types, select the task type page.

Label Images	Label Text	Label Videos and Video Frames	Label 3D Point Clouds
• Classify image objects using a bounding box • Create an image classification job (Single Label) • Create an image classification job (Multi-label) • Identify image contents using semantic segmentation • Label verification and adjustment	• Extract text information using named entity recognition • Categorize text with text classification (Single Label) • Categorize text with text classification (Multi-label)	• Classify videos • Identify objects using video frame object detection • Track objects in video frames using video frame object tracking	• Classify objects in a 3D point cloud with object detection • Understand the 3D point cloud object tracking task type • Understand the 3D point cloud semantic segmentation task type

> **Note**
>
> Each of the video frame and 3D point cloud task types has an *adjustment* task type that you use to verify and adjust labels from a previous labeling job. Select a video frame or 3D point cloud task type page above to learn how to adjust labels created using that task type.

Create instruction pages

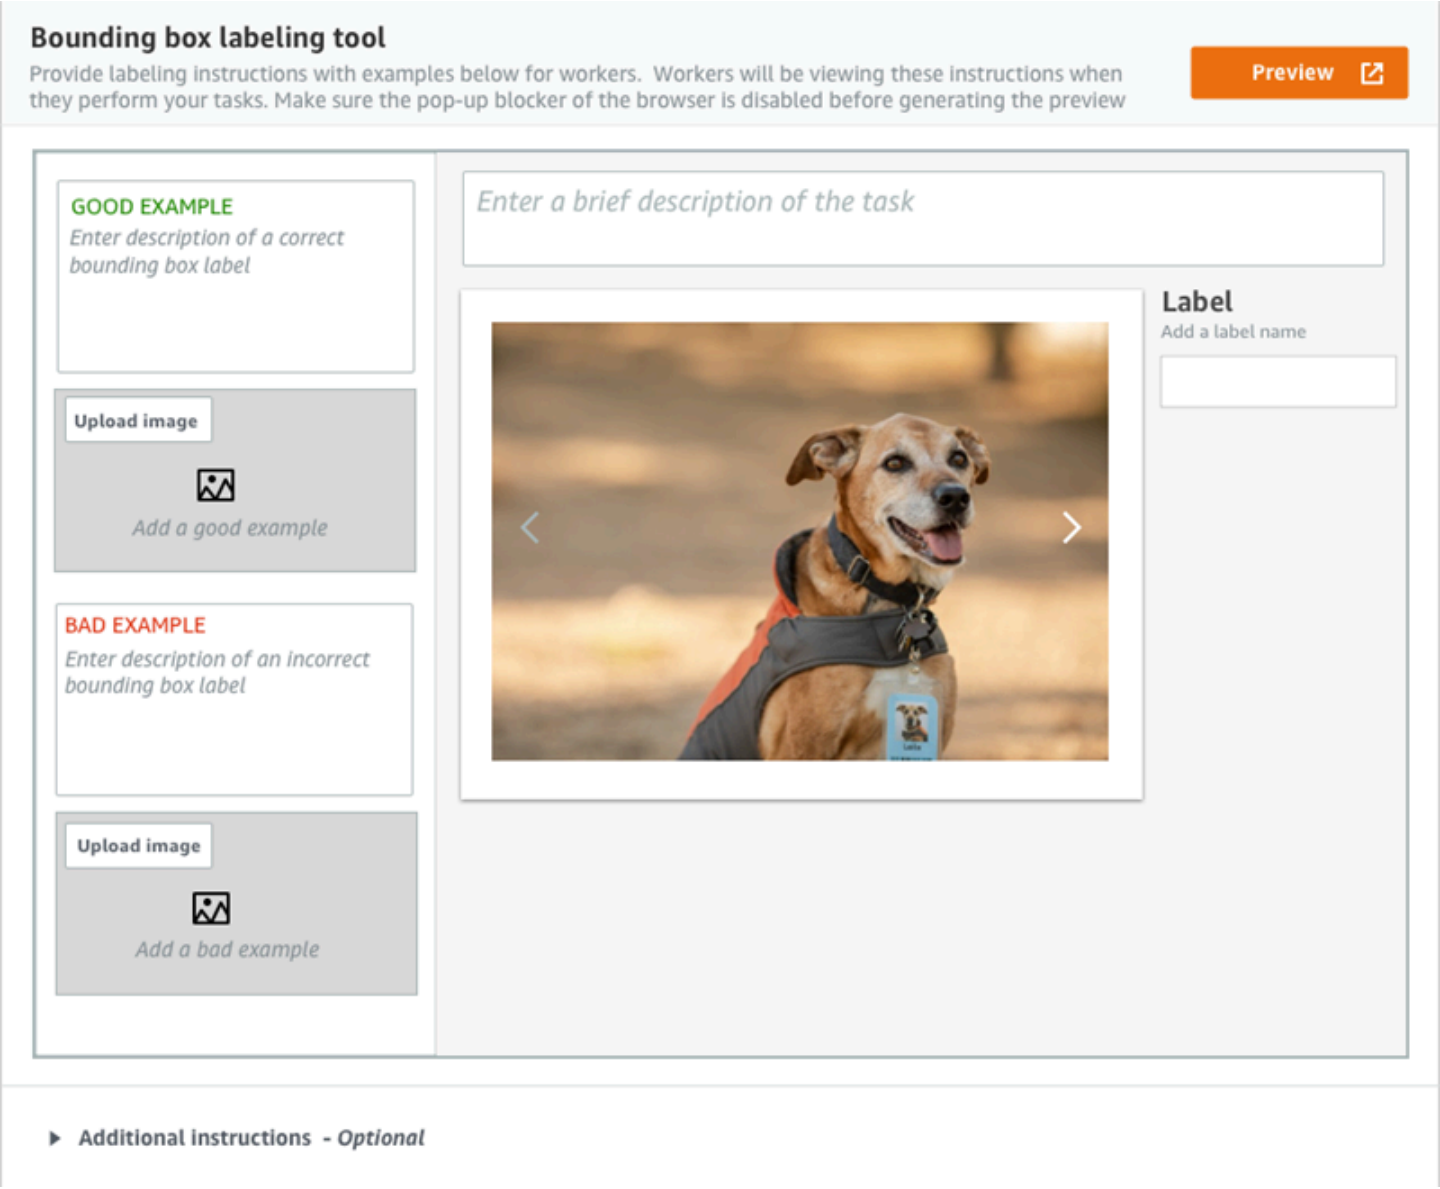
> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Create custom instructions for labeling jobs to improve your worker's accuracy in completing their task. You can modify the default instructions that are provided in the console or you can create your own. The instructions are shown to the worker on the page where they complete their labeling task.

There are two kinds of instructions:

- *Short instructions*—instructions that are shown on the same webpage where the worker completes their task. These instructions should provide an easy reference to show the worker the correct way to label an object.
- *Full instructions*—instructions that are shown on a dialog box that overlays the page where the worker completes their task. We recommend that you provide detailed instructions for completing the task with multiple examples showing edge cases and other difficult situations for labeling objects.

Create instructions in the console when you are creating your labeling job. Start with the existing instructions for the task and use the editor to modify them to suit your labeling job.



> **Note**
>
> Once you create your labeling job, it will automatically start and you will not be able to modify your worker instructions. If you need to change your worker instructions, stop the

labeling job that you created, clone it, and modify your worker instructions before creating a new job.
You can clone a labeling job in the console by selecting the labeling job and then selecting **Clone** in the **Actions** menu.
To clone a labeling job using the Amazon SageMaker API or your preferred Amazon SageMaker SDK, make a new request to the `CreateLabelingJob` operation with the same specifications as your original job after modifying your worker instructions.

For 3D point cloud and video frame labeling jobs, you can add worker instructions to your label category configuration file. You can use a single string to create instructions or you can add HTML mark up to customize the appearance of your instructions and add images. Make sure that any images you include in your instructions are publicly available, or if your instructions are in Amazon S3, that your workers have read access so that they can view them. For more information about the label category configuration file, see the section called “Label category and frame attributes reference”.

Short Instructions

Short instructions appear on the same web page that workers use to label your data object. For example, the following is the editing page for a bounding box task. The short instructions panel is on the left.

Keep in mind that a worker will only spend seconds looking at the short instructions. Workers must be able to scan and understand your information quickly. In all cases it should take less time to understand the instructions than it takes to complete the task. Keep these points in mind:

- Your instructions should be clear and simple.
- Pictures are better than words. Create a simple illustration of your task that your workers can immediately understand.
- If you must use words, use short, concise examples.
- Your short instructions are more important than your full instructions.

The Amazon SageMaker Ground Truth console provides an editor so that you can create your short instructions. Replace the placeholder text and images with instructions for your task. Preview the worker's task page by choosing **Preview**. The preview will open in a new window, be sure to turn off pop-up blocking so that the window will show.

Full Instructions

You can provide additional instructions for your workers in a dialog box that overlays the page where workers label your data objects. Use full instructions to explain more complex tasks and to show workers the proper way to label edge cases or other difficult objects.

You can create full instructions using an editor in the Ground Truth console. As with quick instructions, keep the following in mind:

- Workers will want detailed instruction the first few times that the complete your task. Any information that they *must* have should be in the quick instructions.
- Pictures are more important than words.
- Text should be concise.
- Full instructions should supplement the short instructions. Don't repeat information that appears in the short instructions.

The Ground Truth console provides an editor so that you can create your full instructions. Replace the placeholder text and images with instructions for your task. Preview the full instruction page by choosing **Preview**. The preview will open in a new window, be sure to turn off pop-up blocking so that the window will show.

Add example images to your instructions

Images provide useful examples for your workers. To add a publicly accessible image to your instructions:

- Place the cursor where the image should go in the instructions editor.
- Click the image icon in the editor toolbar.
- Enter the URL of your image.

If your instruction image in Amazon S3 is not publicly accessible:

- As the image URL, enter: {{ 'https://s3.amazonaws.com/*your-bucket-name*/*image-file-name*' | grant_read_access }}.
- This renders the image URL with a short-lived, one-time access code appended so the worker's browser can display it. A broken image icon is displayed in the instructions editor, but previewing the tool displays the image in the rendered preview.

Create a Labeling Job (Console)

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use the Amazon SageMaker AI console to create a labeling job for all of the Ground Truth built-in task types and custom labeling workflows. For built-in task types, we recommend that you use this page alongside the page for your task type. Each task type page includes specific details on creating a labeling job using that task type.

You need to provide the following to create a labeling job in the SageMaker AI console:

- An input manifest file in Amazon S3. You can place your input dataset in Amazon S3 and automatically generate a manifest file using the Ground Truth console (not supported for 3D point cloud labeling jobs).

  Alternatively, you can manually create an input manifest file. To learn how, see Input data.
- An Amazon S3 bucket to store your output data.
- An IAM role with permission to access your resources in Amazon S3 and with a SageMaker AI execution policy attached. For a general solution, you can attach the managed policy, AmazonSageMakerFullAccess, to an IAM role and include `sagemaker` in your bucket name.

  For more granular policies, see the section called “IAM Permissions”.

  3D point cloud task types have additional security considerations. Learn more.
- A work team. You create a work team from a private workforce or a vendor-managed workforce. For more information, see Workforces.

- If you are using a custom labeling workflow, you must save a worker task template in Amazon S3 and provide an Amazon S3 URI for that template. For more information, see Creating a custom worker task template.
- (Optional) An Amazon KMS key ARN if you want SageMaker AI to encrypt the output of your labeling job using your own Amazon KMS encryption key instead of the default Amazon S3 service key.
- (Optional) Existing labels for the dataset you use for your labeling job. Use this option if you want workers to adjust, or approve and reject labels.
- If you want to create an adjustment or verification labeling job, you must have an output manifest file in Amazon S3 that contains the labels you want adjusted or verified. This option is only supported for bounding box and semantic segmentation image labeling jobs and 3D point cloud and video frame labeling jobs. It is recommended that you use the instructions on Label verification and adjustment to create a verification or adjustment labeling job.

> **Important**
>
> Your work team, input manifest file, output bucket, and other resources in Amazon S3 must be in the same Amazon Region you use to create your labeling job.

When you create a labeling job using the SageMaker AI console, you add worker instructions and labels to the worker UI that Ground Truth provides. You can preview and interact with the worker UI while creating your labeling job in the console. You can also see a preview of the worker UI on your built-in task type page.

To create a labeling job (console)

1. Sign in to the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the left navigation pane, choose **Labeling jobs**.
3. On the **Labeling jobs** page, choose **Create labeling job**.
4. For **Job name**, enter a name for your labeling job.
5. (Optional) If you want to identify your labels with a key, select **I want to specify a label attribute name different from the labeling job name**. If you do not select this option, the labeling job name you specified in the previous step will be used to identify your labels in your output manifest file.

6. Choose a data setup to create a connection between your input dataset and Ground Truth.

   - For **Automated data setup**:
     - Follow the instructions in Automate data setup for labeling jobs for image, text, and video clip labeling jobs.
     - Follow the instructions in Set up Automated Video Frame Input Data for video frame labeling jobs.
   - For **Manual data setup**:
     - For **Input dataset location**, provide the location in Amazon S3 in which your input manifest file is located. For example, if your input manifest file, manifest.json, is located in **example-bucket**, enter **s3://example-bucket/manifest.json**.
     - For **Output dataset location**, provide the location in Amazon S3 where you want Ground Truth to store the output data from your labeling job.
7. For **IAM Role**, choose an existing IAM role or create an IAM role with permission to access your resources in Amazon S3, to write to the output Amazon S3 bucket specified above, and with a SageMaker AI execution policy attached.
8. (Optional) For **Additional configuration**, you can specify how much of your dataset you want workers to label, and if you want SageMaker AI to encrypt the output data for your labeling job using an Amazon KMS encryption key. To encrypt your output data, you must have the required Amazon KMS permissions attached to the IAM role you provided in the previous step. For more details, see the section called “IAM Permissions”.
9. In the **Task type** section, under **Task category**, use the dropdown list to select your task category.
10. In **Task selection**, choose your task type.
11. (Optional) Provide tags for your labeling job to make it easier to find in the console later.
12. Choose **Next**.
13. In the **Workers** section, choose the type of workforce you would like to use. For more details about your workforce options see Workforces.
14. (Optional) After you've selected your workforce, specify the **Task timeout**. This is the maximum amount of time a worker has to work on a task.

    For 3D point cloud annotation tasks, the default task timeout is 3 days. The default timeout for text and image classification and label verification labeling jobs is 5 minutes. The default timeout for all other labeling jobs is 60 minutes.

15. (Optional) For bounding box, semantic segmentation, video frame, and 3D point cloud task types, you can select **Display existing labels** if you want to display labels for your input data set for workers to verify or adjust.

    For bounding box and semantic segmentation labeling jobs, this will create an adjustment labeling job.

    For 3D point cloud and video frame labeling jobs:

    - Select **Adjustment** to create an adjustment labeling job. When you select this option, you can add new labels but you cannot remove or edit existing labels from the previous job. Optionally, you can choose label category attributes and frame attributes that you want workers to edit. To make an attribute editable, select the check box **Allow workers to edit this attribute** for that attribute.

      Optionally, you can add new label category and frame attributes.
    - Select **Verification** to create an adjustment labeling job. When you select this option, you cannot add, modify, or remove existing labels from the previous job. Optionally, you can choose label category attributes and frame attributes that you want workers to edit. To make an attribute editable, select the check box **Allow workers to edit this attribute** for that attribute.

      We recommend that you can add new label category attributes to the labels that you want workers to verify, or add one or more frame attributes to have workers provide information about the entire frame.

    For more information, see Label verification and adjustment.
16. Configure your workers' UI:

    - If you are using a built-in task type, specify workers instructions and labels.
      - For image classification and text classification (single and multi-label) you must specify at least two label categories. For all other built-in task types, you must specify at least one label category.
      - (Optional) If you are creating a 3D point cloud or video frame labeling job, you can specify label category attributes (not supported for 3D point cloud semantic segmentation) and frame attributes. Label category attributes can be assigned to one or more labels. Frame attributes will appear on each point cloud or video frame workers label. To learn more,

see Worker user interface (UI) for 3D point cloud and Worker user interface (UI) for video frame.

- (Optional) Add **Additional instructions** to help your worker complete your task.

- If you are creating a custom labeling workflow you must :
  - Enter a custom template in the code box. Custom templates can be created using a combination of HTML, the Liquid templating language and our pre-built web components. Optionally, you can choose a base-template from the drop-down menu to get started.
  - Specify pre-annotation and post-annotation lambda functions. To learn how to create these functions, see Processing data in a custom labeling workflow with Amazon Lambda.

17. (Optional) You can select **See preview** to preview your worker instructions, labels, and interact with the worker UI. Make sure the pop-up blocker of the browser is disabled before generating the preview.
18. Choose **Create**.

After you've successfully created your labeling job, you are redirected to the **Labeling jobs** page. The status of the labeling job you just created is **In progress**. This status progressively updates as workers complete your tasks. When all tasks are successfully completed, the status changes to **Completed**.

If an issue occurs while creating the labeling job, its status changes to **Failed**.

To view more details about the job, choose the labeling job name.

Next Steps

After your labeling job status changes to **Completed**, you can view your output data in the Amazon S3 bucket that you specified while creating that labeling job. For details about the format of your output data, see Labeling job output data.

Create a Labeling Job (API)

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

To create a labeling job using the Amazon SageMaker API, you use the `CreateLabelingJob` operation. For specific instructions on creating a labeling job for a built-in task type, see that task type page. To learn how to create a streaming labeling job, which is a labeling job that runs perpetually, see Create a streaming labeling job.

To use the `CreateLabelingJob` operation, you need the following:

- A worker task template (`UiTemplateS3Uri`) or human task UI ARN (`HumanTaskUiArn`) in Amazon S3.
  - For 3D point cloud jobs, video object detection and tracking jobs, and NER jobs, use the ARN listed in `HumanTaskUiArn` for your task type.
  - If you are using a built-in task type other than 3D point cloud tasks, you can add your worker instructions to one of the pre-built templates and save the template (using a .html or .liquid extension) in your S3 bucket. Find the pre-build templates on your task type page.
  - If you are using a custom labeling workflow, you can create a custom template and save the template in your S3 bucket. To learn how to built a custom worker template, see Creating a custom worker task template. For custom HTML elements that you can use to customize your template, see Crowd HTML Elements Reference. For a repository of demo templates for a variety of labeling tasks, see Amazon SageMaker Ground Truth Sample Task UIs .
- An input manifest file that specifies your input data in Amazon S3. Specify the location of your input manifest file in `ManifestS3Uri`. For information about creating an input manifest, see Input data. If you create a streaming labeling job, this is optional. To learn how to create a streaming labeling job, see Create a streaming labeling job.
- An Amazon S3 bucket to store your output data. You specify this bucket, and optionally, a prefix in `S3OutputPath`.
- A label category configuration file. Each label category name must be unique. Specify the location of this file in Amazon S3 using the `LabelCategoryConfigS3Uri` parameter. The format and label categories for this file depend on the task type you use:
  - For image classification and text classification (single and multi-label) you must specify at least two label categories. For all other task types, the minimum number of label categories required is one.
  - For named entity recognition tasks, you must provide worker instructions in this file. See Provide Worker Instructions in a Label Category Configuration File for details and an example.
  - For 3D point cloud and video frame task type, use the format in Labeling category configuration file with label category and frame attributes reference.

- For all other built-in task types and custom tasks, your label category configuration file must be a JSON file in the following format. Identify the labels you want to use by replacing `label_1`, `label_2`,`...`,`label_n` with your label categories.

```
{
    "document-version": "2018-11-28",
    "labels": [
        {"label": "label_1"},
        {"label": "label_2"},
        ...
        {"label": "label_n"}
    ]
}
```

- An Amazon Identity and Access Management (IAM) role with the AmazonSageMakerGroundTruthExecution managed IAM policy attached and with permissions to access your S3 buckets. Specify this role in `RoleArn`. To learn more about this policy, see Use IAM Managed Policies with Ground Truth. If you require more granular permissions, see the section called "IAM Permissions".

  If your input or output bucket name does not contain `sagemaker`, you can attach a policy similar to the following to the role that is passed to the `CreateLabelingJob` operation.

  JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws-cn:s3:::my_input_bucket/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject"
            ],
```

```
            "Resource": [
                "arn:aws-cn:s3:::my_output_bucket/*"
            ]
        }
    ]
}
```

- A pre-annotation and post-annotation (or annotation-consolidation) Amazon Lambda function Amazon Resource Name (ARN) to process your input and output data.
  - Lambda functions are predefined in each Amazon Region for built-in task types. To find the pre-annotation Lambda ARN for your Region, see PreHumanTaskLambdaArn. To find the annotation-consolidation Lambda ARN for your Region, see AnnotationConsolidationLambdaArn.
  - For custom labeling workflows, you must provide a custom pre- and post-annotation Lambda ARN. To learn how to create these Lambda functions, see Processing data in a custom labeling workflow with Amazon Lambda.
- A work team ARN that you specify in `WorkteamArn`. You receive a work team ARN when you subscribe to a vendor workforce or create a private work team.

  To learn more about work teams and workforces, see Workforces.
- To configure the task, you must provide a task description and title using `TaskDescription` and **`TaskTitle`** respectively. Optionally, you can provide time limits that control how long the workers have to work on an individual task (**`TaskTimeLimitInSeconds`**) and how long tasks remain in the worker portal, available to workers (`TaskAvailabilityLifetimeInSeconds`).
- (Optional) For some task types, you can have multiple workers label a single data object by inputting a number greater than one for the `NumberOfHumanWorkersPerDataObject` parameter. For more information about annotation consolidation, see Annotation consolidation.
- (Optional) To create an automated data labeling job, specify one of the ARNs listed in LabelingJobAlgorithmSpecificationArn in `LabelingJobAlgorithmsConfig`. This ARN identifies the algorithm used in the automated data labeling job. The task type associated with this ARN must match the task type of the `PreHumanTaskLambdaArn` and `AnnotationConsolidationLambdaArn` you specify. Automated data labeling is supported for the following task types: image classification, bounding box, semantic segmentation, and text classification. The minimum number of objects allowed for automated data labeling is 1,250, and we strongly suggest providing a minimum of 5,000 objects. To learn more about automated data labeling jobs, see Automate data labeling.

- (Optional) You can provide `StoppingConditions` that cause the labeling job to stop if one the conditions is met. You can use stopping conditions to control the cost of the labeling job.

Examples

The following code examples demonstrate how to create a labeling job using `CreateLabelingJob`. You can also see these example notebooks on GitHub in the SageMaker AI Examples repository.

Amazon SDK for Python (Boto3)

The following is an example of an Amazon Python SDK (Boto3) request to create a labeling job for a built-in task type in the US East (N. Virginia) Region using a private workforce. Replace all *red-italized text* with your labeling job resources and specifications.

```
response = client.create_labeling_job(
    LabelingJobName="example-labeling-job",
    LabelAttributeName="label",
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': "s3://bucket/path/manifest-with-input-data.json"
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                "FreeOfPersonallyIdentifiableInformation"|"FreeOfAdultContent",
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': "s3://bucket/path/file-to-store-output-data",
        'KmsKeyId': "string"
    },
    RoleArn="arn:aws:iam::*:role/*",
    LabelCategoryConfigS3Uri="s3://bucket/path/label-categories.json",
    StoppingConditions={
        'MaxHumanLabeledObjectCount': 123,
        'MaxPercentageOfInputDatasetLabeled': 123
    },
    HumanTaskConfig={
        'WorkteamArn': "arn:aws:sagemaker:region:*:workteam/private-crowd/*",
```

```
        'UiConfig': {
            'UiTemplateS3Uri': "s3://bucket/path/custom-worker-task-template.html"
        },
        'PreHumanTaskLambdaArn': "arn:aws:lambda:us-
east-1:432418664414:function:PRE-tasktype",
        'TaskKeywords': [
            "Images",
            "Classification",
            "Multi-label"
        ],
        'TaskTitle': "Multi-label image classification task",
        'TaskDescription': "Select all labels that apply to the images shown",
        'NumberOfHumanWorkersPerDataObject': 1,
        'TaskTimeLimitInSeconds': 3600,
        'TaskAvailabilityLifetimeInSeconds': 21600,
        'MaxConcurrentTaskCount': 1000,
        'AnnotationConsolidationConfig': {
            'AnnotationConsolidationLambdaArn': "arn:aws:lambda:us-
east-1:432418664414:function:ACS-"
        },
    Tags=[
        {
            'Key': "string",
            'Value': "string"
        },
    ]
)
```

Amazon CLI

The following is an example of an Amazon CLI request to create a labeling job for a built-in task type in the US East (N. Virginia) Region. For more information, see start-human-loop in the *Amazon CLI Command Reference*. Replace all *red-italized text* with your labeling job resources and specifications.

```
$ aws --region us-east-1 sagemaker create-labeling-job \
--labeling-job-name "example-labeling-job" \
--label-attribute-name "label" \
--role-arn "arn:aws:iam::account-id:role/role-name" \
--input-config '{
        "DataAttributes": {
            "ContentClassifiers": [
                "FreeOfPersonallyIdentifiableInformation",
```

```
                "FreeOfAdultContent"
            ]
        },
        "DataSource": {
            "S3DataSource": {
                "ManifestS3Uri": "s3://bucket/path/manifest-with-input-data.json"
            }
        }
    }' \
--output-config '{
        "KmsKeyId": "",
        "S3OutputPath": "s3://bucket/path/file-to-store-output-data"
    }' \
--human-task-config '{
        "AnnotationConsolidationConfig": {
            "AnnotationConsolidationLambdaArn": "arn:aws:lambda:us-
east-1:432418664414:function:ACS-"
        },
        "TaskAvailabilityLifetimeInSeconds": 21600,
        "TaskTimeLimitInSeconds": 3600,
        "NumberOfHumanWorkersPerDataObject": 1,
        "PreHumanTaskLambdaArn":  "arn:aws:lambda:us-
east-1:432418664414:function:PRE-tasktype",
        "WorkteamArn": "arn:aws:sagemaker:us-east-1:111122223333:workteam/private-
crowd/my-work-team",
        "TaskDescription": "Select all labels that apply to the images shown",
        "MaxConcurrentTaskCount": 1000,
        "TaskTitle": "Multi-label image classification task",
        "TaskKeywords": [
            "Images",
            "Classification",
            "Multi-label"
        ],
        "UiConfig": {
            "UiTemplateS3Uri": "s3://bucket/path/custom-worker-task-template.html"
        }
    }'
```

For more information about this operation, see CreateLabelingJob. For information about how to use other language-specific SDKs, see See Also in the `CreateLabelingJobs` topic.

Create a streaming labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Streaming labeling jobs enable you to send individual data objects in real time to a perpetually running, streaming labeling job. To create a streaming labeling job, you can specify the Amazon SNS *input topic* ARN, `SnsTopicArn`, in the `InputConfig` parameter when making a `CreateLabelingJob` request. Optionally, you can also create an Amazon SNS *output topic* and specify it in `OutputConfig`if you want to receive label data in real time.

> **Important**
>
> If you are a new user of Ground Truth streaming labeling jobs, it is recommended that you review Ground Truth streaming labeling jobs before creating a streaming labeling job. Ground Truth streaming labeling jobs are only supported through the SageMaker API.

Use the following sections to create the resources that you need and can use to create a streaming labeling job:

- Learn how to create SNS topics with the permissions required for Ground Truth streaming labeling jobs by following the steps in Use Amazon SNS Topics for Data Labeling. Your SNS topics must be created in the same Amazon Region as your labeling job.
- See Subscribe an Endpoint to Your Amazon SNS Output Topic to learn how to set up an endpoint to receive labeling task output data at a specified endpoint each time a labeling task is completed.
- To learn how to configure your Amazon S3 bucket to send notifications to your Amazon SNS input topic, see Creating Amazon S3 based bucket event notifications based of the Amazon SNS defined in your labeling job.
- Optionally, add data objects that you want to have labeled as soon as the labeling job starts to your input manifest. For more information, see Create a Manifest File (Optional).

- There are other resources required to create a labeling job, such as an IAM role, Amazon S3 bucket, a worker task template and label categories. These are described in the Ground Truth documentation on creating a labeling job. For more information, see Create a Labeling Job.

> **Important**
>
> When you create a labeling job you must provide an IAM execution role. Attach the Amazon managed policy **AmazonSageMakerGroundTruthExecution** to this role to ensure it has required permissions to execute your labeling job.

When you submit a request to create a streaming labeling job, the state of your labeling job is `Initializing`. Once the labeling job is active, the state changes to `InProgress`. Do not send new data objects to your labeling job or attempt to stop your labeling job while it is in the `Initializing` state. Once the state changes to `InProgress`, you can start sending new data objects using Amazon SNS and the Amazon S3 configuration.

Topics

- Use Amazon SNS Topics for Data Labeling
- Creating Amazon S3 based bucket event notifications based of the Amazon SNS defined in your labeling job
- Create a Manifest File (Optional)
- Create a Streaming Labeling Job with the SageMaker API
- Stop a Streaming Labeling Job

Use Amazon SNS Topics for Data Labeling

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You need to create an Amazon SNS input to create a streaming labeling job. Optionally, you may provide an Amazon SNS output topic.

When you create an Amazon SNS topic to use in your streaming labeling job, note down the topic Amazon Resource Name (ARN). The ARN will be the input values for the parameter `SnsTopicArn` in `InputConfig` and `OutputConfig` when you create a labeling job.

Create an Input Topic

Your input topic is used to send new data objects to Ground Truth. To create an input topic, follow the instructions in Creating an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

Note down your input topic ARN and use it as input for the `CreateLabelingJob` parameter `SnsTopicArn` in `InputConfig`.

Create an Output Topic

If you provide an output topic, it is used to send notifications when a data object is labeled. When you create a topic, you have the option to add an encryption key. Use this option to add a Amazon Key Management Service customer managed key to your topic to encrypt the output data of your labeling job before it is published to your output topic.

To create an output topic, follow the instructions in Creating an Amazon SNS topic in the Amazon Simple Notification Service Developer Guide.

If you add encryption, you must attach additional permission to the topic. See Add Encryption to Your Output Topic (Optional). for more information.

> **Important**
>
> To add a customer managed key to your output topic while creating a topic in the console, do not use the **(Default) alias/aws/sns** option. Select a customer managed key that you created.

Note down your input topic ARN and use it in your `CreateLabelingJob` request in the parameter `SnsTopicArn` in `OutputConfig`.

Add Encryption to Your Output Topic (Optional)

To encrypt messages published to your output topic, you need to provide an Amazon KMS customer managed key to your topic. Modify the following policy and add it to your customer

managed key to give Ground Truth permission to encrypt output data before publishing it to your output topic.

Replace *<account_id>* with the ID of the account that you are using to create your topic. To learn how to find your Amazon account ID, see Finding Your Amazon Account ID.

JSON

```
{
    "Id": "key-console-policy",
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Enable IAM User Permissions",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:root"
            },
            "Action": "kms:*",
            "Resource": "*"
        },
        {
            "Sid": "Allow access for Key Administrators",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:role/Admin"
            },
            "Action": [
                "kms:Create*",
                "kms:Describe*",
                "kms:Enable*",
                "kms:List*",
                "kms:Put*",
                "kms:Update*",
                "kms:Revoke*",
                "kms:Disable*",
                "kms:Get*",
                "kms:Delete*",
                "kms:TagResource",
                "kms:UntagResource",
                "kms:ScheduleKeyDeletion",
                "kms:CancelKeyDeletion"
            ],
```

```
            "Resource": "*"
        }
    ]
}
```

Additionally, you must modify and add the following policy to the execution role that you use to create your labeling job (the input value for `RoleArn`).

Replace *<account_id>* with the ID of the account that you are using to create your topic. Replace *<region>* with the Amazon Region you are using to create your labeling job. Replace *<key_id>* with your customer managed key ID.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "sid1",
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": "arn:aws-cn:kms:us-east-1:111122223333:key/your_key_id"
        }
    ]
}
```

For more information on creating and securing keys, see Creating Keys and Using Key Policies in the Amazon Key Management Service Developer Guide.

Subscribe an Endpoint to Your Amazon SNS Output Topic

When a worker completes a labeling job task from a Ground Truth streaming labeling job, Ground Truth uses your output topic to publish output data to one or more endpoints that you specify. To receive notifications when a worker finishes a labeling task, you must subscribe an endpoint to your Amazon SNS output topic.

To learn how to add endpoints to your output topic, see Subscribing to an Amazon SNS topic in the *Amazon Simple Notification Service Developer Guide*.

To learn more about the output data format that is published to these endpoints, see Labeling job output data.

> **Important**
>
> If you do not subscribe an endpoint to your Amazon SNS output topic, you will not receive notifications when new data objects are labeled.

Creating Amazon S3 based bucket event notifications based of the Amazon SNS defined in your labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Changes to your Amazon S3 bucket, event notifications, are enabled either the Amazon S3 console, API, language specific Amazon SDKs, or the Amazon Command Line Interface. Events must use the same Amazon SNS input topic ARN, `SnsTopicArn`, specified in the `InputConfig` parameter as part of your `CreateLabelingJob` request.

> **Amazon S3 bucket notifications and your input data should not be the same Amazon S3 bucket**
>
> When you create event notifications do not use the same Amazon S3 location that you specified as your `S3OutputPath` in the `OutputConfig` parameters. Linking the two buckets may result in unwanted data objects being processed by Ground Truth for labeling.

You control the types of events that you want to send to your Amazon SNS topic. Ground Truth creates a labeling job when you send object creation events.

The event structure sent to your Amazon SNS input topic must be a JSON message formatted using the same structure found in Event message structure.

To see examples of how you can set up an event notification for your Amazon S3 bucket using the Amazon S3 console, Amazon SDK for .NET, and Amazon SDK for Java, follow this walkthrough,Walkthrough: Configure a bucket for notifications (SNS topic or SQS queue) in the *Amazon Simple Storage Service User Guide*.

Amazon EventBridge notifications are not natively supported. To use EventBridge based notification you must update the output format to match the JSON format used in the Event message structure.

Create a Manifest File (Optional)

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you create a streaming labeling job, you have the one time option to add objects (such as images or text) to an input manifest file that you specify in `ManifestS3Uri` of `CreateLabelingJob`. When the streaming labeling job starts, these objects are sent to workers or added to the Amazon SQS queue if the total number of objects exceed `MaxConcurrentTaskCount`. The results are added to the Amazon S3 path that you specify when creating the labeling job periodically as workers complete labeling tasks. Output data is sent to any endpoint that you subscribe to your output topic.

If you want to provide initial objects to be labeled, create a manifest file that identifies these objects and place it in Amazon S3. Specify the S3 URI of this manifest file in `ManifestS3Uri` within `InputConfig`.

To learn how to format your manifest file, see Input data. To use the SageMaker AI console to automatically generate a manifest file (not supported for 3D point cloud task types), see Automate data setup for labeling jobs.

Create a Streaming Labeling Job with the SageMaker API

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

The following is an example of an Amazon Python SDK (Boto3) request that you can use to start a streaming labeling job for a built-in task type in the US East (N. Virginia) Region. For more details about each parameter below see `CreateLabelingJob`. To learn how you can create a labeling job using this API and associated language specific SDKs, see Create a Labeling Job (API).

In this example, note the following parameters:

- `SnsDataSource` – This parameter appears in `InputConfig` and `OutputConfig` and is used to identify your input and output Amazon SNS topics respectively. To create a streaming labeling job, you are required to provide an Amazon SNS input topic. Optionally, you can also provide an Amazon SNS output topic.
- `S3DataSource` – This parameter is optional. Use this parameter if you want to include an input manifest file of data objects that you want labeled as soon as the labeling job starts.
- `StoppingConditions` – This parameter is ignored when you create a streaming labeling job. To learn more about stopping a streaming labeling job, see Stop a Streaming Labeling Job.
- Streaming labeling jobs do not support automated data labeling. Do not include the `LabelingJobAlgorithmsConfig` parameter.

```
response = client.create_labeling_job(
    LabelingJobName= 'example-labeling-job',
    LabelAttributeName='label',
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': 's3://bucket/path/manifest-with-input-data.json'
            },
            'SnsDataSource': {
                'SnsTopicArn': 'arn:aws:sns:us-east-1:123456789012:your-sns-input-
topic'
```

```
            }
        },
        'DataAttributes': {
            'ContentClassifiers': [
                'FreeOfPersonallyIdentifiableInformation'|'FreeOfAdultContent',
            ]
        }
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/file-to-store-output-data',
        'KmsKeyId': 'string',
        'SnsTopicArn': 'arn:aws:sns:us-east-1:123456789012:your-sns-output-topic'
    },

)
```

Stop a Streaming Labeling Job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can manually stop your streaming labeling job using the operation StopLabelingJob.

If your labeling job remains idle for over 10 days, it is automatically stopped by Ground Truth. In this context, a labeling job is considered *idle* if no objects are sent to the Amazon SNS input topic and no objects remain in your Amazon SQS queue, waiting to be labeled. For example, if no data objects are fed to the Amazon SNS input topic and all the objects fed to the labeling job are already labeled, Ground Truth starts a timer. After the timer starts, if no items are received within a 10 day period, the labeling job is stopped.

When a labeling job is stopped, its status is `STOPPING` while Ground Truth cleans up labeling job resources and unsubscribes your Amazon SNS topic from your Amazon SQS queue. The Amazon SQS is *not* deleted by Ground Truth because this queue may contain unprocessed data objects. You should manually delete the queue if you want to avoid incurring additional charges from Amazon SQS. To learn more, see Amazon SQS pricing .

Labeling category configuration file with label category and frame attributes reference

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you create a 3D point cloud or video frame labeling job using the Amazon SageMaker API operation `CreateLabelingJob`, you use a label category configuration file to specify your labels and worker instructions. Optionally, you can also provide the following in your label category attribute file:

- You can provide *label category attributes* for video frame and 3D point cloud object tracking and object detection task types. Workers can use one or more attributes to give more information about an object. For example, you may want to use the attribute *occluded* to have workers identify when an object is partially obstructed. You can either specify a label category attribute for a single label using the `categoryAttributes` parameter, or for all labels using the `categoryGlobalAttributes` parameter.
- You can provide *frame attributes* for video frame and 3D point cloud object tracking and object detection task types using `frameAttributes`. When you create a frame attribute, it appears on each frame or point cloud in the worker task. In video frame labeling jobs, these are attributes that workers assign to an entire video frame. For 3D point cloud labeling jobs, these attributes are applied to a single point cloud. Use frame attributes to have workers provide more information about the scene in a specific frame or point cloud.
- For video frame labeling jobs, you use the label category configuration file to specify the task type (bounding box, polyline, polygon, or keypoint) sent to workers.

For workers, specifying values for label category attributes and frame attributes will be optional.

> **Important**
>
> You should only provide a label attribute name in `auditLabelAttributeName` if you are running an audit job to verify or adjust labels. Use this parameter to input the LabelAttributeName used in the labeling job that generated the annotations you want your worker to adjust. When you create a labeling job in the console, if you did not specify a label attribute name, the **Name** of your job is used as the LabelAttributeName.

The following topics show examples of a label category configuration file for different kinds of labeling jobs. They also explain the schema and quotas of a category configuration file.

Topics

- Examples: label category configuration files for 3D point cloud labeling jobs
- Examples: label category configuration files for video frame labeling jobs
- Label category configuration file schema
- Label and label category attribute quotas

Examples: label category configuration files for 3D point cloud labeling jobs

The following topics show examples of 3D point cloud label category configuration files for object detection, object tracking, semantic segmentation, adjustment, and verification labeling jobs.

Topics

- Example: 3D point cloud object tracking and object detection
- Example: 3D point cloud semantic segmentation
- Example: 3D point cloud adjustment
- Example: 3D point cloud verification

Example: 3D point cloud object tracking and object detection

The following is an example of a label category configuration file that includes label category attributes for a 3D point cloud object detection or object tracking labeling job. This example includes a two frame attributes, which will be added to all point clouds submitted to the labeling job. The `Car` label will include four label category attributes—`X`, `Y`, `Z`, and the global attribute, `W`.

Example: 3D point cloud semantic segmentation

The following is an example of a label category configuration file for a 3D point cloud semantic segmentation labeling job.

Label category attributes are not supported for 3D point cloud semantic segmentation task types. Frame attributes are supported. If you provide label category attributes for a semantic segmentation labeling job, they will be ignored.

```
{
    "documentVersion": "2020-03-01",
```

```
    "frameAttributes": [
        {
            "name":"count players",
            "description":"How many players to you see in the scene?",
            "type":"number"
        },
        {
            "name":"select one",
            "description":"describe the scene",
            "type":"string",
            "enum":["clear","blurry"]
        },
    ],
    "labels": [
        {
            "label": "Car",
        },
        {
            "label": "Pedestrian",
        },
        {
            "label": "Cyclist",
        }
    ],
    "instructions": {"shortInstruction":"Select the appropriate label and
 paint all objects in the point cloud that it applies to the same color",
 "fullInstruction":"<html markup>"}
}
```

Example: 3D point cloud adjustment

The following is an example of a label category configuration file for a 3D point cloud object detection or object tracking adjustment labeling job. For 3D point cloud semantic segmentation adjustment labeling jobs, `categoryGlobalAttributes` and `categoryAttributes` are not supported.

You must include `auditLabelAttributeName` to specify the label attribute name of the previous labeling job that you use to create the adjustment labeling job. Optionally, you can use the `editsAllowed` parameter to specify whether or not a label or frame attribute can be edited.

```
{
    "documentVersion": "2020-03-01",
    "frameAttributes": [
```

```
        {
            "name":"count players",
            "description":"How many players to you see in the scene?",
            "type":"number"
        },
        {
            "name":"select one",
            "editsAllowed":"none",
            "description":"describe the scene",
            "type":"string",
            "enum":["clear","blurry"]
        },
    ],
    "categoryGlobalAttributes": [
        {

}
```

Examples: label category configuration files for video frame labeling jobs

The annotation tools available to your worker and task type used depends on the value you specify for `annotationType`. For example, if you want workers to use key points to track changes in the pose of specific objects across multiple frames, you would specify `Keypoint` for the `annotationType`. If you do not specify an annotation type, `BoundingBox` will be used by default.

The following topics show examples of video frame category configuration files.

Topics

- Example: video frame keypoint
- Example: video frame adjustment
- Example: video frame verification

Example: video frame keypoint

The following is an example of a video frame keypoint label category configuration file with label category attributes. This example includes two frame attributes, which will be added to all frames submitted to the labeling job. The `Car` label will include four label category attributes—`X`, `Y`, `Z`, and the global attribute, `W`.

```
{
    "documentVersion": "2020-03-01",
    "frameAttributes": [
        {
            "name":"count players",
            "description":"How many players to you see in the scene?",
            "type":"number"
        },
        {
            "name":"select one",
            "description":"describe the scene",
            "type":"string",

Example: video frame adjustment

The following is an example of a label category configuration file you may use for a video frame adjustment labeling job.

You must include `auditLabelAttributeName` to specify the label attribute name of the previous labeling job that you use to create the verification labeling job. Optionally, you can use the `editsAllowed` parameter to specify whether or not labels, label category attributes, or frame attributes can be edited.

```
{
    "documentVersion": "2020-03-01",
    "frameAttributes": [
        {
            "name":"count players",
            "editsAllowed":"none",
            "description":"How many players to you see in the scene?",
            "type":"number"
        },
        {
            "name":"select one",
            "description":"describe the scene",
            "type":"string",
            "enum":["clear","blurry"]
        },
    ],
    "categoryGlobalAttributes": [
        {
            "name":"W",
            "editsAllowed":"any",
            "description":"label-attributes-for-all-labels",
            "type":"string",
            "enum": ["foo", "buz", "buz2"]
        }
    ],
    "labels": [
        {
            "label": "Car",
            "editsAllowed":"any",
            "categoryAttributes": [
                {
                    "name":"X",
                    "description":"enter a number",
                    "type":"number",
                    "editsAllowed":"any"
                },
                {
                    "name":"Y",
```

```
                    "description":"select an option",
                    "type":"string",
                    "enum": ["y1", "y2"],
                    "editsAllowed":"any"
                },
                {
                    "name":"Z",
                    "description":"submit a free-form response",
                    "type":"string",
                    "editsAllowed":"none"
                }
            ]
        },
        {
            "label": "Pedestrian",
            "editsAllowed":"none",
            "categoryAttributes": [...]
        }
    ],
    "annotationType":"Keypoint",
    "instructions": {"shortInstruction":"add example short instructions here",
 "fullInstruction":"<html markup>"},
    // include auditLabelAttributeName for label adjustment jobs
    "auditLabelAttributeName": "myPrevJobLabelAttributeName"
}
```

Example: video frame verification

The following is an example of a label category configuration file for a video frame labeling job.

You must include `auditLabelAttributeName` to specify the label attribute name of the previous labeling job that you use to create the verification labeling job. Additionally, you must use the `editsAllowed` parameter to specify that no labels can be edited.

```
{
    "documentVersion": "2020-03-01",
    "frameAttributes": [
        {
            "name":"count players",
            "editsAllowed":"none",
            "description":"How many players to you see in the scene?",
            "type":"number"
        },
```

```
        {
            "name":"select one",
            "editsAllowed":"any",
            "description":"describe the scene",
            "type":"string",
            "enum":["clear","blurry"]
        },
    ],
    "categoryGlobalAttributes": [
        {
            "name":"W",
            "editsAllowed":"none",
            "description":"label-attributes-for-all-labels",
            "type":"string",
            "enum": ["foo", "buz", "buz2"]
        }
    ],
    "labels": [
        {
            "label": "Car",
            "editsAllowed":"none",
            "categoryAttributes": [
                {
                    "name":"X",
                    "description":"enter a number",
                    "type":"number",
                    "editsAllowed":"any"
                },
                {
                    "name":"Y",
                    "description":"select an option",
                    "type":"string",
                    "enum": ["y1", "y2"],
                    "editsAllowed":"any"
                },
                {
                    "name":"Z",
                    "description":"submit a free-form response",
                    "type":"string",
                    "editsAllowed":"none"
                }
            ]
        },
        {
```

```
            "label": "Pedestrian",
            "editsAllowed":"none",
            "categoryAttributes": [...]
        }
    ],
    "annotationType":"Keypoint",
    "instructions": {"shortInstruction":"add example short instructions here",
 "fullInstruction":"<html markup>"},
    // include auditLabelAttributeName for label adjustment jobs
    "auditLabelAttributeName": "myPrevJobLabelAttributeName"
}
```

Label category configuration file schema

The following table lists elements you can and must include in your label category configuration file.

> **Note**
>
> The parameter `annotationType` is only supported for video frame labeling jobs.

Parameter	Required	Accepted Values	Description

`frameAttributes`	No	A list of JSON objects.
		
		Required Parameters in each JSON Object:
		
		`name`, `type`, `description`
		
		`minimum` and `maximum` are required if `type` is `"number"`
		
		Optional Parameters in each JSON Object:
		
		`enum`, `editsAllowed` , `isRequired`
			Use this parameter to create a frame attribute that is applied to all frames or 3D point clouds in your labeling job. See the third table in this section for more information.

Parameter	Required	Accepted Values	Description

`categoryGlobalAttributes`	No	A list of JSON objects.
		
		Required Parameters in each JSON Object:
		
		`name`, `type`
		
		`minimum` and `maximum` are required if `type` is `"number"`
		
		Optional Parameters in each JSON Object:
		
		`description` , `enum`, `editsAllowed` , `isRequired`
			Use this parameter to create label category attributes that are applied to all labels you specify in `labels`.
			See the third table in this section for more information.

Parameter	Required	Accepted Values	Description

`labels`	Yes	A list of up to 30 JSON objects
		
		Required Parameters in each JSON Object:
		
		`label`
		
		Optional Parameters in each JSON Object:
		
		`categoryAttributes` , `editsAllowed`
			Use this parameter to specify your labels, or classes. Add one `label` for each class.
			
			To add a label category attribute to a label, add `categoryAttributes` to that label.
			
			Use `editsAllowed` to specify whether or not a label can be edited in an adjustment labeling job. Set `editsAllowed` to `"none"` for verification labeling jobs.
			
			See the following table for more information.

Parameter	Required	Accepted Values	Description

`annotationType` (only supported for video frame labeling jobs)	No	String
		
		Accepted Parameters:
		
		`BoundingBox` , `Polyline`, `Polygon`, `Keypoint`
		
		Default:
		
		`BoundingBox`
			Use this to specify the task type for your video frame labeling jobs. For example, for a polygon video frame object detection task, choose `Polygon`.
			
			If you do not specify an `annotationType` when you create a video frame labeling job, Ground Truth will use `BoundingBox` by default.

Parameter	Required	Accepted Values	Description
`instructions`	No	A JSON object **Required Parameters in each JSON Object:** `"shortInstruction"` , `"fullInstruction"`	Use this parameter to add worker instructions to help your workers complete their tasks. For more information about worker instructions, see Worker instructions. Short instructions must be under 255 characters and long instruction must be under 2,048 characters. For more information, see Create instruction pages.

Parameter	Required	Accepted Values	Description
`auditLabelAttributeName`	Required for adjustment and verification task types	String	Enter the LabelAttributeName used in the labeling job you want to adjust annotations of. Only use this parameter if you are creating an adjustment job for video frame and 3D point cloud object detection, object tracking, or 3D point cloud semantic segmentation.

Labels object schema

The following table describes the parameters that you can and must use to create a list of `Labels`. Each parameter should be included in a JSON object.

Parameter	Required	Accepted Values	Description
`label`	Yes	String	The name of the label category that is displayed to workers. Each label category name must be unique.
`categoryAttributes`	No	A list of JSON objects.	Use this parameter to add label category attributes to specific

Parameter	Required	Accepted Values	Description

		Required Parameters in each JSON Object:
		
		`name`, `type`
		
		`minimum` and `maximum` required if `type` is `"number"`
		
		Optional Parameters in each JSON Object:
		
		`description` , `enum`, `editsAllowed` , `isRequired`
			labels you specify in `labels`.
			
			To add one or more label category attributes to a label, include the `categoryAttributes` JSON object in the same `labels` JSON object as that `label`. See the following table for more information.

Parameter	Required	Accepted Values	Description
`editsAllowed`	No	String **Supported Values**: `"none"`: no modifications are not allowed. or `"any"` (Default): all modifications are allowed.	Specifies whether or not a label can be edited by workers. For video frame or 3D point cloud *adjustment* labeling jobs, add this parameter to one or more JSON objects in the `labels` list to specify whether or not a worker can edit a label. For 3D point cloud and video frame *verification* labeling jobs, add this parameter with the value `"none"` to each JSON object in the `labels` list. This will make all labels uneditable.

frameAttributes and categoryGlobalAttributes schema

The following table describes the parameters that you can and must use to create a frame attributes using `frameAttributes` and label category attribute using the `categoryGlobalAttributes` and `categoryAttributes` parameters.

Parameter	Required	Accepted Values	Description
`name`	Yes	String	Use this parameter to assign a name to your label category or frame attribute. This is the attribute name that workers see. Each label category attribute name in your label category configuration file must be unique. Global label category attributes and label specific label category attributes cannot have the same name.
`type`	Yes	String **Required Values**: `"string"` or `"number"`	Use this parameter to define the label category or frame attribute type. If you specify `"string"` for `type` and provide an `enum` value for this attribute, workers will be able to choose from one of the choices you provide.

Parameter	Required	Accepted Values	Description
			If you specify `"string"` for `type` and do not provide an `enum` value, workers can enter free form text. If you specify `number` for `type`, worker can enter a number between the `minimum` and `maximum` numbers you specify.
`enum`	No	List of strings	Use this parameter to define options that workers can choose from for this label category or frame attribute. Workers can choose one value specified in `enum`. For example, if you specify `["foo", "buzz", "bar"]` for `enum`, workers can choose one of `foo`, `buzz`, or `bar`. You must specify `"string"` for `type` to use an `enum` list.

Parameter	Required	Accepted Values	Description
`description`	`frameAttributes` : Yes `categoryAttributes` or `categoryGlobalAttributes` : No	String	Use this parameter to add a description of the label category or frame attribute. You can use this field to give workers more information about the attribute. This field is only required for frame attributes.
`minimum` and `maximum`	Required if attribute `type` is `"number"`	Integers	Use these parameters to specify minimum and maximum (inclusive) values workers can enter for numeric label category or frame attributes. You must specify `"number"` for `type` to use `minimum` and `maximum`.

Parameter	Required	Accepted Values	Description
`editsAllowed`	No	String **Required Values**: `"none"`: no modifications are not allowed. or `"any"` (Default): all modifications are allowed.	Specifies whether or not a label category or frame attribute can be edited by workers. For video frame or 3D point cloud *adjustment* and *verification* labeling jobs, add this parameter to label category and frame attribute JSON objects to specify whether or not a worker can edit an attribute.
`isRequired`	No	Boolean	Specifies whether workers are required to annotate an attribute. Workers cannot submit the job until all required attributes are annotated.

Label and label category attribute quotas

You can specify up to 10 label category attributes per class. This 10-attribute quotas includes global label category attributes. For example, if you create four global label category attributes, and then assign three label category attributes to label `X`, that label will have 4+3=7 label category attributes in total. For all label category and label category attribute limits, refer to the following table.

Type	Min	Max
Labels (`Labels`)	1	30
Label name character quota	1	16
Label category attributes per label (sum of `categoryAttributes` and `categoryGlobalAttributes`)	0	10
Free form text entry label category attributes per label (sum of `categoryAttributes` and `categoryGlobalAttributes`).	0	5
Frame attributes	0	10
Free form text entry attributes in `frameAttributes`.	0	5
Attribute name character quota (`name`)	1	16
Attribute description character quota (`description`)	0	128
Attribute type characters quota (`type`)	1	16
Allowed values in the `enum` list for a `string` attribute	1	10
Character quota for a value in `enum` list	1	16

Type	Min	Max
Maximum characters in free form text response for free form text `frameAttributes`	0	1000
Maximum characters in free form text response for free form text `categoryAttributes` and `categoryGlobalAttributes`	0	80

Use input and output data

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

The input data that you provide to Amazon SageMaker Ground Truth is sent to your workers for labeling. You choose the data to send to your workers by creating a single manifest file that defines all of the data that requires labeling or by sending input data objects to an ongoing, streaming labeling job to be labeled in real time.

The output data is the result of your labeling job. The output data file, or *augmented manifest file*, contains label data for each object you send to the labeling job and metadata about the label assigned to data objects.

When you use image classification (single and multi-label), text classification (single and multi-label), object detection, and semantic segmentation built in task types to create a labeling job, you can use the resulting augmented manifest file to launch a SageMaker training job. For a demonstration of how to use an augmented manifest to train an object detection machine learning

model with Amazon SageMaker AI, see object_detection_augmented_manifest_training.ipynb. For more information, see Augmented Manifest Files for Training Jobs.

Input data

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

The input data are the data objects that you send to your workforce to be labeled. There are two ways to send data objects to Ground Truth for labeling:

- Send a list of data objects that require labeling using an input manifest file.
- Send individual data objects in real time to a perpetually running, streaming labeling job.

If you have a dataset that needs to be labeled one time, and you do not require an ongoing labeling job, create a standard labeling job using an input manifest file.

If you want to regularly send new data objects to your labeling job after it has started, create a streaming labeling job. When you create a streaming labeling job, you can optionally use an input manifest file to specify a group of data that you want labeled immediately when the job starts. You can continuously send new data objects to a streaming labeling job as long as it is active.

> **Note**
>
> Streaming labeling jobs are only supported through the SageMaker API. You cannot create a streaming labeling job using the SageMaker AI console.

The following task types have special input data requirements and options:

- For 3D point cloud labeling job input data requirements, see 3D Point Cloud Input Data.
- For video frame labeling job input data requirements, see Video Frame Input Data.

Input manifest files

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Each line in an input manifest file is an entry containing an object, or a reference to an object, to label. An entry can also contain labels from previous jobs and for some task types, additional information.

Input data and the manifest file must be stored in Amazon Simple Storage Service (Amazon S3). Each has specific storage and access requirements, as follows:

- The Amazon S3 bucket that contains the input data must be in the same Amazon Region in which you are running Amazon SageMaker Ground Truth. You must give Amazon SageMaker AI access to the data stored in the Amazon S3 bucket so that it can read it. For more information about Amazon S3 buckets, see Working with Amazon S3 buckets.
- The manifest file must be in the same Amazon Region as the data files, but it doesn't need to be in the same location as the data files. It can be stored in any Amazon S3 bucket that is accessible

to the Amazon Identity and Access Management (IAM) role that you assigned to Ground Truth when you created the labeling job.

> **Note**
>
> 3D point cloud and video frame task types have different input manifest requirements and attributes.
> For 3D point cloud task types, refer to Input Manifest Files for 3D Point Cloud Labeling Jobs.
> For video frame task types, refer to Create a Video Frame Input Manifest File.

The manifest is a UTF-8 encoded file in which each line is a complete and valid JSON object. Each line is delimited by a standard line break, \n or \r\n. Because each line must be a valid JSON object, you can't have unescaped line break characters. For more information about data format, see JSON Lines.

Each JSON object in the manifest file can be no larger than 100,000 characters. No single attribute within an object can be larger than 20,000 characters. Attribute names can't begin with $ (dollar sign).

Each JSON object in the manifest file must contain one of the following keys: `source-ref` or `source`. The value of the keys are interpreted as follows:

- `source-ref` – The source of the object is the Amazon S3 object specified in the value. Use this value when the object is a binary object, such as an image.
- `source` – The source of the object is the value. Use this value when the object is a text value.

The following is an example of a manifest file for files stored in an Amazon S3 bucket:

```
{"source-ref": "S3 bucket location 1"}
{"source-ref": "S3 bucket location 2"}
   ...
{"source-ref": "S3 bucket location n"}
```

Use the `source-ref` key for image files for bounding box, image classification (single and multi-label), semantic segmentation, and video clips for video classification labeling jobs. 3D point

cloud and video frame labeling jobs also use the `source-ref` key but these labeling jobs require additional information in the input manifest file. For more information see 3D Point Cloud Input Data and Video Frame Input Data.

The following is an example of a manifest file with the input data stored in the manifest:

```
{"source": "Lorem ipsum dolor sit amet"}
{"source": "consectetur adipiscing elit"}
   ...
{"source": "mollit anim id est laborum"}
```

Use the `source` key for single and multi-label text classification and named entity recognition labeling jobs.

You can include other key-value pairs in the manifest file. These pairs are passed to the output file unchanged. This is useful when you want to pass information between your applications. For more information, see Labeling job output data.

Automate data setup for labeling jobs

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use the automated data setup to create manifest files for your labeling jobs in the Ground Truth console using images, videos, video frames, text (.txt) files, and comma-separated value (.csv) files stored in Amazon S3. When you use automated data setup, you specify an Amazon S3 location where your input data is stored and the input data type, and Ground Truth looks for the files that match that type in the location you specify.

> **Note**
>
> Ground Truth does not use an Amazon KMS key to access your input data or write the input manifest file in the Amazon S3 location that you specify. The user or role that creates the labeling job must have permissions to access your input data objects in Amazon S3.

Before using the following procedure, ensure that your input images or files are correctly formatted:

- Image files – Image files must comply with the size and resolution limits listed in the tables found in Input File Size Quota.
- Text files – Text data can be stored in one or more .txt files. Each item that you want labeled must be separated by a standard line break.
- CSV files – Text data can be stored in one or more .csv files. Each item that you want labeled must be in a separate row.
- Videos – Video files can be any of the following formats: .mp4, .ogg, and .webm. If you want to extract video frames from your video files for object detection or object tracking, see Provide Video Files.
- Video frames – Video frames are images extracted from a videos. All images extracted from a single video are referred to as a *sequence of video frames*. Each sequence of video frames must have unique prefix keys in Amazon S3. See Provide Video Frames. For this data type, see Set up Automated Video Frame Input Data

> **Important**
>
> For video frame object detection and video frame object tracking labeling jobs, see Set up Automated Video Frame Input Data to learn how to use the automated data setup.

Use these instructions to automatically set up your input dataset connection with Ground Truth.

Automatically connect your data in Amazon S3 with Ground Truth

1. Navigate to the **Create labeling job** page in the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.

   This link puts you in the North Virginia (us-east-1) Amazon Region. If your input data is in an Amazon S3 bucket in another Region, switch to that Region. To change your Amazon Region, on the navigation bar, choose the name of the currently displayed Region.
2. Select **Create labeling job**.
3. Enter a **Job name**.
4. In the section **Input data setup**, select **Automated data setup**.

5. Enter an Amazon S3 URI for **S3 location for input datasets**.
6. Specify your **S3 location for output datasets**. This is where your output data is stored.
7. Choose your **Data type** using the dropdown list.
8. Use the drop down menu under **IAM Role** to select an execution role. If you select **Create a new role**, specify the Amazon S3 buckets that you want grant this role permission to access. This role must have permission to access the S3 buckets you specified in Steps 5 and 6.
9. Select **Complete data setup**.

The following GIF demonstrates how to use the automated data setup for image data. This example will create a file, `dataset-YYMMDDTHHMMSS.manifest` in the Amazon S3 bucket `example-groundtruth-images` where *YYMMDDTHHmmSS* indicates the year (YY), month (MM), day (DD) and time in hours (HH), minutes (mm) and seconds (ss), that the input manifest file was created.

Supported data formats

When you create an input manifest file for a built-in task types manually, your input data must be in one of the following support file formats for the respective input data type. To learn about automated data setup, see Automate data setup for labeling jobs.

> **Tip**
>
> When you use the automated data setup, additional data formats can be used to generate an input manifest file for video frame and text based task types.

Task Types	Input Data Type	Support Formats	Example Input Manifest Line
Bounding Box, Semantic Segmentation, Image Classification (Single Label and Multi-label), Verify and Adjust Labels	Image	.jpg, .jpeg, .png	`{"source-ref": "s3://amzn-s3-demo-bucket1/example-image.png "}`

Task Types	Input Data Type	Support Formats	Example Input Manifest Line
Named Entity Recognition, Text Classification (Single and Multi-Label)	Text	Raw text	`{"source": "Lorem ipsum dolor sit amet"}`
Video Classification	Video clips	.mp4, .ogg, and .webm	`{"source-ref": "s3:///example-video.mp4 "}`
Video Frame Object Detection, Video Frame Object Tracking (bounding boxes, polylines, polygons or keypoint)	Video frames and video frame sequence files (for Object Tracking)	**Video frames**: .jpg, .jpeg, .png **Sequence files**: .json	Refer to Create a Video Frame Input Manifest File.
3D Point Cloud Semantic Segmentation, 3D Point Cloud Object Detection, 3D Point Cloud Object Tracking	Point clouds and point cloud sequence files (for Object Tracking)	**Point clouds**: Binary pack format and ASCII. For more information see Accepted Raw 3D Data Formats. **Sequence files**: .json	Refer to Input Manifest Files for 3D Point Cloud Labeling Jobs.

Ground Truth streaming labeling jobs

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

If you want to perpetually send new data objects to Amazon SageMaker Ground Truth to be labeled, use a streaming labeling job. Streaming labeling jobs allow you to:

- Send new dataset objects to workers in real time using a perpetually running labeling job. Workers continuously receive new data objects to label as long as the labeling job is active and new objects are being sent to it.
- Gain visibility into the number of objects that have been queued and are waiting to be labeled. Use this information to control the flow of data objects sent to your labeling job.
- Receive label data for individual data objects in real time as workers finish labeling them.

Ground Truth streaming labeling jobs remain active until they are manually stopped or have been idle for more than 10 days. You can intermittently send new data objects to workers while the labeling job is active.

If you are a new user of Ground Truth streaming labeling jobs, it is recommended that you review How it works.

Use Create a streaming labeling job to learn how to create a streaming labeling job.

> **Note**
>
> Ground Truth streaming labeling jobs are only supported through the SageMaker API.

How it works

When you create a Ground Truth streaming labeling job, the job remains active until it is manually stopped, remains idle for more than 10 days, or is unable to access input data sources. You can intermittently send new data objects to workers while it is active. A worker can continue to receive new data objects in real time as long as the total number of tasks currently available to the worker is less than the value in `MaxConcurrentTaskCount`. Otherwise, the data object is sent to a queue that Ground Truth creates on your behalf in Amazon Simple Queue Service (Amazon SQS) for later processing. These tasks are sent to workers as soon as the total number of tasks currently available to a worker falls below `MaxConcurrentTaskCount`. If a data object is not sent to a worker after 14 days, it expires. You can view the number of tasks pending in the queue and adjust the number of objects you send to the labeling job. For example, you may decrease the speed at which you send objects to the labeling job if the backlog of pending objects moves above a threshold.

Topics

- Send data to a streaming labeling job
- Manage labeling requests with an Amazon SQS queue
- Receive output data from a streaming labeling job
- Duplicate message handling

Send data to a streaming labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can optionally submit input data to a streaming labeling job one time when you create the labeling job using an input manifest file. Once the labeling job has started and the state is `InProgress`, you can submit new data objects to your labeling job in real time using your Amazon SNS input topic and Amazon S3 event notifications.

Submit Data Objects When you Start the Labeling Job (One Time):

- **Use an Input Manifest File** – You can optionally specify an input manifest file Amazon S3 URI in `ManifestS3Uri` when you create the streaming labeling job. Ground Truth sends each data object in the manifest file to workers for labeling as soon as the labeling job starts. To learn more, see Create a Manifest File (Optional).

  After you submit a request to create the streaming labeling job, its status will be `Initializing`. Once the labeling job is active, the state changes to `InProgress` and you can start using the real-time options to submit additional data objects for labeling.

Submit Data Objects in Real Time:

- **Send data objects using Amazon SNS messages** – You can send Ground Truth new data objects to label by sending an Amazon SNS message. You will send this message to an Amazon SNS input topic that you create and specify when you create your streaming labeling job. For more information, see Send data objects using Amazon SNS.

- **Send data objects by placing them in an Amazon S3 bucket** – Each time you add a new data object to an Amazon S3 bucket, you can prompt Ground Truth to process that object for labeling. To do this, you add an event notification to the bucket so that it notifies your Amazon SNS input topic each time a new object is added to (or *created in*) that bucket. For more information, see Send data objects using Amazon S3. This option is not available for text-based labeling jobs such as text classification and named entity recognition.

  > **Important**
  >
  > If you use the Amazon S3 configuration, do not use the same Amazon S3 location for your input data configuration and your output data. You specify the S3 prefix for your output data when you create a labeling job.

Send data objects using Amazon SNS

You can send data objects to your streaming labeling job using Amazon Simple Notification Service (Amazon SNS). Amazon SNS is a web service that coordinates and manages the delivery of messages to and from *endpoints* (for example, an email address or Amazon Lambda function). An Amazon SNS *topic* acts as a communication channel between two or more endpoints. You use Amazon SNS to send, or *publish*, new data objects to the topic specified in the `CreateLabelingJob` parameter `SnsTopicArn` in `InputConfig`. The format of these messages is the same as a single line from an input manifest file.

For example, you may send a piece of text to an active text classification labeling job by publishing it to your input topic. The message that you publish may look similar to the following:

```
{"source": "Lorem ipsum dolor sit amet"}
```

To send a new image object to an image classification labeling job, your message may look similar to the following:

```
{"source-ref": "s3://amzn-s3-demo-bucket/example-image.jpg"}
```

> **Note**
>
> You can also include custom deduplication IDs and deduplication keys in your Amazon SNS messages. To learn more, see Duplicate message handling.

When Ground Truth creates your streaming labeling job, it subscribes to your Amazon SNS input topic.

Send data objects using Amazon S3

You can send one or more new data objects to a streaming labeling job by placing them in an Amazon S3 bucket that is configured with an Amazon SNS event notification. You can set up an event to notify your Amazon SNS input topic anytime a new object is created in your bucket. You must specify this same Amazon SNS input topic in the `CreateLabelingJob` parameter `SnsTopicArn` in `InputConfig`.

Anytime you configure an Amazon S3 bucket to send notifications to Amazon SNS, Ground Truth will publish a test event, `"s3:TestEvent"`, to ensure that the topic exists and that the owner of the Amazon S3 bucket specified has permission to publish to the specified topic. It is recommended that you set up your Amazon S3 connection with Amazon SNS before starting a streaming labeling job. If you do not, this test event may register as a data object and be sent to Ground Truth for labeling.

> **Important**
>
> If you use the Amazon S3 configuration, do not use the same Amazon S3 location for your input data configuration and your output data. You specify the S3 prefix for your output data when you create a labeling job.
> For image-based labeling jobs, Ground Truth requires all S3 buckets to have a CORS policy attached. To learn more, see CORS Requirement for Input Image Data.

Once you have configured your Amazon S3 bucket and created your labeling job, you can add objects to your bucket and Ground Truth either sends that object to workers or places it on your Amazon SQS queue.

To learn more, see Creating Amazon S3 based bucket event notifications based of the Amazon SNS defined in your labeling job.

> **Important**
>
> This option is not available for text-based labeling jobs such as text classification and named entity recognition.

Manage labeling requests with an Amazon SQS queue

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When Ground Truth creates your streaming labeling job, it creates an Amazon SQS queue in the Amazon account used to create the labeling job. The queue name is `GroundTruth-`*`labeling_job_name`* where *`labeling_job_name`* is the name of your labeling job, in lowercase letters. When you send data objects to your labeling job, Ground Truth either sends the data objects directly to workers or places the task in your queue to be processed at a later time. If a data object is not sent to a worker after 14 days, it expires and is removed from the queue. You can setup an alarm in Amazon SQS to detect when objects expire and use this mechanism to control the volume of objects you send to your labeling job.

> **Important**
>
> Modifying, deleting, or sending objects directly to the Amazon SQS queue associated with your streaming labeling job may lead to job failures.

Receive output data from a streaming labeling job

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Your Amazon S3 output bucket is periodically updated with new output data from your streaming labeling job. Optionally, you can specify an Amazon SNS output topic. Each time a worker submits a labeled object, a notification with the output data is sent to that topic. You can subscribe an endpoint to your SNS output topic to receive notifications or trigger events when you receive output data from a labeling task. Use an Amazon SNS output topic if you want to do real time

chaining to another streaming job and receive an Amazon SNS notifications each time a data object is submitted by a worker.

To learn more, see Subscribe an Endpoint to Your Amazon SNS Output Topic.

Duplicate message handling

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

For data objects sent in real time, Ground Truth guarantees idempotency by ensuring each unique object is only sent for labeling once, even if the input message referring to that object is received multiple times (duplicate messages). To do this, each data object sent to a streaming labeling job is assigned a *deduplication ID*, which is identified with a *deduplication key*. If you send your requests to label data objects directly through your Amazon SNS input topic using Amazon SNS messages, you can optionally choose a custom deduplication key and deduplication IDs for your objects. For more information, see Specify a deduplication key and ID in an Amazon SNS message.

If you do not provide your own deduplication key, or if you use the Amazon S3 configuration to send data objects to your labeling job, Ground Truth uses one of the following for the deduplication ID:

- For messages sent directly to your Amazon SNS input topic, Ground Truth uses the SNS message ID.
- For messages that come from an Amazon S3 configuration, Ground Truth creates a deduplication ID by combining the Amazon S3 URI of the object with the sequencer token in the message.

Specify a deduplication key and ID in an Amazon SNS message

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you send a data object to your streaming labeling job using an Amazon SNS message, you have the option to specify your deduplication key and deduplication ID in one of the following ways. In all of these scenarios, identify your deduplication key with `dataset-objectid-attribute-name`.

Bring Your Own Deduplication Key and ID

Create your own deduplication key and deduplication ID by configuring your Amazon SNS message as follows. Replace *`byo-key`* with your key and *`UniqueId`* with the deduplication ID for that data object.

```
{
    "source-ref":"s3://amzn-s3-demo-bucket/prefix/object1",
    "dataset-objectid-attribute-name":"byo-key",
    "byo-key":"UniqueId"
}
```

Your deduplication key can be up to 140 characters. Supported patterns include: `"^[$a-zA-Z0-9](-*[a-zA-Z0-9])*"`.

Your deduplication ID can be up to 1,024 characters. Supported patterns include: `^(https|s3)://([^/]+)/?(.*)$`.

Use an Existing Key for your Deduplication Key

You can use an existing key in your message as the deduplication key. When you do this, the value associated with that key is used for the deduplication ID.

For example, you can specify use the `source-ref` key as your deduplication key by formatting your message as follows:

```
{
    "source-ref":"s3://amzn-s3-demo-bucket/prefix/object1",
    "dataset-objectid-attribute-name":"source-ref"
}
```

In this example, Ground Truth uses `"s3://amzn-s3-demo-bucket/prefix/object1"` for the deduplication id.

Find deduplication key and ID in your output data

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can see the deduplication key and ID in your output data. The deduplication key is identified by `dataset-objectid-attribute-name`. When you use your own custom deduplication key, your output contains something similar to the following:

```
"dataset-objectid-attribute-name": "byo-key",
"byo-key": "UniqueId",
```

When you do not specify a key, you can find the deduplication ID that Ground Truth assigned to your data object as follows. The $*label-attribute-name*`-object-id` parameter identifies your deduplication ID.

```
{
    "source-ref":"s3://bucket/prefix/object1",
    "dataset-objectid-attribute-name":"$label-attribute-name-object-id"
    "label-attribute-name" :0,
    "label-attribute-name-metadata": {...},
    "$label-attribute-name-object-id":"<service-generated-key>"
}
```

For *<service-generated-key>*, if the data object came through an Amazon S3 configuration, Ground Truth adds a unique value used by the service and emits a new field keyed by $*sequencer* which shows the Amazon S3 sequencer used. If object was fed to SNS directly, Ground Truth use the SNS message ID.

> **Note**
>
> Do not use the $ character in your label attribute name.

Input Data Quotas

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Input datasets used in semantic segmentation labeling jobs have a quota of 20,000 items. For all other labeling job types, the dataset size quota is 100,000 items. To request an increase to the quota for labeling jobs other than semantic segmentation jobs, review the procedures in Amazon Service Quotas to request a quota increase.

Input image data for active and non-active learning labeling jobs must not exceed size and resolution quotas. *Active learning* refers to labeling job that use automated data labeling. *Non-active learning* refers to labeling jobs that don't use automated data labeling.

Additional quotas apply for label categories for all task types, and for input data and labeling category attributes for 3D point cloud and video frame task types.

Input File Size Quota

Input files can't exceed the following size- quotas for both active and non-active learning labeling jobs. There is no input file size quota for videos used in video classification labeling jobs.

Labeling Job Task Type	Input File Size Quota
Image classification	40 MB
Bounding box (Object detection)	40 MB
Semantic segmentation	40 MB
Bounding box (Object detection) label adjustment	40 MB
Semantic segmentation label adjustment	40 MB

Labeling Job Task Type	Input File Size Quota
Bounding box (Object detection) label verification	40 MB
Semantic segmentation label verification	40 MB

Input Image Resolution Quotas

Image file resolution refers to the number of pixels in an image, and determines the amount of detail an image holds. Image resolution quotas differ depending on the labeling job type and the SageMaker AI built-in algorithm used. The following table lists the resolution quotas for images used in active and non-active learning labeling jobs.

Labeling Job Task Type	Resolution Quota - Non Active Learning	Resolution Quota - Active Learning
Image classification	100 million pixels	3840 x 2160 pixels (4 K)
Bounding box (Object detection)	100 million pixels	3840 x 2160 pixels (4 K)
Semantic segmentation	100 million pixels	1920 x 1080 pixels (1080 p)
Object detection label adjustment	100 million pixels	3840 x 2160 pixels (4 K)
Semantic segmentation label adjustment	100 million pixels	1920 x 1080 pixels (1080 p)
Object detection label verification	100 million pixels	Not available
Semantic segmentation label verification	100 million pixels	Not available

Label Category Quotas

Each labeling job task type has a quota for the number of label categories you can specify. Workers select label categories to create annotations. For example, you may specify label categories *car*, *pedestrian*, and *biker* when creating a bounding box labeling job and workers will select the *car* category before drawing bounding boxes around cars.

> **Important**
>
> Label category names cannot exceed 256 characters.
> All label categories must be unique. You cannot specify duplicate label categories.

The following label category limits apply to labeling jobs. Quotas for label categories depend on whether you use the SageMaker API operation `CreateLabelingJob` or the console to create a labeling job.

Labeling Job Task Type	Label Category Quota - API	Label Category Quota - Console
Image classification (Multi-label)	50	50
Image classification (Single label)	Unlimited	30
Bounding box (Object detection)	50	50
Label verification	Unlimited	30
Semantic segmentation (with active learning)	20	10
Semantic segmentation (without active learning)	Unlimited	10
Named entity recognition	Unlimited	30

Labeling Job Task Type	Label Category Quota - API	Label Category Quota - Console
Text classification (Multi-label)	50	50
Text classification (Single label)	Unlimited	30
Video classification	30	30
Video frame object detection	30	30
Video frame object tracking	30	30
3D point cloud object detection	30	30
3D point cloud object tracking	30	30
3D point cloud semantic segmentation	30	30

Generative AI Labeling Job Quotas

The following quotas apply for question-answer pairs that you provide in the labeling application.

Quota Type	Data Quota
Question-answer pairs	Minimum is one pair. Maximum is 20 pairs.
Word count of a question	Minimum is one word. Maximum is 200 words.
Word count of an answer	Minimum is one word. Maximum is 200 words.

3D Point Cloud and Video Frame Labeling Job Quotas

The following quotas apply for 3D point cloud and video frame labeling job input data.

Labeling Job Task Type	Input Data Quota
Video frame object detection	2,000 video frames (images) per sequence
Video frame object detection	10 video frame sequences per manifest file
Video frame object tracking	2,000 video frames (images) per sequence
Video frame object tracking	10 video frame sequences per manifest file
3D point cloud object detection	100,000 point cloud frames per labeling job
3D point cloud object tracking	100,000 point cloud frame sequences per labeling job
3D point cloud object tracking	500 point cloud frames in each sequence file

When you create a video frame or 3D point cloud labeling job, you can add one or more *label category attributes* to each label category that you specify to have workers provide more information about an annotation.

Each label category attribute has a single label category attribute `name`, and a list of one or more options (values) to choose from. To learn more, see Worker user interface (UI) for 3D point cloud labeling jobs and Worker user interface (UI) for video frame labeling jobs.

The following quotas apply to the number of label category attributes names and values you can specify for labeling jobs.

Labeling Job Task Type	Label Category Attribute (name) Quota	Label Category Attribute Values Quota
Video frame object detection	10	10
Video frame object tracking	10	10
3D point cloud object detection	10	10

Labeling Job Task Type	Label Category Attribute (name) Quota	Label Category Attribute Values Quota
3D point cloud object tracking	10	10
3D point cloud semantic segmentation	10	10

Select Data for Labeling

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use the Amazon SageMaker AI console to select a portion of your dataset for labeling. The data must be stored in an Amazon S3 bucket. You have three options:

- Use the full dataset.
- Choose a randomly selected sample of the dataset.
- Specify a subset of the dataset using a query.

The following options are available in the **Labeling jobs** section of the SageMaker AI console after selecting **Create labeling job**. To learn how to create a labeling job in the console, see Getting started: Create a bounding box labeling job with Ground Truth. To configure the dataset that you use for labeling, in the **Job overview** section, choose **Additional configuration**.

Use the Full Dataset

When you choose to use the **Full dataset**, you must provide a manifest file for your data objects. You can provide the path of the Amazon S3 bucket that contains the manifest file or use the SageMaker AI console to create the file. To learn how to create a manifest file using the console, see Automate data setup for labeling jobs.

Choose a Random Sample

When you want to label a random subset of your data, select **Random sample**. The dataset is stored in the Amazon S3 bucket specified in the **Input dataset location** field.

After you have specified the percentage of data objects that you want to include in the sample, choose **Create subset**. SageMaker AI randomly picks the data objects for your labeling job. After the objects are selected, choose **Use this subset**.

SageMaker AI creates a manifest file for the selected data objects. It also modifies the value in the **Input dataset location** field to point to the new manifest file.

Specify a Subset

> **Amazon S3 Select**
>
> Amazon S3 Select is no longer available to new customers. Existing customers of Amazon S3 Select can continue to use the feature as usual. To learn more see, How to optimize querying your data in Amazon S3

You can specify a subset of your data objects using an Amazon S3 `SELECT` query on the object file names.

The `SELECT` statement of the SQL query is defined for you. You provide the `WHERE` clause to specify which data objects should be returned.

For more information about the Amazon S3 `SELECT` statement, see Selecting Content from Objects.

Choose **Create subset** to start the selection, and then choose **Use this subset** to use the selected data.

SageMaker AI creates a manifest file for the selected data objects. It also updates the value in the **Input dataset location** field to point to the new manifest file.

3D Point Cloud Input Data

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

To create a 3D point cloud labeling job, you must create an input manifest file. Use this topic to learn the formatting requirements of the input manifest file for each task type. To learn about the raw input data formats Ground Truth accepts for 3D point cloud labeling jobs, see the section Accepted Raw 3D Data Formats.

Use your labeling job task type to choose a topics on Input Manifest Files for 3D Point Cloud Labeling Jobs to learn about the formatting requirements for each line of your input manifest file.

Topics

- Accepted Raw 3D Data Formats
- Input Manifest Files for 3D Point Cloud Labeling Jobs
- Understand Coordinate Systems and Sensor Fusion

Accepted Raw 3D Data Formats

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Ground Truth uses your 3D point cloud data to render a 3D scenes that workers annotate. This section describes the raw data formats that are accepted for point cloud data and sensor fusion data for a point cloud frame. To learn how to create an input manifest file to connect your raw input data files with Ground Truth, see Input Manifest Files for 3D Point Cloud Labeling Jobs.

For each frame, Ground Truth supports Compact Binary Pack Format (.bin) and ASCII (.txt) files. These files contain information about the location (x, y, and z coordinates) of all points that make

up that frame, and, optionally, information about the pixel color of each point for colored point clouds. When you create a 3D point cloud labeling job input manifest file, you can specify the format of your raw data in the `format` parameter.

The following table lists elements that Ground Truth supports in point cloud frame files to describe individual points.

Symbol	Value
x	The x coordinate of the point.
y	The y coordinate of the point.
z	The z coordinate of the point.
i	The intensity of the point.
r	The red color channel component. An 8-bit value (0-255).
g	The green color channel component. An 8-bit value (0-255)
b	The blue color channel component. An 8-bit value (0-255)

Ground Truth assumes the following about your input data:

- All of the positional coordinates (x, y, z) are in meters.
- All the pose headings (qx, qy, qz, qw) are measured in Spatial Quaternions .

Compact Binary Pack Format

The Compact Binary Pack Format represents a point cloud as an ordered set of a stream of points. Each point in the stream is an ordered binary pack of 4-byte float values in some variant of the form `xyzirgb`. The `x`, `y`, and `z` elements are required and additional information about that pixel can be included in a variety of ways using `i`, `r`, `g`, and `b`.

To use a binary file to input point cloud frame data to a Ground Truth 3D point cloud labeling job, enter `binary/` in the `format` parameter for your input manifest file and replace with the order of elements in each binary pack. For example, you may enter one of the following for the `format` parameter.

- `binary/xyzi` – When you use this format, your point element stream would be in the following order: `x1y1z1i1x2y2z2i2...`
- `binary/xyzrgb` – When you use this format, your point element stream would be in the following order: `x1y1z1r1g1b1x2y2z2r2g2b2...`
- `binary/xyzirgb` – When you use this format, your point element stream would be in the following order: `x1y1z1i1r1g1b1x2y2z2i2r2g2b2...`

When you use a binary file for your point cloud frame data, if you do not enter a value for `format`, the default pack format `binary/xyzi` is used.

ASCII Format

The ASCII format uses a text file to represent a point cloud, where each line in the ASCII point cloud file represents a single point. Each point is a line the text file and contains white space separated values, each of which is a 4-byte float ASCII values. The `x`, `y`, and `z` elements are required for each point and additional information about that point can be included in a variety of ways using `i`, `r`, `g`, and `b`.

To use a text file to input point cloud frame data to a Ground Truth 3D point cloud labeling job, enter `text/` in the `format` parameter for your input manifest file and replace with the order of point elements on each line.

For example, if you enter `text/xyzi` for `format`, your text file for each point cloud frame should look similar to the following:

```
x1 y1 z1 i1
x2 y2 z2 i2
...
...
```

If you enter `text/xyzrgb`, your text file should look similar to the following:

```
x1 y1 z1 r1 g1 b1
```

```
x2 y2 z2 r2 g2 b1
...
...
```

When you use a text file for your point cloud frame data, if you do not enter a value for `format`, the default format `text/xyzi` will be used.

Point Cloud Resolution Limits

Ground Truth does not have a resolution limit for 3D point cloud frames. However, we recommend that you limit each point cloud frame to 500K points for optimal performance. When Ground Truth renders the 3D point cloud visualization, it must be viewable on your workers' computers, which depends on workers' computer hardware. Point cloud frames that are larger than 1 million points may not render on standard machines, or may take too long to load.

Input Manifest Files for 3D Point Cloud Labeling Jobs

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you create a labeling job, you provide an input manifest file where each line of the manifest describes a unit of task to be completed by annotators. The format of your input manifest file depends on your task type.

- If you are creating a 3D point cloud **object detection** or **semantic segmentation** labeling job, each line in your input manifest file contains information about a single 3D point cloud frame. This is called a *point cloud frame input manifest*. To learn more, see Create a Point Cloud Frame Input Manifest File.
- If you are creating a 3D point cloud **object tracking** labeling job, each line of your input manifest file contains a sequence of 3D point cloud frames and associated data. This is called a *point cloud sequence input manifest*. To learn more, see Create a Point Cloud Sequence Input Manifest.

Create a Point Cloud Frame Input Manifest File

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

The manifest is a UTF-8 encoded file in which each line is a complete and valid JSON object. Each line is delimited by a standard line break, \n or \r\n. Because each line must be a valid JSON object, you can't have unescaped line break characters. In the single-frame input manifest file, each line in the manifest contains data for a single point cloud frame. The point cloud frame data can either be stored in binary or ASCII format (see Accepted Raw 3D Data Formats). This is the manifest file formatting required for 3D point cloud object detection and semantic segmentation. Optionally, you can also provide camera sensor fusion data for each point cloud frame.

Ground Truth supports point cloud and video camera sensor fusion in the world coordinate system for all modalities. If you can obtain your 3D sensor extrinsic (like a LiDAR extrinsic), we recommend that you transform 3D point cloud frames into the world coordinate system using the extrinsic. For more information, see Sensor Fusion.

However, if you cannot obtain a point cloud in world coordinate system, you can provide coordinates in the original coordinate system that the data was captured in. If you are providing camera data for sensor fusion, it is recommended that you provide LiDAR sensor and camera pose in the world coordinate system.

To create a single-frame input manifest file, you will identify the location of each point cloud frame that you want workers to label using the `source-ref` key. Additionally, you must use the `source-ref-metadata` key to identify the format of your dataset, a timestamp for that frame, and, optionally, sensor fusion data and video camera images.

The following example demonstrates the syntax used for an input manifest file for a single-frame point cloud labeling job. The example includes two point cloud frames. For details about each parameter, see the table following this example.

Important

Each line in your input manifest file must be in JSON Lines format. The following code block shows an input manifest file with two JSON objects. Each JSON object is used to point to and provide details about a single point cloud frame. The JSON objects have been expanded for readability, but you must minimize each JSON object to fit on a single line when creating an input manifest file. An example is provided under this code block.

```
{

        }]
    }
}
```

When you create an input manifest file, you must collapse your JSON objects to fit on a single line. For example, the code block above would appear as follows in an input manifest file:

```
{"source-ref":"s3://amzn-s3-demo-bucket/examplefolder/frame1.bin","source-ref-
metadata":{"format":"binary/xyzi","unix-timestamp":1566861644.759115,"ego-vehicle-
pose":{"position":

```

The following table shows the parameters you can include in your input manifest file:

Parameter	Required	Accepted Values	Description
`source-ref`	Yes	String **Accepted string value format**: `s3://<bucket-name> /<folder-name> /point-cloud-frame-file`	The Amazon S3 location of a single point cloud frame.
`source-ref-metadata`	Yes	JSON object **Accepted parameters**: `format`, `unix-timestamp` , `ego-vehicle-pose` , `position`, `prefix`, `images`	Use this parameter to include additional information about the point cloud in `source-ref` , and to provide camera data for sensor fusion.
`format`	No	String **Accepted string values**: `"binary/xyz"` , `"binary/xyzi"` , `"binary/xyzrgb"` , `"binary/xyzirgb"` , `"text/xyz"` , `"text/xyz`	Use this parameter to specify the format of your point cloud data. For more information, see Accepted Raw 3D Data Formats.

Parameter	Required	Accepted Values	Description
		`i" ,"text/xyz rgb" ,"text/xyz irgb"` **Default Values**: When the file identified in `source-ref` has a .bin extension, `binary/xyzi` When the file identified in `source-ref` has a .txt extension, `text/xyzi`	
`unix-timestamp`	Yes	Number A unix timestamp.	The unix timestamp is the number of seconds since January 1st, 1970 until the UTC time that the data was collected by a sensor.
`ego-vehicle-pose`	No	JSON object	The pose of the device used to collect the point cloud data. For more information about this parameter , see Include Vehicle Pose Information in Your Input Manifest.

Parameter	Required	Accepted Values	Description
`prefix`	No	String **Accepted string value format**: `s3://<bucket-name> /<folder-name>/`	The location in Amazon S3 where your metadata, such as camera images, is stored for this frame. The prefix must end with a forward slash: `/`.
`images`	No	List	A list of parameters describing color camera images used for sensor fusion. You can include up to 8 images in this list. For more information about the parameters required for each image, see Include Camera Data in Your Input Manifest.

Include Vehicle Pose Information in Your Input Manifest

Use the ego-vehicle location to provide information about the location of the vehicle used to capture point cloud data. Ground Truth use this information to compute LiDAR extrinsic matrix.

Ground Truth uses extrinsic matrices to project labels to and from the 3D scene and 2D images. For more information, see Sensor Fusion.

The following table provides more information about the `position` and orientation (`heading`) parameters that are required when you provide ego-vehicle information.

Parameter	Required	Accepted Values	Description
`position`	Yes	JSON object **Required Parameters**: `x`, `y`, and `z`. Enter numbers for these parameters.	The translation vector of the ego vehicle in the world coordinate system.
`heading`	Yes	JSON Object **Required Parameters**: `qx`, `qy`, `qz`, and `qw`. Enter numbers for these parameters.	The orientation of the frame of reference of the device or sensor mounted on the vehicle sensing the surroundi ng, measured in quaternions, (`qx`, `qy`, `qz`, `qw`) in the a coordinate system.

Include Camera Data in Your Input Manifest

If you want to include video camera data with a frame, use the following parameters to provide information about each image. The **Required** column below applies when the `images` parameter is included in the input manifest file under `source-ref-metadata`. You are not required to include images in your input manifest file.

If you include camera images, you must include information about the camera `position` and `heading` used the capture the images in the world coordinate system.

If your images are distorted, Ground Truth can automatically undistort them using information you provide about the image in your input manifest file, including distortion coefficients (`k1`, `k2`, `k3`, `k4`, `p1`, `p1`), the camera model and the camera intrinsic matrix. The intrinsic matrix is made up of focal length (`fx`, `fy`), and the principal point (`cx`, `cy`). See Intrinsic Matrix to learn how Ground

Truth uses the camera intrinsic. If distortion coefficients are not included, Ground Truth will not undistort an image.

Parameter	Required	Accepted Values	Description
`image-path`	Yes	String **Example of format**: *<folder-name> /<imagefile.png>*	The relative location, in Amazon S3 of your image file. This relative path will be appended to the path you specify in `prefix`.
`unix-timestamp`	Yes	Number	The unix timestamp is the number of seconds since January 1st, 1970 until the UTC time that the data was collected by a camera.

`camera-model`	No	String:
		
		Accepted Values:
		
		`"pinhole" , "fisheye"`
		
		Default:
		
		`"pinhole"`
			The model of the camera used to capture the image. This information is used to undistort camera images.

`fx, fy`	Yes	Numbers	The focal length of the camera, in the x (`fx`) and y (`fy`) directions.

Parameter	Required	Accepted Values	Description
`cx, cy`	Yes	Numbers	The x (`cx`) and y (`cy`) coordinates of the principal point.
`k1, k2, k3, k4`	No	Number	Radial distortion coefficients. Supported for both **fisheye** and **pinhole** camera models.
`p1, p2`	No	Number	Tangential distortion coefficients. Supported for **pinhole** camera models.
`skew`	No	Number	A parameter to measure the skew of an image.
`position`	Yes	JSON object **Required Parameters**: `x`, `y`, and `z`. Enter numbers for these parameters.	The location or origin of the frame of reference of the camera mounted on the vehicle capturing images.

Parameter	Required	Accepted Values	Description
`heading`	Yes	JSON Object **Required Parameters**: qx, qy, qz, and qw. Enter numbers for these parameters.	The orientation of the frame of reference of the camera mounted on the vehicle capturing images, measured using quaternions, (qx, qy, qz, qw), in the world coordinate system.

Point Cloud Frame Limits

You can include up to 100,000 point cloud frames in your input manifest file. 3D point cloud labeling job have longer pre-processing times than other Ground Truth task types. For more information, see Job pre-processing time.

Create a Point Cloud Sequence Input Manifest

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

The manifest is a UTF-8 encoded file in which each line is a complete and valid JSON object. Each line is delimited by a standard line break, \n or \r\n. Because each line must be a valid JSON object, you can't have unescaped line break characters. In the point cloud sequence input manifest file, each line in the manifest contains a sequence of point cloud frames. The point cloud data for each frame in the sequence can either be stored in binary or ASCII format. For more information, see Accepted Raw 3D Data Formats. This is the manifest file formatting required for 3D point cloud object tracking. Optionally, you can also provide point attribute and camera sensor fusion data for each point cloud frame. When you create a sequence input manifest file, you must provide LiDAR and video camera sensor fusion data in a world coordinate system.

The following example demonstrates the syntax used for an input manifest file when each line in the manifest is a sequence file. Each line in your input manifest file must be in JSON Lines format.

```
{"source-ref": "s3://amzn-s3-demo-bucket/example-folder/seq1.json"}
{"source-ref": "s3://amzn-s3-demo-bucket/example-folder/seq2.json"}
```

The data for each sequence of point cloud frames needs to be stored in a JSON data object. The following is an example of the format you use for a sequence file. Information about each frame is included as a JSON object and is listed in the `frames` list. This is an example of a sequence file with two point cloud frame files, `frame300.bin` and `frame303.bin`. The `...` is used to indicated where you should include information for additional frames. Add a JSON object for each frame in the sequence.

The following code block includes a JSON object for a single sequence file. The JSON object has been expanded for readability.

```
{
  "seq-no": 1,
  "prefix": "s3://amzn-s3-demo-bucket/example_lidar_sequence_dataset/seq1/",
  "number-of-frames": 100,
  "frames":[
    {
        "frame-no": 300,
        "unix-timestamp": 1566861644.759115,

                "z": 1.454614668542299
            },
            "heading": {
                "qx": 0.7594754093069037,
                "qy": 0.02181790885672969,
                "qz": -0.02461725233103356,
                "qw": -0.6496916273040025
            },
            "camera-model": "pinhole"
        }]
    },
    {
        "frame-no": 303,
        "unix-timestamp": 1566861644.759115,
        "frame": "example_lidar_frames/frame303.bin",
        "format": "text/xyzi",
        "ego-vehicle-pose":{...},
        "images":[{...}]
    },
     ...
  ]
}
```

The following table provides details about the top-level parameters of a sequence file. For detailed information about the parameters required for individual frames in the sequence file, see Parameters for Individual Point Cloud Frames.

Parameter	Required	Accepted Values	Description
`seq-no`	Yes	Integer	The ordered number of the sequence.
`prefix`	Yes	String **Accepted Values**: `s3://<bucket-name> /<prefix>/`	The Amazon S3 location where the sequence files are located. The prefix must end with a forward slash: `/`.
`number-of-frames`	Yes	Integer	The total number of frames included in the sequence file. This number must match the total number of frames listed in the `frames` parameter in the next row.
`frames`	Yes	List of JSON objects	A list of frame data. The length of the list must equal `number-of-frames` . In the worker UI, frames in a sequence will be the same as the order of frames in this array. For details about the format of each frame, see Parameter

Parameter	Required	Accepted Values	Description
			s for Individual Point Cloud Frames.

Parameters for Individual Point Cloud Frames

The following table shows the parameters you can include in your input manifest file.

Parameter	Required	Accepted Values	Description
`frame-no`	No	Integer	A frame number. This is an optional identifier specified by the customer to identify the frame within a sequence. It is not used by Ground Truth.
`unix-timestamp`	Yes	Number	The unix timestamp is the number of seconds since January 1st, 1970 until the UTC time that the data was collected by a sensor. The timestamp for each frame must be different and timestamps must be sequential because they are used for cuboid interpola tion. Ideally, this should be the real

Parameter	Required	Accepted Values	Description
			timestamp when the data was collected. If this is not available , you must use an incremental sequence of timestamps, where the first frame in your sequence file corresponds to the first timestamp in the sequence.
`frame`	Yes	String **Example of format** *<folder-name> /<sequence-file.json>*	The relative location, in Amazon S3 of your sequence file. This relative path will be appended to the path you specify in `prefix`.

Parameter	Required	Accepted Values	Description
`format`	No	String **Accepted string values**: `"binary/xyz" ,"binary/xyzi" ,"binary/xyzrgb" ,"binary/xyzirgb" ,"text/xyz" ,"text/xyzi" ,"text/xyzrgb" ,"text/xyzirgb"` **Default Values**: When the file identified in `source-ref` has a .bin extension, `binary/xyzi` When the file identified in `source-ref` has a .txt extension, `text/xyzi`	Use this parameter to specify the format of your point cloud data. For more information, see Accepted Raw 3D Data Formats.
`ego-vehicle-pose`	No	JSON object	The pose of the device used to collect the point cloud data. For more information about this parameter , see Include Vehicle Pose Information in Your Input Manifest.

Parameter	Required	Accepted Values	Description
`prefix`	No	String **Accepted string value format**: `s3://<bucket-name> /<folder-name>/`	The location in Amazon S3 where your metadata, such as camera images, is stored for this frame. The prefix must end with a forward slash: `/`.
`images`	No	List	A list parameters describing color camera images used for sensor fusion. You can include up to 8 images in this list. For more information about the parameters required for each image, see Include Camera Data in Your Input Manifest.

Include Vehicle Pose Information in Your Input Manifest

Use the ego-vehicle location to provide information about the pose of the vehicle used to capture point cloud data. Ground Truth use this information to compute LiDAR extrinsic matrices.

Ground Truth uses extrinsic matrices to project labels to and from the 3D scene and 2D images. For more information, see Sensor Fusion.

The following table provides more information about the `position` and orientation (`heading`) parameters that are required when you provide ego-vehicle information.

Parameter	Required	Accepted Values	Description
`position`	Yes	JSON object **Required Parameters**: `x`, `y`, and `z`. Enter numbers for these parameters.	The translation vector of the ego vehicle in the world coordinate system.
`heading`	Yes	JSON Object **Required Parameters**: `qx`, `qy`, `qz`, and `qw`. Enter numbers for these parameters.	The orientation of the frame of reference of the device or sensor mounted on the vehicle sensing the surroundi ng, measured in quaternions, (`qx`, `qy`, `qz`, `qw`) in the a coordinate system.

Include Camera Data in Your Input Manifest

If you want to include color camera data with a frame, use the following parameters to provide information about each image. The **Required** column in the following table applies when the `images` parameter is included in the input manifest file. You are not required to include images in your input manifest file.

If you include camera images, you must include information about the `position` and orientation (`heading`) of the camera used the capture the images.

If your images are distorted, Ground Truth can automatically undistort them using information you provide about the image in your input manifest file, including distortion coefficients (`k1`, `k2`, `k3`, `k4`, `p1`, `p1`), camera model and focal length (`fx`, `fy`), and the principal point (`cx`, `cy`). To learn more about these coefficients and undistorting images, see Camera calibration With OpenCV. If distortion coefficients are not included, Ground Truth will not undistort an image.

Parameter	Required	Accepted Values	Description
`image-path`	Yes	String **Example of format**: *<folder-name> /<imagefile.png>*	The relative location, in Amazon S3 of your image file. This relative path will be appended to the path you specify in `prefix`.
`unix-timestamp`	Yes	Number	The timestamp of the image.

`camera-model`	No	String:
		
		Accepted Values:
		
		`"pinhole" , "fisheye"`
		
		Default:
		
		`"pinhole"`
			The model of the camera used to capture the image. This information is used to undistort camera images.

`fx, fy`	Yes	Numbers	The focal length of the camera, in the x (`fx`) and y (`fy`) directions.
`cx, cy`	Yes	Numbers	The x (`cx`) and y (`cy`) coordinates of the principal point.
`k1, k2, k3, k4`	No	Number	Radial distortion coefficients. Supported for both **fisheye** and **pinhole** camera models.

Parameter	Required	Accepted Values	Description
`p1, p2`	No	Number	Tangential distortion coefficients. Supported for **pinhole** camera models.
`skew`	No	Number	A parameter to measure any known skew in the image.
`position`	Yes	JSON object **Required Parameters**: x, y, and z. Enter numbers for these parameters.	The location or origin of the frame of reference of the camera mounted on the vehicle capturing images.
`heading`	Yes	JSON Object **Required Parameters**: qx, qy, qz, and qw. Enter numbers for these parameters.	The orientation of the frame of reference of the camera mounted on the vehicle capturing images, measured using quaternions, (qx, qy, qz, qw).

Sequence File and Point Cloud Frame Limits

You can include up to 100,000 point cloud frame sequences in your input manifest file. You can include up to 500 point cloud frames in each sequence file.

Keep in mind that 3D point cloud labeling job have longer pre-processing times than other Ground Truth task types. For more information, see Job pre-processing time.

Understand Coordinate Systems and Sensor Fusion

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Point cloud data is always located in a coordinate system. This coordinate system may be local to the vehicle or the device sensing the surroundings, or it may be a world coordinate system. When you use Ground Truth 3D point cloud labeling jobs, all the annotations are generated using the coordinate system of your input data. For some labeling job task types and features, you must provide data in a world coordinate system.

In this topic, you'll learn the following:

- When you *are required to* provide input data in a world coordinate system or global frame of reference.
- What a world coordinate is and how you can convert point cloud data to a world coordinate system.
- How you can use your sensor and camera extrinsic matrices to provide pose data when using sensor fusion.

Coordinate System Requirements for Labeling Jobs

If your point cloud data was collected in a local coordinate system, you can use an extrinsic matrix of the sensor used to collect the data to convert it to a world coordinate system or a global frame of reference. If you cannot obtain an extrinsic for your point cloud data and, as a result, cannot obtain point clouds in a world coordinate system, you can provide point cloud data in a local coordinate system for 3D point cloud object detection and semantic segmentation task types.

For object tracking, you must provide point cloud data in a world coordinate system. This is because when you are tracking objects across multiple frames, the ego vehicle itself is moving in the world and so all of the frames need a point of reference.

If you include camera data for sensor fusion, it is recommended that you provide camera poses in the same world coordinate system as the 3D sensor (such as a LiDAR sensor).

Using Point Cloud Data in a World Coordinate System

This section explains what a world coordinate system (WCS), also referred to as a *global frame of reference*, is and explains how you can provide point cloud data in a world coordinate system.

What is a World Coordinate System?

A WCS or global frame of reference is a fixed universal coordinate system in which vehicle and sensor coordinate systems are placed. For example, if multiple point cloud frames are located in different coordinate systems because they were collected from two sensors, a WCS can be used to translate all of the coordinates in these point cloud frames into a single coordinate system, where all frames have the same origin, (0,0,0). This transformation is done by translating the origin of each frame to the origin of the WCS using a translation vector, and rotating the three axes (typically x, y, and z) to the right orientation using a rotation matrix. This rigid body transformation is called a *homogeneous transformation*.

A world coordinate system is important in global path planning, localization, mapping, and driving scenario simulations. Ground Truth uses the right-handed Cartesian world coordinate system such as the one defined in ISO 8855, where the x axis is forward toward the car's movement, y axis is left, and the z axis points up from the ground.

The global frame of reference depends on the data. Some datasets use the LiDAR position in the first frame as the origin. In this scenario, all the frames use the first frame as a reference and device heading and position will be near the origin in the first frame. For example, KITTI datasets have the first frame as a reference for world coordinates. Other datasets use a device position that is different from the origin.

Note that this is not the GPS/IMU coordinate system, which is typically rotated by 90 degrees along the z-axis. If your point cloud data is in a GPS/IMU coordinate system (such as OxTS in the open source AV KITTI dataset), then you need to transform the origin to a world coordinate system (typically the vehicle's reference coordinate system). You apply this transformation by multiplying your data with transformation metrics (the rotation matrix and translation vector). This will transform the data from its original coordinate system to a global reference coordinate system. Learn more about this transformation in the next section.

Convert 3D Point Cloud Data to a WCS

Ground Truth assumes that your point cloud data has already been transformed into a reference coordinate system of your choice. For example, you can choose the reference coordinate system

of the sensor (such as LiDAR) as your global reference coordinate system. You can also take point clouds from various sensors and transform them from the sensor's view to the vehicle's reference coordinate system view. You use the a sensor's extrinsic matrix, made up of a rotation matrix and translation vector, to convert your point cloud data to a WCS or global frame of reference.

Collectively, the translation vector and rotation matrix can be used to make up an *extrinsic matrix*, which can be used to convert data from a local coordinate system to a WCS. For example, your LiDAR extrinsic matrix may be composed as follows, where `R` is the rotation matrix and `T` is the translation vector:

```
LiDAR_extrinsic = [R T;0 0 0 1]
```

For example, the autonomous driving KITTI dataset includes a rotation matrix and translation vector for the LiDAR extrinsic transformation matrix for each frame. The pykitti python module can be used for loading the KITTI data, and in the dataset `dataset.oxts[i].T_w_imu` gives the LiDAR extrinsic transform for the i^{th} frame with can be multiplied with points in that frame to convert them to a world frame - `np.matmul(lidar_transform_matrix, points)`. Multiplying a point in LiDAR frame with a LiDAR extrinsic matrix transforms it into world coordinates. Multiplying a point in the world frame with the camera extrinsic matrix gives the point coordinates in the camera's frame of reference.

The following code example demonstrates how you can convert point cloud frames from the KITTI dataset into a WCS.

```
import pykitti
import numpy as np

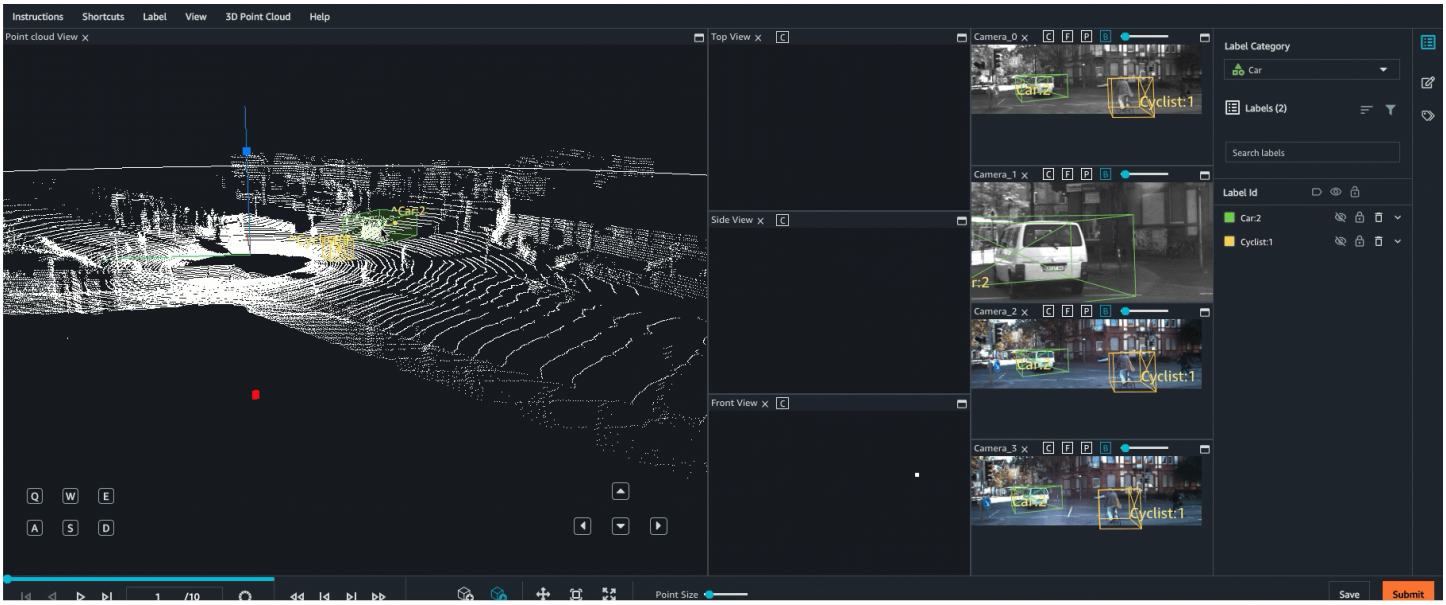
basedir = '/Users/nameofuser/kitti-data'
date = '2011_09_26'
drive = '0079'

# The 'frames' argument is optional - default: None, which loads the whole dataset.
# Calibration, timestamps, and IMU data are read automatically.
# Camera and velodyne data are available via properties that create generators
# when accessed, or through getter methods that provide random access.
data = pykitti.raw(basedir, date, drive, frames=range(0, 50, 5))

# i is frame number
i = 0
```

```
# lidar extrinsic for the ith frame
lidar_extrinsic_matrix = data.oxts[i].T_w_imu

# velodyne raw point cloud in lidar scanners own coordinate system
points = data.get_velo(i)



# transform points from lidar to global frame using lidar_extrinsic_matrix
def generate_transformed_pcd_from_point_cloud(points, lidar_extrinsic_matrix):
    tps = []
    for point in points:
        transformed_points = np.matmul(lidar_extrinsic_matrix, np.array([point[0],
 point[1], point[2], 1], dtype=np.float32).reshape(4,1)).tolist()
       if len(point) > 3 and point[3] is not None:
           tps.append([transformed_points[0][0], transformed_points[1][0],
 transformed_points[2][0], point[3]])

    return tps

# customer transforms points from lidar to global frame using lidar_extrinsic_matrix
transformed_pcl = generate_transformed_pcd_from_point_cloud(points,
 lidar_extrinsic_matrix)
```

Sensor Fusion

Ground Truth supports sensor fusion of point cloud data with up to 8 video camera inputs. This feature allows human labellers to view the 3D point cloud frame side-by-side with the synchronized video frame. In addition to providing more visual context for labeling, sensor fusion allows workers to adjust annotations in the 3D scene and in 2D images and the adjustment are projected into the other view. The following video demonstrates a 3D point cloud labeling job with LiDAR and camera sensor fusion.

For best results, when using sensor fusion, your point cloud should be in a WCS. Ground Truth uses your sensor (such as LiDAR), camera, and ego vehicle pose information to compute extrinsic and intrinsic matrices for sensor fusion.

Extrinsic Matrix

Ground Truth uses sensor (such as LiDAR) extrinsic and camera extrinsic and intrinsic matrices to project objects to and from the point cloud data's frame of reference to the camera's frame of reference.

For example, in order to project a label from the 3D point cloud to camera image plane, Ground Truth transforms 3D points from LiDAR's own coordinate system to the camera's coordinate system. This is typically done by first transforming 3D points from LiDAR's own coordinate system to a world coordinate system (or a global reference frame) using the LiDAR extrinsic matrix. Ground Truth then uses the camera inverse extrinsic (which converts points from a global frame of reference to the camera's frame of reference) to transform the 3D points from world coordinate system obtained in previous step into the camera image plane. The LiDAR extrinsic matrix can also be used to transform 3D data into a world coordinate system. If your 3D data is already transformed into world coordinate system then the first transformation doesn't have any impact on label translation, and label translation only depends on the camera inverse extrinsic. A view matrix is used to visualize projected labels. To learn more about these transformations and the view matrix, see Ground Truth Sensor Fusion Transformations.

Ground Truth computes these extrinsic matrices by using LiDAR and camera *pose data* that you provide: `heading` (in quaternions: `qx`, `qy`, `qz`, and `qw`) and `position` (`x`, `y`, `z`). For the vehicle,

typically the heading and position are described in vehicle's reference frame in a world coordinate system and are called a *ego vehicle pose*. For each camera extrinsic, you can add pose information for that camera. For more information, see Pose.

Intrinsic Matrix

Ground Truth use the camera extrinsic and intrinsic matrices to compute view metrics to transform labels to and from the 3D scene to camera images. Ground Truth computes the camera intrinsic matrix using camera focal length (`fx`, `fy`) and optical center coordinates (`cx`,`cy`) that you provide. For more information, see Intrinsic and Distortion.

Image Distortion

Image distortion can occur for a variety of reasons. For example, images may be distorted due to barrel or fish-eye effects. Ground Truth uses intrinsic parameters along with distortion co-efficient to undistort images you provide when creating 3D point cloud labeling jobs. If a camera image is already been undistorted, all distortion coefficients should be set to 0.

For more information about the transformations Ground Truth performs to undistort images, see Camera Calibrations: Extrinsic, Intrinsic and Distortion.

Ego Vehicle

To collect data for autonomous driving applications, the measurements used to generate point cloud data and are taken from sensors mounted on a vehicle, or the *ego vehicle*. To project label adjustments to and from the 3D scene and 2D images, Ground Truth needs your ego vehicle pose in a world coordinate system. The ego vehicle pose is comprised of position coordinates and orientation quaternion.

Ground Truth uses your ego vehicle pose to compute rotation and transformations matrices. Rotations in 3 dimensions can be represented by a sequence of 3 rotations around a sequence of axes. In theory, any three axes spanning the 3D Euclidean space are enough. In practice, the axes of rotation are chosen to be the basis vectors. The three rotations are expected to be in a global frame of reference (extrinsic). Ground Truth does not a support body centered frame of reference (intrinsic) which is attached to, and moves with, the object under rotation. To track objects, Ground Truth needs to measure from a global reference where all vehicles are moving. When using Ground Truth 3D point cloud labeling jobs, z specifies the axis of rotation (extrinsic rotation) and yaw Euler angles are in radians (rotation angle).

Pose

Ground Truth uses pose information for 3D visualizations and sensor fusion. Pose information you input through your manifest file is used to compute extrinsic matrices. If you already have an extrinsic matrix, you can use it to extract sensor and camera pose data.

For example in the autonomous driving KITTI dataset, the pykitti python module can be used for loading the KITTI data. In the dataset `dataset.oxts[i].T_w_imu` gives the LiDAR extrinsic transform for the i^{th} frame and it can be multiplied with the points to get them in a world frame - `matmul(lidar_transform_matrix, points)`. This transform can be converted into position (translation vector) and heading (in quaternion) of LiDAR for the input manifest file JSON format. Camera extrinsic transform for `cam0` in i^{th} frame can be calculated by `inv(matmul(dataset.calib.T_cam0_velo, inv(dataset.oxts[i].T_w_imu)))` and this can be converted into heading and position for `cam0`.

```
import numpy

rotation = [[ 9.96714314e-01, -8.09890350e-02,  1.16333982e-03],
 [ 8.09967396e-02,  9.96661051e-01, -1.03090934e-02],
 [-3.24531964e-04,  1.03694477e-02,  9.99946183e-01]]

origin= [1.71104606e+00,
          5.80000039e-01,
          9.43144935e-01]

from scipy.spatial.transform import Rotation as R

# position is the origin
position = origin
r = R.from_matrix(np.asarray(rotation))

# heading in WCS using scipy
heading = r.as_quat()
print(f"pose:{position}\nheading: {heading}")
```

Position

In the input manifest file, `position` refers to the position of the sensor with respect to a world frame. If you are unable to put the device position in a world coordinate system, you can use LiDAR data with local coordinates. Similarly, for mounted video cameras you can specify the position and

heading in a world coordinate system. For camera, if you do not have position information, please use (0, 0, 0).

The following are the fields in the position object:

1. x (float) – x coordinate of ego vehicle, sensor, or camera position in meters.
2. y (float) – y coordinate of ego vehicle, sensor, or camera position in meters.
3. z (float) – z coordinate of ego vehicle, sensor, or camera position in meters.

The following is an example of a `position` JSON object:

```
{
    "position": {
        "y": -152.77584902657554,
        "x": 311.21505956090624,
        "z": -10.854137529636024
      }
}
```

Heading

In the input manifest file, `heading` is an object that represents the orientation of a device with respect to world frame. Heading values should be in quaternion. A quaternion is a representation of the orientation consistent with geodesic spherical properties. If you are unable to put the sensor heading in world coordinates, please use the identity quaternion `(qx = 0, qy = 0, qz = 0, qw = 1)`. Similarly, for cameras, specify the heading in quaternions. If you are unable to obtain extrinsic camera calibration parameters, please also use the identity quaternion.

Fields in `heading` object are as follows:

1. `qx` (float) - x component of ego vehicle, sensor, or camera orientation.
2. `qy` (float) - y component of ego vehicle, sensor, or camera orientation.
3. `qz` (float) - z component of ego vehicle, sensor, or camera orientation.
4. `qw` (float) - w component of ego vehicle, sensor, or camera orientation.

The following is an example of a `heading` JSON object:

```
{
```

```
    "heading": {
        "qy": -0.7046155108831117,
        "qx": 0.034278837280808494,
        "qz": 0.7070617895701465,
        "qw": -0.04904659893885366
      }
}
```

To learn more, see Compute Orientation Quaternions and Position.

Compute Orientation Quaternions and Position

Ground Truth requires that all orientation, or heading, data be given in quaternions. A quaternions is a representation of the orientation consistent with geodesic spherical properties that can be used to approximate of rotation. Compared to Euler angles they are simpler to compose and avoid the problem of gimbal lock. Compared to rotation matrices they are more compact, more numerically stable, and more efficient.

You can compute quaternions from a rotation matrix or a transformation matrix.

If you have a rotation matrix (made up of the axis rotations) and translation vector (or origin) in world coordinate system instead of a single 4x4 rigid transformation matrix, then you can directly use the rotation matrix and translation vector to compute quaternions. Libraries like scipy and pyqaternion can help. The following code-block shows an example using these libraries to compute quaternion from a rotation matrix.

```
import numpy

rotation = [[ 9.96714314e-01, -8.09890350e-02,  1.16333982e-03],
 [ 8.09967396e-02,  9.96661051e-01, -1.03090934e-02],
 [-3.24531964e-04,  1.03694477e-02,  9.99946183e-01]]

origin = [1.71104606e+00,
          5.80000039e-01,
          9.43144935e-01]

from scipy.spatial.transform import Rotation as R
# position is the origin
position = origin
r = R.from_matrix(np.asarray(rotation))
# heading in WCS using scipy
```

```
heading = r.as_quat()
print(f"position:{position}\nheading: {heading}")
```

A UI tool like 3D Rotation Converter can also be useful.

If you have a 4x4 extrinsic transformation matrix, note that the transformation matrix is in the form `[R T; 0 0 0 1]` where R is the rotation matrix and T is the origin translation vector. That means you can extract rotation matrix and translation vector from the transformation matrix as follows.

```
import numpy as np

transformation
= [[ 9.96714314e-01, -8.09890350e-02,  1.16333982e-03, 1.71104606e+00],
   [ 8.09967396e-02,  9.96661051e-01, -1.03090934e-02, 5.80000039e-01],
   [-3.24531964e-04,  1.03694477e-02,  9.99946183e-01, 9.43144935e-01],
   [              0,               0,               0,              1]]

transformation  = np.array(transformation )
rotation = transformation[0:3,0:3]
translation= transformation[0:3,3]

from scipy.spatial.transform import Rotation as R
# position is the origin translation
position = translation
r = R.from_matrix(np.asarray(rotation))
# heading in WCS using scipy
heading = r.as_quat()
print(f"position:{position}\nheading: {heading}")
```

With your own setup, you can compute an extrinsic transformation matrix using the GPS/IMU position and orientation (latitude, longitude, altitude and roll, pitch, yaw) with respect to the LiDAR sensor on the ego vehicle. For example, you can compute pose from KITTI raw data using `pose = convertOxtsToPose(oxts)` to transform the oxts data into a local euclidean poses, specified by 4x4 rigid transformation matrices. You can then transform this pose transformation matrix to a global reference frame using the reference frames transformation matrix in the world coordinate system.

```
struct Quaternion
{
    double w, x, y, z;
```

```
};

Quaternion ToQuaternion(double yaw, double pitch, double roll) // yaw (Z), pitch (Y),
 roll (X)
{
    // Abbreviations for the various angular functions
    double cy = cos(yaw * 0.5);
    double sy = sin(yaw * 0.5);
    double cp = cos(pitch * 0.5);
    double sp = sin(pitch * 0.5);
    double cr = cos(roll * 0.5);
    double sr = sin(roll * 0.5);

    Quaternion q;
    q.w = cr * cp * cy + sr * sp * sy;
    q.x = sr * cp * cy - cr * sp * sy;
    q.y = cr * sp * cy + sr * cp * sy;
    q.z = cr * cp * sy - sr * sp * cy;

    return q;
}
```

Ground Truth Sensor Fusion Transformations

The following sections go into greater detail about the Ground Truth sensor fusion transformations that are performed using the pose data you provide.

LiDAR Extrinsic

In order to project to and from a 3D LiDAR scene to a 2D camera image, Ground Truth computes the rigid transformation projection metrics using the ego vehicle pose and heading. Ground Truth computes rotation and translation of a world coordinates into the 3D plane by doing a simple sequence of rotations and translation.

Ground Truth computes rotation metrics using the heading quaternions as follows:

$$M = \begin{pmatrix} 1-2y^2-2z^2 & 2xy+2zw & 2xz-2yw \\ 2xy-2zw & 1-2x^2-2z^2 & 2yz+2xw \\ 2xz+2yw & 2yz-2xw & 1-2x^2-2y^2 \end{pmatrix}$$

Here, `[x, y, z, w]` corresponds to parameters in the `heading` JSON object, `[qx, qy, qz, qw]`. Ground Truth computes the translation column vector as `T = [poseX, poseY, poseZ]`. Then the extrinsic metrics is simply as follows:

```
LiDAR_extrinsic = [R T;0 0 0 1]
```

Camera Calibrations: Extrinsic, Intrinsic and Distortion

Geometric camera calibration, also referred to as *camera resectioning*, estimates the parameters of a lens and image sensor of an image or video camera. You can use these parameters to correct for lens distortion, measure the size of an object in world units, or determine the location of the camera in the scene. Camera parameters include intrinsics and distortion coefficients.

Camera Extrinsic

If the camera pose is given, then Ground Truth computes the camera extrinsic based on a rigid transformation from the 3D plane into the camera plane. The calculation is the same as the one used for the LiDAR Extrinsic, except that Ground Truth uses camera pose (`position` and `heading`) and computes the inverse extrinsic.

```
camera_inverse_extrinsic = inv([Rc Tc;0 0 0 1]) #where Rc and Tc are camera pose
components
```

Intrinsic and Distortion

Some cameras, such as pinhole or fisheye cameras, may introduce significant distortion in photos. This distortion can be corrected using distortion coefficients and the camera focal length. To learn more, see Camera calibration With OpenCV in the OpenCV documentation.

There are two types of distortion Ground Truth can correct for: radial distortion and tangential distortion.

Radial distortion occurs when light rays bend more near the edges of a lens than they do at its optical center. The smaller the lens, the greater the distortion. The presence of the radial distortion manifests in form of the *barrel* or *fish-eye* effect and Ground Truth uses Formula 1 to undistort it.

Formula 1:

$$x_{corrected} = x(1 + k_1 r^2 + k_2 r^4 + k_3 r^6)$$
$$y_{corrected} = y(1 + k_1 r^2 + k_2 r^4 + k_3 r^6)$$

Tangential distortion occurs because the lenses used to take the images are not perfectly parallel to the imaging plane. This can be corrected with Formula 2.

Formula 2:

$$x_{corrected} = x + [2p_1xy + p_2(r^2 + 2x^2)]$$
$$y_{corrected} = y + [p_1(r^2 + 2y^2) + 2p_2xy]$$

In the input manifest file, you can provide distortion coefficients and Ground Truth will undistort your images. All distortion coefficients are floats.

- k1, k2, k3, k4 – Radial distortion coefficients. Supported for both fisheye and pinhole camera models.
- p1 ,p2 – Tangential distortion coefficients. Supported for pinhole camera models.

If images are already undistorted, all distortion coefficients should be 0 in your input manifest.

In order to correctly reconstruct the corrected image, Ground Truth does a unit conversion of the images based on focal lengths. If a common focal length is used with a given aspect ratio for both axes, such as 1, in the upper formula we will have a single focal length. The matrix containing these four parameters is referred to as the *in camera intrinsic calibration matrix*.

$$\begin{Bmatrix} x \\ y \\ w \end{Bmatrix} = \begin{Bmatrix} f_x & 0 & c_x \\ 0 & f_y & c_y \\ 0 & 0 & 1 \end{Bmatrix} \begin{Bmatrix} X \\ Y \\ Z \end{Bmatrix}$$

While the distortion coefficients are the same regardless of the camera resolutions used, these should be scaled with the current resolution from the calibrated resolution.

The following are float values.

- fx - focal length in x direction.
- fy - focal length in y direction.
- cx - x coordinate of principal point.
- cy - y coordinate of principal point.

Ground Truth use the camera extrinsic and camera intrinsic to compute view metrics as shown in the following code block to transform labels between the 3D scene and 2D images.

```
def generate_view_matrix(intrinsic_matrix, extrinsic_matrix):
    intrinsic_matrix = np.c_[intrinsic_matrix, np.zeros(3)]
    view_matrix = np.matmul(intrinsic_matrix, extrinsic_matrix)
    view_matrix = np.insert(view_matrix, 2, np.array((0, 0, 0, 1)), 0)
    return view_matrix
```

Video Frame Input Data

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you create a video frame object detection or object tracking labeling job, you can choose video files (MP4 files) or video frames for input data. All worker tasks are created using video frames, so if you choose video files, use the Ground Truth frame extraction tool to extract video frames (images) from your video files.

For both of these options, you can use the **Automated data setup** option in the Ground Truth section of the Amazon SageMaker AI console to set up a connection between Ground Truth and your input data in Amazon S3 so that Ground Truth knows where to look for your input data when creating your labeling tasks. This creates and stores an input manifest file in your Amazon S3 input dataset location. To learn more, see Set up Automated Video Frame Input Data.

Alternatively, you can manually create sequence files for each sequence of video frames that you want labeled and provide the Amazon S3 location of an input manifest file that references each of these sequences files using the `source-ref` key. To learn more, see Create a Video Frame Input Manifest File.

Choose Video Files or Video Frames for Input Data

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you create a video frame object detection or object tracking labeling job, you can provide a sequence of video frames (images) or you can use the Amazon SageMaker AI console to have Ground Truth automatically extract video frames from your video files. Use the following sections to learn more about these options.

Provide Video Frames

Video frames are sequences of images extracted from a video file. You can create a Ground Truth labeling job to have workers label multiple sequences of video frames. Each sequence is made up of images extracted from a single video.

To create a labeling job using video frame sequences, you must store each sequence using a unique key name prefix in Amazon S3. In the Amazon S3 console, key name prefixes are folders. So in the Amazon S3 console, each sequence of video frames must be located in its own folder in Amazon S3.

For example, if you have two sequences of video frames, you might use the key name prefixes `sequence1/` and `sequence2/` to identify your sequences. In this example, your sequences may be located in `s3://amzn-s3-demo-bucket/video-frames/sequence1/` and `s3://amzn-s3-demo-bucket/video-frames/sequence2/`.

If you are using the Ground Truth console to create an input manifest file, all of the sequence key name prefixes should be in the same location in Amazon S3. For example, in the Amazon S3 console, each sequence could be in a folder in `s3://amzn-s3-demo-bucket/video-frames/`. In this example, your first sequence of video frames (images) may be located in `s3://amzn-s3-demo-bucket/video-frames/sequence1/` and your second sequence may be located in `s3://amzn-s3-demo-bucket/video-frames/sequence2/`.

> **Important**
>
> Even if you only have a single sequence of video frames that you want workers to label, that sequence must have a key name prefix in Amazon S3. If you are using the Amazon S3 console, this means that your sequence is located in a folder. It cannot be located in the root of your S3 bucket.

When creating worker tasks using sequences of video frames, Ground Truth uses one sequence per task. In each task, Ground Truth orders your video frames using UTF-8 binary order.

For example, video frames might be in the following order in Amazon S3:

```
[0001.jpg, 0002.jpg, 0003.jpg, ..., 0011.jpg]
```

They are arranged in the same order in the worker's task: `0001.jpg, 0002.jpg, 0003.jpg, ..., 0011.jpg`.

Frames might also be ordered using a naming convention like the following:

```
[frame1.jpg, frame2.jpg, ..., frame11.jpg]
```

In this case, `frame10.jpg` and `frame11.jpg` come before `frame2.jpg` in the worker task. Your worker sees your video frames in the following order: `frame1.jpg, frame10.jpg, frame11.jpg, frame2.jpg, ..., frame9.jpg`.

Provide Video Files

You can use the Ground Truth frame splitting feature when creating a new labeling job in the console to extract video frames from video files (MP4 files). A series of video frames extracted from a single video file is referred to as a *sequence of video frames*.

You can either have Ground Truth automatically extract all frames, up to 2,000, from the video, or you can specify a frequency for frame extraction. For example, you can have Ground Truth extract every 10^{th} frame from your videos.

You can provide up to 50 videos when you use automated data setup to extract frames, however your input manifest file cannot reference more than 10 video frame sequence files when you create a video frame object tracking and video frame object detection labeling job. If you use the automated data setup console tool to extract video frames from more than 10 video files, you will

need to modify the manifest file the tool generates or create a new one to include 10 video frame sequence files or less. To learn more about these quotas, see 3D Point Cloud and Video Frame Labeling Job Quotas.

To use the video frame extraction tool, see Set up Automated Video Frame Input Data.

When all of your video frames have been successfully extracted from your videos, you will see the following in your S3 input dataset location:

- A key name prefix (a folder in the Amazon S3 console) named after each video. Each of these prefixes leads to:
  - A sequence of video frames extracted from the video used to name that prefix.
  - A sequence file used to identify all of the images that make up that sequence.
- An input manifest file with a .manifest extension. This identifies all of the sequence files that will be used to create your labeling job.

All of the frames extracted from a single video file are used for a labeling task. If you extract video frames from multiple video files, multiple tasks are created for your labeling job, one for each sequence of video frames.

Ground Truth stores each sequence of video frames that it extracts in your Amazon S3 location for input datasets using a unique key name prefix. In the Amazon S3 console, key name prefixes are folders.

Input Data Setup

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

When you create a video frame labeling job, you need to let Ground Truth know where to look for your input data. You can do this in one of two ways:

- You can store your input data in Amazon S3 and have Ground Truth automatically detect the input dataset used for your labeling job. See Set up Automated Video Frame Input Data to learn more about this option.

- You can create an input manifest file and sequence files and upload them to Amazon S3. See Set up Video Frame Input Data Manually to learn more about this option.

Topics

- Set up Automated Video Frame Input Data
- Set up Video Frame Input Data Manually

Set up Automated Video Frame Input Data

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use the Ground Truth automated data setup to automatically detect video files in your Amazon S3 bucket and extract video frames from those files. To learn how, see Provide Video Files.

If you already have video frames in Amazon S3, you can use the automated data setup to use these video frames in your labeling job. For this option, all video frames from a single video must be stored using a unique prefix. To learn about the requirements to use this option, see Provide Video Frames.

Select one of the following sections to learn how to set up your automatic input dataset connection with Ground Truth.

Provide Video Files and Extract Frames

Use the following procedure to connect your video files with Ground Truth and automatically extract video frames from those files for video frame object detection and object tracking labeling jobs.

> **Note**
>
> If you use the automated data setup console tool to extract video frames from more than 10 video files, you will need to modify the manifest file the tool generates or create a new one to include 10 video frame sequence files or less. To learn more, see Provide Video Files.

Make sure your video files are stored in an Amazon S3 bucket in the same Amazon Region that you perform the automated data setup in.

Automatically connect your video files in Amazon S3 with Ground Truth and extract video frames:

1. Navigate to the **Create labeling job** page in the Amazon SageMaker AI console: https://console.amazonaws.cn/sagemaker/groundtruth.

   Your input and output S3 buckets must be located in the same Amazon Region that you create your labeling job in. This link puts you in the North Virginia (us-east-1) Amazon Region. If your input data is in an Amazon S3 bucket in another Region, switch to that Region. To change your Amazon Region, on the navigation bar, choose the name of the currently displayed Region.
2. Select **Create labeling job**.
3. Enter a **Job name**.
4. In the section **Input data setup**, select **Automated data setup**.
5. Enter an Amazon S3 URI for **S3 location for input datasets**. An S3 URI looks like the following: `s3://amzn-s3-demo-bucket/path-to-files/`. This URI should point to the Amazon S3 location where your video files are stored.
6. Specify your **S3 location for output datasets**. This is where your output data is stored. You can choose to store your output data in the **Same location as input dataset** or **Specify a new location** and entering the S3 URI of the location that you want to store your output data.
7. Choose **Video Files** for your **Data type** using the dropdown list.
8. Choose **Yes, extract frames for object tracking and detection tasks**.
9. Choose a method of **Frame extraction**.

   - When you choose **Use all frames extracted from the video to create a labeling task**, Ground Truth extracts all frames from each video in your **S3 location for input datasets**, up to 2,000 frames. If a video in your input dataset contains more than 2,000 frames, the first 2,000 are extracted and used for that labeling task.
   - When you choose **Use every *x* frame from a video to create a labeling task**, Ground Truth extracts every x^{th} frame from each video in your **S3 location for input datasets**.

     For example, if your video is 2 seconds long, and has a frame rate of 30 frames per second, there are 60 frames in your video. If you specify 10 here, Ground Truth extracts every 10^{th}

frame from your video. This means the 1st, 10th, 20th, 30th, 40th, 50th, and 60th frames are extracted.

10. Choose or create an IAM execution role. Make sure that this role has permission to access your Amazon S3 locations for input and output data specified in steps 5 and 6.
11. Select **Complete data setup**.

Provide Video Frames

Use the following procedure to connect your sequences of video frames with Ground Truth for video frame object detection and object tracking labeling jobs.

Make sure your video frames are stored in an Amazon S3 bucket in the same Amazon Region that you perform the automated data setup in. Each sequence of video frames should have a unique prefix. For example, if you have two sequences stored in `s3://amzn-s3-demo-bucket/video-frames/sequences/`, each should have a unique prefix like `sequence1` and `sequence2` and should both be located directly under the `/sequences/` prefix. In the example above, the locations of these two sequences is: `s3://amzn-s3-demo-bucket/video-frames/sequences/sequence1/` and `s3://amzn-s3-demo-bucket/video-frames/sequences/sequence2/`.

Automatically connect your video frame in Amazon S3 with Ground Truth:

1. Navigate to the **Create labeling job** page in the Amazon SageMaker AI console: https://console.amazonaws.cn/sagemaker/groundtruth.

   Your input and output S3 buckets must be located in the same Amazon Region that you create your labeling job in. This link puts you in the North Virginia (us-east-1) Amazon Region. If your input data is in an Amazon S3 bucket in another Region, switch to that Region. To change your Amazon Region, on the navigation bar, choose the name of the currently displayed Region.
2. Select **Create labeling job**.
3. Enter a **Job name**.
4. In the section **Input data setup**, select **Automated data setup**.
5. Enter an Amazon S3 URI for **S3 location for input datasets**.

   This should be the Amazon S3 location where your sequences are stored. For example, if you have two sequences stored in `s3://amzn-s3-demo-bucket/video-frames/sequences/`

`sequence1/`, `s3://amzn-s3-demo-bucket/video-frames/sequences/sequence2/`, enter `s3://amzn-s3-demo-bucket/video-frames/sequences/` here.

6. Specify your **S3 location for output datasets**. This is where your output data is stored. You can choose to store your output data in the **Same location as input dataset** or **Specify a new location** and entering the S3 URI of the location that you want to store your output data.
7. Choose **Video frames** for your **Data type** using the dropdown list.
8. Choose or create an IAM execution role. Make sure that this role has permission to access your Amazon S3 locations for input and output data specified in steps 5 and 6.
9. Select **Complete data setup**.

These procedures will create an input manifest in the Amazon S3 location for input datasets that you specified in step 5. If you are creating a labeling job using the SageMaker API or, Amazon CLI, or an Amazon SDK, use the Amazon S3 URI for this input manifest file as input to the parameter `ManifestS3Uri`.

Set up Video Frame Input Data Manually

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Choose the manual data setup option if you have created sequence files for each of your video frame sequences, and a manifest file listing references to those sequences files.

Create a Video Frame Input Manifest File

Ground Truth uses the input manifest file to identify the location of your input dataset when creating labeling tasks. For video frame object detection and object tracking labeling jobs, each line in the input manifest file identifies the location of a video frame sequence file. Each sequence file identifies the images included in a single sequence of video frames.

Use this page to learn how to create a video frame sequence file and an input manifest file for video frame object tracking and object detection labeling jobs.

If you want Ground Truth to automatically generate your sequence files and input manifest file, see Set up Automated Video Frame Input Data.

Create a Video Frame Sequence Input Manifest

In the video frame sequence input manifest file, each line in the manifest is a JSON object, with a `"source-ref"` key that references a sequence file. Each sequence file identifies the location of a sequence of video frames. This is the manifest file formatting required for all video frame labeling jobs.

The following example demonstrates the syntax used for an input manifest file:

```
{"source-ref": "s3://amzn-s3-demo-bucket/example-folder/seq1.json"}
{"source-ref": "s3://amzn-s3-demo-bucket/example-folder/seq2.json"}
```

Create a Video Frame Sequence File

The data for each sequence of video frames needs to be stored in a JSON data object. The following is an example of the format you use for a sequence file. Information about each frame is included as a JSON object and is listed in the `frames` list. The following JSON has been expanded for readability.

```
{
 "seq-no": 1,
 "prefix": "s3://amzn-s3-demo-bucket/prefix/video1/",
 "number-of-frames": 3,
 "frames":[
   {"frame-no": 1, "unix-timestamp": 1566861644, "frame": "frame0001.jpg" },
   {"frame-no": 2, "unix-timestamp": 1566861644, "frame": "frame0002.jpg" },
   {"frame-no": 3, "unix-timestamp": 1566861644, "frame": "frame0003.jpg" }
 ]
}
```

The following table provides details about the parameters shown in the this code example.

Parameter	Required	Accepted Values	Description
`seq-no`	Yes	Integer	The ordered number of the sequence.

Parameter	Required	Accepted Values	Description
`prefix`	Yes	String **Accepted Values**: `s3://<bucket-name> /<prefix>/`	The Amazon S3 location where the sequence files are located. The prefix must end with a forward slash: `/`.
`number-of-frames`	Yes	Integer	The total number of frames included in the sequence file. This number must match the total number of frames listed in the `frames` parameter in the next row.

`frames`	Yes	List of JSON objects
		
		Required:
		
		`frame-no`, `frame`
		
		Optional:
		
		`unix-timestamp`
			A list of frame data. The length of the list must equal `number-of-frames` . In the worker UI, frames in a sequence are ordered in UTF-8 binary order. To learn more about this ordering, see Provide Video Frames.

Parameter	Required	Accepted Values	Description
`frame-no`	Yes	Integer	The frame order number. This will determine the order of a frame in the sequence.
`unix-timestamp`	No	Integer	The unix timestamp of a frame. The number of seconds since January 1st, 1970 until the UTC time when the frame was captured.
`frame`	Yes	String	The name of a video frame image file.

Labeling job output data

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

The output from a labeling job is placed in the Amazon S3 location that you specified in the console or in the call to the CreateLabelingJob operation. Output data appears in this location when the workers have submitted one or more tasks, or when tasks expire. Note that it may take a few minutes for output data to appear in Amazon S3 after the worker submits the task or the task expires.

Each line in the output data file is identical to the manifest file with the addition of an attribute and value for the label assigned to the input object. The attribute name for the value is defined in the console or in the call to the `CreateLabelingJob` operation. You can't use `-metadata` in the

label attribute name. If you are running an image semantic segmentation, 3D point cloud semantic segmentation, or 3D point cloud object tracking job, the label attribute must end with `-ref`. For any other type of job, the attribute name can't end with `-ref`.

The output of the labeling job is the value of the key-value pair with the label. The label and the value overwrites any existing JSON data in the input file with the new value.

For example, the following is the output from an image classification labeling job where the input data files were stored in an Amazon S3 *amzn-s3-demo-bucket* and the label attribute name was defined as *sport*. In this example the JSON object is formatted for readability, in the actual output file the JSON object is on a single line. For more information about the data format, see JSON Lines.

```
{
    "source-ref": "s3://amzn-s3-demo-bucket/image_example.png",
    "sport":0,
    "sport-metadata":
    {
        "class-name": "football",
        "confidence": 0.00,
        "type":"groundtruth/image-classification",
        "job-name": "identify-sport",
        "human-annotated": "yes",
        "creation-date": "2018-10-18T22:18:13.527256"
    }
}
```

The value of the label can be any valid JSON. In this case the label's value is the index of the class in the classification list. Other job types, such as bounding box, have more complex values.

Any key-value pair in the input manifest file other than the label attribute is unchanged in the output file. You can use this to pass data to your application.

The output from a labeling job can be used as the input to another labeling job. You can use this when you are chaining together labeling jobs. For example, you can send one labeling job to determine the sport that is being played. Then you send another using the same data to determine if the sport is being played indoors or outdoors. By using the output data from the first job as the manifest for the second job, you can consolidate the results of the two jobs into one output file for easier processing by your applications.

The output data file is written to the output location periodically while the job is in progress. These intermediate files contain one line for each line in the manifest file. If an object is labeled, the label is included. If the object hasn't been labeled, it is written to the intermediate output file identically to the manifest file.

Output directories

Ground Truth creates several directories in your Amazon S3 output path. These directories contain the results of your labeling job and other artifacts of the job. The top-level directory for a labeling job is given the same name as your labeling job; the output directories are placed beneath it. For example, if you named your labeling job **`find-people`**, your output would be in the following directories:

```
s3://amzn-s3-demo-bucket/find-people/activelearning
s3://amzn-s3-demo-bucket/find-people/annotations
s3://amzn-s3-demo-bucket/find-people/inference
s3://amzn-s3-demo-bucket/find-people/manifests
s3://amzn-s3-demo-bucket/find-people/training
```

Each directory contains the following output:

Active learning directory

The `activelearning` directory is only present when you are using automated data labeling. It contains the input and output validation set for automated data labeling, and the input and output folder for automatically labeled data.

Annotations directory

The `annotations` directory contains all of the annotations made by the workforce. These are the responses from individual workers that have not been consolidated into a single label for the data object.

There are three subdirectories in the `annotations` directory.

- The first, `worker-response`, contains the responses from individual workers. This contains a subdirectory for each iteration, which in turn contains a subdirectory for each data object in that iteration. The worker response data for each data object is stored in a timestamped JSON file that contains the answers submitted by each worker for that data object, and if you use

a private workforce, metadata about those workers. To learn more about this metadata, see Worker metadata.

- The second, `consolidated-annotation`, contains information required to consolidate the annotations in the current batch into labels for your data objects.
- The third, `intermediate`, contains the output manifest for the current batch with any completed labels. This file is updated as the label for each data object is completed.

> **Note**
>
> We recommend that you do not use files that are not mentioned in the documentation.

Inference directory

The `inference` directory is only present when you are using automated data labeling. This directory contains the input and output files for the SageMaker AI batch transform used while labeling data objects.

Manifest directory

The `manifest` directory contains the output manifest from your labeling job. There is one subdirectory in the manifest directory, `output`. The `output` directory contains the output manifest file for your labeling job. The file is named `output.manifest`.

Training directory

The `training` directory is only present when you are using automated data labeling. This directory contains the input and output files used to train the automated data labeling model.

Confidence score

When you have more than one worker annotate a single task, your label results from annotation consolidation. Ground Truth calculates a confidence score for each label. A *confidence score* is a number between 0 and 1 that indicates how confident Ground Truth is in the label. You can use the confidence score to compare labeled data objects to each other, and to identify the least or most confident labels.

You should not interpret the value of a confidence score as an absolute value, or compare confidence scores across labeling jobs. For example, if all of the confidence scores are between

0.98 and 0.998, you should only compare the data objects with each other and not rely on the high confidence scores.

You should not compare the confidence scores of human-labeled data objects and auto-labeled data objects. The confidence scores for humans are calculated using the annotation consolidation function for the task, while the confidence scores for automated labeling are calculated using a model that incorporates object features. The two models generally have different scales and average confidence.

For a bounding box labeling job, Ground Truth calculates a confidence score per box. You can compare confidence scores within one image or across images for the same labeling type (human or auto). You can't compare confidence scores across labeling jobs.

If a single worker annotates a task (`NumberOfHumanWorkersPerDataObject` is set to 1 or in the console, you enter 1 for **Number of workers per dataset object**), the confidence score is set to `0.00`.

Worker metadata

Ground Truth provides information that you can use to track individual workers in task output data. The following data is located in the directories under the `worker-response` located in the Annotations directory:

- The `acceptanceTime` is the time that the worker accepted the task. The format of this date and time stamp is `YYYY-MM-DDTHH:MM:SS.mmmZ` for the year (`YYYY`), month (`MM`), day (`DD`), hour (`HH`), minute (`MM`), second (`SS`) and millisecond (`mmm`). The date and time are separated by a **T**.
- The `submissionTime` is the time that the worker submitted their annotations using the **Submit** button. The format of this date and time stamp is `YYYY-MM-DDTHH:MM:SS.mmmZ` for the year (`YYYY`), month (`MM`), day (`DD`), hour (`HH`), minute (`MM`), second (`SS`) and millisecond (`mmm`). The date and time are separated by a **T**.
- `timeSpentInSeconds` reports the total time, in seconds, that a worker actively worked on that task. This metric does not include time when a worker paused or took a break.
- The `workerId` is unique to each worker.
- If you use a private workforce, in `workerMetadata`, you see the following.
  - The `identityProviderType` is the service used to manage the private workforce.
  - The `issuer` is the Cognito user pool or OIDC Identity Provider (IdP) issuer associated with the work team assigned to this human review task.

- A unique `sub` identifier refers to the worker. If you create a workforce using Amazon Cognito, you can retrieve details about this worker (such as the name or user name) using this ID using Amazon Cognito. To learn how, see Managing and Searching for User Accounts in Amazon Cognito Developer Guide.

The following is an example of the output you may see if you use Amazon Cognito to create a private workforce. This is identified in the `identityProviderType`.

```
"submissionTime": "2020-12-28T18:59:58.321Z",
"acceptanceTime": "2020-12-28T18:59:15.191Z",
"timeSpentInSeconds": 40.543,
"workerId": "a12b3cdefg4h5i67",
"workerMetadata": {
    "identityData": {
        "identityProviderType": "Cognito",
        "issuer": "https://cognito-idp.aws-region.amazonaws.com/aws-region_123456789",
        "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
    }
}
```

The following is an example of the `workerMetadata` you may see if you use your own OIDC IdP to create a private workforce:

```
"workerMetadata": {
        "identityData": {
            "identityProviderType": "Oidc",
            "issuer": "https://example-oidc-ipd.com/adfs",
            "sub": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
        }
}
```

To learn more about using private workforces, see Private workforce.

Output metadata

The output from each job contains metadata about the label assigned to data objects. These elements are the same for all jobs with minor variations. The following example shows the metadata elements:

```
    "confidence": 0.00,
```

```
    "type": "groundtruth/image-classification",
    "job-name": "identify-animal-species",
    "human-annotated": "yes",
    "creation-date": "2020-10-18T22:18:13.527256"
```

The elements have the following meaning:

- `confidence` – The confidence that Ground Truth has that the label is correct. For more information, see Confidence score.
- `type` – The type of classification job. For job types, see Built-in Task Types.
- `job-name` – The name assigned to the job when it was created.
- `human-annotated` – Whether the data object was labeled by a human or by automated data labeling. For more information, see Automate data labeling.
- `creation-date` – The date and time that the label was created.

Classification job output

The following are sample outputs (output manifest files) from an image classification job and a text classification job. They include the label that Ground Truth assigned to the data object, the value for the label, and metadata that describes the label.

In addition to the standard metadata elements, the metadata for a classification job includes the text value of the label's class. For more information, see Image Classification - MXNet.

The red, italicized text in the examples below depends on labeling job specifications and output data.

```
{
    "source-ref":"s3://amzn-s3-demo-bucket/example_image.jpg",
    "species":"0",
    "species-metadata":
    {
        "class-name": "dog",
        "confidence": 0.00,
        "type": "groundtruth/image-classification",
        "job-name": "identify-animal-species",
        "human-annotated": "yes",
        "creation-date": "2018-10-18T22:18:13.527256"
    }
```

```
}
```

```
{
    "source":"The food was delicious",
    "mood":"1",
    "mood-metadata":
    {
        "class-name": "positive",
        "confidence": 0.8,
        "type": "groundtruth/text-classification",
        "job-name": "label-sentiment",
        "human-annotated": "yes",
        "creation-date": "2020-10-18T22:18:13.527256"
    }
}
```

Multi-label classification job output

The following are example output manifest files from a multi-label image classification job and a multi-label text classification job. They include the labels that Ground Truth assigned to the data object (for example, the image or piece of text) and metadata that describes the labels the worker saw when completing the labeling task.

The label attribute name parameter (for example, `image-label-attribute-name`) contains an array of all of the labels selected by at least one of the workers who completed this task. This array contains integer keys (for example, `[1,0,8]`) that correspond to the labels found in `class-map`. In the multi-label image classification example, `bicycle`, `person`, and `clothing` were selected by at least one of the workers who completed the labeling task for the image, `exampleimage.jpg`.

The `confidence-map` shows the confidence score that Ground Truth assigned to each label selected by a worker. To learn more about Ground Truth confidence scores, see Confidence score.

The red, italicized text in the examples below depends on labeling job specifications and output data.

The following is an example of a multi-label image classification output manifest file.

```
{
    "source-ref": "s3://amzn-s3-demo-bucket/example_image.jpg",
```

```
    "image-label-attribute-name":[1,0,8],
    "image-label-attribute-name-metadata":
       {
        "job-name":"labeling-job/image-label-attribute-name",
        "class-map":
            {
                "1":"bicycle","0":"person","8":"clothing"
            },
        "human-annotated":"yes",
        "creation-date":"2020-02-27T21:36:25.000201",
        "confidence-map":
            {
                "1":0.95,"0":0.77,"8":0.2
            },
        "type":"groundtruth/image-classification-multilabel"
        }
}
```

The following is an example of a multi-label text classification output manifest file. In this example, `approving`, `sad` and `critical` were selected by at least one of the workers who completed the labeling task for the object `exampletext.txt` found in *amzn-s3-demo-bucket*.

```
{
    "source-ref": "s3://amzn-s3-demo-bucket/exampletext.txt",
    "text-label-attribute-name":[1,0,4],
    "text-label-attribute-name-metadata":
       {
        "job-name":"labeling-job/text-label-attribute-name",
        "class-map":
            {
                "1":"approving","0":"sad","4":"critical"
            },
        "human-annotated":"yes",
        "creation-date":"2020-02-20T21:36:25.000201",
        "confidence-map":
            {
                "1":0.95,"0":0.77,"4":0.2
            },
        "type":"groundtruth/text-classification-multilabel"
        }
}
```

Bounding box job output

The following is sample output (output manifest file) from a bounding box job. For this task, three bounding boxes are returned. The label value contains information about the size of the image, and the location of the bounding boxes.

The `class_id` element is the index of the box's class in the list of available classes for the task. The `class-map` metadata element contains the text of the class.

The metadata has a separate confidence score for each bounding box. The metadata also includes the `class-map` element that maps the `class_id` to the text value of the class. For more information, see Object Detection - MXNet.

The red, italicized text in the examples below depends on labeling job specifications and output data.

```
{
    "source-ref": "s3://amzn-s3-demo-bucket/example_image.png",
    "bounding-box-attribute-name":
    {
        "image_size": [{ "width": 500, "height": 400, "depth":3}],
        "annotations":
        [
            {"class_id": 0, "left": 111, "top": 134,
                    "width": 61, "height": 128},
            {"class_id": 5, "left": 161, "top": 250,
                     "width": 30, "height": 30},
            {"class_id": 5, "left": 20, "top": 20,
                     "width": 30, "height": 30}
        ]
    },
    "bounding-box-attribute-name-metadata":
    {
        "objects":
        [
            {"confidence": 0.8},
            {"confidence": 0.9},
            {"confidence": 0.9}
        ],
        "class-map":
        {
            "0": "dog",
            "5": "bone"
```

```
        },
        "type": "groundtruth/object-detection",
        "human-annotated": "yes",
        "creation-date": "2018-10-18T22:18:13.527256",
        "job-name": "identify-dogs-and-toys"
    }
 }
```

The output of a bounding box adjustment job looks like the following JSON. Note that the original JSON is kept intact and two new jobs are listed, each with “adjust-” prepended to the original attribute’s name.

```
{
    "source-ref": "S3 bucket location",
    "bounding-box-attribute-name":
    {
        "image_size": [{ "width": 500, "height": 400, "depth":3}],
        "annotations":
        [
            {"class_id": 0, "left": 111, "top": 134,

        [
            {"class_id": 0, "left": 110, "top": 135,
                    "width": 61, "height": 128},
            {"class_id": 5, "left": 161, "top": 250,
                     "width": 30, "height": 30},
            {"class_id": 5, "left": 10, "top": 10,
                     "width": 30, "height": 30}
        ]
    },
    "adjusted-bounding-box-metadata":
    {
        "objects":
        [
            {"confidence": 0.8},
            {"confidence": 0.9},
            {"confidence": 0.9}
        ],
        "class-map":
        {
            "0": "dog",
            "5": "bone"
        },
        "type": "groundtruth/object-detection",
        "human-annotated": "yes",
        "creation-date": "2018-11-20T22:18:13.527256",
        "job-name": "adjust-bounding-boxes-on-dogs-and-toys",
        "adjustment-status": "adjusted"
    }
}
```

In this output, the job's `type` doesn't change, but an `adjustment-status` field is added. This field has the value of `adjusted` or `unadjusted`. If multiple workers have reviewed the object and at least one adjusted the label, the status is `adjusted`.

Named entity recognition

The following is an example output manifest file from a named entity recognition (NER) labeling task. For this task, seven `entities` are returned.

In the output manifest, the JSON object, `annotations`, includes a list of the `labels` (label categories) that you provided.

Worker responses are in a list named `entities`. Each entity in this list is a JSON object that contains a `label` value that matches one in the `labels` list, an integer `startOffset` value for labeled span's starting Unicode offset, and an integer `endOffset` value for the ending Unicode offset.

The metadata has a separate confidence score for each entity. If a single worker labeled each data object, the confidence value for each entity will be zero.

The red, italicized text in the examples below depends on labeling job inputs and worker responses.

```

                "confidence": 0
            },
            {
                "confidence": 0
            },
            {
                "confidence": 0
            },
            {
                "confidence": 0
            },
            {
                "confidence": 0
            },
            {
                "confidence": 0
            }
        ]
    }
}
```

Label verification job output

The output (output manifest file) of a bounding box verification job looks different than the output of a bounding box annotation job. That's because the workers have a different type of task. They're not labeling objects, but evaluating the accuracy of prior labeling, making a judgment, and then providing that judgment and perhaps some comments.

If human workers are verifying or adjusting prior bounding box labels, the output of a verification job would look like the following JSON. The red, italicized text in the examples below depends on labeling job specifications and output data.

```
{
    "source-ref":"s3://amzn-s3-demo-bucket/image_example.png",
    "bounding-box-attribute-name":
    {
        "image_size": [{ "width": 500, "height": 400, "depth":3}],
        "annotations":
```

```
        [
            {"class_id": 0, "left": 111, "top": 134,
                    "width": 61, "height": 128},
            {"class_id": 5, "left": 161, "top": 250,
                     "width": 30, "height": 30},
            {"class_id": 5, "left": 20, "top": 20,
                     "width": 30, "height": 30}
        ]
    },
    "bounding-box-attribute-name-metadata":
    {
        "objects":
        [
            {"confidence": 0.8},
            {"confidence": 0.9},
            {"confidence": 0.9}
        ],
        "class-map":
        {
            "0": "dog",
            "5": "bone"
        },
        "type": "groundtruth/object-detection",
        "human-annotated": "yes",
        "creation-date": "2018-10-18T22:18:13.527256",
        "job-name": "identify-dogs-and-toys"
    },
    "verify-bounding-box-attribute-name":"1",
    "verify-bounding-box-attribute-name-metadata":
    {
        "class-name": "bad",
        "confidence": 0.93,
        "type": "groundtruth/label-verification",
        "job-name": "verify-bounding-boxes",
        "human-annotated": "yes",
        "creation-date": "2018-11-20T22:18:13.527256",
        "worker-feedback": [
            {"comment": "The bounding box on the bird is too wide on the right side."},
            {"comment": "The bird on the upper right is not labeled."}
        ]
    }
}
```

Although the `type` on the original bounding box output was `groundtruth/object-detection`, the new `type` is `groundtruth/label-verification`. Also note that the `worker-feedback` array provides worker comments. If the worker doesn't provide comments, the empty fields are excluded during consolidation.

Semantic Segmentation Job Output

The following is the output manifest file from a semantic segmentation labeling job. The value of the label for this job is a reference to a PNG file in an Amazon S3 bucket.

In addition to the standard elements, the metadata for the label includes a color map that defines which color is used to label the image, the class name associated with the color, and the confidence score for each color. For more information, see Semantic Segmentation Algorithm.

The red, italicized text in the examples below depends on labeling job specifications and output data.

```
{
    "source-ref": "s3://amzn-s3-demo-bucket/example_city_image.png",
    "city-streets-ref": "S3 bucket location",
    "city-streets-ref-metadata": {
      "internal-color-map": {
        "0": {
           "class-name": "BACKGROUND",
           "confidence": 0.9,
           "hex-color": "#ffffff"
        },
        "1": {
           "class-name": "buildings",
           "confidence": 0.9,
           "hex-color": "#2acf59"
        },
        "2":  {
           "class-name": "road",
           "confidence": 0.9,
           "hex-color": "#f28333"
       }
     },
     "type": "groundtruth/semantic-segmentation",
     "human-annotated": "yes",
     "creation-date": "2018-10-18T22:18:13.527256",
     "job-name": "label-city-streets",
     },
```

```
    "verify-city-streets-ref":"1",
    "verify-city-streets-ref-metadata":
    {
       "class-name": "bad",
       "confidence": 0.93,
       "type": "groundtruth/label-verification",
       "job-name": "verify-city-streets",
       "human-annotated": "yes",
       "creation-date": "2018-11-20T22:18:13.527256",
       "worker-feedback": [
           {"comment": "The mask on the leftmost building is assigned the wrong side
 of the road."},
           {"comment": "The curb of the road is not labeled but the instructions say
 otherwise."}
       ]
    }
}
```

Confidence is scored on a per-image basis. Confidence scores are the same across all classes within an image.

The output of a semantic segmentation adjustment job looks similar to the following JSON.

```
{
    "source-ref": "s3://amzn-s3-demo-bucket/example_city_image.png",
    "city-streets-ref": "S3 bucket location",
    "city-streets-ref-metadata": {
      "internal-color-map": {
        "0": {
           "class-name": "BACKGROUND",
           "confidence": 0.9,
           "hex-color": "#ffffff"
        },
        "1": {
           "class-name": "buildings",
           "confidence": 0.9,
           "hex-color": "#2acf59"
        },
        "2":  {
           "class-name": "road",
           "confidence": 0.9,
           "hex-color": "#f28333"
       }
```

```
    },
    "type": "groundtruth/semantic-segmentation",
    "human-annotated": "yes",
    "creation-date": "2018-10-18T22:18:13.527256",
    "job-name": "label-city-streets",
    },
    "adjusted-city-streets-ref": "s3://amzn-s3-demo-bucket/example_city_image.png",
    "adjusted-city-streets-ref-metadata": {
     "internal-color-map": {
       "0": {
          "class-name": "BACKGROUND",
          "confidence": 0.9,
          "hex-color": "#ffffff"
       },
       "1": {
          "class-name": "buildings",
          "confidence": 0.9,
          "hex-color": "#2acf59"
       },
       "2":  {
          "class-name": "road",
          "confidence": 0.9,
          "hex-color": "#f28333"
      }
    },
    "type": "groundtruth/semantic-segmentation",
    "human-annotated": "yes",
    "creation-date": "2018-11-20T22:18:13.527256",
    "job-name": "adjust-label-city-streets",
    }
}
```

Video frame object detection output

The following is the output manifest file from a video frame object detection labeling job. The *red, italicized text* in the examples below depends on labeling job specifications and output data.

In addition to the standard elements, the metadata includes a class map that lists each class that has at least one label in the sequence. The metadata also includes `job-name` which is the name you assigned to the labeling job. For adjustment tasks, If one or more bounding boxes were modified, there is an `adjustment-status` parameter in the metadata for audit workflows that is set to `adjusted`.

```
{
    "source-ref": "s3://amzn-s3-demo-bucket/example-path/input-manifest.json",
    "CarObjectDetection-ref": "s3://amzn-s3-demo-bucket/output/labeling-job-name/
annotations/consolidated-annotation/output/0/SeqLabel.json",
    "CarObjectDetection-ref-metadata": {
        "class-map": {
            "0": "car",
            "1": "bus"
        },
        "job-name": "labeling-job/labeling-job-name",
        "human-annotated": "yes",
        "creation-date": "2021-09-29T05:50:35.566000",
        "type": "groundtruth/video-object-detection"
        }
}
```

Ground Truth creates one output sequence file for each sequence of video frames that was labeled. Each output sequence file contains the following:

- All annotations for all frames in a sequence in the `detection-annotations` list of JSON objects.
- For each frame that was annotated by a worker, the frame file name (`frame`), number (`frame-no`), a list of JSON objects containing annotations (`annotations`), and if applicable, `frame-attributes`. The name of this list is defined by the task type you use: `polylines`, `polygons`, `keypoints`, and for bounding boxes, `annotations`.

  Each JSON object contains information about a single annotation and associated label. The following table outlines the parameters you'll see for each video frame task type.

Task Type	Parameters
Bounding Box	Box dimensions: `height` and `width` Box top, left corner pixel location: `top` and `left`
Keypoint	Keypoint vertices: `{ "x": int, "y": int }`

Task Type	Parameters
Polygon	A list of polygon vertices: `vertices` Polygon vertices: `{ "x": int, "y": int }` A polygon is a closed shape and so the first point will also represent the last point.
Polyline	A list of polyline vertices: `vertices` Polyline vertices: `{ "x": int, "y": int }`

In addition to task type specific values, you will see the following in each JSON object:

- Values of any `label-category-attributes` that were specified for that label.
- The `class-id` of the box. Use the `class-map` in the output manifest file to see which label category this ID maps to.

The following is an example of a `SeqLabel.json` file from a bounding box video frame object detection labeling job. This file will be located under `s3://`*`amzn-s3-demo-bucket`*`/`*`output-prefix`*`/annotations/consolidated-annotation/output/`*`annotation-number`*`/`

```

Video frame object tracking output

The following is the output manifest file from a video frame object tracking labeling job. The *red, italicized text* in the examples below depends on labeling job specifications and output data.

In addition to the standard elements, the metadata includes a class map that lists each class that has at least one label in the sequence of frames. The metadata also includes `job-name` which is the name you assigned to the labeling job. For adjustment tasks, If one or more bounding boxes were modified, there is an `adjustment-status` parameter in the metadata for audit workflows that is set to `adjusted`.

```
{
    "source-ref": "s3://amzn-s3-demo-bucket/example-path/input-manifest.json",
    "CarObjectTracking-ref": "s3://amzn-s3-demo-bucket/output/labeling-job-name/
annotations/consolidated-annotation/output/0/SeqLabel.json",
    "CarObjectTracking-ref-metadata": {
        "class-map": {
            "0": "car",
            "1": "bus"
        },
        "job-name": "labeling-job/labeling-job-name",
        "human-annotated": "yes",
        "creation-date": "2021-09-29T05:50:35.566000",
        "type": "groundtruth/video-object-tracking"
        }
 }
```

Ground Truth creates one output sequence file for each sequence of video frames that was labeled. Each output sequence file contains the following:

- All annotations for all frames in a sequence in the `tracking-annotations` list of JSON objects.
- For each frame that was annotated by a worker, the frame (`frame`), number (`frame-no`), a list of JSON objects containing annotations (`annotations`), and if applicable, frame attributes (`frame-attributes`). The name of this list is defined by the task type you use: `polylines`, `polygons`, `keypoints`, and for bounding boxes, `annotations`.

  Each JSON object contains information about a single annotation and associated label. The following table outlines the parameters you'll see for each video frame task type.

Task Type	Parameters
Bounding Box	Box dimensions: `height` and `width` Box top, left corner pixel location: `top` and `left`
Keypoint	Keypoint vertices: `{ "x": int, "y": int }`
Polygon	A list of polygon vertices: `vertices` Polygon vertices: `{ "x": int, "y": int }` A polygon is a closed shape and so the first point will also represent the last point.
Polyline	A list of polyline vertices: `vertices` Polyline vertices: `{ "x": int, "y": int }`

In addition to task type specific values, you will see the following in each JSON object:

- Values of any `label-category-attributes` that were specified for that label.
- The `class-id` of the box. Use the `class-map` in the output manifest file to see which label category this ID maps to.
- An `object-id` which identifies an instance of a label. This ID will be the same across frames if a worker identified the same instance of an object in multiple frames. For example, if a car appeared in multiple frames, all bounding boxes uses to identify that car would have the same `object-id`.
- The `object-name` which is the instance ID of that annotation.

The following is an example of a `SeqLabel.json` file from a bounding box video frame object tracking labeling job. This file will be located under `s3://`*`amzn-s3-demo-bucket`*`/`*`output-prefix`*`/annotations/consolidated-annotation/output/`*`annotation-number`*`/`

3D point cloud semantic segmentation output

The following is the output manifest file from a 3D point cloud semantic segmentation labeling job.

In addition to the standard elements, the metadata for the label includes a color map that defines which color is used to label the image, the class name associated with the color, and the confidence score for each color. Additionally, there is an `adjustment-status` parameter in the metadata for audit workflows that is set to `adjusted` if the color mask is modified. If you added one or more `frameAttributes` to your label category configuration file, worker responses for frame attributes are in the JSON object, `dataset-object-attributes`.

The *`your-label-attribute`*`-ref` parameter contains the location of a compressed file with a .zlib extension. When you uncompress this file, it contains an array. Each index in the array corresponds to the index of an annotated point in the input point cloud. The value of the array at a given index gives the class of the point at the same index in the point cloud, based on the semantic color map found in the `color-map` parameter of the `metadata`.

You can use Python code similar to the following to decompress a .zlib file:

```
import zlib
from array import array

# read the label file
compressed_binary_file = open(zlib_file_path/file.zlib, 'rb').read()

# uncompress the label file
binary_content = zlib.decompress(compressed_binary_file)
```

```
# load labels to an array
my_int_array_data = array('B', binary_content);

print(my_int_array_data)
```

The code block above will produce an output similar to the following. Each element of the printed array contains the class of a point at the that index in the point cloud. For example, `my_int_array_data[0] = 1` means `point[0]` in the input point cloud has a class 1. In the following output manifest file example, class `0` corresponds with `"Background"`, 1 with `Car`, and 2 with `Pedestrian`.

```
>> array('B', [1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1,
 1, 1, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2, 2])
```

The following is an example of a semantic segmentation 3D point cloud labeling job output manifest file. The red, italicized text in the examples below depends on labeling job specifications and output data.

3D point cloud object detection output

The following is sample output from a 3D point cloud objected detection job. For this task type, the data about 3D cuboids is returned in the `3d-bounding-box` parameter, in a list named `annotations`. In this list, each 3D cuboid is described using the following information.

- Each class, or label category, that you specify in your input manifest is associated with a `class-id`. Use the `class-map` to identify the class associated with each class ID.
- These classes are used to give each 3D cuboid an `object-name` in the format `<class>:<integer>` where `integer` is a unique number to identify that cuboid in the frame.
- `center-x`, `center-y`, and `center-z` are the coordinates of the center of the cuboid, in the same coordinate system as the 3D point cloud input data used in your labeling job.
- `length`, `width`, and `height` describe the dimensions of the cuboid.
- `yaw` is used to describe the orientation (heading) of the cuboid in radians.

> **Note**
>
> `yaw` is now in the right-handed Cartesian system. Since this feature was added on September 02, 2022 19:02:17 UTC, you can convert the `yaw` measurement in the output data prior to that using the following (all units are in radians):

```
old_yaw_in_output = pi - yaw
```

- In our definition, +x is to the right, +y is to the forward, and +z is up from the ground plane. The rotation order is x - y - z. The `roll`, `pitch` and `yaw` are represented in the right-handed Cartesian system. In 3D space, `roll` is along the x-axis, `pitch` is along the y-axis and `yaw` is along the z-axis. All three are counterclockwise.
- If you included label attributes in your input manifest file for a given class, a `label-category-attributes` parameter is included for all cuboids for which workers selected label attributes.

If one or more cuboids were modified, there is an `adjustment-status` parameter in the metadata for audit workflows that is set to `adjusted`. If you added one or more `frameAttributes` to your label category configuration file, worker responses for frame attributes are in the JSON object, `dataset-object-attributes`.

The *`red, italicized text`* in the examples below depends on labeling job specifications and output data. The ellipses (*`...`*) denote a continuation of that list, where additional objects with the same format as the proceeding object can appear.

```

In the above example, the cuboid data for each frame in `seq1.json` is in `SeqLabel.json` in the Amazon S3 location, `s3://amzn-s3-demo-bucket/<labelingJobName>/annotations/consolidated-annotation/output/<datasetObjectId>/SeqLabel.json`. The following is an example of this label sequence file.

For each frame in the sequence, you see the `frame-number`, `frame-name`, if applicable, `frame-attributes`, and a list of `annotations`. This list contains 3D cubiods that were drawn for that frame. Each annotation includes the following information:

- An `object-name` in the format `<class>:<integer>` where `class` identifies the label category and `integer` is a unique ID across the dataset.
- When workers draw a cuboid, it is associated with a unique `object-id` which is associated with all cuboids that identify the same object across multiple frames.
- Each class, or label category, that you specified in your input manifest is associated with a `class-id`. Use the `class-map` to identify the class associated with each class ID.
- `center-x`, `center-y`, and `center-z` are the coordinates of the center of the cuboid, in the same coordinate system as the 3D point cloud input data used in your labeling job.
- `length`, `width`, and `height` describe the dimensions of the cuboid.
- `yaw` is used to describe the orientation (heading) of the cuboid in radians.

> **Note**
>
> `yaw` is now in the right-handed Cartesian system. Since this feature was added on September 02, 2022 19:02:17 UTC, you can convert the `yaw` measurement in the output data prior to that using the following (all units are in radians):
>
> ```
> old_yaw_in_output = pi - yaw
> ```

- In our definition, +x is to the right, +y is to the forward, and +z is up from the ground plane. The rotation order is x - y - z. The `roll`, `pitch` and `yaw` are represented in the right-handed Cartesian system. In 3D space, `roll` is along the x-axis, `pitch` is along the y-axis and `yaw` is along the z-axis. All three are counterclockwise.
- If you included label attributes in your input manifest file for a given class, a `label-category-attributes` parameter is included for all cuboids for which workers selected label attributes.

3D-2D object tracking point cloud object tracking output

The following is an example of an output manifest file from a 3D point cloud object tracking labeling job. The *red, italicized text* in the examples below depends on labeling job specifications and output data. The ellipses (`...`) denote a continuation of that list, where additional objects with the same format as the proceeding object can appear.

In addition to the standard elements, the metadata includes a class map that lists each class that has at least one label in the sequence. If one or more cuboids were modified, there is an `adjustment-status` parameter in the metadata for audit workflows that is set to `adjusted`.

In the above example, the cuboid data for each frame in `seq2.json` is in `SeqLabel.json` in the Amazon S3 location, `s3://amzn-s3-demo-bucket/<labelingJobName>/annotations/consolidated-annotation/output/<datasetObjectId>/SeqLabel.json`. The following is an example of this label sequence file.

For each frame in the sequence, you see the `frame-number`, `frame-name`, if applicable, `frame-attributes`, and a list of `annotations`. This list contains 3D cubiods that were drawn for that frame. Each annotation includes the following information:

- An `object-name` in the format `<class>:<integer>` where `class` identifies the label category and `integer` is a unique ID across the dataset.
- When workers draw a cuboid, it is associated with a unique `object-id` which is associated with all cuboids that identify the same object across multiple frames.
- Each class, or label category, that you specified in your input manifest is associated with a `class-id`. Use the `class-map` to identify the class associated with each class ID.
- `center-x`, `center-y`, and `center-z` are the coordinates of the center of the cuboid, in the same coordinate system as the 3D point cloud input data used in your labeling job.
- `length`, `width`, and `height` describe the dimensions of the cuboid.

- `yaw` is used to describe the orientation (heading) of the cuboid in radians.

> **Note**
>
> `yaw` is now in the right-handed Cartesian system. Since this feature was added on September 02, 2022 19:02:17 UTC, you can convert the `yaw` measurement in the output data prior to that using the following (all units are in radians):
>
> ```
> old_yaw_in_output = pi - yaw
> ```

- In our definition, +x is to the right, +y is to the forward, and +z is up from the ground plane. The rotation order is x - y - z. The `roll`, `pitch` and `yaw` are represented in the right-handed Cartesian system. In 3D space, `roll` is along the x-axis, `pitch` is along the y-axis and `yaw` is along the z-axis. All three are counterclockwise.
- If you included label attributes in your input manifest file for a given class, a `label-category-attributes` parameter is included for all cuboids for which workers selected label attributes.

Enhanced data labeling

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Amazon SageMaker Ground Truth manages sending your data objects to workers to be labeled. Labeling each data object is a *task*. Workers complete each task until the entire labeling job is complete. Ground Truth divides the total number of tasks into smaller *batches* that are sent to workers. A new batch is sent to workers when the previous one is finished.

Ground Truth provides two features that help improve the accuracy of your data labels and reduce the total cost of labeling your data:

- *Annotation consolidation* helps to improve the accuracy of your data object labels. It combines the results of multiple workers' annotation tasks into one high-fidelity label.
- *Automated data labeling* uses machine learning to label portions of your data automatically without having to send them to human workers.

Topics

- Control the flow of data objects sent to workers
- Annotation consolidation
- Automate data labeling

- Chaining labeling jobs

Control the flow of data objects sent to workers

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Depending on the type of labeling job you create, Amazon SageMaker Ground Truth sends data objects to workers in batches or in a streaming fashion. You can control the flow of data objects to workers in the following ways:

- For both types of labeling jobs, you can use `MaxConcurrentTaskCount` to control the total number of data objects available to all workers at a given point in time when the labeling job is running.
- For streaming labeling jobs, you can control the flow of data objects to workers by monitoring and controlling the number of data objects sent to the Amazon SQS associated with your labeling job.

Use the following sections to learn more about these options.

Topics

- Use MaxConcurrentTaskCount to control the flow of data objects
- Use Amazon SQS to control the flow of data objects to streaming labeling jobs

Use MaxConcurrentTaskCount to control the flow of data objects

`MaxConcurrentTaskCount` defines the maximum number of data objects available at one time in the worker-portal task queue. If you use the console, this parameter is set to 1,000. If you use `CreateLabelingJob`, you can set this parameter to any integer between 1 and 5,000, inclusive.

Use the following example to better understand how the number of entries in your manifest file, the `NumberOfHumanWorkersPerDataObject`, and the `MaxConcurrentTaskCount` define what tasks workers see in their task queue in the worker-portal UI.

1. You have an input manifest files with 600 entries.
2. For each entry in your input manifest file, you can use `NumberOfHumanWorkersPerDataObject` to define the number of human workers that will label an entry from your input manifest file. In this example, you set `NumberOfHumanWorkersPerDataObject` equal to 3. This will create 3 different tasks for each entry in your input manifest file. Also, to be marked as successfully labeled, at least 3 different workers must label the object. This creates a total of 1,800 tasks (600 x 3) to be completed by workers.
3. You want workers to only see 100 tasks at a time in their queue in the worker portal UI. To do this, you set `MaxConcurrentTaskCount` equal to 100. Ground Truth will then fill the worker-portal task queue with 100 tasks per worker.
4. What happens next depends on the type of labeling job you are creating, and if it is a streaming labeling job.
   - **Streaming labeling job**: As long as the total number of objects available to workers is equal to `MaxConcurrentTaskCount`, all remaining dataset objects in your input manifest file and that you send in real time using Amazon SNS are placed on an Amazon SQS queue. When the total number of objects available to workers falls below `MaxConcurrentTaskCount` minus `NumberOfHumanWorkersPerDataObject`, a new data object from the queue is used to create`NumberOfHumanWorkersPerDataObject`-tasks, which are sent to workers in real time.
   - **Non-streaming labeling job**: As workers finish labeling one set of objects, up to `MaxConcurrentTaskCount` times `NumberOfHumanWorkersPerDataObject` number of new tasks will be sent to workers. This process is repeated until all data objects in the input manifest file are labeled.

Use Amazon SQS to control the flow of data objects to streaming labeling jobs

When you create a streaming labeling job, an Amazon SQS queue is automatically created in your account. Data objects are only added to the Amazon SQS queue when the total number of objects sent to workers is above `MaxConcurrentTaskCount`. Otherwise, objects are sent directly to workers.

You can use this queue to manage the flow of data objects to your labeling job. To learn more, see Manage labeling requests with an Amazon SQS queue.

Annotation consolidation

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

An *annotation* is the result of a single worker's labeling task. *Annotation consolidation* combines the annotations of two or more workers into a single label for your data objects. A label, which is assigned to each object in the dataset, is a probabilistic estimate of what the true label should be. Each object in the dataset typically has multiple annotations, but only one label or set of labels.

You decide how many workers annotate each object in your dataset. Using more workers can increase the accuracy of your labels, but also increases the cost of labeling. To learn more about Ground Truth pricing, see Amazon SageMaker Ground Truth pricing .

If you use the Amazon SageMaker AI console to create a labeling job, the following are the defaults for the number of workers who can annotate objects:

- Text classification—3 workers
- Image classification—3 workers
- Bounding boxes—5 workers
- Semantic segmentation—3 workers
- Named entity recognition—3 workers

When you use the `CreateLabelingJob` operation, you set the number of workers to annotate each data object with the `NumberOfHumanWorkersPerDataObject` parameter. You can override the default number of workers that annotate a data object using the console or the `CreateLabelingJob` operation.

Ground Truth provides an annotation consolidation function for each of its predefined labeling tasks: bounding box, image classification, name entity recognition, semantic segmentation, and text classification. These are the functions:

- Multi-class annotation consolidation for image and text classification uses a variant of the Expectation Maximization approach to annotations. It estimates parameters for each worker and

uses Bayesian inference to estimate the true class based on the class annotations from individual workers.

- Bounding box annotation consolidates bounding boxes from multiple workers. This function finds the most similar boxes from different workers based on the Jaccard index, or intersection over union, of the boxes and averages them.
- Semantic segmentation annotation consolidation treats each pixel in a single image as a multi-class classification. This function treats the pixel annotations from workers as "votes," with more information from surrounding pixels incorporated by applying a smoothing function to the image.
- Named entity recognition clusters text selections by Jaccard similarity and calculates selection boundaries based on the mode, or the median if the mode isn't clear. The label resolves to the most assigned entity label in the cluster, breaking ties by random selection.

You can use other algorithms to consolidate annotations. For information, see Annotation consolidation function creation.

Annotation consolidation function creation

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can choose to use your own annotation consolidation function to determine the final labels for your labeled objects. There are many possible approaches for writing a function and the approach that you take depends on the nature of the annotations to consolidate. Broadly, consolidation functions look at the annotations from workers, measure the similarity between them, and then use some form of probabilistic judgment to determine what the most probable label should be.

If you want to use other algorithms to create annotation consolidations functions, you can find the worker responses in the *[project-name]*`/annotations/worker-response` folder of the Amazon S3 bucket where you direct the job output.

Assess similarity

To assess the similarity between labels, you can use one of the following strategies, or you can use one that meets your data labeling needs:

- For label spaces that consist of discrete, mutually exclusive categories, such as multi-class classification, assessing similarity can be straightforward. Discrete labels either match or do not match.
- For label spaces that don't have discrete values, such as bounding box annotations, find a broad measure of similarity. For bounding boxes, one such measure is the Jaccard index. This measures the ratio of the intersection of two boxes with the union of the boxes to assess how similar they are. For example, if there are three annotations, then there can be a function that determines which annotations represent the same object and should be consolidated.

Assess the most probable label

With one of the strategies detailed in the previous sections in mind, make some sort of probabilistic judgment on what the consolidated label should be. In the case of discrete, mutually exclusive categories, this can be straightforward. One of the most common ways to do this is to take the results of a majority vote between the annotations. This weights the annotations equally.

Some approaches attempt to estimate the accuracy of different annotators and weight their annotations in proportion to the probability of correctness. An example of this is the Expectation Maximization method, which is used in the default Ground Truth consolidation function for multi-class annotations.

For more information about creating an annotation consolidation function, see Processing data in a custom labeling workflow with Amazon Lambda.

Automate data labeling

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

If you choose, Amazon SageMaker Ground Truth can use active learning to automate the labeling of your input data for certain built-in task types. *Active learning* is a machine learning technique that identifies data that should be labeled by your workers. In Ground Truth, this functionality is called automated data labeling. Automated data labeling helps to reduce the cost and time that it takes to label your dataset compared to using only humans. When you use automated labeling, you incur SageMaker training and inference costs.

We recommend using automated data labeling on large datasets because the neural networks used with active learning require a significant amount of data for every new dataset. Typically, as you provide more data, the potential for high accuracy predictions goes up. Data will only be auto-labeled if the neural network used in the auto-labeling model can achieve an acceptably high level of accuracy. Therefore, with larger datasets, there is more potential to automatically label the data because the neural network can achieve high enough accuracy for auto-labeling. Automated data labeling is most appropriate when you have thousands of data objects. The minimum number of objects allowed for automated data labeling is 1,250, but we strongly suggest providing a minimum of 5,000 objects.

Automated data labeling is available only for the following Ground Truth built-in task types:

- Create an image classification job (Single Label)
- Identify image contents using semantic segmentation
- Object detection (Classify image objects using a bounding box)
- Categorize text with text classification (Single Label)

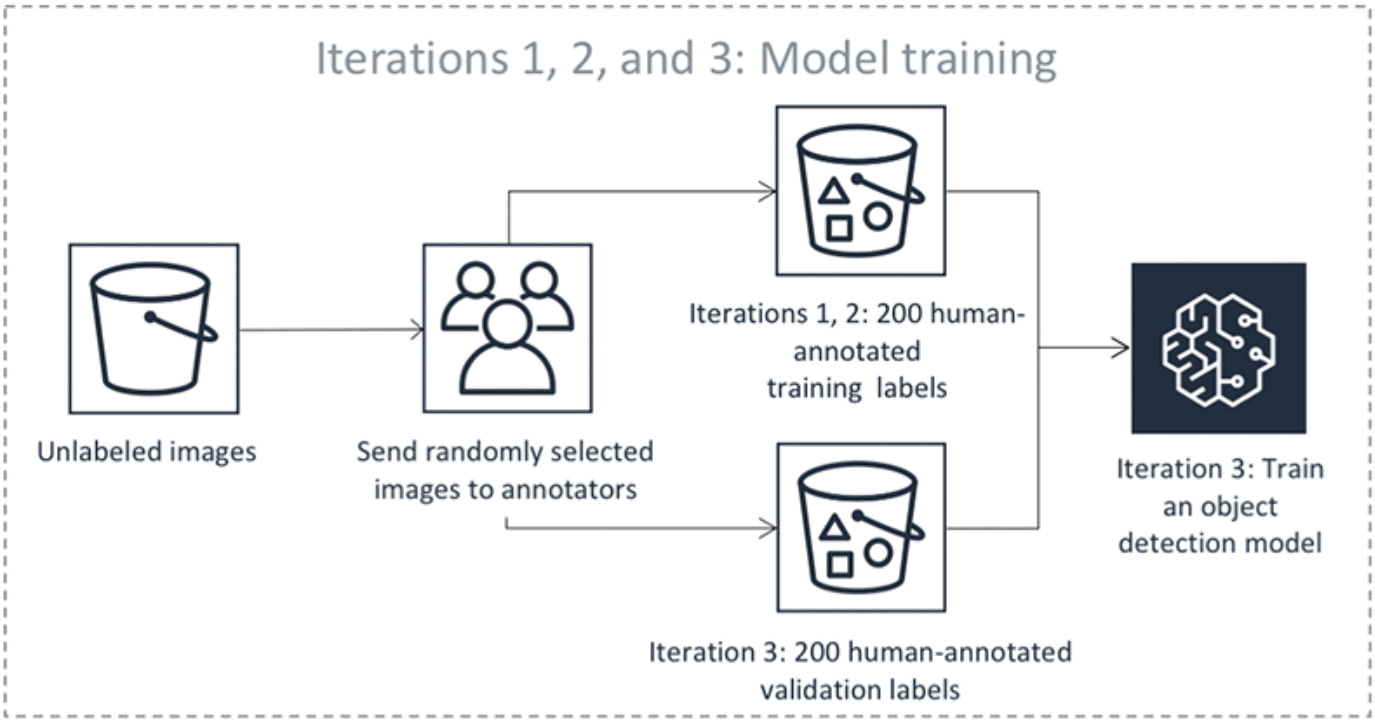
Streaming labeling jobs do not support automated data labeling.

To learn how to create a custom active learning workflow using your own model, see Set up an active learning workflow with your own model.

Input data quotas apply for automated data labeling jobs. See Input Data Quotas for information about dataset size, input data size and resolution limits.

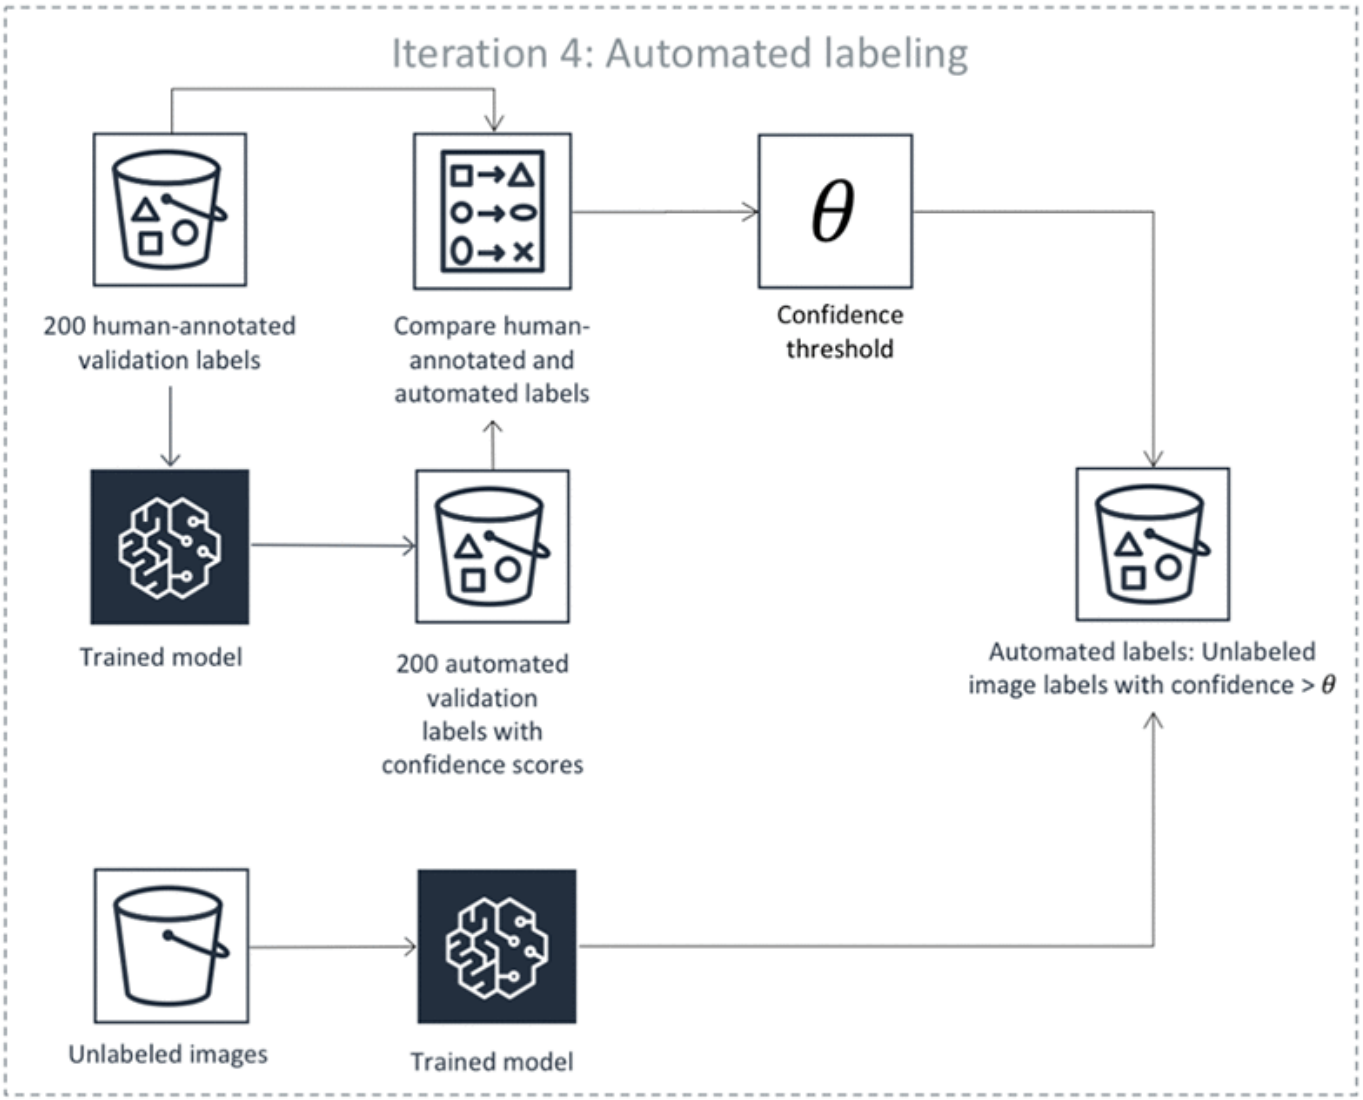
> **Note**
>
> Before you use an the automated-labeling model in production, you need to fine-tune or test it, or both. You might fine-tune the model (or create and tune another supervised model of your choice) on the dataset produced by your labeling job to optimize the model's architecture and hyperparameters. If you decide to use the model for inference without

fine-tuning it, we strongly recommend making sure that you evaluate its accuracy on a representative (for example, randomly selected) subset of the dataset labeled with Ground Truth and that it matches your expectations.



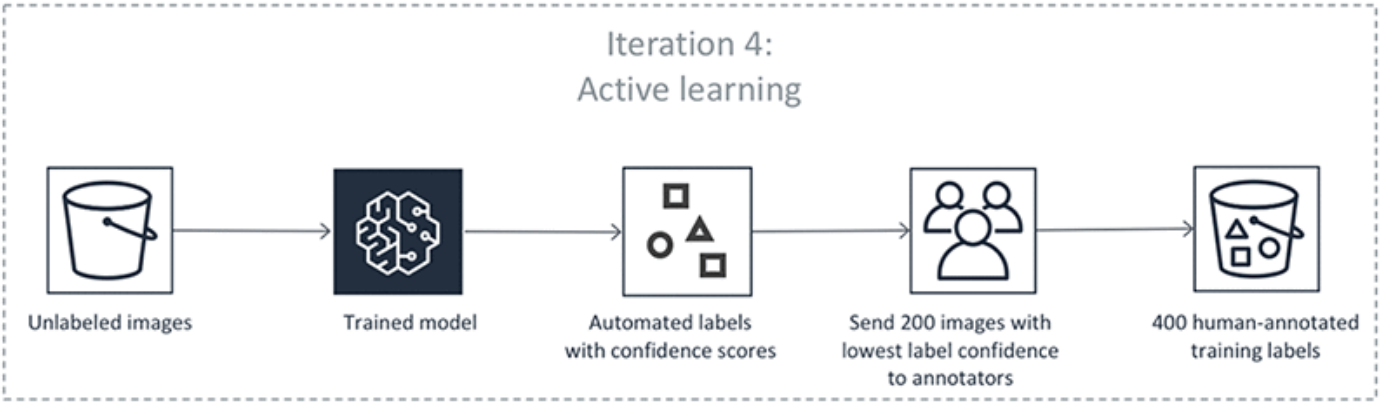
How it works

You enable automated data labeling when you create a labeling job. This is how it works:



1. When Ground Truth starts an automated data labeling job, it selects a random sample of input data objects and sends them to human workers. If more than 10% of these data objects fail, the labeling job will fail. If the labeling job fails, in addition to reviewing any error message Ground Truth returns, check that your input data is displaying correctly in the worker UI, instructions are clear, and that you have given workers enough time to complete tasks.
2. When the labeled data is returned, it is used to create a training set and a validation set. Ground Truth uses these datasets to train and validate the model used for auto-labeling.
3. Ground Truth runs a batch transform job, using the validated model for inference on the validation data. Batch inference produces a confidence score and quality metric for each object in the validation data.
4. The auto labeling component will use these quality metrics and confidence scores to create a *confidence score threshold* that ensures quality labels.
5. Ground Truth runs a batch transform job on the unlabeled data in the dataset, using the same validated model for inference. This produces a confidence score for each object.
6. The Ground Truth auto labeling component determines if the confidence score produced in step 5 for each object meets the required threshold determined in step 4. If the confidence score meets the threshold, the expected quality of automatically labeling exceeds the requested level of accuracy and that object is considered auto-labeled.
7. Step 6 produces a dataset of unlabeled data with confidence scores. Ground Truth selects data points with low confidence scores from this dataset and sends them to human workers.
8. Ground Truth uses the existing human-labeled data and this additional labeled data from human workers to update the model.
9. The process is repeated until the dataset is fully labeled or until another stopping condition is met. For example, auto-labeling stops if your human annotation budget is reached.

The preceding steps happen in iterations. Select each tab in the following table to see an example of the processes that happen in each iteration for an object detection automated labeling job. The number of data objects used in a given step in these images (for example, 200) is specific to this example. If there are fewer than 5,000 objects to label, the validation set size is 20% of the whole dataset. If there are more than 5,000 objects in your input dataset, the validation set size is 10% of the whole dataset. You can control the number of human labels collected per active learning iteration by changing the value for `MaxConcurrentTaskCount` when using the API operation `CreateLabelingJob`. This value is set to 1,000 when you create a labeling job using the console. In the active learning flow illustrated under the **Active Learning** tab, this value is set to 200.



Model Training

Automated Labeling

Active Learning

Accuracy of automated labels

The definition of *accuracy* depends on the built-in task type that you use with automated labeling. For all task types, these accuracy requirements are pre-determined by Ground Truth and cannot be manually configured.

- For image classification and text classification, Ground Truth uses logic to find a label-prediction confidence level that corresponds to at least 95% label accuracy. This means Ground Truth expects the accuracy of the automated labels to be at least 95% when compared to the labels that human labelers would provide for those examples.
- For bounding boxes, the expected mean Intersection Over Union (IoU) of the auto-labeled images is 0.6. To find the mean IoU, Ground Truth calculates the mean IoU of all the predicted and missed boxes on the image for every class, and then averages these values across classes.
- For semantic segmentation, the expected mean IoU of the auto-labeled images is 0.7. To find the mean IoU, Ground Truth takes the mean of the IoU values of all the classes in the image (excluding the background).

At every iteration of Active Learning (steps 3-6 in the list above), the confidence threshold is found using the human-annotated validation set so that the expected accuracy of the auto-labeled objects satisfies certain predefined accuracy requirements.

Create an automated data labeling job (console)

To create a labeling job that uses automated labeling in the SageMaker AI console, use the following procedure.

To create an automated data labeling job (console)

1. Open the Ground Truth **Labeling jobs** section of the SageMaker AI console: https://console.amazonaws.cn/sagemaker/groundtruth.
2. Using Create a Labeling Job (Console) as a guide, complete the **Job overview** and **Task type** sections. Note that auto labeling is not supported for custom task types.
3. Under **Workers**, choose your workforce type.
4. In the same section, choose **Enable automated data labeling**.
5. Using Configure the Bounding Box Tool as a guide, create worker instructions in the section ***Task Type*** **labeling tool**. For example, if you chose **Semantic segmentation** as your labeling job type, this section is called **Semantic segmentation labeling tool**.

6. To preview your worker instructions and dashboard, choose **Preview**.
7. Choose **Create**. This creates and starts your labeling job and the auto labeling process.

You can see your labeling job appear in the **Labeling jobs** section of the SageMaker AI console. Your output data appears in the Amazon S3 bucket that you specified when creating the labeling job. For more information about the format and file structure of your labeling job output data, see Labeling job output data.

Create an automated data labeling job (API)

To create an automated data labeling job using the SageMaker API, use the `LabelingJobAlgorithmsConfig` parameter of the `CreateLabelingJob` operation. To learn how to start a labeling job using the `CreateLabelingJob` operation, see Create a Labeling Job (API).

Specify the Amazon Resource Name (ARN) of the algorithm that you are using for automated data labeling in the LabelingJobAlgorithmSpecificationArn parameter. Choose from one of the four Ground Truth built-in algorithms that are supported with automated labeling:

- Create an image classification job (Single Label)
- Identify image contents using semantic segmentation
- Object detection (Classify image objects using a bounding box)
- Categorize text with text classification (Single Label)

When an automated data labeling job finishes, Ground Truth returns the ARN of the model it used for the automated data labeling job. Use this model as the starting model for similar auto-labeling job types by providing the ARN, in string format, in the InitialActiveLearningModelArn parameter. To retrieve the model's ARN, use an Amazon Command Line Interface (Amazon CLI) command similar to the following.

```
# Fetch the mARN of the model trained in the final iteration of the previous labeling
 job.Ground Truth
pretrained_model_arn = sagemaker_client.describe_labeling_job(LabelingJobName=job_name)
['LabelingJobOutput']['FinalActiveLearningModelArn']
```

To encrypt data on the storage volume attached to the ML compute instance(s) that are used in automated labeling, include an Amazon Key Management Service (Amazon KMS) key in the

`VolumeKmsKeyId` parameter. For information about Amazon KMS keys, see What is Amazon Key Management Service? in the *Amazon Key Management Service Developer Guide*.

For an example that uses the `CreateLabelingJob` operation to create an automated data labeling job, see the **object_detection_tutorial** example in the **SageMaker AI Examples**, **Ground Truth Labeling Jobs** section of a SageMaker AI notebook instance. To learn how to create and open a notebook instance, see Create an Amazon SageMaker notebook instance.

Amazon EC2 instances required for automated data labeling

The following table lists the Amazon Elastic Compute Cloud (Amazon EC2) instances that you need to run automated data labeling for training and batch inference jobs.

Automated Data Labeling Job Type	Training Instance Type	Inference Instance Type
Image classification	ml.p3.2xlarge*	ml.c5.xlarge
Object detection (bounding box)	ml.p3.2xlarge*	ml.c5.4xlarge
Text classification	ml.c5.2xlarge	ml.m4.xlarge
Semantic segmentation	ml.p3.2xlarge*	ml.p3.2xlarge*

* In the Asia Pacific (Mumbai) Region (ap-south-1) use ml.p2.8xlarge instead.

Ground Truth manages the instances that you use for automated data labeling jobs. It creates, configures, and terminates the instances as needed to perform your job. These instances don't appear in your Amazon EC2 instance dashboard.

Set up an active learning workflow with your own model

You can create an active learning workflow with your own algorithm to run training and inferences in that workflow to auto-label your data. The notebook bring_your_own_model_for_sagemaker_labeling_workflows_with_active_learning.ipynb demonstrates this using the SageMaker AI built-in algorithm, BlazingText. This notebook provides an Amazon CloudFormation stack that you can use to execute this workflow using Amazon Step Functions. You can find the notebook and supporting files in this GitHub repository.

Chaining labeling jobs

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Amazon SageMaker Ground Truth can reuse datasets from prior jobs in two ways: cloning and chaining.

Cloning copies the setup of a prior labeling job and allows you to make additional changes before setting it to run.

Chaining uses not only the setup of the prior job, but also the results. This allows you to continue an incomplete job and add labels or data objects to a completed job. Chaining is a more complex operation.

For data processing:

- Cloning uses the prior job's *input* manifest, with optional modifications, as the new job's input manifest.
- Chaining uses the prior job's *output* manifest as the new job's input manifest.

Chaining is useful when you need to:

- Continue a labeling job that was manually stopped.
- Continue a labeling job that failed mid-job, after fixing issues.
- Switch to automated data labeling after manually labeling part of a job (or the other way around).
- Add more data objects to a completed job and start the job from there.
- Add another annotation to a completed job. For example, you have a collection of phrases labeled for topic, then want to run the set again, categorizing them by the topic's implied audience.

In Amazon SageMaker Ground Truth you can configure a chained labeling job with either the console or the API.

Key term: label attribute name

The *label attribute name* (`LabelAttributeName` in the API) is a string used as the key for the key-value pair formed with the label that a worker assigns to the data object.

The following rules apply for the label attribute name:

- It can't end with `-metadata`.
- The names `source` and `source-ref` are reserved and can't be used.
- For semantic segmentation labeling jobs, , it must end with `-ref`. For all other labeling jobs, it *can't* end with `-ref`. If you use the console to create the job, Amazon SageMaker Ground Truth automatically appends `-ref` to all label attribute names except for semantic segmentation jobs.
- For a chained labeling job, if you're using the same label attribute name from the originating job and you configure the chained job to use auto-labeling, then if it had been in auto-labeling mode at any point, Ground Truth uses the model from the originating job.

In an output manifest, the label attribute name appears similar to the following.

```
"source-ref": "<S3 URI>",
"<label attribute name>": {
  "annotations": [{
    "class_id": 0,
    "width": 99,
    "top": 87,
    "height": 62,
    "left": 175
  }],
  "image_size": [{
    "width": 344,
    "depth": 3,
    "height": 234
  }]
},
"<label attribute name>-metadata": {
  "job-name": "<job name>",
  "class-map": {
    "0": "<label attribute name>"
```

```
    },
    "human-annotated": "yes",
    "objects": [{
      "confidence": 0.09
    }],
    "creation-date": "<timestamp>",
    "type": "groundtruth/object-detection"
  }
```

If you're creating a job in the console and don't explicitly set the label attribute name value, Ground Truth uses the job name as the label attribute name for the job.

Start a chained job (console)

Choose a stopped, failed, or completed labeling job from the list of your existing jobs. This enables the **Actions** menu.

From the **Actions** menu, choose **Chain**.

Job overview panel

In the **Job overview** panel, a new **Job name** is set based on the title of the job from which you are chaining this one. You can change it.

You may also specify a label attribute name different from the labeling job name.

If you're chaining from a completed job, the label attribute name uses the name of the new job you're configuring. To change the name, select the check box.

If you're chaining from a stopped or failed job, the label attribute name uses to the name of the job from which you're chaining. It's easy to see and edit the value because the name check box is checked.

Attribute label naming considerations

- **The default** uses the label attribute name Ground Truth has selected. All data objects without data connected to that label attribute name are labeled.
- **Using a label attribute name** not present in the manifest causes the job to process *all* the objects in the dataset.

The **input dataset location** in this case is automatically selected as the output manifest of the chained job. The input field is not available, so you cannot change it.

> **Adding data objects to a labeling job**
>
> You cannot specify an alternate manifest file. Manually edit the output manifest from the previous job to add new items before starting a chained job. The Amazon S3 URI helps you locate where you are storing the manifest in your Amazon S3 bucket. Download the manifest file from there, edit it locally on your computer, and then upload the new version to replace it. Make sure you are not introducing errors during editing. We recommend you use JSON linter to check your JSON. Many popular text editors and IDEs have linter plugins available.

Start a chained job (API)

The procedure is almost the same as setting up a new labeling job with `CreateLabelingJob`, except for two primary differences:

- **Manifest location:** Rather than use your original manifest from the prior job, the value for the `ManifestS3Uri` in the `DataSource` should point to the Amazon S3 URI of the *output manifest* from the prior labeling job.
- **Label attribute name:** Setting the correct `LabelAttributeName` value is important here. This is the key portion of a key-value pair where labeling data is the value. Sample use cases include:
  - **Adding new or more specific labels to a completed job** — Set a new label attribute name.
  - **Labeling the unlabeled items from a prior job** — Use the label attribute name from the prior job.

Use a partially labeled dataset

You can get some chaining benefits if you use an augmented manifest that has already been partially labeled. Check the **Label attribute name** check box and set the name so that it matches the name in your manifest.

If you're using the API, the instructions are the same as those for starting a chained job. However, be sure to upload your manifest to an Amazon S3 bucket and use it instead of using the output manifest from a prior job.

The **Label attribute name** value in the manifest has to conform to the naming considerations discussed earlier.

Ground Truth Security and Permissions

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use the topics on this page to learn about Ground Truth security features and how to configure Amazon Identity and Access Management (IAM) permissions to allow a user or role to create a labeling job. Additionally, learn how to create an *execution role*. An execution role is the role that you specify when you create a labeling job. This role is used to start your labeling job.

If you are a new user and want to get started quickly, or if you do not require granular permissions, see Use IAM Managed Policies with Ground Truth.

For more information about IAM users and roles, see Identities (Users, Groups, and Roles) in the IAM User Guide.

To learn more about using IAM with SageMaker AI, see Amazon Identity and Access Management for Amazon SageMaker AI.

CORS Requirement for Input Image Data

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Earlier in 2020, widely used browsers like Chrome and Firefox changed their default behavior for rotating images based on image metadata, referred to as EXIF data. Previously, browsers would always display images in exactly the manner in which they are stored on disk, which is typically unrotated. After the change, images now rotate according to a piece of image metadata called *orientation value*. This has important implications for the entire machine learning (ML) community. For example, if applications that annotate images do not consider the EXIF orientation, they may display images in unexpected orientations, resulting in incorrect labels.

Starting with Chrome 89, Amazon can no longer automatically prevent the rotation of images because the web standards group W3C has decided that the ability to control rotation of images violates the web's Same-origin Policy. Therefore, to ensure human workers annotate your input images in a predictable orientation when you submit requests to create a labeling job, you must add a CORS header policy to the Amazon S3 buckets that contain your input images.

> **Important**
>
> If you do not add a CORS configuration to the Amazon S3 buckets that contain your input data, labeling tasks for those input data objects will fail.

If you create a job through the Ground Truth console, CORS is enabled by default. If all of your input data is *not* located in the same Amazon S3 bucket as your input manifest file, you must add a CORS configuration to all Amazon S3 buckets that contain input data using the following instructions.

If you are using the `CreateLabelingJob` API to create a Ground Truth labeling job, you can add a CORS policy to an Amazon S3 bucket that contains input data in the S3 console. To set the required CORS headers on the Amazon S3 bucket that contain your input images in the Amazon S3 console, follow the directions detailed in How do I add cross-domain resource sharing with CORS?. Use the

following CORS configuration code for the buckets that host your images. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

> **Important**
>
> If you create a 3D point cloud or video frame labeling job, you must add additional rules to your CORS configuration. To learn more, see 3D point cloud labeling job permission requirements and Video frame job permission requirements respectively.

JSON

```
[{
   "AllowedHeaders": [],
   "AllowedMethods": ["GET"],
   "AllowedOrigins": ["*"],
   "ExposeHeaders": ["Access-Control-Allow-Origin"]
}]
```

XML

```
<CORSConfiguration>
 <CORSRule>
   <AllowedOrigin>*</AllowedOrigin>
   <AllowedMethod>GET</AllowedMethod>
   <ExposeHeader>Access-Control-Allow-Origin</ExposeHeader>
 </CORSRule>
</CORSConfiguration>
```

Assign IAM Permissions to Use Ground Truth

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use the topics in this section to learn how to use Amazon Identity and Access Management (IAM) managed and custom policies to manage access to Ground Truth and associated resources.

You can use the sections on this page to learn the following:

- How to create IAM policies that grant a user or role permission to create a labeling job. Administrators can use IAM policies to restrict access to Amazon SageMaker AI and other Amazon services that are specific to Ground Truth.
- How to create a SageMaker AI *execution role*. An execution role is the role that you specify when you create a labeling job. The role is used to start and manage your labeling job.

The following is an overview of the topics you'll find on this page:

- If you are getting started using Ground Truth, or you do not require granular permissions for your use case, it is recommended that you use the IAM managed policies described in Use IAM Managed Policies with Ground Truth.
- Learn about the permissions required to use the Ground Truth console in Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console. This section includes policy examples that grant an IAM entity permission to create and modify private work teams, subscribe to vendor work teams, and create custom labeling workflows.
- When you create a labeling job, you must provide an execution role. Use Create a SageMaker AI Execution Role for a Ground Truth Labeling Job to learn about the permissions required for this role.

Use IAM Managed Policies with Ground Truth

SageMaker AI and Ground Truth provide Amazon managed policies that you can use to create a labeling job. If you are getting started using Ground Truth and you do not require granular permissions for your use case, it is recommended that you use the following policies:

- `AmazonSageMakerFullAccess` – Use this policy to give a user or role permission to create a labeling job. This is a broad policy that grants a entity permission to use SageMaker AI features, as well as features of necessary Amazon services through the console and API. This policy gives the entity permission to create a labeling job and to create and manage workforces using Amazon Cognito. To learn more, see AmazonSageMakerFullAccess Policy.
- `AmazonSageMakerGroundTruthExecution` – To create an *execution role*, you can attach the policy `AmazonSageMakerGroundTruthExecution` to a role. An execution role is the role that you specify when you create a labeling job and it is used to start your labeling job. This policy

allows you to create both streaming and non-streaming labeling jobs, and to create a labeling job using any task type. Note the following limits of this managed policy.

- **Amazon S3 permissions**: This policy grants an execution role permission to access Amazon S3 buckets with the following strings in the name: `GroundTruth`, `Groundtruth`, `groundtruth`, `SageMaker`, `Sagemaker`, and `sagemaker` or a bucket with an object tag that includes `SageMaker` in the name (case insensitive). Make sure your input and output bucket names include these strings, or add additional permissions to your execution role to grant it permission to access your Amazon S3 buckets. You must give this role permission to perform the following actions on your Amazon S3 buckets: `AbortMultipartUpload`, `GetObject`, and `PutObject`.
- **Custom Workflows**: When you create a custom labeling workflow, this execution role is restricted to invoking Amazon Lambda functions with one of the following strings as part of the function name: `GtRecipe`, `SageMaker`, `Sagemaker`, `sagemaker`, or `LabelingFunction`. This applies to both your pre-annotation and post-annotation Lambda functions. If you choose to use names without those strings, you must explicitly provide `lambda:InvokeFunction` permission to the execution role used to create the labeling job.

To learn how to attach an Amazon managed policy to a user or role, refer to Adding and removing IAM identity permissions in the IAM User Guide.

Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console

To use the Ground Truth area of the SageMaker AI console, you need to grant permission to an entity to access SageMaker AI and other Amazon services that Ground Truth interacts with. Required permissions to access other Amazon services depends on your use-case:

- Amazon S3 permissions are required for all use cases. These permissions must grant access to the Amazon S3 buckets that contain input and output data.
- Amazon Web Services Marketplace permissions are required to use a vendor workforce.
- Amazon Cognito permission are required for private work team setup.
- Amazon KMS permissions are required to view available Amazon KMS keys that can be used for output data encryption.
- IAM permissions are required to either list pre-existing execution roles, or to create a new one. Additionally, you must use add a `PassRole` permission to allow SageMaker AI to use the execution role chosen to start the labeling job.

The following sections list policies you may want to grant to a role to use one or more functions of Ground Truth.

Topics

- Ground Truth Console Permissions
- Custom Labeling Workflow Permissions
- Private Workforce Permissions
- Vendor Workforce Permissions

Ground Truth Console Permissions

To grant permission to a user or role to use the Ground Truth area of the SageMaker AI console to create a labeling job, attach the following policy to the user or role. The following policy will give an IAM role permission to create a labeling job using a built-in task type task type. If you want to create a custom labeling workflow, add the policy in Custom Labeling Workflow Permissions to the following policy. Each `Statement` included in the following policy is described below this code block.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "SageMakerApis",
            "Effect": "Allow",
            "Action": [
                "sagemaker:*"
            ],
            "Resource": "*"
        },

                "s3:PutBucketCors",
                "s3:ListAllMyBuckets",
                "cognito-idp:AdminAddUserToGroup",
                "cognito-idp:AdminCreateUser",
                "cognito-idp:AdminDeleteUser",
                "cognito-idp:AdminDisableUser",
                "cognito-idp:AdminEnableUser",
                "cognito-idp:AdminRemoveUserFromGroup",
                "cognito-idp:CreateGroup",
                "cognito-idp:CreateUserPool",
                "cognito-idp:CreateUserPoolClient",
                "cognito-idp:CreateUserPoolDomain",
                "cognito-idp:DescribeUserPool",
                "cognito-idp:DescribeUserPoolClient",
                "cognito-idp:ListGroups",
                "cognito-idp:ListIdentityProviders",
                "cognito-idp:ListUsers",
                "cognito-idp:ListUsersInGroup",
                "cognito-idp:ListUserPoolClients",
                "cognito-idp:ListUserPools",
                "cognito-idp:UpdateUserPool",
                "cognito-idp:UpdateUserPoolClient"
            ],
            "Resource": "*"
        }
    ]
}
```

This policy includes the following statements. You can scope down any of these statements by adding specific resourses to the `Resource` list for that statement.

`SageMakerApis`

This statement includes `sagemaker:*`, which allows the user to perform all SageMaker AI API actions. You can reduce the scope of this policy by restricting users from performing actions that are not used to create and monitoring a labeling job.

`KmsKeysForCreateForms`

You only need to include this statement if you want to grant a user permission to list and select Amazon KMS keys in the Ground Truth console to use for output data encryption. The policy above grants a user permission to list and select any key in the account in Amazon KMS. To restrict the keys that a user can list and select, specify those key ARNs in `Resource`.

`SecretsManager`

This statement gives the user permission to describe, list, and create resources in Amazon Secrets Manager required to create the labeling job.

`ListAndCreateExecutionRoles`

This statement gives a user permission to list (`ListRoles`) and create (`CreateRole`) IAM roles in your account. It also grants the user permission to create (`CreatePolicy`) policies and attach (`AttachRolePolicy`) policies to entities. These are required to list, select, and if required, create an execution role in the console.

If you have already created an execution role, and want to narrow the scope of this statement so that users can only select that role in the console, specify the ARNs of the roles you want the user to have permission to view in `Resource` and remove the actions `CreateRole`, `CreatePolicy`, and `AttachRolePolicy`.

`AccessAwsMarketplaceSubscriptions`

These permissions are required to view and choose vendor work teams that you are already subscribed to when creating a labeling job. To give the user permission to *subscribe* to vendor work teams, add the statement in Vendor Workforce Permissions to the policy above

`PassRoleForExecutionRoles`

This is required to give the labeling job creator permission to preview the worker UI and verify that input data, labels, and instructions display correctly. This statement gives an entity permissions to pass the IAM execution role used to create the labeling job to SageMaker AI to render and preview the worker UI. To narrow the scope of this policy, add the role ARN of the execution role used to create the labeling job under `Resource`.

`GroundTruthConsole`

- `groundtruthlabeling` – This allows a user to perform actions required to use certain features of the Ground Truth console. These include permissions to describe the labeling job status (`DescribeConsoleJob`), list all dataset objects in the input manifest file (`ListDatasetObjects`), filter the dataset if dataset sampling is selected (`RunFilterOrSampleDatasetJob`), and to generate input manifest files if automated data labeling is used (`RunGenerateManifestByCrawlingJob`). These actions are only available when using the Ground Truth console and cannot be called directly using an API.
- `lambda:InvokeFunction` and `lambda:ListFunctions` – these actions give users permission to list and invoke Lambda functions that are used to run a custom labeling workflow.
- `s3:*` – All Amazon S3 permissions included in this statement are used to view Amazon S3 buckets for automated data setup (`ListAllMyBuckets`), access input data in Amazon S3 (`ListBucket`, `GetObject`), check for and create a CORS policy in Amazon S3 if needed (`GetBucketCors` and `PutBucketCors`), and write labeling job output files to S3 (`PutObject`).
- `cognito-idp` – These permissions are used to create, view and manage and private workforce using Amazon Cognito. To learn more about these actions, refer to the Amazon Cognito API References.

Custom Labeling Workflow Permissions

Add the following statement to a policy similar to the one in Ground Truth Console Permissions to give a user permission to select pre-existing pre-annotation and post-annotation Lambda functions while creating a custom labeling workflow.

```
{
    "Sid": "GroundTruthConsoleCustomWorkflow",
    "Effect": "Allow",
    "Action": [
        "lambda:InvokeFunction",
        "lambda:ListFunctions"
    ],
    "Resource": "*"
}
```

To learn how to give an entity permission to create and test pre-annotation and post-annotation Lambda functions, see Required Permissions To Use Lambda With Ground Truth.

Private Workforce Permissions

When added to a permissions policy, the following permission grants access to create and manage a private workforce and work team using Amazon Cognito. These permissions are not required to use an OIDC IdP workforce.

```
{
    "Effect": "Allow",
    "Action": [
        "cognito-idp:AdminAddUserToGroup",
        "cognito-idp:AdminCreateUser",
        "cognito-idp:AdminDeleteUser",
        "cognito-idp:AdminDisableUser",
        "cognito-idp:AdminEnableUser",
        "cognito-idp:AdminRemoveUserFromGroup",
        "cognito-idp:CreateGroup",
        "cognito-idp:CreateUserPool",
        "cognito-idp:CreateUserPoolClient",
        "cognito-idp:CreateUserPoolDomain",
        "cognito-idp:DescribeUserPool",
        "cognito-idp:DescribeUserPoolClient",
        "cognito-idp:ListGroups",
        "cognito-idp:ListIdentityProviders",
        "cognito-idp:ListUsers",
        "cognito-idp:ListUsersInGroup",
        "cognito-idp:ListUserPoolClients",
        "cognito-idp:ListUserPools",
        "cognito-idp:UpdateUserPool",
        "cognito-idp:UpdateUserPoolClient"
        ],
    "Resource": "*"
}
```

To learn more about creating private workforce using Amazon Cognito, see Amazon Cognito Workforces.

Vendor Workforce Permissions

You can add the following statement to the policy in Grant IAM Permission to Use the Amazon SageMaker Ground Truth Console to grant an entity permission to subscribe to a vendor workforce.

```
{
```

```
    "Sid": "AccessAwsMarketplaceSubscriptions",
    "Effect": "Allow",
    "Action": [
        "aws-marketplace:Subscribe",
        "aws-marketplace:Unsubscribe",
        "aws-marketplace:ViewSubscriptions"
    ],
    "Resource": "*"
}
```

Create a SageMaker AI Execution Role for a Ground Truth Labeling Job

When you configure your labeling job, you need to provide an *execution role*, which is a role that SageMaker AI has permission to assume to start and run your labeling job.

This role must give Ground Truth permission to access the following:

- Amazon S3 to retrieve your input data and write output data to an Amazon S3 bucket. You can either grant permission for an IAM role to access an entire bucket by providing the bucket ARN, or you can grant access to the role to access specific resources in a bucket. For example, the ARN for a bucket may look similar to `arn:aws:s3:::amzn-s3-demo-bucket1` and the ARN of a resource in an Amazon S3 bucket may look similar to `arn:aws:s3:::amzn-s3-demo-bucket1/prefix/file-name.png`. To apply an action to all resources in an Amazon S3 bucket, you can use the wild card: `*`. For example, `arn:aws:s3:::amzn-s3-demo-bucket1/prefix/*`. For more information, see Amazon Amazon S3 Resources in the Amazon Simple Storage Service User Guide.
- CloudWatch to log worker metrics and labeling job statuses.
- Amazon KMS for data encryption. (Optional)
- Amazon Lambda for processing input and output data when you create a custom workflow.

Additionally, if you create a streaming labeling job, this role must have permission to access:

- Amazon SQS to create an interact with an SQS queue used to manage labeling requests.
- Amazon SNS to subscribe to and retrieve messages from your Amazon SNS input topic and to send messages to your Amazon SNS output topic.

All of these permissions can be granted with the `AmazonSageMakerGroundTruthExecution` managed policy *except*:

- Data and storage volume encryption of your Amazon S3 buckets. To learn how to configure these permissions, see Encrypt Output Data and Storage Volume with Amazon KMS.
- Permission to select and invoke Lambda functions that do not include `GtRecipe`, `SageMaker`, `Sagemaker`, `sagemaker`, or `LabelingFunction` in the function name.
- Amazon S3 buckets that do not include either `GroundTruth`, `Groundtruth`, `groundtruth`, `SageMaker`, `Sagemaker`, and `sagemaker` in the prefix or bucket name or an object tag that includes `SageMaker` in the name (case insensitive).

If you require more granular permissions than the ones provided in `AmazonSageMakerGroundTruthExecution`, use the following policy examples to create an execution role that fits your specific use case.

Topics

- Built-In Task Types (Non-streaming) Execution Role Requirements
- Built-In Task Types (Streaming) Execution Role Requirements
- Execution Role Requirements for Custom Task Types
- Automated Data Labeling Permission Requirements

Built-In Task Types (Non-streaming) Execution Role Requirements

The following policy grants permission to create a labeling job for a built-in task type. This execution policy does not include permissions for Amazon KMS data encryption or decryption. Replace each red, italicized ARN with your own Amazon S3 ARNs.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "S3ViewBuckets",
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ],
            "Resource": [
```

```
                "arn:aws-cn:s3:::<input-bucket-name>",
                "arn:aws-cn:s3:::<output-bucket-name>"
            ]
        },
        {
            "Sid": "S3GetPutObjects",
            "Effect": "Allow",
            "Action": [
                "s3:AbortMultipartUpload",
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws-cn:s3:::<input-bucket-name>/*",
                "arn:aws-cn:s3:::<output-bucket-name>/*"
            ]
        },
        {
            "Sid": "CloudWatch",
            "Effect": "Allow",
            "Action": [
                "cloudwatch:PutMetricData",
                "logs:CreateLogStream",
                "logs:CreateLogGroup",
                "logs:DescribeLogStreams",
                "logs:PutLogEvents"
            ],
            "Resource": "*"
        }
    ]
}
```

Built-In Task Types (Streaming) Execution Role Requirements

If you create a streaming labeling job, you must add a policy similar to the following to the execution role you use to create the labeling job. To narrow the scope of the policy, replace the * in `Resource` with specific Amazon resources that you want to grant the IAM role permission to access and use.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:AbortMultipartUpload",
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws-cn:s3:::amzn-s3-demo-bucket/*",
                "arn:aws-cn:s3:::amzn-s3-demo-bucket2/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject"
            ],
            "Resource": "*",
            "Condition": {
                "StringEqualsIgnoreCase": {
                    "s3:ExistingObjectTag/SageMaker": "true"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetBucketLocation",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws-cn:s3:::amzn-s3-demo-bucket",
                "arn:aws-cn:s3:::amzn-s3-demo-bucket2"
            ]
        },
        {
            "Sid": "CloudWatch",

                },
                "StringLike": {
                    "sns:Endpoint": "arn:aws-cn:sns:us-
east-1:111122223333:*GroundTruth*"
                }
            }
        },
        {
            "Sid": "StreamingTopic",
            "Effect": "Allow",
```

```
            "Action": [
                "sns:Publish"
            ],
            "Resource": [
                "arn:aws-cn:sns:us-east-1:111122223333:input-topic-name",
                "arn:aws-cn:sns:us-east-1:111122223333:output-topic-name"
            ]
        },
        {
            "Sid": "StreamingTopicUnsubscribe",
            "Effect": "Allow",
            "Action": [
                "sns:Unsubscribe"
            ],
            "Resource": [
                "arn:aws-cn:sns:us-east-1:111122223333:input-topic-name",
                "arn:aws-cn:sns:us-east-1:111122223333:output-topic-name"
            ]
        }
    ]
}
```

Execution Role Requirements for Custom Task Types

If you want to create a custom labeling workflow, add the following statement to an execution role policy like the ones found in Built-In Task Types (Non-streaming) Execution Role Requirements or Built-In Task Types (Streaming) Execution Role Requirements.

This policy gives the execution role permission to `Invoke` your pre-annotation and post-annotation Lambda functions.

```
{
    "Sid": "LambdaFunctions",
    "Effect": "Allow",
    "Action": [
        "lambda:InvokeFunction"
    ],
    "Resource": [
        "arn:aws:lambda:<region>:<account-id>:function:<pre-annotation-lambda-name>",
        "arn:aws:lambda:<region>:<account-id>:function:<post-annotation-lambda-name>"
    ]
}
```

Automated Data Labeling Permission Requirements

If you want to create a labeling job with automated data labeling enabled, you must 1) add one policy to the IAM policy attached to the execution role and 2) update the trust policy of the execution role.

The following statement allows the IAM execution role to be passed to SageMaker AI so that it can be used to run the training and inference jobs used for active learning and automated data labeling respectively. Add this statement to an execution role policy like the ones found in Built-In Task Types (Non-streaming) Execution Role Requirements or Built-In Task Types (Streaming) Execution Role Requirements. Replace *arn:aws:iam::<account-number>:role/<role-name>* with the execution role ARN. You can find your IAM role ARN in the IAM console under **Roles**.

```
{
    "Effect": "Allow",
    "Action": [
        "iam:PassRole"
    ],
    "Resource": "arn:aws:iam::<account-number>:role/<execution-role-name>",
    "Condition": {
        "StringEquals": {
            "iam:PassedToService": [
                "sagemaker.amazonaws.com"
            ]
        }
    }
}
```

The following statement allows SageMaker AI to assume the execution role to create and manage the SageMaker training and inference jobs. This policy must be added to the trust relationship of the execution role. To learn how to add or modify an IAM role trust policy, see Modifying a role in the IAM User Guide.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Principal": {"Service": "sagemaker.amazonaws.com" },
        "Action": "sts:AssumeRole"
```

```
    }
}
```

Encrypt Output Data and Storage Volume with Amazon KMS

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use Amazon Key Management Service (Amazon KMS) to encrypt output data from a labeling job by specifying a customer managed key when you create the labeling job. If you use the API operation `CreateLabelingJob` to create a labeling job that uses automated data labeling, you can also use a customer managed key to encrypt the storage volume attached to the ML compute instances to run the training and inference jobs.

This section describes the IAM policies you must attach to your customer managed key to enable output data encryption and the policies you must attach to your customer managed key and execution role to use storage volume encryption. To learn more about these options, see Output Data and Storage Volume Encryption.

Encrypt Output Data using KMS

If you specify an Amazon KMS customer managed key to encrypt output data, you must add an IAM policy similar to the following to that key. This policy gives the IAM execution role that you use to create your labeling job permission to use this key to perform all of the actions listed in `"Action"`. To learn more about these actions, see Amazon KMS permissions in the Amazon Key Management Service Developer Guide.

To use this policy, replace the IAM service-role ARN in `"Principal"` with the ARN of the execution role you use to create the labeling job. When you create a labeling job in the console, this is the role you specify for **IAM Role** under the **Job overview** section. When you create a labeling job using `CreateLabelingJob`, this is ARN you specify for `RoleArn`.

```
{
    "Sid": "AllowUseOfKmsKey",
```

```
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::111122223333:role/service-role/example-role"
    },
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
    ],
    "Resource": "*"
}
```

Encrypt Automated Data Labeling ML Compute Instance Storage Volume

If you specify a `VolumeKmsKeyId` to encrypt the storage volume attached to the ML compute instance used for automated data labeling training and inference, you must do the following:

- Attach permissions described in Encrypt Output Data using KMS to the customer managed key.
- Attach a policy similar to the following to the IAM execution role you use to create your labeling job. This is the IAM role you specify for `RoleArn` in `CreateLabelingJob`. To learn more about the `"kms:CreateGrant"` action that this policy permits, see `CreateGrant` in the Amazon Key Management Service API Reference.

JSON

```
{
"Version":"2012-10-17",
"Statement":
 [
   {
    "Effect": "Allow",
    "Action": [
       "kms:CreateGrant"
    ],
    "Resource": "*"
  }
]
}
```

To learn more about Ground Truth storage volume encryption, see Use Your KMS Key to Encrypt Automated Data Labeling Storage Volume (API Only).

Using Amazon SageMaker Ground Truth in an Amazon Virtual Private Cloud

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

With Amazon Virtual Private Cloud (Amazon VPC) you can launch Amazon resources in a logically isolated virtual network that you define. Ground Truth supports running labeling jobs inside an Amazon VPC instead of connecting over the internet. When you launch a labeling job in an Amazon VPC, communication between your VPC and Ground Truth is conducted entirely and securely within the Amazon network.

This guide shows how you can use Ground Truth in an Amazon VPC in the following ways:

1. Run an Amazon SageMaker Ground Truth Labeling Job in an Amazon Virtual Private Cloud
2. Use Amazon VPC Mode from a Private Worker Portal

Run an Amazon SageMaker Ground Truth Labeling Job in an Amazon Virtual Private Cloud

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Ground Truth supports the following functionalities in Amazon VPC.

- You can use Amazon S3 bucket policies to control access to buckets from specific Amazon VPC endpoints, or specific VPCs. If you launch a labeling job and your input data is located in an Amazon S3 bucket that is restricted to users in your VPC, you can add a bucket policy to also grant a Ground Truth endpoint permission to access the bucket. To learn more, see Allow Ground Truth to Access VPC Restricted Amazon S3 Buckets.

- You can launch an automated data labeling job in your VPC. You use a VPC configuration to specify VPC subnets and security groups. SageMaker AI uses this configuration to launch the training and inference jobs used for automated data labeling in your VPC. To learn more, see Create an Automated Data Labeling Job in a VPC.

You may want to use these options in any of the following ways.

- You can use both of these methods to launch a labeling job using a VPC-protected Amazon S3 bucket with automated data labeling enabled.
- You can launch a labeling job using any built-in task type using a VPC-protected bucket.
- You can launch a custom labeling workflow using a VPC-protected bucket. Ground Truth interacts with your pre-annotation and post-annotation Lambda functions using an Amazon PrivateLink endpoint.

We recommend that you review Prerequisites for running a Ground Truth labeling job in a VPC before you create a labeling job in an Amazon VPC.

Prerequisites for running a Ground Truth labeling job in a VPC

Review the following prerequisites before you create a Ground Truth labeling job in an Amazon VPC.

- If you are a new user of Ground Truth, review Getting started to learn how to create a labeling job.
- If your input data is located in a VPC-protected Amazon S3 bucket, your workers must access the worker portal from your VPC. VPC based labeling jobs require the use of a private work team. To learn more about creating a private work team, see Use a Private Workforce.
- The following prerequisites are specific to launching a labeling job in your VPC.
  - Use the instructions in Create an Amazon S3 VPC Endpoint. Training and inference containers used in the automated data labeling workflow use this endpoint to communicate with your buckets in Amazon S3.
  - Review Automate Data Labeling to learn more about this feature. Note that automated data labeling is supported for the following built-in task types: Image Classification (Single Label), Image Semantic Segmentation, Bounding Box, and Text Classification (Single Label). Streaming labeling jobs do not support automated data labeling.

- Review the Ground Truth Security and Permissions section and ensure that you have met the following conditions.
  - The user creating the labeling job has all necessary permissions
  - You have created an IAM execution role with required permissions. If you do not require fine-tuned permissions for your use case, we recommend you use the IAM managed policies described in Grant General Permissions To Get Started Using Ground Truth.
  - Allow your VPC to have access to the `sagemaker-labeling-data-region` and `sm-bxcb-region-saved-task-states` S3 buckets. These are system owned regionalized S3 buckets that are accessed from worker portal when worker is working on a task. We use these buckets to interact with system managed data.

Allow Ground Truth to Access VPC Restricted Amazon S3 Buckets

The following sections provide details about the permissions Ground Truth requires to launch labeling jobs using Amazon S3 buckets that have access restricted to your VPC and VPC endpoints. To learn how to restrict access to an Amazon S3 bucket to a VPC, see Controlling access from VPC endpoints with bucket policies in the Amazon Simple Storage Service User Guide guide. To learn how to add a policy to an S3 bucket, see Adding a bucket policy using the Amazon S3 console.

> **Note**
>
> Modifying policies on existing buckets can cause `IN_PROGRESS` Ground Truth jobs to fail. We recommend you start new jobs using a new bucket. If you want to continue using the same bucket, you can do one of the following.
>
> - Wait for an `IN_PROGRESS` job to finish.
> - Terminate the job using the console or the Amazon CLI.

You can restrict Amazon S3 bucket access to users in your VPC using an Amazon PrivateLink endpoint. For example, the following S3 bucket policy allows access to a specific bucket, *<bucket-name>*, from *<vpc>* and the endpoint *<vpc-endpoint>* only. When you modify this policy, you must replace all *red-italized text* with your resources and specifications.

Note

The following policy *denies* all entities *other than* users within a VPC to perform the actions listed in `Action`. If you do not include actions in this list, they are still accessible to any entity that has access to this bucket and permission to perform those actions. For example, if a user has permission to perform `GetBucketLocation` on your Amazon S3 bucket, the policy below does not restrict the user from performing this action outside of your VPC.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "Policy1415115909152",
    "Statement": [
        {
            "Sid": "AccessToSpecificVPCEOnly",
            "Action": [
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Effect": "Deny",
            "Resource": [
                "arn:aws-cn:s3:::amzn-s3-demo-bucket",
                "arn:aws-cn:s3:::amzn-s3-demo-bucket/*"
            ],
            "Condition": {
                "StringNotEquals": {
                    "aws:sourceVpce": [
                        "vpce-12345678",
                        "vpce-12345678901234567"
                    ]
                }
            }
        }
    ]
}
```

Ground Truth must be able to perform the following Amazon S3 actions on the S3 buckets you use to configure the labeling job.

```
"s3:AbortMultipartUpload",
"s3:GetObject",
"s3:PutObject",
"s3:ListBucket",
"s3:GetBucketLocation"
```

You can do this by adding a Ground Truth endpoint to the bucket policy like the one previously mentioned. The following table includes Ground Truth service endpoints for each Amazon Region. Add an endpoint in the same Amazon Region you use to run your labeling job to your bucket policy.

Amazon Region	Ground Truth endpoint
us-east-2	vpce-02569ba1c40aad0bc
us-east-1	vpce-08408e335ebf95b40
us-west-2	vpce-0ea07aa498eb78469
ca-central-1	vpce-0d46ea4c9ff55e1b7
eu-central-1	vpce-0865e7194a099183d
eu-west-2	vpce-0bccd56798f4c5df0
eu-west-1	vpce-0788e7ed8628e595d
ap-south-1	vpce-0d7fcda14e1783f11
ap-southeast-2	vpce-0b7609e6f305a77d4
ap-southeast-1	vpce-0e7e67b32e9efed27
ap-northeast-2	vpce-007893f89e05f2bbf
ap-northeast-1	vpce-0247996a1a1807dbd

For example, the following policy restricts `GetObject` and `PutObject` actions on:

- An Amazon S3 bucket to users in a VPC (`<vpc>`)

- A VPC endpoint (*<vpc-endpoint>*)
- A Ground Truth service endpoint (*<ground-truth-endpoint>*)

JSON

```
{
    "Version":"2012-10-17",
    "Id": "1",
    "Statement": [
        {
            "Sid": "DenyAccessFromNonGTandCustomerVPC",
            "Effect": "Deny",
            "Principal": "*",
            "Action": [
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws-cn:s3:::bucket-name",
                "arn:aws-cn:s3:::bucket-name/*"
            ],
            "Condition": {
              "StringNotEquals": {
                "aws:SourceVpc": "vpc-12345678",
                "aws:sourceVpce": [
                  "vpce-12345678",
                  "vpce-12345678"
                ]
             }
           }
        }
    ]
}
```

If you want a user to have permission to launch a labeling job using the Ground Truth console, you must also add the user's ARN to the bucket policy using the `aws:PrincipalArn` condition. This user must also have permission to perform the following Amazon S3 actions on the bucket you use to launch the labeling job.

```
"s3:GetObject",
"s3:PutObject",
"s3:ListBucket",
"s3:GetBucketCors",
"s3:PutBucketCors",
"s3:ListAllMyBuckets",
```

The following code is an example of a bucket policy that restricts permission to perform the actions listed in `Action` on the S3 bucket `<bucket-name>` to the following.

- *<role-name>*
- The VPC endpoints listed in `aws:sourceVpce`
- Users within the VPC named *<vpc>*

```
{
    "Version": "2012-10-17",
    "Id": "1",
    "Statement": [
        {
            "Sid": "DenyAccessFromNonGTandCustomerVPC",
            "Effect": "Deny",
            "Principal": "*",
            "Action": [
                "s3:GetObject",
                "s3:PutObject"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket-name>/*",
                "arn:aws:s3:::<bucket-name>"
            ],
            "Condition": {
                "StringNotEquals": {
                    "aws:sourceVpce": [
                        "<vpc-endpoint>",
                        "<ground-truth-endpoint>"
                    ],
                    "aws:PrincipalArn": "arn:aws:iam::<aws-account-id>:role/<role-
name>",
                    "aws:SourceVpc": "<vpc>"
                }
            }
```

```
        }
    ]
}
```

> **Note**
>
> The Amazon VPC interface endpoints and the protected Amazon S3 buckets you use for input and output data must be located in the same Amazon Region that you use to create the labeling job.

After you have granted Ground Truth permission to access your Amazon S3 buckets, you can use one of the topics in Create a Labeling Job to launch a labeling job. Specify the VPC-restricted Amazon S3 buckets for your input and output data buckets.

Create an Automated Data Labeling Job in a VPC

To create an automated data labeling job using an Amazon VPC, you provide a VPC configuration using the Ground Truth console or `CreateLabelingJob` API operation. SageMaker AI uses the subnets and security groups you provide to launch the training and inferences jobs used for automated labeling.

> **Important**
>
> Before you launch an automated data labeling job with a VPC configuration, make sure you have created an Amazon S3 VPC endpoint using the VPC you want to use for the labeling job. To learn how, see Create an Amazon S3 VPC Endpoint.
> Additionally, if you create an automated data labeling job using a VPC-restricted Amazon S3 bucket, you must follow the instructions in Allow Ground Truth to Access VPC Restricted Amazon S3 Buckets to give Ground Truth permission to access the bucket.

Use the following procedures to learn how to add a VPC configuration to your labeling job request.

Add a VPC configuration to an automated data labeling job (console):

1. Follow the instructions in Create a Labeling Job (Console) and complete each step in the procedure, up to step 15.
2. In the **Workers** section, select the checkbox next to **Enable automated data labeling**.

3. Maximize the **VPC configuration** section of the console by selecting the arrow.
4. Specify the **Virtual private cloud (VPC)** that you want to use for your automated data labeling job.
5. Choose the dropdown list under **Subnets** and select one or more subnets.
6. Choose the dropdown list under **Security groups** and select one or more groups.
7. Complete all remaining steps of the procedure in Create a Labeling Job (Console).

Add a VPC configuration to an automated data labeling job (API):

To configure a labeling job using the Ground Truth API operation, `CreateLabelingJob`, follow the instructions in Create an Automated Data Labeling Job (API) to configure your request. In addition to the parameters described in this documentation, you must include a `VpcConfig` parameter in `LabelingJobResourceConfig` to specify one or more subnets and security groups using the following schema.

```
"LabelingJobAlgorithmsConfig": {
      "InitialActiveLearningModelArn": "string",
      "LabelingJobAlgorithmSpecificationArn": "string",
      "LabelingJobResourceConfig": {
         "VolumeKmsKeyId": "string",
         "VpcConfig": {
            "SecurityGroupIds": [ "string" ],
            "Subnets": [ "string" ]
         }
      }
}
```

The following is an example of an Amazon Python SDK (Boto3) request to create an automated data labeling job in the US East (N. Virginia) Region using a private workforce. Replace all *red-italicized text* with your labeling job resources and specifications. To learn more about the `CreateLabelingJob` operation, see the Create a Labeling Job (API) tutorial and CreateLabelingJob API documentation.

```
import boto3
client = boto3.client(service_name='sagemaker')

response = client.create_labeling_job(
    LabelingJobName="example-labeling-job",
    LabelAttributeName="label",
```

```
    InputConfig={
        'DataSource': {
            'S3DataSource': {
                'ManifestS3Uri': "s3://bucket/path/manifest-with-input-data.json"
            }
        }
    },
    "LabelingJobAlgorithmsConfig": {
      "LabelingJobAlgorithmSpecificationArn": "arn:aws:sagemaker:us-
east-1:027400017018:labeling-job-algorithm-specification/tasktype",
      "LabelingJobResourceConfig": {
         "VpcConfig": {
            "SecurityGroupIds": [ "sg-01233456789", "sg-987654321" ],
            "Subnets": [ "subnet-e0123456", "subnet-e7891011" ]
         }
      }
    },
    OutputConfig={
        'S3OutputPath': "s3://bucket/path/file-to-store-output-data",
        'KmsKeyId': "string"
    },
    RoleArn="arn:aws:iam::*:role/*",
    LabelCategoryConfigS3Uri="s3://bucket/path/label-categories.json",
    StoppingConditions={

)
```

Use Amazon VPC Mode from a Private Worker Portal

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

To restrict worker portal access to labelers working inside of your Amazon VPC, you can add a VPC configuration when you create a Ground Truth private workforce. You can also add a VPC configuration to an existing private workforce. Ground Truth automatically creates VPC interface endpoints in your VPC and sets up Amazon PrivateLink between your VPC endpoint and the Ground Truth services. The worker portal URL associated with the workforce can be accessed from your VPC. The worker portal URL can also be accessed from public internet until you set the restriction on the public internet. When you delete the workforce or remove the VPC configuration from your workforce, Ground Truth automatically deletes the VPC endpoints associated with the workforce.

> **Note**
>
> There can be only one VPC supported for a workforce.

Point Cloud and video tasks do not support loading through a VPC.

The guide demonstrates how to complete the necessary steps to add and delete an Amazon VPC configuration to your workforce, and satisfy the prerequisites.

Prerequisites

To run a Ground Truth labeling job in Amazon VPC, review the following prerequisites.

- You have an Amazon VPC configured that you can use. If you have not configured a VPC, follow these instructions for creating a VPC.
- Depending on how a Worker Task Template is written, labeling data stored in an Amazon S3 bucket may be accessed directly from Amazon S3 during labeling tasks. In these cases, the VPC network must be configured to allow traffic from the device used by the human labeler to the S3 bucket containing labeling data.
- Follow View and update DNS attributes for your VPC to enable DNS hostnames and DNS resolution for your VPC.

> **Note**
>
> There are two ways to configure your VPC for your workforce. You can do this through the console or the Amazon SageMaker AI CLI.

Using the SageMaker AI console to manage a VPC config

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

You can use the SageMaker AI console to add or remove a VPC configuration. You can also delete an existing workforce.

Adding a VPC configuration to your workforce

Create a private workforce

- Create a private workforce using Amazon Cognito

- Create a private workforce using OpenID Connect (OIDC) Identity Provider(IdP).

After you have created your private workforce, add a VPC configuration to it.

1. Navigate to Amazon SageMaker Runtime in your console.
2. Select **Labeling workforces** in the left panel.
3. Select **Private** to access your private workforce. After your **Workforce status** is **Active**, select **Add** next to **VPC**.
4. When you are prompted to configure your VPC, provide the following:
   a. Your **VPC**
   b. **Subnets**
      i. Ensure that your VPC has an existing subnet
   c. **Security groups**
      i.
      > **Note**
      >
      > You cannot select more than 5 security groups.
   d. After filling in this information, choose **Confirm**.
5. After you choose **Confirm**, you are redirected back to the **Private** page under **Labeling workforces**. You should see a green banner at the top that reads **Your private workforce update with VPC configuration was successfully initialized.** The workforce status is **Updating**. Next to the **Delete workforce** button is the **Refresh** button, which can be used to retrieve the latest **Workforce status**. After the workforce status has changed to **Active**, the VPC endpoint ID is updated as well.

Removing a VPC configuration from your workforce

Use the following information to remove a VPC configuration from your workforce using the console.

1. Navigate to Amazon SageMaker Runtime in your console.
2. Select **Labeling workforces** in the left panel.
3. Find and select your workforce.
4. Under **Private workforce summary**, find **VPC** and choose **Remove** next to it.

5. Select **Remove**.

Deleting a workforce through the console

If you delete a workforce, you should not have any teams associated with it. You can delete a workforce only if the workforce status is **Active** or **Failed**.

Use the following information to delete a workforce using the console.

1. Navigate to Amazon SageMaker Runtime in your console.
2. Select **Labeling workforces** in the left panel.
3. Find and select your workforce.
4. Choose **Delete workforce**.
5. Choose **Delete**.

Using the SageMaker AI Amazon API to manage a VPC config

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Use the following sections to learn more about managing a VPCs configuration, while maintaining the right level of access to the work team.

Create a workforce with a VPC configuration

If the account already has a workforce, then you must delete it first. You can also update the workforce with VPC configuration.

```
aws sagemaker create-workforce --cognito-config '{"ClientId": "app-client-
id","UserPool": "Pool_ID",}' --workforce-vpc-config \
" {\"VpcId\": \"vpc-id\", \"SecurityGroupIds\": [\"sg-0123456789abcdef0\"], \"Subnets
\": [\"subnet-0123456789abcdef0\"]}" --workforce-name workforce-name
{
    "WorkforceArn": "arn:aws:sagemaker:us-west-2:xxxxxxxxx:workforce/workforce-name"
```

```
}
```

Describe the workforce and make sure the status is `Initializing`.

```
aws sagemaker describe-workforce --workforce-name workforce-name
{
    "Workforce": {
        "WorkforceName": "workforce-name",
        "WorkforceArn": "arn:aws:sagemaker:us-west-2:xxxxxxxxx:workforce/workforce-
name",
        "LastUpdatedDate": 1622151252.451,
        "SourceIpConfig": {
            "Cidrs": []
        },
        "SubDomain": "subdomain.us-west-2.sagamaker.aws.com",
        "CognitoConfig": {
            "UserPool": "Pool_ID",
            "ClientId": "app-client-id"
        },
        "CreateDate": 1622151252.451,
        "WorkforceVpcConfig": {
            "VpcId": "vpc-id",
            "SecurityGroupIds": [
                "sg-0123456789abcdef0"
            ],
            "Subnets": [
                "subnet-0123456789abcdef0"
            ]
        },
        "Status": "Initializing"
    }
}
```

Navigate to the Amazon VPC console. Select **Endpoints** from the left panel. There should be two VPC endpoints created in your account.

Adding a VPC configuration your workforce

Update a non-VPC private workforce with a VPC configuration using the following command.

```
aws sagemaker update-workforce --workforce-name workforce-name\
--workforce-vpc-config "{\"VpcId\": \"vpc-id\", \"SecurityGroupIds\":
 [\"sg-0123456789abcdef0\"], \"Subnets\": [\"subnet-0123456789abcdef0\"]}"
```

Describe the workforce and make sure the status is `Updating`.

```
aws sagemaker describe-workforce --workforce-name workforce-name
{
    "Workforce": {
        "WorkforceName": "workforce-name",
        "WorkforceArn": "arn:aws:sagemaker:us-west-2:xxxxxxxxx:workforce/workforce-
name",
        "LastUpdatedDate": 1622151252.451,
        "SourceIpConfig": {
            "Cidrs": []
        },
        "SubDomain": "subdomain.us-west-2.sagamaker.aws.com",
        "CognitoConfig": {
            "UserPool": "Pool_ID",
            "ClientId": "app-client-id"
        },
        "CreateDate": 1622151252.451,
        "WorkforceVpcConfig": {
            "VpcId": "vpc-id",
            "SecurityGroupIds": [
                "sg-0123456789abcdef0"
            ],
            "Subnets": [
                "subnet-0123456789abcdef0"
            ]
        },
        "Status": "Updating"
    }
}
```

Navigate to your Amazon VPC console. Select **Endpoints** from the left panel. There should be two VPC endpoints created in your account.

Removing a VPC configuration from your workforce

Update a VPC private workforce with an empty VPC configuration to remove VPC resources.

```
aws sagemaker update-workforce --workforce-name workforce-name\
--workforce-vpc-config "{}"
```

Describe the workforce and make sure the status is `Updating`.

```
aws sagemaker describe-workforce --workforce-name workforce-name
{
    "Workforce": {
        "WorkforceName": "workforce-name",
        "WorkforceArn": "arn:aws:sagemaker:us-west-2:xxxxxxxxx:workforce/workforce-
name",
        "LastUpdatedDate": 1622151252.451,
        "SourceIpConfig": {
            "Cidrs": []
        },
        "SubDomain": "subdomain.us-west-2.sagamaker.aws.com",
        "CognitoConfig": {
            "UserPool": "Pool_ID",
            "ClientId": "app-client-id"
        },
        "CreateDate": 1622151252.451,
        "Status": "Updating"
    }
}
```

Naviagate to your Amazon VPC console. Select **Endpoints** from the left panel. The two VPC endpoints should be deleted.

Restrict public access to the worker portal while maintaining access through a VPC

The workers in a VPC or non-VPC worker portal are be able to see the labeling job tasks assigned to them. The assignment comes from assigning workers in a work team through OIDC groups. It is the customer's responsibility to restrict the access to their public worker portal by setting the `sourceIpConfig` in their workforce.

> **Note**
>
> You can restrict access to the worker portal only through the SageMaker API. This cannot be done through the console.

Use the following command to restrict public access to the worker portal.

```
aws sagemaker update-workforce --region us-west-2 \
--workforce-name workforce-demo --source-ip-config '{"Cidrs":["10.0.0.0/16"]}'
```

After the `sourceIpConfig` is set on the workforce, the workers can access the worker portal in VPC but not through public internet.

> **Note**
>
> You can not set the `sourceIP` restriction for worker portal in VPC.

Output Data and Storage Volume Encryption

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

With Amazon SageMaker Ground Truth, you can label highly sensitive data, stay in control of your data, and employ security best practices. While your labeling job is running, Ground Truth encrypts data in transit and at rest. Additionally, you can use Amazon Key Management Service (Amazon KMS) with Ground Truth to do the following:

- Use a customer managed key to encrypt your output data.
- Use Amazon KMS customer managed key with your automated data labeling job to encrypt the storage volume attached to the compute instance used for model training and inference.

Use the topics on this page to learn more about these Ground Truth security features.

Use Your KMS Key to Encrypt Output Data

Optionally, you can provide an Amazon KMS customer managed key when you create a labeling job, which Ground Truth uses to encrypt your output data.

If you don't provide a customer managed key, Amazon SageMaker AI uses the default Amazon managed key for Amazon S3 for your role's account to encrypt your output data.

If you provide a customer managed key, you must add the required permissions to the key described in Encrypt Output Data and Storage Volume with Amazon KMS. When you use the API operation `CreateLabelingJob`, you can specify your customer managed key ID using the parameter `KmsKeyId`. See the following procedure to learn how to add a customer managed key when you create a labeling job using the console.

To add an Amazon KMS key to encrypt output data (console):

1. Complete the first 7 steps in Create a Labeling Job (Console).
2. In step 8, select the arrow next to **Additional configuration** to expand this section.
3. For **Encryption key**, select the Amazon KMS key that you want to use to encrypt output data.
4. Complete the rest of steps in Create a Labeling Job (Console) to create a labeling job.

Use Your KMS Key to Encrypt Automated Data Labeling Storage Volume (API Only)

When you create a labeling job with automated data labeling using the `CreateLabelingJob` API operation, you have the option to encrypt the storage volume attached to the ML compute instances that run the training and inference jobs. To add encryption to your storage volume, use the parameter `VolumeKmsKeyId` to input an Amazon KMS customer managed key. For more information about this parameter, see `LabelingJobResourceConfig`.

If you specify a key ID or ARN for `VolumeKmsKeyId`, your SageMaker AI execution role must include permissions to call `kms:CreateGrant`. To learn how to add this permission to an execution role, see Create a SageMaker AI Execution Role for a Ground Truth Labeling Job.

> **Note**
>
> If you specify an Amazon KMS customer managed key when you create a labeling job in the console, that key is *only* used to encrypt your output data. It is not used to encrypt the storage volume attached to the ML compute instances used for automated data labeling.

Workforce Authentication and Restrictions

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

Ground Truth enables you to use your own private workforce to work on labeling jobs. A *private workforce* is an abstract concept which refers to a set of people who work for you. Each labeling job is created using a work team, composed of workers in your workforce. Ground Truth supports private workforce creation using Amazon Cognito.

A Ground Truth workforce maps to a Amazon Cognito user pool. A Ground Truth work team maps to a Amazon Cognito user group. Amazon Cognito manages the worker authentication. Amazon Cognito supports Open ID connection (OIDC) and customers can set up Amazon Cognito federation with their own identity provider (IdP).

Ground Truth only allows one workforce per account per Amazon Region. Each workforce has a dedicated Ground Truth work portal login URL.

You can also restrict workers to a Classless Inter-Domain Routing (CIDR) block/IP address range. This means annotators must be on a specific network to access the annotation site. You can add up to ten CIDR blocks for one workforce. To learn more, see Private workforce management using the Amazon SageMaker API.

To learn how you can create a private workforce, see Create a Private Workforce (Amazon Cognito).

Restrict access to workforce types

Amazon SageMaker Ground Truth work teams fall into one of two workforce types: private and vendor. To restrict user access to a specific work team using one of these types or the work team

ARN, use the `sagemaker:WorkteamType` and/or the `sagemaker:WorkteamArn` condition keys. For the `sagemaker:WorkteamType` condition key, use string condition operators. For the `sagemaker:WorkteamArn` condition key, use Amazon Resource Name (ARN) condition operators. If the user attempts to create a labeling job with a restricted work team, SageMaker AI returns an access denied error.

The policies below demonstrate different ways to use the `sagemaker:WorkteamType` and `sagemaker:WorkteamArn` condition keys with appropriate condition operators and valid condition values.

The following example uses the `sagemaker:WorkteamType` condition key with the `StringEquals` condition operator to restrict access to a work team. It accepts condition values in the following format: *`workforcetype`*`-crowd`, where *`workforcetype`* can equal `private` or `vendor`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "sagemaker:WorkteamType": "private-crowd"
                }
            }
        }
    ]
}
```

The following policies show how to restrict access to a work team using the `sagemaker:WorkteamArn` condition key. The first shows how to use it with a valid IAM regex-variant of the work team ARN and the `ArnLike` condition operator. The second shows how to use it with the `ArnEquals` condition operator and the work team ARN.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "ArnLike": {
                    "sagemaker:WorkteamArn": "arn:aws-cn:sagemaker:*:*:workteam/
private-crowd/*"
                }
            }
        }
    ]
}
```

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "RestrictWorkteamType",
            "Effect": "Deny",
            "Action": "sagemaker:CreateLabelingJob",
            "Resource": "*",
            "Condition": {
                "ArnEquals": {
                    "sagemaker:WorkteamArn": "arn:aws-cn:sagemaker:us-
east-1:123456789012:workteam/private-crowd/private-workteam-name"
                }
            }
        }
    ]
}
```

Monitor Labeling Job Status

> **Note**
>
> Amazon SageMaker Ground Truth is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Ground Truth, but we do not plan to introduce new features.

To monitor the status of your labeling jobs, you can set up an Amazon CloudWatch Events (CloudWatch Events) rule for Amazon SageMaker Ground Truth (Ground Truth) to send an event to CloudWatch Events when a labeling job status changes to `Completed`, `Failed`, or `Stopped` or when a worker accepts, declines, submits, or returns a task.

Once you create a rule, you can add a *target* to it. CloudWatch Events uses this target to invoke another Amazon service to process the event. For example, you can create a target using a Amazon Simple Notification Service (Amazon SNS) topic to send a notification to your email when a labeling job status changes.

Prerequisites:

To create a CloudWatch Events rule, you will need an Amazon Identity and Access Management (IAM) role with an events.amazonaws.com trust policy attached. The following is an example of an events.amazonaws.com trust policy.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "events.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
```

```
    }
  ]
}
```

Topics

- Send Events to CloudWatch Events
- Set Up a Target to Process Events
- Labeling Job Expiration
- Declining Tasks

Send Events to CloudWatch Events

To configure a CloudWatch Events rule to get status updates, or *events*, for your Ground Truth labeling jobs, use the Amazon Command Line Interface (Amazon CLI) `put-rule` command. You can filter events that are sent to your rule by status change. For example, you can create a rule that notifies you only if a labeling job status changes to `Completed`. When using the `put-rule` command, specify the following to receive labeling job statuses:

- `\"source\":[\"aws.sagemaker\"]`
- `\"detail-type\":[\"SageMaker Ground Truth Labeling Job State Change\"]`

To configure a CloudWatch Events rule to watch for all status changes, use the following command and replace the placeholder text. For example, replace *"GTLabelingJobStateChanges"* with a unique CloudWatch Events rule name and *"arn:aws:iam::111122223333:role/MyRoleForThisRule"* with the Amazon Resource Number (ARN) of an IAM role with an events.amazonaws.com trust policy attached.

```
aws events put-rule --name "GTLabelingJobStateChanges"
    --event-pattern "{\"source\":[\"aws.sagemaker\"],\"detail-type\":[\"SageMaker
 Ground Truth Labeling Job State Change\"]}"
    --role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"
    --region "region"
```

To filter by job status, use the `\"detail\":{\"LabelingJobStatus\":[\"Status\"]}}"` syntax. Valid values for *Status* are `Completed`, `Failed`, and `Stopped`.

The following example creates a CloudWatch Events rule that notifies you when a labeling job in us-west-2 (Oregon) changes to `Completed`.

```
aws events put-rule --name "LabelingJobCompleted"
    --event-pattern "{\"source\":[\"aws.sagemaker\"],\"detail-type\":[\"SageMaker
 Ground Truth Labeling Job State Change\"], \"detail\":{\"LabelingJobStatus\":
[\"Completed\"]}}"
    --role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"
    --region us-west-2
```

The following example creates a CloudWatch Events rule that notifies you when a labeling job in us-east-1 (Virginia) changes to `Completed` or `Failed`.

```
aws events put-rule --name "LabelingJobCompletedOrFailed"
    --event-pattern "{\"source\":[\"aws.sagemaker\"],\"detail-type\":[\"SageMaker
 Ground Truth Labeling Job State Change\"], \"detail\":{\"LabelingJobStatus\":
[\"Completed\", \"Failed\"]}}"
    --role-arn "arn:aws:iam::111122223333:role/MyRoleForThisRule"
    --region us-east-1
```

To learn more about the `put-rule` request, see Event Patterns in CloudWatch Events in the *Amazon CloudWatch Events User Guide*.

Set Up a Target to Process Events

After you have created a rule, events similar to the following are sent to CloudWatch Events. In this example, the labeling job `test-labeling-job`'s status changed to `Completed`.

```
{
    "version": "0",
    "id": "111e1111-11d1-111f-b111-1111b11dcb11",
    "detail-type": "SageMaker Ground Truth Labeling Job State Change",
    "source": "aws.sagemaker",
    "account": "111122223333",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:sagemaker:us-east-1:111122223333:labeling-job/test-labeling-job"
    ],
    "detail": {
        "LabelingJobStatus": "Completed"
```

```
    }
}
```

To process events, you need to set up a target. For example, if you want to receive an email when your labeling job status changes, use a procedure in Setting Up Amazon SNS Notifications in the *Amazon CloudWatch User Guide* to set up an Amazon SNS topic and subscribe your email to it. Once you have create a topic, you can use it to create a target.

To add a target to your CloudWatch Events rule

1. Open the CloudWatch console: https://console.amazonaws.cn/cloudwatch/home
2. In the navigation pane, choose **Rules**.
3. Choose the rule that you want to add a target to.
4. Choose **Actions**, and then choose **Edit**.
5. Under **Targets**, choose **Add Target** and choose the Amazon service you want to act when a labeling job status change event is detected.
6. Configure your target. For instructions, see the topic for configuring a target in the Amazon documentation for that service.
7. Choose **Configure details**.
8. For **Name**, enter a name and, optionally, provide details about the purpose of the rule in **Description**.
9. Make sure that the check box next to **State** is selected so that your rule is listed as **Enabled**.
10. Choose **Update rule**.

Labeling Job Expiration

If your labeling job is not completed after 30 days, it will expire. If your labeling job expires, you can chain the job to create a new labeling job that will only send unlabeled data to workers. For more information, and to learn how to create a labeling job using chaining, see Chaining labeling jobs.

Declining Tasks

Workers are able to decline tasks.

Workers decline a task if the instructions are not clear, input data is not displaying correctly, or if they encounter some other issue with the task. If the number of workers per dataset object

(`NumberOfHumanWorkersPerDataObject`) decline the task, the data object is marked as expired and will not be sent to additional workers.

Workforces

This feature is not available in the China Regions.

A *workforce* is the group of workers that you have selected to label your dataset. You can choose a vendor-managed workforce or create your own private workforce to label or review your dataset. Whichever workforce type you choose, Amazon SageMaker AI takes care of sending tasks to workers.

When you use a private workforce, you also create *work teams*, a group of workers from your workforce that are assigned to specific *jobs*— Amazon SageMaker Ground Truth labeling jobs or Amazon Augmented AI human review tasks. You can have multiple work teams and can assign one or more work teams to each job.

You can use Amazon Cognito or your own private OpenID Connect (OIDC) Identity Provider (IdP) to manage your private workforce and work teams. For more information about the permissions required to manage your workforce this way, see Permissions required to use the Amazon SageMaker Ground Truth console.

Topics

- Subscribe to vendor workforces
- Private workforce

Subscribe to vendor workforces

You can use a vendor-managed workforce to label your data using Amazon SageMaker Ground Truth (Ground Truth) and Amazon Augmented AI (Amazon A2I). Vendors have extensive experience in providing data labeling services for the purpose of machine learning. Vendor workforces for these two services must be created and managed seperately through the Amazon SageMaker AI console.

Vendors make their services available via the Amazon Marketplace. You can find details of the vendor's services on their detail page, such as the number of workers and the hours that they work.

You can use these details to make estimates of how much the labeling job will cost and the amount of time that you can expect the job to take. Once you have chosen a vendor you subscribe to their services using the Amazon Marketplace.

A subscription is an agreement between you and the vendor. The agreement spells out the details of the agreement, such as price, schedule, or refund policy. You work directly with the vendor if there are any issues with your labeling job.

You can subscribe to any number of vendors to meet your data annotation needs. When you create a labeling job or human review worklow you can specify that the job be routed to a specific vendor.

> **Important**
>
> Before you send sensitive data to a vendor, check the vendor's security and compliance practices on their detail page and review the end user license agreement (EULA) that is part of your subscription agreement. You are responsible for ensuring that the vendor meets your compliance requirements for personal or confidential information. Do not share protected health information with this workforce.

You must use the console to subscribe to a vendor workforce. Once you have a subscription, you can use the `ListSubscribedWorkteams` operation to list your subscribed vendors.

To subscribe to a vendor workforce

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. Choose the appropriate page in the SageMaker AI console.
   - For Ground Truth labeling jobs, choose **Labeling workforces**, choose **Vendor**, and then choose **Find data labeling services**.
   - For Amazon A2I human review workflows, choose **Human review workforces**, choose **Vendor**, and then choose **Find human review services**.
3. The console opens the Amazon Web Services Marketplace with:
   - data labeling services category selected for Ground Truth
   - human review services category selected for Amazon A2I

   Here you see a list of the vendor services available for this service.

4. Choose a vendor. The Amazon Web Services Marketplace shows detailed information about the data labeling or human review service. Use this information to determine if the vendor meets your requirements for your task.
5. If the vendor meets your requirements, choose **Continue to subscribe**.
6. Review the details of the subscription. If you agree to the terms, choose **Subscribe** to complete your subscription to the service.

Private workforce

A **private workforce** is a group of workers that *you* choose. These can be employees of your company or a group of subject matter experts from your industry. For example, if the task is to label medical images, you could create a private workforce of people knowledgeable about the images in question.

Each Amazon account has access to a single private workforce per region, and the owner has the ability to create multiple **private work teams** within that workforce. A single private work team is used to complete a labeling job or human review task, or a *job*. You can assign each work team to a separate job or use a single team for multiple jobs. A single worker can be in more than one work team.

Your private workforce can either be created and managed using Amazon Cognito or your own private OpenID Connect (OIDC) Identity Provider (IdP).

If you are a new user of Amazon SageMaker Ground Truth or Amazon Augmented AI and do not require your workers to be managed with your own IdP, it is recommended that you use Amazon Cognito to create and manage your private workforce.

After you create a workforce, in addition to creating and managing work teams, you can do the following:

- Track worker performance
- Create and manage Amazon SNS topics to notify workers when labeling tasks are available
- Manage Private Workforce Access to Tasks Using IP Addresses

> **Note**
>
> Your private workforce is shared between Ground Truth and Amazon A2I. To create and manage private work teams used by Augmented AI, use the Ground Truth section of the SageMaker AI console.

- Amazon Cognito Workforces
- OIDC IdP Workforces
- Private workforce management using the Amazon SageMaker API
- Track Worker Performance Metrics
- Create the Amazon SNS topic

Amazon Cognito Workforces

Create and manage your private workforce using Amazon Cognito when you want to create your workforce using the Amazon SageMaker AI console or you don't want the overhead of managing worker credentials and authentication. When you create a private workforce with Amazon Cognito, it provides authentication, authorization, and user management for your private workers.

Topics

- Create a Private Workforce (Amazon Cognito)
- Manage a Private Workforce (Amazon Cognito)

Create a Private Workforce (Amazon Cognito)

When you use Amazon Cognito, you can create a private workforce in one of the following ways:

- Create a new workforce while you are creating your labeling job. To learn how, see Create an Amazon Cognito Workforce When Creating a Labeling Job.
- Create a new workforce before you create your labeling job. To learn how, see Create an Amazon Cognito Workforce Using the Labeling Workforces Page.
- Import an existing workforce after creating a user pool in the Amazon Cognito console. To learn how, see Create a Private Workforce (Amazon Cognito Console).

Once you create a private workforce, that workforce and all work teams and workers associated with it are available to use for all Ground Truth labeling job tasks and Amazon Augmented AI human review workflows tasks.

If you are new to Amazon SageMaker AI and want to test Ground Truth or Amazon A2I, we suggest that you create a private work team consisting of people from your organization using the console. Use this work team when creating labeling or human review workflows (flow definitions) to test your worker UI and job workflow.

Topics

- Create a Private Workforce (Amazon SageMaker AI Console)
- Create a Private Workforce (Amazon Cognito Console)

Create a Private Workforce (Amazon SageMaker AI Console)

You can create a private workforce in the Amazon SageMaker AI console in one of two ways:

- When creating a labeling job in the **Labeling jobs** page of the Amazon SageMaker Ground Truth section.
- Using the **Labeling workforces** page of the Amazon SageMaker Ground Truth section. If you are creating a private workforce for an Amazon A2I human review workflow, use this method.

Both of these methods also create a default work team containing all of the members of the workforce. This private workforce is available to use for both Ground Truth and Amazon Augmented AI jobs.

When you create a private workforce using the console, SageMaker AI uses Amazon Cognito as an identity provider for your workforce. If you want to use your own OpenID Connect (OIDC) Identity Provider (IdP) to create and manage your private workforce, you must create a workforce using the SageMaker API operation `CreateWorkforce`. To learn more, see Create a Private Workforce (OIDC IdP).

Create an Amazon Cognito Workforce When Creating a Labeling Job

If you haven't created a private workforce when you create your labeling job and you choose to use private workers, you are prompted to create a work team. This will create a private workforce using Amazon Cognito.

To create a workforce while creating a labeling job (console)

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, choose **Labeling jobs** and fill in all required fields. For instructions on how to start a labeling job, see Getting started: Create a bounding box labeling job with Ground Truth. Choose **Next**.
3. Choose **Private** for the workforce type.
4. In the **Workers** section, enter:
    a. The **Team name**.
    b. Email addresses for up to 100 workforce members. Email addresses are case sensitive. Your workers must log in using the same case used when the address was initially entered. You can add additional workforce members after the job has been created.
    c. The name of your organization. SageMaker AI uses this to customize the email sent to the workers.
    d. A contact email address for workers to report issues related to the task.

When you create the labeling job, an email is sent to each worker inviting them to join the workforce. After creating the workforce, you can add, delete, and disable workers using the SageMaker AI console or the Amazon Cognito console.

Create an Amazon Cognito Workforce Using the Labeling Workforces Page

To create and manage your private workforce using Amazon Cognito, you can use the **Labeling workforces** page. When following the instructions below, you have the option to create a private workforce by entering worker emails importing a pre-existing workforce from an Amazon Cognito user pool. To import a workforce, see Create a Private Workforce (Amazon Cognito Console).

To create a private workforce using worker emails

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, choose **Labeling workforces**.
3. Choose **Private**, then choose **Create private team**.
4. Choose **Invite new workers by email**.
5. Paste or type a list of up to 50 email addresses, separated by commas, into the email addresses box.

6. Enter an organization name and contact email.
7. Optionally, choose an SNS topic to which to subscribe the team so workers are notified by email when new Ground Truth labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.
8. Click the **Create private team** button.

After you import your private workforce, refresh the page. On the **Private workforce summary** page, you can see information about the Amazon Cognito user pool for your workforce, a list of work teams for your workforce, and a list of all of the members of your private workforce.

> **Note**
>
> If you delete all of your private work teams, you have to repeat this process to use a private workforce in that region.

Create a Private Workforce (Amazon Cognito Console)

Amazon Cognito is used to define and manage your private workforce and your work teams. It is a service that you can use to create identities for your workers and authenticate these identities with identity providers. A private workforce corresponds to a single **Amazon Cognito user pool**. Private work teams correspond to **Amazon Cognito user groups** within that user pool.

Example identity providers supported by Amazon Cognito:

- Social sign-in providers such as Facebook and Google
- OpenID Connect (OIDC) providers
- Security Assertion Markup Language (SAML) providers such as Active Directory
- The Amazon Cognito built-in identity provider

For more information, see What Is Amazon Cognito?.

To create a private workforce using Amazon Cognito, you must have an existing Amazon Cognito user pool containing at least one user group. See Tutorial: Creating a User Pool to learn how to create a user pool. See Adding Groups to a User Pool to learn how to add a user group to a pool.

Once your user pool has been created, follow the steps below to create a private workforce by importing that user pool into Amazon SageMaker AI.

To create a private workforce by importing a Amazon Cognito user pool

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, choose **Labeling workforces**.
3. Choose **Private**.
4. Choose **Create private team**. This creates a private workforce and a work team.
5. Choose **Import workers from existing Amazon Cognito user groups**.
6. Choose a user pool that you have created. User pools require a domain and an existing user group. If you get an error that the domain is missing, set it in the **Domain name** options on the **App integration** page of the Amazon Cognito console for your group.
7. Choose an app client. We recommend using a client generated by SageMaker AI.
8. Choose a user group from your pool to import its members.
9. Optionally choose an Amazon Simple Notification Service (Amazon SNS) topic to which to subscribe the team so that workers are notified by email when new labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.
10. Choose **Create private team**.

> **Important**
>
> After you create a workforce using an Amazon Cognito user pool, it should not be deleted without first deleting all work teams associated with that pool in the SageMaker AI console.

After you import your private workforce, refresh the page to see the **Private workforce summary** page. On this page, you can see information about the Amazon Cognito user pool for your workforce, a list of work teams for your workforce, and a list of all of the members of your private workforce. This workforce is now available to use in both Amazon Augmented AI and Amazon SageMaker Ground Truth for human review tasks and data labeling jobs respectively.

Manage a Private Workforce (Amazon Cognito)

After you have created a private workforce using Amazon Cognito, you can create and manage work teams using the Amazon SageMaker AI console and API operations.

You can do the following using either the SageMaker AI console or Amazon Cognito console.

- Add and delete work teams.
- Add workers to your workforce and one or more work teams.
- Disable or remove workers from your workforce and one or more workteams. If you add workers to a workforce using the Amazon Cognito console, you must use the same console to remove the worker from the workforce.

You can restrict access to tasks to workers at specific IP addresses using the SageMaker API. For more information, see Private workforce management using the Amazon SageMaker API.

Topics

- Manage a Workforce (Amazon SageMaker AI Console)
- Manage a Private Workforce (Amazon Cognito Console)

Manage a Workforce (Amazon SageMaker AI Console)

You can use the Amazon SageMaker AI console to create and manage the work teams and individual workers that make up a private workforce.

Use a work team to assign members of your private workforce to a labeling or human review *job*. When you create your workforce using the SageMaker AI console, there is a work team called **Everyone-in-private-workforce** that enables you to assign your entire workforce to a job. Because an imported Amazon Cognito user pool may contain members that you don't want to include in your work teams, a similar work team is not created for Amazon Cognito user pools.

You have two choices to create a new work team:

- You can create a work team in the SageMaker AI console and add members from your workforce to the team.
- You can create a user group by using the Amazon Cognito console and then create a work team by importing the user group. You can import more than one user group into each work team.

You manage the members of the work team by updating the user group in the Amazon Cognito console. See Manage a Private Workforce (Amazon Cognito Console) for more information.

Create a Work Team Using the SageMaker AI Console

You can create a new Amazon Cognito user group or import an existing user group using the SageMaker AI console, on the **Labeling workforces** page. For more information on creating a user group in the Amazon Cognito console, see Manage a Private Workforce (Amazon Cognito Console).

To create a work team using the SageMaker AI console

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. Choose **Labeling workforces** from the left menu.
3. Under **Private**, choose **Create private team**.
4. Under **Team details**, enter a **Team name**. The name must be unique in your account in an Amazon Region.
5. Under **Add workers**, choose a method to add workers to the team using a user group.
   - If you chose **Create a team by adding workers to a new Amazon Cognito user group**, select the workers to add to the team.
   - If you chose **Create a team by importing existing Amazon Cognito user groups**, choose the user groups that are part of the new team.
6. If you select an **SNS topic**, all workers added to the team are subscribed to the Amazon SNS topic and notified when new work items are available to the team. Select from a list of your existing Ground Truth related Amazon SNS topics or select **Create new topic** to open a topic-creation dialog.

   Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

Workers in a workteam subscribed to a topic receive notifications when a new Ground Truth labeling job for that team becomes available and when one is about to expire.

Read Create the Amazon SNS topic for more information about using Amazon SNS topic.

Subscriptions

After you have created a work team, you can see more information about the team and change or set the Amazon SNS topic to which its members are subscribed by visiting the Amazon Cognito console. If you added any team members before you subscribed the team to a topic, you need to manually subscribe those members to that topic. Read Create and manage Amazon SNS topics for your work teams for more information on creating and managing the Amazon SNS topic.

Add or Remove Workers

A *work team* is a group of workers within your workforce to whom you can assign jobs. A worker can be added to more than one work team. Once a worker has been added to a work team, that worker can be disabled or removed.

Add Workers to the Workforce

Adding a worker to the workforce enables you to add that worker to any work team within that work force.

To add workers using the private workforce summary page

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. Choose **Labeling workforces** to navigate to your private workforce summary page.
3. Choose **Private**.
4. Choose **Invite new workers**.
5. Paste or type a list of email addresses, separated by commas, into the email addresses box. You can have up to 50 email addresses in this list.

Add a Worker to a Work Team

A worker must be added to the workforce before being added to a work team. To add a worker to a work team, first navigate to the **Private workforce summary** page using the steps above.

To add a worker to a work team from the private workforce summary page

1. In the **Private teams** section, choose the team to which you want to add the workers.
2. Choose the **Workers** tab.
3. Choose **Add workers to team** and choose the boxes next to the workers that you want to add.

4. Click **Add workers to team**.

Disable and Remove a Worker from the Workforce

Disabling a worker stops the worker from receiving a job. This action does not remove the worker from the workforce, or from any work team with which the worker is associated. To disable or remove a worker from a work team, first navigate to the private workforce summary page using the steps above.

To deactivate a worker using the private workforce summary page

1. In the **Workers** section, choose the worker that you would like to disable.
2. Choose **Disable**.

If desired, you can subsequently **Enable** a worker after they have been disabled.

You can remove workers from your private workforce directly in the SageMaker AI console if that worker was added in this console. If you added the worker (user) in the Amazon Cognito console, see Manage a Private Workforce (Amazon Cognito Console) to learn how to remove the worker in the Amazon Cognito console.

To remove a worker using the private workforce summary page

1. In the **Workers** section, choose the worker that you would like to delete.
2. If the worker has not been disabled, choose **Disable**.
3. Select the worker and choose **Delete**.

Manage a Private Workforce (Amazon Cognito Console)

A private workforce corresponds to a single **Amazon Cognito user pool**. Private work teams correspond to **Amazon Cognito user groups** within that user pool. Workers correspond to **Amazon Cognito users** within those groups.

After your workforce has been created, you can add work teams and individual workers through the Amazon Cognito console. You can also delete workers from your private workforce or remove them from individual teams in the Amazon Cognito console.

Important

You can't delete work teams from the Amazon Cognito console. Deleting a Amazon Cognito user group that is associated with an Amazon SageMaker AI work team will result in an error. To remove work teams, use the SageMaker AI console.

Create Work Teams (Amazon Cognito Console)

You can create a new work team to complete a job by adding a Amazon Cognito user group to the user pool associated with your private workforce. To add a Amazon Cognito user group to an existing worker pool, see Adding groups to a User Pool.

To create a work team using an existing Amazon Cognito user group

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, choose **Workforces**.
3. For **Private teams**, choose **Create private team**.
4. Under **Team details**, give the team a name. The name must be unique in your account in an Amazon Region.
5. For **Add workers,** choose **Import existing Amazon Cognito user groups**, and choose one or more user groups that are part of the new team.
6. If you choose an **SNS topic**, all workers added to the team are subscribed to the Amazon Simple Notification Service (Amazon SNS) topic and notified when new work items are available to the team. Choose from a list of your existing SNS topics related to SageMaker Ground Truth or Amazon Augmented AI or choose **Create new topic** to create one.

   Note

   Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to receive SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.

Subscriptions

After you have created a work team, you can see more information about the team and change or set the SNS topic to which its members are subscribed using the Amazon Cognito console. If you added any team members before you subscribed the team to a topic, you need to manually subscribe those members to that topic. For more information, see Create the Amazon SNS topic.

Add and Remove Workers (Amazon Cognito Console)

When using the Amazon Cognito console to add workers to a work team, you must add a user to the user pool associated with the workforce before adding that user to a user group. Users can be added to a user pool in various ways. For more information, see Signing Up and Confirming User Accounts.

Add a Worker to a Work Team

After a user has been added to a pool, the user can be associated with user groups inside of that pool. After a user has been added to a user group, that user becomes a worker on any work team created using that user group.

To add a user to a user group

1. Open the Amazon Cognito console: https://console.amazonaws.cn/cognito/.
2. Choose **Manage User Pools**.
3. Choose the user pool associated with your SageMaker AI workforce.
4. Under **General Settings**, choose **Users and Groups** and do one of the following:
    - Choose **Groups**, choose the group that you want to add the user to, and choose **Add users**. Choose the users that you want to add by choosing the plus-icon to the right of the user's name.
    - Choose **Users**, choose the user that you want to add to the user group, and choose **Add to group**. From the dropdown menu, choose the group and choose **Add to group**.

Disable and Remove a Worker From a Work Team

Disabling a worker stops the worker from receiving jobs. This action doesn't remove the worker from the workforce, or from any work team the worker is associated with. To remove a user from a work team in Amazon Cognito, you remove the user from the user group associated with that team.

To deactivate a worker (Amazon Cognito console)

1. Open the Amazon Cognito console: https://console.amazonaws.cn/cognito/.
2. Choose **Manage User Pools**.
3. Choose the user pool associated with your SageMaker AI workforce.
4. Under **General Settings**, choose **Users and Groups**.
5. Choose the user that you want to disable.
6. Choose **Disable User**.

You can enable a disabled user by choosing **Enable User**.

To remove a user from a user group (Amazon Cognito console)

1. Open the Amazon Cognito console: https://console.amazonaws.cn/cognito/.
2. Choose **Manage User Pools**.
3. Choose the user pool associated with your SageMaker AI workforce.
4. Under **General Settings**, choose **Users and Groups**.
5. For **User** tab, choose the **X** icon to the right of the group from which you want to remove the user.

OIDC IdP Workforces

Create a private workforce using an OpenID Connect (OIDC) Identity Provider (IdP) when you want to manage and authenticate your workers using your own OIDC IdP. Individual worker credentials and other data will be kept private. Ground Truth and Amazon A2I will only have visibility into worker information you provide through the claims that you send to these services. To create a workforce using an OIDC IdP, your IdP must support *groups* because Ground Truth and Amazon A2I map one or more groups in your IdP to a work team. To learn more, see Send Required and Optional Claims to Ground Truth and Amazon A2I.

If you are a new user of Ground Truth or Amazon A2I, you can test your worker UI and job workflow by creating a private work team and adding yourself as a worker. Use this work team when you create a labeling job or human review workflow. First, create a private OIDC IdP workforce using the instructions in Create a Private Workforce (OIDC IdP). Next, refer to Manage a Private Workforce (OIDC IdP) to learn how to create a work team.

Topics

- Create a Private Workforce (OIDC IdP)
- Manage a Private Workforce (OIDC IdP)

Create a Private Workforce (OIDC IdP)

Create a private workforce using an OpenID Connect (OIDC) Identity Provider (IdP) when you want to authenticate and manage workers using your own identity provider. Use this page to learn how to configure your IdP to communicate with Amazon SageMaker Ground Truth (Ground Truth) or Amazon Augmented AI (Amazon A2I) and to learn how to create a workforce using your own IdP.

To create a workforce using an OIDC IdP, your IdP must support *groups* because Ground Truth and Amazon A2I use one or more groups that you specify to create work teams. You use work teams to specify workers for your labeling jobs and human review tasks. Because groups are not a standard claim, your IdP may have a different naming convention for a group of users (workers). Therefore, you must identify one or more user groups to which a worker belongs using the custom claim `sagemaker:groups` that is sent to Ground Truth or Amazon A2I from your IdP. To learn more, see Send Required and Optional Claims to Ground Truth and Amazon A2I.

You create an OIDC IdP workforce using the SageMaker API operation `CreateWorkforce`. Once you create a private workforce, that workforce and all work teams and workers associated with it are available to use for all Ground Truth labeling job tasks and Amazon A2I human review workflows tasks. To learn more, see Create an OIDC IdP Workforce.

Send Required and Optional Claims to Ground Truth and Amazon A2I

When you use your own IdP, Ground Truth and Amazon A2I use your `Issuer`, `ClientId`, and `ClientSecret` to authenticate workers by obtaining an authentication CODE from your `AuthorizationEndpoint`.

Ground Truth and Amazon A2I will use this CODE to obtain a custom claim from either your IdP's `TokenEndpoint` or `UserInfoEndpoint`. You can either configure `TokenEndpoint` to return a JSON web token (JWT) or `UserInfoEndpoint` to return a JSON object. The JWT or JSON object must contain required and optional claims that you specify. A claim is a key-value pair that contains information about a worker or metadata about the OIDC service. The following table lists the claims that must be included, and that can optionally be included in the JWT or JSON object that your IdP returns.

Note

Some of the parameters in the following table can be specified using a `:` or a `-`. For example, you can specify the groups a worker belongs to using `sagemaker:groups` or `sagemaker-groups` in your claim.

Name	Required	Accepted Format and Values	Description	Example
`sagemaker:groups` or `sagemaker-groups`	Yes	**Data type**: If a worker belongs to a single group, identify the group using a string. If a worker belongs to multiple groups, use a list of up to 10 strings. **Allowable characters**: Regex: [\p{L}\p{M}\p{S}\p{N}\p{P}]+ **Quotas**: 10 groups per worker 63 characters per group name	Assigns a worker to one or more groups. Groups are used to map the worker into work teams.	Example of worker that belongs to a single group: `"work_team1"` Example of a worker that belongs to more than one groups: `["work_team1", "work_team2"]`
`sagemaker:sub` or	Yes	**Data type**:	This is mandatory to track a worker	`"11101110 1-1234567`

Name	Required	Accepted Format and Values	Description	Example
`sagemaker-sub`		String	identity inside the Ground Truth platform for auditing and to identify tasks worked on by that worker. For ADFS: Customers must use the Primary Security Identifier (SID).	`89-368705 6437-1111"`
`sagemaker :client_id` or `sagemaker -client_id`	Yes	**Data type**: String **Allowable characters**: Regex: [\w+-]+ **Quotes**: 128 characters	A client ID. All tokens must be issued for this client ID.	`"00b600bb -1f00-05d 0-bd00-00 be00fbd0e0"`
`sagemaker :name` or `sagemaker-name`	Yes	**Data type**: String	The worker name to be displayed in the worker portal.	`"Jane Doe"`

Name	Required	Accepted Format and Values	Description	Example
`email`	No	**Data type**: String	The worker email. Ground Truth uses this email to notify workers that they have been invited to work on labeling tasks. Ground Truth will also use this email to notify your workers when labeling tasks become available if you set up an Amazon SNS topic for a work team that this worker is on.	`"example-email@domain.com"`
`email_verified`	No	**Data type**: Bool **Accepted Values:** `True`, `False`	Indicates if the user email was verified or not.	`True`

The following an example of the JSON object syntax your `UserInfoEndpoint` can return.

```
{
    "sub":"122",
    "exp":"10000",
    "sagemaker-groups":["group1","group2"]
    "sagemaker-name":"name",
    "sagemaker-sub":"122",
    "sagemaker-client_id":"123456"
}
```

Ground Truth or Amazon A2I compares the groups listed in `sagemaker:groups` or `sagemaker-groups` to verify that your worker belongs to the work team specified in the labeling job or human review task. After the work team has been verified, labeling or human review tasks are sent to that worker.

Create an OIDC IdP Workforce

You can create a workforce using the SageMaker API operation `CreateWorkforce` and associated language-specific SDKs. Specify a `WorkforceName` and information about your OIDC IDP in the parameter `OidcConfig`. It is recommended that you configure your OIDC with a place-holder redirect URI, and then update the URI with the worker portal URL after you create the workforce. To learn more, see Configure your OIDC IdP.

The following shows an example of the request. See `CreateWorkforce` to learn more about each parameter in this request.

```
CreateWorkforceRequest: {
    #required fields
    WorkforceName: "example-oidc-workforce",
    OidcConfig: {
        ClientId: "clientId",
        ClientSecret: "secret",
        Issuer: "https://example-oidc-idp.com/adfs",
        AuthorizationEndpoint: "https://example-oidc-idp.com/adfs/oauth2/authorize",
        TokenEndpoint: "https://example-oidc-idp.com/adfs/oauth2/token",
        UserInfoEndpoint: "https://example-oidc-idp.com/adfs/oauth2/userInfo",
        LogoutEndpoint: "https://example-oidc-idp.com/adfs/oauth2/log-out",
        JwksUri: "https://example-oidc-idp.com/adfs/discovery/keys"
    },
    SourceIpConfig: {
        Cidrs: ["string", "string"]
    }
}
```

Configure your OIDC IdP

How you configure your OIDC IdP depends on the IdP you use, and your business requirements.

When you configure your IdP, you must to specify a callback or redirect URI. After Ground Truth or Amazon A2I authenticates a worker, this URI will redirect the worker to the worker portal where the workers can access labeling or human review tasks. To create a worker portal URL, you need

to create a workforce with your OIDC IdP details using the `CreateWorkforce` API operation. Specifically, you must configure your OIDC IdP with required custom sagemaker claims (see the next section for more details). Therefore, it is recommended that you configure your OIDC with a place-holder redirect URI, and then update the URI after you create the workforce. See Create an OIDC IdP Workforce to learn how to create a workforce using this API.

You can view your worker portal URL in the SageMaker Ground Truth console, or using the SageMaker API operation, `DescribeWorkforce`. The worker portal URL is in the `SubDomain` parameter in the response.

> **Important**
>
> Make sure you add the workforce subdomain to your OIDC IdP allow list. When you add the subdomain to your allow list, it must end with `/oauth2/idpresponse`.

To view your worker portal URL after creating a private workforce (Console):

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, choose **Labeling workforces**.
3. Select the **Private** tab.
4. In **Private workforce summary** you will see **Labeling portal sign-in URL**. This is your worker portal URL.

To view your worker portal URL after creating a private workforce (API):

When you create a private workforce using `CreateWorkforce`, you specify a `WorkforceName`. Use this name to call `DescribeWorkforce`. The following table includes examples of requests using the Amazon CLI and Amazon SDK for Python (Boto3).

SDK for Python (Boto3)

```
response = client.describe_workforce(WorkforceName='string')
print(f'The workforce subdomain is: {response['SubDomain']}')
```

Amazon CLI

```
$ C:\>  describe-workforce --workforce-name 'string'
```

Validate Your OIDC IdP Workforce Authentication Response

After you have created your OIDC IdP workforce, you can use the following procedure to validate its authentication workflow using cURL. This procedure assumes you have access to a terminal, and that you have cURL installed.

To validate your OIDC IdP authorization response:

1. Get an authorization code using a URI configured as follows:

   ```
   {AUTHORIZE ENDPOINT}?client_id={CLIENT ID}&redirect_uri={REDIRECT
    URI}&scope={SCOPE}&response_type=code
   ```

   a. Replace *{AUTHORIZE ENDPOINT}* with the authorize endpoint for your OIDC IdP.

   b. Replace *{CLIENT ID}* with the Client ID from your OAuth client.

   c. Replace *{REDIRECT URI}* with the worker portal URL. If it is not already present, you must add `/oauth2/idpresponse` to the end of the URL.

   d. If you have a custom scope, use it to replace *{SCOPE}*. If you do not have a custom scope, replace *{SCOPE}* with `openid`.

   The following is an example of a URI after the modifications above are made:

   ```
   https://example.com/authorize?
   client_id=f490a907-9bf1-4471-97aa-6bfd159f81ac&redirect_uri=https%3A%2F%2F
   %2Fexample.labeling.sagemaker.aws
   %2Foauth2%2Fidpresponse&response_type=code&scope=openid
   ```

2. Copy and paste the modified URI from step 1 into your browser and press Enter on your keyboard.
3. Authenticate using your IdP.
4. Copy the authentication code query parameter in the URI. This parameter beings with `code=`. The following is an example of what the response might look like. In this example, copy `code=MCNYDB...` and everything thereafter.

   ```
   https://example.labeling.sagemaker.aws/oauth2/idpresponse?code=MCNYDB....
   ```

5. Open a terminal and enter the following command after making required modifications listed below:

```
curl --request POST \
  --url '{TOKEN ENDPOINT}' \
  --header 'content-type: application/x-www-form-urlencoded' \
  --data grant_type=authorization_code \
  --data 'client_id={CLIENT ID}' \
  --data client_secret={CLIENT SECRET} \
  --data code={CODE} \
  --data 'redirect_uri={REDIRECT URI}'
```

a. Replace *{TOKEN ENDPOINT}* with the token endpoint for your OIDC IdP.

b. Replace *{CLIENT ID}* with the Client ID from your OAuth client.

c. Replace *{CLIENT SECRET}* with the Client Secret from your OAuth client.

d. Replace *{CODE}* with the authentication code query parameter you copied in step 4.

e. Replace *{REDIRECT URI}* with the worker portal URL.

The following is an example of the cURL request after making the modifications described above:

```
curl --request POST \
  --url 'https://example.com/token' \
  --header 'content-type: application/x-www-form-urlencoded' \
  --data grant_type=authorization_code \
  --data 'client_id=f490a907-9bf1-4471-97aa-6bfd159f81ac' \
  --data client_secret=client-secret \
  --data code=MCNYDB... \
  --data 'redirect_uri=https://example.labeling.sagemaker.aws/oauth2/idpresponse'
```

6. This step depends on the type of `access_token` your IdP returns, a plain text access token or a JWT access token.

   - If your IdP does not support JWT access tokens, `access_token` may be plain text (for example, a UUID). The response you see may look similar to the following. In this case, move to step 7.

     ```
     {
       "access_token":"179c144b-fccb-4d96-a28f-eea060f39c13",
       "token_type":"Bearer",
       "expires_in":3600,
     ```

```
  "refresh_token":"ef43e52e-9b4f-410c-8d4c-d5c5ee57631a",
  "scope":"openid"
}
```

- If your IdP supports JWT access tokens, step 5 should generate an access token in JWT format. For example, the response may look similar to the following:

```
{
    "access_token":"eyJh...JV_adQssw5c",
    "refresh_token":"i6mapTIAVSp2oJkgUnCACKKfZxt_H5MBLiqcybBBd04",
    "refresh_token_expires_in":6327,
    "scope":"openid",
    "id_token":"eyJ0eXAiOiJK9...-rDaQzUHl6cQQWNiDpWOl_lxXjQEvQ"
}
```

  Copy the JWT and decode it. You can use python script or a third party website to decode it. For example, you can go to the website https://jwt.io/ and paste the JWT into the **Encoded** box to decode it.

  Make sure the decoded response contains the following:

  - The **Required** SageMaker AI claims in the table found in Send Required and Optional Claims to Ground Truth and Amazon A2I. If it does not, you must reconfigure your OIDC IdP to contain these claims.
  - The Issuer you specified when you set up the IdP workforce.

7. In a terminal and enter the following command after making required modifications listed below:

```
curl -X POST -H 'Authorization: Bearer {ACCESS TOKEN}' -d '' -k -v {USERINFO
 ENDPOINT}
```

   a. Replace *{USERINFO ENDPOINT}* with the user info endpoint for your OIDC IdP.

   b. Replace *{ACCESS TOKEN}* with the access token in the response you received in step 7. This is the entry for the `"access_token"` parameter.

   The following is an example of the cURL request after making the modifications described above:

```
 curl -X POST -H 'Authorization: Bearer eyJ0eX...' -d '' -k -v https://example.com/
userinfo
```

8. The response to the final step in the procedure above may look similar to the following code block.

   If the `access_token` returned in step 6 was plain text, you must verify that this response contains required information. In this case, the response must contain the **Required** SageMaker AI claims in the table found in Send Required and Optional Claims to Ground Truth and Amazon A2I. For example, `sagemaker-groups`, `sagamaker-name`.

```
{
    "sub":"122",
    "exp":"10000",
    "sagemaker-groups":["group1","group2"]
    "sagemaker-name":"name",
    "sagemaker-sub":"122",
    "sagemaker-client_id":"123456"
}
```

Next Steps

Once you've created a private workforce using your IdP and verified your IdP authentication response, you can create work teams using your IdP groups. To learn more, see Manage a Private Workforce (OIDC IdP).

You can restrict worker access to tasks to specific IP addresses, and update or delete your workforce using the SageMaker API. To learn more, see Private workforce management using the Amazon SageMaker API.

Manage a Private Workforce (OIDC IdP)

Once you've created a private workforce using your OpenID Connect (OIDC) Identity Provider (IdP), you can manage your workers using your IdP. For example, you can add, remove, and group workers directly through your IdP.

To add workers to an Amazon SageMaker Ground Truth (Ground Truth) labeling job or Amazon Augmented AI (Amazon A2I) human review task, you create work teams using 1-10 IdP groups and assign that work team to a job or task. You assign a work team to a job or task by specifing that

work team when you create a labeling job (Ground Truth) or a human review workflow (Amazon A2I).

You can only assign one team to each labeling job or human review workflow. You can use the same team to create multiple labeling jobs or human review tasks. You can also create multiple work teams to work on different labeling jobs or human review tasks.

Prerequisites

To create and manage private work teams using your OIDC IdP groups, first you must create a workforce using the SageMaker API operation `CreateWorkforce`. To learn more, see Create a Private Workforce (OIDC IdP).

Add work teams

You can use the SageMaker AI console to create a private work team using your OIDC IdP workforce on the **Labeling workforces** page under **Ground Truth**. If you are creating a Ground Truth labeling job, you can also create a private work team while creating a labeling job.

> **Note**
>
> You create and manage work teams for Amazon A2I in the Ground Truth area of the SageMaker AI console.

You can also use the SageMaker API and associated language-specific SDKs to create a private work team.

Use the following procedures to learn how to create a private work team using the SageMaker AI console and API.

To create a private work team on the Labeling workforces page (console)

1. Go to the Ground Truth area of the SageMaker AI console: https://console.amazonaws.cn/sagemaker/groundtruth.
2. Select **Labeling workforces**.
3. Select **Private**.
4. In the **Private teams** section, select **Create private team**.

5. In the **Team details** section, enter a **Team name**.
6. In the **Add workers** section, enter the name of a single user group. All workers associated with this group in your IdP are added to this work team.
7. To add more than one user group, select **Add new user group** and enter the names of the user groups you want to add to this work team. Enter one user group per line.
8. (Optional) For Ground Truth labeling jobs, if you provide an email for workers in your JWT, Ground Truth notifies workers when a new labeling task is available if you select an SNS topic.
9. Select **Create private team**.

To create a private work team while creating a Ground Truth labeling job (console)

1. Go to the Ground Truth area of the SageMaker AI console: https://console.amazonaws.cn/sagemaker/groundtruth.
2. Select **Labeling jobs**.
3. Use the instructions in Create a Labeling Job (Console) to create a labeling job. Stop when you get to the **Workers** section on the second page.
4. Select **Private** for your worker type.
5. Enter a **Team name**.
6. In the **Add workers** section, enter the name of a single user group under **User groups**. All workers associated with this group in your IdP are added to this work team.

> **Important**
>
> The group names you specify for **User groups** must match the group names specified in your OIDC IdP.

7. To add more than one user group, select **Add new user group** and enter the names of the user groups you want to add to this work team. Enter one user group per line.
8. Complete all remaining steps to create your labeling job.

The private team that you create is used for this labeling job, and is listed in the **Labeling workforces** section of the SageMaker AI console.

To create a private work team using the SageMaker API

You can create a private work team using the SageMaker API operation `CreateWorkteam`.

When you use this operation, list all user groups that you want included in the work team in the `OidcMemberDefinition` parameter `Groups`.

> **Important**
>
> The group names you specify for `Groups` must match the group names specified in your OIDC IdP.

For example, if your user group names are `group1`, `group2`, and `group3` in your OIDC IdP, configure `OidcMemberDefinition` as follows:

```
"OidcMemberDefinition": {
   "Groups": ["group1", "group2", "group3"]
 }
```

Additionally, you must give the work team a name using the `WorkteamName` parameter.

Add or remove IdP groups from work teams

After you've created a work team, you can use the SageMaker API to manage that work team. Use the `UpdateWorkteam` operation to update the IdP user groups included in that work team.

- Use the `WorkteamName` parameter to identify the work team that you want to update.
- When you use this operation, list all user groups that you want included in the work team in the `OidcMemberDefinition` parameter `Groups`. If a user group is associated with a work team and you do *not* include it in this list, that user group is no longer associated with this work team.

Delete a work team

You can delete a work team using the SageMaker AI console and SageMaker API.

To delete a private work team in the SageMaker AI console

1. Go to the Ground Truth area of the SageMaker AI console: https://console.amazonaws.cn/sagemaker/groundtruth.
2. Select **Labeling workforces**.

3. Select **Private**.
4. In the **Private teams** section, select the work team that you want to delete.
5. Select **Delete**.

To delete a private work team (API)

You can delete a private work team using the SageMaker API operation `DeleteWorkteam`.

Manage Individual Workers

When you create a workforce using your own OIDC IdP, you cannot use Ground Truth or Amazon A2I to manage individual workers.

- To add a worker to a work team, add that worker to a group associated with that work team.
- To remove a worker from a work team, remove that worker from all user groups associated with that work team.

Update, Delete, and Describe Your Workforce

You can update, delete, and describe your OIDC IdP workforce using the SageMaker API. The following is a list of API operations that you can use to manage your workforce. For additional details, including how you can locate your workforce name, see Private workforce management using the Amazon SageMaker API.

- `UpdateWorkforce` – You may want to update a workforce created using your own OIDC IdP to specify a different authorization endpoint, token endpoint, or issuer. You can update any parameter found in `OidcConfig` using this operation.

  You can only update your OIDC IdP configuration when there are no work teams associated with your workforce. To learn how to delete work teams, see Delete a work team.
- `DeleteWorkforce` – Use this operation to delete your private workforce. If you have any work teams associated with your workforce, you must delete those work teams before you delete your work force. For more information, see Delete a work team.
- `DescribeWorkforce` – Use this operation to list private workforce information, including workforce name, Amazon Resource Name (ARN), and, if applicable, allowed IP address ranges (CIDRs).

Private workforce management using the Amazon SageMaker API

You can use Amazon SageMaker API operations to manage, update, and delete your private workforce. For each API operation listed on the following topics, you can find a list of supported language-specific SDKs and their documentation in the **See Also** section of the API documentation.

Topics

- Find your workforce name
- Restrict worker access to tasks to allowable IP addresses
- Enable a dual-stack workforce
- Update OIDC Identity Provider workforce configuration
- Delete a private workforce

Find your workforce name

Some of the SageMaker AI workforce-related API operations require your workforce name as input. You can see your Amazon Cognito or OIDC IdP private and vendor workforce names in an Amazon Region using the `ListWorkforces` API operation in that Amazon Region. If you created your workforce using your own OIDC IdP, you can find your workforce name in the Ground Truth area of the SageMaker AI console.

To find your workforce name in the SageMaker AI console

1. Go to the Ground Truth area of the SageMaker AI console: https://console.amazonaws.cn/sagemaker/groundtruth.
2. Select **Labeling workforces**.
3. Select **Private**.
4. In the **Private workforce summary** section, locate your workforce ARN. Your workforce name is located at the end of this ARN. For example, if the ARN is `arn:aws:sagemaker:us-east-2:111122223333:workforce/example-workforce`, the workforce name is `example-workforce`.

Restrict worker access to tasks to allowable IP addresses

By default, a workforce isn't restricted to specific IP addresses. You can use the `UpdateWorkforce` operation to require that workers use a specific range of IP addresses (CIDRs) to access tasks. If

you specify one or more CIDRs, workers who attempt to access tasks using any IP address outside the specified ranges are denied and will get a HTTP 204 No Content error message on the worker portal. You can specify up to 10 CIDR values using `UpdateWorkforce`.

After you have restricted your workforce to one or more CIDRs, the output of `UpdateWorkforce` lists all allowable CIDRs. You can also use the `DescribeWorkforce` operation to view all allowable CIDRs for a workforce.

Enable a dual-stack workforce

You can enable a dual-stack workforce by using the CreateWorkforce and UpdateWorkforce API operations. Creating a dual-stack workforce, updating an existing workforce to dual-stack, and changing a workforce from dual-stack back to IPv4 are not supported in Amazon Web Services Management Console.

> **Important**
>
> A workforce without a defined `IpAddressType` defaults to `IPv4`.

Create a dual-stack workforce

The process for creating a dual-stack workforce is similar to creating an IPv4-only workforce, with the exceptions noted below. For more information, see CreateWorkforce.

- To attach a VPC to the private workforce, ensure the VPC is also dual-stack, with IPv6 CIDR blocks associated with the VPC's subnets.
- To use the `SourceIpConfig` parameter to restrict traffic to a specific IP address range, ensure that IPv6 CIDR blocks are also included in the list.
- To implement policies with `SourceIp` conditions on S3 buckets accessed by your tasks, ensure those policies are updated to be dual-stack compatible.
- Your identity provider authentication endpoint supports dual-stack. For more information, see Authentication flow.

Example `CreateWorkforce` SDK call using boto3

For more information, see create_workforce.

```
import boto3
```

```
client = boto3.resource('sagemaker')

# IpAddressType = 'dualstack'|'ipv4'
client.create_workforce(
    WorkforceName='string',
    IpAddressType='dualstack',
    WorkforceConfig={
        'CognitoConfig': {
            'UserPool': 'string',
            'Client': 'string'
        }
    }
)
```

Update a dual-stack workforce

When updating an existing workforce to be dual-stack, note the following. For more information, see UpdateWorkforce and IPv6 support for your VPC.

- If a VPC is attached to the workforce, you must update the VPC to be dual-stack. Also ensure that any security groups for the VPC allow IPv6 traffic.
- If you're using the `SourceIpConfig` parameter, update it to include IPv6 CIDR blocks.
- To implement policies with `SourceIp` conditions on S3 buckets accessed by your tasks, ensure those policies are updated to be dual-stack compatible.
- Your identity provider authentication endpoint supports dual-stack. For more information, see Authentication flow.

Example `UpdateWorkforce` SDK call using boto3

For more information, see update_workforce.

```
import boto3

client = boto3.resource('sagemaker')

# IpAddressType = 'dualstack'|'ipv4'
client.update_workforce(
    WorkforceName='string',
    IpAddressType='dualstack'
```

```
)
```

Update OIDC Identity Provider workforce configuration

You may want to update a workforce created using your own OIDC IdP to specify a different authorization endpoint, token endpoint, or issuer. You can update any parameter found in `OidcConfig` using the `UpdateWorkforce` operation.

> **Important**
>
> You can only update your OIDC IdP configuration when there are no work teams associated with your workforce. You can delete a private work team using the `DeleteWorkteam` operation.

Delete a private workforce

You can only have one private workforce in each Amazon Region. You may want to delete your private workforce in an Amazon Region when:

- You want to create a workforce using a new Amazon Cognito user pool.
- You have already created a private workforce using Amazon Cognito and you want to create a workforce using your own OpenID Connect (OIDC) Identity Provider (IdP).

To delete a private workforce, use the `DeleteWorkforce` API operation. If you have any work teams associated with your workforce, you must delete those work teams before you delete your workforce. You can delete a private work team using the `DeleteWorkteam` operation.

Track Worker Performance Metrics

Amazon SageMaker Ground Truth logs worker events to Amazon CloudWatch, such as when a worker starts or submits a task. Use Amazon CloudWatch metrics to measure and track throughput across a team or for individual workers.

> **Important**
>
> Worker event tracking is not available for Amazon Augmented AI human review workflows.

Enable Tracking

During the set-up process for a new work team, the permissions for Amazon CloudWatch logging of worker events are created. Since this feature was added in August 2019, work teams created prior to that may not have the correct permissions. If all of your work teams were created before August 2019, create a new work team. It does not need any members and may be deleted after creation, but by creating it, you establish the permissions and apply them to all of your work teams, regardless of when they were created.

Track Metrics Using Logs

After tracking is enabled, the activity of your workers is logged. Open the Amazon CloudWatch console and choose **Logs** in the navigation pane. You should see a log group named **/aws/sagemaker/groundtruth/WorkerActivity**.

Each completed task is represented by a log entry, which contains information about the worker, their team, the job, when the task was accepted, and when it was submitted.

Example Log entry

```
{
  "worker_id": "cd449a289e129409",
  "cognito_user_pool_id": "us-east-2_IpicJXXXX",
  "cognito_sub_id": "d6947aeb-0650-447a-ab5d-894db61017fd",
  "task_accepted_time": "Wed Aug 14 16:00:59 UTC 2019",
  "task_submitted_time": "Wed Aug 14 16:01:04 UTC 2019",
  "task_returned_time": "",
  "task_declined_time": "",
  "workteam_arn": "arn:aws:sagemaker:us-east-2:############:workteam/private-crowd/
Sample-labeling-team",
  "labeling_job_arn": "arn:aws:sagemaker:us-east-2:############:labeling-job/metrics-
demo",
  "work_requester_account_id": "############",
  "job_reference_code": "############",
  "job_type": "Private",
  "event_type": "TasksSubmitted",
  "event_timestamp": "1565798464"
}
```

A useful data point in each event is the `cognito_sub_id`. You can match that to an individual worker.

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. Under the **Ground Truth** section, choose **Workforces**.
3. Choose **Private**.
4. Choose the name of a team in the **Private teams** section.
5. In the **Team summary** section, choose the user group identified under **Amazon Cognito user group**. That will take you to the group in the Amazon Cognito console.
6. The **Group** page lists the users in the group. Choose any user's link in the **Username** column to see more information about the user, including a unique **sub** ID.

To get information about all of the team's members, use the ListUsers action (examples) in the Amazon Cognito API.

Track Metrics Using the CloudWatch Console

If you don't want to write your own scripts to process and visualize the raw log information, Amazon CloudWatch metrics provide insights into worker activity for you.

To view metrics

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the `AWS/SageMaker/Workteam` name space, then explore the available metrics. For example, selecting the **Workteam** and **Workforce** metrics lets you calculate the average time per submitted task for a specific labeling job.

For more information, see Using Amazon CloudWatch Metrics.

Create the Amazon SNS topic

The steps for creating Amazon SNS topics for work team notifications are similar to the steps in Getting Started in the *Amazon SNS Developer Guide*, with one significant addition—you must add an access policy so that Amazon SageMaker AI can publish messages to the topic on your behalf.

If you create a work team using the console, the console provides an option to create a new topic for the team so that you don't have to perform these steps.

> **Important**
>
> The Amazon SNS feature is not supported by Amazon A2I. If you subscribe your work team to an Amazon SNS topic, workers will only receive notifications about Ground Truth labeling jobs. Workers will not receive notifications about new Amazon A2I human review tasks.

To add the policy when you create the topic

1. Open the Amazon SNS console at https://console.amazonaws.cn/sns/v3/home.
2. In **Create topic**, enter the name of your topic and then choose **Next steps**.
3. In **Access policy**, choose **Advanced**.
4. In the **JSON editor**, find the `Resource` property, which displays the topic's ARN.
5. Copy the `Resource` ARN value.
6. Before the final closing brace (`]`), add the following policy.

```
   , {
        "Sid": "AwsSagemaker_SnsAccessPolicy",
        "Effect": "Allow",
        "Principal": {
            "Service": "sagemaker.amazonaws.com"
        },
        "Action": "sns:Publish",
        "Resource": "arn:partition:sns:region:111122223333:MyTopic", # ARN of the
topic you copied in the previous step
        "Condition": {
            "ArnLike": {
                "aws:SourceArn":
"arn:partition:sagemaker:region:111122223333:workteam/*" # Workteam ARN
            },
            "StringEquals": {
                "aws:SourceAccount": "111122223333" # SNS topic account
            }
        }
   }
```

7. Create the topic.

After you create the topic, it appears in your **Topics** summary screen. For more information about creating topics, see Creating a Topic in the *Amazon SNS Developer Guide*.

Manage worker subscriptions

If you subscribe a work team to a topic after you've already created the work team, the individual work team members who were added to the team when the work team was created are not automatically subscribed to the topic. For information about subscribing workers' email addresses to the topic, see Subscribing an Endpoint to an Amazon SNS Topic in the *Amazon SNS Developer Guide*.

The only situation in which workers are automatically subscribed to your topic is when you create or import an Amazon Cognito user group at the time that you create a work team ***and*** you set up the topic subscription when you create that work team. For more information about creating and managing your workteams with Amazon Cognito, see Create Work Teams (Amazon Cognito Console).

Crowd HTML Elements Reference

This feature is not available in the China Regions.

Crowd HTML Elements are web components, a web standard that abstracts HTML markup, CSS, and JavaScript functionality into an HTML tag or set of tags. Amazon SageMaker AI provides customers with the ability to design their own custom task templates in HTML.

As a starting point, you can use a template built using Crowd HTML Elements from one of the following GitHub repositories:

- Example task UIs for Amazon SageMaker Ground Truth
- Over 60 example task UIs for Amazon Augmented AI (A2I)

These repositories include templates designed for audio, image, text, video, and other types of data labeling and annotation tasks.

For more information about how to implement custom templates in Amazon SageMaker Ground Truth, see Custom labeling workflows. To learn more about custom templates in Amazon Augmented AI, see Create Custom Worker Task Templates.

SageMaker AI Crowd HTML Elements

The following is a list of Crowd HTML Elements that make building a custom template easier and provide a familiar UI for workers. These elements are supported in Ground Truth and Augmented AI.

crowd-alert

A message that alerts the worker to a current situation.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-alert>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

dismissible

A Boolean switch that, if present, allows the message to be closed by the worker.

type

A string that specifies the type of message to be displayed. The possible values are "info" (the default), "success", "error", and "warning".

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-badge

An icon that floats over the top right corner of another element to which it is attached.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template that uses the `<crowd-badge>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

for

A string that specifies the ID of the element to which the badge is attached.

icon

A string that specifies the icon to be displayed in the badge. The string must be either the name of an icon from the open-source *iron-icons* set, which is pre-loaded, or the URL to a custom icon.

This attribute overrides the *label* attribute.

The following is an example of the syntax that you can use to add an iron-icon to a `<crowd-badge>` HTML element. Replace *`icon-name`* with the name of the icon you'd like to use from this Icons set.

```
<crowd-badge icon="icon-name" for="short-instructions"/>
```

label

The text to display in the badge. Three characters or less is recommended because text that is too large will overflow the badge area. An icon can be displayed instead of text by setting the *icon* attribute.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-button

A styled button that represents some action.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template that uses the `<crowd-button>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the button as disabled and prevents clicks.

form-action

A switch that either submits its parent crowd-form element, if set to "submit", or resets its parent <crowd-form> element, if set to "reset".

href

The URL to an online resource. Use this property if you need a link styled as a button.

icon

A string that specifies the icon to be displayed next to the button's text. The string must be the name of an icon from the open-source *iron-icons* set, which is pre-loaded. For example, to insert the search iron-icon, use the following:

```
<crowd-button>
    <iron-icon icon="search"/>
```

```
</crowd-button>
```

The icon is positioned to either the left or the right of the text, as specified by the *icon-align* attribute.

To use a custom icon see **icon-url**.

icon-align

The left or right position of the icon relative to the button's text. The default is "left".

icon-url

A URL to a custom image for the icon. A custom image can be used in place of a standard icon that is specified by the *icon* attribute.

loading

A Boolean switch that, if present, displays the button as being in a loading state. This attribute has precedence over the *disabled* attribute if both attributes are present.

target

When you use the `href` attribute to make the button act as a hyperlink to a specific URL, the `target` attribute optionally targets a frame or window where the linked URL should load.

variant

The general style of the button. Use "primary" for primary buttons, "normal" for secondary buttons, "link" for tertiary buttons, or "icon" to display only the icon without text.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth

- Crowd HTML Elements Reference

crowd-bounding-box

A widget for drawing rectangles on an image and assigning a label to the portion of the image that is enclosed in each rectangle.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-bounding-box>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template. For more examples, see this GitHub repository.

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

An array of JSON objects, each of which sets a bounding box when the component is loaded. Each JSON object in the array contains the following properties. Bounding boxes set via the `initial-value` property can be adjusted and whether or not a worker answer was adjusted is tracked via an `initialValueModified` boolean in the worker answer output.

- **height** – The height of the box in pixels.
- **label** – The text assigned to the box as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the <crowd-bounding-box> element.
- **left** – Distance of the top-left corner of the box from the left side of the image, measured in pixels.
- **top** – Distance of the top-left corner of the box from the top of the image, measured in pixels.
- **width** – The width of the box in pixels.

  You can extract the bounding box initial value from a manifest file of a previous job in a custom template using the Liquid templating language:

```
initial-value="[
  {% for box in task.input.manifestLine.label-attribute-name-from-prior-
job.annotations %}
    {% capture class_id %}{{ box.class_id }}{% endcapture %}
    {% assign label = task.input.manifestLine.label-attribute-name-from-prior-job-
metadata.class-map[class_id] %}
    {
      label: {{label | to_json}},
      left: {{box.left}},
      top: {{box.top}},
      width: {{box.width}},
      height: {{box.height}},
    },
  {% endfor %}
 ]"
```

labels

A JSON formatted array of strings, each of which is a label that a worker can assign to the image portion enclosed by a rectangle. **Limit:** 10 labels.

name

The name of this widget. It's used as a key for the widget's input in the form output.

src

The URL of the image on which to draw bounding boxes.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions

Regions

The following regions are required by this element.

full-instructions

General instructions about how to draw bounding boxes.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

boundingBoxes

An array of JSON objects, each of which specifies a bounding box that has been created by the worker. Each JSON object in the array contains the following properties.

- **height** – The height of the box in pixels.
- **label** – The text assigned to the box as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the <crowd-bounding-box> element.
- **left** – Distance of the top-left corner of the box from the left side of the image, measured in pixels.
- **top** – Distance of the top-left corner of the box from the top of the image, measured in pixels.
- **width** – The width of the box in pixels.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example: Sample Element Outputs

The following are samples of outputs from common use scenarios for this element.

Single Label, Single Box / Multiple Label, Single Box

```
[
  {
    "annotatedResult": {
      "boundingBoxes": [
        {
          "height": 401,
          "label": "Dog",
          "left": 243,
          "top": 117,
          "width": 187
        }
      ],
      "inputImageProperties": {
        "height": 533,
        "width": 800
      }
    }
  }
]
```

Single Label, Multiple Box

```
[
  {
    "annotatedResult": {
      "boundingBoxes": [
        {
          "height": 401,
          "label": "Dog",
          "left": 243,
          "top": 117,
          "width": 187
        },
        {
          "height": 283,
          "label": "Dog",
          "left": 684,
          "top": 120,
          "width": 116
        }
      ],
      "inputImageProperties": {
        "height": 533,
```

```
        "width": 800
      }
    }
  }
]
```

Multiple Label, Multiple Box

```
[
  {
    "annotatedResult": {
      "boundingBoxes": [
        {
          "height": 395,
          "label": "Dog",
          "left": 241,
          "top": 125,
          "width": 158
        },
        {
          "height": 298,
          "label": "Cat",
          "left": 699,
          "top": 116,
          "width": 101
        }
      ],
      "inputImageProperties": {
        "height": 533,
        "width": 800
      }
    }
  }
]
```

You could have many labels available, but only the ones that are used appear in the output.

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-card

A box with an elevated appearance for displaying information.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template designed for sentiment analysis tasks that uses the `<crowd-card>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

heading

The text displayed at the top of the box.

image

A URL to an image to be displayed within the box.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-checkbox

A UI component that can be checked or unchecked allowing a user to select multiple options from a set.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-checkbox>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

checked

A Boolean switch that, if present, displays the check box as checked.

The following is an example of the syntx used to check a checkbox by default.

```
  <crowd-checkbox name="checkedBox" value="checked" checked>This box is checked</crowd-
checkbox>
```

disabled

A Boolean switch that, if present, displays the check box as disabled and prevents it from being checked.

The following is an example of the syntax used to disable a checkbox.

```
  <crowd-checkbox name="disabledCheckBox" value="Disabled" disabled>Cannot be
 selected</crowd-checkbox>
```

name

A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

required

A Boolean switch that, if present, requires the worker to provide input.

The following is an example of the syntax used to require a checkbox be selected.

```
  <crowd-checkbox name="work_verified" required>Instructions were clear</crowd-
checkbox>
```

value

A string used as the name for the check box state in the output. Defaults to "on" if not specified.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

Output

Provides a JSON object. The `name` string is the object name and the `value`string is the property name for a Boolean value based on the check box state; true if checked, false if not checked.

Example: Sample Element Outputs

Using the same `name` value for multiple boxes.

```
<!-- INPUT -->
<div><crowd-checkbox name="image_attributes" value="blurry"> Blurry </crowd-checkbox></
div>
<div><crowd-checkbox name="image_attributes" value="dim"> Too Dim </crowd-checkbox></
div>
<div><crowd-checkbox name="image_attributes" value="exposed"> Too Bright </crowd-
checkbox></div>
```

```
//Output with "blurry" and "dim" checked
[
  {
    "image_attributes": {
      "blurry": true,
      "dim": true,
      "exposed": false
    }
  }
]
```

Note that all three color values are properties of a single object.

Using different name values for each box.

```
<!-- INPUT -->
<div><crowd-checkbox name="Stop" value="Red"> Red </crowd-checkbox></div>
<div><crowd-checkbox name="Slow" value="Yellow"> Yellow </crowd-checkbox></div>
<div><crowd-checkbox name="Go" value="Green"> Green </crowd-checkbox></div>
```

```
//Output with "Red" checked
[
  {
    "Go": {
      "Green": false
    },
    "Slow": {
      "Yellow": false
    },
    "Stop": {
      "Red": true
    }
  }
]
```

See Also

- Crowd HTML Elements Reference

crowd-classifier

A widget for classifying non-image content, such as audio, video, or text.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an HTML worker task template built using `crowd-classifier`. This example uses the Liquid template language to automate:

- Label categories in the `categories` parameter
- The objects that are being classified in the `classification-target` parameter.

Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

categories

A JSON formatted array of strings, each of which is a category that a worker can assign to the text. You should include "other" as a category, otherwise the worker my not be able to provide an answer.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

name

The name of this widget. It is used as a key for the widget's input in the form output.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: classification-target, full-instructions, short-instructions

Regions

The following regions are supported by this element.

classification-target

The content to be classified by the worker. This can be plain text or HTML. Examples of how the HTML can be used include *but are not limited to* embedding a video or audio player, embedding a PDF, or performing a comparison of two or more images.

full-instructions

General instructions about how to do text classification.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The output of this element is an object using the specified `name` value as a property name, and a string from the `categories` as the property's value.

Example: Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "<name>": {
      "label": "<value>"
    }
  }
]
```

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-classifier-multi-select

A widget for classifying various forms of content—such as audio, video, or text—into one or more categories. The content to classify is referred to as an *object*.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an HTML worker task template built using this element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by the `crowd-classifier-multi-select` element. Each attribute accepts a string value or string values.

categories

Required. A JSON-formatted array of strings, each of which is a category that a worker can assign to the object.

header

Required. The text to display above the image. This is typically a question or simple instruction for workers.

name

Required. The name of this widget. In the form output, the name is used as a key for the widget's input.

exclusion-category

Optional. A JSON-formatted string with the following format: "`{ text: 'default-value' }`". This attribute sets a default value that workers can choose if none of the labels applies to the object shown in the worker UI.

Element Hierarchy

This element has the following parent and child elements:

- **Parent elements**: crowd-form
- **Child elements**: classification-target, full-instructions, short-instructions

Regions

This element uses the following regions.

classification-target

The content to be classified by the worker. Content can be plain text or an object that you specify in the template using HTML. For example, you can use HTML elements to include a video or audio player, embedding a PDF file, or include a comparison of two or more images.

full-instructions

General instructions about how to classify text.

short-instructions

Important task-specific instructions. These instructions are displayed prominently.

Output

The output of this element is an object that uses the specified `name` value as a property name, and a string from `categories` as the property's value.

Example: Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "<name>": {
        labels: ["label_a", "label_b"]
    }
  }
]
```

See Also

For more information, see the following:

- Categorize text with text classification (Multi-label)
- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-entity-annotation

A widget for labeling words, phrases, or character strings within a longer text. Workers select a label, and highlight the text that the label applies to.

> **Important: Self-contained Widget**
>
> Do not use `<crowd-entity-annotation>` element with the `<crowd-form>` element. It contains its own form submission logic and **Submit** button.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a template that uses the `<crowd-entity-annotation>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

A JSON formatted array of objects, each of which defines an annotation to apply to the text at initialization. Objects contain a `label` value that matches one in the `labels` attribute, an integer `startOffset` value for labeled span's starting unicode offset, and an integer `endOffset` value for the ending unicode offset.

Example

```
[
  {
    label: 'person',
    startOffset: 0,
    endOffset: 16
  },
  ...
]
```

labels

A JSON formatted array of objects, each of which contains:

- **`label`** (required): The name used to identify entities.
- **`fullDisplayName`** (optional): Used for the label list in the task widget. Defaults to the label value if not specified.

- **`shortDisplayName`** (optional): An abbreviation of 3-4 letters to display above selected entities. Defaults to the label value if not specified.

> **`shortDisplayName` is highly recommended**
>
> Values displayed above the selections can overlap and create difficulty managing labeled entities in the workspace. Providing a 3-4 character `shortDisplayName` for each label is highly recommended to prevent overlap and keep the workspace manageable for your workers.

Example

```
[
  {
    label: 'person',
    shortDisplayName: 'per',
    fullDisplayName: 'person'
  }
]
```

name

Serves as the widget's name in the DOM. It is also used as the label attribute name in form output and the output manifest.

text

The text to be annotated. The templating system escapes quotes and HTML strings by default. If your code is already escaped or partially escaped, see Variable filters for more ways to control escaping.

Element Hierarchy

This element has the following parent and child elements.

- **Child elements**: full-instructions, short-instructions

Regions

The following regions are supported by this element.

full-instructions

General instructions about how to work with the widget.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

entities

A JSON object that specifies the start, end, and label of an annotation. This object contains the following properties.

- **label** – The assigned label.
- **startOffset** – The Unicode offset of the beginning of the selected text.
- **endOffset** – The Unicode offset of the first character after the selection.

Example: Sample Element Outputs

The following is a sample of the output from this element.

```
{
  "myAnnotatedResult": {
    "entities": [
      {
        "endOffset": 54,
        "label": "person",
        "startOffset": 47
      },
      {
        "endOffset": 97,
        "label": "event",
        "startOffset": 93
      },
      {
        "endOffset": 219,
        "label": "date",
        "startOffset": 212
```

```
      },
      {
        "endOffset": 271,
        "label": "location",
        "startOffset": 260
      }
    ]
  }
}
```

See Also

crowd-fab

A floating button with an image in its center.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed for image classification that uses the `<crowd-fab>` element. This template uses JavaScript to enable workers to report issues with the worker UI. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the floating button as disabled and prevents clicks.

icon

A string that specifies the icon to be displayed in the center of the button. The string must be either the name of an icon from the open-source *iron-icons* set, which is pre-loaded, or the URL to a custom icon.

The following is an example of the syntax that you can use to add an iron-icon to a <crowd-fab> HTML element. Replace *icon-name* with the name of the icon you'd like to use from this Icons set.

```
<crowd-fab "id="button1" icon="icon-name" title="Issue"/>
```

label

A string consisting of a single character that can be used instead of an icon. Emojis or multiple characters may result in the button displaying an ellipsis instead.

title

A string that will display as a tool tip when the mouse hovers over the button.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-form

The form wrapper for all custom tasks. Sets and implements important actions for the proper submission of your form data.

If a crowd-button of type "submit" is not included inside the <crowd-form> element, it will automatically be appended within the <crowd-form> element.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an image classification template that uses the <crowd-form> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: none
- **Child elements**: Any of the UI Template elements

Element Events

The `crowd-form` element extends the standard HTML `form` element and inherits its events, such as `onclick` and `onsubmit`.

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-icon-button

A button with an image placed in the center. When the user touches the button, a ripple effect emanates from the center of the button.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed for image classification that uses the `<crowd-icon-button>` element. This template uses JavaScript to enable workers to report issues with the worker UI. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the button as disabled and prevents clicks.

icon

A string that specifies the icon to be displayed in the center of the button. The string must be either the name of an icon from the open-source *iron-icons* set, which is pre-loaded, or the URL to a custom icon.

The following is an example of the syntax that you can use to add an iron-icon to a `<crowd-icon-button>` HTML element. Replace *`icon-name`* with the name of the icon you'd like to use from this Icons set.

```
<crowd-icon-button id="button1" icon="icon-name" title="Issue"/>
```

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-image-classifier

A widget for classifying an image. Use one of the following supported image formats: APNG, BMP, GIF, ICO, JPEG, PNG, SVG. Images do not have a size limit.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an image classification template that uses the `<crowd-image-classifier>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are required by this element.

categories

A JSON formatted array of strings, each of which is a category that a worker can assign to the image. You should include "other" as a category, so that the worker can provide an answer. You can specify up to 10 categories.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

name

The name of this widget. It is used as a key for the widget's input in the form output.

overlay

Information to be overlaid on the source image. This is for verification workflows of bounding-box, semantic-segmentation, and instance-segmentation tasks.

It is a JSON object containing an object with the name of the task-type in camelCase as the key. That key's value is an object that contains the labels and other necessary information from the previous task.

An example of a `crowd-image-classifier` element with attributes for verifying a bounding-box task follows:

```
<crowd-image-classifier
    name="boundingBoxClassification"
    header="Rate the quality of the annotations based on the background section
       in the instructions on the left hand side."
    src="https://i.imgur.com/CIPKVJo.jpg"
    categories="['good', 'bad', 'okay']"
    overlay='{
        "boundingBox": {
            labels: ["bird", "cat"],
            value: [
                {
                  height: 284,
                  label: "bird",
                  left: 230,
```

```
                  top: 974,
                  width: 223
                },
                {
                  height: 69,
                  label: "bird",
                  left: 79,
                  top: 889,
                  width: 247
                }
            ]
        },
    }'
> ... </crowd-image-classifier>
```

A semantic segmentation verification task would use the `overlay` value as follows:

```
<crowd-image-classifier
  name='crowd-image-classifier'
  categories='["good", "bad"]'
  src='URL of image to be classified'
  header='Please classify'
  overlay='{
    "semanticSegmentation": {
      "labels": ["Cat", "Dog", "Bird", "Cow"],
      "labelMappings": {
        "Bird": {
          "color": "#ff7f0e"
        },
        "Cat": {
          "color": "#2ca02c"
        },
        "Cow": {
          "color": "#d62728"
        },
        "Dog": {
          "color": "#2acf59"
        }
      },
      "src": "URL of overlay image",
    }
  }'
> ... </crowd-image-classifier>
```

An instance-segmentation task would use the `overlay` value as follows:

```
<crowd-image-classifier
  name='crowd-image-classifier'
  categories='["good", "bad"]'
  src='URL of image to be classified'
  header='Please classify instances of each category'
  overlay='{
    "instanceSegmentation": {
       "labels": ["Cat", "Dog", "Bird", "Cow"],
       "instances": [
        {
         "color": "#2ca02c",
         "label": "Cat"
        },
        {
         "color": "#1f77b4",
         "label": "Cat"
        },
        {
         "color": "#d62728",
         "label": "Dog"
        }
       ],
       "src": "URL of overlay image",
    }
  }'
> ... </crowd-image-classifier>
```

src

The URL of the image to be classified.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions, worker-comment

Regions

The following regions are used by this element.

full-instructions

General instructions for the worker on how to classify an image.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

worker-comment

Use this in verification workflows when you need workers to explain why they made the choice they did. Use the text between the opening and closing tags to provide instructions for workers on what information should be included in the comment.

It uses the following attributes:

header

A phrase with a call to action for leaving a comment. Used as the title text for a modal window where the comment is added.

Optional. Defaults to "Add a comment."

link-text

This text appears below the categories in the widget. When clicked, it opens a modal window where the worker may add a comment.

Optional. Defaults to "Add a comment."

placeholder

An example text in the comment text area that is overwritten when worker begins to type. This does not appear in output if the worker leaves the field blank.

Optional. Defaults to blank.

Output

The output of this element is a string that specifies one of the values defined in the *categories* attribute of the <crowd-image-classifier> element.

Example: Sample Element Outputs

The following is a sample of output from this element.

```
[
  {
    "<name>": {
      "label": "<value>"
      "workerComment": "Comment - if no comment is provided, this field will not be
 present"
    }
  }
]
```

crowd-image-classifier-multi-select

A widget for classifying an image into one or more categories. Use one of the following supported image formats: APNG, BMP, GIF, ICO, JPEG, PNG, SVG. Images do not have a size limit.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an HTML worker task template built using this crowd element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by the `crowd-image-classifier-multi-select` element. Each attribute accepts a string value or string values.

categories

Required. A JSON-formatted array of strings, each of which is a category that a worker can assign to the image. A worker must choose at least one category and can choose all categories.

header

Required. The text to display above the image. This is typically a question or simple instruction for workers.

name

Required. The name of this widget. In the form output, the name is used as a key for the widget's input.

src

Required. The URL of the image to be classified.

exclusion-category

Optional. A JSON-formatted string with the following format: "`{ text: 'default-value' }`". This attribute sets a default value that workers can choose if none of the labels applies to the image shown in the worker UI.

Element Hierarchy

This element has the following parent and child elements:

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions, worker-comment

Regions

This element uses the following regions

full-instructions

General instructions for the worker on how to classify an image.

short-instructions

Important task-specific instructions. These instructions are displayed prominently.

Output

The output of this element is a string that specifies one or more of the values defined in the `categories` attribute of the `<crowd-image-classifier-multi-select>` element.

Example: Sample Element Outputs

The following is a sample of output from this element.

```
[
```

```
  {
    "<name>": {
        labels: ["label_a", "label_b"]
    }
  }
]
```

See Also

For more information, see the following:

- Create an image classification job (Multi-label)
- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-input

A box that accepts input data.

> **Cannot be self-closing**
>
> Unlike the `input` element in the HTML standard, this element cannot be self-closed by putting a slash before the ending bracket, e.g. `<crowd-input ... />`. It must be followed with a `</crowd-input>` to close the element.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-input>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

allowed-pattern

A regular expression that is used with the *auto-validate* attribute to ignore non-matching characters as the worker types.

auto-focus

When the value is set to true, the browser places focus inside the input area after loading. This way, the worker can start typing without having to select it first.

auto-validate

A Boolean switch that, if present, turns on input validation. The behavior of the validator can be modified by the *error-message* and *allowed-pattern* attributes.

disabled

A Boolean switch that, if present, displays the input area as disabled.

error-message

The text to be displayed below the input field, on the left side, if validation fails.

label

A string that is displayed inside a text field.

This text shrinks and rises up above a text field when the worker starts typing in the field or when the *value* attribute is set.

max-length

A maximum number of characters the input will accept. Input beyond this limit is ignored.

min-length

A minimum length for the input in the field

name

Sets the name of the input to be used in the DOM and the output of the form.

placeholder

A string value that is used as placeholder text, displayed until the worker starts entering data into the input, It is not used as a default value.

required

A Boolean switch that, if present, requires the worker to provide input.

type

Takes a string to set the HTML5 `input-type` behavior for the input. Examples include `file` and `date`.

value

A preset that becomes the default if the worker does not provide input. The preset appears in a text field.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

Output

Provides a `name` string as the property name, and the text that was entered in the field as its value.

Example: Sample JSON Output

The values for multiple elements are output in the same object, with their `name` attribute value as their property name. Elements with no input do not appear in the output. For example, let's use three inputs:

```
<crowd-input name="tag1" label="Word/phrase 1"></crowd-input>
<crowd-input name="tag2" label="Word/phrase 2"></crowd-input>
<crowd-input name="tag3" label="Word/phrase 3"></crowd-input>
```

This is the output if only two have input:

```
[
  {
    "tag1": "blue",
    "tag2": "red"
  }
]
```

This means any code built to parse these results should be able to handle the presence or absence of each input in the answers.

crowd-instance-segmentation

A widget for identifying individual instances of specific objects within an image and creating a colored overlay for each labeled instance.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-instance-segmentation>`. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Use a template similar to the following to allow workers to add their own categories (labels).

```
<script src="https://assets.crowd.aws/crowd-html-elements.js"></script>
<crowd-form>
  <crowd-instance-segmentation
    id="annotator"
    name="myTexts"
    src="{{ task.input.taskObject | grant_read_access }}"
    header="Click Instructions to add new labels."
    labels="['placeholder']"
  >
    <short-instructions>
      <h3>Add a label to describe each type of object in this image.</h3>
      <h3>Cover each instance of each object with a segmentation mask.</h3>
      <br>
      <h3>
        Add new label
      </h3>
      <crowd-input name="_customLabel" id="customLabel"></crowd-input>
      <crowd-button id="addLabel">Add</crowd-button>
```

```
      <br><br><br>
      <h3>
      Manage labels
      </h3>
      <div id="labelsSection"></div>
    </short-instructions>

    <full-instructions>
      Describe your task in more detail here.
    </full-instructions>
  </crowd-instance-segmentation>
</crowd-form>

<script>
  document.addEventListener('all-crowd-elements-ready', function(event) {
    document.querySelector('crowd-instance-segmentation').labels = [];
  });

  function populateLabelsSection() {
    labelsSection.innerHTML = '';
    annotator.labels.forEach(function(label) {
      const labelContainer = document.createElement('div');
      labelContainer.innerHTML = label + ' <a href="javascript:void(0)">(Delete)</a>';
      labelContainer.querySelector('a').onclick = function() {
        annotator.labels = annotator.labels.filter(function(l) {
          return l !== label;
        });
        populateLabelsSection();
      };
      labelsSection.appendChild(labelContainer);
    });
  }

  addLabel.onclick = function() {
    annotator.labels = annotator.labels.concat([customLabel.value]);
    customLabel.value = null;

    populateLabelsSection();
  };
</script>
```

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

labels

A JSON formatted array of strings, each of which is a label that a worker can assign to an instance of an object in the image. Workers can generate different overlay colors for each relevant instance by selecting "add instance" under the label in the tool.

name

The name of this widget. It is used as a key for the labeling data in the form output.

src

The URL of the image that is to be labeled.

initial-value

A JSON object containing the color mappings of a prior instance segmentation job and a link to the overlay image output by the prior job. Include this when you want a human worker to verify the results of a prior labeling job and adjust it if necessary.

The attribute will appear as follows:

```
initial-value="{
  "instances": [
    {
      "color": "#2ca02c",
      "label": "Cat"
    },
    {
      "color": "#1f77b4",
      "label": "Cat"
    },
    {
      "color": "#d62728",
      "label": "Dog"
    }
  ],
  "src": {{ "S3 file URL for image" | grant_read_access }}
```

```
}"
```

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions

Regions

The following regions are supported by this element.

full-instructions

General instructions about how to do image segmentation.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

labeledImage

A JSON Object containing a Base64 encoded PNG of the labels.

instances

A JSON Array containing objects with the instance labels and colors.

- **color** – The hexadecimal value of the label's RGB color in the `labeledImage` PNG.
- **label** – The label given to overlay(s) using that color. This value may repeat, because the different instances of the label are identified by their unique color.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example: Sample Element Outputs

The following is an example of output from this element.

```
[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 533,
        "width": 800
      },
      "instances": [
        {
          "color": "#1f77b4",
          "label": "<Label 1>":
        },
        {
          "color": "#2ca02c",
          "label": "<Label 1>":
        },
        {
          "color": "#ff7f0e",
          "label": "<Label 3>":
        },
      ],
      "labeledImage": {
        "pngImageData": "<Base-64 Encoded Data>"
      }
    }
  }
]
```

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-instructions

An element that displays instructions on three tabbed pages, **Summary**, **Detailed Instructions**, and **Examples**, when the worker clicks on a link or button.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that used the `<crowd-instructions>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

link-text

The text to display for opening the instructions. The default is **Click for instructions**.

link-type

A string that specifies the type of trigger for the instructions. The possible values are "link" (default) and "button".

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

Regions

The following regions are supported by this element.

detailed-instructions

Content that provides specific instructions for a task. This appears on the page of the "Detailed Instructions" tab.

negative-example

Content that provides examples of inadequate task completion. This appears on the page of the "Examples" tab. More than one example may be provided within this element.

positive-example

Content that provides examples of proper task completion. This appears on the page of the "Examples" tab.

short-summary

A brief statement that summarizes the task to be completed. This appears on the page of the "Summary" tab. More than one example may be provided within this element.

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-keypoint

Generates a tool to select and annotate key points on an image.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of an Liquid template that uses the `<crowd-keypoint>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

An array, in JSON format, of keypoints to be applied to the image on start. For example:

```
initial-value="[
  {
    'label': 'Left Eye',
```

```
    'x': 1022,
    'y': 429
  },
  {
    'label': 'Beak',
    'x': 941,
    'y': 403
  }
]
```

> **Note**
>
> Please note that label values used in this attribute must have a matching value in the `labels` attribute or the point will not be rendered.

labels

An array, in JSON format, of strings to be used as keypoint annotation labels.

name

A string used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

src

The source URI of the image to be annotated.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions

Regions

The following regions are required by this element.

full-instructions

General instructions about how to annotate the image.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

keypoints

An array of JSON objects containing the coordinates and label of a keypoint. Each object contains the following properties.

- **label** – The assigned label for the keypoint.
- **x** – The X coordinate, in pixels, of the keypoint on the image.
- **y** – The Y coordinate, in pixels, of the keypoint on the image.

> **Note**
>
> X and Y coordinates are based on 0,0 being the top left corner of the image.

Example: Sample Element Outputs

The following is a sample output from using this element.

```
[
  {
    "crowdKeypoint": {
      "inputImageProperties": {
        "height": 1314,
        "width": 962
```

```
      },
      "keypoints": [
        {
          "label": "dog",
          "x": 155,
          "y": 275
        },
        {
          "label": "cat",
          "x": 341,
          "y": 447
        },
        {
          "label": "cat",
          "x": 491,
          "y": 513
        },
        {
          "label": "dog",
          "x": 714,
          "y": 578
        },
        {
          "label": "cat",
          "x": 712,
          "y": 763
        },
        {
          "label": "cat",
          "x": 397,
          "y": 814
        }
      ]
    }
  }
]
```

You may have many labels available, but only the ones that are used appear in the output.

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth

- Crowd HTML Elements Reference

crowd-line

A widget for drawing lines on an image. Each line is associated with a label, and output data will report the starting and ending points of each line.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-line>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template. For more examples, see this GitHub repository.

Attributes

The following attributes are supported by this element.

header

Optional. The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

Optional. An array of JSON objects, each of which sets a line when the component is loaded. Each JSON object in the array contains the following properties:

- **label** – The text assigned to the line as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the `<crowd-line>` element.
- **vertices** – the `x` and `y` pixel corrdinates of the start point and end point of the line, relative to the top-left corner of the image.

```
initial-value="{
    lines: [
    {
        label: 'sideline', // label of this line annotation
        vertices:[         // an array of vertices which decide the position of the
 line
        {
            x: 84,
            y: 110
```

```
        },
        {
            x: 60,
            y: 100
        }
        ]
    },
    {
        label: 'yardline',
        vertices:[
        {
            x: 651,
            y: 498
        },
        {
            x: 862,
            y: 869
        }
        ]
    }
   ]
}"
```

Lines set via the `initial-value` property can be adjusted. Whether or not a worker answer was adjusted is tracked via an `initialValueModified` boolean in the worker answer output.

labels

Required. A JSON formatted array of strings, each of which is a label that a worker can assign to the line.

Limit: 10 labels

label-colors

Optional. An array of strings. Each string is a hexadecimal (hex) code for a label.

name

Required. The name of this widget. It's used as a key for the widget's input in the form output.

src

Required. The URL of the image on which to draw lines.

Regions

The following regions are required by this element.

full-instructions

General instructions about how to draw lines.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: short-instructions, full-instructions

Output

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

lines

A JSON Array containing objects with the line labels and vertices.

- **label** – The label given to a line.
- vertices – the x and y pixel corrdinates of the start point and end point of the line, relative to the top-left corner of the image.

Example: Sample Element Outputs

The following is an example of output from this element.

```
{
    "crowdLine": { //This is the name you set for the crowd-line
      "inputImageProperties": {
        "height": 1254,
        "width": 2048
      },
      "lines": [
        {
          "label": "yardline",
          "vertices": [
            {
              "x": 58,
              "y": 295
            },
            {
              "x": 1342,
              "y": 398
            }
          ]
        },
        {
          "label": "sideline",
          "vertices": [
            {
              "x": 472,
              "y": 910
            },
            {
              "x": 1480,
              "y": 600
            }
          ]
        }
      ]
    }
  }
```

crowd-modal

A small window that pops up on the display when it is opened.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of the syntax that you can use with the `<crowd-modal>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

link-text

The text to display for opening the modal. The default is "Click to open modal".

link-type

A string that specifies the type of trigger for the modal. The possible values are "link" (default) and "button".

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-polygon

A widget for drawing polygons on an image and assigning a label to the portion of the image that is enclosed in each polygon.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-polygon>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

labels

A JSON formatted array of strings, each of which is a label that a worker can assign to the image portion enclosed by a polygon.

name

The name of this widget. It's used as a key for the widget's input in the form output.

src

The URL of the image on which to draw polygons.

initial-value

An array of JSON objects, each of which defines a polygon to be drawn when the component is loaded. Each JSON object in the array contains the following properties.

- **label** – The text assigned to the polygon as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the <crowd-polygon> element.
- **vertices** – An array of JSON objects. Each object contains an x and y coordinate value for a point in the polygon.

Example

An `initial-value` attribute might look something like this.

```
initial-value =
  '[
     {
     "label": "dog",
     "vertices":
       [
         {
            "x": 570,
            "y": 239
         },
        ...
         {
            "x": 759,
            "y": 281
         }
       ]
     }
  ]'
```

Because this will be within an HTML element, the JSON array must be enclosed in single or double quotes. The example above uses single quotes to encapsulate the JSON and double quotes within the JSON itself. If you must mix single and double quotes inside your JSON, replace them with their HTML entity codes (`"` for double quote, `'` for single) to safely escape them.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions

Regions

The following regions are required.

full-instructions

General instructions about how to draw polygons.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

polygons

An array of JSON objects, each of which describes a polygon that has been created by the worker. Each JSON object in the array contains the following properties.

- **label** – The text assigned to the polygon as part of the labeling task.
- **vertices** – An array of JSON objects. Each object contains an x and y coordinate value for a point in the polygon. The top left corner of the image is 0,0.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example: Sample Element Outputs

The following are samples of outputs from common use scenarios for this element.

Single Label, Single Polygon

```
{
    "annotatedResult":
    {
      "inputImageProperties": {
        "height": 853,
        "width": 1280
      },
      "polygons":
      [
        {
          "label": "dog",
          "vertices":
          [
            {
```

```
              "x": 570,
              "y": 239
            },
            {
              "x": 603,
              "y": 513
            },
            {
              "x": 823,
              "y": 645
            },
            {
              "x": 901,
              "y": 417
            },
            {
              "x": 759,
              "y": 281
            }
          ]
        }
      ]
    }
  }
]
```

Single Label, Multiple Polygons

```
[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 853,
        "width": 1280
      },
      "polygons": [
        {
          "label": "dog",
          "vertices": [
            {
              "x": 570,
              "y": 239
            },
```

```
            {
              "x": 603,
              "y": 513
            },
            {
              "x": 823,
              "y": 645
            },
            {
              "x": 901,
              "y": 417
            },
            {
              "x": 759,
              "y": 281
            }
          ]
        },
        {
          "label": "dog",
          "vertices": [
            {
              "x": 870,
              "y": 278
            },
            {
              "x": 908,
              "y": 446
            },
            {
              "x": 1009,
              "y": 602
            },
            {
              "x": 1116,
              "y": 519
            },
            {
              "x": 1174,
              "y": 498
            },
            {
              "x": 1227,
              "y": 479
```

```
            },
            {
              "x": 1179,
              "y": 405
            },
            {
              "x": 1179,
              "y": 337
            }
          ]
        }
      ]
    }
  }
]
```

Multiple Labels, Multiple Polygons

```
[
  {
    "annotatedResult": {
      "inputImageProperties": {
        "height": 853,
        "width": 1280
      },
      "polygons": [
        {
          "label": "dog",
          "vertices": [
            {
              "x": 570,
              "y": 239
            },
            {
              "x": 603,
              "y": 513
            },
            {
              "x": 823,
              "y": 645
            },
            {
              "x": 901,
```

```
            "y": 417
          },
          {
            "x": 759,
            "y": 281
          }
        ]
      },
      {
        "label": "cat",
        "vertices": [
          {
            "x": 870,
            "y": 278
          },
          {
            "x": 908,
            "y": 446
          },
          {
            "x": 1009,
            "y": 602
          },
          {
            "x": 1116,
            "y": 519
          },
          {
            "x": 1174,
            "y": 498
          },
          {
            "x": 1227,
            "y": 479
          },
          {
            "x": 1179,
            "y": 405
          },
          {
            "x": 1179,
            "y": 337
          }
        ]
```

```
        }
      ]
    }
  }
]
```

You could have many labels available, but only the ones that are used appear in the output.

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-polyline

A widget for drawing polylines or lines on an image. Each polyline is associated with a label and can include two or more vertices. A polyline can intersect itself and its starting and ending points can be placed anywhere on the image.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-polyline>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template. For more examples, see this GitHub repository.

Attributes

The following attributes are supported by this element.

header

Optional. The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

Optional. An array of JSON objects, each of which sets a polyline when the component is loaded. Each JSON object in the array contains the following properties:

- **label** – The text assigned to the polyline as part of the labeling task. This text must match one of the labels defined in the *labels* attribute of the `<crowd-polyline>` element.

- **vertices** – the x and y pixel corrdinates of the vertices of a polyline, relative to the top-left corner of the image.

```
initial-value= "{
   polylines: [
   {
       label: 'sideline', // label of this line annotation
       vertices:[         // an array of vertices which decide the position of the
line
       {
           x: 84,
           y: 110
       },
       {
           x: 60,
           y: 100
       }
       ]
   },
   {
       label: 'yardline',
       vertices:[
       {
           x: 651,
           y: 498
       },
       {
           x: 862,
           y: 869
       },
       {
           x: 1000,
           y: 869
       }
       ]
   }
  ]
}"
```

Polylines set via the `initial-value` property can be adjusted. Whether or not a worker answer was adjusted is tracked via an `initialValueModified` boolean in the worker answer output.

labels

Required. A JSON formatted array of strings, each of which is a label that a worker can assign to the line.

Limit: 10 labels

label-colors

Optional. An array of strings. Each string is a hexadecimal (hex) code for a label.

name

Required. The name of this widget. It's used as a key for the widget's input in the form output.

src

Required. The URL of the image on which to draw polylines.

Regions

The following regions are required by this element.

full-instructions

General instructions about how to draw polylines.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: short-instructions, full-instructions

Output

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

polylines

A JSON Array containing objects with polylines' labels and vertices.

- **label** – The label given to a line.
- vertices – the x and y pixel corrdinates of the vertices of a polyline, relative to the top-left corner of the image.

Example: Sample Element Outputs

The following is an example of output from this element.

```
{
   "crowdPolyline": { //This is the name you set for the crowd-polyline
     "inputImageProperties": {
       "height": 1254,
       "width": 2048
     },
     "polylines": [
       {
         "label": "sideline",
         "vertices": [
           {
             "x": 651,
             "y": 498
           },
           {
             "x": 862,
             "y": 869
           },
           {
             "x": 1449,
             "y": 611
           }
         ]
       },
       {
         "label": "yardline",
```

```
          "vertices": [
            {
              "x": 1148,
              "y": 322
            },
            {
              "x": 1705,
              "y": 474
            },
            ,
            {
              "x": 1755,
              "y": 474
            }
          ]
        }
      ]
    }
  }
```

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-radio-button

A button that can be either checked or unchecked. When radio buttons are inside a radio group, exactly one radio button in the group can be checked at any time. The following is an example of how to configure a `crowd-radio-button` element inside of a `crowd-radio-group` element.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of the syntax that you can use with the `<crowd-radio-button>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

The previous example can be seen in a custom worker task template in this GitHub example: entity recognition labeling job custom template.

Crowd HTML Element radio buttons do not support the HTML tag, `required`. To make a radio button selection required, use `<input type="radio">` elements to create radio buttons and add the `required` tag. The `name` attribute for all `<input>` elements that belong to the same group of radio buttons must be the same. For example, the following template requires the user to select a radio button in the `animal-type` group before submitting.

Attributes

The following attributes are supported by this element.

checked

A Boolean switch that, if present, displays the radio button as checked.

disabled

A Boolean switch that, if present, displays the button as disabled and prevents it from being checked.

name

A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

> **Note**
>
> If you use the buttons outside of a crowd-radio-group element, but with the same `name` string and different `value` strings, the `name` object in the output will contain a Boolean value for each `value` string. To ensure that only one button in a group is selected, make them children of a crowd-radio-group element and use different name values.

value

A property name for the element's boolean value. If not specified, it uses "on" as the default, e.g. `{ "<name>": { "<value>": <true or false> } }`.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-radio-group
- **Child elements**: none

Output

Outputs an object with the following pattern: `{ "<name>": { "<value>": <true or false> } }`. If you use the buttons outside of a crowd-radio-group element, but with the same `name` string and different `value` strings, the name object will contain a Boolean value for each `value` string. To ensure that only one in a group of buttons is selected, make them children of a crowd-radio-group element and use different name values.

Example Sample output of this element

```
[
  {
    "btn1": {
      "yes": true
    },
    "btn2": {
      "no": false
    }
  }
]
```

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-radio-group

A group of radio buttons. Only one radio button within the group can be selected. Choosing one radio button clears any previously chosen radio button within the same group. For an example of a custom UI template that uses the `crowd-radio-group` element, see this entity recognition labeling job custom template.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of the syntax that you can use with the <crowd-radio-group> element. Copy the following code and save it in a file with the extension .html. Open the file in any browser to preview and interact with this template.

Attributes

No special attributes are supported by this element.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: crowd-radio-button

Output

Outputs an array of objects representing the crowd-radio-button elements within it.

Example Sample of Element Output

```
[
  {
    "btn1": {
      "yes": true
    },
    "btn2": {
      "no": false
    }
  }
]
```

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-semantic-segmentation

A widget for segmenting an image and assigning a label to each image segment.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-semantic-segmentation>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

header

The text to display above the image. This is typically a question or simple instruction for the worker.

initial-value

A JSON object containing the color mappings of a prior semantic segmentation job and a link to the overlay image output by the prior job. Include this when you want a human worker to verify the results of a prior labeling job and adjust it if necessary.

The attribute would appear as follows:

```
initial-value='{
  "labelMappings": {
      "Bird": {
        "color": "#ff7f0e"
      },
      "Cat": {
        "color": "#2ca02c"
      },
      "Cow": {
        "color": "#d62728"
      },
      "Dog": {
        "color": "#1f77b4"
      }
    },
  "src": {{ "S3 file URL for image" | grant_read_access }}
}'
```

When using Ground Truth built in task types with annotation consolidation (where more than one worker labels a single image), label mappings are included in individual worker output records, however the overall result is represented as the `internal-color-map` in the consolidated results.

You can convert the `internal-color-map` to `label-mappings` in a custom template using the Liquid templating language:

```
initial-value="{
  'src' : '{{ task.input.manifestLine.label-attribute-name-from-prior-job|
 grant_read_access }}',
  'labelMappings': {
     {% for box in task.input.manifestLine.label-attribute-name-from-prior-job-
metadata.internal-color-map %}
       {% if box[1]['class-name'] != 'BACKGROUND' %}
         {{ box[1]['class-name'] | to_json }}: {
           'color': {{ box[1]['hex-color'] | to_json }}
         },
       {% endif %}
     {% endfor %}
   }
}"
```

labels

A JSON formatted array of strings, each of which is a label that a worker can assign to a segment of the image.

name

The name of this widget. It is used as a key for the widget's input in the form output.

src

The URL of the image that is to be segmented.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: full-instructions, short-instructions

Regions

The following regions are supported by this element.

full-instructions

General instructions about how to do image segmentation.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Output

The following output is supported by this element.

labeledImage

A JSON Object containing a Base64 encoded PNG of the labels.

labelMappings

A JSON Object containing objects with named with the segmentation labels.

- **color** – The hexadecimal value of the label's RGB color in the `labeledImage` PNG.

initialValueModified

A boolean representing whether the initial values have been modified. This is only included when the output is from an adjustment task.

inputImageProperties

A JSON object that specifies the dimensions of the image that is being annotated by the worker. This object contains the following properties.

- **height** – The height, in pixels, of the image.
- **width** – The width, in pixels, of the image.

Example: Sample Element Outputs

The following is a sample of output from this element.

```
[
```

```
  {
    "annotatedResult": {
      "inputImageProperties": {

- Crowd HTML Elements Reference

crowd-slider

A bar with a sliding knob that allows a worker to select a value from a range of values by moving the knob. The slider makes it a great choice for settings that reflect intensity levels, such as volume, brightness, or color saturation.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a survey template that uses the `<crowd-slider>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

disabled

A Boolean switch that, if present, displays the slider as disabled.

editable

A Boolean switch that, if present, displays an up/down button that can be chosen to select the value.

Selecting the value via the up/down button is an alternative to selecting the value by moving the knob on the slider. The knob on the slider will move synchronously with the up/down button choices.

max

A number that specifies the maximum value on the slider.

min

A number that specifies the minimum value on the slider.

name

A string that is used to identify the answer submitted by the worker. This value will match a key in the JSON object that specifies the answer.

pin

A Boolean switch that, if present, displays the current value above the knob as the knob is moved.

required

A Boolean switch that, if present, requires the worker to provide input.

secondary-progress

When used with a `crowd-slider-secondary-color` CSS attribute, the progress bar is colored to the point represented by the `secondary-progress`. For example, if this was representing

the progress on a streaming video, the `value` would represent where the viewer was in the video timeline. The `secondary-progress` value would represent the point on the timeline to which the video had buffered.

step

A number that specifies the difference between selectable values on the slider.

value

A preset that becomes the default if the worker does not provide input.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-tab

A component styled to look like a tab with information below.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example template that uses the `<crowd-tab>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

header

The text appearing on the tab. This is usually some short descriptive name indicative of the information contained below the tab.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-tabs
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-tabs

A container for tabbed information.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example template that uses the `<crowd-tabs>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

This element has no attributes.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: crowd-tab

See Also

For more information, see the following.

crowd-text-area

A field for text input.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template designed to transcribe audio clips that uses the `<crowd-text-area>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

allowed-pattern

A regular expression that is used with the *auto-validate* attribute to ignore non-matching characters as the worker types.

auto-focus

A Boolean switch that, if present, puts the cursor in this element on-load so that users can immediately begin typing without having to click inside the element.

auto-validate

A Boolean switch that, if present, turns on input validation. The behavior of the validator can be modified by the *error-message* and *allowed-pattern* attributes.

char-counter

A Boolean switch that, if present, puts a small text field beneath the lower-right corner of the element, displaying the number of characters inside the element.

disabled

A Boolean switch that, if present, displays the input area as disabled.

error-message

The text to be displayed below the input field, on the left side, if validation fails.

label

A string that is displayed inside a text field.

This text shrinks and rises up above a text field when the worker starts typing in the field or when the *value* attribute is set.

max-length

An integer that specifies the maximum number of characters allowed by the element. Characters typed or pasted beyond the maximum are ignored.

max-rows

An integer that specifies the maximum number of rows of text that are allowed within a crowd-text-area. Normally the element expands to accommodate new rows. If this is set, after the number of rows exceeds it, content scrolls upward out of view and a scrollbar control appears.

name

A string used to represent the element's data in the output.

placeholder

A string presented to the user as placeholder text. It disappears after the user puts something in the input area.

rows

An integer that specifies the height of the element in rows of text.

value

A preset that becomes the default if the worker does not provide input. The preset appears in a text field.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

Output

This element outputs the `name` as a property name and the element's text contents as the value. Carriage returns in the text are represented as `\n`.

Example Sample output for this element

```
[
  {
    "textInput1": "This is the text; the text that\nmakes the crowd go wild."
  }
]
```

See Also

For more information, see the following.

- Crowd HTML Elements Reference

crowd-toast

A subtle notification that temporarily appears on the display. Only one crowd-toast is visible.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following is an example of a Liquid template that uses the `<crowd-toast>` element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

duration

A number that specifies the duration, in milliseconds, that the notification appears on the screen.

text

The text to display in the notification.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

See Also

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-toggle-button

A button that acts as an ON/OFF switch, toggling a state.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

The following example shows different ways you can use to use the `<crowd-toggle-button>` HTML element. Copy the following code and save it in a file with the extension `.html`. Open the file in any browser to preview and interact with this template.

Attributes

The following attributes are supported by this element.

checked

A Boolean switch that, if present, displays the button switched to the ON position.

disabled

A Boolean switch that, if present, displays the button as disabled and prevents toggling.

invalid

When in an off position, a button using this attribute, will display in an alert color. The standard is red, but may be changed in CSS. When toggled on, the button will display in the same color as other buttons in the on position.

name

A string that is used to identify the answer submitted by the worker. This value matches a key in the JSON object that specifies the answer.

required

A Boolean switch that, if present, requires the worker to provide input.

value

A value used in the output as the property name for the element's Boolean state. Defaults to "on" if not provided.

Element Hierarchy

This element has the following parent and child elements.

- **Parent elements**: crowd-form
- **Child elements**: none

Output

This element outputs the `name` as the name of an object, containing the `value` as a property name and the element's state as Boolean value for the property. If no value for the element is specified, the property name defaults to "on."

Example Sample output for this element

```
[
  {
    "theToggler": {
      "on": true
    }
  }
```

```
]
```

Crowd HTML Elements V2

Crowd HTML V2 Elements introduce enhanced labeling capabilities designed to support workers, with new features tailored for GenAI model training use cases. These V2 elements are compatible with the Crowd HTML Elements crowd-form, short-instructions, crowd-button, crowd-tabs, and crowd-tab. If you use other elements with V2 elements, the annotation application won't work properly.

crowd-text-ranking

A widget for workers to slide and rank various text inputs based on dimensions that you specify.

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

Attributes

The following are attributes supported by this element.

text

The text or S3 reference to the text to reference when ranking the responses.

ordinal-ranking-dimensions

A required array of the `ordinal-ranking-dimensions` object, which specify the dimension on which to rank the responses. This dimension contains a **name** and a property named **allowTie**, which determines whether a worker can give responses the same ranking.

responses

A required array of the `ordinal-ranking-dimensions` object, which specify the dimension on which to rank the responses. This dimension contains a **name** and a property named **allowTie**, which determines whether a worker can give responses the same ranking.

name

A required string field that identifies the answer submitted that the worker submits. It matches a key in the output data contract of the worker submission.

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

crowd-question-answer-generation

A widget for workers to highlight sections of text and assign question and answer pairs based on your instructions

See an interactive example of an HTML template that uses this Crowd HTML Element in CodePen.

Attributes

The following are attributes supported by this element.

text

The text or S3 reference to the text to reference when ranking the responses.

min-questions

Optional integer that specifies the minimum amount of questions that a worker would have to create during the task. If not provided, you will be asked to write at least one question and answer pair.

max-questions

Optional integer that specifies the maximum amount of questions a worker can create during the task.

question-min-words

Optional integer that specifies the minimum amount of words allowed in an question. If not provided, you will be asked to provide at least one word in the question.

question-max-words

Optional integer that specifies the maximum amount of words allowed in an question.

answer-min-words

Optional integer that specifies the minimum amount of words allowed in an answer. If not provided, you will be asked to write at least one word in the answer.

answer-max-words

Optional integer that specifies the maximum amount of words allowed in an answer.

question-tags

A required array of strings that specifies the possible tags a worker can assign to a question-answer pair. If this array is empty, then question-tags field isn't visible.

allow-custom-question-tags

Required Boolean field that indicates whether a worker can specify a custom question tag.

name

A required string field that identifies the answer submitted that the worker submits. It matches a key in the output data contract of the worker submission.

For more information, see the following.

- Training data labeling using humans with Amazon SageMaker Ground Truth
- Crowd HTML Elements Reference

Augmented AI Crowd HTML Elements

The following Crowd HTML Elements are only available for Amazon Augmented AI human workflow tasks.

crowd-textract-analyze-document

A widget to enable human review of a Amazon Textract document analysis result.

Attributes

The following attributes are supported by this element.

header

This is the text that is displayed as the header.

src

This is a link to the image to be analyzed by the worker.

initialValue

This sets initial values for attributes found in the worker UI.

The following is an example of an `initialValue` input:

```
[
            {
                "blockType": "KEY_VALUE_SET",
                "confidence": 38.43309020996094,
                "geometry": {
                    "boundingBox": {
                        "width": 0.32613086700439453,
                        "weight": 0.0942094624042511,
                        "left": 0.4833833575248718,
                        "top": 0.5227988958358765
                    },
                    "polygon": [
                        {"x": 0.123, "y": 0.345}, ...
                    ]
                }
                "id": "8c97b240-0969-4678-834a-646c95da9cf4",
                "relationships": [
                    {
                        "type": "CHILD",
                        "ids": [
                            "7ee7b7da-ee1b-428d-a567-55a3e3affa56",
                            "4d6da730-ba43-467c-a9a5-c6137ba0c472"
                        ]
                    },
                    {
                        "type": "VALUE",
                        "ids": [
                            "6ee7b7da-ee1b-428d-a567-55a3e3affa54"
                        ]
                    }
                ],
                "entityTypes": [
                    "KEY"
                ],
```

```
                "text": "Foo bar"
            },
]
```

blockTypes

This determines the kind of analysis the workers can do. Only `KEY_VALUE_SET` is currently supported.

keys

This specifies new keys and the associated text value the worker can add. The input values for `keys` can include the following elements:

- `importantFormKey` accepts strings, and is used to specify a single key.
- `importantFormKeyAliases` can be used to specify aliases that are acceptable alternatives to the keys supplied. Use this element to identify alternative spellings or presentations of your keys. This parameter accepts a list of one or more strings.

The following is an example of an input for `keys`.

```
[
      {
        importantFormKey: 'Address',
        importantFormKeyAliases: [
          'address',
          'Addr.',
          'Add.',
        ]
      },
      {
        importantFormKey: 'Last name',
        importantFormKeyAliases: ['Surname']
      }
]
```

no-key-edit

This prevents the workers from editing the keys of annotations passed through `initialValue`. This prevents workers from editing the keys that have been detected on your documents. This is required.

no-geometry-edit

This prevents workers from editing the polygons of annotations passed through `initialValue`. For example, this would prevent the worker from editing the bounding box around a given key. This is required.

Element Hierarchy

This element has the following parent and child elements.

- Parent elements – crowd-form
- Child elements – full-instructions, short-instructions

Regions

The following regions are supported by this element. You can use custom HTML and CSS code within these regions to format your instructions to workers. For example, use the `short-instructions` section to provide good and bad examples of how to complete a task.

full-instructions

General instructions about how to work with the widget.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Example of a Worker Template Using the crowd Element

An example of a worker template using this crowd element would look like the following.

Output

The following is a sample of the output from this element. You can find a detailed explanation of this output in the Amazon Textract AnalyzeDocument API documentation.

```
{
  "AWS/Textract/AnalyzeDocument/Forms/V1": {
    blocks: [
      {
        "blockType": "KEY_VALUE_SET",
```

```
        "id": "8c97b240-0969-4678-834a-646c95da9cf4",
        "relationships": [
          {
            "type": "CHILD",
            "ids": ["7ee7b7da-ee1b-428d-a567-55a3e3affa56", "4d6da730-ba43-467c-a9a5-
c6137ba0c472"]
          },
          {
            "type": "VALUE",
            "ids": ["6ee7b7da-ee1b-428d-a567-55a3e3affa54"]
          }
        ],
        "entityTypes": ["KEY"],
        "text": "Foo bar baz"
      }
    ]
  }
}
```

crowd-rekognition-detect-moderation-labels

A widget to enable human review of an Amazon Rekognition image moderation result.

Attributes

The following attributes are supported by this element.

header

This is the text that is displayed as the header.

src

This is a link to the image to be analyzed by the worker.

categories

This supports `categories` as an array of strings **or** an array of objects where each object has a `name` field.

If the categories come in as objects, the following applies:

- The displayed categories are the value of the `name` field.

- The returned answer contains the **full** objects of any selected categories.

If the categories come in as strings, the following applies:

- The returned answer is an array of all the strings that were selected.

exclusion-category

By setting this attribute you create a button underneath the categories in the UI.

- When a user chooses the button, all categories are deselected and disabled.
- Choosing the button again re-enables the categories so that users can choose them.
- If you submit after choosing the button, it returns an empty array.

Element Hierarchy

This element has the following parent and child elements.

- Parent elements – crowd-form
- Child elements – full-instructions, short-instructions

Amazon Regions

The following Amazon Regions are supported by this element. You can use custom HTML and CSS code within these Regions to format your instructions to workers. For example, use the `short-instructions` section to provide good and bad examples of how to complete a task.

full-instructions

General instructions about how to work with the widget.

short-instructions

Important task-specific instructions that are displayed in a prominent place.

Example Worker Template with the crowd Element

An example of a worker template using the crowd element would look like the following.

Output

The following is a sample of the output from this element. For details about this output, see Amazon Rekognition DetectModerationLabels API documentation.

```
{
  "AWS/Rekognition/DetectModerationLabels/Image/V3": {
    "ModerationLabels": [
        { name: 'Gore', parentName: 'Violence' },
        { name: 'Corpses', parentName: 'Violence' },
    ]
  }
}
```

Using Amazon Augmented AI for Human Review

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

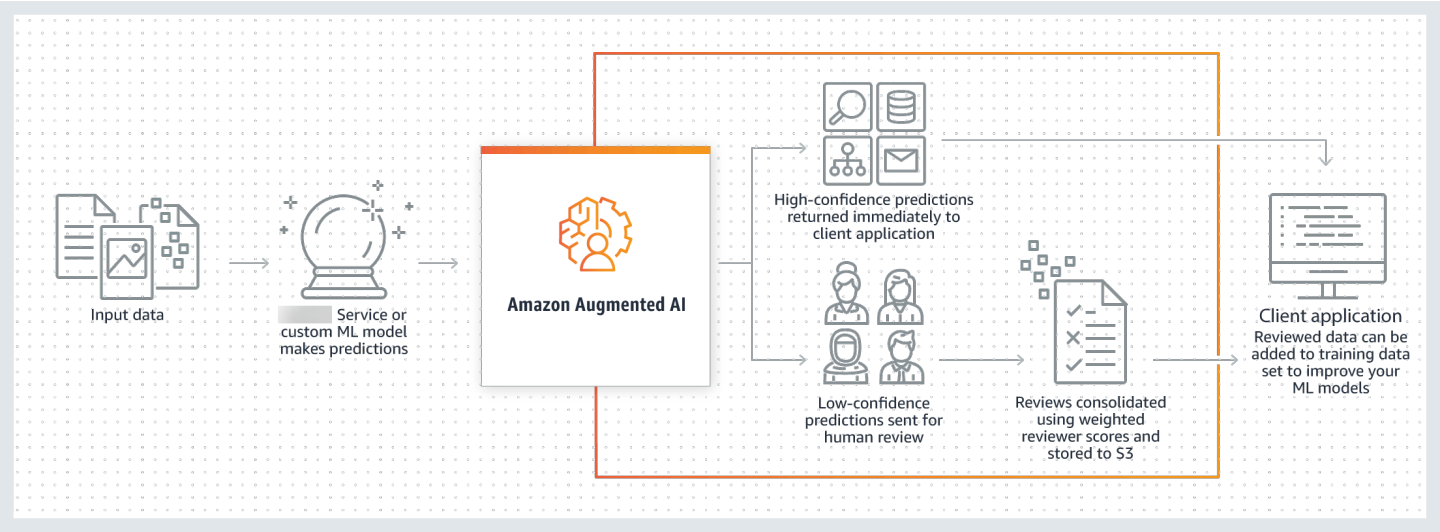
This feature is not available in the China Regions.

When you use AI applications such as Amazon Rekognition, Amazon Textract, or your custom machine learning (ML) models, you can use Amazon Augmented AI to get human review of low-confidence predictions or random prediction samples.

What is Amazon Augmented AI?

Amazon Augmented AI (Amazon A2I) is a service that brings human review of ML predictions to all developers by removing the heavy lifting associated with building human review systems or managing large numbers of human reviewers.

Many ML applications require humans to review low-confidence predictions to ensure the results are correct. For example, extracting information from scanned mortgage application forms can



require human review due to low-quality scans or poor handwriting. Building human review systems can be time-consuming and expensive because it involves implementing complex processes or *workflows*, writing custom software to manage review tasks and results, and managing large groups of reviewers.

Amazon A2I streamlines building and managing human reviews for ML applications. Amazon A2I provides built-in human review workflows for common ML use cases, such as content moderation and text extraction from documents. You can also create your own workflows for ML models built on SageMaker AI or any other tools. Using Amazon A2I, you can allow human reviewers to step in when a model is unable to make a high-confidence prediction or to audit its predictions on an ongoing basis.

Amazon A2I Use Case Examples

The following examples demonstrate how you can use Amazon A2I to integrate a human review loop into your ML application. For each of these examples, you can find a Jupyter Notebook that demonstrates that workflow in Use Cases and Examples Using Amazon A2I.

- **Use Amazon A2I with Amazon Textract** – Have humans review important key-value pairs in single-page documents or have Amazon Textract randomly sample and send documents from your dataset to humans for review.
- **Use Amazon A2I with Amazon Rekognition** – Have humans review unsafe images for explicit adult or violent content if Amazon Rekognition returns a low-confidence score, or have Amazon Rekognition randomly sample and send images from your dataset to humans for review.
- **Use Amazon A2I to review real-time ML inferences** – Use Amazon A2I to review real-time, low-confidence inferences made by a model deployed to a SageMaker AI hosted endpoint and incrementally train your model using Amazon A2I output data.
- **Use Amazon A2I with Amazon Comprehend** – Have humans review Amazon Comprehend inferences about text data such as sentiment analysis, text syntax, and entity detection.
- **Use Amazon A2I with Amazon Transcribe** – Have humans review Amazon Transcribe transcriptions of video or audio files. Use the results of transcription human review loops to create a custom vocabulary and improve future transcriptions of similar video or audio content.
- **Use Amazon A2I with Amazon Translate** – Have humans review low-confidence translations returned from Amazon Translate.
- **Use Amazon A2I to review tabular data** – Use Amazon A2I to integrate a human review loop into an ML application that uses tabular data.

Get Started with Amazon Augmented AI

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

To get started using Amazon Augmented AI, review the Core Components of Amazon A2I and Prerequisites to Using Augmented AI. Then, use the following documentation to learn how to use the Amazon A2I console and API.

- Tutorial: Get Started in the Amazon A2I Console
- Tutorial: Get Started Using the Amazon A2I API

You can also get stared using the Amazon A2I API by following a Jupyter Notebook tutorial. See Use Cases and Examples Using Amazon A2I for a list of notebooks and use cases.

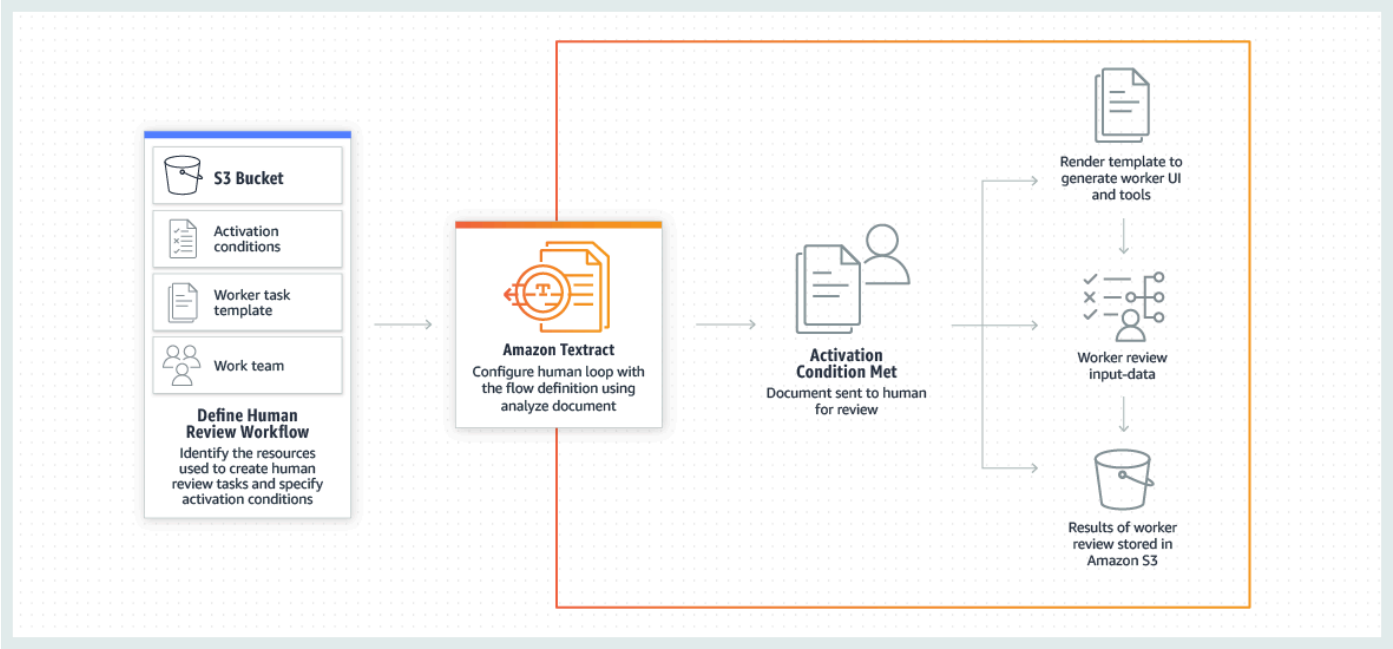
Core Components of Amazon A2I

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

Review the following terms to familiarize yourself with the core components of Amazon A2I.

Task Types

The AI/ML workflow into which you integrate Amazon A2I defines an Amazon A2I *task type*.



Amazon A2I supports:

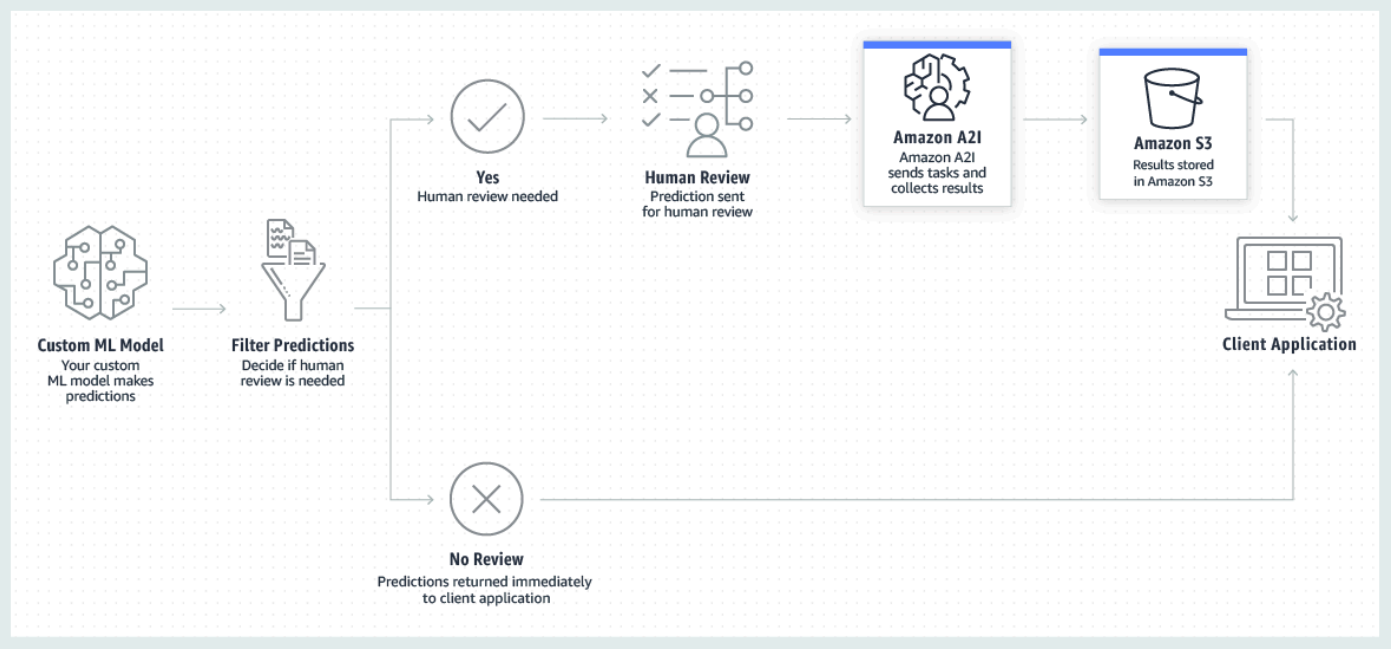
- Two *built-in task types*: Amazon Textract key-value pair extraction and Amazon Rekognition image moderation.
- A custom task type: Use a custom task type to integrate a human review loop into *any* machine learning workflow. You can use a custom task type to integrate Amazon A2I with other Amazon services like Amazon Comprehend, Amazon Transcribe, and Amazon Translate, as well as your own custom machine learning workflows. To learn more, see Use Cases and Examples Using Amazon A2I.

Select a tab in the following table to see diagrams that illustrate how Amazon A2I works with each task type. Select the task type page using the links in the preceding list to learn more about that task type.

Amazon Textract – Key-value pair extraction

This image depicts the Amazon A2I built-in workflow with Amazon Textract. On the left, the resources that are required to create an Amazon Textract human review workflow are depicted: an Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Textract to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

Amazon Rekognition – Image moderation



This image depicts the Amazon A2I built-in workflow with Amazon Rekognition. On the left, the resources that are required to create an Amazon Rekognition human review workflow are depicted: an Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Rekognition to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps:

1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

Custom Task Type

The following image depicts the Amazon A2I custom workflow. A custom ML model is used to generate predictions. The client application filters these predictions using user-defined criteria and determines if a human review is required. If so, these predictions are sent to Amazon A2I for human review. Amazon A2I collects the results of human review in Amazon S3, which can access by the client application. If the filter determines that no human review is needed, predictions can be fed directly to the client application.

Human Review Workflow (Flow Definition)

You use a human review workflow to specify your human *work team*, to set up your worker UI using a *worker task template*, and to provide information about how workers should complete the review task.

For built-in task types, you also use the human review workflow to identify the conditions under which a human loop is initiated. For example, Amazon Rekognition can perform image content moderation using machine learning. You can use the human review workflow to specify that an image is sent to a human for content moderation review if Amazon Rekognition's confidence is too low.

You can use a human review workflow to create multiple human loops.

You can create a flow definition in the SageMaker AI console or with the SageMaker API. To learn more about both of these options, see Create a Human Review Workflow.

Work Team

A *work team* is a group of human workers to whom you send your human review tasks.

When you create a human review workflow, you specify a single work team.

Your work team can come from a vendor-managed workforce or your own private workforce. When you use the private workforce, you can create multiple work teams. Each work team can be used

in multiple human review workflows. To learn how to create a workforce and work teams, see Workforces.

Worker Task Template and Human Task UI

You use a *worker task template* to create a worker UI (a *human task UI*) for your human review tasks.

The human task UI displays your input data, such as documents or images, and instructions to workers. It also provides interactive tools that the worker uses to complete your tasks.

For built-in task types, you must use the Amazon A2I worker task template provided for that task type.

Human Loops

A *human loop* is used to create a single human review job. For each human review job, you can choose the number of workers that are sent a *task* to review a single data object. For example, if you set the number of workers per object to 3 for an image classification labeling job, three workers classify each input image. Increasing the number of workers per object can improve label accuracy.

A human loop is created using a human review workflow as follows:

- For built-in task types, the conditions specified in the human review workflow determine when the human loop is created.
- Human review tasks are sent to the work team specified in the human review workflow.
- The worker task template specified in the human review workflow is used to render the human task UI.

When do human loops get created?

When you use one of the *built-in task types*, the corresponding Amazon service creates and starts a human loop on your behalf when the conditions specified in your human review workflow are met. For example:

- When you use Augmented AI with Amazon Textract, you can integrate Amazon A2I into a document review task using the API operation `AnalyzeDocument`. A human loop is created every time Amazon Textract returns inferences about key-value pairs that meet the conditions you specify in your human review workflow.

- When you use Augmented AI with Amazon Rekognition, you can integrate Amazon A2I into an image moderation task using the API operation `DetectModerationLabels`. A human loop is created every time Amazon Rekognition returns inferences about image content that meet the conditions you specify in your human review workflow.

When using a *custom task type*, you start a human loop using the Amazon Augmented AI Runtime API. When you call `StartHumanLoop` in your custom application, a task is sent to human reviewers.

To learn how to create and start a human loop, see Create and Start a Human Loop.

To generate these resources and create a human review workflow, Amazon A2I integrates multiple APIs, including the Amazon Augmented AI Runtime Model, the SageMaker APIs, and APIs associated with your task type. To learn more, see Use APIs in Amazon Augmented AI.

> **Note**
>
> Amazon Region availability may differ when you use Augmented AI with other Amazon services, such as Amazon Textract. Create Augmented AI resources in the same Amazon Region that you use to interact with those Amazon services. For Amazon Region availability for all services, see the Region Table.

Prerequisites to Using Augmented AI

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

Amazon A2I uses resources in IAM, SageMaker AI, and Amazon S3 to create and run your human review workflows. You can create some of these resources in the Amazon A2I console when you create a human review workflow. To learn how, see Tutorial: Get Started in the Amazon A2I Console.

To use Amazon A2I, you need the following resources:

- One or more Amazon S3 buckets in the same Amazon Region as the workflow for your input and output data. To create a bucket, follow the instructions in Create a Bucket in the *Amazon Simple Storage Service Console User Guide*.
- An IAM role with required permissions to create a human review workflow and an IAM user or role with permission to access Augmented AI. For more information, see Permissions and Security in Amazon Augmented AI.
- A private or vendor workforce for your human review workflows. If you plan to use a private workforce, you need to set one up ahead of time in the same Amazon Region as your Amazon A2I workflow. To learn more about these workforce types, see Workforces.

> **Important**
>
> To learn about the compliance programs that cover Amazon Augmented AI at this time, see Amazon Services in Scope by Compliance Program. If you use Amazon Augmented AI in conjunction with other Amazon services (such as Amazon Rekognition and Amazon Textract), note that Amazon Augmented AI may not be in scope for the same compliance programs as those other services. You are responsible for how you use Amazon Augmented AI, including understanding how the service processes or stores customer data and any impact on the compliance of your data environment. You should discuss your workload objectives and goals with your Amazon account team; they can help you evaluate whether the service is a good fit for your proposed use case and architecture.

Tutorial: Get Started in the Amazon A2I Console

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

The following tutorial shows you how to get started using Amazon A2I in the Amazon A2I console.

The tutorial gives you the option to use Augmented AI with Amazon Textract for document review or Amazon Rekognition for image content review.

Prerequisites

To get started using Amazon A2I, complete the following prerequisites.

- Create an Amazon S3 bucket in the same Amazon Region as the workflow for your input and output data. For example, if you are using Amazon A2I with Amazon Textract in us-east-1, create your bucket in us-east-1. To create a bucket, follow the instructions in Create a Bucket in the *Amazon Simple Storage Service Console User Guide*.
- Do one of the following:
  - If you want to complete the tutorial using Amazon Textract, download the following image and place it in your Amazon S3 bucket.

  - If you want to complete the tutorial using Amazon Rekognition, download the following image and place it in your Amazon S3 bucket.

> **Note**
>
> The Amazon A2I console is embedded in the SageMaker AI console.

Step 1: Create a Work Team

First, create a work team in the Amazon A2I console and add yourself as a worker so that you can preview the worker review task.

> **Important**
>
> This tutorial uses a private work team. The Amazon A2I private workforce is configured in the Ground Truth area of the SageMaker AI console and is shared between Amazon A2I and Ground Truth.

To create a private workforce using worker emails

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, choose **Labeling workforces** under **Ground Truth**.
3. Choose **Private**, then choose **Create private team**.
4. Choose **Invite new workers by email**.
5. For this tutorial, enter your email and any others that you want to be able to preview the human task UI. You can paste or type a list of up to 50 email addresses, separated by commas, into the email addresses box.
6. Enter an organization name and contact email.
7. Optionally, choose an Amazon SNS topic to which to subscribe the team so workers are notified by email when new Ground Truth labeling jobs become available. Amazon SNS notifications are supported by Ground Truth and are not supported by Augmented AI. If you subscribe workers to Amazon SNS notifications, they only receive notifications about Ground Truth labeling jobs. They do not receive notifications about Augmented AI tasks.
8. Choose **Create private team**.

If you add yourself to a private work team, you receive an email from `no-reply@verificationemail.com` with login information. Use the link in this email to reset your password and log in to your worker portal. This is where your human review tasks appear when you create a human loop.

Step 2: Create a Human Review Workflow

In this step, you create a human review workflow. Each human review workflow is created for a specific task type. This tutorial allows you to choose between the built-in task types: Amazon Rekognition and Amazon Textract.

To create a human review workflow:

1. Open the Augmented AI console at https://console.amazonaws.cn/a2i to access the **Human review workflows** page.
2. Select **Create human review workflow**.
3. In **Workflow settings**, enter a workflow **Name**, **S3 bucket**, and the **IAM role** that you created for this tutorial, with the Amazon managed policy `AmazonAugmentedAIIntegratedAPIAccess` attached.

4. For **Task type**, select **Textract – Key-value pair extraction** or **Rekognition – Image moderation**.
5. Select the task type that you chose from the following table for instructions for that task type.

   Amazon Textract – Key-value pair extraction

   1. Select **Trigger a human review for specific form keys based on the form key confidence score or when specific form keys are missing**.

   2. For **Key name**, enter `Mail Address`.

   3. Set the identification confidence threshold between `0` and 99.

   4. Set the qualification confidence threshold between `0` and 99.

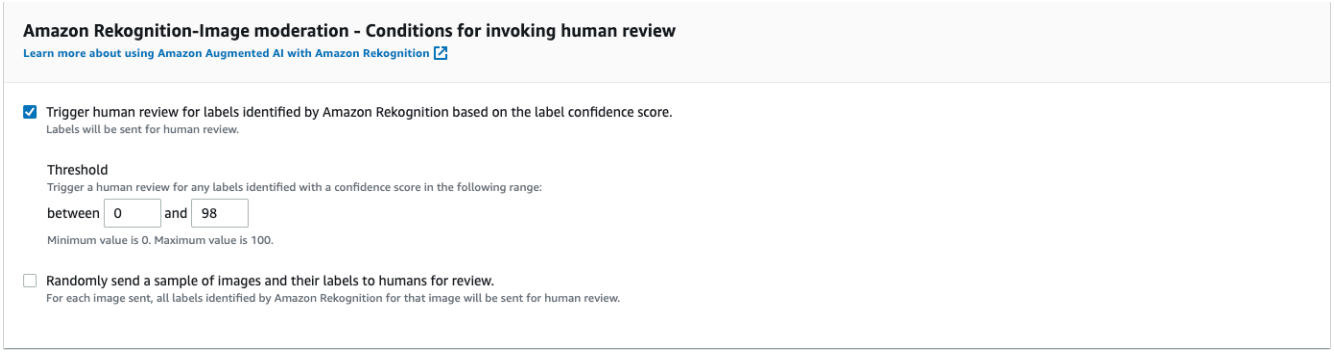
   5. Select **Trigger a human review for all form keys identified by Amazon Textract with confidence scores in a specific range**.

   6. Set the identification confidence threshold between `0` and `90`.

   7. Set the qualification confidence threshold between `0` and `90`.

   This initiates a human review if Amazon Textract returns a confidence score that is less than 99 for `Mail Address` and its key, or if it returns a confidence score less than `90` for any key value pair detected in the document.

   The following image shows the Amazon Textract form extraction - Conditions for invoking human review section of the Amazon A2I console. In the image, the check boxes for the two types of triggers explained in the proceeding paragraph are checked, and `Mail Address` is used as a **Key name** for the first trigger. The identification confidence threshold is defined using confidence scores for key-value pairs detect within the form and is set between 0 and 99. The qualification confidence threshold is defined using confidence scores for text contained within keys and values in a form and is set between 0 and 99.



Amazon Rekognition – Image moderation

1. Select **Trigger human review for labels identified by Amazon Rekognition based on label confidence score**.

2. Set the **Threshold** between `0` and 98.

This initiates a human review if Amazon Rekognition returns a confidence score that is less than 98 for an image moderation job.

The following image shows how you can select the **Trigger human review for labels identified by Amazon Rekognition based on label confidence score** option and enter a **Threshold** between 0 and 98 in the Amazon A2I console.

6. Under **Worker task template creation**, select **Create from a default template**.
7. Enter a **Template name**.
8. In **Task description** field, enter the following text:

   ```
   Read the instructions carefully and complete the task.
   ```

9. Under **Workers**, select **Private**.
10. Select the private team that you created.
11. Choose **Create**.

Once your human review workflow is created, it appears in the table on the **Human review workflows** page. When the **Status** is `Active`, copy and save the Workflow ARN. You need it for the next step.

Step 3: Start a Human Loop

You must use an API operation to start a human loop. There are a variety of language-specific SDKs that you can use to interact with these API operations. To see documentation for each of these SDKs, refer to the **See Also** section in the API documentation, as shown in the following image.

For this tutorial, you use one of the following APIs:

- If you chose the Amazon Textract task type, you use the `AnalyzeDocument` operation.
- If you chose the Amazon Rekognition task type, you use the `DetectModerationLabels` operation.

You can interact with these APIs using a SageMaker notebook instance (recommended for new users) or the Amazon Command Line Interface (Amazon CLI). Choose one of the following to learn more about these options:

- To learn more about and set up a notebook instance, see Amazon SageMaker notebook instances.
- To learn more about and get started using the Amazon CLI, see What Is the Amazon Command Line Interface? in the *Amazon Command Line Interface User Guide*.

Select your task type in the following table to see example requests for Amazon Textract and Amazon Rekognition using the Amazon SDK for Python (Boto3).

Amazon Textract – Key-value pair extraction

The following example uses the Amazon SDK for Python (Boto3) to call `analyze_document` in us-west-2. Replace the italicized red text with your resources. For more information, see the `analyze_document` documention in the *Amazon SDK for Python (Boto) API Reference*.

```
   response = client.analyze_document(
         Document={
                "S3Object": {
                    "Bucket": "amzn-s3-demo-bucket",
                    "Name": "document-name.pdf"
                }
         },
         HumanLoopConfig={
            "FlowDefinitionArn":"arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
            "HumanLoopName":"human-loop-name",
            "DataAttributes" : {
                "ContentClassifiers":
["FreeOfPersonallyIdentifiableInformation","FreeOfAdultContent"]
            }
         },
         FeatureTypes=["TABLES", "FORMS"])
```

Amazon Rekognition – Image moderation

The following example uses the Amazon SDK for Python (Boto3) to call `detect_moderation_labels` in us-west-2. Replace the italicized red text with your resources. For more information, see the `detect_moderation_labels` documentation in the *Amazon SDK for Python (Boto) API Reference*.

```
   response = client.detect_moderation_labels(
            Image={
                "S3Object":{
                    "Bucket": "amzn-s3-demo-bucket",
                    "Name": "image-name.png"
                }
            },
            HumanLoopConfig={
```

```
                "FlowDefinitionArn":"arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
                "HumanLoopName":"human-loop-name",
                "DataAttributes":{
                     ContentClassifiers:
["FreeOfPersonallyIdentifiableInformation"|"FreeOfAdultContent"]
                 }
             })
```

Step 4: View Human Loop Status in Console

When you start a human loop, you can view its status in the Amazon A2I console.

To view your human loop status

1. Open the Augmented AI console at https://console.amazonaws.cn/a2i to access the **Human review workflows** page.
2. Select the human review workflow that you used to start your human loop.
3. In the **Human loops** section, you can see your human loop. View its status in the **Status** column.

Step 5: Download Output Data

Your output data is stored in the Amazon S3 bucket you specified when you created a human review workflow.

To view your Amazon A2I output data

1. Open the Amazon S3 console.
2. Select the Amazon S3 bucket you specified when you created your human review workflow in step 2 of this example.
3. Starting with the folder that is named after your human review workflow, navigate to your output data by selecting the folder with the following naming convention:

   ```
   s3://output-bucket-specified-in-human-review-workflow/human-review-workflow-
   name/YYYY/MM/DD/hh/mm/ss/human-loop-name/output.json
   ```

4. Select `output.json` and choose **Download**.

Tutorial: Get Started Using the Amazon A2I API

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

This tutorial explains the API operations you can use to get started using Amazon A2I.

To use a Jupyter Notebook to run these operations, select a Jupyter Notebook from Use Cases and Examples Using Amazon A2I and use Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook to learn how to use it in a SageMaker AI notebook instance.

To learn more about the API operations you can use with Amazon A2I, see Use APIs in Amazon Augmented AI.

Create a Private Work Team

You can create a private work team and add yourself as a worker so that you can preview Amazon A2I.

If you are not familiar with Amazon Cognito, we recommend that you use the SageMaker AI console to create a private workforce and add yourself as a private worker. For instructions, see Step 1: Create a Work Team.

If you are familiar with Amazon Cognito, you can use the following instructions to create a private work team using the SageMaker API. After you create a work team, note the work team ARN (`WorkteamArn`).

To learn more about the private workforce and other available configurations, see Private workforce.

Create a private workforce

If you have not created a private workforce, you can do so using an Amazon Cognito user pool. Make sure that you have added yourself to this user pool. You can create a private work team using the Amazon SDK for Python (Boto3) `create_workforce` function. For other language-specific SDKs, refer to the list in CreateWorkforce.

```
response = client.create_workforce(
    CognitoConfig={
        "UserPool": "Pool_ID",
        "ClientId": "app-client-id"
    },
    WorkforceName="workforce-name"
)
```

Create a private work team

After you have created a private workforce in the Amazon Region to configure and start your human loop, you can create a private work team using the Amazon SDK for Python (Boto3) `create_workteam` function. For other language-specific SDKs, refer to the list in `CreateWorkteam`.

```
response = client.create_workteam(
    WorkteamName="work-team-name",
    WorkforceName= "workforce-name",
    MemberDefinitions=[
        {
            "CognitoMemberDefinition": {
                "UserPool": "<aws-region>_ID",
                "UserGroup": "user-group",
                "ClientId": "app-client-id"
            },
        }
    ]
)
```

Access your work team ARN as follows:

```
workteamArn = response["WorkteamArn"]
```

List private work teams in your account

If you have already created a private work team, you can list all work teams in a given Amazon Region in your account using the Amazon SDK for Python (Boto3) `list_workteams` function. For other language-specific SDKs, refer to the list in `ListWorkteams`.

```
    response = client.list_workteams()
```

If you have numerous work teams in your account, you may want to use `MaxResults`, `SortBy`, and `NameContains` to filter your results.

Create a Human Review Workflow

You can create a human review workflow using the Amazon A2I `CreateFlowDefinition` operation. Before you create your human review workflow, you need to create a human task UI. You can do this with the `CreateHumanTaskUi` operation.

If you are using Amazon A2I with the Amazon Textract or Amazon Rekognition integrations, you can specify activation conditions using a JSON.

Create a Human Task UI

If you are creating a human review workflow to be used with Amazon Textract or Amazon Rekognition integrations, you need to use and modify pre-made worker task template. For all custom integrations, you can use your own custom worker task template. Use the following table to learn how to create a human task UI using a worker task template for the two built-in integrations. Replace the template with your own to customize this request.

Amazon Textract – Key-value pair extraction

To learn more about this template, see Custom Template Example for Amazon Textract.

Amazon Rekognition – Image moderation

To learn more about this template, see Custom Template Example for Amazon Rekognition.

Custom Integration

The following is an example template that can be used in a custom integration. This template is used in this notebook, demonstrating a custom integration with Amazon Comprehend.

Using the template specified above, you can create a template using the Amazon SDK for Python (Boto3) `create_human_task_ui` function. For other language-specific SDKs, refer to the list in `CreateHumanTaskUi`.

```
    response = client.create_human_task_ui(
```

```
        HumanTaskUiName="human-task-ui-name",
        UiTemplate={
            "Content": template
        }
    )
```

This response element contains the human task UI ARN. Save this as follows:

```
    humanTaskUiArn = response["HumanTaskUiArn"]
```

Create JSON to specify activation conditions

For Amazon Textract and Amazon Rekognition built-in integrations, you can save activation conditions in a JSON object and use this in your `CreateFlowDefinition` request.

Next, select a tab to see example activation conditions you can use for these built-in integrations. For additional information about activation condition options, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI.

Amazon Textract – Key-value pair extraction

This example specifies conditions for specific keys (such as `Mail address`) in the document. If Amazon Textract's confidence falls outside of the thresholds set here, the document is sent to a human for review, with the specific keys that initiated the human loop prompted to the worker.

```
     import json

     humanLoopActivationConditions = json.dumps(
       {
           "Conditions": [
               {
                 "Or": [

                   {
                       "ConditionType": "ImportantFormKeyConfidenceCheck",
                       "ConditionParameters": {
                           "ImportantFormKey": "Mail address",
                           "ImportantFormKeyAliases": ["Mail Address:","Mail
address:", "Mailing Add:","Mailing Addresses"],
                           "KeyValueBlockConfidenceLessThan": 100,
```

```
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                        "ConditionType": "MissingImportantFormKey",
                        "ConditionParameters": {
                            "ImportantFormKey": "Mail address",
                            "ImportantFormKeyAliases": ["Mail Address:","Mail
address:","Mailing Add:","Mailing Addresses"]
                        }
                    },
                    {
                        "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "Phone Number",
                            "ImportantFormKeyAliases": ["Phone number:", "Phone
No.:", "Number:"],
                            "KeyValueBlockConfidenceLessThan": 100,
                            "WordBlockConfidenceLessThan": 100
                        }
                    },
                    {
                      "ConditionType": "ImportantFormKeyConfidenceCheck",
                      "ConditionParameters": {
                        "ImportantFormKey": "*",
                        "KeyValueBlockConfidenceLessThan": 100,
                        "WordBlockConfidenceLessThan": 100
                      }
                    },
                    {
                      "ConditionType": "ImportantFormKeyConfidenceCheck",
                      "ConditionParameters": {
                        "ImportantFormKey": "*",
                        "KeyValueBlockConfidenceGreaterThan": 0,
                        "WordBlockConfidenceGreaterThan": 0
                      }
                    }
            ]
        }
            ]
        }
    )
```

Amazon Rekognition – Image moderation

The human loop activation conditions used here are tailored towards Amazon Rekognition content moderation; they are based on the confidence thresholds for the `Suggestive` and `Female Swimwear Or Underwear` moderation labels.

```
    import json

    humanLoopActivationConditions = json.dumps(
    {
        "Conditions": [
            {
              "Or": [
                {
                    "ConditionType": "ModerationLabelConfidenceCheck",
                    "ConditionParameters": {
                        "ModerationLabelName": "Suggestive",
                        "ConfidenceLessThan": 98
                    }
                },
                {
                    "ConditionType": "ModerationLabelConfidenceCheck",
                    "ConditionParameters": {
                        "ModerationLabelName": "Female Swimwear Or Underwear",
                        "ConfidenceGreaterThan": 98
                    }
                }
              ]
            }
        ]
    }
)
```

Create a human review workflow

This section gives an example of the `CreateFlowDefinition` Amazon SDK for Python (Boto3) request using the resources created in the previous sections. For other language-specific SDKs, refer to the list in CreateFlowDefinition. Use the tabs in the following table to see the requests to create a human review workflow for Amazon Textract and Amazon Rekognition built-in integrations.

Amazon Textract – Key-value pair extraction

If you use the built-in integration with Amazon Textract, you must specify `"AWS/Textract/AnalyzeDocument/Forms/V1"` for `"AwsManagedHumanLoopRequestSource"` in `HumanLoopRequestSource`.

```
    response = client.create_flow_definition(
        FlowDefinitionName="human-review-workflow-name",
        HumanLoopRequestSource={
            "AwsManagedHumanLoopRequestSource": "AWS/Textract/AnalyzeDocument/Forms/
V1"
        },
        HumanLoopActivationConfig={
            "HumanLoopActivationConditionsConfig": {
                "HumanLoopActivationConditions": humanLoopActivationConditions
            }
        },
        HumanLoopConfig={
            "WorkteamArn": workteamArn,
            "HumanTaskUiArn": humanTaskUiArn,
            "TaskTitle": "Document entry review",
            "TaskDescription": "Review the document and instructions. Complete the
 task",
            "TaskCount": 1,
            "TaskAvailabilityLifetimeInSeconds": 43200,
            "TaskTimeLimitInSeconds": 3600,
            "TaskKeywords": [
                "document review",
            ],
        },
        OutputConfig={
            "S3OutputPath": "s3://amzn-s3-demo-bucket/prefix/",
        },
        RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
        Tags=[
            {
                "Key": "string",
                "Value": "string"
            },
        ]
    )
```

Amazon Rekognition – Image moderation

If you use the built-in integration with Amazon Rekognition, you must specify `"AWS/Rekognition/DetectModerationLabels/Image/V3"` for `"AwsManagedHumanLoopRequestSource"` in `HumanLoopRequestSource`.

```
    response = client.create_flow_definition(
        FlowDefinitionName="human-review-workflow-name",
        HumanLoopRequestSource={
            "AwsManagedHumanLoopRequestSource": "AWS/Rekognition/
DetectModerationLabels/Image/V3"
        },
        HumanLoopActivationConfig={
            "HumanLoopActivationConditionsConfig": {
                "HumanLoopActivationConditions": humanLoopActivationConditions
            }
        },
        HumanLoopConfig={
            "WorkteamArn": workteamArn,
            "HumanTaskUiArn": humanTaskUiArn,
            "TaskTitle": "Image content moderation",
            "TaskDescription": "Review the image and instructions. Complete the
 task",
            "TaskCount": 1,
            "TaskAvailabilityLifetimeInSeconds": 43200,
            "TaskTimeLimitInSeconds": 3600,
            "TaskKeywords": [
                "content moderation",
            ],
        },
        OutputConfig={
            "S3OutputPath": "s3://amzn-s3-demo-bucket/prefix/",
        },
        RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
        Tags=[
            {
                "Key": "string",
                "Value": "string"
            },
        ]
    )
```

Custom Integration

If you use a custom integration, exclude the following parameters: `HumanLoopRequestSource`, `HumanLoopActivationConfig`.

```
   response = client.create_flow_definition(
       FlowDefinitionName="human-review-workflow-name",
       HumanLoopConfig={
           "WorkteamArn": workteamArn,
           "HumanTaskUiArn": humanTaskUiArn,
           "TaskTitle": "Image content moderation",
           "TaskDescription": "Review the image and instructions. Complete the
task",
           "TaskCount": 1,
           "TaskAvailabilityLifetimeInSeconds": 43200,
           "TaskTimeLimitInSeconds": 3600,
           "TaskKeywords": [
               "content moderation",
           ],
       },
       OutputConfig={
           "S3OutputPath": "s3://amzn-s3-demo-bucket/prefix/",
       },
       RoleArn="arn:aws:iam::<account-number>:role/<role-name>",
       Tags=[
           {
               "Key": "string",
               "Value": "string"
           },
       ]
   )
```

After you create a human review workflow, you can retrieve the flow definition ARN from the response:

```
   humanReviewWorkflowArn = response["FlowDefinitionArn"]
```

Create a Human Loop

The API operation you use to start a human loop depends on the Amazon A2I integration you use.

- If you use the Amazon Textract built-in integration, you use the AnalyzeDocument operation.
- If you use the Amazon Rekognition built-in integration, you use the DetectModerationLabels operation.
- If you use a custom integration, you use the StartHumanLoop operation.

Select your task type in the following table to see example requests for Amazon Textract and Amazon Rekognition using the Amazon SDK for Python (Boto3).

Amazon Textract – Key-value pair extraction

The following example uses the Amazon SDK for Python (Boto3) to call `analyze_document` in us-west-2. Replace the italicized red text with your resources. For more information, see the analyze_document documention in the *Amazon SDK for Python (Boto) API Reference*.

```
   response = client.analyze_document(
         Document={"S3Object": {"Bucket": "amzn-s3-demo-bucket", "Name": "document-
name.pdf"},
         HumanLoopConfig={
            "FlowDefinitionArn":"arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
            "HumanLoopName":"human-loop-name",
            "DataAttributes" : {ContentClassifiers:
["FreeOfPersonallyIdentifiableInformation"|"FreeOfAdultContent"]}
         }
         FeatureTypes=["FORMS"]
    )
```

Human loops are only created if Amazon Textract's confidence for document analysis task meets the activation conditions you specified in your human review workflow. You can check the `response` element to determine if a human loop has been created. To see everything included in this response, see `HumanLoopActivationOutput`.

```
   if "HumanLoopArn" in analyzeDocumentResponse["HumanLoopActivationOutput"]:
       # A human loop has been started!
       print(f"A human loop has been started with ARN:
 {analyzeDocumentResponse["HumanLoopActivationOutput"]["HumanLoopArn"]}"
```

Amazon Rekognition – Image moderation

The following example uses the Amazon SDK for Python (Boto3) to call `detect_moderation_labels` in us-west-2. Replace the italicized red text with your resources. For more information, see the detect_moderation_labels documention in the *Amazon SDK for Python (Boto) API Reference*.

```
   response = client.detect_moderation_labels(
            Image={"S3Object":{"Bucket": "amzn-s3-demo-bucket", "Name": "image-
name.png"}},
            HumanLoopConfig={
               "FlowDefinitionArn":"arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
               "HumanLoopName":"human-loop-name",
               "DataAttributes":{ContentClassifiers:
["FreeOfPersonallyIdentifiableInformation"|"FreeOfAdultContent"]}
             }
    )
```

Human loops are only created if Amazon Rekognition's confidence for an image moderation task meets the activation conditions you specified in your human review workflow. You can check the `response` element to determine if a human loop has been created. To see everything included in this response, see `HumanLoopActivationOutput`.

```
    if "HumanLoopArn" in response["HumanLoopActivationOutput"]:
        # A human loop has been started!
        print(f"A human loop has been started with ARN:
 {response["HumanLoopActivationOutput"]["HumanLoopArn"]}")
```

Custom Integration

The following example uses the Amazon SDK for Python (Boto3) to call `start_human_loop` in us-west-2. Replace the italicized red text with your resources. For more information, see the start_human_loop documention in the *Amazon SDK for Python (Boto) API Reference*.

```
   response = client.start_human_loop(
        HumanLoopName= "human-loop-name",
```

```
        FlowDefinitionArn= "arn:aws:sagemaker:us-west-2:111122223333:flow-
definition/flow-definition-name",
        HumanLoopInput={"InputContent": inputContentJson},
        DataAttributes={"ContentClassifiers":
["FreeOfPersonallyIdentifiableInformation"|"FreeOfAdultContent"]}
    )
```

This example stores input content in the variable *inputContentJson*. Assume that the input content contains two elements: a text blurb and sentiment (such as `Positive`, `Negative`, or `Neutral`), and it is formatted as follows:

```
    inputContent = {
        "initialValue": sentiment,
         "taskObject": blurb
     }
```

The keys `initialValue` and `taskObject` must correspond to the keys used in the liquid elements of the worker task template. Refer to the custom template in Create a Human Task UI to see an example.

To create *inputContentJson*, do the following:

```
    import json

    inputContentJson = json.dumps(inputContent)
```

A human loop starts each time you call `start_human_loop`. To check the status of your human loop, use describe_human_loop:

```
    human_loop_info = a2i.describe_human_loop(HumanLoopName="human_loop_name")
    print(f"HumanLoop Status: {resp["HumanLoopStatus"]}")
    print(f"HumanLoop Output Destination: {resp["HumanLoopOutput"]}")
```

Use Cases and Examples Using Amazon A2I

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

You can use Amazon Augmented AI to incorporate a human review into your workflow for *built-in task types*, Amazon Textract and Amazon Rekognition, or your own custom tasks using a *custom task type*.

When you create a human review workflow using one of the built-in task types, you can specify conditions, such as confidence thresholds, that initiate a human review. The service (Amazon Rekognition or Amazon Textract) creates a human loop on your behalf when these conditions are met and supplies your input data directly to Amazon A2I to send to human reviewers. To learn more about the built-in task types, use the following:

- Use Amazon Augmented AI with Amazon Textract
- Use Amazon Augmented AI with Amazon Rekognition

When you use a custom task type, you create and start a human loop using the Amazon A2I Runtime API. Use the custom task type to incorporate a human review workflow with other Amazon services or your own custom ML application.

- For more details, see Use Amazon Augmented AI with Custom Task Types

The following table outlines a variety of Amazon A2I use cases that you can explore using SageMaker AI Jupyter Notebooks. To get started with a Jupyter Notebook, use the instructions in Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook. For more examples, see this GitHub repository.

Use Case	Description	Task Type
Use Amazon A2I with Amazon Textract	Have humans review single-page documents to review	Built-in

Use Case	Description	Task Type
	important form key-value pairs, or have Amazon Textract randomly sample and send documents from your dataset to humans for review.	
Use Amazon A2I with Amazon Rekognition	Have humans review unsafe images for explicit adult or violent content if Amazon Rekognition returns a low confidence score, or have Amazon Rekognition randomly sample and send images from your dataset to humans for review.	Built-in
Use Amazon A2I with Amazon Comprehend	Have humans review Amazon Comprehend inferences about text data such as sentiment analysis, text syntax, and entity detection.	Custom
Use Amazon A2I with Amazon Transcribe	Have humans review Amazon Transcribe transcriptions of video or audio files. Use the results of transcription human review loops to create a custom vocabulary and improve future transcrip tions of similar video or audio content.	Custom

Use Case	Description	Task Type
Use Amazon A2I with Amazon Translate	Have humans review low-confidence translations returned from Amazon Translate.	Custom
Use Amazon A2I to review real time ML inferences	Use Amazon A2I to review real-time, low-confidence inferences made by a model deployed to a SageMaker AI hosted endpoint and incrementally train your model using Amazon A2I output data.	Custom
Use Amazon A2I to review tabular data	Use Amazon A2I to integrate a human review loop into an ML application that uses tabular data.	Custom

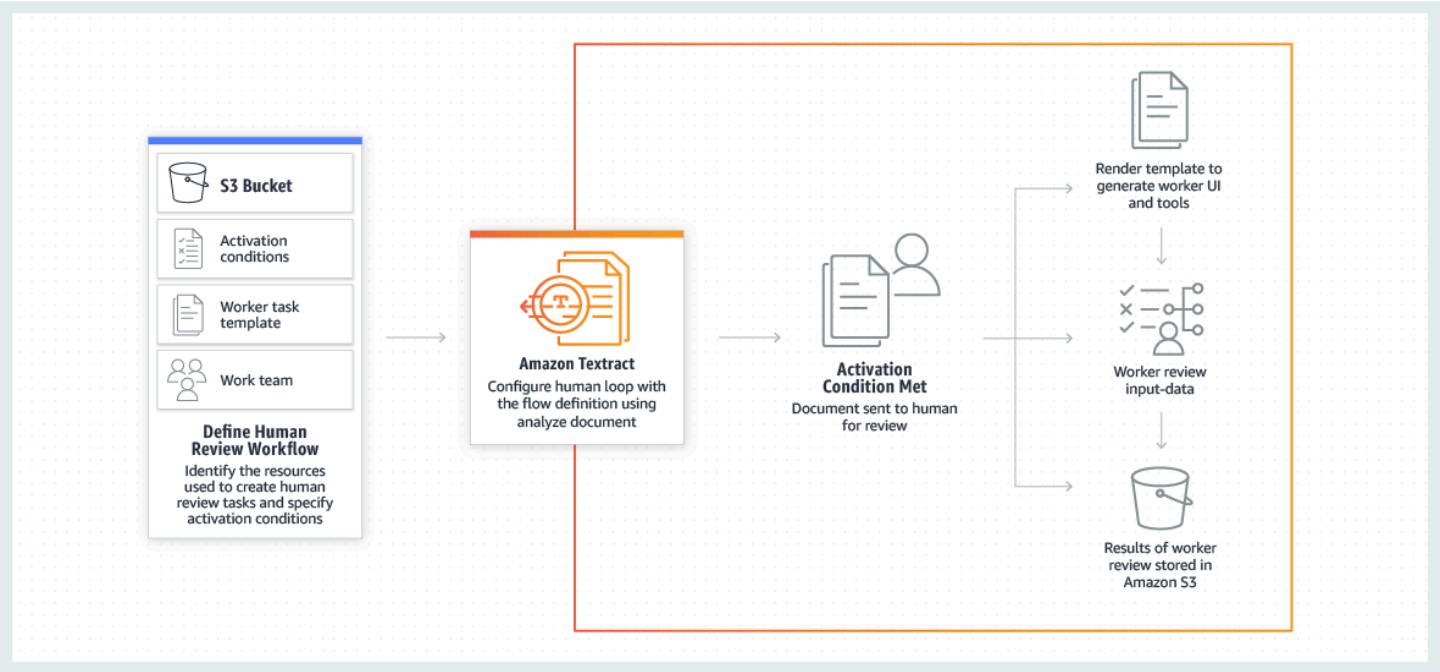
- Use Amazon Augmented AI with Custom Task Types

Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook

For an end-to-end example that demonstrates how to integrate an Amazon A2I human review loop into a machine learning workflow, you can use a Jupyter Notebook from this GitHub Repository in a SageMaker notebook instance.

To use an Amazon A2I custom task type sample notebook in an Amazon SageMaker notebook instance:

1. If you do not have an active SageMaker notebook instance, create one by following the instructions in Create an Amazon SageMaker Notebook Instance for the tutorial.
2. When your notebook instance is active, choose **Open JupyterLab** to the right of the notebook instance's name. It may take a few moments for JupyterLab to load.
3. Choose the add Github repository icon () to clone a GitHub repository into your workspace.
4. Enter the amazon-a2i-sample-jupyter-notebooks repository HTTPS URL.
5. Choose **CLONE**.
6. Open the notebook that you would like to run.
7. Follow the instructions in the notebook to configure your human review workflow and human loop and run the cells.
8. To avoid incurring unnecessary charges, when you are done with the demo, stop and delete your notebook instance in addition to any Amazon S3 buckets, IAM roles, and CloudWatch Events resources created during the walkthrough.



Use Amazon Augmented AI with Amazon Textract

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

Amazon Textract enables you to add document text detection and analysis to your applications. Amazon Augmented AI (Amazon A2I) directly integrates with Amazon Textract's `AnalyzeDocument` API operation. You can use `AnalyzeDocument` to analyze a document for relationships between detected items. When you add an Amazon A2I human review loop to an `AnalyzeDocument` request, Amazon A2I monitors the Amazon Textract results and sends a document to one or more human workers for review when the conditions specified in your flow definition are met. For example, if you want a human to review a specific key like `Full name:` and their associated input values, you can create an activation condition that starts a human review any

time the `Full name:` key is detected or when the inference confidence for that key falls within a range that you specify.

The following image depicts the Amazon A2I built-in workflow with Amazon Textract. On the left, the resources that are required to create an Amazon Textract human review workflow are depicted: and Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Textract to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers,2) workers review input data, and finally, 3) results are saved in Amazon S3.

You can specify when Amazon Textract sends a task to a human worker for review when creating a human review workflow or flow definition by specifying *activation conditions*.

You can set the following activation conditions when using the Amazon Textract task type:

- Initiate a human review for specific form keys based on the form key confidence score.
- Initiate a human review when specific form keys are missing.
- Initiate human review for all form keys identified by Amazon Textract with confidence scores in a specified range.

- Randomly send a sample of forms to humans for review.

When your activation condition depends on form key confidence scores, you can use two types of prediction confidence to initiate human loops:

- **Identification confidence** – The confidence score for key-value pairs detected within a form.
- **Qualification confidence** – The confidence score for text contained within key and value in a form.

In the image in the following section, **Full Name: Jane Doe** is the key-value pair, **Full Name** is the key, and **Jane Doe** is the value.

You can set these activation conditions using the Amazon SageMaker AI console when you create a human review workflow, or by creating a JSON for human loop activation conditions and specifying this as input in the `HumanLoopActivationConditions` parameter of `CreateFlowDefinition` API operation. To learn how specify activation conditions in JSON format, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI and Use Human Loop Activation Conditions JSON Schema with Amazon Textract.

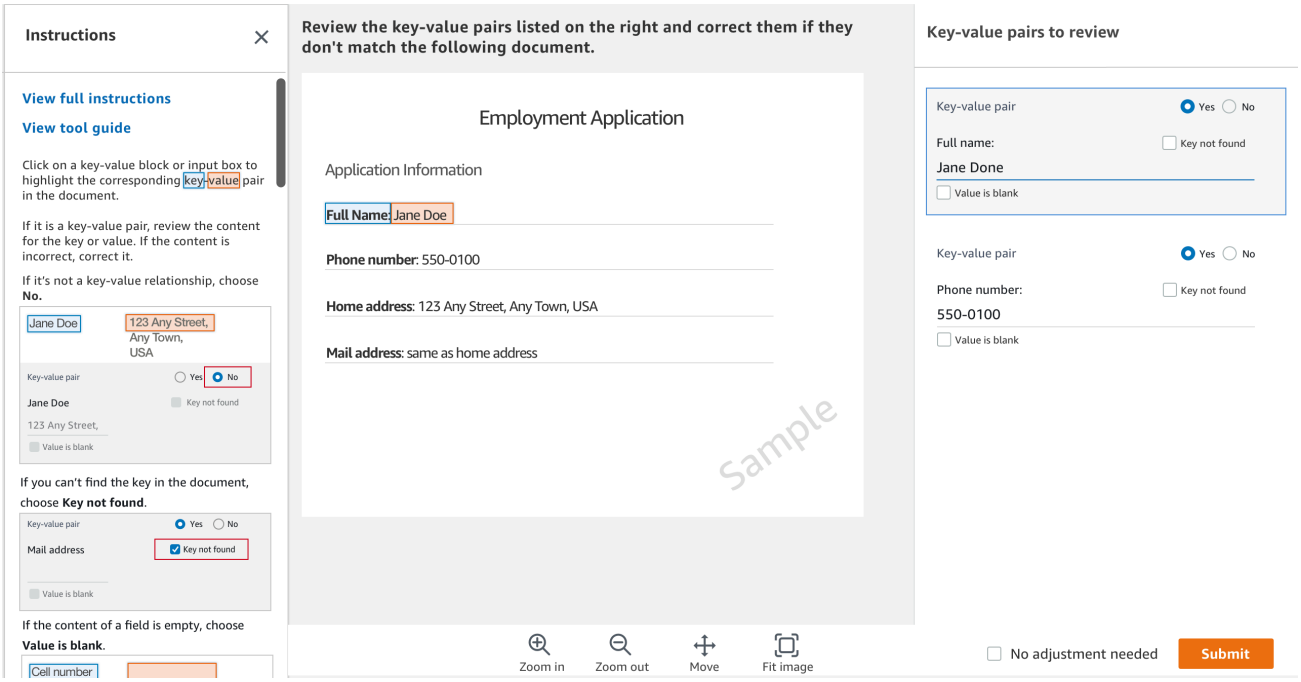
> **Note**
>
> When using Augmented AI with Amazon Textract, create Augmented AI resources in the same Amazon Region you use to call `AnalyzeDocument`.

Get Started: Integrate a Human Review into an Amazon Textract Analyze Document Job

To integrate a human review into an Amazon Textract text detection and analysis job, you need to create a flow definition, and then use the Amazon Textract API to integrate that flow definition into your workflow. To learn how to create a flow definition using the SageMaker AI console or Augmented AI API, see the following topics:

- Create a Human Review Workflow (Console)
- Create a Human Review Workflow (API)

After you've created your flow definition, see Using Augmented AI with Amazon Textract to learn how to integrate your flow definition into your Amazon Textract task.



End-to-End Example Using Amazon Textract and Amazon A2I

For an end-to-end example that demonstrates how to use Amazon Textract with Amazon A2I using the console, see Tutorial: Get Started in the Amazon A2I Console.

To learn how to use the Amazon A2I API to create and start a human review, you can use Amazon Augmented AI (Amazon A2I) integration with Amazon Textract's Analyze Document [Example] in a SageMaker Notebook instance. To get started, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook.

A2I Textract Worker Console Preview

When they're assigned a review task in an Amazon Textract workflow, workers might see a user interface similar to the following:

You can customize this interface in the SageMaker AI console when you create your human review definition, or by creating and using a custom template. To learn more, see Create and Manage Worker Task Templates.

Use Amazon Augmented AI with Amazon Rekognition

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

Amazon Rekognition makes it easy to add image analysis to your applications. The Amazon Rekognition `DetectModerationLabels` API operation is directly integrated with Amazon A2I so that you can easily create a human loop to review unsafe images, such as explicit adult or violent content. You can use `DetectModerationLabels` to configure a human loop using a flow definition ARN. This enables Amazon A2I to analyze predictions made by Amazon Rekognition and send results to a human for review to ensure they meet the conditions set in your flow definition.

The following image depicts the Amazon A2I built-in workflow with Amazon Rekognition. On the left, the resources that are required to create an Amazon Rekognition human review workflow are depicted: and Amazon S3 bucket, activation conditions, a worker task template, and a work team. These resources are used to create a human review workflow, or flow definition. An arrow points right to the next step in the workflow: using Amazon Rekognition to configure a human loop with the human review workflow. A second arrow points right from this step to the step in which activation conditions specified in the human review workflow are met. This initiates the creation of a human loop. On the right of the image, the human loop is depicted in three steps: 1) the worker UI and tools are generated and the task is made available to workers, 2) workers review input data, and finally, 3) results are saved in Amazon S3.

You can set the following activation conditions when using the Amazon Rekognition task type:

- Initiate human review for labels identified by Amazon Rekognition based on the label confidence score.
- Randomly send a sample of images to humans for review.

You can set these activation conditions using the Amazon SageMaker AI console when you create a human review workflow, or by creating a JSON for human loop activation conditions and specifying this as input in the `HumanLoopActivationConditions` parameter of the `CreateFlowDefinition` API operation. To learn how specify activation conditions in JSON format, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI and Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition.

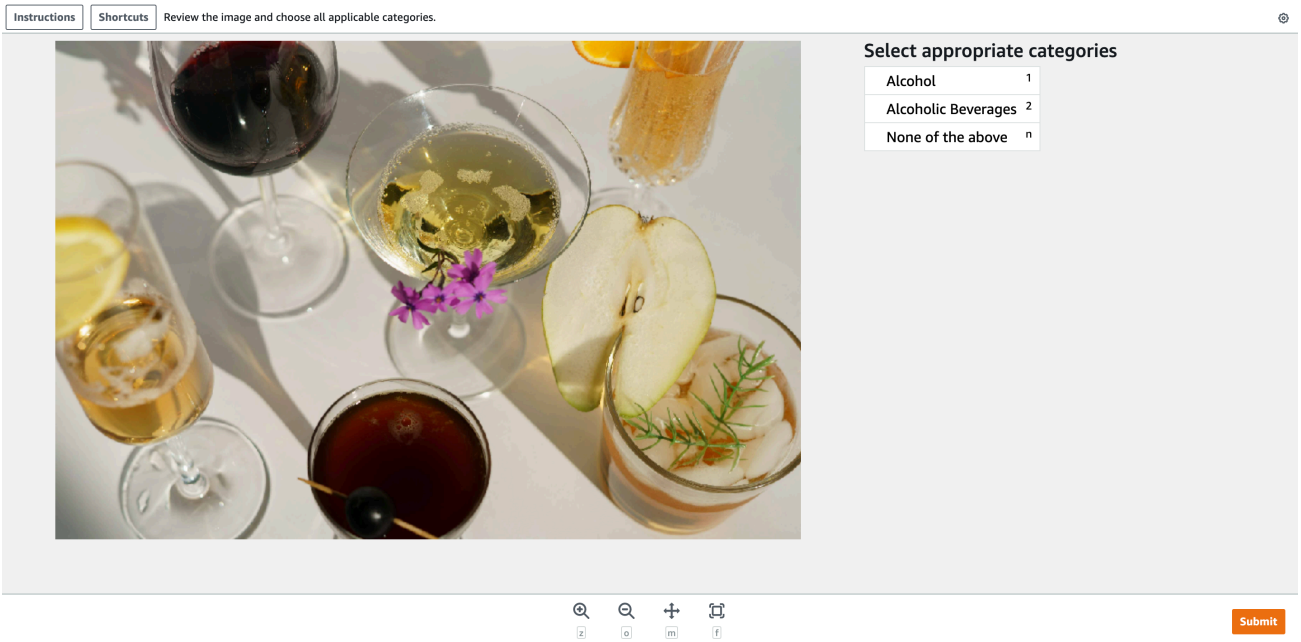
> **Note**
>
> When using Augmented AI with Amazon Rekognition, create Augmented AI resources in the same Amazon Region you use to call `DetectModerationLabels`.

Get Started: Integrate a Human Review into an Amazon Rekognition Image Moderation Job

To integrate a human review into an Amazon Rekognition, see the following topics:

- Create a Human Review Workflow (Console)
- Create a Human Review Workflow (API)

After you've created your flow definition, see Using Augmented AI with Amazon Rekognition to learn how to integrate your flow definition into your Amazon Rekognition task.



End-to-end Demo Using Amazon Rekognition and Amazon A2I

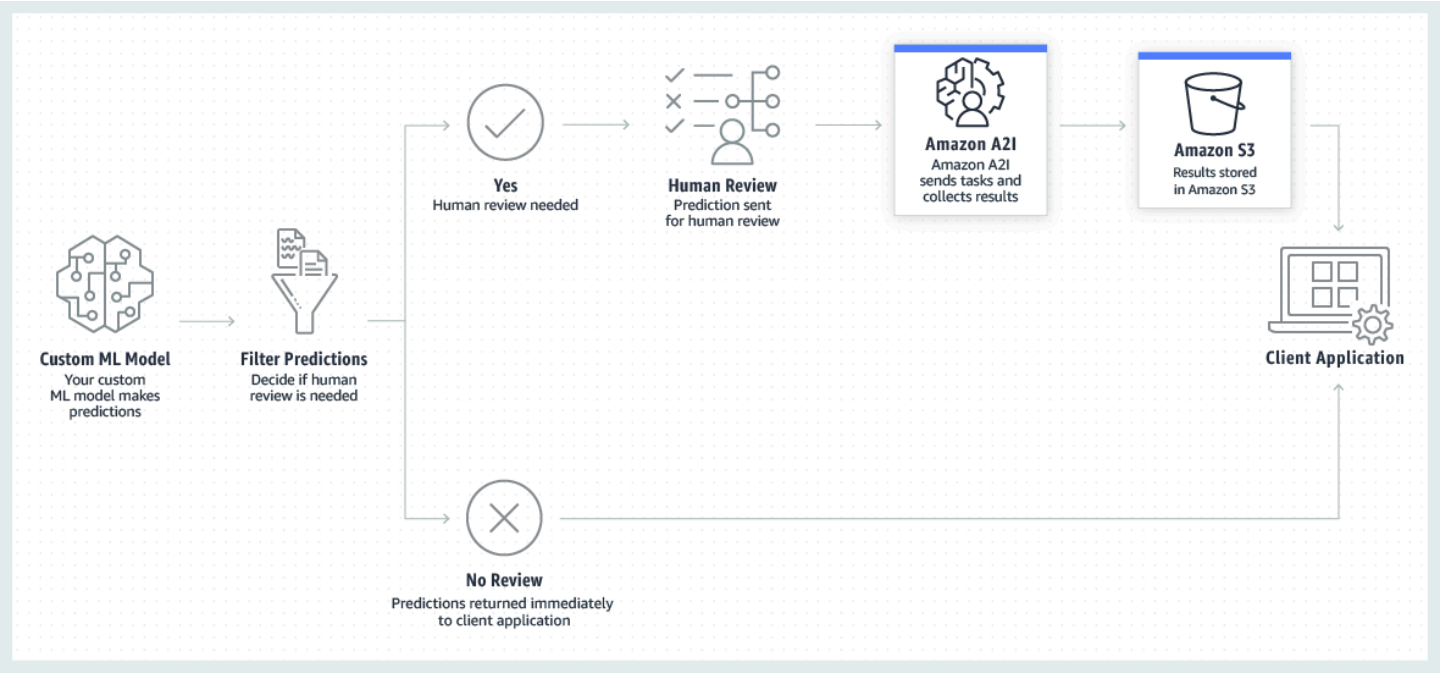
For an end-to-end example that demonstrates how to use Amazon Rekognition with Amazon A2I using the console, see Tutorial: Get Started in the Amazon A2I Console.

To learn how to use the Amazon A2I API to create and start a human review, you can use Amazon Augmented AI (Amazon A2I) integration with Amazon Rekognition [Example] in a SageMaker notebook instance. To get started, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook.

A2I Rekognition Worker Console Preview

When they're assigned a review task in an Amazon Rekognition workflow, workers might see a user interface similar to the following:

You can customize this interface in the SageMaker AI console when you create your human review definition, or by creating and using a custom template. To learn more, see Create and Manage Worker Task Templates.



Use Amazon Augmented AI with Custom Task Types

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

You can use Amazon Augmented AI (Amazon A2I) to incorporate a human review (human loop) into *any* machine learning workflow using the *custom task type*. This options gives you the most flexibility to customize the conditions under which your data objects are sent to humans for review, as well as the look and feel of your worker user interface.

When you use a custom task type, you create a custom human review workflow and specify the conditions under which a data object is sent for human review directly in your application.

The following image depicts the Amazon A2I custom workflow. A custom ML model is used to generate predictions. The client application filters these predictions using user-defined criteria and determines if a human review is required. If so, these predictions are sent to Amazon A2I for human review. Amazon A2I collects the results of human review in Amazon S3, which can access by the client application. If the filter determines that no human review is needed, predictions can be fed directly to the client application.

Use the procedures on this page to learn how to integrate Amazon A2I into any machine learning workflow using the custom task type.

Create a human loop using a flow definition, integrate it into your application, and monitor the results

1. Complete the Amazon A2I Prerequisites to Using Augmented AI. Note the following:
   - The path to the Amazon Simple Storage Service (Amazon S3) bucket or buckets where you store your input and output data.
   - The Amazon Resource Name (ARN) of an Amazon Identity and Access Management (IAM) role with required permissions attached.
   - (Optional) The ARN of your private workforce, if you plan to use one.
2. Using HTML elements, create a custom worker template which Amazon A2I uses to generate your worker task UI. To learn how to create a custom template, see Create Custom Worker Task Templates.
3. Use the custom worker template from step 2 to generate a worker task template in the Amazon SageMaker AI console. To learn how, see Create a Worker Task Template.

   In the next step, you create a flow definition:
   - If you want to create a flow definition using the SageMaker API, note the ARN of this worker task template for the next step.
   - If you are creating a flow definition using the console, your template automatically appears in **Worker task template** section when you choose **Create human review workflow**.
4. When creating your flow definition, provide the path to your S3 buckets, your IAM role ARN, and your worker template.
   - To learn how to create a flow definition using the SageMaker AI `CreateFlowDefinition` API, see Create a Human Review Workflow (API).
   - To learn how to create a flow definition using the SageMaker AI console, see Create a Human Review Workflow (Console).
5. Configure your human loop using the Amazon A2I Runtime API. To learn how, see Create and Start a Human Loop.
6. To control when human reviews are initiated in your application, specify conditions under which `StartHumanLoop` is called in your application. Human loop activation conditions, such

as confidence thresholds that initiate the human loop, are not available when using Amazon A2I with custom task types. Every `StartHumanLoop` invocation results in a human review.

Once you have started a human loop, you can manage and monitor your loops using the Amazon Augmented AI Runtime API and Amazon EventBridge (also known as Amazon CloudWatch Events). To learn more, see Monitor and Manage Your Human Loop.

End-to-end Tutorial Using Amazon A2I Custom Task Types

For an end-to-end examples that demonstrates how to integrate Amazon A2I into a variety of ML workflows, see the table in Use Cases and Examples Using Amazon A2I. To get started using one of these notebooks, see Use SageMaker Notebook Instance with Amazon A2I Jupyter Notebook.

Create a Human Review Workflow

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

Use an Amazon Augmented AI (Amazon A2I) *human review workflow*, or *flow definition*, to specify the following:

- For the Amazon Textract and Amazon Rekognition built-in task types, the conditions under which your human loop is called
- The workforce to which your tasks are sent
- The set of instructions that your workforce receives, which is called a *worker task template*
- The configuration of your worker tasks, including the number of workers that receive a task and time limits to complete tasks
- Where your output data is stored

You can create a human review workflow in the SageMaker AI console or using the SageMaker AI `CreateFlowDefinition` operation. You can build a worker task template using the console for Amazon Textract and Amazon Rekognition task types while creating your flow definition.

Important

Human loop activation conditions, which initiate the human loop—for example, confidence thresholds—aren't available for Amazon A2I custom task types. When using the console to create a flow definition for a custom task type, you can't specify activation conditions. When using the Amazon A2I API to create a flow definition for a custom task type, you can't set the `HumanLoopActivationConditions` attribute of the `HumanLoopActivationConditionsConfig` parameter. To control when human reviews are initiated, specify conditions under which `StartHumanLoop` is called in your custom application. In this case, every `StartHumanLoop` invocation results in a human review. For more information, see Use Amazon Augmented AI with Custom Task Types.

Prerequisites

To create a human review workflow definition, you must have completed the prerequisites described in Prerequisites to Using Augmented AI.

If you use the API to create a flow definition for any task type, or if you use a custom task type when creating a flow definition in the console, first create a worker task template. For more information, see Create and Manage Worker Task Templates.

If you want to preview your worker task template while creating a flow definition for a built-in task type in the console, ensure that you grant the role that you use to create the flow definition permission to access the Amazon S3 bucket that contains your template artifacts using a policy like the one described in Enable Worker Task Template Previews.

Topics

- Create a Human Review Workflow (Console)
- Create a Human Review Workflow (API)
- JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI

Create a Human Review Workflow (Console)

Use this procedure to create a Amazon Augmented AI (Amazon A2I) human review workflow using the SageMaker AI console. If you are new to Amazon A2I, we recommend that you create a private work team using people in your organization, and use this work team's ARN when creating your

flow definition. To learn how to set up a private workforce and create a work team, see Create a Private Workforce (Amazon SageMaker AI Console). If you have already set up a private workforce, see Create a Work Team Using the SageMaker AI Console to learn how to add a work team to that workforce.

If you are using Amazon A2I with one of the built-in task types, you can create worker instructions using a default worker task template provided by Augmented AI while creating a human review workflow in the console. To see samples of the default templates provided by Augmented AI, see the built-in task types in Use Cases and Examples Using Amazon A2I.

To create flow definition (console)

1. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, under the **Augmented AI** section, choose **Human review workflows** and then choose **Create human review workflow**.
3. In **Overview**, do the following:

    a. For **Name**, enter a unique workflow name. The name must be lowercase, unique within the Amazon Region in your account, and can have up to 63 characters. Valid characters include: a-z, 0-9, and - (hyphen).

    b. For **S3 location for output**, enter the S3 bucket where you want to store the human review results. The bucket must be located in the same Amazon Region as the workflow.

    c. For **IAM role**, choose the role that has the required permissions. If you choose a built-in task type and want to preview your worker template in the console, provide a role with the type of policy described in Enable Worker Task Template Previews attached.
4. For **Task type**, choose the task type that you want the human worker to perform.
5. If you chose the Amazon Rekognition or Amazon Textract task type, specify the conditions that invoke human review.

    - For Amazon Rekognition image moderation tasks, choose an inference confidence score threshold interval that initiates human review.
    - For Amazon Textract tasks, you can initiate a human review when specific form keys are missing or when form key detection confidence is low. You can also initiate a human review if, after evaluating all of the form keys in the text, confidence is lower than your required threshold for any form key. Two variables specify your confidence thresholds: **Identification confidence** and **Qualification confidence**. To learn more about these variables, see Use Amazon Augmented AI with Amazon Textract.

- For both task types, you can randomly send a percentage of data objects (images or forms) and their labels to humans for review.

6. Configure and specify your worker task template:

   a. If you are using the Amazon Rekognition or Amazon Textract task type:

      - In the **Create template** section:

        - To create instructions for your workers using the Amazon A2I default template for Amazon Rekognition and Amazon Textract task types, choose **Build from a default template**.

          - If you choose **Build from a default template**, create your instructions under **Worker task design**:

            - Provide a **Template name** that is unique in the Amazon Region you are in.

            - In the **Instructions** section, provide detailed instructions on how to complete your task. To help workers achieve greater accuracy, provide good and bad examples.

            - (Optional) In **Additional instructions**, provide your workers with additional information and instructions.

              For information on creating effective instructions, see Creating Good Worker Instructions.

        - To select a custom template that you've created, choose it from the **Template** menu and provide a **Task description** to briefly describe the task for your workers. To learn how to create a custom template, see Create a Worker Task Template.

   b. If you are using the custom task type:

      - In the **Worker task template** section, select your template from the list. All of the templates that you have created in the SageMaker AI console appear in this list. To learn how to create a template for custom task types, see Create and Manage Worker Task Templates.

7. (Optional) Preview your worker template:

   For Amazon Rekognition and Amazon Textract task types, you have the option to choose **See a sample worker task** to preview your worker task UI.

If you are creating a flow definition for a custom task type, you can preview your worker task UI using the `RenderUiTemplate` operation. For more information, see Preview a Worker Task Template.

8. For **Workers**, choose a workforce type.
9. Choose **Create**.

Next Steps

After you've created a human review workflow, it appears in the console under **Human review workflows**. To see your flow definition's Amazon Resource Name (ARN) and configuration details, choose the workflow by selecting its name.

If you are using a built-in task type, you can use the flow definition ARN to start a human loop using that Amazon service's API (for example, the Amazon Textract API). For custom task types, you can use the ARN to start a human loop using the Amazon Augmented AI Runtime API. To learn more about both options, see Create and Start a Human Loop.

Create a Human Review Workflow (API)

To create a flow definition using the SageMaker API, you use the `CreateFlowDefinition` operation. After you complete the Prerequisites to Using Augmented AI, use the following procedure to learn how to use this API operation.

For an overview of the `CreateFlowDefinition` operation, and details about each parameter, see `CreateFlowDefinition`.

To create a flow definition (API)

1. For `FlowDe#nitionName`, enter a unique name. The name must be unique within the Amazon Region in your account, and can have up to 63 characters. Valid characters include: a-z, 0-9, and - (hyphen).
2. For `RoleArn`, enter the ARN of the role that you configured to grant access to your data sources.
3. For `HumanLoopConfig`, enter information about the workers and what they should see. For information about each parameter in `HumanLoopConfig`, see HumanLoopConfig.
4. (Optional) If you are using a built-in task type, provide conditions that initiate a human loop in `HumanLoopActivationCon#g`. To learn how to create the input required for the

HumanLoopActivationCon#g parameter, see JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI. If you do not specify conditions here, when you provide a flow definition to the Amazon service associated with a built-in task type (for example, Amazon Textract or Amazon Rekognition), that service sends every task to a human worker for review.

If you are using a custom task type, HumanLoopActivationConfig is disabled. To learn how to control when tasks are sent to human workers using a custom task type, see Use Amazon Augmented AI with Custom Task Types.

5. (Optional) If you are using a built-in task type, specify the integration source (for example, Amazon Rekognition or Amazon Textract) in the HumanLoopRequestSource parameter.
6. For OutputConfig, indicate where in Amazon Simple Storage Service (Amazon S3) to store the output of the human loop.
7. (Optional) Use Tags to enter key-value pairs to help you categorize and organize a flow definition. Each tag consists of a key and a value, both of which you define.

Amazon Textract – Key-value pair extraction

The following is an example of a request to create an Amazon Textract human review workflow (flow definition) using the Amazon SDK for Python (Boto3). You must use 'AWS/Textract/AnalyzeDocument/Forms/V1' to create a Amazon Textract human loop.

```
sagemaker_client = boto3.client('sagemaker', aws_region)

response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopRequestSource={
         'AwsManagedHumanLoopRequestSource': 'AWS/Textract/AnalyzeDocument/Forms/V1'
    },
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '{...}'
        }
    },
    HumanLoopConfig={
        'WorkteamArn': 'arn:aws:sagemaker:aws_region:aws_account_number:workteam/
private-crowd/workteam_name',
        'HumanTaskUiArn': 'arn:aws:sagemaker:aws_region:aws_account_number:human-
task-ui/template_name',
```

```
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': [
            'Keyword1','Keyword2'
        ]
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::aws_account_number:role/role_name',
    Tags=[
        {
            'Key': 'KeyName',
            'Value': 'ValueName'
        },
    ]
)
```

Amazon Rekognition – Image moderation

The following is an example of a request to create an Amazon Rekognition human review workflow (flow definition) using the Amazon SDK for Python (Boto3). You must use `'AWS/Rekognition/DetectModerationLabels/Image/V3'` to create an Amazon Rekognition flow definition.

```
sagemaker_client = boto3.client('sagemaker', aws_region)

response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopRequestSource={
         'AwsManagedHumanLoopRequestSource': 'AWS/Rekognition/
DetectModerationLabels/Image/V3'
    },
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '{...}'
        }
    },
    HumanLoopConfig={
```

```
        'WorkteamArn': 'arn:aws:sagemaker:aws_region:aws_account_number:workteam/
private-crowd/workteam_name',
        'HumanTaskUiArn': 'arn:aws:sagemaker:aws_region:aws_account_number:human-
task-ui/template_name',
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': [
            'Keyword1','Keyword2'
        ]
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::aws_account_number:role/role_name',
    Tags=[
        {
            'Key': 'KeyName',
            'Value': 'ValueName'
        },
    ]
)
```

Custom Workflow

The following is an example of a request to create a human review workflow (flow definition) for a custom integration. To create this type of human review workflow, omit `HumanLoopRequestSource` from the flow definition request.

```
sagemaker_client = boto3.client('sagemaker', aws_region)

response = sagemaker_client.create_flow_definition(
    FlowDefinitionName='ExampleFlowDefinition',
    HumanLoopActivationConfig={
        'HumanLoopActivationConditionsConfig': {
            'HumanLoopActivationConditions': '{...}'
        }
    },
    HumanLoopConfig={
```

```
        'WorkteamArn': 'arn:aws:sagemaker:aws_region:aws_account_number:workteam/
private-crowd/workteam_name',
        'HumanTaskUiArn': 'arn:aws:sagemaker:aws_region:aws_acount_number:human-
task-ui/template_name',
        'TaskTitle': 'Example task title',
        'TaskDescription': 'Example task description.',
        'TaskCount': 123,
        'TaskAvailabilityLifetimeInSeconds': 123,
        'TaskTimeLimitInSeconds': 123,
        'TaskKeywords': [
            'Keyword1','Keyword2'
        ]
    },
    OutputConfig={
        'S3OutputPath': 's3://bucket/path/',
        'KmsKeyId': '1234abcd-12ab-34cd-56ef-1234567890ab'
    },
    RoleArn='arn:aws:iam::account_number:role/role_name',
    Tags=[
        {
            'Key': 'KeyName',
            'Value': 'ValueName'
        },
    ]
)
```

Next Steps

The return value of a successful call of the `CreateFlowDefinition` API operation is a flow definition Amazon Resource Name (ARN).

If you are using a built-in task type, you can use the flow definition ARN to start a human loop using that Amazon service's API (i.e. the Amazon Textract API). For custom task types, you can use the ARN to start a human loop using the Amazon Augmented AI Runtime API. To learn more about both of these options, see Create and Start a Human Loop.

JSON Schema for Human Loop Activation Conditions in Amazon Augmented AI

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

The `HumanLoopActivationConditions` is an input parameter of the `CreateFlowDefinition` API. This parameter is a JSON-formatted string. The JSON models the conditions under which a human loop is created when those conditions are evaluated against the response from an integrating AI service API (such as `Rekognition.DetectModerationLabels` or `Textract.AnalyzeDocument`). This response is referred to as an *inference*. For example, Amazon Rekognition sends an inference of a moderation label with an associated confidence score. In this example, the inference is the model's best estimate of the appropriate label for an image. For Amazon Textract, inference is made on the association between blocks of text (*key-value pairs*), such as the association between `Name:` and `Sue` in a form as well as content within a block of text, or *word block*, such as 'Name'.

The following is the schema for the JSON. At the top level, the `HumanLoopActivationConditions` has a JSON array, `Conditions`. Each member of this array is an independent condition that, if evaluated to `true`, results in Amazon A2I creating a human loop. Each such independent condition can be a simple condition or a complex condition. A simple condition has the following attributes:

- `ConditionType`: This attribute identifies the type of condition. Each Amazon AI service API that integrates with Amazon A2I defines its own set of allowed `ConditionTypes`.
  - Rekognition `DetectModerationLabels` – This API supports the `ModerationLabelConfidenceCheck` and `Sampling` `ConditionType` values.
  - Textract `AnalyzeDocument` – This API supports the `ImportantFormKeyConfidenceCheck`, `MissingImportantFormKey`, and `Sampling` `ConditionType` values.
- `ConditionParameters` – This is a JSON object that parameterizes the condition. The set of allowed attributes of this object is dependent on the value of the `ConditionType`. Each `ConditionType` defines its own set of `ConditionParameters`.

A member of the `Conditions` array can model a complex condition. This is accomplished by logically connecting simple conditions using the `And` and `Or` logical operators and nesting the underlying simple conditions. Up to two levels of nesting are supported.

```
{
    "$schema": "http://json-schema.org/draft-07/schema#",
    "definitions": {
        "Condition": {
            "type": "object",
            "properties": {
                "ConditionType": {
                    "type": "string"
                },
                "ConditionParameters": {
                    "type": "object"
                }
            },
            "required": [
                "ConditionType"
            ]
        },
        "OrConditionArray": {
            "type": "object",
            "properties": {
                "Or": {
                    "type": "array",

                    "items": {
                        "$ref": "#/definitions/ComplexCondition"
                    }
                }
            }
        },
        "AndConditionArray": {
            "type": "object",
            "properties": {
                "And": {
                    "type": "array",
                    "minItems": 2,
                    "items": {
                        "$ref": "#/definitions/ComplexCondition"
                    }
                }
```

```
            }
        },
        "ComplexCondition": {
            "anyOf": [
                {
                    "$ref": "#/definitions/Condition"
                },
                {
                    "$ref": "#/definitions/OrConditionArray"
                },
                {
                    "$ref": "#/definitions/AndConditionArray"
                }
            ]
        }
    },
    "type": "object",
    "properties": {
        "Conditions": {
            "type": "array",
            "items": {
                "$ref": "#/definitions/ComplexCondition"
            }
        }
    }
}
```

Note

Human loop activation conditions aren't available for human review workflows that are integrated with custom task types. The `HumanLoopActivationConditions` parameter is disabled for custom task types.

Topics

- Use Human Loop Activation Conditions JSON Schema with Amazon Textract
- Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition

Use Human Loop Activation Conditions JSON Schema with Amazon Textract

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

When used with Amazon A2I, the `AnalyzeDocument` operation supports the following inputs in the `ConditionType` parameter:

- `ImportantFormKeyConfidenceCheck` – Use this condition to create a human loop when inference confidence is within a specified range for document form keys and word blocks. A *form key* is any word in a document that is associated with an input. The input is called a *value*. Together, form keys and values are referred to as *key-value pairs*. A *word block* refers to the words that Amazon Textract recognizes inside of a detected block of text. To learn more about Amazon Textract document blocks, see Documents and Block Objects in the *Amazon Textract Developer Guide*.
- `MissingImportantFormKey` – Use this condition to create a human loop when Amazon Textract did not identify the key or its associated aliases within the document.
- `Sampling` – Use this condition to specify a percentage of forms to send to humans for review, regardless of inference confidence scores. Use this condition to do the following:
  - Audit your ML model by randomly sampling all forms analyzed by your model and sending a specified percentage to humans for review.
  - Using the `ImportantFormKeyConfidenceCheck` condition, randomly sample a percentage of the inferences that met the conditions specified in `ImportantFormKeyConfidenceCheck` to start a human loop and send only the specified percentage to humans for review.

> **Note**
>
> If you send the same request to `AnalyzeDocument` multiple times, the result of `Sampling` does not change for the inference of that input. For example, if you make an `AnalyzeDocument` request once, and `Sampling` doesn't initiate a human loop,

subsequent requests to `AnalyzeDocument` with the same configuration do not initiate a human loop.

`ImportantFormKeyConfidenceCheck` Inputs and Results

The `ImportantFormKeyConfidenceCheck` `ConditionType` supports the following `ConditionParameters`:

- `ImportantFormKey` – A string representing a key in a key-value pair detected by Amazon Textract that needs to be reviewed by human workers. If the value of this parameter is the special catch-all value (*), then all keys are considered to be matched to the condition. You can use this to model the case where any key-value pair satisfying certain confidence thresholds needs human review.
- `ImportantFormKeyAliases` – An array that represents alternate spellings or logical equivalents for the important form key.
- `KeyValueBlockConfidenceEquals`
- `KeyValueBlockConfidenceLessThan`
- `KeyValueBlockConfidenceLessThanEquals`
- `KeyValueBlockConfidenceGreaterThan`
- `KeyValueBlockConfidenceGreaterThanEquals`
- `WordBlockConfidenceEquals`
- `WordBlockConfidenceLessThan`
- `WordBlockConfidenceLessThanEquals`
- `WordBlockConfidenceGreaterThan`
- `WordBlockConfidenceGreaterThanEquals`

When you use the `ImportantFormKeyConfidenceCheck` `ConditionType`, Amazon A2I sends the key-value block and word block inferences of the key-value blocks and associated aliases that you specified in `ImportantFormKey` and `ImportantFormKeyAliases` for human review.

When creating a flow definition, if you use the default worker task template that is provided in the **Human review workflows** section of the Amazon SageMaker AI console, key-value and block inferences sent for human review by this activation condition are included in the worker UI. If you use a custom worker task template, you need to include the

`{{ task.input.selectedAiServiceResponse.blocks }}` element to include initial-value input data (inferences) from Amazon Textract. For an example of a custom template that uses this input element, see Custom Template Example for Amazon Textract.

`MissingImportantFormKey` Inputs and Results

The `MissingImportantFormKey` `ConditionType` supports the following `ConditionParameters`:

- `ImportantFormKey` – A string representing a key in a key-value pair detected by Amazon Textract that needs to be reviewed by human workers.
- `ImportantFormKeyAliases` – An array that represents alternate spellings or logical equivalents for the important form key.

When you use the `MissingImportantFormKey` `ConditionType`, if the key in `ImportantFormKey` or aliases in `ImportantFormKeyAliases` are not included in the Amazon Textract inference, that form is sent to human for review and no predicted key-value pairs are included. For example, if Amazon Textract only identified `Address` and `Phone` in a form, but was missing the `ImportantFormKey` `Name` (in the `MissingImportantFormKey` condition type) that form would be sent to humans for review without any of the form keys detected (`Address` and `Phone`).

If you use the default worker task template that is provided in the SageMaker AI console, a task is created asking workers to identify the key in `ImportantFormKey` and associated value. If you use a custom worker task template, you need to include the `<task.input.humanLoopContext>` custom HTML element to configure this task.

Sampling Inputs and Results

The `Sampling` `ConditionType` supports the `RandomSamplingPercentage` `ConditionParameters`. The input for `RandomSamplingPercentage` must be real number between 0.01 and 100. This number represents the percentage of data that qualifies for a human review and is sent to humans for review. If you use the `Sampling` condition without any other conditions, this number represents the percentage of all resulting inferences made by the `AnalyzeDocument` operation from a single request that is sent to humans for review.

If you specify the `Sampling` condition without any other condition type, all key-value and block inferences are sent to workers for review.

When creating a flow definition, if you use the default worker task template that is provided in the **Human review workflows** section of the SageMaker AI console, all key-value and block inferences sent for human review by this activation condition are included in the worker UI. If you use a custom worker task template, you need to include the `{{ task.input.selectedAiServiceResponse.blocks }}` element to include initial-value input data (inferences) from Amazon Textract. For an example of a custom template that uses this input element, see Custom Template Example for Amazon Textract.

Examples

While only one condition needs to evaluate to `true` to initiate a human loop, Amazon A2I evaluates all conditions for each object analyzed by Amazon Textract. The human reviewers are asked to review the important form keys for all the conditions that evaluated to `true`.

Example 1: Detect important form keys with confidence scores in a specified range that initiate a human loop

The following example shows a `HumanLoopActivationConditions` JSON that initiates a human loop if any one of the following three conditions is met:

- The Amazon Textract `AnalyzeDocument` API returns a key-value pair whose key is one of `Employee Name`, `Name`, or `EmployeeName`, with the confidence of the key-value block being less than 60 and the confidences of each of the word blocks making up the key and value being less than 85.
- The Amazon Textract `AnalyzeDocument` API returns a key-value pair whose key is one of `Pay Date`, `PayDate`, `DateOfPay`, or `pay-date`, with the confidence of the key-value block being less than 65 and the confidences of each of the word blocks making up the key and value being less than 85.
- The Amazon Textract `AnalyzeDocument` API returns a key-value pair whose key is one of `Gross Pay`, `GrossPay`, or `GrossAmount`, with the confidence of the key-value block being less than 60 and the confidences of each of the word blocks making up the key and value being less than 85.

```
{
    "Conditions": [
        {
            "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Employee Name",
                "ImportantFormKeyAliases": [
```

```
                    "Name",
                    "EmployeeName"
                ],
                "KeyValueBlockConfidenceLessThan": 60,
                "WordBlockConfidenceLessThan": 85
            }
        },
        {
            "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Pay Date",
                "ImportantFormKeyAliases": [
                    "PayDate",
                    "DateOfPay",
                    "pay-date"
                ],
                "KeyValueBlockConfidenceLessThan": 65,
                "WordBlockConfidenceLessThan": 85
            }
        },
        {
            "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Gross Pay",
                "ImportantFormKeyAliases": [
                    "GrossPay",
                    "GrossAmount"
                ],
                "KeyValueBlockConfidenceLessThan": 60,
                "WordBlockConfidenceLessThan": 85
            }
        }
    ]
}
```

Example 2: Use `ImportantFormKeyConfidenceCheck`

In the following example, if Amazon Textract detects a key-value pair whose confidence for the key-value block is less than 60 and is less than 90 for any underlying word blocks, it creates a human loop. The human reviewers are asked to review all the form key-value pairs that matched the confidence value comparisons.

```
{
```

```
    "Conditions": [
        {
            "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "*",
                "KeyValueBlockConfidenceLessThan": 60,
                "WordBlockConfidenceLessThan": 90
            }
        }
    ]
}
```

Example 3: Use Sampling

In the following example, 5% of inferences resulting from an Amazon Textract `AnalyzeDocument` request are sent to human workers for review. All detected key-value pairs returned by Amazon Textract are sent to workers for review.

```
{
  "Conditions": [
    {
      "ConditionType": "Sampling",
      "ConditionParameters": {
        "RandomSamplingPercentage": 5
      }
    }
  ]
}
```

Example 4: Use `MissingImportantFormKey`

In the following example, if `Mailing Address` or its alias, `Mailing Address:`, is missing from keys detected by Amazon Textract, a human review is initiated. When using the default worker task template, the worker UI asks workers to identify the key `Mailing Address` or `Mailing Address:` and its associated value.

```
{
    "ConditionType": "MissingImportantFormKey",
    "ConditionParameters": {
        "ImportantFormKey": "Mailing Address",
        "ImportantFormKeyAliases": ["Mailing Address:"]
    }
```

```
}
```

Example 5: Use Sampling and `ImportantFormKeyConfidenceCheck` with the `And` operator

In this example, 5% of key-value pairs detected by Amazon Textract whose key is one of `Pay Date`, `PayDate`, `DateOfPay`, or `pay-date`, with the confidence of the key-value block less than 65 and the confidences of each of the word blocks making up the key and value less than 85, are sent to workers for review.

```
{
  "Conditions": [
    {
      "And": [
        {
          "ConditionType": "Sampling",
          "ConditionParameters": {
            "RandomSamplingPercentage": 5
          }
        },
        {
          "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Pay Date",
                "ImportantFormKeyAliases": [
                    "PayDate",
                    "DateOfPay",
                    "pay-date"
                ],
                "KeyValueBlockConfidenceLessThan": 65,
                "WordBlockConfidenceLessThan": 85
            }
        }
      ]
    }
  ]
}
```

Example 6: Use Sampling and `ImportantFormKeyConfidenceCheck` with the `And` operator

Use this example to configure your human review workflow to always send low confidence inferences of a specified key-value pair for human review and sample high confidence inference of a key-value pair at a specified rate.

In the following example, a human review is initiated in one of the following ways:

- Key-value pairs detected whose key is one of `Pay Date`, `PayDate`, `DateOfPay`, or `pay-date`, with key-value and word block confidences less than 60, are sent for human review. Only the `Pay Date` form key (and its aliases) and associated values are sent to workers to review.
- 5% of key-value pairs detected whose key is one of `Pay Date`, `PayDate`, `DateOfPay`, or `pay-date`, with key-value and word block confidences greater than 90, are sent for human review. Only the `Pay Date` form key (and its aliases) and associated values are sent to workers to review.

```
{
  "Conditions": [
    {
      "Or": [
       {
          "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Pay Date",
                "ImportantFormKeyAliases": [
                    "PayDate",
                    "DateOfPay",
                    "pay-date"
                ],
                "KeyValueBlockConfidenceLessThan": 60,
                "WordBlockConfidenceLessThan": 60
            }
        },
        {
            "And": [
                {
                    "ConditionType": "Sampling",
                    "ConditionParameters": {
                        "RandomSamplingPercentage": 5
                    }
                },
                {
                    "ConditionType": "ImportantFormKeyConfidenceCheck",
                        "ConditionParameters": {
                            "ImportantFormKey": "Pay Date",
                            "ImportantFormKeyAliases": [
                                "PayDate",
```

```
                                "DateOfPay",
                                "pay-date"
                            ],
                            "KeyValueBlockConfidenceLessThan": 90
                            "WordBlockConfidenceGreaterThan": 90
                        }
                    }
                ]
            }
        ]
    }
  ]
}
```

Example 7: Use Sampling and `ImportantFormKeyConfidenceCheck` with the `Or` operator

In the following example, the Amazon Textract `AnalyzeDocument` operation returns a key-value pair whose key is one of `Pay Date`, `PayDate`, `DateOfPay`, or `pay-date`, with the confidence of the key-value block less than 65 and the confidences of each of the word blocks making up the key and value less than 85. Additionally, 5% of all other forms initiate a human loop. For each form randomly chosen, all key-value pairs detected for that form are sent to humans for review.

```
{
  "Conditions": [
    {
      "Or": [
        {
          "ConditionType": "Sampling",
          "ConditionParameters": {
            "RandomSamplingPercentage": 5
          }
        },
        {
           "ConditionType": "ImportantFormKeyConfidenceCheck",
            "ConditionParameters": {
                "ImportantFormKey": "Pay Date",
                "ImportantFormKeyAliases": [
                    "PayDate",
                    "DateOfPay",
                    "pay-date"
                ],
                "KeyValueBlockConfidenceLessThan": 65,
                "WordBlockConfidenceLessThan": 85
```

```
            }
          }
        }
      ]
    }
  ]
}
```

Use Human Loop Activation Conditions JSON Schema with Amazon Rekognition

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

When used with Amazon A2I, the Amazon Rekognition `DetectModerationLabels` operation supports the following inputs in the `ConditionType` parameters:

- `ModerationLabelConfidenceCheck` – Use this condition type to create a human loop when inference confidence is low for one or more specified labels.
- `Sampling` – Use this condition to specify a percentage of all inferences to send to humans for review. Use this condition to do the following:
  - Audit your ML model by randomly sampling all of your model's inferences and sending a specified percentage to humans for review.
  - Using the `ModerationLabelConfidenceCheck` condition, randomly sample a percentage of the inferences that met the conditions specified in `ModerationLabelConfidenceCheck` to start a human loop and send only the specified percentage to humans for review.

> **Note**
>
> If you send the same request to `DetectModerationLabels` multiple times, the result of `Sampling` does not change for the inference of that input. For example, if you make a `DetectModerationLabels` request once, and `Sampling` does not initiate a human loop, subsequent requests to `DetectModerationLabels` with the same configuration don't initiate a human loop.

When creating a flow definition, if you use the default worker task template that is provided in the **Human review workflows** section of the Amazon SageMaker AI console, inferences sent for human review by these activation conditions are included in the worker UI when a worker opens your task. If you use a custom worker task template, you need to include the `<task.input.selectedAiServiceResponse.blocks>` custom HTML element to access these inferences. For an example of a custom template that uses this HTML element, see Custom Template Example for Amazon Rekognition.

`ModerationLabelConfidenceCheck` Inputs

For the `ModerationLabelConfidenceCheck` `ConditionType`, the following `ConditionParameters` are supported:

- `ModerationLabelName` – The exact (case-sensitive) name of a ModerationLabel detected by the Amazon Rekognition `DetectModerationLabels` operation. You can specify the special catch-all value (*) to denote any moderation label.
- `ConfidenceEquals`
- `ConfidenceLessThan`
- `ConfidenceLessThanEquals`
- `ConfidenceGreaterThan`
- `ConfidenceGreaterThanEquals`

When you use the `ModerationLabelConfidenceCheck` `ConditionType`, Amazon A2I sends label inferences for the labels that you specified in `ModerationLabelName` for human review.

Sampling Inputs

The `Sampling` `ConditionType` supports the `RandomSamplingPercentage` `ConditionParameters`. The input for the `RandomSamplingPercentage` prameter should be real number between 0.01 and 100. This number represents the percentage of inferences that qualifies for a human review that are sent to humans for review. If you use the `Sampling` condition without any other conditions, this number represents the percentage of all inferences that result from a single `DetectModerationLabel` request that are sent to humans for review.

Examples

Example 1: Use `ModerationLabelConfidenceCheck` with the And operator

The following example of a `HumanLoopActivationConditions` condition initiates a human loop when one or more of the following conditions are met:

- Amazon Rekognition detects the `Graphic Male Nudity` moderation label with a confidence between 90 and 99.
- Amazon Rekognition detects the `Graphic Female Nudity` moderation label with a confidence between 80 and 99.

Note the use of the `Or` and `And` logical operators to model this logic.

Although only one of the two conditions under the `Or` operator needs to evaluate to `true` for a human loop to be created, Amazon Augmented AI evaluates all conditions. Human reviewers are asked to review the moderation labels for all the conditions that evaluated to `true`.

```
{
     "Conditions": [{
         "Or": [{
                 "And": [{
                         "ConditionType": "ModerationLabelConfidenceCheck",
                         "ConditionParameters": {
                             "ModerationLabelName": "Graphic Male Nudity",
                             "ConfidenceLessThanEquals": 99
                         }
                     },
                     {
                         "ConditionType": "ModerationLabelConfidenceCheck",
                         "ConditionParameters": {
                             "ModerationLabelName": "Graphic Male Nudity",
                             "ConfidenceGreaterThanEquals": 90
                         }
                     }
                 ]
             },
             {
                 "And": [{
                         "ConditionType": "ModerationLabelConfidenceCheck",
                         "ConditionParameters": {
                             "ModerationLabelName": "Graphic Female Nudity",
                             "ConfidenceLessThanEquals": 99
                         }
                     },
```

```
                    {
                        "ConditionType": "ModerationLabelConfidenceCheck",
                        "ConditionParameters": {
                            "ModerationLabelName": "Graphic Female Nudity",
                            "ConfidenceGreaterThanEquals": 80
                        }
                    }
                ]
            }
        ]
    }]
}
```

Example 2: Use `ModerationLabelConfidenceCheck` with the catch-all value (*)

In the following example, if any moderation label with a confidence greater than or equal to 75 is detected, a human loop is initiated. Human reviewers are asked to review all moderation labels with confidence scores greater than or equal to 75.

```
{
    "Conditions": [
        {
            "ConditionType": "ModerationLabelConfidenceCheck",
            "ConditionParameters": {
                "ModerationLabelName": "*",
                "ConfidenceGreaterThanEquals": 75
            }
        }
    ]
}
```

Example 3: Use Sampling

In the following example, 5% of Amazon Rekognition inferences from a `DetectModerationLabels` request are sent to human workers. When using the default worker task template provided in the SageMaker AI console, all moderation labels returned by Amazon Rekognition are sent to workers for review.

```
{
  "Conditions": [
    {
```

```
      "ConditionType": "Sampling",
      "ConditionParameters": {
        "RandomSamplingPercentage": 5
      }
    }
  ]
}
```

Example 4: Use Sampling and `ModerationLabelConfidenceCheck` with the `And` operator

In this example, 5% of Amazon Rekognition inferences of the `Graphic Male Nudity` moderation label with a confidence greater than 50 are sent workers for review. When using the default worker task template provided in the SageMaker AI console, only the inferences of the `Graphic Male Nudity` label are sent to workers for review.

```
{
  "Conditions": [
    {
      "And": [
        {
          "ConditionType": "Sampling",
          "ConditionParameters": {
            "RandomSamplingPercentage": 5
          }
        },
        {
          "ConditionType": "ModerationLabelConfidenceCheck",
          "ConditionParameters": {
            "ModerationLabelName": "Graphic Male Nudity",
            "ConfidenceGreaterThan": 50
          }
        }
      ]
    }
  ]
}
```

Example 5: Use Sampling and `ModerationLabelConfidenceCheck` with the `And` operator

Use this example to configure your human review workflow to always send low-confidence inferences of a specified label for human review and sample high-confidence inferences of a label at a specified rate.

In the following example, a human review is initiated in one of the following ways:

- Inferences for the `Graphic Male Nudity` moderation label the with confidence scores less than 60 are always sent for human review. Only the `Graphic Male Nudity` label is sent to workers to review.
- 5% of all inferences for the `Graphic Male Nudity` moderation label the with confidence scores greater than 90 are sent for human review. Only the `Graphic Male Nudity` label is sent to workers to review.

```
{
  "Conditions": [
    {
      "Or": [
        {
          "ConditionType": "ModerationLabelConfidenceCheck",
          "ConditionParameters": {
            "ModerationLabelName": "Graphic Male Nudity",
            "ConfidenceLessThan": 60
          }
        },
        {
            "And": [
                {
                    "ConditionType": "Sampling",
                    "ConditionParameters": {
                        "RandomSamplingPercentage": 5
                    }
                },
                {
                    "ConditionType": "ModerationLabelConfidenceCheck",
                    "ConditionParameters": {
                        "ModerationLabelName": "Graphic Male Nudity",
                        "ConfidenceGreaterThan": 90
                    }
                }
            ]
        }
      ]
    }
  ]
}
```

Example 6: Use Sampling and `ModerationLabelConfidenceCheck` with the `Or` operator

In the following example, a human loop is created if the Amazon Rekognition inference response contains the 'Graphic Male Nudity' label with inference confidence greater than 50. Additionally, 5% of all other inferences initiate a human loop.

```
{
  "Conditions": [
    {
      "Or": [
        {
          "ConditionType": "Sampling",
          "ConditionParameters": {
            "RandomSamplingPercentage": 5
          }
        },
        {
          "ConditionType": "ModerationLabelConfidenceCheck",
          "ConditionParameters": {
            "ModerationLabelName": "Graphic Male Nudity",
            "ConfidenceGreaterThan": 50
          }
        }
      ]
    }
  ]
}
```

Delete a Human Review Workflow

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

When you delete a human review workflow or you delete your Amazon account while a human loop is in process, your human review workflow status changes to `Deleting`. Amazon A2I automatically stops and deletes all associated human loops if workers have not started tasks created by those human loops. If human workers are already working on a task, that task continues

to be available until it is completed or expires. As long as workers are still working on a task, your human review workflow's status is `Deleting`. If these tasks are completed, the results are stored in the Amazon S3 bucket specified in your flow definition.

Deleting a flow definition does not remove any worker answers from your S3 bucket. If the tasks are completed, but you deleted your Amazon account, the results are stored in the Augmented AI service bucket for 30 days and then permanently deleted.

After all human loops have been deleted, the human review workflow is permanently deleted. When a human review workflow has been deleted, you can reuse its name to create a new human review workflow.

You might want to delete a human review workflow for any of the following reasons:

- You have sent data to a set of human reviewers and you want to delete all non-started human loops because you do not want those workers to work on those tasks any longer.
- The worker task template used to generate your worker UI does not render correctly or is not functioning as expected.

After you delete a human review workflow, the following changes occur:

- The human review workflow no longer appears on the **Human review workflows** page in the Augmented AI area of the Amazon SageMaker AI console.
- When you use the human review workflow name as input to the API operations `DescribeFlowDefinition` or `DeleteFlowDefinition`, Augmented AI returns a `ResourceNotFound` error.
- When you use `ListFlowDefinitions`, deleted human review workflows aren't included in the results.
- When you use the human review workflow ARN as input to the Augmented AI Runtime API operation `ListHumanLoops`, Augmented AI returns a `ResourceNotFoundException`.

Delete a Flow Definition Using the Console or the SageMaker API

You can delete a human review workflow on the **Human review workflows** page in the Augmented AI area of the SageMaker AI console or by using the SageMaker AI API.

Flow definitions can only be deleted if their status is `Active`.

Delete a human review workflow (console)

1. Navigate to the Augmented AI console at https://console.amazonaws.cn/a2i/.
2. In the navigation pane, under the **Augmented AI** section, choose **Human review workflows**.
3. Select the hyperlinked name of the human review workflow that you want to delete.
4. On the **Summary** page of your human review workflow, choose **Delete**.
5. In the dialog box asking you to confirm that you want to delete your human review workflow, choose **Delete**.

You're automatically redirected to the **Human review workflows** page. While your human review workflow is being deleted, the status **Deleting** appears in the status column for that workflow. After it's deleted, it doesn't appear in the list of workflows on this page.

Delete a human review workflow (API)

You can delete a human review workflow (flow definition) using the SageMaker AI DeleteFlowDefinition API operation. This API operation is supported through the Amazon CLI and a variety of language specific SDKs. The following table shows example requests using SDK for Python (Boto3) and the Amazon CLI to delete the human review workflow, *example-flow-definition*.

Amazon SDK for Python (Boto3)

The following request example uses the SDK for Python (Boto3) to delete the human review workflow. For more information, see delete_flow_definition in the *Amazon SDK for Python (Boto) API Reference*.

```
import boto3

sagemaker_client = boto3.client('sagemaker')
response = sagemaker_client.delete_flow_definition(FlowDefinitionName='example-flow-definition')
```

Amazon CLI

The following request example uses the Amazon CLI to delete the human review workflow. For more information, see delete-flow-definition in the *Amazon CLI Command Reference*.

```
$ aws sagemaker delete-flow-definition --flow-definition-name 'example-flow-definition'
```

If the action is successful, Augmented AI sends back an HTTP 200 response with an empty HTTP body.

Create and Start a Human Loop

> **Note**
>
> Amazon SageMaker A2I is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for A2I, but we do not plan to introduce new features.

A *human loop* starts your human review workflow and sends data review tasks to human workers. When you use one of the Amazon A2I built-in task types, the corresponding Amazon service creates and starts a human loop on your behalf when the conditions specified in your flow definition are met. If no conditions are specified in your flow definition, a human loop is created for each object. When using Amazon A2I for a custom task, a human loop starts when your application calls `StartHumanLoop`.

Use the following instructions to configure a human loop with Amazon Rekognition or Amazon Textract built-in task types and custom task types.

Prerequisites

To create and start a human loop, you must attach the `AmazonAugmentedAIFullAccess` policy to the Amazon Identity and Access Management (IAM) user or role that configures or starts the human loop. This is the identity that you use to configure the human loop using `HumanLoopConfig` for built-in task types. For custom task types, this is the identity that you use to call `StartHumanLoop`.

Additionally, when using a built-in task type, your user or role must have permission to invoke API operations of the Amazon service associated with your task type. For example, if you are using Amazon Rekognition with Augmented AI, you must attach permissions required to call `DetectModerationLabels`. For examples of identity-based policies you can use

to grant these permissions, see Amazon Rekognition Identity-Based Policy Examples and Amazon Textract Identity-Based Policy Examples. You can also use the more general policy `AmazonAugmentedAIIntegratedAPIAccess` to grant these permissions. For more information, see Create a User With Permissions to Invoke Amazon A2I, Amazon Textract, and Amazon Rekognition API Operations.

To create and start a human loop, you need a flow definition ARN. To learn how to create a flow definition (or human review workflow), see Create a Human Review Workflow.
