- **Enable Amazon S3 bucket encryption.** Ensure that the Amazon S3 buckets used for model artifacts and benchmark results have server-side encryption enabled.

- **Use tags for access control.** Apply tags to your AI workload configurations, benchmark jobs, and recommendation jobs. You can use tag-based conditions in IAM policies to control access to specific resources.

Detective best practices

- **Enable Amazon CloudTrail.** CloudTrail provides a record of all SageMaker AI API calls made in your account, including inference optimization operations.
- **Monitor with Amazon CloudWatch.** Use Amazon CloudWatch metrics and alarms to monitor the status and performance of your benchmark and recommendation jobs.
- **Review IAM Access Analyzer findings.** Use IAM Access Analyzer to identify IAM policies that grant overly broad access to your SageMaker AI resources.
- **Enable Amazon S3 access logging.** Enable server access logging on Amazon S3 buckets used for model artifacts and benchmark results to track access patterns.

Optimization techniques

Amazon SageMaker AI supports the following optimization techniques.

Compilation

Compilation optimizes the model for the best available performance on the chosen hardware type without a loss in accuracy. You can apply model compilation to optimize LLMs for accelerated hardware, such as GPU instances, Amazon Trainium instances, or Amazon Inferentia instances.

When you optimize a model with compilation, you benefit from ahead-of-time compilation. You reduce the model's deployment time and auto-scaling latency because the model weights don't require just-in-time compilation when the model deploys to a new instance.

If you choose to compile your model for a GPU instance, SageMaker AI uses the TensorRT-LLM library to run the compilation. If you choose to compile your model for an Amazon Trainium or Amazon Inferentia instance, SageMaker AI uses the Amazon Neuron SDK to run the compilation.

Quantization

Quantization is a technique to reduce the hardware requirements of a model by using a less precise data type for the weights and activations. After you optimize a model with quantization, you can host it on less expensive and more available GPUs. However, the quantized model might be less accurate than the source model that you optimized.

The data formats that SageMaker AI supports for quantization vary from model to model. The supported formats include the following:

- INT4-AWQ – A 4-bit data format. Activation-aware Weight Quantization (AWQ) is a quantization technique for LLMs that is efficient, accurate, low-bit, and weight-only.
- FP8 – 8-bit Floating Point (FP8) is a low-precision format for floating point numbers. It balances memory efficiency and model accuracy by representing values with fewer bits than standard FP16 floating point format.
- INT8-SmoothQuant – AN 8-bit data format. SmoothQuant is a mixed-precision quantization method that scales activations and weights jointly by balancing their dynamic ranges.

Speculative decoding

Speculative decoding is a technique to speed up the decoding process of large LLMs. It optimizes models for latency without compromising the quality of the generated text.

This technique uses a smaller but faster model called the *draft* model. The draft model generates candidate tokens, which are then validated by the larger but slower *target* model. At each iteration, the draft model generates multiple candidate tokens. The target model verifies the tokens, and if it finds that a particular token is not acceptable, it rejects the token and regenerates it. So, the target model both verifies tokens and generates a small amount of them.

The draft model is significantly faster than the target model. It generates all the tokens quickly and then sends batches of them to the target model for verification. The target model evaluate them all in parallel, which speeds up the final response.

SageMaker AI offers a pre-built draft model that you can use, so you don't have to build your own. If you prefer to use your own custom draft model, SageMaker AI also supports this option.

Fast model loading

The *fast model loading* technique prepares an LLM so that SageMaker AI can load it onto an ML instance more quickly.

To prepare the model, SageMaker AI shards it in advance by dividing it into portions that can each reside on a separate GPU for distributed inference. Also, SageMaker AI stores the model weights in equal-sized chunks that SageMaker AI can load onto the instance concurrently.

When SageMaker AI loads the optimized model onto the instance, it streams the model weights directly from Amazon S3 onto the GPUs of the instance. By streaming the weights, SageMaker AI

omits several time-consuming steps that are normally necessary. These steps include downloading the model artifacts from Amazon S3 to disk, loading the model artifacts onto the host memory, and sharding the model on the host before finally loading the shards onto the GPUs.

After you optimize your model for faster loading, you can deploy it more quickly to a SageMaker AI endpoint. Also, if you configure the endpoint to use auto scaling, it scales out more quickly to accommodate increases in traffic.

Deploy a pre-optimized model

Some models in JumpStart are pre-optimized by SageMaker AI, which means that you can deploy optimized versions of these models without first creating an inference optimization job.

For the list of models with pre-optimized options, see Pre-optimized JumpStart models.

Amazon SageMaker Studio

Use the following procedure to deploy a pre-optimized JumpStart model using Amazon SageMaker Studio.

To deploy a pre-optimized model

1. In Studio, in the navigation menu on the left, choose **JumpStart**.
2. On the **All public models** page, choose one of the models that are pre-optimized.
3. On the model details page, choose **Deploy**.
4. On the deployment page, some JumpStart models require you to sign an end-user license agreement (EULA) before you can proceed. If requested, review the license terms in the **License agreement** section. If the terms are acceptable for your use case, select the checkbox for **I accept the EULA, and read the terms and conditions.**

   For more information, see End-user license agreements.
5. For **Endpoint name** and **Initial instance count**, accept the default values or set custom ones.
6. For **Instance type**, keep the default value. Otherwise, you can't deploy a pre-optimized configuration.
7. Under **Models**, expand the model configuration. Studio shows a table that provides the pre-optimized configurations that you can choose from. Each option has metrics for latency and throughput. Choose the option that best suits your application needs.
8. Choose **Deploy**.

SageMaker AI Python SDK

You can deploy a pre-optimized model by using the SageMaker AI Python SDK in your project. First, you define a `Model` instance by using the `ModelBuilder` class. Then, you use the `set_deployment_config()` method to set the pre-optimized configuration that you want to deploy. Then, you use the `build()` method to build the model. Finally, you use the `deploy()` method to deploy it to an inference endpoint.

For more information about the classes and methods used in the following examples, see APIs in the SageMaker AI Python SDK documentation.

To set up your project

1. In your application code, import the necessary libraries. The following example imports the SDK for Python (Boto3). It also imports the modules from the SageMaker AI Python SDK that you use to define and work with models:

```
import boto3
from sagemaker.serve.model_builder import ModelBuilder
from sagemaker.serve.builder.schema_builder import SchemaBuilder
from sagemaker.core.helper.session_helper import Session
```

2. Initialize a SageMaker AI session. The following example uses the `Session()` class:

```
sagemaker_session = Session()
```

To define your model

1. Create a `SchemaBuilder` instance, and provide input and output samples. You supply this instance to the `ModelBuilder` class when you define a model. With it, SageMaker AI automatically generates the marshalling functions for serializing and deserializing the input and output.

   For more information about using the `SchemaBuilder` and `ModelBuilder` classes, see Create a model in Amazon SageMaker AI with ModelBuilder.

   The following example provides sample input and output strings to the `SchemaBuilder` class:

```
response = "Jupiter is the largest planet in the solar system. It is the fifth
 planet from the sun."
```

```
sample_input = {
    "inputs": "What is the largest planet in the solar system?",
    "parameters": {"max_new_tokens": 128, "top_p": 0.9, "temperature": 0.6},
}
sample_output = [{"generated_text": response}]
schema_builder = SchemaBuilder(sample_input, sample_output)
```

2. Define your model to SageMaker AI. The following example sets the parameters to initialize a `ModelBuilder` instance:

```
model_builder = ModelBuilder(
    model="jumpstart-model-id",
    schema_builder=schema_builder,
    sagemaker_session=sagemaker_session,
    role_arn=sagemaker_session.get_caller_identity_arn(),
)
```

This example uses a JumpStart model. Replace *`jumpstart-model-id`* with the ID of a JumpStart model, such as `meta-textgeneration-llama-3-70b`.

To retrieve benchmark metrics

1. To determine which pre-optimized configuration you want to deploy, look up the options that SageMaker AI provides. The following example displays them:

```
model_builder.display_benchmark_metrics()
```

This `display_benchmark_metrics()` method prints a table like the following:

```
| Instance Type   | Config Name   |   Concurrent Users |   Latency, TTFT (P50 in
 sec) |   Throughput (P50 in tokens/sec/user) |
|:----------------|:--------------|-------------------:|----------------------------:|----
| ml.g5.48xlarge  | lmi-optimized |                  1 |
 2.25 |                                49.70 |
| ml.g5.48xlarge  | lmi-optimized |                  2 |
 2.28 |                                21.10 |
| ml.g5.48xlarge  | lmi-optimized |                  4 |
 2.37 |                                14.10 |
. . .
| ml.p4d.24xlarge | lmi-optimized |                  1 |
 0.10 |                               137.40 |
```

```
| ml.p4d.24xlarge | lmi-optimized |                  2 |
 0.11 |                                109.20 |
| ml.p4d.24xlarge | lmi-optimized |                  4 |
 0.13 |                                 85.00 |
. . .
```

In the first column, the table lists potential instance types that you can use to host your chosen JumpStart model. For each instance type, under `Config Name`, it lists the names of the pre-optimized configurations. The configurations that SageMaker AI provides are named `lmi-optimized`. For each instance type and configuration, the table provides benchmark metrics. These metrics indicate the throughput and latency that your model will support for different numbers of concurrent users.

2. Based on the benchmark metrics, pick the instance type and configuration name that best supports your performance needs. You will use these values when you create a deployment configuration.

To deploy a pre-optimized model

1. Create a deployment configuration. The following example uses a `ModelBuilder` instance. It passes an instance type and configuration name to the to the `set_deployment_config()` method:

```
model_builder.set_deployment_config(
    config_name="config-name",
    instance_type="instance-type",
)
```

Replace *`config-name`* with a configuration name from the table, such as such as `lmi-optimized`. Replace *`instance-type`* with an instance type from the table, such as `ml.p4d.24xlarge`.

2. Build your model. The following example uses the `.build()` method of the `ModelBuilder` instance:

```
optimized_model = model_builder.build()
```

The `.build()` method returns a deployable `Model` instance.

3. Deploy your model to an inference endpoint. The following example uses the `.deploy()` method of the `ModelBuilder` instance:

```
endpoint = model_builder.deploy(accept_eula=True)
```

The `deploy()` method returns an `Endpoint` object, which you can use to send inference requests to the model.

To test your model with an inference request

- After you deploy your model to an inference endpoint, test the model's predictions. The following example sends an inference request by using the `Endpoint` object:

```
import json

response = endpoint.invoke(body=json.dumps(sample_input),
 content_type="application/json")
result = json.loads(response.body.read().decode('utf-8'))
```

The model returns the text that it generates with a response like the following:

```
{'generated_text': ' Jupiter is the largest planet in the solar system. It is the
 fifth planet from the sun. It is a gas giant with . . .'}
```

Pre-optimized JumpStart models

The following are the JumpStart models that have pre-optimized configurations.

Meta

- Llama 3.1 70B Instruct
- Llama 3.1 70B
- Llama 3.1 405B Instruct FP8
- Llama 3.1 405B FP8
- Llama 3 8B Instruct
- Llama 3 8B
- Llama 3 70B Instruct

- Llama 3 70B
- Llama 2 70B Chat
- Llama 2 7B Chat
- Llama 2 13B Chat

HuggingFace

- Mixtral 8x7B Instruct
- Mixtral 8x7B
- Mistral 7B Instruct
- Mistral 7B

Pre-compiled JumpStart models

For some models and configurations, SageMaker AI provides models that are pre-compiled for specific Amazon Inferentia and Amazon Trainium instances. For these, if you create a compilation optimization job, and you choose ml.inf2.48xlarge or ml.trn1.32xlarge as the deployment instance type, SageMaker AI fetches the compiled artifacts. Because the job uses a model that's already compiled, it completes quickly without running the compilation from scratch.

The following are the JumpStart models for which SageMaker AI has pre-compiled models:

Meta

- Llama3 8B
- Llama3 70B
- Llama2 7B
- Llama2 70B
- Llama2 13B
- Code Llama 7B
- Code Llama 70B

HuggingFace

- Mistral 7B

Create an inference optimization job

You can create an inference optimization job by using Studio or the SageMaker AI Python SDK. The job optimizes your model by applying the techniques that you choose. For more information, see Optimization techniques.

> **Instance pricing for inference optimization jobs**
>
> When you create a inference optimization job that applies quantization or compilation, SageMaker AI chooses which instance type to use to run the job. You are charged based on the instance used.
> For the possible instance types and their pricing details, see the inference optimization pricing information on the Amazon SageMaker pricing page.
> You incur no additional costs for jobs that apply speculative decoding.

For the supported models that you can optimize, see Supported models reference.

Amazon SageMaker Studio

Complete the following steps to create an inference optimization job in Studio.

To begin creating an optimization job

1. In SageMaker AI Studio, create an optimization job through any of the following paths:
   - To create a job for a JumpStart model, do the following:
     a. In the navigation menu, choose **JumpStart**.
     b. On the **All public models** page, choose a model provider, and then choose one of the models that supports optimization.
     c. On the model details page, choose **Optimize**. This button is enabled only for models that support optimization.
     d. On the **Create inference optimization job** page, some JumpStart models require you to sign an end-user license agreement (EULA) before you can proceed. If requested, review the license terms in the **License agreement** section. If the terms are acceptable for your use case, select the checkbox for **I accept the EULA, and read the terms and conditions.**
   - To create a job for a fine-tuned JumpStart model, do the following:

a. In the navigation menu, under **Jobs**, choose **Training**.

b. On the **Training Jobs** page, choose the name of a job that you used to fine tune a JumpStart model. These jobs have the type **JumpStart training** in the **Job type** column.

c. On the details page for the training job, choose **Optimize**.

- To create a job for a custom model, do the following:

  a. In the navigation menu, under **Jobs**, choose **Inference optimization**.

  b. Choose **Create new job**.

  c. On the **Create inference optimization job** page, choose **Add model**.

  d. In the **Add model** window, choose **Custom Model**.

  e. Choose one of the following options:

     Use your existing model - Select this option to optimize a model that you've already created in SageMaker AI.

     Existing model name - enter the name of your SageMaker AI model.

     From S3 - Select this option to provide model artifacts from Amazon S3. For **S3 URI**, enter the URI for the location in Amazon S3 where you've stored your model artifacts.

  f. (Optional) For **Output model name**, you can enter a custom name for the optimized model that the job creates. If you don't provide a name, Studio automatically generates one based on your selection.

2. On the **Create inference optimization job** page, for **Job name**, you can accept the default name that SageMaker AI assigns. Or, to enter a custom job name, choose the **Job name** field, and choose **Enter job name**.

To set the optimization configurations

1. For **Deployment instance type**, choose the instance type that you want to optimize the model for.

   The instance type affects what optimization techniques you can choose. For most types that use GPU hardware, the supported techniques are **Quantization** and **Speculative decoding**. If you choose an instance that uses custom silicon, like the Amazon Inferentia instance

ml.inf2.8xlarge, the supported technique is **Compilation**, which you can use to compile the model for that specific hardware type.

2. Select one or more of the optimization techniques that Studio provides:

   - If you select **Quantization**, choose a data type for **Precision data type**.
   - If you select **Speculative decoding**, choose one of the following options:
     - **Use SageMaker AI draft model** – Choose to use the draft model that SageMaker AI provides.

       > **Note**
       >
       > If you choose to use the SageMaker AI draft model, you must also enable network isolation. Studio provides this option under **Security**.

     - **Choose JumpStart draft model** – Choose to select a model from the JumpStart catalog to use as your draft model.
     - **Choose your own draft model** – Choose to use your own draft model, and provide the S3 URI that locates it.
   - If you choose **Fast model loading**, Studio shows the `OPTION_TENSOR_PARALLEL_DEGREE` environment variable. Use the **Value** field to set the degree of tensor parallelism. The value must evenly divide the number of GPUs in the instance you chose for **Deployment instance type**. For example, to shard your model while using an instance with 8 GPUs, use the values 2, 4, or 8.
   - If you set **Deployment instance type** to an Amazon Inferentia or Amazon Trainium instance, Studio might show that **Compilation** is the one supported option. In that case, Studio selects this option for you.

3. For **Output**, enter the URI of a location in Amazon S3. There, SageMaker AI stores the artifacts of the optimized model that your job creates.
4. (Optional) Expand **Advanced options** for more fine-grained control over settings such as the IAM role, VPC, and environment variables. For more information, see *Advanced options* below.
5. When you're finished configuring the job, choose **Create job**.

   Studio shows the job details page, which shows the job status and all of its settings.

Advanced options

You can set the following advanced options when you create an inference optimization job.

Under **Configurations**, you can set the following options:

Tensor parallel degree

A value for the degree of *tensor parallelism*. Tensor parallelism is a type of model parallelism in which specific model weights, gradients, and optimizer states are split across devices. The value must evenly divide the number of GPUs in your cluster.

Maximum token length

The limit for the number of tokens to be generated by the model. Note that the model might not always generate the maximum number of tokens.

Concurrency

The ability to run multiple instances of a model on the same underlying hardware. Use concurrency to serve predictions to multiple users and to maximize hardware utilization.

Batch size

If your model does *batch inferencing*, use this option to control the size of the batches that your model processes.

Batch inferencing generates model predictions on a batch of observations. It's a good option for large datasets or if you don't need an immediate response to an inference request.

Under **Security**, you can set the following options:

IAM Role

An IAM role that enables SageMaker AI to perform tasks on your behalf. During model optimization, SageMaker AI needs your permission to:

- Read input data from an S3 bucket
- Write model artifacts to an S3 bucket
- Write logs to Amazon CloudWatch Logs
- Publish metrics to Amazon CloudWatch

You grant permissions for all of these tasks to an IAM role.

For more information, see How to use SageMaker AI execution roles.

Encryption KMS key

A key in Amazon Key Management Service (Amazon KMS). SageMaker AI uses they key to encrypt the artifacts of the optimized model when SageMaker AI uploads the model to Amazon S3.

VPC

SageMaker AI uses this information to create network interfaces and attach them to your model containers. The network interfaces provide your model containers with a network connection within your VPC that is not connected to the internet. They also enable your model to connect to resources in your private VPC.

For more information, see Give SageMaker AI Hosted Endpoints Access to Resources in Your Amazon VPC.

Enable network isolation

Activate this option if you want to restrict your container's internet access. Containers that run with network isolation can't make any outbound network calls.

> **Note**
>
> You must activate this option when you optimize with speculative decoding and you use the SageMaker AI draft model.
> For more information about network isolation, see Network Isolation.

Under **Advanced container definition**, you can set the following options:

Stopping condition

Specifies a limit to how long a job can run. When the job reaches the time limit, SageMaker AI ends the job. Use this option to cap costs.

Tags

Key-value pairs associated with the optimization job.

For more information about tags, see Tagging your Amazon resources in the *Amazon Web Services General Reference*.

Environment variables

Key-value pairs that define the environment variables to set in the model container.

SageMaker AI Python SDK

You can create an inference optimization job by using the SageMaker AI Python SDK in your project. First, you define a `Model` instance by using the `ModelBuilder` class. Then, you use the `optimize()` method to run a job that optimizes your model with quantization, speculative decoding, or compilation. When the job completes, you deploy the model to an inference endpoint by using the `deploy()` method.

For more information about the classes and methods used in the following examples, see APIs in the SageMaker AI Python SDK documentation.

To set up your project

1. In your application code, import the necessary libraries. The following example imports the SDK for Python (Boto3). It also imports the classes from the SageMaker AI Python SDK that you use to define and work with models:

```
import boto3
from sagemaker.serve.model_builder import ModelBuilder
from sagemaker.serve.builder.schema_builder import SchemaBuilder
from sagemaker.core.helper.session_helper import Session
from pathlib import Path
```

2. Initialize a SageMaker AI session. The following example uses the `Session()` class:

```
sagemaker_session = Session()
```

To define your model

1. Create a `SchemaBuilder` instance, and provide input and output samples. You supply this instance to the `ModelBuilder` class when you define a model. With it, SageMaker AI automatically generates the marshalling functions for serializing and deserializing the input and output.

For more information about using the `SchemaBuilder` and `ModelBuilder` classes, see Create a model in Amazon SageMaker AI with ModelBuilder.

The following example provides sample input and output strings to the `SchemaBuilder` class:

```
response = "Jupiter is the largest planet in the solar system. It is the fifth
 planet from the sun."
sample_input = {
    "inputs": "What is the largest planet in the solar system?",
    "parameters": {"max_new_tokens": 128, "top_p": 0.9, "temperature": 0.6},
}
sample_output = [{"generated_text": response}]
schema_builder = SchemaBuilder(sample_input, sample_output)
```

2. Define your model to SageMaker AI. The following example sets the parameters to initialize a `ModelBuilder` instance:

```
model_builder = ModelBuilder(
    model="jumpstart-model-id",
    schema_builder=schema_builder,
    sagemaker_session=sagemaker_session,
    role_arn=sagemaker_session.get_caller_identity_arn(),
)
```

This example uses a JumpStart model. Replace *`jumpstart-model-id`* with the ID of a JumpStart model, such as `meta-textgeneration-llama-3-70b`.

> **Note**
>
> If you want to optimize with speculative decoding, and you want to use the SageMaker AI draft, you must enable network isolation. To enable it, include the following argument when you initialize a `ModelBuilder` instance:
>
> ```
> enable_network_isolation=True,
> ```
>
> For more information about network isolation, see Network Isolation.

To optimize with quantization

1. To run a quantization job, use the `optimize()` method, and set the `quantization_config` argument. The following example sets `OPTION_QUANTIZE` as an environment variable in the optimization container:

```
optimized_model = model_builder.optimize(
    instance_type="instance-type",
    accept_eula=True,
    quantization_config={
        "OverrideEnvironment": {
            "OPTION_QUANTIZE": "awq",
        },
    },
    output_path="s3://output-path",
)
```

   In this example, replace *instance-type* with an ML instance, such as `ml.p4d.24xlarge`. Replace *s3://output-path* with the path to the S3 location where you store the optimized model that the job creates.

   The `optimize()` method returns a `Model` object, which you can use to deploy your model to an endpoint.

2. When the job completes, deploy the model. The following example uses the `deploy()` method:

```
endpoint = model_builder.deploy(
    instance_type="instance-type",
    accept_eula=True,
)
```

   In this example, replace *instance-type* with an ML instance, such as `ml.p4d.24xlarge`.

   The `deploy()` method returns an `Endpoint` object, which you can use to send inference requests to the endpoint that hosts the model.

To optimize with speculative decoding using the SageMaker AI draft model

When you optimize your model with speculative decoding, you can choose to use a draft model that SageMaker AI provides, or you can use your own. The following examples use the SageMaker AI draft model.

> **Prerequisite**
>
> To optimize with speculative decoding and the SageMaker AI draft model, you must enable network isolation when you define your model.

1. To run a speculative decoding job, use the `optimize()` method, and set the `speculative_decoding_config` argument. The following example sets the `ModelProvider` key to `SAGEMAKER` to use the draft model that SageMaker AI provides.

   ```
   optimized_model = model_builder.optimize(
       instance_type="instance-type",
       accept_eula=True,
       speculative_decoding_config={
           "ModelProvider": "SAGEMAKER",
       },
   )
   ```

   In this example, replace *instance-type* with an ML instance, such as `ml.p4d.24xlarge`.

   The `optimize()` method returns a `Model` object, which you can use to deploy your model to an endpoint.

2. When the job completes, deploy the model. The following example uses the `deploy()` method:

   ```
   endpoint = model_builder.deploy(accept_eula=True)
   ```

   The `deploy()` method returns an `Endpoint` object, which you can use to send inference requests to the endpoint that hosts the model.

To optimize with speculative decoding using a custom draft model

Before you can provide your custom draft model to SageMaker AI, you must first upload the model artifacts to Amazon S3.

The following examples demonstrate one possible way to provide a custom draft model. The examples download the draft model from the Hugging Face Hub, upload it to Amazon S3, and provide the S3 URI to the `speculative_decoding_config` argument.

1. If you want to download a model from the Hugging Face Hub, add the `huggingface_hub` library to your project, and download a model with the `snapshot_download()` method. The following example downloads a model to a local directory:

   ```
   import huggingface_hub

   huggingface_hub.snapshot_download(
       repo_id="model-id",
       revision="main",
       local_dir=download-dir,
       token=hf-access-token,
   )
   ```

   In this example, replace *`model-id`* with the ID of a model the Hugging Face Hub, such as `meta-llama/Meta-Llama-3-8B`. Replace *`download-dir`* with a local directory. Replace *`hf-access-token`* with your user access token. To learn how to get your access token, see User access tokens in the Hugging Face documentation.

   For more information about the `huggingface_hub` library, see Hub client library in the Hugging Face documentation.

2. To make your downloaded model available to SageMaker AI, upload it to Amazon S3. The following example uploads the model with the `sagemaker_session` object:

   ```
   custom_draft_model_uri = sagemaker_session.upload_data(
       path=hf_local_download_dir.as_posix(),
       bucket=sagemaker_session.default_bucket(),
       key_prefix="prefix",
   )
   ```

   In this example, replace *`prefix`* with a qualifier that helps you distinguish the draft model in S3, such as `spec-dec-custom-draft-model`.

The `upload_data()` method returns the S3 URI for the model artifacts.

3. To run a speculative decoding job, use the `optimize()` method, and set the `speculative_decoding_config` argument. The following example sets the `ModelSource` key to the S3 URI of the custom draft model:

```
optimized_model = model_builder.optimize(
    instance_type="instance-type",
    accept_eula=True,
    speculative_decoding_config={
        "ModelSource": custom_draft_model_uri + "/",
    },
)
```

In this example, replace *`instance-type`* with an ML instance, such as `ml.p4d.24xlarge`.

The `optimize()` method returns a `Model` object, which you can use to deploy your model to an endpoint.

4. When the job completes, deploy the model. The following example uses the `deploy()` method:

```
endpoint = model_builder.deploy(accept_eula=True)
```

The `deploy()` method returns an `Endpoint` object, which you can use to send inference requests to the endpoint that hosts the model.

To optimize with compilation

1. To run a compilation job, use the `optimize()` method, and set the `compilation_config` argument. The following example uses the `OverrideEnvironment` key to set the necessary environment variables in the optimization container:

```
optimized_model = model_builder.optimize(
    instance_type="instance-type",
    accept_eula=True,
    compilation_config={
        "OverrideEnvironment": {
            "OPTION_TENSOR_PARALLEL_DEGREE": "24",
            "OPTION_N_POSITIONS": "8192",
```

```
            "OPTION_DTYPE": "fp16",
            "OPTION_ROLLING_BATCH": "auto",
            "OPTION_MAX_ROLLING_BATCH_SIZE": "4",
            "OPTION_NEURON_OPTIMIZE_LEVEL": "2",
        }
    },
    output_path="s3://output-path",
)
```

In this example, set *instance-type* to an ML instance type with accelerated hardware. For example, for accelerated inference with Amazon Inferentia, you could set the type to an Inf2 instance, such as `ml.inf2.48xlarge`. Replace *s3://output-path* with the path to the S3 location where you store the optimized model that the job creates.

2. When the job completes, deploy the model. The following example uses the `deploy()` method:

```
endpoint = model_builder.deploy(accept_eula=True)
```

The `deploy()` method returns an `Endpoint` object, which you can use to send inference requests to the endpoint that hosts the model.

To test your model with an inference request

- To send a test inference request to your deployed model, use the `invoke()` method of the `Endpoint` object. The following example passes the `sample_input` variable that was also passed to the `SchemaBuilder` class in the examples to define your model:

```
import json

response = endpoint.invoke(body=json.dumps(sample_input),
 content_type="application/json")
result = json.loads(response.body.read().decode('utf-8'))
```

The sample input has the prompt, `"What is the largest planet in the solar system?"`. The `invoke()` method returns the response that the model generated, as shown by the following example:

```
{'generated_text': ' Jupiter is the largest planet in the solar system. It is the
 fifth planet from the sun. It is a gas giant with . . .'}
```

Amazon SDK for Python (Boto3)

You can use the Amazon SDK for Python (Boto3) to programmatically create and manage inference optimization jobs. This section provides examples for different optimization techniques.

Prerequisites

Before creating an optimization job with Boto3, ensure you have:

- Configured Amazon credentials - Set up your Amazon credentials with appropriate permissions
- Created a SageMaker AI model (if using an existing model)
- Prepared training data in S3 (for speculative decoding optimization, supported context length up to 4096)
- IAM role with necessary permissions - Your execution role must have permissions to access S3 and create SageMaker resources

Example: Create an Optimization Job with EAGLE Speculative Decoding (Llama 3.3 70B)

This example demonstrates creating an optimization job for a large language model using the EAGLE speculative decoding technique:

```
import boto3

# Initialize SageMaker client
sagemaker_client = boto3.client('sagemaker', region_name='us-west-2')

# Step 1: Create a SageMaker model (if not already created)
model_response = sagemaker_client.create_model(
    ModelName='meta-llama-3-3-70b-instruct',
    ExecutionRoleArn='arn:aws:iam::123456789012:role/SageMakerExecutionRole',
    PrimaryContainer={
        'Image': '763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:<tag>',
        'ModelDataSource': {
            'S3DataSource': {
                'S3Uri': 's3://my-bucket/models/Llama-3.3-70B-Instruct/',
                'S3DataType': 'S3Prefix',
```

```
                'CompressionType': 'None'
            }
        },
        'Environment': {
            'SAGEMAKER_ENV': '1',
            'SAGEMAKER_MODEL_SERVER_TIMEOUT': '3600'
        }
    }
)

# Step 2: Create optimization job with speculative decoding
optimization_response = sagemaker_client.create_optimization_job(
    OptimizationJobName='llama-optim-job-eagle-speculative-decoding',
    RoleArn='arn:aws:iam::123456789012:role/SageMakerExecutionRole',
    ModelSource={
        'SageMakerModel': {
            'ModelName': 'meta-llama-3-3-70b-instruct'
        }
    },
    DeploymentInstanceType='ml.p4d.24xlarge',
    # MaxInstanceCount specifies the maximum number of instances for distributed
 training
    MaxInstanceCount=4,
    OptimizationConfigs=[
        {
            'ModelSpeculativeDecodingConfig': {
                'Technique': 'EAGLE',
                'TrainingDataSource': {
                    'S3Uri': 's3://my-bucket/training_data/ultrachat_8k/',
                    'S3DataType': 'S3Prefix'
                }
            }
        }
    ],
    OutputConfig={
        'S3OutputLocation': 's3://my-bucket/optimized-models/llama-optim-output/',
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 432000  # 5 days
    }
)

print(f"Optimization job ARN: {optimization_response['OptimizationJobArn']}")
```

Example: Create an Optimization Job from S3 Model Artifacts (Qwen3 32B)

This example shows how to create an optimization job using model artifacts directly from S3:

```
import boto3

sagemaker_client = boto3.client('sagemaker', region_name='us-west-2')

# Create model from S3 artifacts
model_response = sagemaker_client.create_model(
    ModelName='qwen3-32b',
    ExecutionRoleArn='arn:aws:iam::123456789012:role/SageMakerExecutionRole',
    PrimaryContainer={
        'Image': '763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:<tag>',
        'Mode': 'SingleModel',
        'ModelDataSource': {
            'S3DataSource': {
                'S3Uri': 's3://my-bucket/models/qwen3-32b/',
                'S3DataType': 'S3Prefix',
                'CompressionType': 'None'
            }
        },
        'Environment': {
            'AWS_REGION': 'us-west-2'
        }
    }
)

# Create optimization job with smaller training dataset
optimization_response = sagemaker_client.create_optimization_job(
    OptimizationJobName='qwen3-optim-job-eagle',
    RoleArn='arn:aws:iam::123456789012:role/SageMakerExecutionRole',
    ModelSource={
        'SageMakerModel': {
            'ModelName': 'qwen3-32b'
        }
    },
    DeploymentInstanceType='ml.g6.48xlarge',
    MaxInstanceCount=4,
    OptimizationConfigs=[
        {
            'ModelSpeculativeDecodingConfig': {
                'Technique': 'EAGLE',
                'TrainingDataSource': {
```

```
                    'S3Uri': 's3://my-bucket/training_data/ultrachat_1k/',
                    'S3DataType': 'S3Prefix'
                }
            }
        }
    ],
    OutputConfig={
        'S3OutputLocation': 's3://my-bucket/optimized-models/qwen3-optim-output/',
    },
    StoppingCondition={
        'MaxRuntimeInSeconds': 432000  # 5 days
    }
)

print(f"Optimization job ARN: {optimization_response['OptimizationJobArn']}")
```

Example: Monitor and Manage Optimization Jobs

After creating an optimization job, you can monitor its progress and manage it using these commands:

```
import boto3

sagemaker_client = boto3.client('sagemaker', region_name='us-west-2')

# Describe optimization job to check status
describe_response = sagemaker_client.describe_optimization_job(
    OptimizationJobName='llama-optim-job-eagle-speculative-decoding'
)

print(f"Job Status: {describe_response['OptimizationJobStatus']}")

# List all optimization jobs (with pagination)
list_response = sagemaker_client.list_optimization_jobs(
    MaxResults=10,
    SortBy='CreationTime',
    SortOrder='Descending'
)

print("\nRecent optimization jobs:")
for job in list_response['OptimizationJobSummaries']:
    print(f"- {job['OptimizationJobName']}: {job['OptimizationJobStatus']}")
```

```
# Stop a running optimization job if needed
# sagemaker_client.stop_optimization_job(
#     OptimizationJobName='llama-optim-job-eagle-speculative-decoding'
# )

# Delete a completed or failed optimization job
# sagemaker_client.delete_optimization_job(
#     OptimizationJobName='llama-optim-job-eagle-speculative-decoding'
# )
```

Speculative decoding with Eagle Heads runs four sequential training jobs. Each job produces output that becomes the input to the next. Only the output from the final job is delivered to your S3 bucket. The intermediate outputs are encrypted and stored in an internal SageMaker AI service bucket for upto 20 days. SageMaker AI does not have permissions to de-crypt them. If you want the intermediate data removed before that time period, ensure your job has been completed or has stopped, and then open a support case [https://docs.aws.amazon.com/awssupport/latest/user/case-management.html#creating-a-support-case] for this data to be deleted. Include in the request your Amazon account ID and the optimization job ARN.

Limitations of the SageMaker AI draft model

For any model that you optimize with the SageMaker AI draft model, be aware of the requirements, restrictions, and supported environment variables.

Requirements

You must do the following:

- Use a model that's provided by SageMaker JumpStart.
- Enable network isolation for the model deployment.
- If you deploy the model to a Large Model Inference (LMI) container, use a DJLServing container at version 0.28.0 or above.

  For the available containers, see Large Model Inference Containers in the Deep Learning Containers GitHub repository.
- If you fine tune the JumpStart model, use the safetensors format for the model weights.

  For more information about this format, see Safetensors in the Hugging Face documentation.

Restrictions

You can't do the following:

- Use the model in local test environments that you create with local mode.

  For more information about local mode, see Local Mode in the SageMaker AI Python SDK documentation.
- Access the model container through the Amazon Systems Manager Agent (SSM Agent). The SSM Agent provides shell-level access to your model container so that you can debug processes and log commands with Amazon CloudWatch.

  For more information about this feature, see Access containers through SSM.
- Configure the model container for a core dump that occurs if the process crashes.

  For more information about core dumps from model containers, see ProductionVariantCoreDumpConfig.
- Deploy the model to multi-model endpoints, multi-container endpoints, or endpoints that host inference components.

  For more information about these endpoint types, see Multi-model endpoints, Multi-container endpoints, and Inference components.
- Create a model package for the model. You use model packages to create deployable models that you publish on Amazon Web Services Marketplace.

  For more information about this feature, see Create a Model Package Resource.
- Use your own inference code in the model container.
- Use a `requirements.txt` file in the model container. This type of file lists package dependencies.
- Enable the Hugging Face parameter `trust_remote_code`.

Supported environment variables

You can configure the container only with the following environment variables:

- Common environment variables for large model inference (LMI) containers.

For more information about these variables, see Environment Variable Configurations in the LMI container documentation.

- Common environment variables for packages that the Hugging Face Hub provides in its Git repositories.

  For the repositories, see Hugging Face on GitHub.

- Common PyTorch & CUDA environment variables.

  For more information about these variables, see Torch Environment Variables in the PyTorch documentation.

View the optimization job results

After you've created one or more optimization jobs, you can use Studio to view a summary table of all of your jobs, and you can view the details for any individual job.

Amazon SageMaker Studio

To view the optimization job summary table

- In the Studio navigation menu, under **Jobs**, choose **Inference optimization**.

  The **Inference optimization** page shows a table that displays the jobs that you've created. For each job, it shows the optimization configurations that you applied and the job status.

To view the details for a job

- On the **Inference optimization** page, in the summary table, choose the name of the job.

  Studio shows the job details page, which shows the job status and all of the settings that you applied when you created the job. If the job completed successfully, SageMaker AI stored the optimized model artifacts in the Amazon S3 location under **Optimized model S3 URI**.

Evaluate the performance of optimized models

After you use an optimization job to create an optimized model, you can run an evaluation of model performance. This evaluation yields metrics for latency, throughput, and price. Use these

metrics to determine whether the optimized model meets the needs of your use case or whether it requires further optimization.

You can run performance evaluations only by using Studio. This feature is not provided through the Amazon SageMaker AI API or Python SDK.

Before you begin

Before you can create a performance evaluation, you must first optimize a model by creating an inference optimization job. In Studio, you can evaluate only the models that you create with these jobs.

Create the performance evaluation

Complete the following steps in Studio to create a performance evaluation for an optimized model.

1. In the Studio navigation menu, under **Jobs**, choose **Inference optimization**.
2. Choose the name of the job that created the optimized model that you want to evaluate.
3. On the job details page, choose **Evaluate performance**.
4. On the **Evaluate performance** page, some JumpStart models require you to sign an end-user license agreement (EULA) before you can proceed. If requested, review the license terms in the **License agreement** section. If the terms are acceptable for your use case, select the checkbox for **I accept the EULA, and read the terms and conditions.**
5. For **Select a model for tokenizer**, accept the default, or a choose a specific model to act as the tokenizer for your evaluation.
6. For **Input datasets**, choose whether to:
   - Use the default sample datasets from SageMaker AI.
   - Provide an S3 URI that points to your own sample datasets.
7. For **S3 URI for performance results**, provide a URI that points to the location in Amazon S3 where you want to store the evaluation results.
8. Choose **Evaluate**.

   Studio shows the **Performance evaluations** page, where your evaluation job is shown in the table. The **Status** column shows the status of your evaluation.
9. When the status is **Completed**, choose the name of the job to see the evaluation results.

The evaluation details page shows tables that provide the performance metrics for latency, throughput, and price. For more information about each metric, see the Metrics reference for inference performance evaluations.

Metrics reference for inference performance evaluations

After you successfully evaluate the performance of an optimized model, the evaluation details page in Studio shows the following metrics.

Latency metrics

The **Latency** section shows the following metrics

Concurrency

The number of concurrent users that the evaluation simulated to invoke the endpoint simultaneously.

Time to first token (ms)

The time that elapsed between when request is sent and when the first token of a streaming response is received.

Inter-token latency (ms)

The time to generate an output token for each request.

Client latency (ms)

The request latency from the time the request is sent to the time the entire response is received.

Input tokens/sec (count)

The total number of generated input tokens, across all requests, divided by the total duration in seconds for the concurrency.

Output tokens/sec (count)

The total number of generated output tokens, across all requests, divided by total duration in seconds for the concurrency.

Client invocations (count)

The total number of inference requests sent to the endpoint across all users at a concurrency.

Client invocation errors (count)

The total number of inference requests sent to the endpoint across all users at a given concurrency that resulted in an invocation error.

Tokenizer failed (count)

The total number of inference requests where the tokenizer failed to parse the request or the response.

Empty inference response (count)

The total number of inference requests that resulted in zero output tokens or the tokenizer failing to parse the response.

Throughput metrics

The **Throughput** section shows the following metrics.

Concurrency

The number of concurrent users that the evaluation simulated to invoke the endpoint simultaneously.

Input tokens/sec/req (count)

The total number of generated input tokens per second per request.

Output tokens/sec/req (count)

The total number of generated output tokens per second per request.

Input tokens (count)

The total number of generated input tokens per request.

Output tokens (count)

The total number of generated output tokens per request.

Price metrics

The **Price** section shows the following metrics.

Concurrency

The number of concurrent users that the evaluation simulated to invoke the endpoint simultaneously.

Price per million input tokens

Cost of processing 1M input tokens.

Price per million output tokens

Cost of generating 1M output tokens.

Supported models reference

The following tables show the models for which SageMaker AI support inference optimization, and they show the supported optimization techniques.

Supported Llama models

Model Name	Supported Data Formats for Quantization	Supports Speculative Decoding	Supports Fast Model Loading	Libraries Used for Compilation
Meta Llama 2 13B	INT4-AWQ INT8-SmoothQuant FP8	Yes	Yes	Amazon Neuron TensorRT-LLM
Meta Llama 2 13B Chat	INT4-AWQ INT8-SmoothQuant FP8	Yes	Yes	Amazon Neuron TensorRT-LLM
Meta Llama 2 70B	INT4-AWQ INT8-SmoothQuant	Yes	Yes	Amazon Neuron TensorRT-LLM

Model Name	Supported Data Formats for Quantization	Supports Speculative Decoding	Supports Fast Model Loading	Libraries Used for Compilation
	FP8

Supported Model Architectures and EAGLE Type

Model Architecture Name	EAGLE Type
LlamaForCausalLM	EAGLE 3
Qwen3ForCausalLM	EAGLE 3
Qwen3NextForCausalLM	EAGLE 2
Qwen3MoeForCausalLM	EAGLE 3
Qwen2ForCausalLM	EAGLE 3
GptOssForCausalLM	EAGLE 3

Options for evaluating your machine learning model in Amazon SageMaker AI

After training a model, evaluate it to determine whether its performance and accuracy enable you to achieve your business goals. You might generate multiple models using different methods and evaluate each. For example, you could apply different business rules for each model, and then apply various measures to determine each model's suitability. You might consider whether your model needs to be more sensitive than specific (or vice versa).

You can evaluate your model using historical data (offline) or live data:

- **Offline testing**—Use historical, not live, data to send requests to the model for inferences.

  Deploy your trained model to an alpha endpoint, and use historical data to send inference requests to it. To send the requests, use a Jupyter notebook in your Amazon SageMaker AI notebook instance and either the Amazon SDK for Python (Boto) or the high-level Python library provided by SageMaker AI.
- **Online testing with live data**—SageMaker AI supports A/B testing for models in production by using production variants. Production variants are models that use the same inference code and are deployed on the same SageMaker AI endpoint. You configure the production variants so that a small portion of the live traffic goes to the model that you want to validate. For example, you might choose to send 10% of the traffic to a model variant for evaluation. After you are satisfied with the model's performance, you can route 100% traffic to the updated model. For an example of testing models in production, see Testing models with production variants.

For more information, see articles and books about how to evaluate models, for example, Evaluating Machine Learning Models.

Options for offline model evaluation include:

- **Validating using a holdout set**—Machine learning practitioners often set aside a part of the data as a "holdout set." They don't use this data for model training.

  With this approach, you evaluate how well your model provides inferences on the holdout set. You then assess how effectively the model generalizes what it learned in the initial training, as opposed to using model memory. This approach to validation gives you an idea of how often the model is able to infer the correct answer.

In some ways, this approach is similar to teaching elementary school students. First, you provide them with a set of examples to learn, and then test their ability to generalize from their learning. With homework and tests, you pose problems that were not included in the initial learning and determine whether they are able to generalize effectively. Students with perfect memories could memorize the problems, instead of learning the rules.

Typically, the holdout dataset is of 20-30% of the training data.

- **k-fold validation**—In this validation approach, you split the example dataset into *k* parts. You treat each of these parts as a holdout set for *k* training runs, and use the other *k*-1 parts as the training set for that run. You produce *k* models using a similar process, and aggregate the models to generate your final model. The value *k* is typically in the range of 5-10.

Predictive ML

Get instance recommendations and run load tests for your predictive ML models.

Amazon SageMaker Inference Recommender

Amazon SageMaker Inference Recommender is a capability of Amazon SageMaker AI. It reduces the time required to get machine learning (ML) models in production by automating load testing and model tuning across SageMaker AI ML instances. You can use Inference Recommender to deploy your model to a real-time or serverless inference endpoint that delivers the best performance at the lowest cost. Inference Recommender helps you select the best instance type and configuration for your ML models and workloads. It considers factors like instance count, container parameters, model optimizations, max concurrency, and memory size.

Amazon SageMaker Inference Recommender only charges you for the instances used while your jobs are executing.

How it Works

To use Amazon SageMaker Inference Recommender, you can either create a SageMaker AI model or register a model to the SageMaker Model Registry with your model artifacts. Use the Amazon SDK for Python (Boto3) or the SageMaker AI console to run benchmarking jobs for different SageMaker AI endpoint configurations. Inference Recommender jobs help you collect and visualize metrics across performance and resource utilization to help you decide on which endpoint type and configuration to choose.

How to Get Started

If you are a first-time user of Amazon SageMaker Inference Recommender, we recommend that you do the following:

1. Read through the Prerequisites for using Amazon SageMaker Inference Recommender section to make sure you have satisfied the requirements to use Amazon SageMaker Inference Recommender.
2. Read through the Recommendation jobs with Amazon SageMaker Inference Recommender section to launch your first Inference Recommender recommendation jobs.
3. Explore the introductory Amazon SageMaker Inference Recommender Jupyter notebook example, or review the example notebooks in the following section.

Example notebooks

The following example Jupyter notebooks can help you with the workflows for multiple use cases in Inference Recommender:

- If you want an introductory notebook that benchmarks a TensorFlow model, see the SageMaker Inference Recommender TensorFlow notebook.
- If you want to benchmark a HuggingFace model, see the SageMaker Inference Recommender for HuggingFace notebook.
- If you want to benchmark an XGBoost model, see the SageMaker Inference Recommender XGBoost notebook.
- If you want to review CloudWatch metrics for your Inference Recommender jobs, see the SageMaker Inference Recommender CloudWatch metrics notebook.

Prerequisites for using Amazon SageMaker Inference Recommender

Before you can use Amazon SageMaker Inference Recommender, you must complete the prerequisite steps. As an example, we show how to use a PyTorch (v1.7.1) ResNet-18 pre-trained model for both types of Amazon SageMaker Inference Recommender recommendation jobs. The examples shown use the Amazon SDK for Python (Boto3).

Note

- The following code examples use Python. Remove the ! prefix character if you run any of the following code samples in your terminal or Amazon CLI.
- You can run the following examples with the Python 3 (TensorFlow 2.6 Python 3.8 CPU Optimized) kernel in an Amazon SageMaker Studio notebook. For more information about Studio, see Amazon SageMaker Studio.

1. **Create an IAM role for Amazon SageMaker AI.**

   Create an IAM role for Amazon SageMaker AI that has the `AmazonSageMakerFullAccess` IAM managed policy attached.

2. **Set up your environment.**

   Import dependencies and create variables for your Amazon Web Services Region, your SageMaker AI IAM role (from Step 1), and the SageMaker AI client.

   ```
   !pip install --upgrade pip awscli botocore boto3  --quiet
   from sagemaker.core.helper.session_helper import get_execution_role, Session
   from sagemaker.core import image_uris
   import boto3

   region = boto3.Session().region_name
   role = get_execution_role()
   sagemaker_client = boto3.client("sagemaker", region_name=region)
   sagemaker_session = Session()
   ```

3. **(Optional) Review existing models benchmarked by Inference Recommender.**

   Inference Recommender benchmarks models from popular model zoos. Inference Recommender supports your model even if it is not already benchmarked.

Use `ListModelMetaData` to get a response object that lists the domain, framework, task, and model name of machine learning models found in common model zoos.

You use the domain, framework, framework version, task, and model name in later steps to both select an inference Docker image and register your model with SageMaker Model Registry. The following demonstrates how to list model metadata with SDK for Python (Boto3):

```
list_model_metadata_response=sagemaker_client.list_model_metadata()
```

The output includes model summaries (`ModelMetadataSummaries`) and response metadata (`ResponseMetadata`) similar to the following example:

```
{
    'ModelMetadataSummaries': [{
            'Domain': 'NATURAL_LANGUAGE_PROCESSING',
            'Framework': 'PYTORCH:1.6.0',
             'Model': 'bert-base-cased',
             'Task': 'FILL_MASK'
             },
            {
             'Domain': 'NATURAL_LANGUAGE_PROCESSING',
             'Framework': 'PYTORCH:1.6.0',
             'Model': 'bert-base-uncased',
             'Task': 'FILL_MASK'
             },
            {
            'Domain': 'COMPUTER_VISION',
             'Framework': 'MXNET:1.8.0',
             'Model': 'resnet18v2-gluon',
             'Task': 'IMAGE_CLASSIFICATION'
             },
             {
             'Domain': 'COMPUTER_VISION',
             'Framework': 'PYTORCH:1.6.0',
             'Model': 'resnet152',
             'Task': 'IMAGE_CLASSIFICATION'
             }],
    'ResponseMetadata': {
                            'HTTPHeaders': {
                            'content-length': '2345',
```

```
                            'content-type': 'application/x-amz-json-1.1',
                            'date': 'Tue, 19 Oct 2021 20:52:03 GMT',
                            'x-amzn-requestid': 'xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx'
                        },
    'HTTPStatusCode': 200,
    'RequestId': 'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx',
    'RetryAttempts': 0
    }
}
```

For this demo, we use a PyTorch (v1.7.1) ResNet-18 model to perform image classification. The following Python code sample stores the framework, framework version, domain, and task into variables for later use:

```
# ML framework details
framework = 'pytorch'
framework_version = '1.7.1'

# ML model details
ml_domain = 'COMPUTER_VISION'
ml_task = 'IMAGE_CLASSIFICATION'
```

4. **Upload your machine learning model to Amazon S3.**

   Use this PyTorch (v1.7.1) ResNet-18 model if you do not have a pre-trained machine learning model:

```
# Optional: Download a sample PyTorch model
import torch
from torchvision import models, transforms, datasets

# Create an example input for tracing
image = torch.zeros([1, 3, 256, 256], dtype=torch.float32)

# Load a pretrained resnet18 model from TorchHub
model = models.resnet18(pretrained=True)

# Tell the model we are using it for evaluation (not training). Note this is
 required for Inferentia compilation.
model.eval()
model_trace = torch.jit.trace(model, image)
```

```
# Save your traced model
model_trace.save('model.pth')
```

Download a sample inference script `inference.py`. Create a `code` directory and move the inference script to the `code` directory.

```
# Download the inference script
!wget https://aws-ml-blog-artifacts.s3.us-east-2.amazonaws.com/inference.py

# move it into a code/ directory
!mkdir code
!mv inference.py code/
```

Amazon SageMaker AI requires pre-trained machine learning models to be packaged as a compressed TAR file (`*.tar.gz`). Compress your model and inference script to satisfy this requirement:

```
!tar -czf test.tar.gz model.pth code/inference.py
```

When your endpoint is provisioned, the files in the archive are extracted to `/opt/ml/model/` on the endpoint.

After you compress your model and model artifacts as a `.tar.gz` file, upload them to your Amazon S3 bucket. The following example demonstrates how to upload your model to Amazon S3 using the Amazon CLI:

```
!aws s3 cp test.tar.gz s3://{your-bucket}/models/
```

5. **Select a prebuilt Docker inference image or create your own Inference Docker Image.**

   SageMaker AI provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker AI images, see Available Deep Learning Containers Images.

   If none of the existing SageMaker AI containers meet your needs and you don't have an existing container of your own, create a new Docker image. See Containers with custom inference code for information about how to create your Docker image.

The following demonstrates how to retrieve a PyTorch version 1.7.1 inference image using the SageMaker Python SDK:

```
from sagemaker.core import image_uris

## Uncomment and replace with your own values if you did not define
## these variables a previous step.
#framework = 'pytorch'
#framework_version = '1.7.1'

# Note: you can use any CPU-based instance here,
# this is just to set the arch as CPU for the Docker image
instance_type = 'ml.m5.2xlarge'

image_uri = image_uris.retrieve(framework,
                                region,
                                version=framework_version,
                                py_version='py3',
                                instance_type=instance_type,
                                image_scope='inference')
```

For a list of available SageMaker AI Instances, see Amazon SageMaker AI Pricing.

6. **Create a sample payload archive.**

   Create an archive that contains individual files that the load testing tool can send to your SageMaker AI endpoints. Your inference code must be able to read the file formats from the sample payload.

   The following downloads a .jpg image that this example uses in a later step for the ResNet-18 model.

   ```
   !wget https://cdn.pixabay.com/photo/2020/12/18/05/56/flowers-5841251_1280.jpg
   ```

   Compress the sample payload as a tarball:

   ```
   !tar -cvzf payload.tar.gz flowers-5841251_1280.jpg
   ```

   Upload the sample payload to Amazon S3 and note the Amazon S3 URI:

```
!aws s3 cp payload.tar.gz s3://{bucket}/models/
```

You need the Amazon S3 URI in a later step, so store it in a variable:

```
bucket_prefix='models'
bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
payload_s3_key = f"{bucket_prefix}/payload.tar.gz"
sample_payload_url= f"s3://{bucket}/{payload_s3_key}"
```

7. **Prepare your model input for the recommendations job**

   For the last prerequisite, you have two options to prepare your model input. You can either register your model with SageMaker Model Registry, which you can use to catalog models for production, or you can create a SageMaker AI model and specify it in the `ContainerConfig` field when creating a recommendations job. The first option is best if you want to take advantage of the features that Model Registry provides, such as managing model versions and automating model deployment. The second option is ideal if you want to get started quickly. For the first option, go to step 7. For the second option, skip step 7 and go to step 8.

8. **Option 1: Register your model in the model registry**

   With SageMaker Model Registry, you can catalog models for production, manage model versions, associate metadata (such as training metrics) with a model, manage the approval status of a model, deploy models to production, and automate model deployment with CI/CD.

   When you use SageMaker Model Registry to track and manage your models, they are represented as a versioned model package within model package groups. Unversioned model packages are not part of a model group. Model package groups hold multiple versions or iterations of a model. Though it is not required to create them for every model in the registry, they help organize various models that all have the same purpose and provide automatic versioning.

   To use Amazon SageMaker Inference Recommender, you must have a versioned model package. You can create a versioned model package programmatically with the Amazon SDK for Python (Boto3) or with Amazon SageMaker Studio Classic. To create a versioned model package programmatically, first create a model package group with the `CreateModelPackageGroup` API. Next, create a model package using the `CreateModelPackage` API. Calling this method makes a versioned model package.

See Create a Model Group and Register a Model Version for detailed instructions about how to programmatically and interactively create a model package group and how to create a versioned model package, respectively, with the Amazon SDK for Python (Boto3) and Amazon SageMaker Studio Classic.

The following code sample demonstrates how to create a versioned model package using the Amazon SDK for Python (Boto3).

> **Note**
>
> You do not need to approve the model package to create an Inference Recommender job.

a. **Create a model package group**

Create a model package group with the `CreateModelPackageGroup` API. Provide a name to the model package group for the `ModelPackageGroupName` and optionally provide a description of the model package in the `ModelPackageGroupDescription` field.

```
model_package_group_name = '<INSERT>'
model_package_group_description = '<INSERT>'

model_package_group_input_dict = {
 "ModelPackageGroupName" : model_package_group_name,
 "ModelPackageGroupDescription" : model_package_group_description,
}

model_package_group_response =
 sagemaker_client.create_model_package_group(**model_package_group_input_dict)
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to `CreateModelPackageGroup`.

Create a model package by specifying a Docker image that runs your inference code and the Amazon S3 location of your model artifacts and provide values for `InferenceSpecification`. `InferenceSpecification` should contain information

about inference jobs that can be run with models based on this model package, including the following:

- The Amazon ECR paths of images that run your inference code.
- (Optional) The instance types that the model package supports for transform jobs and real-time endpoints used for inference.
- The input and output content formats that the model package supports for inference.

In addition, you must specify the following parameters when you create a model package:

- Domain: The machine learning domain of your model package and its components. Common machine learning domains include computer vision and natural language processing.
- Task: The machine learning task your model package accomplishes. Common machine learning tasks include object detection and image classification. Specify "OTHER" if none of the tasks listed in the API Reference Guide satisfy your use case. See the Task API field descriptions for a list of supported machine learning tasks.
- SamplePayloadUrl: The Amazon Simple Storage Service (Amazon S3) path where the sample payload are stored. This path must point to a single GZIP compressed TAR archive (.tar.gz suffix).
- Framework: The machine learning framework of the model package container image.
- FrameworkVersion: The framework version of the model package container image.

If you provide an allow list of instance types to use to generate inferences in real-time for the SupportedRealtimeInferenceInstanceTypes, Inference Recommender limits the search space for instance types during a `Default` job. Use this parameter if you have budget constraints or know there's a specific set of instance types that can support your model and container image.

In a previous step, we downloaded a pre-trained ResNet18 model and stored it in an Amazon S3 bucket in a directory called `models`. We retrieved a PyTorch (v1.7.1) Deep Learning Container inference image and stored the URI in a variable called `image_uri`. Use those variables in the following code sample to define a dictionary used as input to the `CreateModelPackage` API.

```
# Provide the Amazon S3 URI of your compressed tarfile
```

```
# so that Model Registry knows where to find your model artifacts
bucket_prefix='models'
bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
model_s3_key = f"{bucket_prefix}/test.tar.gz"
model_url= f"s3://{bucket}/{model_s3_key}"

# Similar open source model to the packaged model
# The name of the ML model as standardized by common model zoos
nearest_model_name = 'resnet18'

# The supported MIME types for input and output data. In this example,
# we are using images as input.
input_content_type='image/jpeg'

# Optional - provide a description of your model.
model_package_description = '<INSERT>'

## Uncomment if you did not store the domain and task in an earlier
## step
#ml_domain = 'COMPUTER_VISION'
#ml_task = 'IMAGE_CLASSIFICATION'

## Uncomment if you did not store the framework and framework version
## in a previous step.
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# Optional: Used for optimizing your model using SageMaker Neo
# PyTorch uses NCHW format for images
data_input_configuration = "[[1,3,256,256]]"

# Create a dictionary to use as input for creating a model pacakge group
model_package_input_dict = {
        "ModelPackageGroupName" : model_package_group_name,
        "ModelPackageDescription" : model_package_description,
        "Domain": ml_domain,
        "Task": ml_task,
        "SamplePayloadUrl": sample_payload_url,
        "InferenceSpecification": {
                "Containers": [
                    {
                        "Image": image_uri,
                        "ModelDataUrl": model_url,
```

```
                        "Framework": framework.upper(),
                        "FrameworkVersion": framework_version,
                        "NearestModelName": nearest_model_name,
                        "ModelInput": {"DataInputConfig":
 data_input_configuration}
                    }
                    ],
                "SupportedContentTypes": [input_content_type]
        }
    }
```

b. **Create a model package**

Use the `CreateModelPackage` API to create a model package. Pass the input dictionary defined in the previous step:

```
model_package_response =
 sagemaker_client.create_model_package(**model_package_input_dict)
```

You need the model package ARN to use Amazon SageMaker Inference Recommender. Note the ARN of the model package or store it in a variable:

```
model_package_arn = model_package_response["ModelPackageArn"]

print('ModelPackage Version ARN : {}'.format(model_package_arn))
```

9. **Option 2: Create a model and configure the `ContainerConfig` field**

Use this option if you want to start an inference recommendations job and don't need to register your model in the Model Registry. In the following steps, you create a model in SageMaker AI and configure the `ContainerConfig` field as input for the recommendations job.

a. **Create a model**

Create a model with the `CreateModel` API. For an example that calls this method when deploying a model to SageMaker AI Hosting, see Create a Model (Amazon SDK for Python (Boto3)).

In a previous step, we downloaded a pre-trained ResNet18 model and stored it in an Amazon S3 bucket in a directory called `models`. We retrieved a PyTorch (v1.7.1) Deep

Learning Container inference image and stored the URI in a variable called `image_uri`. We use those variables in the following code example where we define a dictionary used as input to the `CreateModel` API.

```
model_name = '<name_of_the_model>'
# Role to give SageMaker permission to access AWS services.
sagemaker_role= "arn:aws:iam::<region>:<account>:role/*"

# Provide the Amazon S3 URI of your compressed tarfile
# so that Model Registry knows where to find your model artifacts
bucket_prefix='models'
bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
model_s3_key = f"{bucket_prefix}/test.tar.gz"
model_url= f"s3://{bucket}/{model_s3_key}"

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': image_uri,
        'ModelDataUrl': model_url,
    })
```

b. **Configure the `ContainerConfig` field**

Next, you must configure the ContainerConfig field with the model you just created and specify the following parameters in it:

- `Domain`: The machine learning domain of the model and its components, such as computer vision or natural language processing.
- `Task`: The machine learning task that the model accomplishes, such as image classification or object detection.
- `PayloadConfig`: The configuration for the payload for a recommendation job. For more information about the subfields, see `RecommendationJobPayloadConfig`.
- `Framework`: The machine learning framework of the container image, such as PyTorch.
- `FrameworkVersion`: The framework version of the container image.
- (Optional) `SupportedInstanceTypes`: A list of the instance types that are used to generate inferences in real-time.

If you use the `SupportedInstanceTypes` parameter, Inference Recommender limits the search space for instance types during a `Default` job. Use this parameter if you have budget constraints or know there's a specific set of instance types that can support your model and container image.

In the following code example, we use the previously defined parameters, along with `NearestModelName`, to define a dictionary used as input to the `CreateInferenceRecommendationsJob` API.

```
## Uncomment if you did not store the domain and task in a previous step
#ml_domain = 'COMPUTER_VISION'
#ml_task = 'IMAGE_CLASSIFICATION'

## Uncomment if you did not store the framework and framework version in a
 previous step
#framework = 'PYTORCH'
#framework_version = '1.7.1'

# The name of the ML model as standardized by common model zoos
nearest_model_name = 'resnet18'

# The supported MIME types for input and output data. In this example,
# we are using images as input
input_content_type='image/jpeg'

# Optional: Used for optimizing your model using SageMaker Neo
# PyTorch uses NCHW format for images
data_input_configuration = "[[1,3,256,256]]"

# Create a dictionary to use as input for creating an inference recommendation
 job
container_config = {
        "Domain": ml_domain,
        "Framework": framework.upper(),
        "FrameworkVersion": framework_version,
        "NearestModelName": nearest_model_name,
        "PayloadConfig": {
            "SamplePayloadUrl": sample_payload_url,
            "SupportedContentTypes": [ input_content_type ]
         },
        "DataInputConfig": data_input_configuration
```

```
        "Task": ml_task,
        }
```

Recommendation jobs with Amazon SageMaker Inference Recommender

Amazon SageMaker Inference Recommender can make two types of recommendations:

1. Inference recommendations (`Default` job type) run a set of load tests on the recommended instance types. You can also load test for a serverless endpoint.. You only need to provide a model package Amazon Resource Name (ARN) to launch this type of recommendation job. Inference recommendation jobs complete within 45 minutes.
2. Endpoint recommendations (`Advanced` job type) are based on a custom load test where you select your desired ML instances or a serverless endpoint, provide a custom traffic pattern, and provide requirements for latency and throughput based on your production requirements. This job takes an average of 2 hours to complete depending on the job duration set and the total number of inference configurations tested.

Both types of recommendations use the same APIs to create, describe, and stop jobs. The output is a list of instance configuration recommendations with associated environment variables, cost, throughput, and latency metrics. Recommendation jobs also provide an initial instance count, which you can use to configure an autoscaling policy. To differentiate between the two types of jobs, when you're creating a job through either the SageMaker AI console or the APIs, specify `Default` to create preliminary endpoint recommendations and `Advanced` for custom load testing and endpoint recommendations.

> **Note**
>
> You do not need to do both types of recommendation jobs in your own workflow. You can do either independently of the other.

Inference Recommender can also provide you with a list of prospective instances, or the top five instance types that are optimized for cost, throughput and latency for model deployment, along with a confidence score. You can choose these instances when deploying your model. Inference Recommender automatically performs benchmarking against your model for you to provide the prospective instances. Since these are preliminary recommendations, we recommend that you run further instance recommendation jobs to get more accurate results. To view the prospective

instances, go to your SageMaker AI model details page. For more information, see Get instant prospective instances.

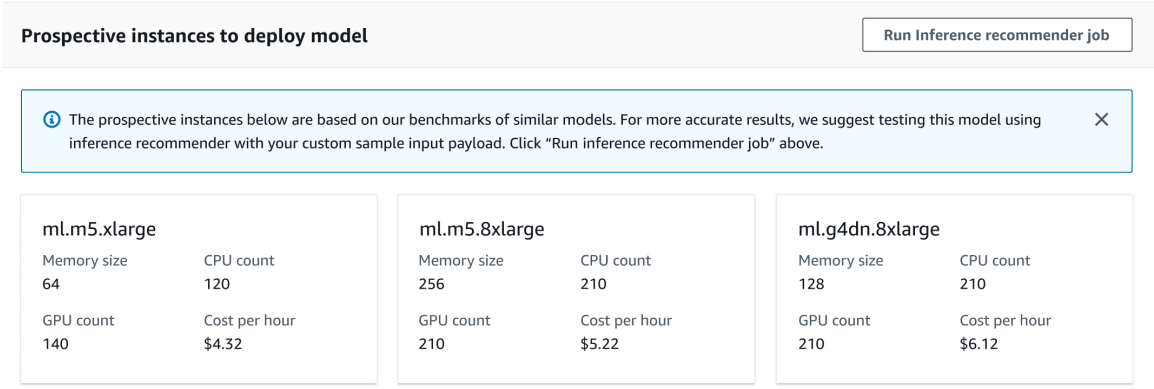
Topics

- Get instant prospective instances
- Inference recommendations
- Get an inference recommendation for an existing endpoint
- Stop your inference recommendation
- Compiled recommendations with Neo
- Recommendation results
- Get autoscaling policy recommendations
- Run a custom load test
- Stop your load test
- Troubleshoot Inference Recommender errors

Get instant prospective instances

Inference Recommender can also provide you with a list of *prospective instances*, or instance types that might be suitable for your model, on your SageMaker AI model details page. Inference Recommender automatically performs preliminary benchmarking against your model for you to provide the top five prospective instances. Since these are preliminary recommendations, we recommend that you run further instance recommendation jobs to get more accurate results.

You can view a list of prospective instances for your model either programmatically by using the DescribeModel API, the SageMaker Python SDK, or the SageMaker AI console.



> **Note**
>
> You won't get prospective instances for models that you created in SageMaker AI before this feature became available.

To view the prospective instances for your model through the console, do the following:

1. Go to the SageMaker console at https://console.amazonaws.cn/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Models**.

3. From the list of models, choose your model.

On the details page for your model, go to the **Prospective instances to deploy model** section. The following screenshot shows this section.

In this section, you can view the prospective instances that are optimized for cost, throughput, and latency for model deployment, along with additional information for each instance type such as the memory size, CPU and GPU count, and cost per hour.

If you decide that you want to benchmark a sample payload and run a full inference recommendation job for your model, you can start a default inference recommendation job from this page. To start a default job through the console, do the following:

1. On your model details page in the **Prospective instances to deploy model section**, choose **Run Inference recommender job**.
2. In the dialog box that pops up, for **S3 bucket for benchmarking payload**, enter the Amazon S3 location where you've stored a sample payload for your model.
3. For **Payload content type**, enter the MIME types for your payload data.
4. (Optional) In the **Model compilation using SageMaker Neo** section, for the **Data input configuration**, enter a data shape in dictionary format.
5. Choose **Run job**.

Inference Recommender starts the job, and you can view the job and its results from the **Inference recommender** list page in the SageMaker AI console.

If you want to run an advanced job and perform custom load tests, or if you want to configure additional settings and parameters for your job, see Run a custom load test.

Inference recommendations

Inference recommendation jobs run a set of load tests on recommended instance types or a serverless endpoint. Inference recommendation jobs use performance metrics that are based on load tests using the sample data you provided during model version registration.

> **Note**
>
> Before you create an Inference Recommender recommendation job, make sure you have satisfied the Prerequisites for using Amazon SageMaker Inference Recommender.

The following demonstrates how to use Amazon SageMaker Inference Recommender to create an inference recommendation based on your model type using the Amazon SDK for Python (Boto3), Amazon CLI, and Amazon SageMaker Studio Classic, and the SageMaker AI console

Topics

- Create an inference recommendation
- Get your inference recommendation job results

Create an inference recommendation

Create an inference recommendation programmatically using the Amazon SDK for Python (Boto3) or the Amazon CLI, or interactively using Studio Classic or the SageMaker AI console. Specify a job name for your inference recommendation, an Amazon IAM role ARN, an input configuration, and either a model package ARN when you registered your model with the model registry, or your model name and a `ContainerConfig` dictionary from when you created your model in the **Prerequisites** section.

Amazon SDK for Python (Boto3)

Use the `CreateInferenceRecommendationsJob` API to start an inference recommendation job. Set the `JobType` field to `'Default'` for inference recommendation jobs. In addition, provide the following:

- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.

- A model package ARN or model name. Inference Recommender supports either one model package ARN or a model name as input. Specify one of the following:
  - The ARN of the versioned model package you created when you registered your model with SageMaker AI model registry. Define this for `ModelPackageVersionArn` in the `InputConfig` field.
  - The name of the model you created. Define this for `ModelName` in the `InputConfig` field. Also, provide the `ContainerConfig` dictionary, which includes the required fields that need to be provided with the model name. Define this for `ContainerConfig` in the `InputConfig` field. In the `ContainerConfig`, you can also optionally specify the `SupportedEndpointType` field as either `RealTime` or `Serverless`. If you specify this field, Inference Recommender returns recommendations for only that endpoint type. If you don't specify this field, Inference Recommender returns recommendations for both endpoint types.
- A name for your Inference Recommender recommendation job for the `JobName` field. The Inference Recommender job name must be unique within the Amazon Region and within your Amazon account.

Import the Amazon SDK for Python (Boto3) package and create a SageMaker AI client object using the client class. If you followed the steps in the **Prerequisites** section, only specify one of the following:

- Option 1: If you would like to create an inference recommendations job with a model package ARN, then store the model package group ARN in a variable named `model_package_arn`.
- Option 2: If you would like to create an inference recommendations job with a model name and `ContainerConfig`, store the model name in a variable named `model_name` and the `ContainerConfig` dictionary in a variable named `container_config`.

```
# Create a low-level SageMaker service client.
import boto3
aws_region = '<INSERT>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide only one of model package ARN or model name, not both.
# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn = '<INSERT>'
```

```
## Uncomment if you would like to create an inference recommendations job with a
## model name instead of a model package ARN, and comment out model_package_arn
 above
## Provide your model name
# model_name = '<INSERT>'
## Provide your container config
# container_config = '<INSERT>'

# Provide a unique job name for SageMaker Inference Recommender job
job_name = '<INSERT>'

# Inference Recommender job type. Set to Default to get an initial recommendation
job_type = 'Default'

# Provide an IAM Role that gives SageMaker Inference Recommender permission to
# access AWS services
role_arn = 'arn:aws:iam::<account>:role/*'

sagemaker_client.create_inference_recommendations_job(
    JobName = job_name,
    JobType = job_type,
    RoleArn = role_arn,
    # Provide only one of model package ARN or model name, not both.
    # If you would like to create an inference recommendations job with a model
 name,
    # uncomment ModelName and ContainerConfig, and comment out
 ModelPackageVersionArn.
    InputConfig = {
        'ModelPackageVersionArn': model_package_arn
        # 'ModelName': model_name,
        # 'ContainerConfig': container_config
    }
)
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to `CreateInferenceRecommendationsJob`.

Amazon CLI

Use the `create-inference-recommendations-job` API to start an inference recommendation job. Set the `job-type` field to `'Default'` for inference recommendation jobs. In addition, provide the following:

- The Amazon Resource Name (ARN) of an IAM role that enables Amazon SageMaker Inference Recommender to perform tasks on your behalf. Define this for the `role-arn` field.
- A model package ARN or model name. Inference Recommender supports either one model package ARN or a model name as input. Specify one of the following
  - The ARN of the versioned model package you created when you registered your model with Model Registry. Define this for `ModelPackageVersionArn` in the `input-config` field.
  - The name of the model you created. Define this for `ModelName` in the `input-config` field. Also, provide the `ContainerConfig` dictionary which includes the required fields that need to be provided with the model name. Define this for `ContainerConfig` in the `input-config` field. In the `ContainerConfig`, you can also optionally specify the `SupportedEndpointType` field as either `RealTime` or `Serverless`. If you specify this field, Inference Recommender returns recommendations for only that endpoint type. If you don't specify this field, Inference Recommender returns recommendations for both endpoint types.
- A name for your Inference Recommender recommendation job for the `job-name` field. The Inference Recommender job name must be unique within the Amazon Region and within your Amazon account.

To create an inference recommendation jobs with a model package ARN, use the following example:

```
aws sagemaker create-inference-recommendations-job
    --region <region>\
    --job-name <job_name>\
    --job-type Default\
    --role-arn arn:aws:iam::<account:role/*>\
    --input-config "{
        \"ModelPackageVersionArn\": \"arn:aws:sagemaker:<region:account:role/*>\",
        }"
```

To create an inference recommendation jobs with a model name and `ContainerConfig`, use the following example. The example uses the `SupportedEndpointType` field to specify that we only want to return real-time inference recommendations:

```
aws sagemaker create-inference-recommendations-job
    --region <region>\
    --job-name <job_name>\
```

```
    --job-type Default\
    --role-arn arn:aws:iam::<account:role/*>\
    --input-config "{
        \"ModelName\": \"model-name\",
        \"ContainerConfig\" : {
                \"Domain\": \"COMPUTER_VISION\",
                \"Framework\": \"PYTORCH\",
                \"FrameworkVersion\": \"1.7.1\",
                \"NearestModelName\": \"resnet18\",
                \"PayloadConfig\":
                    {
                        \"SamplePayloadUrl\": \"s3://{bucket}/{payload_s3_key}\",
                        \"SupportedContentTypes\": [\"image/jpeg\"]
                    },
                \"SupportedEndpointType\": \"RealTime\",
                \"DataInputConfig\": \"[[1,3,256,256]]\",
                \"Task\": \"IMAGE_CLASSIFICATION\",
            },
        }"
```

Amazon SageMaker Studio Classic

Create an inference recommendation job in Studio Classic.

1. In your Studio Classic application, choose the home icon ().
2. In the left sidebar of Studio Classic, choose **Models**.
3. Choose **Model Registry** from the dropdown list to display models you have registered with the model registry.

   The left panel displays a list of model groups. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio Classic.
4. Select the name of your model group. When you select your model group, the right pane of Studio Classic displays column heads such as **Versions** and **Setting**.

   If you have one or more model packages within your model group, you see a list of those model packages within the **Versions** column.
5. Choose the **Inference recommender** column.

6. Choose an IAM role that grants Inference Recommender permission to access Amazon services. You can create a role and attach the `AmazonSageMakerFullAccess` IAM managed policy to accomplish this. Or you can let Studio Classic create a role for you.
7. Choose **Get recommendations**.

   The inference recommendation can take up to 45 minutes.

   > **Warning**
   >
   > Do not close this tab. If you close this tab, you cancel the instance recommendation job.

SageMaker AI console

Create an instance recommendation job through the SageMaker AI console by doing the following:

1. Go to the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, choose **Create job**.
4. For **Step 1: Model configuration**, do the following:
   a. For **Job type**, choose **Default recommender job**.
   b. If you're using a model registered in the SageMaker AI model registry, then turn on the **Choose a model from the model registry** toggle and do the following:
      i. From the **Model group** dropdown list, choose the model group in SageMaker AI model registry where your model is located.
      ii. From the **Model version** dropdown list, choose the desired version of your model.
   c. If you're using a model that you've created in SageMaker AI, then turn off the **Choose a model from the model registry toggle** and do the following:
      - For the **Model name** field, enter the name of your SageMaker AI model.
   d. From the **IAM role** dropdown list, you can select an existing Amazon IAM role that has the necessary permissions to create an instance recommendation job. Alternatively, if you don't have an existing role, you can choose **Create a new role** to open the role

creation pop-up, and SageMaker AI adds the necessary permissions to the new role that you create.

e. For **S3 bucket for benchmarking payload**, enter the Amazon S3 path to your sample payload archive, which should contain sample payload files that Inference Recommender uses to benchmark your model on different instance types.

f. For **Payload content type**, enter the MIME types of your sample payload data.

g. (Optional) If you turned off the **Choose a model from the model registry toggle** and specified a SageMaker AI model, then for **Container configuration**, do the following:

i. For the **Domain** dropdown list, select the machine learning domain of the model, such as computer vision, natural language processing, or machine learning.

ii. For the **Framework** dropdown list, select the framework of your container, such as TensorFlow or XGBoost.

iii. For **Framework version**, enter the framework version of your container image.

iv. For the **Nearest model name** dropdown list, select the pre-trained model that mostly closely matches your own.

v. For the **Task** dropdown list, select the machine learning task that the model accomplishes, such as image classification or regression.

h. (Optional) For **Model compilation using SageMaker Neo**, you can configure the recommendation job for a model that you've compiled using SageMaker Neo. For **Data input configuration**, enter the correct input data shape for your model in a format similar to `{'input':[1,1024,1024,3]}`.

i. Choose **Next**.

5. For **Step 2: Instances and environment parameters**, do the following:

a. (Optional) For **Select instances for benchmarking**, you can select up to 8 instance types that you want to benchmark. If you don't select any instances, Inference Recommender considers all instance types.

b. Choose **Next**.

6. For **Step 3: Job parameters**, do the following:

a. (Optional) For the **Job name** field, enter a name for your instance recommendation job. When you create the job, SageMaker AI appends a timestamp to the end of this name.

b. (Optional) For the **Job description** field, enter a description for the job.

c. (Optional) For the **Encryption key** dropdown list, choose an Amazon KMS key by name or enter its ARN to encrypt your data.

d. (Optional) For **Max test duration (s)**, enter the maximum number of seconds you want each test to run for.

e. (Optional) For **Max invocations per minute**, enter the maximum number of requests per minute the endpoint can reach before stopping the recommendation job. After reaching this limit, SageMaker AI ends the job.

f. (Optional) For **P99 Model latency threshold (ms)**, enter the model latency percentile in milliseconds.

g. Choose **Next**.

7. For **Step 4: Review job**, review your configurations and then choose **Submit**.

Get your inference recommendation job results

Collect the results of your inference recommendation job programmatically with Amazon SDK for Python (Boto3), the Amazon CLI, Studio Classic, or the SageMaker AI console.

Amazon SDK for Python (Boto3)

Once an inference recommendation is complete, you can use `DescribeInferenceRecommendationsJob` to get the job details and recommendations. Provide the job name that you used when you created the inference recommendation job.

```
job_name='<INSERT>'
response = sagemaker_client.describe_inference_recommendations_job(
                    JobName=job_name)
```

Print the response object. The previous code sample stored the response in a variable named `response`.

```
print(response['Status'])
```

This returns a JSON response similar to the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing serverless inference recommendations, see the example after this one).

```
{
```

```
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Default',

        'RetryAttempts': 0
        }
}
```

The first few lines provide information about the inference recommendation job itself. This includes the job name, role ARN, and creation and deletion times.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed Amazon machine learning model) that was used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Amazon SageMaker AI metrics in Amazon CloudWatch for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) in US dollars for your real-time endpoint, the expected maximum number of `InvokeEndpoint` requests per minute sent to the endpoint (`MaxInvocations`), and the model latency (`ModelLatency`), which is the interval of time (in microseconds) that your model took to respond to SageMaker AI. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

The following example shows the `InferenceRecommendations` part of the response for an inference recommendations job configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
      {
         "EndpointConfiguration": {
            "EndpointName": "value",
            "InitialInstanceCount": value,
            "InstanceType": "value",
            "VariantName": "value",
            "ServerlessConfig": {
                "MaxConcurrency": value,
                "MemorySizeInMb": value
            }
         },
         "InvocationEndTime": value,
         "InvocationStartTime": value,
         "Metrics": {
            "CostPerHour": value,
            "CostPerInference": value,
            "CpuUtilization": value,
            "MaxInvocations": value,
            "MemoryUtilization": value,
            "ModelLatency": value,
            "ModelSetupTime": value
         },
```

```
         "ModelConfiguration": {
            "Compiled": "False",
            "EnvironmentParameters": [],
            "InferenceSpecificationName": "value"
         },
         "RecommendationId": "value"
      }
   ]
```

You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the `ServerlessConfig`, which tells you the metrics returned for a serverless endpoint with the given `MemorySizeInMB` and when `MaxConcurrency = 1`. To increase the throughput possible on the endpoint, increase the value of `MaxConcurrency` linearly. For example, if the inference recommendation shows `MaxInvocations` as `1000`, then increasing `MaxConcurrency` to 2 would support 2000 `MaxInvocations`. Note that this is true only up to a certain point, which can vary based on your model and code. Serverless recommendations also measure the metric `ModelSetupTime`, which measures (in microseconds) the time it takes to launch computer resources on a serverless endpoint. For more information about setting up serverless endpoints, see the Serverless Inference documentation.

Amazon CLI

Once an inference recommendation is complete, you can use `describe-inference-recommendations-job` to get the job details and recommended instance types. Provide the job name that you used when you created the inference recommendation job.

```
aws sagemaker describe-inference-recommendations-job\
    --job-name <job-name>\
    --region <aws-region>
```

The JSON response similar should resemble the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing serverless inference recommendations, see the example after this one).

```
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Default',
    'JobArn': 'arn:aws:sagemaker:region:account-id:inference-recommendations-
job/resource-id',
```

```
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 20, 4, 57, 627000,
 tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 20, 25, 1, 997000,
 tzinfo=tzlocal()),
    'InputConfig': {
                'ModelPackageVersionArn': 'arn:aws:sagemaker:region:account-
id:model-package/resource-id',
                'JobDurationInSeconds': 0
                },
    'InferenceRecommendations': [{
            'Metrics': {
                'CostPerHour': 0.20399999618530273,
                'CostPerInference': 5.246913588052848e-06,
                'MaximumInvocations': 648,
                'ModelLatency': 263596
                },
            'EndpointConfiguration': {
                'EndpointName': 'endpoint-name',
                'VariantName': 'variant-name',
                'InstanceType': 'ml.c5.xlarge',
                'InitialInstanceCount': 1
                },
            'ModelConfiguration': {
                'Compiled': False,
                'EnvironmentParameters': []
                }
        },
        {
            'Metrics': {
                'CostPerHour': 0.11500000208616257,
                'CostPerInference': 2.92620870823157e-06,
                'MaximumInvocations': 655,
                'ModelLatency': 826019
                },
            'EndpointConfiguration': {
                'EndpointName': 'endpoint-name',
                'VariantName': 'variant-name',
                'InstanceType': 'ml.c5d.large',
                'InitialInstanceCount': 1
                },
            'ModelConfiguration': {
                'Compiled': False,
                'EnvironmentParameters': []
```

```
                }
            },
            {
                'Metrics': {
                    'CostPerHour': 0.11500000208616257,
                    'CostPerInference': 3.3625731248321244e-06,
                    'MaximumInvocations': 570,
                    'ModelLatency': 1085446
                    },
                'EndpointConfiguration': {
                    'EndpointName': 'endpoint-name',
                    'VariantName': 'variant-name',
                    'InstanceType': 'ml.m5.large',
                    'InitialInstanceCount': 1
                    },
                'ModelConfiguration': {
                    'Compiled': False,
                    'EnvironmentParameters': []
                    }
            }],
    'ResponseMetadata': {
        'RequestId': 'request-id',
        'HTTPStatusCode': 200,
        'HTTPHeaders': {
            'x-amzn-requestid': 'x-amzn-requestid',
            'content-type': 'content-type',
            'content-length': '1685',
            'date': 'Tue, 26 Oct 2021 20:31:10 GMT'
            },
        'RetryAttempts': 0
        }
}
```

The first few lines provide information about the inference recommendation job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed Amazon machine learning model) used during the recommendation job. You can use the endpoint and variant

name for monitoring in Amazon CloudWatch Events. See Amazon SageMaker AI metrics in Amazon CloudWatch for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) in US dollars for your real-time endpoint, the expected maximum number of `InvokeEndpoint` requests per minute sent to the endpoint (`MaxInvocations`), and the model latency (`ModelLatency`), which is the interval of time (in milliseconds) that your model took to respond to SageMaker AI. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

The following example shows the `InferenceRecommendations` part of the response for an inference recommendations job configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
      {
         "EndpointConfiguration": {
            "EndpointName": "value",
            "InitialInstanceCount": value,
            "InstanceType": "value",
            "VariantName": "value",
            "ServerlessConfig": {
                "MaxConcurrency": value,
                "MemorySizeInMb": value
            }
         },
         "InvocationEndTime": value,
         "InvocationStartTime": value,
         "Metrics": {
            "CostPerHour": value,
            "CostPerInference": value,
            "CpuUtilization": value,
            "MaxInvocations": value,
            "MemoryUtilization": value,
            "ModelLatency": value,
            "ModelSetupTime": value
         },
         "ModelConfiguration": {
            "Compiled": "False",
            "EnvironmentParameters": [],
            "InferenceSpecificationName": "value"
```

```
        },
        "RecommendationId": "value"
    }
]
```

You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the `ServerlessConfig`, which tells you the metrics returned for a serverless endpoint with the given `MemorySizeInMB` and when `MaxConcurrency = 1`. To increase the throughput possible on the endpoint, increase the value of `MaxConcurrency` linearly. For example, if the inference recommendation shows `MaxInvocations` as `1000`, then increasing `MaxConcurrency` to 2 would support 2000 `MaxInvocations`. Note that this is true only up to a certain point, which can vary based on your model and code. Serverless recommendations also measure the metric `ModelSetupTime`, which measures (in microseconds) the time it takes to launch computer resources on a serverless endpoint. For more information about setting up serverless endpoints, see the Serverless Inference documentation.

Amazon SageMaker Studio Classic

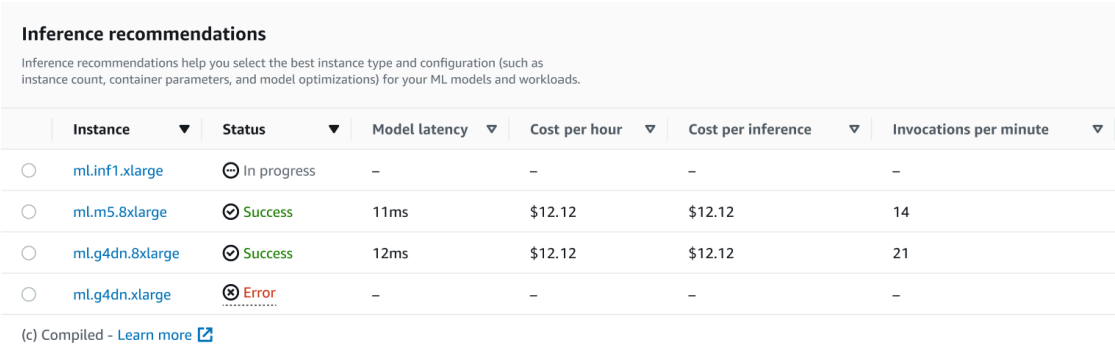
The inference recommendations populate in a new **Inference recommendations** tab within Studio Classic. It can take up to 45 minutes for the results to show up. This tab contains **Results** and **Details** column headings.

The **Details** column provides information about the inference recommendation job, such as the name of the inference recommendation, when the job was created (**Creation time**), and more. It also provides **Settings** information, such as the maximum number of invocations that occurred per minute and information about the Amazon Resource Names used.

The **Results** column provides a **Deployment goals** and **SageMaker AI recommendations** window in which you can adjust the order that the results are displayed based on deployment importance. There are three dropdown menus that you can use to provide the level of importance of the **Cost**, **Latency**, and **Throughput** for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: **Lowest Importance**, **Low Importance**, **Moderate importance**, **High importance**, or **Highest importance**.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the **SageMaker recommendation** field on the right of the panel, along with the estimated cost per hour and inference request. It also provides information about the expected model latency, maximum number of invocations, and the number of instances. For

serverless recommendations, you can see the ideal values for the maximum concurrency and endpoint memory size.



In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the **All runs** section.

SageMaker AI console

You can view your instance recommendation jobs in the SageMaker AI console by doing the following:

1. Go to the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, choose the name of your inference recommendation job.

On the details page for your job, you can view the **Inference recommendations**, which are the instance types SageMaker AI recommends for your model, as shown in the following screenshot.

In this section, you can compare the instance types by various factors such as **Model latency**, **Cost per hour**, **Cost per inference**, and **Invocations per minute**.

On this page, you can also view the configurations you specified for your job. In the **Monitor** section, you can view the Amazon CloudWatch metrics that were logged for each instance type. To learn more about interpreting these metrics, see Interpret results.

For more information about interpreting the results of your recommendation job, see Recommendation results.

Get an inference recommendation for an existing endpoint

Inference recommendation jobs run a set of load tests on recommended instance types and an existing endpoint. Inference recommendation jobs use performance metrics that are based on load tests using the sample data you provided during model version registration.

You can benchmark and get inference recommendations for an existing SageMaker AI Inference endpoint to help you improve the performance of your endpoint. The procedure of getting recommendations for an existing SageMaker AI Inference endpoint is similar to the procedure for getting inference recommendations without an endpoint. There are several feature exclusions to take note of when benchmarking an existing endpoint:

- You can only use one existing endpoint per Inference Recommender job.
- You can only have one variant on your endpoint.
- You can't use an endpoint that enables autoscaling.
- This functionality is only supported for Real-Time Inference.
- This functionality doesn't support Real-Time Multi-Model Endpoints.

> **Warning**
>
> We strongly recommend that you don't run an Inference Recommender job on a production endpoint that handles live traffic. The synthetic load during benchmarking can affect your production endpoint and cause throttling or provide inaccurate benchmark results. We recommend that you use a non-production or developer endpoint for comparison purposes.

The following sections demonstrate how to use Amazon SageMaker Inference Recommender to create an inference recommendation for an existing endpoint based on your model type using the Amazon SDK for Python (Boto3) and the Amazon CLI.

> **Note**
>
> Before you create an Inference Recommender recommendation job, make sure you have satisfied the Prerequisites for using Amazon SageMaker Inference Recommender.

Prerequisites

If you don't already have a SageMaker AI Inference endpoint, you can either get an inference recommendation without an endpoint, or you can create a Real-Time Inference endpoint by following the instructions in Create your endpoint and deploy your model.

Create an inference recommendation job for an existing endpoint

Create an inference recommendation programmatically using Amazon SDK for Python (Boto3), or the Amazon CLI. Specify a job name for your inference recommendation, the name of an existing SageMaker AI Inference endpoint, an Amazon IAM role ARN, an input configuration, and your model package ARN from when you registered your model with the model registry.

Amazon SDK for Python (Boto3)

Use the `CreateInferenceRecommendationsJob` API to get an inference recommendation. Set the `JobType` field to `'Default'` for inference recommendation jobs. In addition, provide the following:

- Provide a name for your Inference Recommender recommendation job for the `JobName` field. The Inference Recommender job name must be unique within the Amazon Region and within your Amazon account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.
- The ARN of the versioned model package you created when you registered your model with the model registry. Define this for `ModelPackageVersionArn` in the `InputConfig` field.
- Provide the name of an existing SageMaker AI Inference endpoint that you want to benchmark in Inference Recommender for `Endpoints` in the `InputConfig` field.

Import the Amazon SDK for Python (Boto3) package and create a SageMaker AI client object using the client class. If you followed the steps in the **Prerequisites** section, the model package group ARN was stored in a variable named `model_package_arn`.

```
# Create a low-level SageMaker service client.
import boto3
aws_region = '<region>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)
```

```
# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn = '<model-package-arn>'

# Provide a unique job name for SageMaker Inference Recommender job
job_name = '<job-name>'

# Inference Recommender job type. Set to Default to get an initial recommendation
job_type = 'Default'

# Provide an IAM Role that gives SageMaker Inference Recommender permission to
# access AWS services
role_arn = '<arn:aws:iam::<account>:role/*>'

# Provide endpoint name for your endpoint that want to benchmark in Inference
 Recommender
endpoint_name = '<existing-endpoint-name>'

sagemaker_client.create_inference_recommendations_job(
    JobName = job_name,
    JobType = job_type,
    RoleArn = role_arn,
    InputConfig = {
        'ModelPackageVersionArn': model_package_arn,
        'Endpoints': [{'EndpointName': endpoint_name}]
    }
)
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to `CreateInferenceRecommendationsJob`.

Amazon CLI

Use the `create-inference-recommendations-job` API to get an instance endpoint recommendation. Set the `job-type` field to `'Default'` for instance endpoint recommendation jobs. In addition, provide the following:

- Provide a name for your Inference Recommender recommendation job for the `job-name` field. The Inference Recommender job name must be unique within the Amazon Region and within your Amazon account.
- The Amazon Resource Name (ARN) of an IAM role that enables Amazon SageMaker Inference Recommender to perform tasks on your behalf. Define this for the `role-arn` field.

- The ARN of the versioned model package you created when you registered your model with Model Registry. Define this for `ModelPackageVersionArn` in the `input-config` field.
- Provide the name of an existing SageMaker AI Inference endpoint that you want to benchmark in Inference Recommender for `Endpoints` in the `input-config` field.

```
aws sagemaker create-inference-recommendations-job
    --region <region>\
    --job-name <job_name>\
    --job-type Default\
    --role-arn arn:aws:iam::<account:role/*>\
    --input-config "{
        \"ModelPackageVersionArn\": \"arn:aws:sagemaker:<region:account:role/*>\",
        \"Endpoints\": [{\"EndpointName\": <endpoint_name>}]
        }"
```

Get your inference recommendation job results

You can collect the results of your inference recommendation job programmatically with the same procedure for standard inference recommendation jobs. For more information, see Get your inference recommendation job results.

When you get inference recommendation job results for an existing endpoint, you should receive a JSON response similar to the following:

```
{
    "JobName": "job-name",
    "JobType": "Default",
    "JobArn": "arn:aws:sagemaker:region:account-id:inference-recommendations-
job/resource-id",
    "RoleArn": "iam-role-arn",
    "Status": "COMPLETED",
    "CreationTime": 1664922919.2,
    "LastModifiedTime": 1664924208.291,
    "InputConfig": {
        "ModelPackageVersionArn": "arn:aws:sagemaker:region:account-id:model-
package/resource-id",
        "Endpoints": [
            {
                "EndpointName": "endpoint-name"
            }
```

```
        ]
    },
    "InferenceRecommendations": [
        {
            "Metrics": {
                "CostPerHour": 0.7360000014305115,
                "CostPerInference": 7.456940238625975e-06,
                "MaxInvocations": 1645,
                "ModelLatency": 171
            },
            "EndpointConfiguration": {
                "EndpointName": "sm-endpoint-name",
                "VariantName": "variant-name",
                "InstanceType": "ml.g4dn.xlarge",
                "InitialInstanceCount": 1
            },
            "ModelConfiguration": {
                "EnvironmentParameters": [
                    {
                        "Key": "TS_DEFAULT_WORKERS_PER_MODEL",
                        "ValueType": "string",
                        "Value": "4"
                    }
                ]
            }
        }
    ],
    "EndpointPerformances": [
        {
            "Metrics": {
                "MaxInvocations": 184,
                "ModelLatency": 1312
            },
            "EndpointConfiguration": {
                "EndpointName": "endpoint-name"
            }
        }
    ]
}
```

The first few lines provide information about the inference recommendation job itself. This includes the job name, role ARN, and creation and latest modification times.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed Amazon machine learning model) that was used during the recommendation job.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) in US dollars for your real-time endpoint, the expected maximum number of `InvokeEndpoint` requests per minute sent to the endpoint (`MaxInvocations`), and the model latency (`ModelLatency`), which is the interval of time (in milliseconds) that your model took to respond to SageMaker AI. The model latency includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.

The `EndpointPerformances` nested dictionary contains the name of your existing endpoint on which the recommendation job was run (`EndpointName`) and the performance metrics for your endpoint (`MaxInvocations` and `ModelLatency`).

Stop your inference recommendation

You might want to stop a job that is currently running if you began a job by mistake or no longer need to run the job. Stop your Inference Recommender inference recommendation jobs programmatically with the `StopInferenceRecommendationsJob` API or with Studio Classic.

Amazon SDK for Python (Boto3)

Specify the name of the inference recommendation job for the `JobName` field:

```
sagemaker_client.stop_inference_recommendations_job(
                                    JobName='<INSERT>'
                                    )
```

Amazon CLI

Specify the job name of the inference recommendation job for the `job-name` flag:

```
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

Amazon SageMaker Studio Classic

Close the tab in which you initiated the inference recommendation to stop your Inference Recommender inference recommendation.

SageMaker AI console

To stop your instance recommendation job through the SageMaker AI console, do the following:

1. Go to the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, select your instance recommendation job.
4. Choose **Stop job**.
5. In the dialog box that pops up, choose **Confirm**.

After stopping your job, the job's **Status** should change to **Stopping**.

Compiled recommendations with Neo

In Inference Recommender, you can compile your model with Neo and get endpoint recommendations for your compiled model. SageMaker Neo is a service that can optimize your model for a target hardware platform (that is, a specific instance type or environment). Optimizing a model with Neo might improve the performance of your hosted model.

For Neo-supported frameworks and containers, Inference Recommender automatically suggests Neo-optimized recommendations. To be eligible for Neo compilation, your input must meet the following prerequisites:

- You are using a SageMaker AI owned DLC or XGBoost container.
- You are using a framework version supported by Neo. For the framework versions supported by Neo, see Cloud Instances in the SageMaker Neo documentation.
- Neo requires that you provide a correct input data shape for your model. You can specify this data shape as the `DataInputConfig` in the `InferenceSpecification` when you create a model package. For information about the correct data shapes for each framework, see Prepare Model for Compilation in the SageMaker Neo documentation.

The following example shows how to specify the `DataInputConfig` field in the `InferenceSpecification`, where `data_input_configuration` is a variable that contains the data shape in dictionary format (for example, `{'input':[1,1024,1024,3]}`).

```
"InferenceSpecification": {
        "Containers": [
            {
                "Image": dlc_uri,
                "Framework": framework.upper(),
                "FrameworkVersion": framework_version,
                "NearestModelName": model_name,
                "ModelInput": {"DataInputConfig": data_input_configuration},
            }
        ],
        "SupportedContentTypes": input_mime_types,  # required, must be non-null
        "SupportedResponseMIMETypes": [],
        "SupportedRealtimeInferenceInstanceTypes":
 supported_realtime_inference_types,  # optional
    }
```

If these conditions are met in your request, then Inference Recommender runs scenarios for both compiled and uncompiled versions of your model, giving you multiple recommendation combinations to choose from. You can compare the configurations for compiled and uncompiled versions of the same inference recommendation and determine which one best suits your use case. The recommendations are ranked by cost per inference.

To get the Neo compilation recommendations, you don't have to do any additional configuration besides making sure that your input meets the preceding requirements. Inference Recommender automatically runs Neo compilation on your model if your input meets the requirements, and you receive a response that includes Neo recommendations.

If you run into errors during your Neo compilation, see Troubleshoot Neo Compilation Errors.

The following table is an example of a response you might get from an Inference Recommender job that includes recommendations for compiled models. If the `InferenceSpecificationName` field is `None`, then the recommendation is an uncompiled model. The last row, in which the value for the **InferenceSpecificationName** field is `neo-00011122-2333-4445-5566-677788899900`, is for a model compiled with Neo. The value in the field is the name of the Neo job used to compile and optimize your model.

EndpointName	InstanceType	InitialInstanceCount	EnvironmentParameters	CostPerHour	CostPerInference	MaxInvocations	ModelLatency	InferenceSpecificationName
sm-epc-example-00111222	ml.c5.9xlarge	1	[]	1.836	9.15E-07	33456	7	None
sm-epc-example-11222333	ml.c5.2xlarge	1	[]	0.408	2.11E-07	32211	21	None
sm-epc-example-22333444	ml.c5.xlarge	1	[]	0.204	1.86E-07	18276	92	None
sm-epc-example-33444555	ml.c5.xlarge	1	[]	0.204	1.60E-07	21286	42	neo-00011122-2333-4445-5566-677788899900

Get started

The general steps for creating an Inference Recommender job that includes Neo-optimized recommendations are as follows:

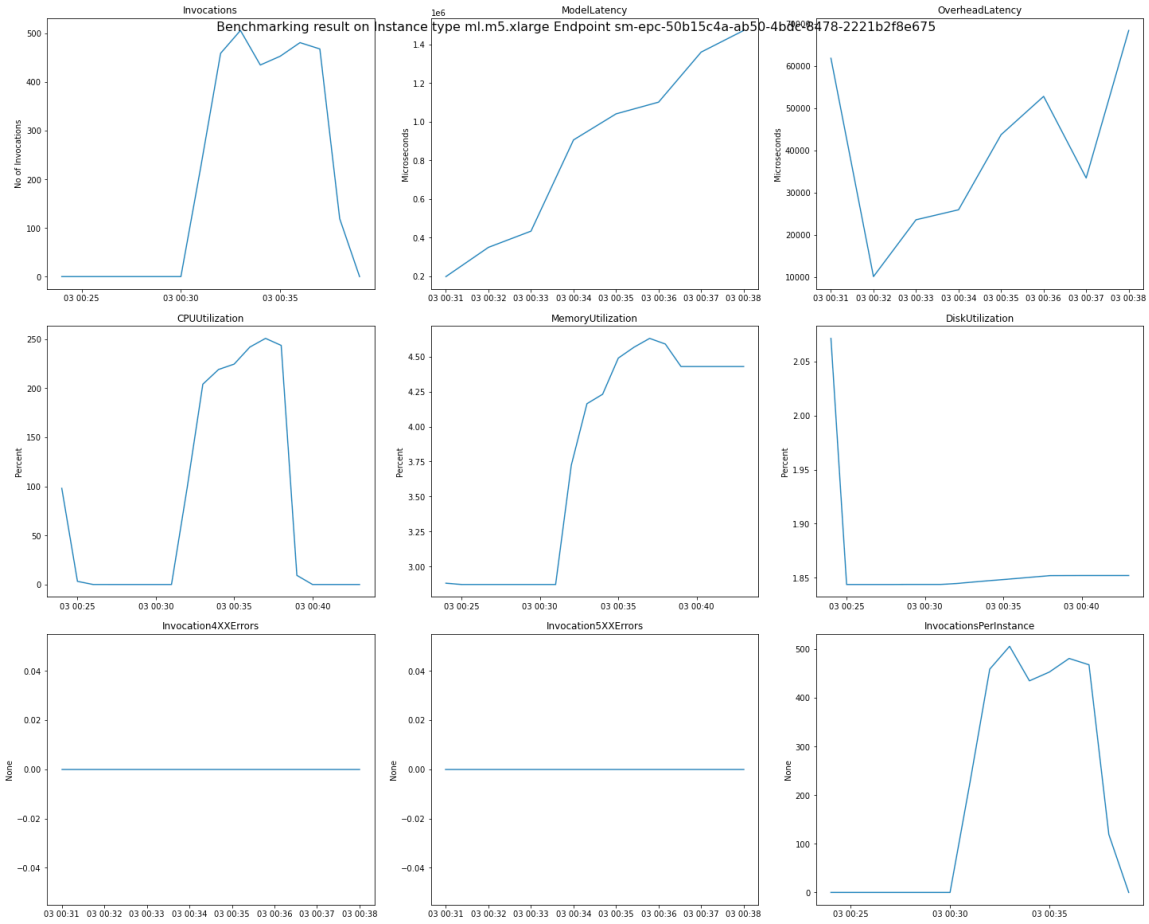
- Prepare your ML model for compilation. For more information, see Prepare Model for Compilation in the Neo documentation.
- Package your model in a model archive (`.tar.gz` file).
- Create a sample payload archive.
- Register your model in SageMaker Model Registry.
- Create an Inference Recommender job.

- View the results of the Inference Recommender job and choose a configuration.
- Debug compilation failures, if any. For more information, see Troubleshoot Neo Compilation Errors.

For an example that demonstrates the previous workflow and how to get Neo-optimized recommendations using XGBoost, see the following example notebook. For an example that show how to get Neo-optimized recommendations using TensorFlow, see the following example notebook.

Recommendation results

Each Inference Recommender job result includes `InstanceType`, `InitialInstanceCount`, and `EnvironmentParameters`, which are tuned environment variable parameters for your container to improve its latency and throughput. The results also include performance and cost metrics such as `MaxInvocations`, `ModelLatency`, `CostPerHour`, `CostPerInference`, `CpuUtilization`, and `MemoryUtilization`.



In the table below we provide a description of these metrics. These metrics can help you narrow down your search for the best endpoint configuration that suits your use case. For example, if your motivation is overall price performance with an emphasis on throughput, then you should focus on `CostPerInference`.

Metric	Description	Use case
`ModelLatency`	The interval of time taken by a model to respond as viewed from SageMaker AI. This interval includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container. Units: Milliseconds	Latency sensitive workloads such as ad serving and medical diagnosis

Metric	Description	Use case
`MaximumInvocations`	The maximum number of `InvokeEndpoint` requests sent to a model endpoint in a minute. Units: None	Throughput-focused workloads such as video processing or batch inference
`CostPerHour`	The estimated cost per hour for your real-time endpoint. Units: US Dollars	Cost sensitive workloads with no latency deadlines
`CostPerInference`	The estimated cost per inference call for your real-time endpoint. Units: US Dollars	Maximize overall price performance with a focus on throughput
`CpuUtilization`	The expected CPU utilizati on at maximum invocations per minute for the endpoint instance. Units: Percent	Understand instance health during benchmarking by having visibility into core CPU utilization of the instance
`MemoryUtilization`	The expected memory utilization at maximum invocations per minute for the endpoint instance. Units: Percent	Understand instance health during benchmarking by having visibility into core memory utilization of the instance

In some cases you might want to explore other SageMaker AI Endpoint Invocation metrics such as `CPUUtilization`. Every Inference Recommender job result includes the names of endpoints spun up during the load test. You can use CloudWatch to review the logs for these endpoints even after they've been deleted.

The following image is an example of CloudWatch metrics and charts you can review for a single endpoint from your recommendation result. This recommendation result is from a Default job. The way to interpret the scalar values from the recommendation results is that they are based on the time point when the Invocations graph first begins to level out. For example, the `ModelLatency` value reported is at the beginning of the plateau around `03:00:31`.

For full descriptions of the CloudWatch metrics used in the preceding charts, see SageMaker AI Endpoint Invocation metrics.

You can also see performance metrics like `ClientInvocations` and `NumberOfUsers` published by Inference Recommender in the `/aws/sagemaker/InferenceRecommendationsJobs` namespace. For a full list of metrics and descriptions published by Inference Recommender, see SageMaker Inference Recommender jobs metrics.

See the Amazon SageMaker Inference Recommender - CloudWatch Metrics Jupyter notebook in the amazon-sagemaker-examples Github repository for an example of how to use the Amazon SDK for Python (Boto3) to explore CloudWatch metrics for your endpoints.

Get autoscaling policy recommendations

With Amazon SageMaker Inference Recommender, you can get recommendations for autoscaling policies for your SageMaker AI endpoint based on your anticipated traffic pattern. If you've already completed an inference recommendation job, you can provide the details of the job to get a recommendation for an autoscaling policy that you can apply to your endpoint.

Inference Recommender benchmarks different values for each metric to determine the ideal autoscaling configuration for your endpoint. The autoscaling recommendation returns a recommended autoscaling policy for each metric that was defined in your inference recommendation job. You can save the policies and apply them to your endpoint with the PutScalingPolicy API.

To get started, review the following prerequisites.

Prerequisites

Before you begin, you must have completed a successful inference recommendation job. In the following section, you can provide either an inference recommendation ID or the name of a SageMaker AI endpoint that was benchmarked during an inference recommendation job.

To retrieve your recommendation job ID or endpoint name, you can either view the details of your inference recommendation job in the SageMaker AI console, or you can use the `RecommendationId` or `EndpointName` fields returned by the DescribeInferenceRecommendationsJob API.

Create an autoscaling configuration recommendation

To create an autoscaling recommendation policy, you can use the Amazon SDK for Python (Boto3).

The following example shows the fields for the GetScalingConfigurationRecommendation API. Use the following fields when you call the API:

- `InferenceRecommendationsJobName` – Enter the name of your inference recommendation job.
- `RecommendationId` – Enter the ID of an inference recommendation from a recommendation job. This is optional if you've specified the `EndpointName` field.
- `EndpointName` – Enter the name of an endpoint that was benchmarked during an inference recommendation job. This is optional if you've specified the `RecommendationId` field.

- `TargetCpuUtilizationPerCore` – (Optional) Enter a percentage value of how much utilization you want an instance on your endpoint to use before autoscaling. The default value if you don't specify this field is 50%.
- `ScalingPolicyObjective` – (Optional) An object where you specify your anticipated traffic pattern.
  - `MinInvocationsPerMinute` – (Optional) The minimum number of expected requests to your endpoint per minute.
  - `MaxInvocationsPerMinute` – (Optional) The maximum number of expected requests to your endpoint per minute.

```
{
    "InferenceRecommendationsJobName": "string", // Required
    "RecommendationId": "string", // Optional, provide one of RecommendationId or
 EndpointName
    "EndpointName": "string", // Optional, provide one of RecommendationId or
 EndpointName
    "TargetCpuUtilizationPerCore": number, // Optional
    "ScalingPolicyObjective": { // Optional
        "MinInvocationsPerMinute": number,
        "MaxInvocationsPerMinute": number
    }
}
```

After submitting your request, you'll receive a response with autoscaling policies defined for each metric. See the following section for information about interpreting the response.

Review your autoscaling configuration recommendation results

The following example shows the response from the GetScalingConfigurationRecommendation API:

```
{
    "InferenceRecommendationsJobName": "string",
    "RecommendationId": "string", // One of RecommendationId or EndpointName is shown
    "EndpointName": "string",
    "TargetUtilizationPercentage": Integer,
    "ScalingPolicyObjective": {
        "MinInvocationsPerMinute": Integer,
        "MaxInvocationsPerMinute": Integer
    },
```

```
    "Metric": {
        "ModelLatency": Integer,
        "InvocationsPerInstance": Integer
    },
    "DynamicScalingConfiguration": {
        "MinCapacity": number,
        "MaxCapacity": number,
        "ScaleInCooldown": number,
        "ScaleOutCooldown": number,
        "ScalingPolicies": [
            {
                "TargetTracking": {
                    "MetricSpecification": {
                        "Predefined" {
                            "PredefinedMetricType": "string"
                         },
                        "Customized": {
                            "MetricName": "string",
                            "Namespace": "string",
                            "Statistic": "string"
                         }
                    },
                    "TargetValue": Double
                }
            }
        ]
    }
}
```

The `InferenceRecommendationsJobName`, `RecommendationID` or `EndpointName`, `TargetCpuUtilizationPerCore`, and the `ScalingPolicyObjective` object fields are copied from your initial request.

The `Metric` object lists the metrics that were benchmarked in your inference recommendation job, along with a calculation of the values for each metric when the instance utilization would be the same as the `TargetCpuUtilizationPerCore` value. This is useful for anticipating the performance metrics on your endpoint when it scales in and out with the recommended autoscaling policy. For example, consider if your instance utilization was 50% in your inference recommendation job and your `InvocationsPerInstance` value was originally 4. If you specify the `TargetCpuUtilizationPerCore` value to be 100% in your autoscaling recommendation request, then the `InvocationsPerInstance` metric value returned in the response is 2 because you anticipated allocating twice as much instance utilization.

The `DynamicScalingConfiguration` object returns the values that you should specify for the TargetTrackingScalingPolicyConfiguration when you call the PutScalingPolicy API. This includes the recommended minimum and maximum capacity values, the recommended scale in and scale out cooldown times, and the `ScalingPolicies` object, which contains the recommended `TargetValue` you should specify for each metric.

Run a custom load test

Amazon SageMaker Inference Recommender load tests conduct extensive benchmarks based on production requirements for latency and throughput, custom traffic patterns, and either serverless endpoints or real-time instances (up to 10) that you select.

The following sections demonstrate how to create, describe, and stop a load test programmatically using the Amazon SDK for Python (Boto3) and the Amazon CLI, or interactively using Amazon SageMaker Studio Classic or the SageMaker AI console.

Create a load test job

Create a load test programmatically using the Amazon SDK for Python (Boto3), with the Amazon CLI, or interactively using Studio Classic or the SageMaker AI console. As with Inference Recommender inference recommendations, specify a job name for your load test, an Amazon IAM role ARN, an input configuration, and your model package ARN from when you registered your model with the model registry. Load tests require that you also specify a traffic pattern and stopping conditions.

Amazon SDK for Python (Boto3)

Use the `CreateInferenceRecommendationsJob` API to create an Inference Recommender load test. Specify `Advanced` for the `JobType` field and provide:

- A job name for your load test (`JobName`). The job name must be unique within your Amazon Region and within your Amazon account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `RoleArn` field.
- An endpoint configuration dictionary (`InputConfig`) where you specify the following:
  - For `TrafficPattern`, specify either the phases or stairs traffic pattern. With the phases traffic pattern, new users spawn every minute at the rate you specify. With the stairs traffic pattern, new users spawn at timed intervals (or *steps*) at a rate you specify. Choose one of the following:

- For `TrafficType`, specify PHASES. Then, for the `Phases` array, specify the `InitialNumberOfUsers` (how many concurrent users to start with, with a minimum of 1 and a maximum of 3), `SpawnRate` (the number of users to be spawned in a minute for a specific phase of load testing, with a minimum of 0 and maximum of 3), and `DurationInSeconds` (how long the traffic phase should be, with a minimum of 120 and maximum of 3600).
- For `TrafficType`, specify STAIRS. Then, for the `Stairs` array, specify the `DurationInSeconds` (how long the traffic phase should be, with a minimum of 120 and maximum of 3600), `NumberOfSteps` (how many intervals are used during the phase), and `UsersPerStep` (how many users are added during each interval). Note that the length of each step is the value of `DurationInSeconds / NumberOfSteps`. For example, if your `DurationInSeconds` is `600` and you specify 5 steps, then each step is 120 seconds long.

  > **Note**
  >
  > A user is defined as a system-generated actor that runs in a loop and invokes requests to an endpoint as part of Inference Recommender. For a typical XGBoost container running on an `ml.c5.large` instance, endpoints can reach 30,000 invocations per minute (500 tps) with just 15-20 users.

- For `ResourceLimit`, specify `MaxNumberOfTests` (the maximum number of benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10) and `MaxParallelOfTests` (the maximum number of parallel benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10).
- For `EndpointConfigurations`, you can specify one of the following:
  - The `InstanceType` field, where you specify the instance type on which you want to run your load tests.
  - The `ServerlessConfig`, in which you specify your ideal values for `MaxConcurrency` and `MemorySizeInMB` for a serverless endpoint. For more information, see the Serverless Inference documentation.
- A stopping conditions dictionary (`StoppingConditions`), where if any of the conditions are met, the Inference Recommender job stops. For this example, specify the following fields in the dictionary:

- For `MaxInvocations`, specify the maximum number of requests per minute expected for the endpoint, with a minimum of 1 and a maximum of 30,000.
- For `ModelLatencyThresholds`, specify `Percentile` (the model latency percentile threshold) and `ValueInMilliseconds` (the model latency percentile value in milliseconds).
- (Optional) For `FlatInvocations`, you can specify whether to continue the load test when the TPS (invocations per minute) rate flattens. A flattened TPS rate usually means that the endpoint has reached capacity. However, you might want to continue monitoring the endpoint under full capacity conditions. To continue the load test when this happens, specify this value as `Continue`. Otherwise, the default value is `Stop`.

```
# Create a low-level SageMaker service client.
import boto3
aws_region=<INSERT>
sagemaker_client=boto3.client('sagemaker', region=aws_region)

# Provide a name to your recommendation based on load testing
load_test_job_name="<INSERT>"

# Provide the name of the sagemaker instance type
instance_type="<INSERT>"

# Provide the IAM Role that gives SageMaker permission to access AWS services
role_arn='arn:aws:iam::<account>:role/*'

# Provide your model package ARN that was created when you registered your
# model with Model Registry
model_package_arn='arn:aws:sagemaker:<region>:<account>:role/*'

sagemaker_client.create_inference_recommendations_job(
                        JobName=load_test_job_name,
                        JobType="Advanced",
                        RoleArn=role_arn,
                        InputConfig={
                            'ModelPackageVersionArn': model_package_arn,
                            "JobDurationInSeconds": 7200,
                            'TrafficPattern' : {
                                # Replace PHASES with STAIRS to use the stairs
 traffic pattern
                                'TrafficType': 'PHASES',
```

```
                                'Phases': [
                                    {
                                        'InitialNumberOfUsers': 1,
                                        'SpawnRate': 1,
                                        'DurationInSeconds': 120
                                    },
                                    {
                                        'InitialNumberOfUsers': 1,
                                        'SpawnRate': 1,
                                        'DurationInSeconds': 120
                                    }
                                ]
                                # Uncomment this section and comment out the Phases
object above to use the stairs traffic pattern
                                # 'Stairs' : {
                                #   'DurationInSeconds': 240,
                                #   'NumberOfSteps': 2,
                                #   'UsersPerStep': 2
                                # }
                            },

                                        'MaxNumberOfTests': 10,
                                        'MaxParallelOfTests': 3
                                    },
                            "EndpointConfigurations" : [{
                                        'InstanceType': 'ml.c5.xlarge'
                                    },
                                    {
                                        'InstanceType': 'ml.m5.xlarge'
                                    },
                                    {
                                        'InstanceType': 'ml.r5.xlarge'
                                    }]
                                    # Uncomment the ServerlessConfig and comment out
the InstanceType field if you want recommendations for a serverless endpoint
                                    # "ServerlessConfig": {
                                    #     "MaxConcurrency": value,
                                    #     "MemorySizeInMB": value
                                    # }
                        },
                        StoppingConditions={
                            'MaxInvocations': 1000,
                            'ModelLatencyThresholds':[{
                                'Percentile': 'P95',
```

```
                                'ValueInMilliseconds': 100
                            }],
                            # Change 'Stop' to 'Continue' to let the load test
continue if invocations flatten
                            'FlatInvocations': 'Stop'
                        }
                )
```

See the Amazon SageMaker API Reference Guide for a full list of optional and required arguments you can pass to `CreateInferenceRecommendationsJob`.

Amazon CLI

Use the `create-inference-recommendations-job` API to create an Inference Recommender load test. Specify `Advanced` for the `JobType` field and provide:

- A job name for your load test (`job-name`). The job name must be unique within your Amazon Region and within your Amazon account.
- The Amazon Resource Name (ARN) of an IAM role that enables Inference Recommender to perform tasks on your behalf. Define this for the `role-arn` field.
- An endpoint configuration dictionary (`input-config`) where you specify the following:
  - For `TrafficPattern`, specify either the phases or stairs traffic pattern. With the phases traffic pattern, new users spawn every minute at the rate you specify. With the stairs traffic pattern, new users spawn at timed intervals (or *steps*) at a rate you specify. Choose one of the following:
    - For `TrafficType`, specify PHASES. Then, for the `Phases` array, specify the `InitialNumberOfUsers` (how many concurrent users to start with, with a minimum of 1 and a maximum of 3), `SpawnRate` (the number of users to be spawned in a minute for a specific phase of load testing, with a minimum of 0 and maximum of 3), and `DurationInSeconds` (how long the traffic phase should be, with a minimum of 120 and maximum of 3600).
    - For `TrafficType`, specify STAIRS. Then, for the `Stairs` array, specify the `DurationInSeconds` (how long the traffic phase should be, with a minimum of 120 and maximum of 3600), `NumberOfSteps` (how many intervals are used during the phase), and `UsersPerStep` (how many users are added during each interval). Note that the length of each step is the value of `DurationInSeconds / NumberOfSteps`. For example, if your `DurationInSeconds` is `600` and you specify 5 steps, then each step is 120 seconds long.

> **Note**
>
> A user is defined as a system-generated actor that runs in a loop and invokes requests to an endpoint as part of Inference Recommender. For a typical XGBoost container running on an `ml.c5.large` instance, endpoints can reach 30,000 invocations per minute (500 tps) with just 15-20 users.

- For `ResourceLimit`, specify `MaxNumberOfTests` (the maximum number of benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10) and `MaxParallelOfTests` (the maximum number of parallel benchmarking load tests for an Inference Recommender job, with a minimum of 1 and a maximum of 10).
- For `EndpointConfigurations`, you can specify one of the following:
  - The `InstanceType` field, where you specify the instance type on which you want to run your load tests.
  - The `ServerlessConfig`, in which you specify your ideal values for `MaxConcurrency` and `MemorySizeInMB` for a serverless endpoint.

- A stopping conditions dictionary (`stopping-conditions`), where if any of the conditions are met, the Inference Recommender job stops. For this example, specify the following fields in the dictionary:
  - For `MaxInvocations`, specify the maximum number of requests per minute expected for the endpoint, with a minimum of 1 and a maximum of 30,000.
  - For `ModelLatencyThresholds`, specify `Percentile` (the model latency percentile threshold) and `ValueInMilliseconds` (the model latency percentile value in milliseconds).
  - (Optional) For `FlatInvocations`, you can specify whether to continue the load test when the TPS (invocations per minute) rate flattens. A flattened TPS rate usually means that the endpoint has reached capacity. However, you might want to continue monitoring the endpoint under full capacity conditions. To continue the load test when this happens, specify this value as `Continue`. Otherwise, the default value is `Stop`.

```
aws sagemaker create-inference-recommendations-job\
    --region <region>\
    --job-name <job-name>\
```

```
    --job-type ADVANCED\
    --role-arn arn:aws:iam::<account>:role/*\
    --input-config \"{
        \"ModelPackageVersionArn\": \"arn:aws:sagemaker:<region>:<account>:role/*\",
        \"JobDurationInSeconds\": 7200,

                }
                # Use the ServerlessConfig and leave out the InstanceType fields if
you want recommendations for a serverless endpoint
                # \"ServerlessConfig\": {
                #     \"MaxConcurrency\": value,
                #     \"MemorySizeInMB\": value
                # }
            ]
```

```
        }\"
    --stopping-conditions \"{
        \"MaxInvocations\": 1000,
        \"ModelLatencyThresholds\":[
                {
                    \"Percentile\": \"P95\",
                    \"ValueInMilliseconds\": 100
                }
        ],
        # Change 'Stop' to 'Continue' to let the load test continue if invocations
flatten
        \"FlatInvocations\": \"Stop\"
    }\"
```

Amazon SageMaker Studio Classic

Create a load test with Studio Classic.

1. In your Studio Classic application, choose the home icon ().
2. In the left sidebar of Studio Classic, choose **Deployments**.
3. Choose **Inference recommender** from the dropdown list.
4. Choose **Create inference recommender job**. A new tab titled **Create inference recommender job** opens.
5. Select the name of your model group from the dropdown **Model group** field. The list includes all the model groups registered with the model registry in your account, including models registered outside of Studio Classic.
6. Select a model version from the dropdown **Model version** field.
7. Choose **Continue**.
8. Provide a name for the job in the **Name** field.
9. (Optional) Provide a description of your job in the **Description** field.
10. Choose an IAM role that grants Inference Recommender permission to access Amazon services. You can create a role and attach the `AmazonSageMakerFullAccess` IAM managed policy to accomplish this, or you can let Studio Classic create a role for you.
11. Choose **Stopping Conditions** to expand the available input fields. Provide a set of conditions for stopping a deployment recommendation.

a. Specify the maximum number of requests per minute expected for the endpoint in the **Max Invocations Per Minute** field.

b. Specify the model latency threshold in microseconds in the **Model Latency Threshold** field. The **Model Latency Threshold** depicts the interval of time taken by a model to respond as viewed from Inference Recommender. The interval includes the local communication time taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

12. Choose **Traffic Pattern** to expand the available input fields.

    a. Set the initial number of virtual users by specifying an integer in the **Initial Number of Users** field.

    b. Provide an integer number for the **Spawn Rate** field. The spawn rate sets the number of users created per second.

    c. Set the duration for the phase in seconds by specifying an integer in the **Duration** field.

    d. (Optional) Add additional traffic patterns. To do so, choose **Add**.

13. Choose the **Additional** setting to reveal the **Max test duration** field. Specify, in seconds, the maximum time a test can take during a job. New jobs are not scheduled after the defined duration. This helps ensure jobs that are in progress are not stopped and that you only view completed jobs.

14. Choose **Continue**.

15. Choose **Selected Instances**.

16. In the **Instances for benchmarking** field, choose **Add instances to test**. Select up to 10 instances for Inference Recommender to use for load testing.

17. Choose **Additional settings**.

    a. Provide an integer that sets an upper limit on the number of tests a job can make for the **Max number of tests field**. Note that each endpoint configuration results in a new load test.

    b. Provide an integer for the **Max parallel** test field. This setting defines an upper limit on the number of load tests that can run in parallel.

18. Choose **Submit**.

    The load test can take up to 2 hours.

> **Warning**
>
> Do not close this tab. If you close this tab, you cancel the Inference Recommender load test job.

SageMaker AI console

Create a custom load test through the SageMaker AI console by doing the following:

1. Go to the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, choose **Create job**.
4. For **Step 1: Model configuration**, do the following:
    a. For **Job type**, choose **Advanced recommender job**.
    b. If you're using a model registered in the SageMaker AI model registry, then turn on the **Choose a model from the model registry** toggle and do the following:
        i. For the **Model group** dropdown list, choose the model group in SageMaker AI model registry where your model is.
        ii. For the **Model version** dropdown list, choose the desired version of your model.
    c. If you're using a model that you've created in SageMaker AI, then turn off the **Choose a model from the model registry** toggle and do the following:
        - For the **Model name** field, enter the name of your SageMaker AI model.
    d. For **IAM role**, you can select an existing Amazon IAM role that has the necessary permissions to create an instance recommendation job. Alternatively, if you don't have an existing role, you can choose **Create a new role** to open the role creation pop-up, and SageMaker AI adds the necessary permissions to the new role that you create.
    e. For **S3 bucket for benchmarking payload**, enter the Amazon S3 path to your sample payload archive, which should contain sample payload files that Inference Recommender uses to benchmark your model on different instance types.
    f. For **Payload content type**, enter the MIME types of your sample payload data.
    g. For **Traffic pattern**, configure phases for the load test by doing the following:

i. For **Initial number of users**, specify how many concurrent users you want to start with (with a minimum of 1 and a maximum of 3).

ii. For **Spawn rate**, specify the number of users to be spawned in a minute for the phase (with a minimum of 0 and a maximum of 3).

iii. For **Duration (seconds)**, specify how low the traffic phase should be in seconds (with a minimum of 120 and a maximum of 3600).

h. (Optional) If you turned off the **Choose a model from the model registry toggle** and specified a SageMaker AI model, then for **Container configuration**, do the following:

i. For the **Domain** dropdown list, select the machine learning domain of the model, such as computer vision, natural language processing, or machine learning.

ii. For the **Framework** dropdown list, select the framework of your container, such as TensorFlow or XGBoost.

iii. For **Framework version**, enter the framework version of your container image.

iv. For the **Nearest model name** dropdown list, select the pre-trained model that mostly closely matches your own.

v. For the **Task** dropdown list, select the machine learning task that the model accomplishes, such as image classification or regression.

i. (Optional) For **Model compilation using SageMaker Neo**, you can configure the recommendation job for a model that you've compiled using SageMaker Neo. For **Data input configuration**, enter the correct input data shape for your model in a format similar to `{'input':[1,1024,1024,3]}`.

j. Choose **Next**.

5. For **Step 2: Instances and environment parameters**, do the following:

a. For **Select instances for benchmarking**, select up to 8 instance types that you want to benchmark against.

b. (Optional) For **Environment parameter ranges**, you can specify environment parameters that help optimize your model. Specify the parameters as **Key** and **Value** pairs.

c. Choose **Next**.

6. For **Step 3: Job parameters**, do the following:

a. (Optional) For the **Job name** field, enter a name for your instance recommendation job. When you create the job, SageMaker AI appends a timestamp to the end of this name.

b. (Optional) For the **Job description** field, enter a description for the job.

c. (Optional) For the **Encryption key** dropdown list, choose an Amazon KMS key by name or enter its ARN to encrypt your data.

d. (Optional) For **Max number of tests**, enter the number of test that you want to run during the recommendation job.

e. (Optional) For **Max parallel tests**, enter the maximum number of parallel tests that you want to run during the recommendation job.

f. For **Max test duration (s)**, enter the maximum number of seconds you want each test to run for.

g. For **Max invocations per minute**, enter the maximum number of requests per minute the endpoint can reach before stopping the recommendation job. After reaching this limit, SageMaker AI ends the job.

h. For **P99 Model latency threshold (ms)**, enter the model latency percentile in milliseconds.

i. Choose **Next**.

7. For **Step 4: Review job**, review your configurations and then choose **Submit**.

Get your load test results

You can programmatically collect metrics across all load tests once the load tests are done with Amazon SDK for Python (Boto3), the Amazon CLI, Studio Classic, or the SageMaker AI console.

Amazon SDK for Python (Boto3)

Collect metrics with the `DescribeInferenceRecommendationsJob` API. Specify the job name of the load test for the `JobName` field:

```
load_test_response = sagemaker_client.describe_inference_recommendations_job(
                                                        JobName=load_test_job_name
                                                        )
```

Print the response object.

```
load_test_response['Status']
```

This returns a JSON response similar to the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing serverless inference recommendations, see the example after this one).

```
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Advanced',
    'JobArn': 'arn:aws:sagemaker:region:account-id:inference-recommendations-

            'content-length': '1199',
            'date': 'Tue, 26 Oct 2021 19:57:42 GMT'
            },
        'RetryAttempts': 0}
    }
```

The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed Amazon machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Amazon SageMaker AI metrics in Amazon CloudWatch for more information.

The `EndpointConfiguration` nested dictionary also contains the instance count (`InitialInstanceCount`) recommendation. This is the number of instances that you should provision in the endpoint to meet the `MaxInvocations` specified in the `StoppingConditions`. For example, if the `InstanceType` is `ml.m5.large` and the

`InitialInstanceCount` is 2, then you should provision 2 `ml.m5.large` instances for your endpoint so that it can handle the TPS specified in the `MaxInvocations` stopping condition.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) for your real-time endpoint, the maximum number of `InvokeEndpoint` requests sent to the endpoint, and the model latency (`ModelLatency`), which is the interval of time (in microseconds) that your model took to respond to SageMaker AI. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

The following example shows the `InferenceRecommendations` part of the response for a load test job that was configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
      {
         "EndpointConfiguration": {
            "EndpointName": "value",
            "InitialInstanceCount": value,
            "InstanceType": "value",
            "VariantName": "value",
            "ServerlessConfig": {
                "MaxConcurrency": value,
                "MemorySizeInMb": value
            }
         },
         "InvocationEndTime": value,
         "InvocationStartTime": value,
         "Metrics": {
            "CostPerHour": value,
            "CostPerInference": value,
            "CpuUtilization": value,
            "MaxInvocations": value,
            "MemoryUtilization": value,
            "ModelLatency": value,
            "ModelSetupTime": value
         },
         "ModelConfiguration": {
            "Compiled": "False",
            "EnvironmentParameters": [],
            "InferenceSpecificationName": "value"
         },
```

```
        "RecommendationId": "value"
      }
   ]
```

You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the `ServerlessConfig`, which tells you the values you specified for `MaxConcurrency` and `MemorySizeInMB` when setting up the load test. Serverless recommendations also measure the metric `ModelSetupTime`, which measures (in microseconds) the time it takes to launch compute resources on a serverless endpoint. For more information about setting up serverless endpoints, see the Serverless Inference documentation.

Amazon CLI

Collect metrics with the `describe-inference-recommendations-job` API. Specify the job name of the load test for the `job-name` flag:

```
aws sagemaker describe-inference-recommendations-job --job-name <job-name>
```

This returns a response similar to the following example. Note that this example shows the recommended instance types for real-time inference (for an example showing Serverless Inference recommendations, see the example after this one).

```
{
    'JobName': 'job-name',
    'JobDescription': 'job-description',
    'JobType': 'Advanced',
    'JobArn': 'arn:aws:sagemaker:region:account-id:inference-recommendations-
job/resource-id',
    'Status': 'COMPLETED',
    'CreationTime': datetime.datetime(2021, 10, 26, 19, 38, 30, 957000,
 tzinfo=tzlocal()),
    'LastModifiedTime': datetime.datetime(2021, 10, 26, 19, 46, 31, 399000,
 tzinfo=tzlocal()),
    'InputConfig': {
        'ModelPackageVersionArn': 'arn:aws:sagemaker:region:account-id:model-
package/resource-id',
        'JobDurationInSeconds': 7200,
        'TrafficPattern': {
            'TrafficType': 'PHASES'
            },
        'ResourceLimit': {
            'MaxNumberOfTests': 100,
```

```
            'MaxParallelOfTests': 100
            },
        'EndpointConfigurations': [{
            'InstanceType': 'ml.c5d.xlarge'
            }]
        },
    'StoppingConditions': {
        'MaxInvocations': 1000,
        'ModelLatencyThresholds': [{
            'Percentile': 'P95',
            'ValueInMilliseconds': 100
            }]
        },
    'InferenceRecommendations': [{
        'Metrics': {
        'CostPerHour': 0.6899999976158142,
        'CostPerInference': 1.0332434612791985e-05,
        'MaximumInvocations': 1113,
        'ModelLatency': 100000
        },
        'EndpointConfiguration': {
            'EndpointName': 'endpoint-name',
            'VariantName': 'variant-name',
            'InstanceType': 'ml.c5d.xlarge',
            'InitialInstanceCount': 3
            },
        'ModelConfiguration': {
            'Compiled': False,
            'EnvironmentParameters': []
            }
        }],
    'ResponseMetadata': {
        'RequestId': 'request-id',
        'HTTPStatusCode': 200,
        'HTTPHeaders': {
            'x-amzn-requestid': 'x-amzn-requestid',
            'content-type': 'content-type',
            'content-length': '1199',
            'date': 'Tue, 26 Oct 2021 19:57:42 GMT'
            },
        'RetryAttempts': 0
        }
    }
```

The first few lines provide information about the load test job itself. This includes the job name, role ARN, creation, and deletion time.

The `InferenceRecommendations` dictionary contains a list of Inference Recommender inference recommendations.

The `EndpointConfiguration` nested dictionary contains the instance type (`InstanceType`) recommendation along with the endpoint and variant name (a deployed Amazon machine learning model) used during the recommendation job. You can use the endpoint and variant name for monitoring in Amazon CloudWatch Events. See Amazon SageMaker AI metrics in Amazon CloudWatch for more information.

The `Metrics` nested dictionary contains information about the estimated cost per hour (`CostPerHour`) for your real-time endpoint in US dollars, the estimated cost per inference (`CostPerInference`) for your real-time endpoint, the maximum number of `InvokeEndpoint` requests sent to the endpoint, and the model latency (`ModelLatency`), which is the interval of time (in microseconds) that your model took to respond to SageMaker AI. The model latency includes the local communication times taken to send the request and to fetch the response from the model container and the time taken to complete the inference in the container.

The following example shows the `InferenceRecommendations` part of the response for a load test job that was configured to return serverless inference recommendations:

```
"InferenceRecommendations": [
      {
         "EndpointConfiguration": {
            "EndpointName": "value",
            "InitialInstanceCount": value,
            "InstanceType": "value",
            "VariantName": "value",
            "ServerlessConfig": {
                "MaxConcurrency": value,
                "MemorySizeInMb": value
            }
         },
         "InvocationEndTime": value,
         "InvocationStartTime": value,
         "Metrics": {
            "CostPerHour": value,
            "CostPerInference": value,
            "CpuUtilization": value,
            "MaxInvocations": value,
```

```
            "MemoryUtilization": value,
            "ModelLatency": value,
            "ModelSetupTime": value
         },
         "ModelConfiguration": {
            "Compiled": "False",
            "EnvironmentParameters": [],
            "InferenceSpecificationName": "value"
         },
         "RecommendationId": "value"
      }
   ]
```

You can interpret the recommendations for serverless inference similarly to the results for real-time inference, with the exception of the `ServerlessConfig`, which tells you the values you specified for `MaxConcurrency` and `MemorySizeInMB` when setting up the load test. Serverless recommendations also measure the metric `ModelSetupTime`, which measures (in microseconds) the time it takes to launch computer resources on a serverless endpoint. For more information about setting up serverless endpoints, see the Serverless Inference documentation.

Amazon SageMaker Studio Classic

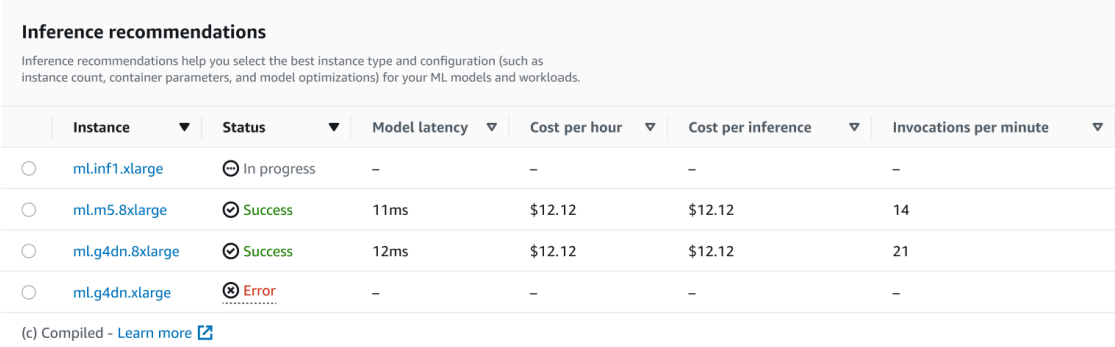
The recommendations populate in a new tab called **Inference recommendations** within Studio Classic. It can take up to 2 hours for the results to show up. This tab contains **Results** and **Details** columns.

The **Details** column provides information about the load test job, such as the name given to the load test job, when the job was created (**Creation time**), and more. It also contains **Settings** information, such as the maximum number of invocation that occurred per minute and information about the Amazon Resource Names used.

The **Results** column provides **Deployment goals** and **SageMaker AI recommendations** windows in which you can adjust the order in which results are displayed based on deployment importance. There are three dropdown menus in which you can provide the level of importance of the **Cost**, **Latency**, and **Throughput** for your use case. For each goal (cost, latency, and throughput), you can set the level of importance: **Lowest Importance**, **Low Importance**, **Moderate importance**, **High importance**, or **Highest importance**.

Based on your selections of importance for each goal, Inference Recommender displays its top recommendation in the **SageMaker recommendation** field on the right of the panel, along

with the estimated cost per hour and inference request. It also provides Information about the expected model latency, maximum number of invocations, and the number of instances.



In addition to the top recommendation displayed, you can also see the same information displayed for all instances that Inference Recommender tested in the **All runs** section.

SageMaker AI console

You can view your custom load test job results in the SageMaker AI console by doing the following:

1. Go to the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, choose the name of your inference recommendation job.

On the details page for your job, you can view the **Inference recommendations**, which are the instance types SageMaker AI recommends for your model, as shown in the following screenshot.

In this section, you can compare the instance types by various factors such as **Model latency**, **Cost per hour**, **Cost per inference**, and **Invocations per minute**.

On this page, you can also view the configurations you specified for your job. In the **Monitor** section, you can view the Amazon CloudWatch metrics that were logged for each instance type. To learn more about interpreting these metrics, see Interpret results.

Stop your load test

You might want to stop a job that is currently running if you began a job by mistake or no longer need to run the job. Stop your load test jobs programmatically with the

`StopInferenceRecommendationsJob` API, or through Studio Classic or the SageMaker AI console.

Amazon SDK for Python (Boto3)

Specify the job name of the load test for the `JobName` field:

```
sagemaker_client.stop_inference_recommendations_job(
                                    JobName='<INSERT>'
                                    )
```

Amazon CLI

Specify the job name of the load test for the `job-name` flag:

```
aws sagemaker stop-inference-recommendations-job --job-name <job-name>
```

Amazon SageMaker Studio Classic

Close the tab where you initiated your custom load job to stop your Inference Recommender load test.

SageMaker AI console

To stop your load test job through the SageMaker AI console, do the following:

1. Go to the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the left navigation pane, choose **Inference**, and then choose **Inference recommender**.
3. On the **Inference recommender jobs** page, select your load test job.
4. Choose **Stop job**.
5. In the dialog box that pops up, choose **Confirm**.

After stopping your job, the job's **Status** should change to **Stopping**.

Troubleshoot Inference Recommender errors

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors.

How to troubleshoot

You can attempt to resolve your error by going through the following steps:

- Check if you've covered all the prerequisites to use Inference Recommender. See the Inference Recommender Prerequisites.
- Check that you are able to deploy your model from Model Registry to an endpoint and that it can process your payloads without errors. See Deploy a Model from the Registry.
- When you kick off an Inference Recommender job, you should see endpoints being created in the console and you can review the CloudWatch logs.

Common errors

Review the following table for common Inference Recommender errors and their solutions.

Error	Solution
Specify `Domain` in the Model Package version 1. `Domain` is a mandatory parameter for the job.	Make sure you provide the ML domain or `OTHER` if unknown.
Provided role ARN cannot be assumed and an `AWSSecurityTokenServiceException` error occurred.	Make sure the execution role provided has the necessary permissions specified in the prerequisites.
Specify `Framework` in the Model Package version 1.`Framework` is a mandatory parameter for the job.	Make sure you provide the ML Framework or `OTHER` if unknown.
Users at the end of prev phase is 0 while initial users of current phase is 1.	Users here refers to virtual users or threads used to send requests. Each phase starts with A users and ends with B users such that B > A. Between sequential phases, x_1 and x_2, we require that abs(x_2.A - x_1.B) <= 3 and >= 0.
Total Traffic duration (across) should not be more than Job duration.	The total duration of all your Phases cannot exceed the Job duration.

Error	Solution
Burstable instance type ml.t2.medium is not allowed.	Inference Recommender doesn't support load testing on t2 instance family because burstable instances do not provide consistent performance.
ResourceLimitExceeded when calling CreateEndpoint operation	You have exceeded a SageMaker AI resource limit. For example, Inference Recommender might be unable to provision endpoints for benchmarking if the account has reached the endpoint quota. For more information about SageMaker AI limits and quotas, see Amazon SageMaker AI endpoints and quotas.
ModelError when calling InvokeEndpoint operation	A model error can happen for the following reasons: • The invocation timed out while waiting for a response from the model container. • The model couldn't process the input payload.
PayloadError when calling InvokeEndpoint operation	A payload error can happen for following reasons: • The payload source isn't in the Amazon S3 bucket. • The payload is in a non-file object format. • The payload is in an invalid file type. For example, a model expects an image type payload but is passed a text file. • The payload is empty.

Check CloudWatch

When you kick off an Inference Recommender job, you should see endpoints being created in the console. Select one of the endpoints and view the CloudWatch logs to monitor for any 4xx/5xx errors. If you have a successful Inference Recommender job, you will be able to see the endpoint names as part of the results. Even if your Inference Recommender job is unsuccessful, you can still check the CloudWatch logs for the deleted endpoints by following the steps below:

1. Open the Amazon CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Select the Region in which you created the Inference Recommender job from the **Region** dropdown list in the top right.
3. In the navigation pane of CloudWatch, choose **Logs**, and then select **Log groups**.
4. Search for the log group called `/aws/sagemaker/Endpoints/sm-epc-*`. Select the log group based on your most recent Inference Recommender job.

You can also troubleshoot your job by checking the Inference Recommender CloudWatch logs. The Inference Recommender logs, which are published in the `/aws/sagemaker/InferenceRecommendationsJobs` CloudWatch log group, give a high level view on the progress of the job in the *<jobName>*`/execution` log stream. You can find detailed information on each of the endpoint configurations being tested in the *<jobName>*`/Endpoint/`*<endpointName>* log stream.

Overview of the Inference Recommender log streams

- *<jobName>*`/execution` contains overall job information such as endpoint configurations scheduled for benchmarking, compilation job skip reason, and validation failure reason.
- *<jobName>*`/Endpoint/`*<endpointName>* contains information such as resource creation progress, test configuration, load test stop reason, and resource cleanup status.
- *<jobName>*`/CompilationJob/`*<compilationJobName>* contains information on compilation jobs created by Inference Recommender, such as the compilation job configuration and compilation job status.

Create an alarm for Inference Recommender error messages

Inference Recommender outputs log statements for errors that might be helpful while troubleshooting. With a CloudWatch log group and a metric filter, you can look for terms and

patterns in this log data as the data is sent to CloudWatch. Then, you can create a CloudWatch alarm based on the log group-metric filter. For more information, see Create a CloudWatch alarm based on a log group-metric filter.

Check benchmarks

When you kick off an Inference Recommender job, Inference Recommender creates several benchmarks to evaluate the performance of your model on different instance types. You can use the ListInferenceRecommendationsJobSteps API to view the details for all the benchmarks. If you have a failed benchmark, you can see the failure reasons as part of the results.

To use the ListInferenceRecommendationsJobSteps API, provide the following values:

- For `JobName`, provide the name of the Inference Recommender job.
- For `StepType`, use `BENCHMARK` to return details about the job's benchmarks.
- For `Status`, use `FAILED` to return details about only the failed benchmarks. For a list of the other status types, see the `Status` field in the ListInferenceRecommendationsJobSteps API.

```
# Create a low-level SageMaker service client.
import boto3
aws_region = '<region>'
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Provide the job name for the SageMaker Inference Recommender job
job_name = '<job-name>'

# Filter for benchmarks
step_type = 'BENCHMARK'

# Filter for benchmarks that have a FAILED status
status = 'FAILED'

response = sagemaker_client.list_inference_recommendations_job_steps(
    JobName = job_name,
    StepType = step_type,
    Status = status
)
```

You can print the response object to view the results. The preceding code example stored the response in a variable called `response`:

```
print(response)
```

Real-time inference

Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. You can deploy your model to SageMaker AI hosting services and get an endpoint that can be used for inference. These endpoints are fully managed and support autoscaling (see Automatic scaling of Amazon SageMaker AI models). You can monitor individual instances and containers on your endpoints with enhanced metrics (see Amazon SageMaker AI enhanced metrics for inference endpoints).

Topics

- Deploy models for real-time inference
- Invoke models for real-time inference
- Invoke endpoints with OpenAI-compatible APIs
- Endpoints
- Hosting options
- Automatic scaling of Amazon SageMaker AI models
- Instance storage volumes
- Validation of models in production
- Online explainability with SageMaker Clarify
- Deploy to multiple instance types with instance pools
- Fine-tune models with adapter inference components
- Using GPU partitions on SageMaker AI real-time endpoints

Deploy models for real-time inference

Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio

and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.
Amazon managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

There are several options to deploy a model using SageMaker AI hosting services. You can interactively deploy a model with SageMaker Studio. Or, you can programmatically deploy a model using an Amazon SDK, such as the SageMaker Python SDK or the SDK for Python (Boto3). You can also deploy by using the Amazon CLI.

Before you begin

Before you deploy a SageMaker AI model, locate and make note of the following:

- The Amazon Web Services Region where your Amazon S3 bucket is located
- The Amazon S3 URI path where the model artifacts are stored
- The IAM role for SageMaker AI
- The Docker Amazon ECR URI registry path for the custom image that contains the inference code, or the framework and version of a built-in Docker image that is supported and by Amazon

For a list of Amazon Web Services services available in each Amazon Web Services Region, see Region Maps and Edge Networks. See Creating IAM roles for information on how to create an IAM role.

Important

The Amazon S3 bucket where the model artifacts are stored must be in the same Amazon Web Services Region as the model that you are creating.

Shared resource utilization with multiple models

You can deploy one or more models to an endpoint with Amazon SageMaker AI. When multiple models share an endpoint, they jointly utilize the resources that are hosted there, such as the ML

compute instances, CPUs, and accelerators. The most flexible way to deploy multiple models to an endpoint is to define each model as an *inference component*.

Inference components

An inference component is a SageMaker AI hosting object that you can use to deploy a model to an endpoint. In the inference component settings, you specify the model, the endpoint, and how the model utilizes the resources that the endpoint hosts. To specify the model, you can specify a SageMaker AI Model object, or you can directly specify the model artifacts and image.

In the settings, you can optimize resource utilization by tailoring how the required CPU cores, accelerators, and memory are allocated to the model. You can deploy multiple inference components to an endpoint, where each inference component contains one model and the resource utilization needs for that model.

After you deploy an inference component, you can directly invoke the associated model when you use the InvokeEndpoint action in the SageMaker API.

Inference components provide the following benefits:

Flexibility

The inference component decouples the details of hosting the model from the endpoint itself. This provides more flexibility and control over how models are hosted and served with an endpoint. You can host multiple models on the same infrastructure, and you can add or remove models from an endpoint as needed. You can update each model independently.

Scalability

You can specify how many copies of each model to host, and you can set a minimum number of copies to ensure that the model loads in the quantity that you require to serve requests. You can scale any inference component copy down to zero, which makes room for another copy to scale up.

To run several inference components on one GPU, each in its own partition, see Deploy models to GPU partitions with inference components.

SageMaker AI packages your models as inference components when you deploy them by using:

- SageMaker Studio Classic.

- The SageMaker Python SDK to deploy a Model object (where you set the endpoint type to `EndpointType.INFERENCE_COMPONENT_BASED`).
- The Amazon SDK for Python (Boto3) to define `InferenceComponent` objects that you deploy to an endpoint.

Deploy models with the SageMaker AI console

Use the SageMaker AI console to create a real-time endpoint and host one or more models on it. When you create the endpoint, you select an endpoint type. The endpoint type determines how the models share the resources of the endpoint.

The console supports the following endpoint types.

Inference Components

The endpoint hosts one or more Inference Components. Each Inference Component contains one model and the compute resources for that model. Use this type to host multiple models on shared infrastructure. You can manage, scale, and update each model independently.

Single Model Endpoint (SME)

The endpoint hosts a single model for each production variant, without Inference Components. This is the classic model-based endpoint.

Create Inference Component Endpoints

Create an endpoint that uses Inference Components to host multiple models on shared infrastructure and manage, scale, and update each model independently. Before you begin, create a SageMaker AI model for each model that you want to host.

The Inference Components that you add to the endpoint use the CPU, accelerator, and memory from the instance type and instance count that you choose for the endpoint.

To create an Inference Component endpoint (console)

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, choose **Inference**, and then choose **Endpoints**.
3. Choose **Create endpoint**.

4. For **Endpoint name**, enter a name for the endpoint.
5. For the endpoint type, choose **Inference Components**.
6. For **Instance type** and **Initial instance count**, choose the compute for the endpoint.
7. For **Execution role**, choose the IAM role that grants the endpoint permission to access your model artifacts and other Amazon resources.
8. (Optional) For **Encryption key**, choose an Amazon KMS key to encrypt data on the storage volume attached to the endpoint.
9. (Optional) Select **Enable network isolation** to prevent the endpoint containers from making outbound network calls.
10. Choose **Create endpoint**.

> **Note**
>
> The endpoint status is `Creating` while SageMaker AI provisions the compute. This process might take several minutes.

Add an Inference Component to an endpoint

Add an Inference Component for each model that you want to host on an endpoint. You can add an Inference Component to an endpoint that is in the `InService`, `Creating`, or `Updating` state. The Inference Component attaches after the endpoint compute is ready. You can't add an Inference Component to an endpoint that is in the `Deleting` state.

The **GPUs** field is available only when the instance type of the endpoint provides accelerators. For instance types without accelerators, the value is `0`. For **Memory**, the minimum value is 128 MB. To see the total, allocated, and available capacity on the endpoint, choose **View availability** next to each compute field. Use it to avoid allocating more resources than the endpoint has available.

To add an Inference Component (console)

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, choose **Inference**, and then choose **Endpoints**.
3. Choose the endpoint, and then choose the **Inference components** tab.
4. Choose **Create inference component**.

5. For **Inference component name**, enter a name that is unique within the endpoint.
6. For **Model**, choose the SageMaker AI model to host.
7. For **GPUs**, **vCPUs**, and **Memory**, enter the compute resources for each copy of the model.
8. For **Copies**, enter the number of copies of the model to host. To serve more requests, host more copies.
9. Choose **Create**.

> **Note**
>
> SageMaker AI adds the Inference Component to the endpoint. The Inference Component might take several minutes to reach the `InService` state. After the Inference Component is `InService`, you can invoke its model by selecting the Inference Component in the console.

To change the resource allocation or copy count for a model later, select the Inference Component on the **Inference components** tab and choose **Edit**. For more information about adjusting the number of copies automatically in response to traffic, see Automatic scaling.

Deploy models with SageMaker Studio

Complete the following steps to create and deploy your model interactively through SageMaker Studio. For more information about Studio, see the Studio documentation. For more walkthroughs of various deployment scenarios, see the blog Package and deploy classical ML models and LLMs easily with Amazon SageMaker AI – Part 2.

Prepare your artifacts and permissions

Complete this section before creating a model in SageMaker Studio.

You have two options for bringing your artifacts and creating a model in Studio:

1. You can bring a pre-packaged `tar.gz` archive, which should include your model artifacts, any custom inference code, and any dependencies listed in a `requirements.txt` file.
2. SageMaker AI can package your artifacts for you. You only have to bring your raw model artifacts and any dependencies in a `requirements.txt` file, and SageMaker AI can provide

default inference code for you (or you can override the default code with your own custom inference code). SageMaker AI supports this option for the following frameworks: PyTorch, XGBoost.

In addition to bringing your model, your Amazon Identity and Access Management (IAM) role, and a Docker container (or desired framework and version for which SageMaker AI has a pre-built container), you must also grant permissions to create and deploy models through SageMaker AI Studio.

You should have the AmazonSageMakerFullAccess policy attached to your IAM role so that you can access SageMaker AI and other relevant services. To see the prices of the instance types in Studio, you also must attach the AmazonPriceListServiceFullAccess policy (or if you don't want to attach the whole policy, more specifically, the `pricing:GetProducts` action).

If you choose to upload your model artifacts when creating a model (or upload a sample payload file for inference recommendations), then you must create an Amazon S3 bucket. The bucket name must be prefixed by the word `SageMaker AI`. Alternate capitalizations of SageMaker AI are also acceptable: `Sagemaker` or `sagemaker`.

We recommend that you use the bucket naming convention `sagemaker-{`*`Region`*`}-{`*`accountID`*`}`. This bucket is used to store the artifacts that you upload.

After creating the bucket, attach the following CORS (cross-origin resource sharing) policy to the bucket:

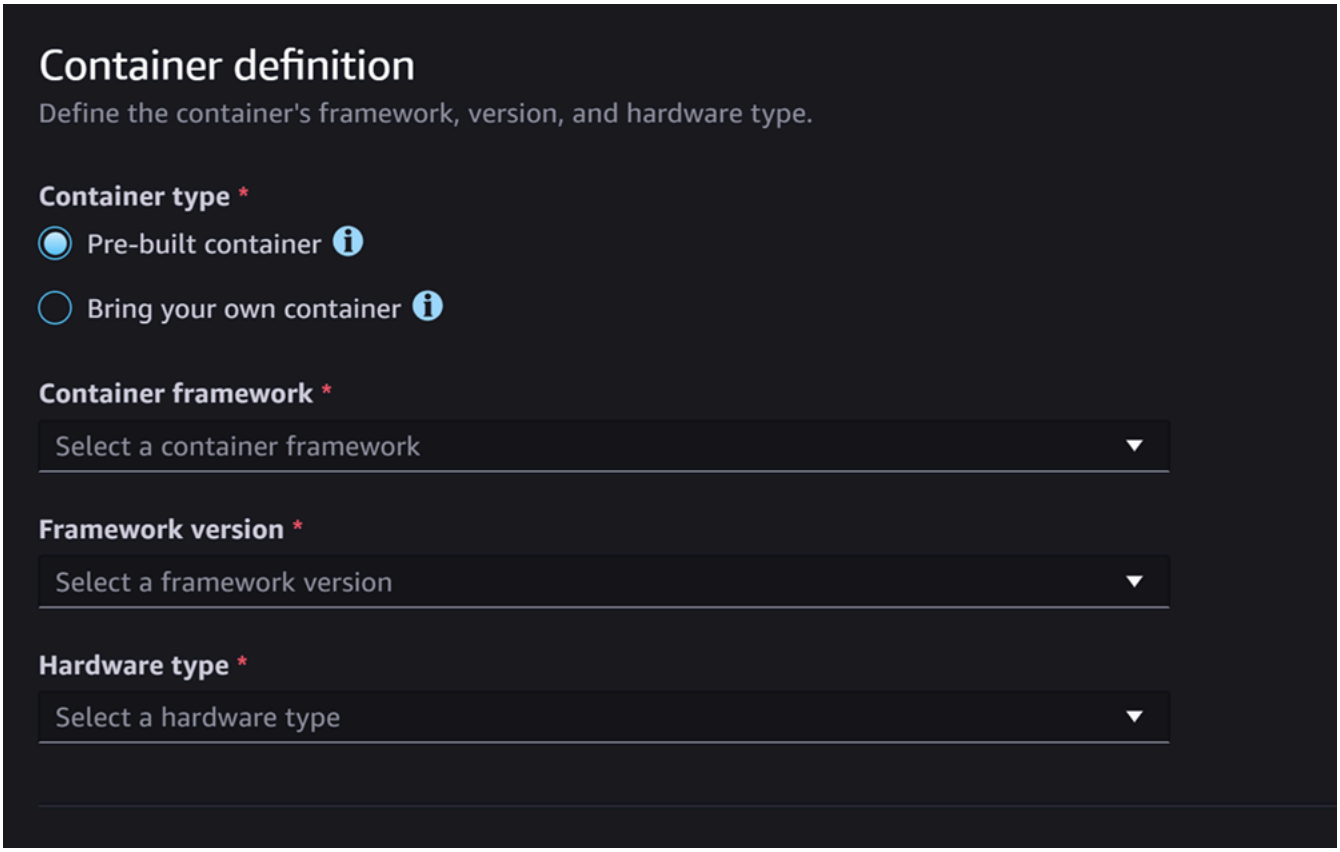
```
[
    {
        "AllowedHeaders": ["*"],
        "ExposeHeaders": ["Etag"],
        "AllowedMethods": ["PUT", "POST"],
        "AllowedOrigins": ['https://*.sagemaker.aws'],
    }
]
```

You can attach a CORS policy to an Amazon S3 bucket by using any of the following methods:

- Through the Edit cross-origin resource sharing (CORS) page in the Amazon S3 console
- Using the Amazon S3 API PutBucketCors
- Using the put-bucket-cors Amazon CLI command:

```
aws s3api put-bucket-cors --bucket="..." --cors-configuration="..."
```

Create a deployable model

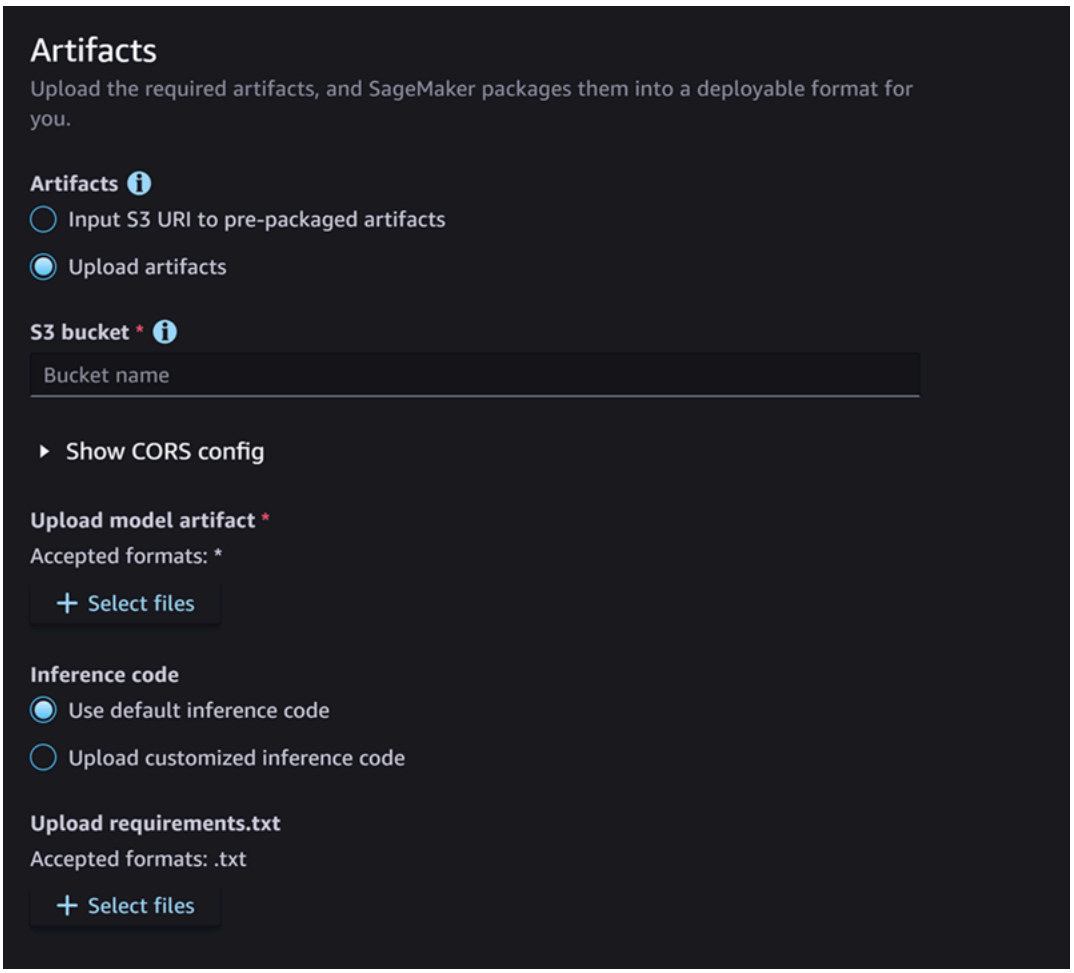


In this step, you create a deployable version of your model in SageMaker AI by providing your artifacts along with additional specifications, such as your desired container and framework, any custom inference code, and network settings.

Create a deployable model in SageMaker Studio by doing the following:

1. Open the SageMaker Studio application.
2. In the left navigation pane, choose **Models**.
3. Choose the **Deployable models** tab.
4. On the **Deployable models** page, choose **Create**.
5. On the **Create deployable model** page, for the **Model name** field, enter a name for the model.

There are several more sections for you to fill out on the **Create deployable model** page.



The **Container definition** section looks like the following screenshot:

For the Container definition section, do the following:

1. For **Container type**, select **Pre-built container** if you'd like to use a SageMaker AI managed container, or select **Bring your own container** if you have your own container.
2. If you selected **Pre-built container**, select the **Container framework**, **Framework version**, and **Hardware type** that you'd like to use.
3. If you selected **Bring your own container**, enter an Amazon ECR path for **ECR path to container image**.

Then, fill out the **Artifacts** section, which looks like the following screenshot:

For the Artifacts section, do the following:

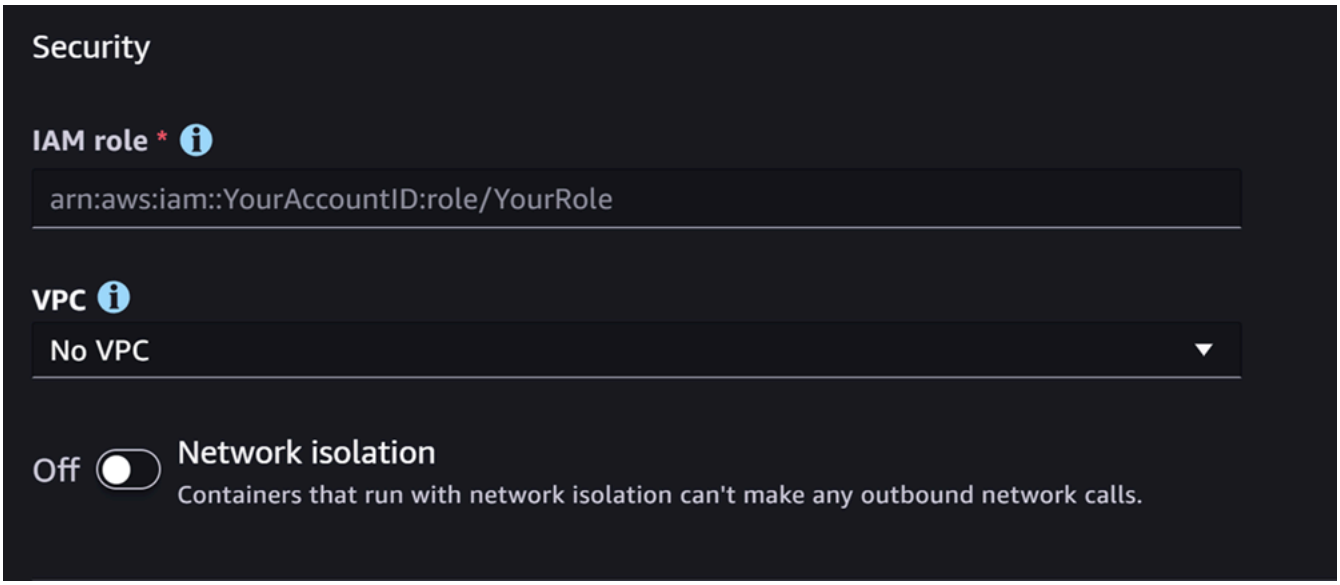
1. If you're using one of the frameworks that SageMaker AI supports for packaging model artifacts (PyTorch or XGBoost), then for **Artifacts**, you can choose the **Upload artifacts** option. With this option, you can simply specify your raw model artifacts, any custom inference code you have, and your requirements.txt file, and SageMaker AI handles packaging the archive for you. Do the following:

   a. For **Artifacts**, select **Upload artifacts** to continue providing your files. Otherwise, if you already have a `tar.gz` archive that contains your model files, inference code, and `requirements.txt` file, then select **Input S3 URI to pre-packaged artifacts**.

   b. If you chose to upload your artifacts, then for **S3 bucket**, enter the Amazon S3 path to a bucket where you'd like SageMaker AI to store your artifacts after packaging them for you. Then, complete the following steps.

   c. For **Upload model artifacts**, upload your model files.

d. For **Inference code**, select **Use default inference code** if you'd like to use default code that SageMaker AI provides for serving inference. Otherwise, select **Upload customized inference code** to use your own inference code.



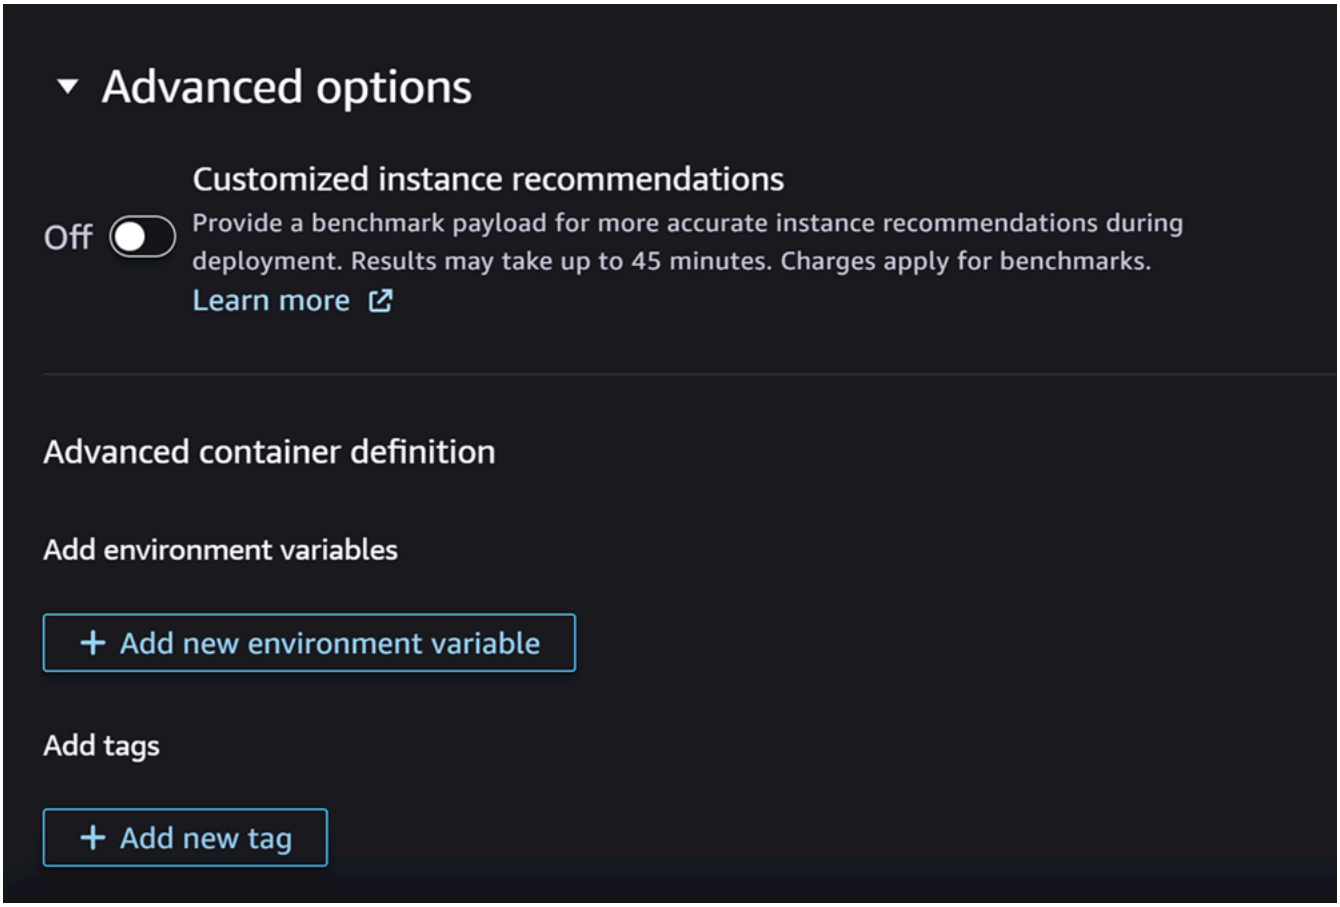
e. For **Upload requirements.txt**, upload a text file that lists any dependencies that you want to install at runtime.

2. If you're not using a framework that SageMaker AI supports for packaging model artifacts, then Studio shows you the **Pre-packaged artifacts** option, and you must provide all of your artifacts already packaged as a `tar.gz` archive. Do the following:

a. For **Pre-packaged artifacts**, select **Input S3 URI for pre-packaged model artifacts** if you have your `tar.gz` archive already uploaded to Amazon S3. Select **Upload pre-packaged model artifacts** if you want to directly upload your archive to SageMaker AI.

b. If you selected **Input S3 URI for pre-packaged model artifacts**, enter the Amazon S3 path to your archive for **S3 URI**. Otherwise, select and upload the archive from your local machine.

The next section is **Security**, which looks like the following screenshot:



For the Security section, do the following:

1. For **IAM role**, enter the ARN for an IAM role.
2. (Optional) For **Virtual Private Cloud (VPC)**, you can select an Amazon VPC for storing your model configuration and artifacts.

3. (Optional) Turn on the **Network isolation** toggle if you want to restrict your container's internet access.

Finally, you can optionally fill out the **Advanced options** section, which looks like the following screenshot:

(Optional) For the Advanced options section, do the following:

1. Turn on the **Customized instance recommendations** toggle if you want to run an Amazon SageMaker Inference Recommender job on your model after its creation. Inference Recommender is a feature that provides you with recommended instance types for optimizing inference performance and cost. You can view these instance recommendations when preparing to deploy your model.
2. For **Add environment variables**, enter an environment variables for your container as key-value pairs.
3. For **Tags**, enter any tags as key-value pairs.
4. After finishing your model and container configuration, choose **Create deployable model**.

You should now have a model in SageMaker Studio that is ready for deployment.

Deploy your model

Finally, you deploy the model you configured in the previous step to an HTTPS endpoint. You can deploy either a single model or multiple models to the endpoint.

Model and endpoint compatibility

Before you can deploy a model to an endpoint, the model and endpoint must be compatible by having the same values for the following settings:

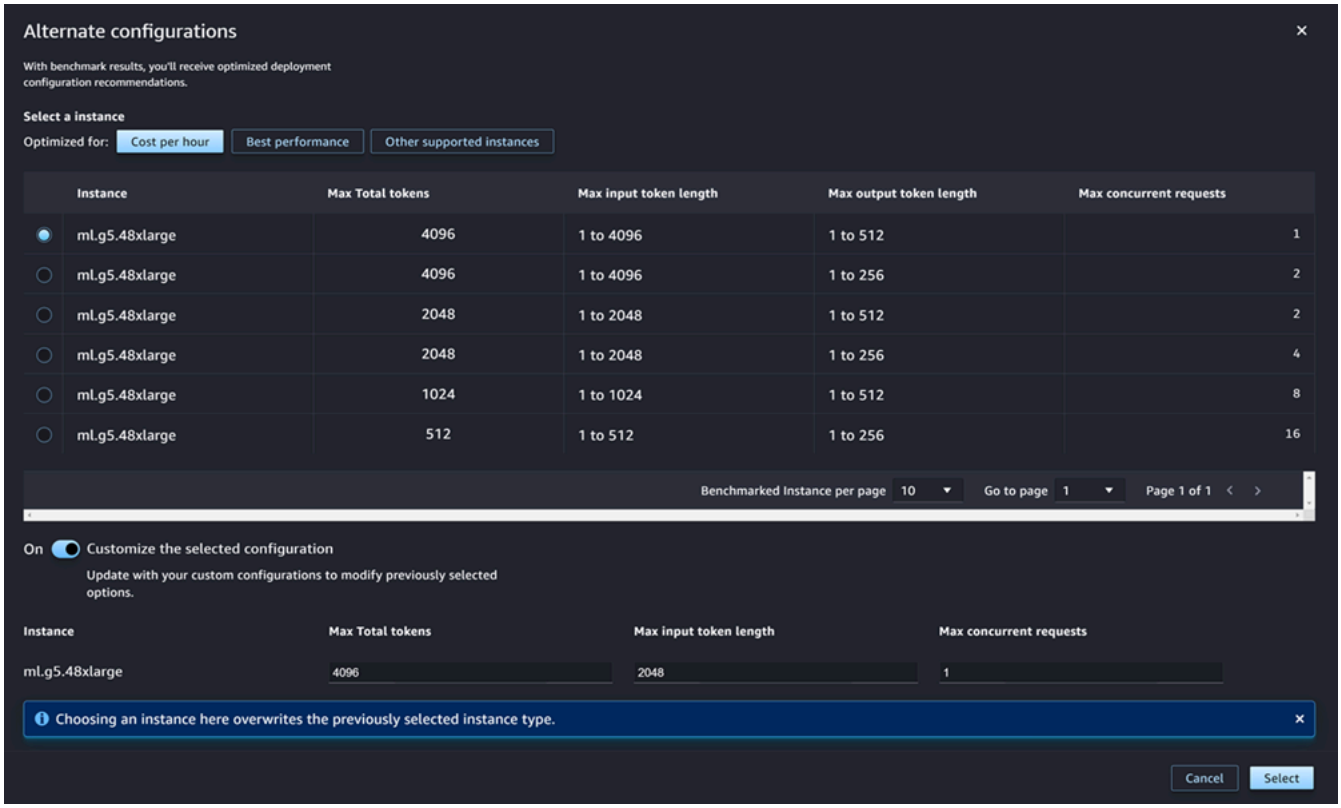
- The IAM role
- The Amazon VPC, including its subnets and security groups
- The network isolation (enabled or disabled)

Studio prevents you from deploying models to incompatible endpoints in the following ways:

- If you attempt to deploy a model to a new endpoint, SageMaker AI configures the endpoint with initial settings that are compatible. If you break the compatibility by changing these settings, Studio shows an alert and prevents your deployment.
- If you attempt to deploy to an existing endpoint, and that endpoint is incompatible, Studio shows an alert and prevents your deployment.
- If you attempt to add multiple models to a deployment, Studio prevents you from deploying models that are incompatible with each other.

When Studio shows the alert about model and endpoint incompatibility, you can choose **View details** in the alert to see which settings are incompatible.

One way to deploy a model is by doing the following in Studio:



1. Open the SageMaker Studio application.
2. In the left navigation pane, choose **Models**.
3. On the **Models** page, select one or more models from the list of SageMaker AI models.
4. Choose **Deploy**.

5. For **Endpoint name**, open the dropdown menu. You can either select an existing endpoint or you can create a new endpoint to which you deploy the model.
6. For **Instance type**, select the instance type that you want to use for the endpoint. If you previously ran an Inference Recommender job for the model, your recommended instance types appear in the list under the title **Recommended**. Otherwise, you'll see a few **Prospective instances** that might be suitable for your model.

   > **Instance type compatibility for JumpStart**
   >
   > If you're deploying a JumpStart model, Studio only shows instance types that the model supports.

7. For **Initial instance count**, enter the initial number of instances that you'd like to provision for your endpoint.
8. For **Maximum instance count**, specify the maximum number of instances that the endpoint can provision when it scales up to accommodate an increase in traffic.
9. If the model you're deploying is one of the most used JumpStart LLMs from the model hub, then the **Alternate configurations** option appears after the instance type and instance count fields.

   For the most popular JumpStart LLMs, Amazon has pre-benchmarked instance types to optimize for either cost or performance. This data can help you decide which instance type to use for deploying your LLM. Choose **Alternate configurations** to open a dialog box that contains the pre-benchmarked data. The panel looks like the following screenshot:

In the **Alternate configurations** box, do the following:

a. Select an instance type. You can choose **Cost per hour** or **Best performance** to see instance types that optimize either cost or performance for the specified model. You can also choose **Other supported instances** to see a list of other instance types that are compatible with the JumpStart model. Note that selecting an instance type here overwrites any previous instance selection specified in Step 6.

b. (Optional) Turn on the **Customize the selected configuration** toggle to specify **Max total tokens** (the maximum number of tokens that you want to allow, which is the sum of your input tokens and the model's generated output), **Max input token length** (the maximum number of tokens you want to allow for the input of each request), and **Max concurrent requests** (the maximum number of requests that the model can process at a time).

c. Choose **Select** to confirm your instance type and configuration settings.

10. The **Model** field should already be populated with the name of the model or models that you're deploying. You can choose **Add model** to add more models to the deployment. For each model that you add, fill out the following fields:

    a. For **Number of CPU cores**, enter the CPU cores that you'd like to dedicate for the model's usage.

b. For **Min number of copies**, enter the minimum number of model copies that you want to have hosted on the endpoint at any given time.

c. For **Min CPU memory (MB)**, enter the minimum amount of memory (in MB) that the model requires.

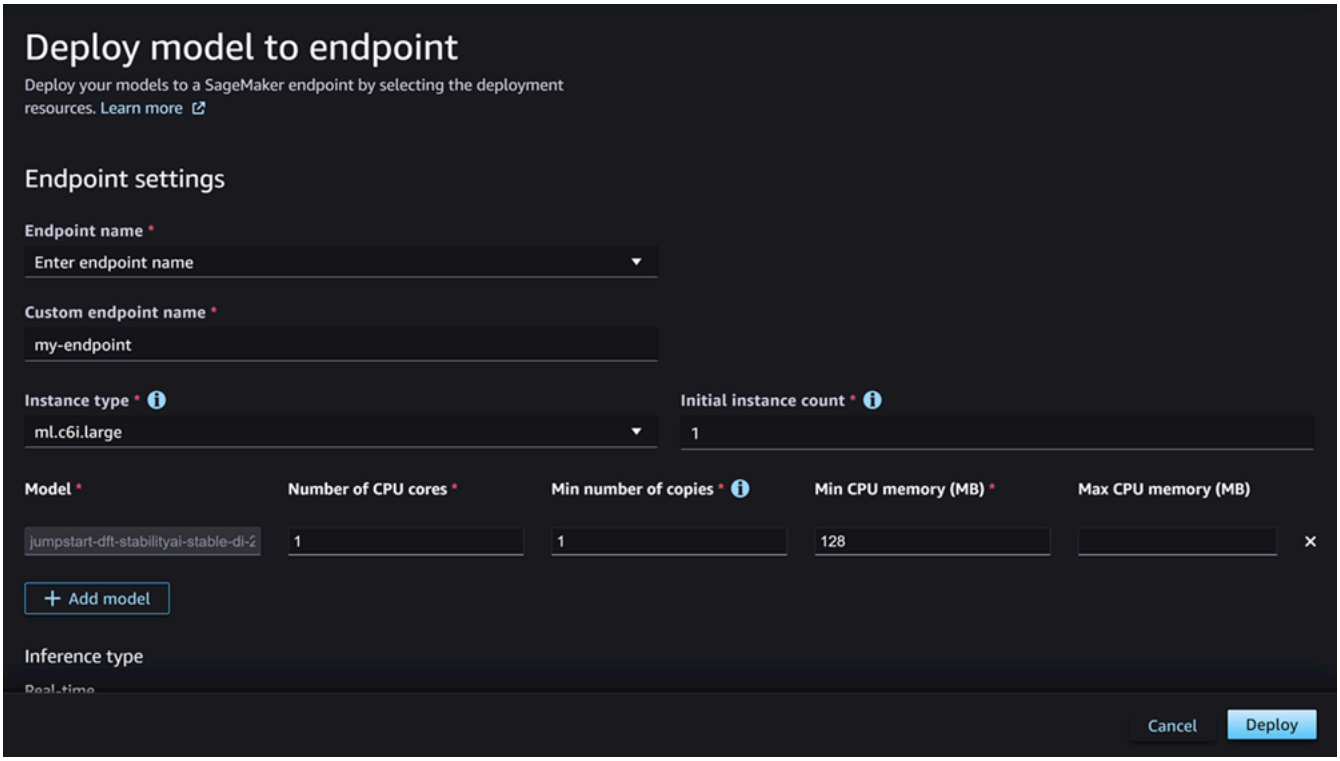
d. For **Max CPU memory (MB)**, enter the maximum amount of memory (in MB) that you'd like to allow the model to use.

11. (Optional) For the **Advanced options**, do the following:

a. For **IAM role**, use either the default SageMaker AI IAM execution role, or specify your own role that has the permissions you need. Note that this IAM role must be the same as the role that you specified when creating the deployable model.

b. For **Virtual Private Cloud (VPC)**, you can specify a VPC in which you want to host your endpoint.

c. For **Encryption KMS key**, select an Amazon KMS key to encrypt data on the storage volume attached to the ML compute instance that hosts the endpoint.



d. Turn on the **Enable network isolation** toggle to restrict your container's internet access.

e. For **Timeout configuration**, enter values for the **Model data download timeout (seconds)** and **Container startup health check timeout (seconds)** fields. These values determine the maximum amount of time that SageMaker AI allows for downloading the model to the container and starting up the container, respectively.

f. For **Tags**, enter any tags as key-value pairs.

> **Note**
>
> SageMaker AI configures the IAM role, VPC, and network isolation settings with initial values that are compatible with the model that you're deploying. If you break the compatibility by changing these settings, Studio shows an alert and prevents your deployment.

After configuring your options, the page should look like the following screenshot.

After configuring your deployment, choose **Deploy** to create the endpoint and deploy your model.

Deploy models with the Python SDKs

Using the SageMaker Python SDK, you can build your model in two ways. The first is to create a model object from the `Model` or `ModelBuilder` class. If you use the `Model` class to create your `Model` object, you need to specify the model package or inference code (depending on your model server), scripts to handle serialization and deserialization of data between the client and server, and any dependencies to be uploaded to Amazon S3 for consumption. The second way to build your model is to use `ModelBuilder` for which you provide model artifacts or inference code. `ModelBuilder` automatically captures your dependencies, infers the needed serialization and deserialization functions, and packages your dependencies to create your `Model` object. For more information about `ModelBuilder`, see Create a model in Amazon SageMaker AI with ModelBuilder.

The following section describes both methods to create your model and deploy your model object.

Set up

The following examples prepare for the model deployment process. They import the necessary libraries and define the S3 URL that locates the model artifacts.

SageMaker Python SDK

Example import statements

The following example imports modules from the SageMaker Python SDK v3. These modules provide useful methods that help you deploy models, and they're used by the remaining examples that follow.

```
import boto3
from sagemaker.serve import ModelBuilder
from sagemaker.core.resources import Endpoint
from sagemaker.core.helper.session_helper import Session
```

Boto3 (Inference Components)

Example import statements

The following example imports modules from the SDK for Python (Boto3) and the Python Standard Library. These modules provide useful methods that help you deploy models, and they're used by the remaining examples that follow.

```
import boto3
import botocore
import sys
import time
```

Boto3 (Model-based)

Example import statements

The following example imports modules from the SDK for Python (Boto3) and the Python Standard Library. These modules provide useful methods that help you deploy models, and they're used by the remaining examples that follow.

```
import boto3
import botocore
import datetime
from time import gmtime, strftime
```

Example model artifact URL

The following code builds an example Amazon S3 URL. The URL locates the model artifacts for a pre-trained model in an Amazon S3 bucket.

```
# Create a variable w/ the model S3 URL

# The name of your S3 bucket:
s3_bucket = "amzn-s3-demo-bucket"
# The directory within your S3 bucket your model is stored in:
bucket_prefix = "sagemaker/model/path"
# The file name of your model artifact:
model_filename = "my-model-artifact.tar.gz"
# Relative S3 path:
model_s3_key = f"{bucket_prefix}/"+model_filename
# Combine bucket name, model file name, and relate S3 path to create S3 model URL:
model_url = f"s3://{s3_bucket}/{model_s3_key}"
```

The full Amazon S3 URL is stored in the variable `model_url`, which is used in the examples that follow.

Overview

There are multiple ways that you can deploy models with the SageMaker Python SDK or the SDK for Python (Boto3). The following sections summarize the steps that you complete for several possible approaches. These steps are demonstrated by the examples that follow.

SageMaker Python SDK

Using the SageMaker Python SDK v3, you build and deploy your model with `ModelBuilder`. You provide model artifacts or inference code, and `ModelBuilder` automatically captures your dependencies, infers the needed serialization and deserialization functions, and packages your dependencies to create your model. To deploy a model, you complete the following steps:

1. Create a `ModelBuilder` object with your model artifacts, role, and instance type.
2. Call `deploy()` to deploy the model to an endpoint.

Boto3 (Inference Components)

The examples that follow demonstrate how to assign a model to an inference component and then deploy the inference component to an endpoint. To deploy a model in this way, you complete the following steps:

1. (Optional) Create a SageMaker AI model object by using the `create_model` method.
2. Specify the settings for your endpoint by creating an endpoint configuration object. To create one, you use the `create_endpoint_config` method.
3. Create your endpoint by using the `create_endpoint` method, and in your request, provide the endpoint configuration that you created.
4. Create an inference component by using the `create_inference_component` method. In the settings, you specify a model by doing either of the following:
   - Specifying a SageMaker AI model object
   - Specifying the model image URI and S3 URL

   You also allocate endpoint resources to the model. By creating the inference component, you deploy the model to the endpoint. You can deploy multiple models to an endpoint by creating multiple inference components — one for each model.

Boto3 (Model-based)

The examples that follow demonstrate how to create a model object and then deploy the model to an endpoint. To deploy a model in this way, you complete the following steps:

1. Create a SageMaker AI model by using the `create_model` method.
2. Specify the settings for your endpoint by creating an endpoint configuration object. To create one, you use the `create_endpoint_config` method. In the endpoint configuration, you assign the model object to a production variant.
3. Create your endpoint by using the `create_endpoint` method. In your request, provide the endpoint configuration that you created.

   When you create the endpoint, SageMaker AI provisions the endpoint resources, and it deploys the model to the endpoint.

Configure

The following examples configure the resources that you require to deploy a model to an endpoint.

SageMaker Python SDK

The following example configures a `ModelBuilder` with your model artifacts. `ModelBuilder` provides a unified interface for model packaging and deployment.

```
from sagemaker.serve import ModelBuilder

model_builder = ModelBuilder(
    image_uri="image-uri",
    s3_model_data_url=model_url,
    role_arn="arn:aws:iam::111122223333:role/service-role/role-name",
    instance_type="ml.p4d.24xlarge",
)
```

Boto3 (Inference Components)

The following example configures an endpoint with the `create_endpoint_config` method. You assign this configuration to an endpoint when you create it. In the configuration, you define one or more production variants. For each variant, you can choose the instance type that you want Amazon SageMaker AI to provision, and you can enable managed instance scaling.

```
endpoint_config_name = "endpoint-config-name"
endpoint_name = "endpoint-name"
inference_component_name = "inference-component-name"
variant_name = "variant-name"

sagemaker_client.create_endpoint_config(
    EndpointConfigName = endpoint_config_name,
    ExecutionRoleArn = "arn:aws:iam::111122223333:role/service-role/role-name",
    ProductionVariants = [
        {
            "VariantName": variant_name,
            "InstanceType": "ml.p4d.24xlarge",
            "InitialInstanceCount": 1,
            "ManagedInstanceScaling": {
                "Status": "ENABLED",
                "MinInstanceCount": 1,
                "MaxInstanceCount": 2,
```

```
            },
        }
    ],
)
```

Boto3 (Model-based)

Example model definition

The following example defines a SageMaker AI model with the `create_model` method in the Amazon SDK for Python (Boto3).

```
model_name = "model-name"

create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = "arn:aws:iam::111122223333:role/service-role/role-name",
    PrimaryContainer = {
        "Image": "image-uri",
        "ModelDataUrl": model_url,
    }
)
```

This example specifies the following:

- `ModelName`: A name for your model (in this example it is stored as a string variable called `model_name`).
- `ExecutionRoleArn`: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker AI can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- `PrimaryContainer`: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.

Example endpoint configuration

The following example configures an endpoint with the `create_endpoint_config` method. Amazon SageMaker AI uses this configuration to deploy models. In the configuration, you identify one or more models, created with the `create_model` method, to deploy the resources that you want Amazon SageMaker AI to provision.

```
endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName = "endpoint-config-name",
    # List of ProductionVariant objects, one for each model that you want to host at
 this endpoint:
    ProductionVariants = [
        {
            "VariantName": "variant-name", # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": "ml.p4d.24xlarge",
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ]
)
```

This example specifies the following keys for the `ProductionVariants` field:

- `VariantName`: The name of the production variant.
- `ModelName`: The name of the model that you want to host. This is the name that you specified when creating the model.
- `InstanceType`: The compute instance type. See the `InstanceType` field in https://docs.amazonaws.cn/sagemaker/latest/APIReference/API_ProductionVariant.html and SageMaker AI Pricing for a list of supported compute instance types and pricing for each instance type.

Deploy

The following examples deploy a model to an endpoint.

SageMaker Python SDK

The following example deploys the model to a real-time, HTTPS endpoint using the `deploy` method of `ModelBuilder`.

```
endpoint = model_builder.deploy(
    endpoint_name="endpoint-name",
    instance_type="ml.p4d.24xlarge",
    initial_instance_count=1,
)

# Invoke the endpoint
```

```
response = endpoint.invoke(
    body=test_payload,
    content_type="application/json"
)
print(response)
```

Boto3 (Inference Components)

Once you have an endpoint configuration, use the create_endpoint method to create your endpoint. The endpoint name must be unique within an Amazon Web Services Region in your Amazon account.

The following example creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker AI uses the endpoint to provision resources.

```
sagemaker_client.create_endpoint(
    EndpointName = endpoint_name,
    EndpointConfigName = endpoint_config_name,
)
```

After you've created an endpoint, you can deploy one or models to it by creating inference components. The following example creates one with the `create_inference_component` method.

```
sagemaker_client.create_inference_component(
    InferenceComponentName = inference_component_name,
    EndpointName = endpoint_name,
    VariantName = variant_name,
    Specification = {
        "Container": {
            "Image": "image-uri",
            "ArtifactUrl": model_url,
        },
        "ComputeResourceRequirements": {
            "NumberOfCpuCoresRequired": 1,
            "MinMemoryRequiredInMb": 1024
        }
    },
    RuntimeConfig = {"CopyCount": 2}
)
```

Boto3 (Model-based)

Example deployment

Provide the endpoint configuration to SageMaker AI. The service launches the ML compute instances and deploys the model or models as specified in the configuration.

Once you have your model and endpoint configuration, use the create_endpoint method to create your endpoint. The endpoint name must be unique within an Amazon Web Services Region in your Amazon account.

The following example creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker AI uses the endpoint to provision resources and deploy models.

```
create_endpoint_response = sagemaker_client.create_endpoint(
    # The endpoint name must be unique within an Amazon Region in your Amazon
 account:
    EndpointName = "endpoint-name"
    # The name of the endpoint configuration associated with this endpoint:
    EndpointConfigName = "endpoint-config-name")
```

Deploy models with the Amazon CLI

You can deploy a model to an endpoint by using the Amazon CLI.

Overview

When you deploy a model with the Amazon CLI, you can deploy it with or without using an inference component. The following sections summarize the commands that you run for both approaches. These commands are demonstrated by the examples that follow.

With inference components

To deploy a model with an inference component, do the following:

1. (Optional) Create a model with the `create-model` command.
2. Specify the settings for your endpoint by creating an endpoint configuration. To create one, you run the `create-endpoint-config` command.
3. Create your endpoint by using the `create-endpoint` command. In the command body, specify the endpoint configuration that you created.

4. Create an inference component by using the `create-inference-component` command. In the settings, you specify a model by doing either of the following:

   - Specifying a SageMaker AI model object
   - Specifying the model image URI and S3 URL

   You also allocate endpoint resources to the model. By creating the inference component, you deploy the model to the endpoint. You can deploy multiple models to an endpoint by creating multiple inference components — one for each model.

Without inference components

To deploy a model without using an inference component, do the following:

1. Create a SageMaker AI model by using the `create-model` command.
2. Specify the settings for your endpoint by creating an endpoint configuration object. To create one, you use the `create-endpoint-config` command. In the endpoint configuration, you assign the model object to a production variant.
3. Create your endpoint by using the `create-endpoint` command. In your command body, specify the endpoint configuration that you created.

   When you create the endpoint, SageMaker AI provisions the endpoint resources, and it deploys the model to the endpoint.

Configure

The following examples configure the resources that you require to deploy a model to an endpoint.

With inference components

Example create-endpoint-config command

The following example creates an endpoint configuration with the create-endpoint-config command.

```
aws sagemaker create-endpoint-config \
--endpoint-config-name endpoint-config-name \
--execution-role-arn arn:aws:iam::111122223333:role/service-role/role-name\
```

```
--production-variants file://production-variants.json
```

In this example, the file `production-variants.json` defines a production variant with the following JSON:

```
[
    {
        "VariantName": "variant-name",
        "ModelName": "model-name",
        "InstanceType": "ml.p4d.24xlarge",
        "InitialInstanceCount": 1
    }
]
```

If the command succeeds, the Amazon CLI responds with the ARN for the resource you created.

```
{
    "EndpointConfigArn": "arn:aws:sagemaker:us-west-2:111122223333:endpoint-config/
endpoint-config-name"
}
```

Without inference components

Example create-model command

The following example creates a model with the create-model command.

```
aws sagemaker create-model \
--model-name model-name \
--execution-role-arn arn:aws:iam::111122223333:role/service-role/role-name \
--primary-container "{ \"Image\": \"image-uri\", \"ModelDataUrl\": \"model-s3-
url\"}"
```

If the command succeeds, the Amazon CLI responds with the ARN for the resource you created.

```
{
    "ModelArn": "arn:aws:sagemaker:us-west-2:111122223333:model/model-name"
}
```

Example create-endpoint-config command

The following example creates an endpoint configuration with the create-endpoint-config command.

```
aws sagemaker create-endpoint-config \
--endpoint-config-name endpoint-config-name \
--production-variants file://production-variants.json
```

In this example, the file `production-variants.json` defines a production variant with the following JSON:

```
[
    {
        "VariantName": "variant-name",
        "ModelName": "model-name",
        "InstanceType": "ml.p4d.24xlarge",
        "InitialInstanceCount": 1
    }
]
```

If the command succeeds, the Amazon CLI responds with the ARN for the resource you created.

```
{
    "EndpointConfigArn": "arn:aws:sagemaker:us-west-2:111122223333:endpoint-config/
endpoint-config-name"
}
```

Deploy

The following examples deploy a model to an endpoint.

With inference components

Example create-endpoint command

The following example creates an endpoint with the create-endpoint command.

```
aws sagemaker create-endpoint \
```

```
--endpoint-name endpoint-name \
--endpoint-config-name endpoint-config-name
```

If the command succeeds, the Amazon CLI responds with the ARN for the resource you created.

```
{
    "EndpointArn": "arn:aws:sagemaker:us-west-2:111122223333:endpoint/endpoint-name"
}
```

Example create-inference-component command

The following example creates an inference component with the create-inference-component command.

```
aws sagemaker create-inference-component \
--inference-component-name inference-component-name \
--endpoint-name endpoint-name \
--variant-name variant-name \
--specification file://specification.json \
--runtime-config "{\"CopyCount\": 2}"
```

In this example, the file `specification.json` defines the container and compute resources with the following JSON:

```
{
    "Container": {
        "Image": "image-uri",
        "ArtifactUrl": "model-s3-url"
    },
    "ComputeResourceRequirements": {
        "NumberOfCpuCoresRequired": 1,
        "MinMemoryRequiredInMb": 1024
    }
}
```

If the command succeeds, the Amazon CLI responds with the ARN for the resource you created.

```
{
    "InferenceComponentArn": "arn:aws:sagemaker:us-west-2:111122223333:inference-
component/inference-component-name"
```

```
}
```

Without inference components

Example create-endpoint command

The following example creates an endpoint with the create-endpoint command.

```
aws sagemaker create-endpoint \
--endpoint-name endpoint-name \
--endpoint-config-name endpoint-config-name
```

If the command succeeds, the Amazon CLI responds with the ARN for the resource you created.

```
{
    "EndpointArn": "arn:aws:sagemaker:us-west-2:111122223333:endpoint/endpoint-name"
}
```

Invoke models for real-time inference

After you use Amazon SageMaker AI to deploy a model to an endpoint, you can interact with the model by sending inference requests to it. To send an inference request to a model, you invoke the endpoint that hosts it. You can invoke your endpoints using Amazon SageMaker Studio, the Amazon SDKs, or the Amazon CLI.

Invoke Your Model Using Amazon SageMaker Studio

After you deploy your model to an endpoint, you can view the endpoint through Amazon SageMaker Studio and test your endpoint by sending single inference requests.

> **Note**
>
> SageMaker AI only supports endpoint testing in Studio for real-time endpoints.

To send a test inference request to your endpoint

1. Launch Amazon SageMaker Studio.
2. In the navigation pane on the left, choose **Deployments**.

3. From the dropdown, choose **Endpoints**.
4. Find for your endpoint by name, and choose the name in the table. The endpoint names listed in the **Endpoints** panel are defined when you deploy a model. The Studio workspace opens the **Endpoint** page in a new tab.
5. Choose the **Test inference** tab.
6. For **Testing Options**, select one of the following:

    a. Select **Test the sample request** to immediately send a request to your endpoint. Use the **JSON editor** to provide sample data in JSON format, and choose **Send Request** to submit the request to your endpoint. After submitting your request, Studio shows the inference output in a card to the right of the JSON editor.

    b. Select **Use Python SDK example code** to view the code for sending a request to the endpoint. Then, copy the code example from the **Example inference request** section and run the code from your testing environment.

The top of the card shows the type of request that was sent to the endpoint (only JSON is accepted). The card shows the following fields:

- **Status** – displays one of the following status types:
    - `Success` – The request succeeded.
    - `Failed` – The request failed. A response appears under **Failure Reason**.
    - `Pending` – While the inference request is pending, the status shows a spinning, circular icon.
- **Execution Length** – How long the invocation took (end time minus the start time) in milliseconds.
- **Request Time** – How many minutes have passed since the request was sent.
- **Result Time** – How many minutes have passed since the result was returned.

Invoke Your Model by Using the Amazon SDK for Python (Boto3)

If you want to invoke a model endpoint in your application code, you can use one of the Amazon SDKs, including the Amazon SDK for Python (Boto3). To invoke your endpoint with this SDK, you use one of the following Python methods:

- `invoke_endpoint` – Sends an inference request to a model endpoint and returns the response that the model generates.

This method returns the inference payload as one response after the model finishes generating it. For more information, see invoke_endpoint in the *Amazon SDK for Python (Boto3) API Reference*.

- `invoke_endpoint_with_response_stream` – Sends an inference request to a model endpoint and streams the response incrementally while the model generates it.

  With this method, your application receives parts of the response as soon as the parts become available. For more information, see invoke_endpoint in the *Amazon SDK for Python (Boto3) API Reference*.

  Use this method only to invoke models that support inference streaming.

Before you can use these methods in your application code, you must initialize a SageMaker AI Runtime client, and you must specify the name of your endpoint. The following example sets up the client and endpoint for the rest of the examples that follow:

```
import boto3

sagemaker_runtime = boto3.client(
    "sagemaker-runtime", region_name='aws_region')

endpoint_name='endpoint-name'
```

Invoke to Get an Inference Response

The following example uses the `invoke_endpoint` method to invoke an endpoint with the Amazon SDK for Python (Boto3):

```
# Gets inference from the model hosted at the specified endpoint:
response = sagemaker_runtime.invoke_endpoint(
    EndpointName=endpoint_name,
    Body=bytes('{"features": ["This is great!"]}', 'utf-8')
    )

# Decodes and prints the response body:
print(response['Body'].read().decode('utf-8'))
```

This example provide input data in the Body field for SageMaker AI to pass to the model. This data must be in the same format that was used for training. The example assigns the response to the `response` variable.

The `response` variable provides access to the HTTP status, the name of the deployed model, and other fields. The following snippet prints the HTTP status code:

```
print(response["HTTPStatusCode"])
```

Invoke to Stream an Inference Response

If you deployed a model that supports inference streaming, you can invoke the model to receive its inference payload as a stream of parts. The model delivers these parts incrementally as the model generates them. When an application receives an inference stream, the application doesn't need to wait for the model to generate the whole response payload. Instead, the application immediately receives parts of the response as they become available.

By consuming an inference stream in your application, you can create interactions where your users perceive the inference to be fast because they get the first part immediately. You can implement streaming to support fast interactive experiences, such as chatbots, virtual assistants, and music generators. For example, you could create a chatbot that incrementally shows the text generated by a large language model (LLM).

To get an inference stream, you can use the `invoke_endpoint_with_response_stream` method. In the response body, the SDK provides an `EventStream` object, which gives the inference as a series of `PayloadPart` objects.

Example Inference Stream

The following example is a stream of `PayloadPart` objects:

```
{'PayloadPart': {'Bytes': b'{"outputs": [" a"]}\n'}}
{'PayloadPart': {'Bytes': b'{"outputs": [" challenging"]}\n'}}
{'PayloadPart': {'Bytes': b'{"outputs": [" problem"]}\n'}}
. . .
```

In each payload part, the `Bytes` field provides a portion of the inference response from the model. This portion can be any content type that a model generates, such as text, image, or audio data. In this example, the portions are JSON objects that contain generated text from an LLM.

Usually, the payload part contains a discrete chunk of data from the model. In this example, the discrete chunks are whole JSON objects. Occasionally, the streaming response splits the chunks over multiple payload parts, or it combines multiple chunks into one payload part. The following example shows a chunk of data in JSON format that's split over two payload parts:

```
{'PayloadPart': {'Bytes': b'{"outputs": '}}
{'PayloadPart': {'Bytes': b'[" problem"]}\n'}}
```

When you write application code that processes an inference stream, include logic that handles these occasional splits and combinations of data. As one strategy, you could write code that concatenates the contents of `Bytes` while your application receives the payload parts. By concatenating the example JSON data here, you would combine the data into a newline-delimited JSON body. Then, your code could process the stream by parsing the whole JSON object on each line.

The following example shows the newline-delimited JSON that you would create when you concatenate the example contents of `Bytes`:

```
{"outputs": [" a"]}
{"outputs": [" challenging"]}
{"outputs": [" problem"]}
. . .
```

Example Code to Process an Inference Stream

The following example Python class, `SmrInferenceStream`, demonstrates how you can process an inference stream that sends text data in JSON format:

```
import io
import json

# Example class that processes an inference stream:
class SmrInferenceStream:

    def __init__(self, sagemaker_runtime, endpoint_name):
        self.sagemaker_runtime = sagemaker_runtime
        self.endpoint_name = endpoint_name
        # A buffered I/O stream to combine the payload parts:
        self.buff = io.BytesIO()
        self.read_pos = 0
```

```
    def stream_inference(self, request_body):
        # Gets a streaming inference response
        # from the specified model endpoint:
        response = self.sagemaker_runtime\
            .invoke_endpoint_with_response_stream(
                EndpointName=self.endpoint_name,
                Body=json.dumps(request_body),
                ContentType="application/json"
        )
        # Gets the EventStream object returned by the SDK:
        event_stream = response['Body']
        for event in event_stream:
            # Passes the contents of each payload part
            # to be concatenated:
            self._write(event['PayloadPart']['Bytes'])
            # Iterates over lines to parse whole JSON objects:
            for line in self._readlines():
                resp = json.loads(line)
                part = resp.get("outputs")[0]
                # Returns parts incrementally:
                yield part

    # Writes to the buffer to concatenate the contents of the parts:
    def _write(self, content):
        self.buff.seek(0, io.SEEK_END)
        self.buff.write(content)

    # The JSON objects in buffer end with '\n'.
    # This method reads lines to yield a series of JSON objects:
    def _readlines(self):
        self.buff.seek(self.read_pos)
        for line in self.buff.readlines():
            self.read_pos += len(line)
            yield line[:-1]
```

This example processes the inference stream by doing the following:

- Initializes a SageMaker AI Runtime client and sets the name of a model endpoint. Before you can get an inference stream, the model that the endpoint hosts must support inference streaming.
- In the example `stream_inference` method, receives a request body and passes it to the `invoke_endpoint_with_response_stream` method of the SDK.
- Iterates over each event in the `EventStream` object that the SDK returns.

- From each event, gets the contents of the `Bytes` object in the `PayloadPart` object.
- In the example `_write` method, writes to a buffer to concatenate the contents of the `Bytes` objects. The combined contents form a newline-delimited JSON body.
- Uses the example `_readlines` method to get an iterable series of JSON objects.
- In each JSON object, gets a piece of the inference.
- With the `yield` expression, returns the pieces incrementally.

The following example creates and uses a `SmrInferenceStream` object:

```
request_body = {"inputs": ["Large model inference is"],
                "parameters": {"max_new_tokens": 100,
                               "enable_sampling": "true"}}
smr_inference_stream = SmrInferenceStream(
    sagemaker_runtime, endpoint_name)
stream = smr_inference_stream.stream_inference(request_body)
for part in stream:
    print(part, end='')
```

This example passes a request body to the `stream_inference` method. It iterates over the response to print each piece that the inference stream returns.

The example assumes that the model at the specified endpoint is an LLM that generates text. The output from this example is a body of generated text that prints incrementally:

```
a challenging problem in machine learning. The goal is to . . .
```

Invoke Your Model by Using the Amazon CLI

You can invoke your model endpoint by running commands with the Amazon Command Line Interface (Amazon CLI). The Amazon CLI supports standard inference requests with the `invoke-endpoint` command, and it supports asynchronous inference requests with the `invoke-endpoint-async` command.

> **Note**
>
> The Amazon CLI doesn't support streaming inference requests.

The following example uses the `invoke-endpoint` command to send an inference request to a model endpoint:

```
aws sagemaker-runtime invoke-endpoint \
    --endpoint-name endpoint_name \
    --body fileb://$file_name \
    output_file.txt
```

For the `--endpoint-name` parameter, provide the endpoint name that you specified when you created the endpoint. For the `--body` parameter, provide input data for SageMaker AI to pass to the model. The data must be in the same format that was used for training. This example shows how to send binary data to your endpoint.

For more information on when to use `file://` over `fileb://` when passing the contents of a file to a parameter of the Amazon CLI, see Best Practices for Local File Parameters.

For more information, and to see additional parameters that you can pass, see `invoke-endpoint` in the *Amazon CLI Command Reference*.

If the `invoke-endpoint` command succeeds it returns a response such as the following:

```
{
    "ContentType": "<content_type>; charset=utf-8",
    "InvokedProductionVariant": "<Variant>"
}
```

If the command doesn't succeed, check whether the input payload is in the correct format.

View the output of the invocation by checking the file output file (`output_file.txt` in this example).

```
more output_file.txt
```

Invoke Your Model by Using the Amazon SDK for Python

Invoke to Bidirectionally Stream an Inference Request and Response

If you want to invoke a model endpoint in your application code to supports bidirectional streaming, you can use the new experimental SDK for Python that supports bidirectional streaming capability with HTTP/2 support. This SDK enables real-time, two-way communication between your client application and the SageMaker endpoint, allowing you to send inference requests

incrementally while simultaneously receiving streaming responses as the model generates them. This is particularly useful for interactive applications where both the client and server need to exchange data continuously over a persistent connection.

> **Note**
>
> The new experimental SDK is different from the standard Boto3 SDK and supports persistent bidirectional connections for data exchange. While using the experimental Python SDK we strongly advise strict pinning to a version of the SDK for any non-experimental use cases.

To invoke your endpoint with bidirectional streaming, use the `invoke_endpoint_with_bidirectional_stream` method. This method establishes a persistent connection that allows you to stream multiple payload chunks to your model while receiving responses in real-time as the model processes data. The connection remains open until you explicitly close the input stream or the endpoint closes the connection, supporting up to 30 minutes of connection time.

Prerequisites

Before you can use bidirectional streaming in your application code, you must:

1. Install the experimental SageMaker Runtime HTTP/2 SDK
2. Set up Amazon credentials for your SageMaker Runtime client
3. Deploy a model that supports bidirectional streaming to a SageMaker endpoint

Set up the bidirectional streaming client

The following example shows how to initialize the required components for bidirectional streaming:

```
from sagemaker_runtime_http2.client import SageMakerRuntimeHTTP2Client
from sagemaker_runtime_http2.config import Config, HTTPAuthSchemeResolver
from smithy_aws_core.identity import EnvironmentCredentialsResolver
from smithy_aws_core.auth.sigv4 import SigV4AuthScheme

# Configuration
AWS_REGION = "us-west-2"
```

```
BIDI_ENDPOINT = f"https://runtime.sagemaker.{AWS_REGION}.amazonaws.com:8443"
ENDPOINT_NAME = "your-endpoint-name"

# Initialize the client configuration
config = Config(
    endpoint_uri=BIDI_ENDPOINT,
    region=AWS_REGION,
    aws_credentials_identity_resolver=EnvironmentCredentialsResolver(),
    auth_scheme_resolver=HTTPAuthSchemeResolver(),
    auth_schemes={"aws.auth#sigv4": SigV4AuthScheme(service="sagemaker")}
)

# Create the SageMaker Runtime HTTP/2 client
client = SageMakerRuntimeHTTP2Client(config=config)
```

Complete bidirectional streaming client

The following example demonstrates how to create a bidirectional streaming client that sends multiple text payloads to a SageMaker endpoint and processes responses in real-time:

```
import asyncio
import logging
from sagemaker_runtime_http2.client import SageMakerRuntimeHTTP2Client
from sagemaker_runtime_http2.config import Config, HTTPAuthSchemeResolver
from sagemaker_runtime_http2.models import (
    InvokeEndpointWithBidirectionalStreamInput,
    RequestStreamEventPayloadPart,
    RequestPayloadPart
)
from smithy_aws_core.identity import EnvironmentCredentialsResolver
from smithy_aws_core.auth.sigv4 import SigV4AuthScheme

logging.basicConfig(level=logging.INFO)
logger = logging.getLogger(__name__)

class SageMakerBidirectionalClient:

    def __init__(self, endpoint_name, region="us-west-2"):
        self.endpoint_name = endpoint_name
        self.region = region
        self.client = None
        self.stream = None
        self.response_task = None
```

```
        self.is_active = False

    def _initialize_client(self):
        bidi_endpoint = f"runtime.sagemaker.{self.region}.amazonaws.com:8443"
        config = Config(
            endpoint_uri=bidi_endpoint,
            region=self.region,
            aws_credentials_identity_resolver=EnvironmentCredentialsResolver(),
            auth_scheme_resolver=HTTPAuthSchemeResolver(),
            auth_schemes={"aws.auth#sigv4": SigV4AuthScheme(service="sagemaker")}
        )
        self.client = SageMakerRuntimeHTTP2Client(config=config)

    async def start_session(self):
        """Establish a bidirectional streaming connection with the endpoint."""
        if not self.client:
            self._initialize_client()

        logger.info(f"Starting session with endpoint: {self.endpoint_name}")
        self.stream = await self.client.invoke_endpoint_with_bidirectional_stream(

InvokeEndpointWithBidirectionalStreamInput(endpoint_name=self.endpoint_name)
        )
        self.is_active = True

        # Start processing responses concurrently
        self.response_task = asyncio.create_task(self._process_responses())

    async def send_message(self, message):
        """Send a single message to the endpoint."""
        if not self.is_active:
            raise RuntimeError("Session not active. Call start_session() first.")

        logger.info(f"Sending message: {message}")
        payload = RequestPayloadPart(bytes_=message.encode('utf-8'))
        event = RequestStreamEventPayloadPart(value=payload)
        await self.stream.input_stream.send(event)

    async def send_multiple_messages(self, messages, delay=1.0):
        """Send multiple messages with a delay between each."""
        for message in messages:
            await self.send_message(message)
            await asyncio.sleep(delay)
```

```
    async def end_session(self):
        """Close the bidirectional streaming connection."""
        if not self.is_active:
            return

        await self.stream.input_stream.close()
        self.is_active = False
        logger.info("Stream closed")

        # Cancel the response processing task
        if self.response_task and not self.response_task.done():
            self.response_task.cancel()

    async def _process_responses(self):
        """Process incoming responses from the endpoint."""
        try:
            output = await self.stream.await_output()
            output_stream = output[1]

            while self.is_active:
                result = await output_stream.receive()

                if result is None:
                    logger.info("No more responses")
                    break

                if result.value and result.value.bytes_:
                    response_data = result.value.bytes_.decode('utf-8')
                    logger.info(f"Received: {response_data}")

        except Exception as e:
            logger.error(f"Error processing responses: {e}")

# Example usage
async def run_bidirectional_client():
    client = SageMakerBidirectionalClient(endpoint_name="your-endpoint-name")

    try:
        # Start the session
        await client.start_session()

        # Send multiple messages
        messages = [
            "I need help with",
```

```
            "my account balance",
            "I can help with that",
            "and recent charges"
        ]
        await client.send_multiple_messages(messages)

        # Wait for responses to be processed
        await asyncio.sleep(2)

        # End the session
        await client.end_session()
        logger.info("Session ended successfully")

    except Exception as e:
        logger.error(f"Client error: {e}")
        await client.end_session()

if __name__ == "__main__":
    asyncio.run(run_bidirectional_client())
```

The client initializes the SageMaker Runtime HTTP/2 client with the regional endpoint URI on port 8443, which is required for bidirectional streaming connections. The start_session() method calls invoke_endpoint_with_bidirectional_stream() to establish the persistent connection and creates an asynchronous task to process incoming responses concurrently.

The send_event() method wraps payload data in the appropriate request objects and sends them through the input stream, while the _process_responses() method continuously listens for and processes responses from the endpoint as they arrive. This bidirectional approach enables real-time interaction where both sending requests and receiving responses happen simultaneously over the same connection.

Invoke endpoints with OpenAI-compatible APIs

Amazon SageMaker AI real-time inference endpoints support an OpenAI-compatible API path. Customers using the OpenAI SDK, LangChain, or Strands Agents can invoke models on SageMaker AI by changing only their endpoint URL, without requiring custom clients, SigV4 wrappers, or code rewrites.

With this capability, SageMaker AI endpoints expose an /openai/v1/chat/completions path that accepts Chat Completions requests and returns responses directly from the container,

including streaming. OpenAI-compatible endpoints are available on all endpoints and inference components using standard SageMaker AI APIs and SDKs.

SageMaker AI routes requests based on the endpoint name in the URL. Any OpenAI-compatible client works without additional configuration. You can create short-lived bearer tokens for your endpoints and use them with your OpenAI clients.

Prerequisites

Before you begin, make sure you have the following:

- An Amazon account with permissions to create SageMaker AI endpoints.
- The SageMaker AI Python SDK installed (`pip install sagemaker`).
- The OpenAI Python SDK installed (`pip install openai`).
- A model stored in Amazon S3 (for example, Qwen3-4B downloaded from Hugging Face).
- An IAM execution role with the `AmazonSageMakerFullAccess` policy to create the endpoints.
- An IAM role or user with the `sagemaker:CallWithBearerToken` and `sagemaker:InvokeEndpoint` permissions to invoke the endpoint.

Authentication with bearer tokens

SageMaker AI OpenAI-compatible endpoints use bearer token authentication. The SageMaker AI Python SDK includes a token generator that creates short-lived tokens (valid up to 12 hours) from your existing Amazon credentials. No additional secrets or API keys are required.

The token contains your role or user credentials and requires the `sagemaker:CallWithBearerToken` and `sagemaker:InvokeEndpoint` action permissions.

Generate a token

Use the `generate_token` function from the SageMaker AI Python SDK to create a bearer token:

```
from sagemaker.core.token_generator import generate_token
from datetime import timedelta

token = generate_token(region="us-west-2", expiry=timedelta(minutes=5))
```

The `generate_token` function generates a short-lived bearer token for authenticating with SageMaker AI APIs. By default, tokens are valid for 12 hours. You can override this with the `expiry` parameter using a `timedelta` value anywhere between 1 second and 12 hours.

The function accepts a `region`, an optional `aws_credentials_provider`, and the `expiry` duration. If no region is provided, it falls back to the `AWS_REGION` environment variable. If no credentials provider is supplied, it resolves credentials using the default Amazon credential chain, which searches multiple sources including environment variables, `~/.aws/credentials`, `~/.aws/config`, container credentials, and instance profiles. For the full resolution order, see the boto3 credentials documentation.

Auto-refresh tokens for long-running applications

For applications that run continuously, you can implement an auto-refreshing pattern using `httpx` so that a fresh token is generated on each request:

```
import httpx
from sagemaker.core.token_generator import generate_token

class SageMakerAuth(httpx.Auth):
    def __init__(self, region: str):
        self.region = region

    def auth_flow(self, request):
        request.headers["Authorization"] = f"Bearer
 {generate_token(region=self.region)}"
        yield request

http_client = httpx.Client(auth=SageMakerAuth(region="us-west-2"))
```

IAM permissions

The IAM role or user invoking the endpoint needs the following permissions:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "sagemaker:InvokeEndpoint",
            "Resource": "arn:aws:sagemaker:REGION:ACCOUNT_ID:endpoint/ENDPOINT_NAME"
        },
```

```
        {
            "Effect": "Allow",
            "Action": "sagemaker:CallWithBearerToken",
            "Resource": "*"
        }
    ]
}
```

Important

Always restrict the `Resource` for `sagemaker:InvokeEndpoint` to specific endpoint ARNs rather than using a wildcard. The bearer token generated from this role has the same level of access, so a narrowly scoped policy limits the blast radius if a token is inadvertently exposed.

Note

`sagemaker:CallWithBearerToken` requires a wildcard (`"*"`) for the `Resource` field. It does not support resource-level restrictions.

How the token works

The bearer token is a base64-encoded SigV4 pre-signed URL. When you call `generate_token`, the SageMaker AI SDK constructs a request to the SageMaker AI service for the `CallWithBearerToken` action, signs it locally using your Amazon credentials, and encodes the resulting signed URL as a portable token string. No network call is made during token generation — the signing happens entirely on the client side.

When you present this token to a SageMaker AI endpoint, the service decodes it, validates the SigV4 signature, verifies that the token has not expired, and confirms that the originating IAM identity has the required permissions. The token's effective lifetime is the lesser of the `expiry` value and the remaining validity of the Amazon credentials used to sign it.

Security best practices

The bearer token carries the same authorization as the underlying Amazon credentials used to generate it. Treat tokens with the same care as credentials. Follow these best practices:

- Scope the IAM role used for token generation to the minimum permissions required — specifically `sagemaker:InvokeEndpoint` and `sagemaker:CallWithBearerToken` on only the endpoint ARNs that the caller needs to access.
- Do not generate tokens from roles with expansive permissions, such as those granted by `AdministratorAccess` or `AmazonSageMakerFullAccess` managed policies.
- Do not store tokens on disk, in environment variables, in configuration files, in databases, or in distributed caches. Do not log tokens, and only transmit them over encrypted communication protocols such as HTTPS.
- Token generation is a local operation with no network overhead. Generate a fresh token at the point of use or use the auto-refreshing `httpx.Auth` pattern shown above.
- Set the token expiry to the shortest duration your workload requires.

Invoke a single-model endpoint

A single-model endpoint hosts one model and serves requests directly. The following example deploys Qwen3-4B using the SageMaker AI vLLM Deep Learning Container on an `ml.g6.2xlarge` instance.

> **Note**
>
> SageMaker AI endpoints incur charges while in service, regardless of traffic. See the SageMaker AI pricing page for details.

Deploy the endpoint

```
import boto3
import sagemaker
import time
from sagemaker.core.helper.session_helper import Session
from sagemaker.core.helper.session_helper import get_execution_role

# AWS configuration
REGION = "us-west-2"

# Automatically resolve account ID and default SageMaker execution role
session = Session(boto_session=boto3.Session(region_name=REGION))
ACCOUNT_ID = boto3.client("sts", region_name=REGION).get_caller_identity()["Account"]
```

```
EXECUTION_ROLE = get_execution_role(sagemaker_session=session)

# HF Model ID
MODEL_HF_ID = "Qwen/Qwen3-4B"

# SageMaker vLLM Deep Learning Container
VLLM_IMAGE = (
    f"763104351884.dkr.ecr.{REGION}.amazonaws.com/"
    f"vllm:0.20.2-gpu-py312-cu130-ubuntu22.04-sagemaker"
)

# Instance type (1x NVIDIA L4 GPU)
INSTANCE_TYPE = "ml.g6.2xlarge"

sagemaker_client = boto3.client("sagemaker", region_name=REGION)
```

Create the model, endpoint configuration, and endpoint:

```
TIMESTAMP = str(int(time.time()))

SME_MODEL_NAME = f"openai-compat-sme-model-{TIMESTAMP}"
SME_ENDPOINT_CONFIG_NAME = f"openai-compat-sme-epc-{TIMESTAMP}"
SME_ENDPOINT_NAME = f"openai-compat-sme-ep-{TIMESTAMP}"

sagemaker_client.create_model(
    ModelName=SME_MODEL_NAME,
    ExecutionRoleArn=EXECUTION_ROLE,
    PrimaryContainer={
        "Image": VLLM_IMAGE,
        "Environment": {
            "HF_MODEL_ID": MODEL_HF_ID,
            "SM_VLLM_TENSOR_PARALLEL_SIZE": "1",
            "SM_VLLM_MAX_NUM_SEQS": "4",
            "SM_VLLM_ENABLE_AUTO_TOOL_CHOICE": "true",
            "SM_VLLM_TOOL_CALL_PARSER": "hermes",
            "SAGEMAKER_ENABLE_LOAD_AWARE": "1",
        },
    },
)

sagemaker_client.create_endpoint_config(
    EndpointConfigName=SME_ENDPOINT_CONFIG_NAME,
    ProductionVariants=[
```

```
        {
            "VariantName": "variant1",
            "ModelName": SME_MODEL_NAME,
            "InstanceType": INSTANCE_TYPE,
            "InitialInstanceCount": 1,
        }
    ],
)

sagemaker_client.create_endpoint(
    EndpointName=SME_ENDPOINT_NAME,
    EndpointConfigName=SME_ENDPOINT_CONFIG_NAME,
)

# Wait for endpoint to reach InService status (5-10 minutes)
waiter = sagemaker_client.get_waiter("endpoint_in_service")
waiter.wait(
    EndpointName=SME_ENDPOINT_NAME,
    WaiterConfig={"Delay": 30, "MaxAttempts": 40},
)
```

The endpoint transitions to `InService` status within a few minutes. Once ready, it serves both the standard SageMaker AI `/invocations` path and the OpenAI-compatible path at `/openai/v1/chat/completions`.

Invoke the endpoint

With the endpoint in service, invoke it using the OpenAI Python SDK. The base URL follows this format:

```
https://runtime.sagemaker.REGION.amazonaws.com/endpoints/ENDPOINT_NAME/openai/v1
```

```
from openai import OpenAI
from sagemaker.core.token_generator import generate_token

REGION = "us-west-2"
sme_base_url = (
    f"https://runtime.sagemaker.{REGION}.amazonaws.com"
    f"/endpoints/{SME_ENDPOINT_NAME}/openai/v1"
)

client = OpenAI(
```

```
    base_url=sme_base_url,
    api_key=generate_token(region=REGION),
)

stream = client.chat.completions.create(
    model="",
    messages=[
        {"role": "system", "content": "You are a helpful assistant."},
        {"role": "user", "content": "Explain how transformers work in machine learning,
 in three sentences."},
    ],
    stream=True,
)

for chunk in stream:
    if chunk.choices[0].delta.content:
        print(chunk.choices[0].delta.content, end="")
print()
```

The `model` field is passed through to the container. Because SageMaker AI routes requests based on the endpoint name in the URL, you can leave this field empty or set it to match the model name your container expects.

Invoke inference components

Inference components allow you to host multiple models on a single endpoint, each with dedicated compute resource allocations. With inference components, the model is associated with the component rather than the endpoint configuration.

Deploy an inference component endpoint

```
IC_MODEL_NAME = f"openai-compat-ic-model-{TIMESTAMP}"
IC_ENDPOINT_CONFIG_NAME = f"openai-compat-ic-epc-{TIMESTAMP}"
IC_ENDPOINT_NAME = f"openai-compat-ic-ep-{TIMESTAMP}"
IC_NAME = f"openai-compat-ic-qwen3-4b-{TIMESTAMP}"

sagemaker_client.create_model(
    ModelName=IC_MODEL_NAME,
    ExecutionRoleArn=EXECUTION_ROLE,
    PrimaryContainer={
        "Image": VLLM_IMAGE,
        "Environment": {
            "HF_MODEL_ID": MODEL_HF_ID,
```

```
            "SM_VLLM_TENSOR_PARALLEL_SIZE": "1",
            "SM_VLLM_MAX_NUM_SEQS": "4",
            "SM_VLLM_ENABLE_AUTO_TOOL_CHOICE": "true",
            "SM_VLLM_TOOL_CALL_PARSER": "hermes",
            "SAGEMAKER_ENABLE_LOAD_AWARE": "1",
        },
    },
)

sagemaker_client.create_endpoint_config(
    EndpointConfigName=IC_ENDPOINT_CONFIG_NAME,
    ExecutionRoleArn=EXECUTION_ROLE,
    ProductionVariants=[
        {
            "VariantName": "variant1",
            "InstanceType": INSTANCE_TYPE,
            "InitialInstanceCount": 1,
        }
    ],
)

sagemaker_client.create_endpoint(
    EndpointName=IC_ENDPOINT_NAME,
    EndpointConfigName=IC_ENDPOINT_CONFIG_NAME,
)

# Wait for endpoint
waiter = sagemaker_client.get_waiter("endpoint_in_service")
waiter.wait(
    EndpointName=IC_ENDPOINT_NAME,
    WaiterConfig={"Delay": 30, "MaxAttempts": 40},
)

# Create the inference component
sagemaker_client.create_inference_component(
    InferenceComponentName=IC_NAME,
    EndpointName=IC_ENDPOINT_NAME,
    VariantName="variant1",
    Specification={
        "ModelName": IC_MODEL_NAME,
        "ComputeResourceRequirements": {
            "MinMemoryRequiredInMb": 1024,
            "NumberOfCpuCoresRequired": 2,
            "NumberOfAcceleratorDevicesRequired": 1,
```

```
        },
    },
    RuntimeConfig={"CopyCount": 1},
)

# Wait for inference component
while True:
    desc =
 sagemaker_client.describe_inference_component(InferenceComponentName=IC_NAME)
    status = desc["InferenceComponentStatus"]
    if status == "InService":
        break
    elif status == "Failed":
        raise RuntimeError(f"Inference component failed: {desc.get('FailureReason',
 'unknown')}")
    time.sleep(30)
```

You can create additional inference components on the same endpoint to host multiple models with independent scaling and resource allocation.

Invoke an inference component

To invoke a specific inference component, include its name in the URL path:

```
https://runtime.sagemaker.REGION.amazonaws.com/endpoints/ENDPOINT_NAME/inference-
components/IC_NAME/openai/v1
```

The following example shows how to invoke an inference component using the OpenAI SDK with a shared connection pool:

```
import httpx
from openai import OpenAI
from sagemaker.core.token_generator import generate_token

shared_http = httpx.Client()

client_a = OpenAI(
    base_url=(
        f"https://runtime.sagemaker.{REGION}.amazonaws.com"
        f"/endpoints/{IC_ENDPOINT_NAME}/inference-components/{IC_NAME}/openai/v1"
    ),
    api_key=generate_token(region=REGION),
    http_client=shared_http,
```

```
)

response = client_a.chat.completions.create(
    model="",
    messages=[{"role": "user", "content": "What is 42 * 3? Reply with the number."}],
)
print(response.choices[0].message.content)
```

The shared `httpx.Client` allows multiple OpenAI client instances to reuse the same TLS sessions and connection pool when targeting different inference components on the same endpoint.

Supported containers

The following containers support OpenAI-compatible APIs on SageMaker AI. The container must implement the `/v1/chat/completions` path and return streaming responses in SSE format.

Container	Support status
SageMaker AI vLLM Deep Learning Container	Supported
SageMaker AI SGLang Deep Learning Container	Supported
Custom containers implementing OpenAI API paths and `/ping`	Supported

Endpoints

After deploying your model to an endpoint, you might want to view and manage the endpoint. With SageMaker AI, you can view the status and details of your endpoint, check metrics and logs to monitor your endpoint's performance, update the models deployed to your endpoint, and more.

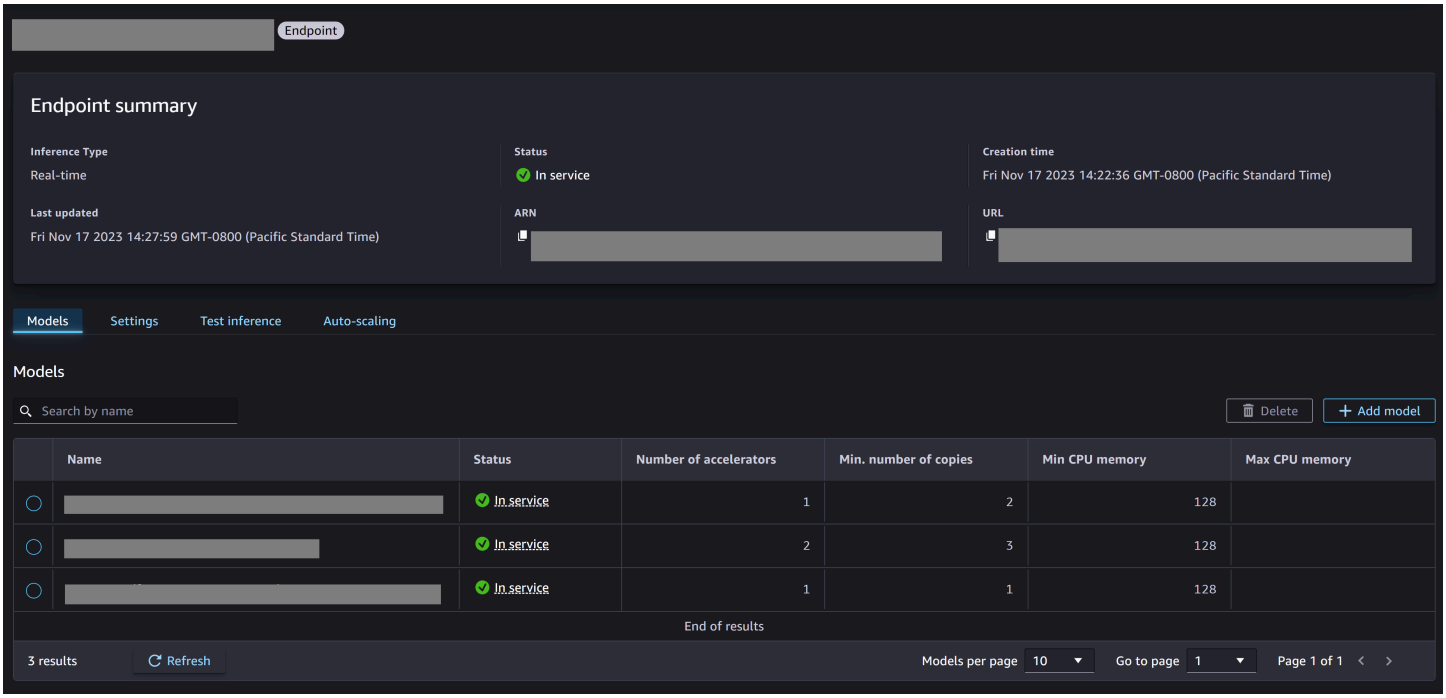
The following sections show how you can manage endpoints within Amazon SageMaker Studio or within the Amazon Web Services Management Console.

The following page describes how to interactively view and make changes to your endpoints using the Amazon SageMaker AI console or SageMaker Studio.

Topics

- View endpoint details in SageMaker Studio
- View endpoint details in the SageMaker AI console

View endpoint details in SageMaker Studio



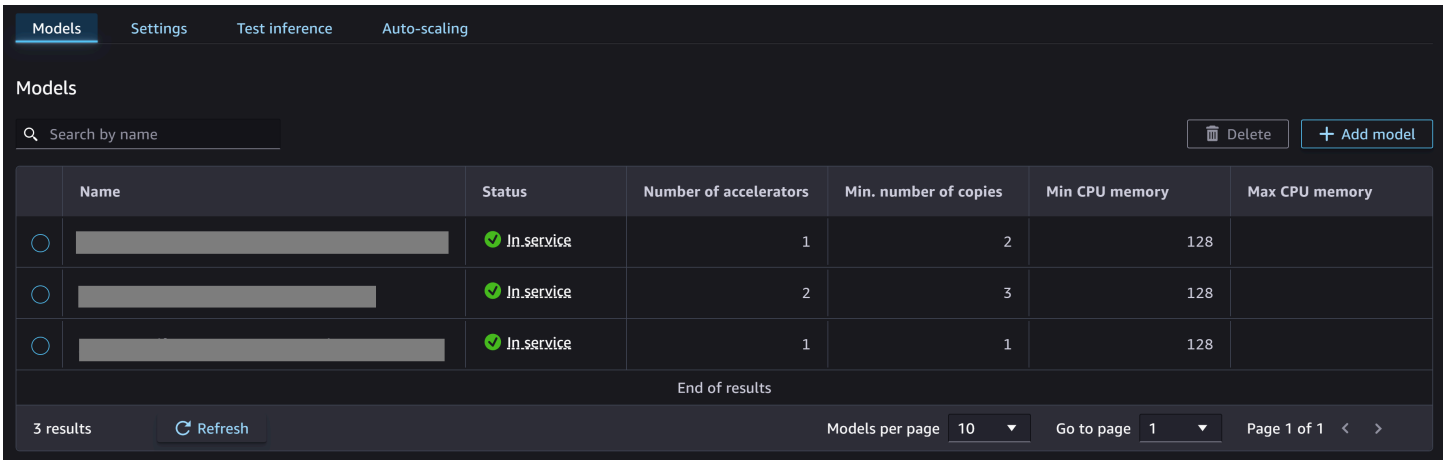
In Amazon SageMaker Studio, you can view and manage your SageMaker AI Hosting endpoints. To learn more about Studio, see Amazon SageMaker Studio.

To find the list of your endpoints in SageMaker Studio do the following:

1. Open the Studio application.
2. In the left navigation pane, choose **Deployments**.
3. From the dropdown menu, choose **Endpoints**.

The **Endpoints** page opens, which lists all of your SageMaker AI Hosting endpoints. From this page, you can see the endpoints and their **Status**. You can also create a new endpoint, edit an existing endpoint, or delete an endpoint.

To see the details for a specific endpoint, choose an endpoint from the list. On the endpoint's details page, you get an overview like the following screenshot.



Each endpoint details page contains the following tabs of information:

View Variants (or Models)

The **Variants** tab (also called the **Models** tab if your endpoint has multiple models deployed) shows you the list of model variants or models currently deployed to your endpoint. The following

screenshot shows you what the overview and **Models** section looks like for an endpoint with multiple models deployed.

You can add or edit the settings for each variant or model. You can also select a variant and enable a default auto-scaling policy, which you can edit later in the **Auto-scaling** tab.

View settings

On the **Settings** tab, you can view the endpoint's associated Amazon IAM role, the Amazon KMS key used for encryption (if applicable), the name of your VPC, and the network isolation settings.

Test inference

On the **Test inference** tab, you can send a test inference request to a deployed model. This is useful if you'd like to verify that your endpoint responds to requests as expected.

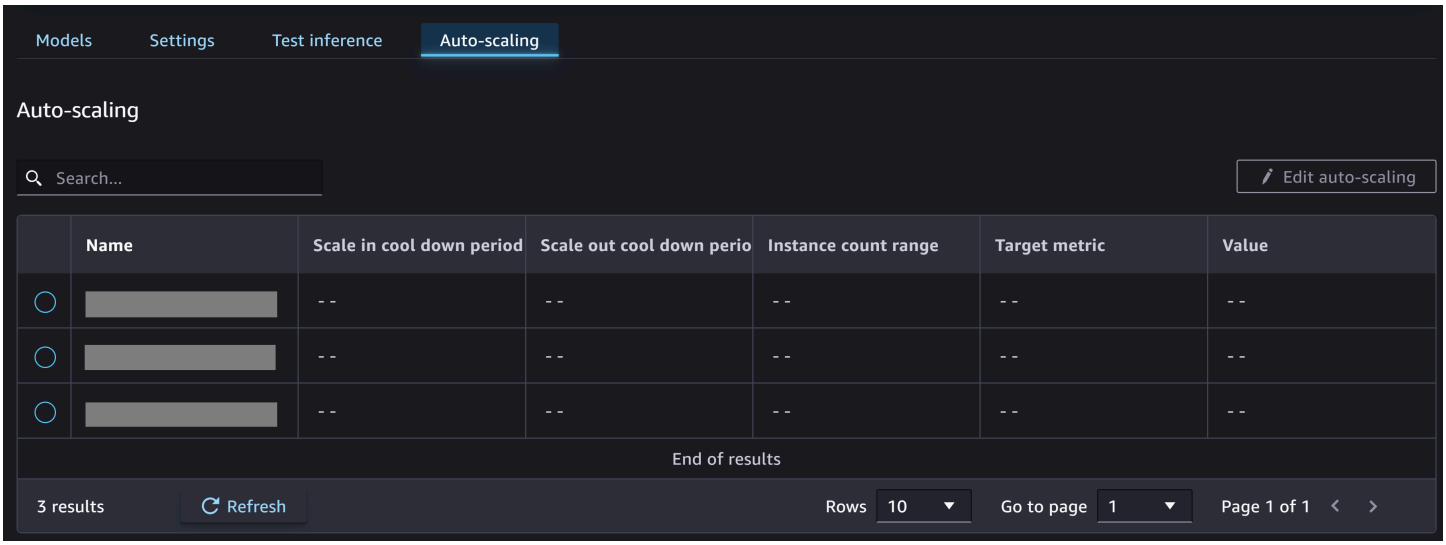
To test inference, do the following:

1. On the model's **Test inference** tab, choose one of the following options:

    a. Select **Enter the request body** if you'd like to test the endpoint and receive a response through the Studio interface.

    b. Select **Copy example code (Python)** if you'd like to copy an Amazon SDK for Python (Boto3) example that you can use to invoke your endpoint from a local environment and receive a response programmatically.

2. For **Model**, select the model that you want to test on the endpoint.
3. If you chose the Studio interface testing method, then you can also choose your desired **Content type** for the response from the dropdown.



After configuring your request, then you can either choose **Send request** (to receive a response through the Studio interface) or **Copy** to copy the Python example.

If you receive a response through the Studio interface, it'll look like the following screenshot.

Auto-scaling

On the **Auto-scaling** tab, you can view any auto-scaling policies configured for the models hosted on your endpoint. The following screenshot shows you the **Auto-scaling** tab.

You can choose **Edit auto-scaling** to change any of the policies and turn on or turn off the default auto-scaling policy.

To learn more about auto-scaling for real-time endpoints, see Automatically Scale Amazon SageMaker AI Models. If you're not sure how to configure an auto-scaling policy for your endpoint, you can use an Inference Recommender autoscaling recommendations job to get recommendations for an auto-scaling policy.

View endpoint details in the SageMaker AI console

To view your endpoints in the SageMaker AI console, do the following:

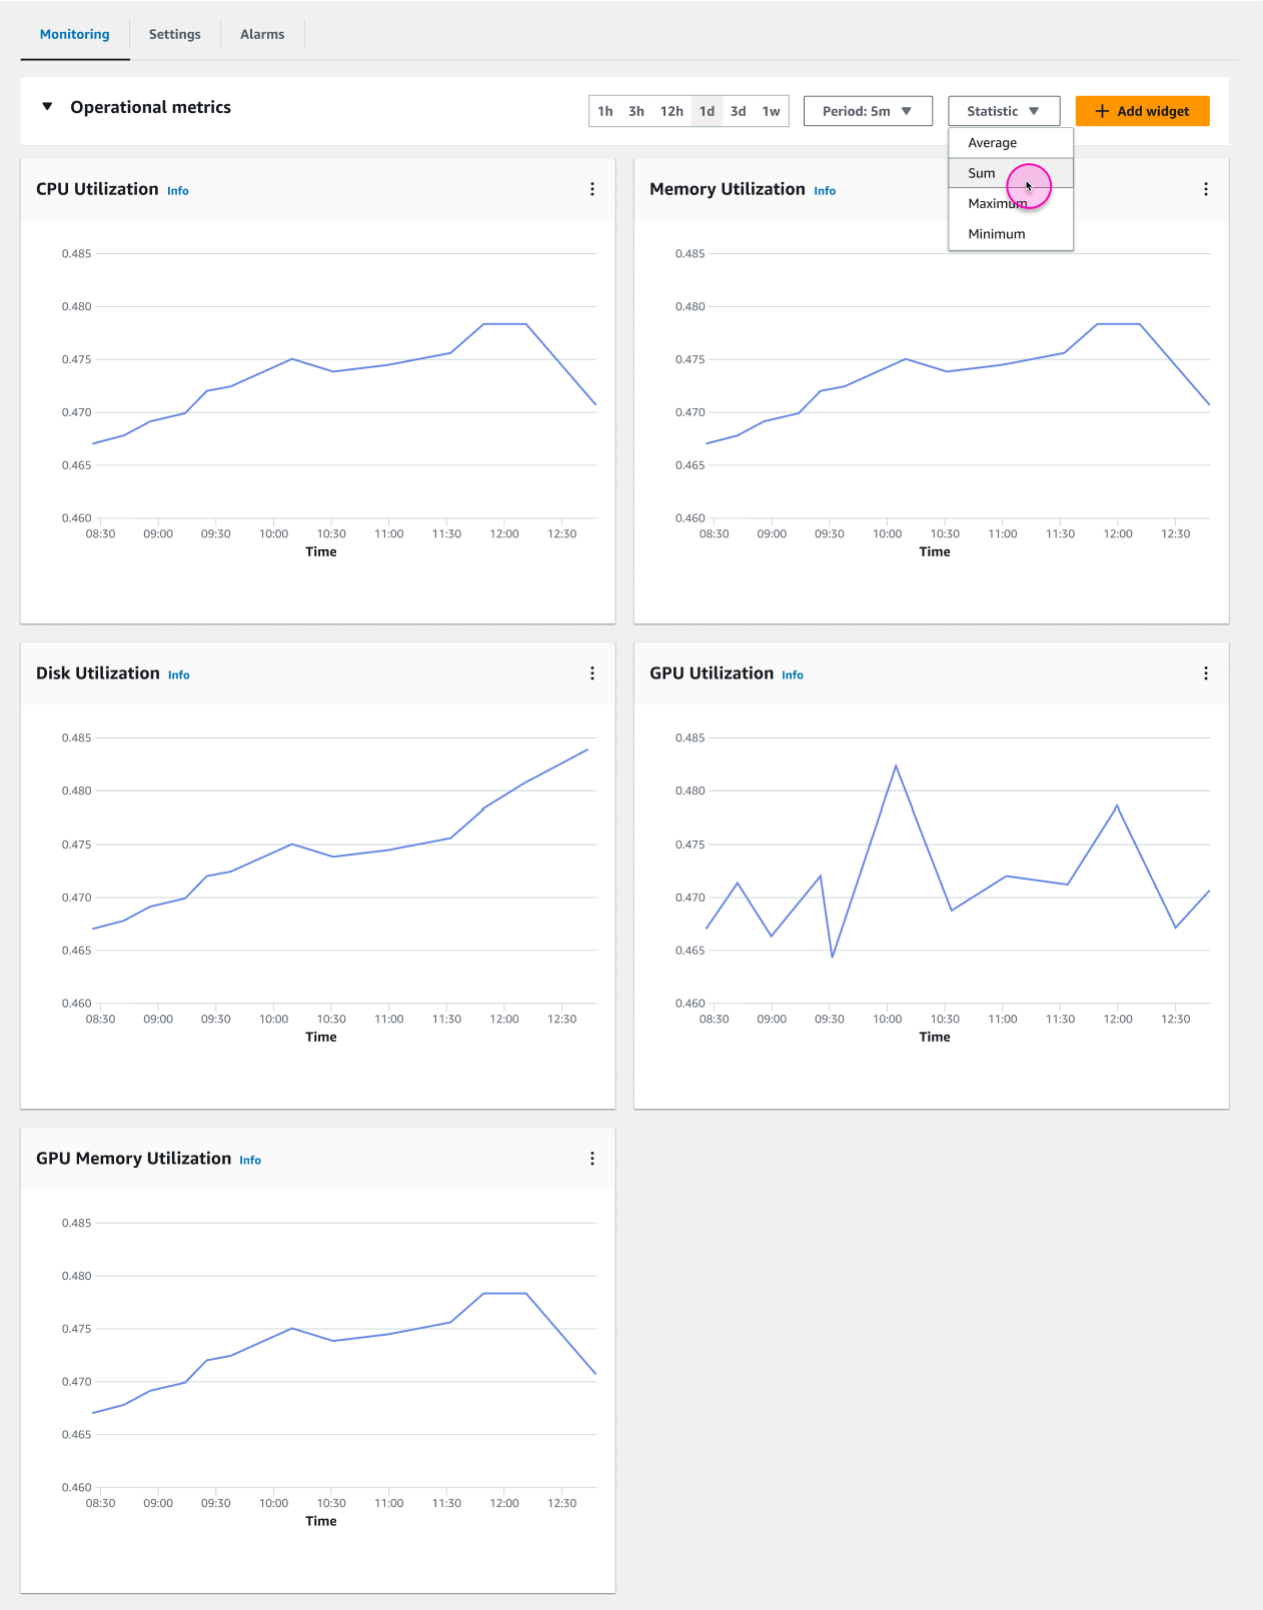
1. Go to the SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the left navigation pane, choose **Inference**.
3. From the dropdown list, choose **Endpoints**.
4. On the **Endpoints** page, choose your endpoint.

The endpoint details page should open, showing you a summary of your endpoint and metrics that have been collected for your endpoint.

The following sections describe the tabs on the endpoints details page.

Endpoints monitoring

After creating a SageMaker AI Hosting endpoint, you can monitor your endpoint using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. Using these metrics, you can access historical information and gain a better perspective on how your endpoint is performing. For more information, see the *Amazon CloudWatch User Guide*.



From the **Monitoring** tab on the endpoint details page, you can view CloudWatch metrics data that has been collected from your endpoint.

The **Monitoring** tab includes the following sections:

- **Operational metrics**: View metrics that track the utilization of your endpoint's resources, such as CPU Utilization and Memory Utilization.
- **Invocation metrics**: View metrics that track the number, health, and status of `InvokeEndpoint` requests coming to your endpoint, such as Invocation Model Errors and Model Latency.
- **Health metrics**: View metrics that track your endpoint's overall health, such as Invocation Failures and Notification Failures.

For detailed descriptions of each metric, see Monitor SageMaker AI with CloudWatch.

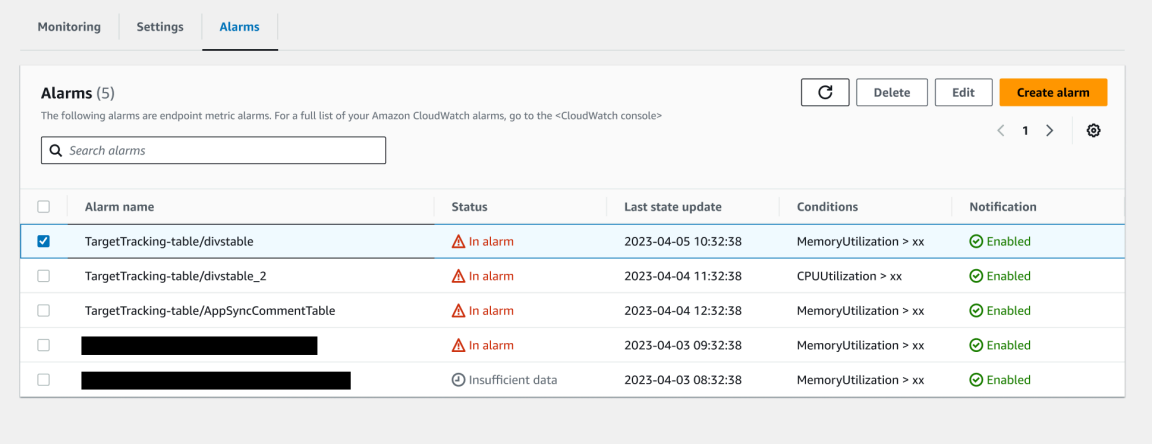
The following screenshot shows the **Operational metrics** section for a serverless endpoint.

You can adjust the **Period** and **Statistic** that you want to track for the metrics in a given section, as well as the length of time for which you want to view metrics data. You can also add and remove metric widgets from the view for each section by choosing **Add widget**. In the **Add widget** dialog box, you can select and deselect the metrics that you want to see.

The metrics that are available may depend on your endpoint type. For example, serverless endpoints have some metrics that aren't available for real-time endpoints. For more specific metrics information by endpoint type, see the following pages:

- Monitor a serverless endpoint
- Monitor an asynchronous endpoint
- CW Metrics for Multi-Model Endpoint Deployments
- Inference Pipeline Logs and Metrics

Settings



You can choose the **Settings** tab to view additional information about your endpoint, such as the data capture settings, the endpoint configuration, and tags.

Create and view alarms

From the **Alarms** tab on your endpoint details page, you can view and create simple static threshold metric alarms, where you specify a threshold value for a metric. If the metric breaches the threshold value, the alarm goes into the `ALARM` state. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms.

In the **Endpoint summary** section, you can view the **Alarms** field, which tells you how many alarms are currently active on your endpoint.

To view which alarms are in the `ALARM` state, choose the **Alarms** tab. The **Alarms** tab shows you a full list of your endpoint alarms, along with details about their status and conditions. The following screenshot shows a list of alarms in this section that have been configured for an endpoint.

An alarm's status can be `In alarm`, `OK`, or `Insufficient data` if there isn't enough metrics data being collected.

To create a new alarm for your endpoint, do the following:

1. In the **Alarms** tab, choose **Create alarm**.
2. The **Create alarm** page opens. For **Alarm name**, enter a name for the alarm.
3. (Optional) Enter a description for the alarm.
4. For **Metric**, choose the CloudWatch metric that you want the alarm to track.
5. For **Variant name**, choose the endpoint model variant that you want to monitor.
6. For **Statistic**, choose one of the available statistics for the metric you selected.
7. For **Period**, choose the time period to use for calculating each statistical value. For example, if you choose the Average statistic and a 5 minute period, each data point monitored by the alarm is the average of the metric's data points at 5 minute intervals.
8. For **Evaluation periods**, enter the number of data points that you want the alarm to consider when evaluating whether to enter the alarm state or not.
9. For **Condition**, choose the conditional that you want to use for your alarm threshold.
10. For **Threshold value**, enter the desired value for your threshold.
11. (Optional) For **Notification**, you can choose **Add notification** to create or specify an Amazon SNS topic that receives a notification when your alarm state changes.
12. Choose **Create alarm**.

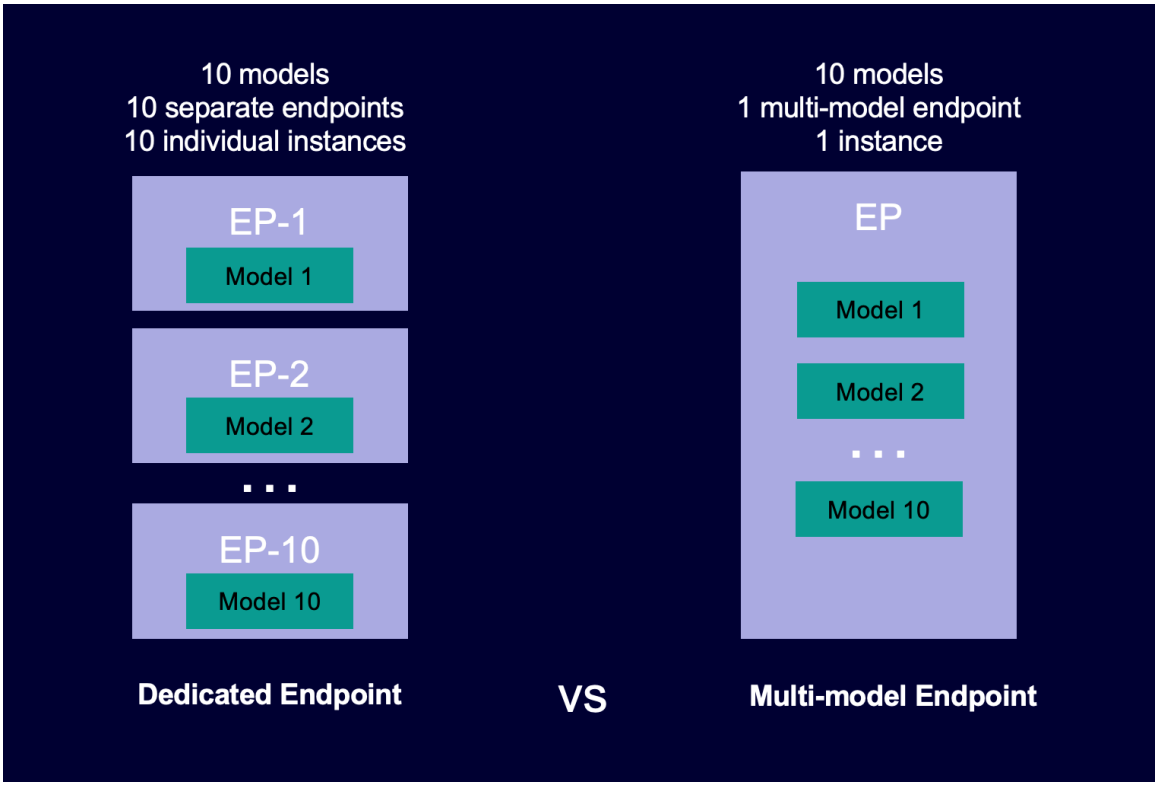
After creating your alarm, you can return to the **Alarms** tab to view its status at any time. From this section, you can also select the alarm and either **Edit** or **Delete** it.

Hosting options

The following topics describe available SageMaker AI realtime hosting options along with how to set up, invoke, and delete each hosting option.

Topics

- Single-model endpoints
- Multi-model endpoints
- Multi-container endpoints
- Inference pipelines in Amazon SageMaker AI
- Delete Endpoints and Resources



Single-model endpoints

You can create, update, and delete real-time inference endpoints that host a single model with Amazon SageMaker Studio, the Amazon SDK for Python (Boto3), the SageMaker Python SDK, or the Amazon CLI. For procedures and code examples, see Deploy models for real-time inference.

Multi-model endpoints

Multi-model endpoints provide a scalable and cost-effective solution to deploying large numbers of models. They use the same fleet of resources and a shared serving container to host all of your models. This reduces hosting costs by improving endpoint utilization compared with using single-model endpoints. It also reduces deployment overhead because Amazon SageMaker AI manages loading models in memory and scaling them based on the traffic patterns to your endpoint.

The following diagram shows how multi-model endpoints work compared to single-model endpoints.

Multi-model endpoints are ideal for hosting a large number of models that use the same ML framework on a shared serving container. If you have a mix of frequently and infrequently accessed models, a multi-model endpoint can efficiently serve this traffic with fewer resources and higher cost savings. Your application should be tolerant of occasional cold start-related latency penalties that occur when invoking infrequently used models.

Multi-model endpoints support hosting both CPU and GPU backed models. By using GPU backed models, you can lower your model deployment costs through increased usage of the endpoint and its underlying accelerated compute instances.

Multi-model endpoints also enable time-sharing of memory resources across your models. This works best when the models are fairly similar in size and invocation latency. When this is the case, multi-model endpoints can effectively use instances across all models. If you have models that have significantly higher transactions per second (TPS) or latency requirements, we recommend hosting them on dedicated endpoints.

You can use multi-model endpoints with the following features:

- Amazon PrivateLink and VPCs
- Auto scaling

- Serial inference pipelines (but only one multi-model enabled container can be included in an inference pipeline)
- A/B testing

You can use the Amazon SDK for Python (Boto) or the SageMaker AI console to create a multi-model endpoint. For CPU backed multi-model endpoints, you can create your endpoint with custom-built containers by integrating the Multi Model Server library.

How multi-model endpoints work

SageMaker AI manages the lifecycle of models hosted on multi-model endpoints in the container's memory. Instead of downloading all of the models from an Amazon S3 bucket to the container when you create the endpoint, SageMaker AI dynamically loads and caches them when you invoke them. When SageMaker AI receives an invocation request for a particular model, it does the following:

1. Routes the request to an instance behind the endpoint.
2. Downloads the model from the S3 bucket to that instance's storage volume.
3. Loads the model to the container's memory (CPU or GPU, depending on whether you have CPU or GPU backed instances) on that accelerated compute instance. If the model is already loaded

in the container's memory, invocation is faster because SageMaker AI doesn't need to download and load it.

SageMaker AI continues to route requests for a model to the instance where the model is already loaded. However, if the model receives many invocation requests, and there are additional instances for the multi-model endpoint, SageMaker AI routes some requests to another instance to accommodate the traffic. If the model isn't already loaded on the second instance, the model is downloaded to that instance's storage volume and loaded into the container's memory.

When an instance's memory utilization is high and SageMaker AI needs to load another model into memory, it unloads unused models from that instance's container to ensure that there is enough memory to load the model. Models that are unloaded remain on the instance's storage volume and can be loaded into the container's memory later without being downloaded again from the S3 bucket. If the instance's storage volume reaches its capacity, SageMaker AI deletes any unused models from the storage volume.

To delete a model, stop sending requests and delete it from the S3 bucket. SageMaker AI provides multi-model endpoint capability in a serving container. Adding models to, and deleting them from, a multi-model endpoint doesn't require updating the endpoint itself. To add a model, you upload it to the S3 bucket and invoke it. You don’t need code changes to use it.

> **Note**
>
> When you update a multi-model endpoint, initial invocation requests on the endpoint might experience higher latencies as Smart Routing in multi-model endpoints adapt to your traffic pattern. However, once it learns your traffic pattern, you can experience low latencies for most frequently used models. Less frequently used models may incur some cold start latencies since the models are dynamically loaded to an instance.

Sample notebooks for multi-model endpoints

To learn more about how to use multi-model endpoints, you can try the following sample notebooks:

- Examples for multi-model endpoints using CPU backed instances:
  - Multi-Model Endpoint XGBoost Sample Notebook – This notebook shows how to deploy multiple XGBoost models to an endpoint.

  - Multi-Model Endpoints BYOC Sample Notebook – This notebook shows how to set up and deploy a customer container that supports multi-model endpoints in SageMaker AI.
- Example for multi-model endpoints using GPU backed instances:
  - Run multiple deep learning models on GPUs with Amazon SageMaker AI Multi-model endpoints (MME) – This notebook shows how to use an NVIDIA Triton Inference container to deploy ResNet-50 models to a multi-model endpoint.

For instructions on how to create and access Jupyter notebook instances that you can use to run the previous examples in SageMaker AI, see Amazon SageMaker notebook instances. After you've created a notebook instance and opened it, choose the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. The multi-model endpoint notebooks are located in the **ADVANCED FUNCTIONALITY** section. To open a notebook, choose its **Use** tab and choose **Create copy**.

For more information about use cases for multi-model endpoints, see the following blogs and resources:

- Video: Hosting thousands of models on SageMaker AI
- Video: SageMaker AI ML for SaaS
- Blog: How to scale machine learning inference for multi-tenant SaaS use cases
- Case study: Veeva Systems

Supported algorithms, frameworks, and instances for multi-model endpoints

For information about the algorithms, frameworks, and instance types that you can use with multi-model endpoints, see the following sections.

Supported algorithms, frameworks, and instances for multi-model endpoints using CPU backed instances

The inference containers for the following algorithms and frameworks support multi-model endpoints:

- XGBoost algorithm with Amazon SageMaker AI
- K-Nearest Neighbors (k-NN) Algorithm
- Linear Learner Algorithm
- Random Cut Forest (RCF) Algorithm

- Resources for using TensorFlow with Amazon SageMaker AI
- Resources for using Scikit-learn with Amazon SageMaker AI
- Resources for using Apache MXNet with Amazon SageMaker AI
- Resources for using PyTorch with Amazon SageMaker AI

To use any other framework or algorithm, use the SageMaker AI inference toolkit to build a container that supports multi-model endpoints. For information, see Build Your Own Container for SageMaker AI Multi-Model Endpoints.

Multi-model endpoints support all of the CPU instance types.

Supported algorithms, frameworks, and instances for multi-model endpoints using GPU backed instances

Hosting multiple GPU backed models on multi-model endpoints is supported through the SageMaker AI Triton Inference server. This supports all major inference frameworks such as NVIDIA® TensorRT™, PyTorch, MXNet, Python, ONNX, XGBoost, scikit-learn, RandomForest, OpenVINO, custom C++, and more.

To use any other framework or algorithm, you can use Triton backend for Python or C++ to write your model logic and serve any custom model. After you have the server ready, you can start deploying 100s of Deep Learning models behind one endpoint.

Multi-model endpoints support the following GPU instance types:

Instance family	Instance type	vCPUs	GiB of memory per vCPU	GPUs	GPU memory
p2	ml.p2.xlarge	4	15.25	1	12
p3	ml.p3.2xlarge	8	7.62	1	16
g5	ml.g5.xlarge	4	4	1	24
g5	ml.g5.2xlarge	8	4	1	24
g5	ml.g5.4xlarge	16	4	1	24

Instance family	Instance type	vCPUs	GiB of memory per vCPU	GPUs	GPU memory
g5	ml.g5.8xlarge	32	4	1	24
g5	ml.g5.16x large	64	4	1	24
g4dn	ml.g4dn.x large	4	4	1	16
g4dn	ml.g4dn.2 xlarge	8	4	1	16
g4dn	ml.g4dn.4 xlarge	16	4	1	16
g4dn	ml.g4dn.8 xlarge	32	4	1	16
g4dn	ml.g4dn.1 6xlarge	64	4	1	16

Instance recommendations for multi-model endpoint deployments

There are several items to consider when selecting a SageMaker AI ML instance type for a multi-model endpoint:

- Provision sufficient Amazon Elastic Block Store (Amazon EBS) capacity for all of the models that need to be served.
- Balance performance (minimize cold starts) and cost (don't over-provision instance capacity). For information about the size of the storage volume that SageMaker AI attaches for each instance type for an endpoint and for a multi-model endpoint, see Instance storage volumes.
- For a container configured to run in `MultiModel` mode, the storage volume provisioned for its instances are larger than the default `SingleModel` mode. This allows more models to be cached on the instance storage volume than in `SingleModel` mode.

When choosing a SageMaker AI ML instance type, consider the following:

- Multi-model endpoints are currently supported for all CPU instances types and on single-GPU instance types.
- For the traffic distribution (access patterns) to the models that you want to host behind the multi-model endpoint, along with the model size (how many models could be loaded in memory on the instance), keep the following information in mind:
  - Think of the amount of memory on an instance as the cache space for models to be loaded, and think of the number of vCPUs as the concurrency limit to perform inference on the loaded models (assuming that invoking a model is bound to CPU).
  - For CPU backed instances, the number of vCPUs impacts your maximum concurrent invocations per instance (assuming that invoking a model is bound to CPU). A higher amount of vCPUs enables you to invoke more unique models concurrently.
  - For GPU backed instances, a higher amount of instance and GPU memory enables you to have more models loaded and ready to serve inference requests.
  - For both CPU and GPU backed instances, have some "slack" memory available so that unused models can be unloaded, and especially for multi-model endpoints with multiple instances. If an instance or an Availability Zone fails, the models on those instances will be rerouted to other instances behind the endpoint.
- Determine your tolerance to loading/downloading times:
  - d instance type families (for example, m5d, c5d, or r5d) and g5s come with an NVMe (non-volatile memory express) SSD, which offers high I/O performance and might reduce the time it takes to download models to the storage volume and for the container to load the model from the storage volume.
  - Because d and g5 instance types come with an NVMe SSD storage, SageMaker AI does not attach an Amazon EBS storage volume to these ML compute instances that hosts the multi-model endpoint. Auto scaling works best when the models are similarly sized and homogenous, that is when they have similar inference latency and resource requirements.

You can also use the following guidance to help you optimize model loading on your multi-model endpoints:

Choosing an instance type that can't hold all of the targeted models in memory

In some cases, you might opt to reduce costs by choosing an instance type that can't hold all of the targeted models in memory at once. SageMaker AI dynamically unloads models when it runs

out of memory to make room for a newly targeted model. For infrequently requested models, you sacrifice dynamic load latency. In cases with more stringent latency needs, you might opt for larger instance types or more instances. Investing time up front for performance testing and analysis helps you to have successful production deployments.

Evaluating your model cache hits

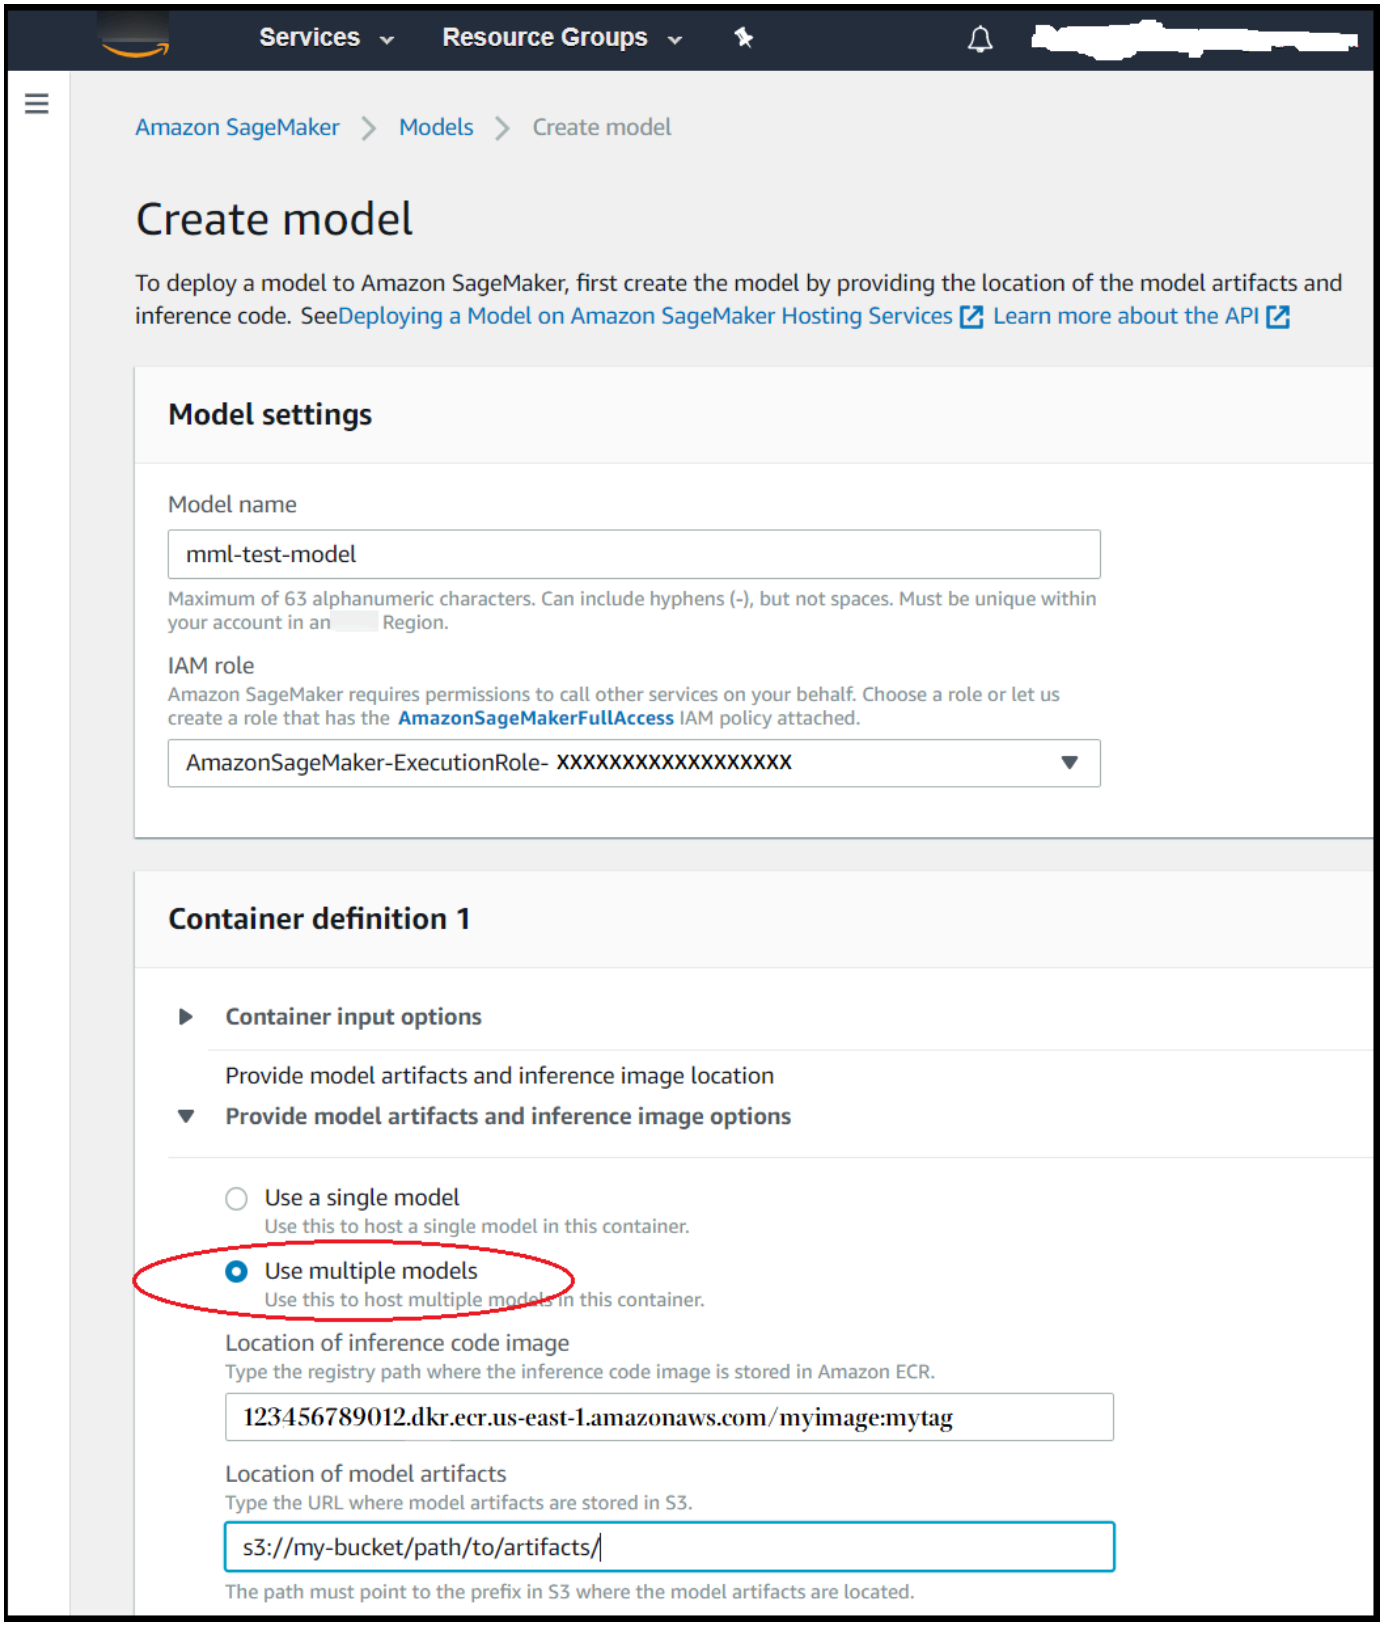
Amazon CloudWatch metrics can help you evaluate your models. For more information about metrics you can use with multi-model endpoints, see CloudWatch Metrics for Multi-Model Endpoint Deployments.

You can use the `Average` statistic of the `ModelCacheHit` metric to monitor the ratio of requests where the model is already loaded. You can use the `SampleCount` statistic for the `ModelUnloadingTime` metric to monitor the number of unload requests sent to the container during a time period. If models are unloaded too frequently (an indicator of *thrashing*, where models are being unloaded and loaded again because there is insufficient cache space for the working set of models), consider using a larger instance type with more memory or increasing the number of instances behind the multi-model endpoint. For multi-model endpoints with multiple instances, be aware that a model might be loaded on more than 1 instance.

Create a Multi-Model Endpoint

You can use the SageMaker AI console or the Amazon SDK for Python (Boto) to create a multi-model endpoint. To create either a CPU or GPU backed endpoint through the console, see the console procedure in the following sections. If you want to create a multi-model endpoint with the Amazon SDK for Python (Boto), use either the CPU or GPU procedure in the following sections. The CPU and GPU workflows are similar but have several differences, such as the container requirements.

Topics



- Create a multi-model endpoint (console)
- Create a multi-model endpoint using CPUs with the Amazon SDK for Python (Boto3)
- Create a multi-model endpoint using GPUs with the Amazon SDK for Python (Boto3)

Create a multi-model endpoint (console)

You can create both CPU and GPU backed multi-model endpoints through the console. Use the following procedure to create a multi-model endpoint through the SageMaker AI console.

To create a multi-model endpoint (console)

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. Choose **Model**, and then from the **Inference** group, choose **Create model**.
3. For **Model name**, enter a name.
4. For **IAM role**, choose or create an IAM role that has the `AmazonSageMakerFullAccess` IAM policy attached.
5. In the **Container definition** section, for **Provide model artifacts and inference image options**, choose **Use multiple models**.

6. For the **Inference container image**, enter the Amazon ECR path for your desired container image.

For GPU models, you must use a container backed by the NVIDIA Triton Inference Server. For a list of container images that work with GPU backed endpoints, see the NVIDIA Triton Inference Containers (SM support only). For more information about the NVIDIA Triton Inference Server, see Use Triton Inference Server with SageMaker AI.

7. Choose **Create model**.
8. Deploy your multi-model endpoint as you would a single model endpoint. For instructions, see Deploy the Model to SageMaker AI Hosting Services.

Create a multi-model endpoint using CPUs with the Amazon SDK for Python (Boto3)

Use the following section to create a multi-model endpoint backed by CPU instances. You create a multi-model endpoint using the Amazon SageMaker AI `create_model`, `create_endpoint_config`, and `create_endpoint` APIs just as you would create a single model endpoint, but with two changes. When defining the model container, you need to pass a new `Mode` parameter value, `MultiModel`. You also need to pass the `ModelDataUrl` field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model.

For a sample notebook that uses SageMaker AI to deploy multiple XGBoost models to an endpoint, see Multi-Model Endpoint XGBoost Sample Notebook.

The following procedure outlines the key steps used in that sample to create a CPU backed multi-model endpoint.

To deploy the model (Amazon SDK for Python (Boto 3))

1. Get a container with an image that supports deploying multi-model endpoints. For a list of built-in algorithms and framework containers that support multi-model endpoints, see Supported algorithms, frameworks, and instances for multi-model endpoints. For this example, we use the K-Nearest Neighbors (k-NN) Algorithm built-in algorithm. We call the SageMaker Python SDK utility function `image_uris.retrieve()` to get the address for the K-Nearest Neighbors built-in algorithm image.

```
import sagemaker
region = sagemaker_session.boto_region_name
image = image_uris.retrieve("knn",region=region)
container = {
              'Image':        image,
```

```
              'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
              'Mode':         'MultiModel'
            }
```

2. Get an Amazon SDK for Python (Boto3) SageMaker AI client and create the model that uses this container.

```
import boto3
sagemaker_client = boto3.client('sagemaker')
response = sagemaker_client.create_model(
              ModelName        = '<MODEL_NAME>',
              ExecutionRoleArn = role,
              Containers       = [container])
```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the `Containers` argument of `CreateModel`:

```
preprocessor_container = {
               'Image':
 '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<PREPROCESSOR_IMAGE>:<TAG>'
            }

multi_model_container = {
              'Image':
 '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<IMAGE>:<TAG>',
              'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
              'Mode':         'MultiModel'
            }

response = sagemaker_client.create_model(
              ModelName        = '<MODEL_NAME>',
              ExecutionRoleArn = role,
              Containers       = [preprocessor_container, multi_model_container]
            )
```

> **Note**
>
> You can use only one multi-model-enabled endpoint in a serial inference pipeline.

4. (Optional) If your use case does not benefit from model caching, set the value of the `ModelCacheSetting` field of the `MultiModelConfig` parameter to `Disabled`, and

include it in the `Container` argument of the call to `create_model`. The value of the `ModelCacheSetting` field is `Enabled` by default.

```
container = {
                'Image': image,
                'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
                'Mode': 'MultiModel'
                'MultiModelConfig': {
                        // Default value is 'Enabled'
                        'ModelCacheSetting': 'Disabled'
                }
            }

response = sagemaker_client.create_model(
               ModelName        = '<MODEL_NAME>',
               ExecutionRoleArn = role,
               Containers       = [container]
            )
```

5. Configure the multi-model endpoint for the model. We recommend configuring your endpoints with at least two instances. This allows SageMaker AI to provide a highly available set of predictions across multiple Availability Zones for the models.

```
response = sagemaker_client.create_endpoint_config(
                EndpointConfigName = '<ENDPOINT_CONFIG_NAME>',
                ProductionVariants=[
                     {
                        'InstanceType':        'ml.m4.xlarge',
                        'InitialInstanceCount': 2,
                        'InitialVariantWeight': 1,
                        'ModelName':            '<MODEL_NAME>',
                        'VariantName':          'AllTraffic'
                      }
                ]
            )
```

> **Note**
>
> You can use only one multi-model-enabled endpoint in a serial inference pipeline.

6. Create the multi-model endpoint using the `EndpointName` and `EndpointConfigName` parameters.

```
response = sagemaker_client.create_endpoint(
              EndpointName       = '<ENDPOINT_NAME>',
              EndpointConfigName = '<ENDPOINT_CONFIG_NAME>')
```

Create a multi-model endpoint using GPUs with the Amazon SDK for Python (Boto3)

Use the following section to create a GPU backed multi-model endpoint. You create a multi-model endpoint using the Amazon SageMaker AI `create_model`, `create_endpoint_config`, and `create_endpoint` APIs similarly to creating single model endpoints, but there are several changes. When defining the model container, you need to pass a new `Mode` parameter value, `MultiModel`. You also need to pass the `ModelDataUrl` field that specifies the prefix in Amazon S3 where the model artifacts are located, instead of the path to a single model artifact, as you would when deploying a single model. For GPU backed multi-model endpoints, you also must use a container with the NVIDIA Triton Inference Server that is optimized for running on GPU instances. For a list of container images that work with GPU backed endpoints, see the NVIDIA Triton Inference Containers (SM support only).

For an example notebook that demonstrates how to create a multi-model endpoint backed by GPUs, see Run mulitple deep learning models on GPUs with Amazon SageMaker AI Multi-model endpoints (MME).

The following procedure outlines the key steps to create a GPU backed multi-model endpoint.

To deploy the model (Amazon SDK for Python (Boto 3))

1. Define the container image. To create a multi-model endpoint with GPU support for ResNet models, define the container to use the NVIDIA Triton Server image. This container supports multi-model endpoints and is optimized for running on GPU instances. We call the SageMaker AI Python SDK utility function `image_uris.retrieve()` to get the address for the image. For example:

```
import sagemaker
region = sagemaker_session.boto_region_name

// Find the sagemaker-tritonserver image at
```

```
// https://github.com/aws/amazon-sagemaker-examples/blob/main/sagemaker-triton/
resnet50/triton_resnet50.ipynb
// Find available tags at https://github.com/aws/deep-learning-containers/blob/
master/available_images.md#nvidia-triton-inference-containers-sm-support-only

image = "<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/sagemaker-
tritonserver:<TAG>".format(
    account_id=account_id_map[region], region=region
)

container = {
              'Image':        image,
              'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
              'Mode':         'MultiModel',
              "Environment": {"SAGEMAKER_TRITON_DEFAULT_MODEL_NAME": "resnet"},
            }
```

2. Get an Amazon SDK for Python (Boto3) SageMaker AI client and create the model that uses this container.

```
import boto3
sagemaker_client = boto3.client('sagemaker')
response = sagemaker_client.create_model(
              ModelName        = '<MODEL_NAME>',
              ExecutionRoleArn = role,
              Containers       = [container])
```

3. (Optional) If you are using a serial inference pipeline, get the additional container(s) to include in the pipeline, and include it in the `Containers` argument of `CreateModel`:

```
preprocessor_container = {
               'Image':
 '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<PREPROCESSOR_IMAGE>:<TAG>'
            }

multi_model_container = {
              'Image':
 '<ACCOUNT_ID>.dkr.ecr.<REGION_NAME>.amazonaws.com/<IMAGE>:<TAG>',
              'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
              'Mode':         'MultiModel'
            }

response = sagemaker_client.create_model(
```

```
                ModelName        = '<MODEL_NAME>',
                ExecutionRoleArn = role,
                Containers       = [preprocessor_container, multi_model_container]
            )
```

> **Note**
>
> You can use only one multi-model-enabled endpoint in a serial inference pipeline.

4. (Optional) If your use case does not benefit from model caching, set the value of the `ModelCacheSetting` field of the `MultiModelConfig` parameter to `Disabled`, and include it in the `Container` argument of the call to `create_model`. The value of the `ModelCacheSetting` field is `Enabled` by default.

```
container = {
                'Image': image,
                'ModelDataUrl': 's3://<BUCKET_NAME>/<PATH_TO_ARTIFACTS>',
                'Mode': 'MultiModel'
                'MultiModelConfig': {
                        // Default value is 'Enabled'
                        'ModelCacheSetting': 'Disabled'
                }
            }

response = sagemaker_client.create_model(
                ModelName        = '<MODEL_NAME>',
                ExecutionRoleArn = role,
                Containers       = [container]
            )
```

5. Configure the multi-model endpoint with GPU backed instances for the model. We recommend configuring your endpoints with more than one instance to allow for high availability and higher cache hits.

```
response = sagemaker_client.create_endpoint_config(
                EndpointConfigName = '<ENDPOINT_CONFIG_NAME>',
                ProductionVariants=[
                    {
                        'InstanceType':        'ml.g4dn.4xlarge',
                        'InitialInstanceCount': 2,
                        'InitialVariantWeight': 1,
```

```
                    'ModelName':            '<MODEL_NAME>',
                    'VariantName':          'AllTraffic'
                }
            ]
        )
```

6. Create the multi-model endpoint using the `EndpointName` and `EndpointConfigName` parameters.

```
response = sagemaker_client.create_endpoint(
              EndpointName       = '<ENDPOINT_NAME>',
              EndpointConfigName = '<ENDPOINT_CONFIG_NAME>')
```

Invoke a Multi-Model Endpoint

To invoke a multi-model endpoint, use the `invoke_endpoint` from the SageMaker AI Runtime just as you would invoke a single model endpoint, with one change. Pass a new `TargetModel` parameter that specifies which of the models at the endpoint to target. The SageMaker AI Runtime `InvokeEndpoint` request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker AI system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

The following procedures are the same for both CPU and GPU-backed multi-model endpoints.

Amazon SDK for Python (Boto 3)

The following example prediction request uses the Amazon SDK for Python (Boto 3) in the sample notebook.

```
response = runtime_sagemaker_client.invoke_endpoint(
                        EndpointName = "<ENDPOINT_NAME>",
                        ContentType  = "text/csv",
                        TargetModel  = "<MODEL_FILENAME>.tar.gz",
                        Body         = body)
```

Amazon CLI

The following example shows how to make a CSV request with two rows using the Amazon Command Line Interface (Amazon CLI):

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name "<ENDPOINT_NAME>" \
  --body "1.0,2.0,5.0"$'\n'"2.0,3.0,4.0" \
  --content-type "text/csv" \
  --target-model "<MODEL_NAME>.tar.gz"
  output_file.txt
```

An `output_file.txt` with information about your inference requests is made if the inference was successful. For more examples on how to make predictions with the Amazon CLI, see Making predictions with the Amazon CLI in the SageMaker Python SDK documentation.

The multi-model endpoint dynamically loads target models as needed. You can observe this when running the MME Sample Notebook as it iterates through random invocations against multiple target models hosted behind a single endpoint. The first request against a given model takes longer because the model has to be downloaded from Amazon Simple Storage Service (Amazon S3) and loaded into memory. This is called a *cold start*, and it is expected on multi-model endpoints to optimize for better price performance for customers. Subsequent calls finish faster because there's no additional overhead after the model has loaded.

> **Note**
>
> For GPU backed instances, the HTTP response code with 507 from the GPU container indicates a lack of memory or other resources. This causes unused models to be unloaded from the container in order to load more frequently used models.

Retry Requests on ModelNotReadyException Errors

The first time you call `invoke_endpoint` for a model, the model is downloaded from Amazon Simple Storage Service and loaded into the inference container. This makes the first call take longer to return. Subsequent calls to the same model finish faster, because the model is already loaded.

SageMaker AI returns a response for a call to `invoke_endpoint` within 60 seconds. Some models are too large to download within 60 seconds. If the model does not finish loading before the 60 second timeout limit, the request to `invoke_endpoint` returns with the error code `ModelNotReadyException`, and the model continues to download and load into the inference container for up to 360 seconds. If you get a `ModelNotReadyException` error code

for an `invoke_endpoint` request, retry the request. By default, the Amazon SDKs for Python (Boto 3) (using Legacy retry mode) and Java retry `invoke_endpoint` requests that result in `ModelNotReadyException` errors. You can configure the retry strategy to continue retrying the request for up to 360 seconds. If you expect your model to take longer than 60 seconds to download and load into the container, set the SDK socket timeout to 70 seconds. For more information about configuring the retry strategy for the Amazon SDK for Python (Boto3), see Configuring a retry mode. The following code shows an example that configures the retry strategy to retry calls to `invoke_endpoint` for up to 180 seconds.

```
import boto3
from botocore.config import Config

# This example retry strategy sets the retry attempts to 2.
# With this setting, the request can attempt to download and/or load the model
# for upto 180 seconds: 1 orginal request (60 seconds) + 2 retries (120 seconds)
config = Config(
    read_timeout=70,
    retries={
        'max_attempts': 2  # This value can be adjusted to 5 to go up to the 360s max
 timeout
    }
)
runtime_sagemaker_client = boto3.client('sagemaker-runtime', config=config)
```

Add or Remove Models

You can deploy additional models to a multi-model endpoint and invoke them through that endpoint immediately. When adding a new model, you don't need to update or bring down the endpoint, so you avoid the cost of creating and running a separate endpoint for each new model. The process for adding and removing models is the same for CPU and GPU-backed multi-model endpoints.

SageMaker AI unloads unused models from the container when the instance is reaching memory capacity and more models need to be downloaded into the container. SageMaker AI also deletes unused model artifacts from the instance storage volume when the volume is reaching capacity and new models need to be downloaded. The first invocation to a newly added model takes longer because the endpoint takes time to download the model from S3 to the container's memory in instance hosting the endpoint

With the endpoint already running, copy a new set of model artifacts to the Amazon S3 location there you store your models.

```
# Add an AdditionalModel to the endpoint and exercise it
aws s3 cp AdditionalModel.tar.gz s3://amzn-s3-demo-bucket/path/to/artifacts/
```

Important

To update a model, proceed as you would when adding a new model. Use a new and unique name. Don't overwrite model artifacts in Amazon S3 because the old version of the model might still be loaded in the containers or on the storage volume of the instances on the endpoint. Invocations to the new model could then invoke the old version of the model.

Client applications can request predictions from the additional target model as soon as it is stored in S3.

```
response = runtime_sagemaker_client.invoke_endpoint(
                        EndpointName='<ENDPOINT_NAME>',
                        ContentType='text/csv',
                        TargetModel='AdditionalModel.tar.gz',
                        Body=body)
```

To delete a model from a multi-model endpoint, stop invoking the model from the clients and remove it from the S3 location where model artifacts are stored.

Build Your Own Container for SageMaker AI Multi-Model Endpoints

Refer to the following sections for bringing your own container and dependencies to multi-model endpoints.

Topics

- Bring your own dependencies for multi-model endpoints on CPU backed instances
- Bring your own dependencies for multi-model endpoints on GPU backed instances
- Use the SageMaker AI Inference Toolkit
- Custom Containers Contract for Multi-Model Endpoints

Bring your own dependencies for multi-model endpoints on CPU backed instances

If none of the pre-built container images serve your needs, you can build your own container for use with CPU backed multi-model endpoints.

Custom Amazon Elastic Container Registry (Amazon ECR) images deployed in Amazon SageMaker AI are expected to adhere to the basic contract described in Custom Inference Code with Hosting Services that govern how SageMaker AI interacts with a Docker container that runs your own inference code. For a container to be capable of loading and serving multiple models concurrently, there are additional APIs and behaviors that must be followed. This additional contract includes new APIs to load, list, get, and unload models, and a different API to invoke models. There are also different behaviors for error scenarios that the APIs need to abide by. To indicate that the container complies with the additional requirements, you can add the following command to your Docker file:

```
LABEL com.amazonaws.sagemaker.capabilities.multi-models=true
```

SageMaker AI also injects an environment variable into the container

```
SAGEMAKER_MULTI_MODEL=true
```

If you are creating a multi-model endpoint for a serial inference pipline, your Docker file must have the required labels for both multi-models and serial inference pipelines. For more information about serial information pipelines, see Run Real-time Predictions with an Inference Pipeline.

To help you implement these requirements for a custom container, two libraries are available:

- Multi Model Server is an open source framework for serving machine learning models that can be installed in containers to provide the front end that fulfills the requirements for the new multi-model endpoint container APIs. It provides the HTTP front end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and performs inference on a specified loaded model. It also provides a pluggable backend that supports a pluggable custom backend handler where you can implement your own algorithm.
- SageMaker AI Inference Toolkit is a library that bootstraps Multi Model Server with a configuration and settings that make it compatible with SageMaker AI multi-model endpoints. It also allows you to tweak important performance parameters, such as the number of workers per model, depending on the needs of your scenario.

Bring your own dependencies for multi-model endpoints on GPU backed instances

The bring your own container (BYOC) capability on multi-model endpoints with GPU backed instances is not currently supported by the Multi Model Server and SageMaker AI Inference Toolkit libraries.

For creating multi-model endpoints with GPU backed instances, you can use the SageMaker AI supported NVIDIA Triton Inference Server. with the NVIDIA Triton Inference Containers. To bring your own dependencies, you can build your own container with the SageMaker AI supported NVIDIA Triton Inference Server as the base image to your Docker file:

```
FROM 301217895009.dkr.ecr.us-west-2.amazonaws.com/sagemaker-tritonserver:22.07-py3
```

Important

Containers with the Triton Inference Server are the only supported containers you can use for GPU backed multi-model endpoints.

Use the SageMaker AI Inference Toolkit

Note

The SageMaker AI Inference Toolkit is only supported for CPU backed multi-model endpoints. The SageMaker AI Inference Toolkit is not currently not supported for GPU backed multi-model endpoints.

Pre-built containers that support multi-model endpoints are listed in Supported algorithms, frameworks, and instances for multi-model endpoints. If you want to use any other framework or algorithm, you need to build a container. The easiest way to do this is to use the SageMaker AI Inference Toolkit to extend an existing pre-built container. The SageMaker AI inference toolkit is an implementation for the multi-model server (MMS) that creates endpoints that can be deployed in SageMaker AI. For a sample notebook that shows how to set up and deploy a custom container that supports multi-model endpoints in SageMaker AI, see the Multi-Model Endpoint BYOC Sample Notebook.

> **Note**
>
> The SageMaker AI inference toolkit supports only Python model handlers. If you want to implement your handler in any other language, you must build your own container that implements the additional multi-model endpoint APIs. For information, see Custom Containers Contract for Multi-Model Endpoints.

To extend a container by using the SageMaker AI inference toolkit

1. Create a model handler. MMS expects a model handler, which is a Python file that implements functions to pre-process, get preditions from the model, and process the output in a model handler. For an example of a model handler, see model_handler.py from the sample notebook.
2. Import the inference toolkit and use its `model_server.start_model_server` function to start MMS. The following example is from the `dockerd-entrypoint.py` file from the sample notebook. Notice that the call to `model_server.start_model_server` passes the model handler described in the previous step:

```
import subprocess
import sys
import shlex
import os
from retrying import retry
from subprocess import CalledProcessError
from sagemaker_inference import model_server

def _retry_if_error(exception):
    return isinstance(exception, CalledProcessError or OSError)

@retry(stop_max_delay=1000 * 50,
       retry_on_exception=_retry_if_error)
def _start_mms():
    # by default the number of workers per model is 1, but we can configure it
 through the
    # environment variable below if desired.
    # os.environ['SAGEMAKER_MODEL_SERVER_WORKERS'] = '2'
    model_server.start_model_server(handler_service='/home/model-server/
model_handler.py:handle')

def main():
    if sys.argv[1] == 'serve':
```

```
        _start_mms()
    else:
        subprocess.check_call(shlex.split(' '.join(sys.argv[1:])))

    # prevent docker exit
    subprocess.call(['tail', '-f', '/dev/null'])

main()
```

3. In your `Dockerfile`, copy the model handler from the first step and specify the Python file from the previous step as the entrypoint in your `Dockerfile`. The following lines are from the Dockerfile used in the sample notebook:

```
# Copy the default custom service file to handle incoming data and inference
 requests
COPY model_handler.py /home/model-server/model_handler.py

# Define an entrypoint script for the docker image
ENTRYPOINT ["python", "/usr/local/bin/dockerd-entrypoint.py"]
```

4. Build and register your container. The following shell script from the sample notebook builds the container and uploads it to an Amazon Elastic Container Registry repository in your Amazon account:

```
%%sh

# The name of our algorithm
algorithm_name=demo-sagemaker-multimodel

cd container

account=$(aws sts get-caller-identity --query Account --output text)

# Get the region defined in the current configuration (default to us-west-2 if none
 defined)
region=$(aws configure get region)
region=${region:-us-west-2}

fullname="${account}.dkr.ecr.${region}.amazonaws.com/${algorithm_name}:latest"

# If the repository doesn't exist in ECR, create it.
aws ecr describe-repositories --repository-names "${algorithm_name}" > /dev/null
 2>&1
```

```
if [ $? -ne 0 ]
then
    aws ecr create-repository --repository-name "${algorithm_name}" > /dev/null
fi

# Get the login command from ECR and execute it directly
$(aws ecr get-login --region ${region} --no-include-email)

# Build the docker image locally with the image name and then push it to ECR
# with the full name.

docker build -q -t ${algorithm_name} .
docker tag ${algorithm_name} ${fullname}

docker push ${fullname}
```

You can now use this container to deploy multi-model endpoints in SageMaker AI.

Topics

- Custom Containers Contract for Multi-Model Endpoints

Custom Containers Contract for Multi-Model Endpoints

To handle multiple models, your container must support a set of APIs that enable Amazon SageMaker AI to communicate with the container for loading, listing, getting, and unloading models as required. The `model_name` is used in the new set of APIs as the key input parameter. The customer container is expected to keep track of the loaded models using `model_name` as the mapping key. Also, the `model_name` is an opaque identifier and is not necessarily the value of the `TargetModel` parameter passed into the `InvokeEndpoint` API. The original `TargetModel` value in the `InvokeEndpoint` request is passed to container in the APIs as a `X-Amzn-SageMaker-Target-Model` header that can be used for logging purposes.

> **Note**
>
> Multi-model endpoints for GPU backed instances are currently supported only with SageMaker AI's NVIDIA Triton Inference Server container. This container already

implements the contract defined below. Customers can directly use this container with their multi-model GPU endpoints, without any additional work.

You can configure the following APIs on your containers for CPU backed multi-model endpoints.

Topics

- Load Model API
- List Model API
- Get Model API
- Unload Model API
- Invoke Model API

Load Model API

Instructs the container to load a particular model present in the `url` field of the body into the memory of the customer container and to keep track of it with the assigned `model_name`. After a model is loaded, the container should be ready to serve inference requests using this `model_name`.

```
POST /models HTTP/1.1
Content-Type: application/json
Accept: application/json

{
     "model_name" : "{model_name}",
     "url" : "/opt/ml/models/{model_name}/model",
}
```

Note

If `model_name` is already loaded, this API should return 409. Any time a model cannot be loaded due to lack of memory or to any other resource, this API should return a 507 HTTP status code to SageMaker AI, which then initiates unloading unused models to reclaim.

List Model API

Returns the list of models loaded into the memory of the customer container.

```
GET /models HTTP/1.1
Accept: application/json

Response =
{
    "models": [
        {
             "modelName" : "{model_name}",
             "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        ....
    ]
}
```

This API also supports pagination.

```
GET /models HTTP/1.1
Accept: application/json

Response =
{
    "models": [
        {
             "modelName" : "{model_name}",
             "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        {
            "modelName" : "{model_name}",
            "modelUrl" : "/opt/ml/models/{model_name}/model",
        },
        ....
    ]
}
```

SageMaker AI can initially call the List Models API without providing a value for `next_page_token`. If a `nextPageToken` field is returned as part of the response, it will be provided as the value for `next_page_token` in a subsequent List Models call. If a `nextPageToken` is not returned, it means that there are no more models to return.

Get Model API

This is a simple read API on the `model_name` entity.

```
GET /models/{model_name} HTTP/1.1
Accept: application/json

{
     "modelName" : "{model_name}",
     "modelUrl" : "/opt/ml/models/{model_name}/model",
}
```

> **Note**
>
> If `model_name` is not loaded, this API should return 404.

Unload Model API

Instructs the SageMaker AI platform to instruct the customer container to unload a model from memory. This initiates the eviction of a candidate model as determined by the platform when starting the process of loading a new model. The resources provisioned to `model_name` should be reclaimed by the container when this API returns a response.

```
DELETE /models/{model_name}
```

> **Note**
>
> If `model_name` is not loaded, this API should return 404.

Invoke Model API

Makes a prediction request from the particular `model_name` supplied. The SageMaker AI Runtime `InvokeEndpoint` request supports `X-Amzn-SageMaker-Target-Model` as a new header that takes the relative path of the model specified for invocation. The SageMaker AI system constructs the absolute path of the model by combining the prefix that is provided as part of the `CreateModel` API call with the relative path of the model.

```
POST /models/{model_name}/invoke HTTP/1.1
Content-Type: ContentType
Accept: Accept
X-Amzn-SageMaker-Custom-Attributes: CustomAttributes
X-Amzn-SageMaker-Target-Model: [relativePath]/{artifactName}.tar.gz
```

Note

If `model_name` is not loaded, this API should return 404.

Additionally, on GPU instances, if `InvokeEndpoint` fails due to a lack of memory or other resources, this API should return a 507 HTTP status code to SageMaker AI, which then initiates unloading unused models to reclaim.

Multi-Model Endpoint Security

Models and data in a multi-model endpoint are co-located on instance storage volume and in container memory. All instances for Amazon SageMaker AI endpoints run on a single tenant container that you own. Only your models can run on your multi-model endpoint. It's your responsibility to manage the mapping of requests to models and to provide access for users to the correct target models. SageMaker AI uses IAM roles to provide IAM identity-based policies that you use to specify allowed or denied actions and resources and the conditions under which actions are allowed or denied.

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-model endpoint can invoke any model at the address of the S3 prefix defined in the `CreateModel` operation, provided that the IAM Execution Role defined in operation has permissions to download the model. If you need to restrict `InvokeEndpoint` access to a limited set of models in S3, you can do one of the following:

- Restrict `InvokeEndpont` calls to specific models hosted at the endpoint by using the `sagemaker:TargetModel` IAM condition key. For example, the following policy allows `InvokeEndpont` requests only when the value of the `TargetModel` field matches one of the specified regular expressions:

  JSON

  ```
  {
  ```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Allow",
            "Resource":
            "arn:aws-cn:sagemaker:us-
east-1:111122223333:endpoint/endpoint_name",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetModel": ["company_a/*", "common/*"]
                }
            }
        }
    ]
}
```

For information about SageMaker AI condition keys, see Condition Keys for Amazon SageMaker AI in the *Amazon Identity and Access Management User Guide*.

- Create multi-model endpoints with more restrictive S3 prefixes.

For more information about how SageMaker AI uses roles to manage access to endpoints and perform operations on your behalf, see How to use SageMaker AI execution roles. Your customers might also have certain data isolation requirements dictated by their own compliance requirements that can be satisfied using IAM identities.

CloudWatch Metrics for Multi-Model Endpoint Deployments

Amazon SageMaker AI provides metrics for endpoints so you can monitor the cache hit rate, the number of models loaded and the model wait times for loading, downloading, and uploading at a multi-model endpoint. Some of the metrics are different for CPU and GPU backed multi-model endpoints, so the following sections describe the Amazon CloudWatch metrics that you can use for each type of multi-model endpoint.

For more information about the metrics, see **Multi-Model Endpoint Model Loading Metrics** and **Multi-Model Endpoint Model Instance Metrics** in Amazon SageMaker AI metrics in Amazon CloudWatch. Per-model metrics aren't supported.

CloudWatch metrics for CPU backed multi-model endpoints

You can monitor the following metrics on CPU backed multi-model endpoints.

The `AWS/SageMaker` namespace includes the following model loading metrics from calls to InvokeEndpoint.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see GetMetricStatistics in the *Amazon CloudWatch API Reference*.

Multi-Model Endpoint Model Loading Metrics

Metric	Description
`ModelLoadingWaitTime`	The interval of time that an invocation request has waited for the target model to be downloaded, or loaded, or both in order to perform inference. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count
`ModelUnloadingTime`	The interval of time that it took to unload the model through the container's `UnloadModel` API call. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count
`ModelDownloadingTime`	The interval of time that it took to download the model from Amazon Simple Storage Service (Amazon S3). Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count
`ModelLoadingTime`	The interval of time that it took to load the model through the container's `LoadModel` API call. Units: Microseconds

Metric	Description
	Valid statistics: Average, Sum, Min, Max, Sample Count
`ModelCacheHit`	The number of `InvokeEndpoint` requests sent to the multi-model endpoint for which the model was already loaded. The Average statistic shows the ratio of requests for which the model was already loaded. Units: None Valid statistics: Average, Sum, Sample Count

Dimensions for Multi-Model Endpoint Model Loading Metrics

Dimension	Description
`EndpointName, VariantName`	Filters endpoint invocation metrics for a `ProductionVariant` of the specified endpoint and variant.

The `/aws/sagemaker/Endpoints` namespaces include the following instance metrics from calls to InvokeEndpoint.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see GetMetricStatistics in the *Amazon CloudWatch API Reference*.

Multi-Model Endpoint Model Instance Metrics

Metric	Description
`LoadedModelCount`	The number of models loaded in the containers of the multi-model endpoint. This metric is emitted per instance. The Average statistic with a period of 1 minute tells you the average number of models loaded per instance.

Metric	Description
	The Sum statistic tells you the total number of models loaded across all instances in the endpoint. The models that this metric tracks are not necessarily unique because a model might be loaded in multiple containers at the endpoint. Units: None Valid statistics: Average, Sum, Min, Max, Sample Count
`CPUUtilization`	The sum of each individual CPU core's utilization. The CPU utilization of each core range is 0–100. For example, if there are four CPUs, the `CPUUtilization` range is 0%–400%. For endpoint variants, the value is the sum of the CPU utilization of the primary and supplementary containers on the instance. Units: Percent
`MemoryUtilization`	The percentage of memory that is used by the containers on an instance. This value range is 0%–100%. For endpoint variants, the value is the sum of the memory utilization of the primary and supplementary containers on the instance. Units: Percent
`DiskUtilization`	The percentage of disk space used by the containers on an instance. This value range is 0%–100%. For endpoint variants, the value is the sum of the disk space utilization of the primary and supplementary containers on the instance. Units: Percent

CloudWatch metrics for GPU multi-model endpoint deployments

You can monitor the following metrics on GPU backed multi-model endpoints.

The AWS/SageMaker namespace includes the following model loading metrics from calls to InvokeEndpoint.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see GetMetricStatistics in the *Amazon CloudWatch API Reference*.

Multi-Model Endpoint Model Loading Metrics

Metric	Description
ModelLoadingWaitTime	The interval of time that an invocation request has waited for the target model to be downloaded, or loaded, or both in order to perform inference. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count
ModelUnloadingTime	The interval of time that it took to unload the model through the container's UnloadModel API call. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count
ModelDownloadingTime	The interval of time that it took to download the model from Amazon Simple Storage Service (Amazon S3). Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count
ModelLoadingTime	The interval of time that it took to load the model through the container's LoadModel API call. Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count

Metric	Description
`ModelCacheHit`	The number of `InvokeEndpoint` requests sent to the multi-model endpoint for which the model was already loaded. The Average statistic shows the ratio of requests for which the model was already loaded. Units: None Valid statistics: Average, Sum, Sample Count

Dimensions for Multi-Model Endpoint Model Loading Metrics

Dimension	Description
`EndpointName, VariantName`	Filters endpoint invocation metrics for a `ProductionVariant` of the specified endpoint and variant.

The `/aws/sagemaker/Endpoints` namespaces include the following instance metrics from calls to InvokeEndpoint.

Metrics are available at a 1-minute frequency.

For information about how long CloudWatch metrics are retained for, see GetMetricStatistics in the *Amazon CloudWatch API Reference*.

Multi-Model Endpoint Model Instance Metrics

Metric	Description
`LoadedModelCount`	The number of models loaded in the containers of the multi-model endpoint. This metric is emitted per instance. The Average statistic with a period of 1 minute tells you the average number of models loaded per instance.

Metric	Description
	The Sum statistic tells you the total number of models loaded across all instances in the endpoint. The models that this metric tracks are not necessarily unique because a model might be loaded in multiple containers at the endpoint. Units: None Valid statistics: Average, Sum, Min, Max, Sample Count
`CPUUtilization`	The sum of each individual CPU core's utilization. The CPU utilization of each core range is 0-100. For example, if there are four CPUs, the `CPUUtilization` range is 0%–400%. For endpoint variants, the value is the sum of the CPU utilization of the primary and supplementary containers on the instance. Units: Percent
`MemoryUtilization`	The percentage of memory that is used by the containers on an instance. This value range is 0%-100%. For endpoint variants, the value is the sum of the memory utilization of the primary and supplementary containers on the instance. Units: Percent
`GPUUtilization`	The percentage of GPU units that are used by the containers on an instance. The value can range betweenrange is 0-100 and is multiplied by the number of GPUs. For example, if there are four GPUs, the `GPUUtilization` range is 0%–400%. For endpoint variants, the value is the sum of the GPU utilization of the primary and supplementary containers on the instance. Units: Percent

Metric	Description
`GPUMemoryUtilization`	The percentage of GPU memory used by the containers on an instance. The value range is 0-100 and is multiplied by the number of GPUs. For example, if there are four GPUs, the `GPUMemoryUtilization` range is 0%-400%. For endpoint variants, the value is the sum of the GPU memory utilizati on of the primary and supplementary containers on the instance. Units: Percent
`DiskUtilization`	The percentage of disk space used by the containers on an instance. This value range is 0%–100%. For endpoint variants, the value is the sum of the disk space utilization of the primary and supplementary containers on the instance. Units: Percent

Set SageMaker AI multi-model endpoint model caching behavior

By default, multi-model endpoints cache frequently used models in memory (CPU or GPU, depending on whether you have CPU or GPU backed instances) and on disk to provide low latency inference. The cached models are unloaded and/or deleted from disk only when a container runs out of memory or disk space to accommodate a newly targeted model.

You can change the caching behavior of a multi-model endpoint and explicitly enable or disable model caching by setting the parameter `ModelCacheSetting` when you call create_model.

We recommend setting the value of the `ModelCacheSetting` parameter to `Disabled` for use cases that do not benefit from model caching. For example, when a large number of models need to be served from the endpoint but each model is invoked only once (or very infrequently). For such use cases, setting the value of the `ModelCacheSetting` parameter to `Disabled` allows higher transactions per second (TPS) for `invoke_endpoint` requests compared to the default caching mode. Higher TPS in these use cases is because SageMaker AI does the following after the `invoke_endpoint` request:

- Asynchronously unloads the model from memory and deletes it from disk immediately after it is invoked.
- Provides higher concurrency for downloading and loading models in the inference container. For both CPU and GPU backed endpoints, the concurrency is a factor of the number of the vCPUs of the container instance.

For guidelines on choosing a SageMaker AI ML instance type for a multi-model endpoint, see Instance recommendations for multi-model endpoint deployments.

Set Auto Scaling Policies for Multi-Model Endpoint Deployments

SageMaker AI multi-model endpoints fully support automatic scaling, which manages replicas of models to ensure models scale based on traffic patterns. We recommend that you configure your multi-model endpoint and the size of your instances based on Instance recommendations for multi-model endpoint deployments and also set up instance based auto scaling for your endpoint. The invocation rates used to trigger an auto-scale event are based on the aggregate set of predictions across the full set of models served by the endpoint. For additional details on setting up endpoint auto scaling, see Automatically Scale Amazon SageMaker AI Models.

You can set up auto scaling policies with predefined and custom metrics on both CPU and GPU backed multi-model endpoints.

> **Note**
>
> SageMaker AI multi-model endpoint metrics are available at one-minute granularity.

Define a scaling policy

To specify the metrics and target values for a scaling policy, you can configure a target-tracking scaling policy. You can use either a predefined metric or a custom metric.

Scaling policy configuration is represented by a JSON block. You save your scaling policy configuration as a JSON block in a text file. You use that text file when invoking the Amazon CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see `TargetTrackingScalingPolicyConfiguration` in the *Application Auto Scaling API Reference*.

The following options are available for defining a target-tracking scaling policy configuration.

Use a predefined metric

To quickly define a target-tracking scaling policy for a variant, use the `SageMakerVariantInvocationsPerInstance` predefined metric. `SageMakerVariantInvocationsPerInstance` is the average number of times per minute that each instance for a variant is invoked. We strongly recommend using this metric.

To use a predefined metric in a scaling policy, create a target tracking configuration for your policy. In the target tracking configuration, include a `PredefinedMetricSpecification` for the predefined metric and a `TargetValue` for the target value of that metric.

The following example is a typical policy configuration for target-tracking scaling for a variant. In this configuration, we use the `SageMakerVariantInvocationsPerInstance` predefined metric to adjust the number of variant instances so that each instance has an `InvocationsPerInstance` metric of `70`.

```
{"TargetValue": 70.0,
    "PredefinedMetricSpecification":
    {
        "PredefinedMetricType": "InvocationsPerInstance"
    }
}
```

> **Note**
>
> We recommend that you use `InvocationsPerInstance` while using multi-model endpoints. The `TargetValue` for this metric depends on your application's latency requirements. We also recommend that you load test your endpoints to set up suitable scaling parameter values. To learn more about load testing and setting up autoscaling for your endpoints, see the blog Configuring autoscaling inference endpoints in Amazon SageMaker AI.

Use a custom metric

If you need to define a target-tracking scaling policy that meets your custom requirements, define a custom metric. You can define a custom metric based on any production variant metric that changes in proportion to scaling.

Not all SageMaker AI metrics work for target tracking. The metric must be a valid utilization metric, and it must describe how busy an instance is. The value of the metric must increase or decrease in inverse proportion to the number of variant instances. That is, the value of the metric should decrease when the number of instances increases.

> **Important**
>
> Before deploying automatic scaling in production, you must test automatic scaling with your custom metric.

Example custom metric for a CPU backed multi-model endpoint

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a model named `my-model`, a custom metric of `CPUUtilization` adjusts the instance count on the endpoint based on an average CPU utilization of 50% across all instances.

```
{"TargetValue": 50,
    "CustomizedMetricSpecification":
    {"MetricName": "CPUUtilization",
        "Namespace": "/aws/sagemaker/Endpoints",
        "Dimensions": [
            {"Name": "EndpointName", "Value": "my-endpoint" },
            {"Name": "ModelName","Value": "my-model"}
        ],
        "Statistic": "Average",
        "Unit": "Percent"
    }
}
```

Example custom metric for a GPU backed multi-model endpoint

The following example is a target-tracking configuration for a scaling policy. In this configuration, for a model named `my-model`, a custom metric of `GPUUtilization` adjusts the instance count on the endpoint based on an average GPU utilization of 50% across all instances.

```
{"TargetValue": 50,
    "CustomizedMetricSpecification":
    {"MetricName": "GPUUtilization",
        "Namespace": "/aws/sagemaker/Endpoints",
        "Dimensions": [
```

```
            {"Name": "EndpointName", "Value": "my-endpoint" },
            {"Name": "ModelName","Value": "my-model"}
        ],
        "Statistic": "Average",
        "Unit": "Percent"
    }
}
```

Add a cooldown period

To add a cooldown period for scaling out your endpoint, specify a value, in seconds, for `ScaleOutCooldown`. Similarly, to add a cooldown period for scaling in your model, add a value, in seconds, for `ScaleInCooldown`. For more information about `ScaleInCooldown` and `ScaleOutCooldown`, see `TargetTrackingScalingPolicyConfiguration` in the *Application Auto Scaling API Reference*.

The following is an example target-tracking configuration for a scaling policy. In this configuration, the `SageMakerVariantInvocationsPerInstance` predefined metric is used to adjust scaling based on an average of `70` across all instances of that variant. The configuration provides a scale-in cooldown period of 10 minutes and a scale-out cooldown period of 5 minutes.

```
{"TargetValue": 70.0,
    "PredefinedMetricSpecification":
    {"PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    },
    "ScaleInCooldown": 600,
    "ScaleOutCooldown": 300
}
```

Multi-container endpoints

SageMaker AI multi-container endpoints enable customers to deploy multiple containers, that use different models or frameworks, on a single SageMaker AI endpoint. The containers can be run in a sequence as an inference pipeline, or each container can be accessed individually by using direct invocation to improve endpoint utilization and optimize costs.

For information about invoking the containers in a multi-container endpoint in sequence, see Inference pipelines in Amazon SageMaker AI.

For information about invoking a specific container in a multi-container endpoint, see Invoke a multi-container endpoint with direct invocation

Topics

- Create a multi-container endpoint (Boto 3)
- Update a multi-container endpoint
- Invoke a multi-container endpoint with direct invocation
- Security with multi-container endpoints with direct invocation
- Metrics for multi-container endpoints with direct invocation
- Autoscale multi-container endpoints
- Troubleshoot multi-container endpoints

Create a multi-container endpoint (Boto 3)

Create a Multi-container endpoint by calling CreateModel, CreateEndpointConfig, and CreateEndpoint APIs as you would to create any other endpoints. You can run these containers sequentially as an inference pipeline, or run each individual container by using direct invocation. Multi-container endpoints have the following requirements when you call `create_model`:

- Use the `Containers` parameter instead of `PrimaryContainer`, and include more than one container in the `Containers` parameter.
- The `ContainerHostname` parameter is required for each container in a multi-container endpoint with direct invocation.
- Set the `Mode` parameter of the `InferenceExecutionConfig` field to `Direct` for direct invocation of each container, or `Serial` to use containers as an inference pipeline. The default mode is `Serial`.

> **Note**
>
> Currently there is a limit of up to 15 containers supported on a multi-container endpoint.

The following example creates a multi-container model for direct invocation.

1. Create container elements and `InferenceExecutionConfig` with direct invocation.

```
container1 = {
                'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/
myimage1:mytag',
```

```
                'ContainerHostname': 'firstContainer'
            }

container2 = {
                'Image': '123456789012.dkr.ecr.us-east-1.amazonaws.com/
myimage2:mytag',
                'ContainerHostname': 'secondContainer'
            }
inferenceExecutionConfig = {'Mode': 'Direct'}
```

2. Create the model with the container elements and set the `InferenceExecutionConfig` field.

```
import boto3
sm_client = boto3.Session().client('sagemaker')

response = sm_client.create_model(
               ModelName = 'my-direct-mode-model-name',
               InferenceExecutionConfig = inferenceExecutionConfig,
               ExecutionRoleArn = role,
               Containers = [container1, container2]
           )
```

To create an endoint, you would then call create_endpoint_config and create_endpoint as you would to create any other endpoint.

Update a multi-container endpoint

To update an Amazon SageMaker AI multi-container endpoint, complete the following steps.

1. Call create_model to create a new model with a new value for the `Mode` parameter in the `InferenceExecutionConfig` field.
2. Call create_endpoint_config to create a new endpoint config with a different name by using the new model you created in the previous step.
3. Call update_endpoint to update the endpoint with the new endpoint config you created in the previous step.

Invoke a multi-container endpoint with direct invocation

SageMaker AI multi-container endpoints enable customers to deploy multiple containers to deploy different models on a SageMaker AI endpoint. You can host up to 15 different inference containers on a single endpoint. By using direct invocation, you can send a request to a specific inference container hosted on a multi-container endpoint.

To invoke a multi-container endpoint with direct invocation, call invoke_endpoint as you would invoke any other endpoint, and specify which container you want to invoke by using the `TargetContainerHostname` parameter.

The following example directly invokes the `secondContainer` of a multi-container endpoint to get a prediction.

```
import boto3
runtime_sm_client = boto3.Session().client('sagemaker-runtime')

response = runtime_sm_client.invoke_endpoint(
   EndpointName ='my-endpoint',
   ContentType = 'text/csv',
   TargetContainerHostname='secondContainer',
   Body = body)
```

For each direct invocation request to a multi-container endpoint, only the container with the `TargetContainerHostname` processes the invocation request. You will get validation errors if you do any of the following:

- Specify a `TargetContainerHostname` that does not exist in the endpoint
- Do not specify a value for `TargetContainerHostname` in a request to an endpoint configured for direct invocation
- Specify a value for `TargetContainerHostname` in a request to an endpoint that is not configured for direct invocation.

Security with multi-container endpoints with direct invocation

For multi-container endpoints with direct invocation, there are multiple containers hosted in a single instance by sharing memory and a storage volume. It's your responsibility to use secure containers, maintain the correct mapping of requests to target containers, and provide users with

the correct access to target containers. SageMaker AI uses IAM roles to provide IAM identity-based policies that you use to specify whether access to a resource is allowed or denied to that role, and under what conditions. For information about IAM roles, see IAM roles in the *Amazon Identity and Access Management User Guide*. For information about identity-based policies, see Identity-based policies and resource-based policies.

By default, an IAM principal with `InvokeEndpoint` permissions on a multi-container endpoint with direct invocation can invoke any container inside the endpoint with the endpoint name that you specify when you call `invoke_endpoint`. If you need to restrict `invoke_endpoint` access to a limited set of containers inside a multi-container endpoint, use the `sagemaker:TargetContainerHostname` IAM condition key. The following policies show how to limit calls to specific containers within an endpoint.

The following policy allows `invoke_endpoint` requests only when the value of the `TargetContainerHostname` field matches one of the specified regular expressions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Allow",
            "Resource": "arn:aws-cn:sagemaker:us-
east-1:111122223333:endpoint/endpoint_name",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetModel": [
                        "customIps*",
                        "common*"
                    ]
                }
            }
        }
    ]
}
```

The following policy denies `invoke_endpoint` requests when the value of the `TargetContainerHostname` field matches one of the specified regular expressions in the `Deny` statement.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Allow",
            "Resource": "arn:aws-cn:sagemaker:us-
east-1:111122223333:endpoint/endpoint_name",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetModel": [
                        "model_name*"
                    ]
                }
            }
        },
        {
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Effect": "Deny",
            "Resource": "arn:aws-cn:sagemaker:us-
east-1:111122223333:endpoint/endpoint_name",
            "Condition": {
                "StringLike": {
                    "sagemaker:TargetModel": [
                        "special-model_name*"
                    ]
                }
            }
        }
    ]
}
```

For information about SageMaker AI condition keys, see Condition Keys for SageMaker AI in the *Amazon Identity and Access Management User Guide*.

Metrics for multi-container endpoints with direct invocation

In addition to the endpoint metrics that are listed in Amazon SageMaker AI metrics in Amazon CloudWatch, SageMaker AI also provides per-container metrics.

Per-container metrics for multi-container endpoints with direct invocation are located in CloudWatch and categorized into two namespaces: `AWS/SageMaker` and `aws/sagemaker/Endpoints`. The `AWS/SageMaker` namespace includes invocation-related metrics, and the `aws/sagemaker/Endpoints` namespace includes memory and CPU utilization metrics.

The following table lists the per-container metrics for multi-container endpoints with direct invocation. All the metrics use the [`EndpointName, VariantName, ContainerName`] dimension, which filters metrics at a specific endpoint, for a specific variant and corresponding to a specific container. These metrics share the same metric names as in those for inference pipelines, but at a per-container level [`EndpointName, VariantName, ContainerName`].

Metric Name	Description	Dimension	NameSpace
`Invocations`	The number of `InvokeEndpoint` requests sent to a container inside an endpoint. To get the total number of requests sent to that container, use the `Sum` statistic. Units: None Valid statistics: `Sum`, `Sample Count`	`EndpointName , VariantName , ContainerName`	`AWS/SageMaker`
`Invocation4XX Errors`	The number of `InvokeEndpoint` requests that the model returned a `4xx` HTTP response	`EndpointName , VariantName , ContainerName`	`AWS/SageMaker`

	code for on a specific container. For each 4xx response, SageMaker AI sends a 1. Units: None Valid statistics: Average, Sum		
Invocation5XX Errors	The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for on a specific container. For each 5xx response, SageMaker AI sends a 1. Units: None Valid statistics: Average, Sum	EndpointName , VariantName , ContainerName	AWS/SageMaker

`Container Latency`	The time it took for the target container to respond as viewed from SageMaker AI. `Container Latency` includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container . Units: Microseconds Valid statistics: `Average`, `Sum`, `Min`, `Max`, `Sample Count`	`EndpointName` , `VariantName` , `ContainerName`	`AWS/SageMaker`

`OverheadLatency`	The time added to the time taken to respond to a client request by SageMaker AI for overhead. `OverheadLatency` is measured from the time that SageMaker AI receives the request until it returns a response to the client, minus the`ModelLatency` . Overhead latency can vary depending on request and response payload sizes, request frequency, and authentication or authorization of the request, among other factors. Units: Microseconds Valid statistics: `Average`, `Sum`, `Min`, `Max`, `Sample Count `	`EndpointName` , `VariantName` , `ContainerName`	`AWS/SageMaker`

`CPUUtilization`	The percentage of CPU units that are used by each container running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, `CPUUtilization` can range from 0% to 400%. For endpoints with direct invocation, the number of CPUUtilization metrics equals the number of containers in that endpoint. Units: Percent	`EndpointName`, `VariantName`, `ContainerName`	`aws/sagemaker/Endpoints`

`MemoryUti lizaton`	The percentage of memory that is used by each container running on an instance. This value ranges from 0% to 100%. Similar as CPUUtilization, in endpoints with direct invocatio n, the number of MemoryUtilization metrics equals the number of container s in that endpoint. Units: Percent	`EndpointName , VariantName , ContainerName`	`aws/sagemaker/ Endpoints`

All the metrics in the previous table are specific to multi-container endpoints with direct invocation. Besides these special per-container metrics, there are also metrics at the variant level with dimension `[EndpointName, VariantName]` for all the metrics in the table expect `ContainerLatency`.

Autoscale multi-container endpoints

If you want to configure automatic scaling for a multi-container endpoint using the `InvocationsPerInstance` metric, we recommend that the model in each container exhibits similar CPU utilization and latency on each inference request. This is recommended because if traffic to the multi-container endpoint shifts from a low CPU utilization model to a high CPU utilization model, but the overall call volume remains the same, the endpoint does not scale out and there may not be enough instances to handle all the requests to the high CPU utilization model. For information about automatically scaling endpoints, see Automatic scaling of Amazon SageMaker AI models.

Troubleshoot multi-container endpoints

The following sections can help you troubleshoot errors with multi-container endpoints.

Ping Health Check Errors

With multiple containers, endpoint memory and CPU are under higher pressure during endpoint creation. Specifically, the `MemoryUtilization` and `CPUUtilization` metrics are higher than for single-container endpoints, because utilization pressure is proportional to the number of containers. Because of this, we recommend that you choose instance types with enough memory and CPU to ensure that there is enough memory on the instance to have all the models loaded (the same guidance applies to deploying an inference pipeline). Otherwise, your endpoint creation might fail with an error such as `XXX did not pass the ping health check`.

Missing accept-bind-to-port=true Docker label

The containers in a multi-container endpoints listen on the port specified in the `SAGEMAKER_BIND_TO_PORT` environment variable instead of port 8080. When a container runs in a multi-container endpoint, SageMaker AI automatically provides this environment variable to the container. If this environment variable isn't present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

Otherwise, You will see an error message such as `Your Ecr Image XXX does not contain required com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true Docker label(s).`

If your container needs to listen on a second port, choose a port in the range specified by the `SAGEMAKER_SAFE_PORT_RANGE` environment variable. Specify the value as an inclusive range in the format *XXXX*-*YYYY*, where XXXX and YYYY are multi-digit integers. SageMaker AI provides this value automatically when you run the container in a multi-container endpoint.

Inference pipelines in Amazon SageMaker AI

An *inference pipeline* is a Amazon SageMaker AI model that is composed of a linear sequence of two to fifteen containers that process requests for inferences on data. You use an inference pipeline to define and deploy any combination of pretrained SageMaker AI built-in algorithms and your own custom algorithms packaged in Docker containers. You can use an inference pipeline to combine preprocessing, predictions, and post-processing data science tasks. Inference pipelines are fully managed.

You can add SageMaker AI Spark ML Serving and scikit-learn containers that reuse the data transformers developed for training models. The entire assembled inference pipeline can be considered as a SageMaker AI model that you can use to make either real-time predictions or to process batch transforms directly without any external preprocessing.

Within an inference pipeline model, SageMaker AI handles invocations as a sequence of HTTP requests. The first container in the pipeline handles the initial request, then the intermediate response is sent as a request to the second container, and so on, for each container in the pipeline. SageMaker AI returns the final response to the client.

When you deploy the pipeline model, SageMaker AI installs and runs all of the containers on each Amazon Elastic Compute Cloud (Amazon EC2) instance in the endpoint or transform job. Feature processing and inferences run with low latency because the containers are co-located on the same EC2 instances. You define the containers for a pipeline model using the `CreateModel` operation or from the console. Instead of setting one `PrimaryContainer`, you use the `Containers` parameter to set the containers that make up the pipeline. You also specify the order in which the containers are executed.

A pipeline model is immutable, but you can update an inference pipeline by deploying a new one using the `UpdateEndpoint` operation. This modularity supports greater flexibility during experimentation.

For information on how to create an inference pipeline with the SageMaker Model Registry, see Model Registration Deployment with Model Registry.

There are no additional costs for using this feature. You pay only for the instances running on an endpoint.

Topics

- Create a Pipeline Model
- Run Real-time Predictions with an Inference Pipeline
- Batch transforms with inference pipelines
- Inference Pipeline Logs and Metrics
- Troubleshoot Inference Pipelines

Sample Notebooks for Inference Pipelines

For an example that shows how to create and deploy inference pipelines, see the Inference Pipeline with Scikit-learn and Linear Learner sample notebook. For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances.

To see a list of all the SageMaker AI samples, after creating and opening a notebook instance, choose the **SageMaker AI Examples** tab. There are three inference pipeline notebooks. The first two inference pipeline notebooks just described are located in the `advanced_functionality` folder and the third notebook is in the `sagemaker-python-sdk` folder. To open a notebook, choose its **Use** tab, then choose **Create copy**.

Feature Processing with Spark ML and Scikit-learn

Before training a model with either Amazon SageMaker AI built-in algorithms or custom algorithms, you can use Spark and scikit-learn preprocessors to transform your data and engineer features.

Feature Processing with Spark ML

You can run Spark ML jobs with Amazon Glue, a serverless ETL (extract, transform, load) service, from your SageMaker AI notebook. You can also connect to existing EMR clusters to run Spark ML jobs with Amazon EMR. To do this, you need an Amazon Identity and Access Management (IAM) role that grants permission for making calls from your SageMaker AI notebook to Amazon Glue.

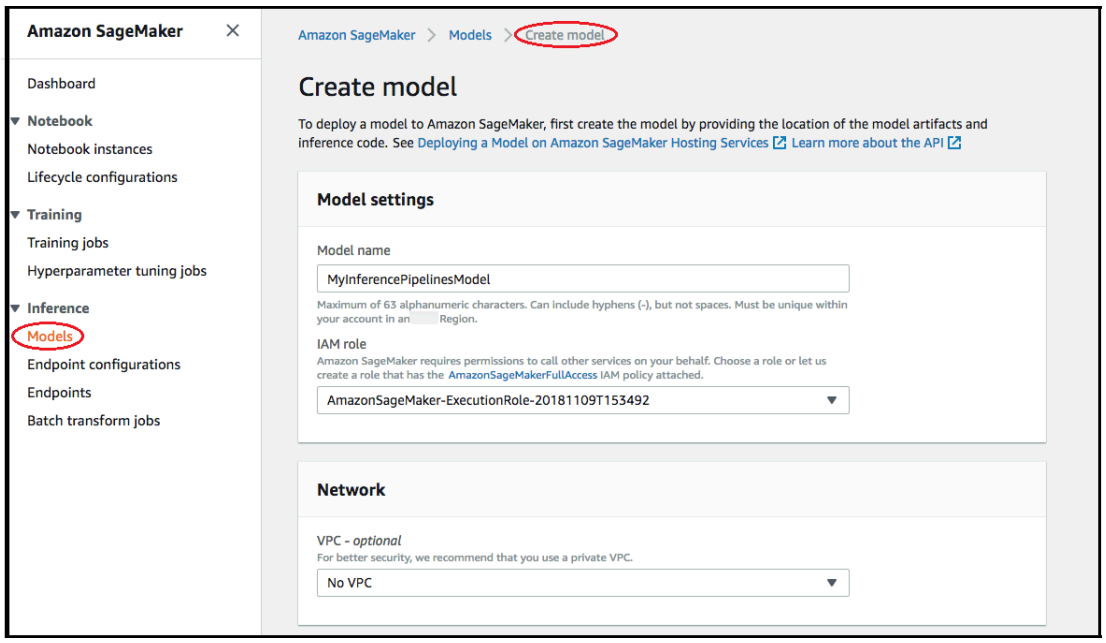
> **Note**
>
> To see which Python and Spark versions Amazon Glue supports, refer to Amazon Glue Release Notes.

After engineering features, you package and serialize Spark ML jobs with MLeap into MLeap containers that you can add to an inference pipeline. You don't need to use externally managed Spark clusters. With this approach, you can seamlessly scale from a sample of rows to terabytes of data. The same transformers work for both training and inference, so you don't need to duplicate preprocessing and feature engineering logic or develop a one-time solution to make the models persist. With inference pipelines, you don't need to maintain outside infrastructure, and you can make predictions directly from data inputs.

When you run a Spark ML job on Amazon Glue, a Spark ML pipeline is serialized into MLeap format. Then, you can use the job with the SparkML Model Serving Container in a SageMaker AI Inference Pipeline. *MLeap* is a serialization format and execution engine for machine learning pipelines. It supports Spark, Scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

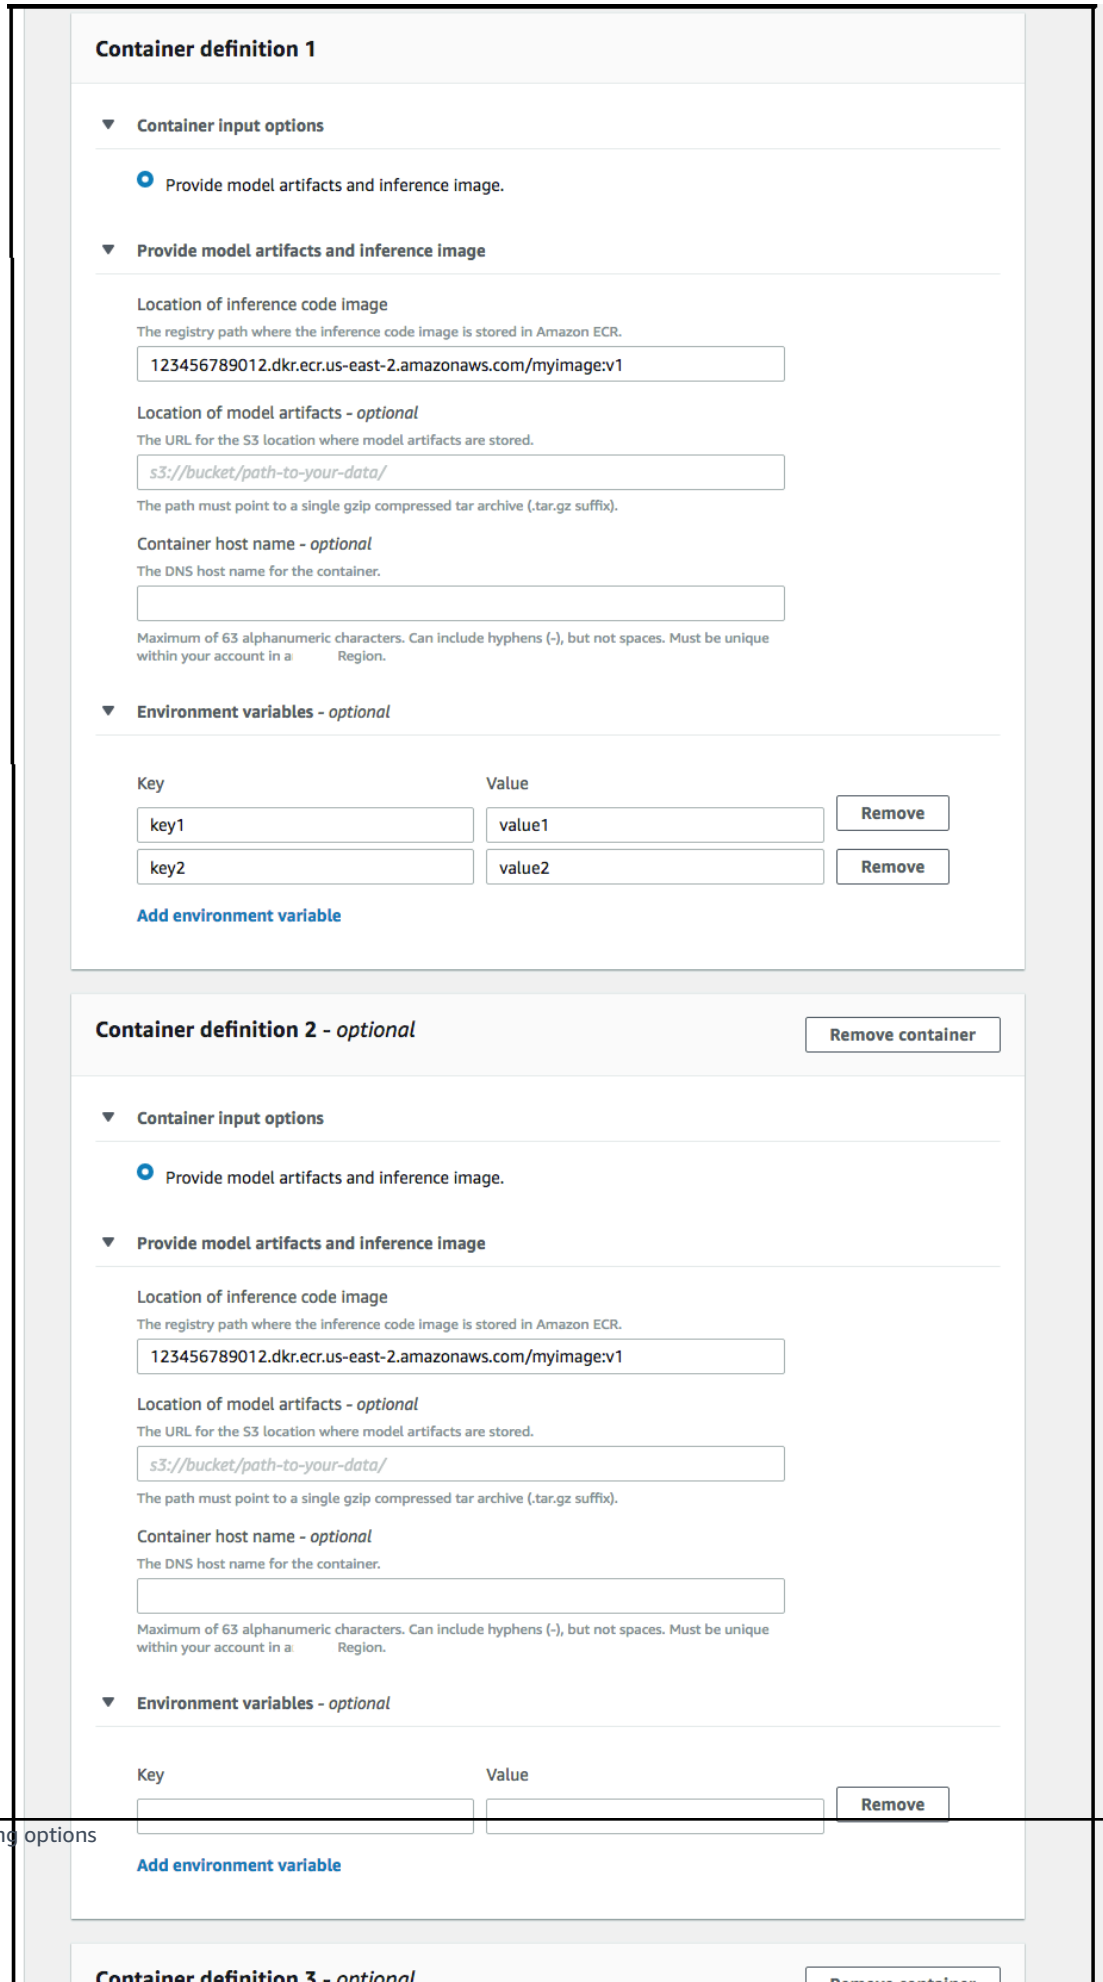
For an example that shows how to feature process with Spark ML, see the Train an ML Model using Apache Spark in Amazon EMR and deploy in SageMaker AI sample notebook.

Feature Processing with Scikit-Learn



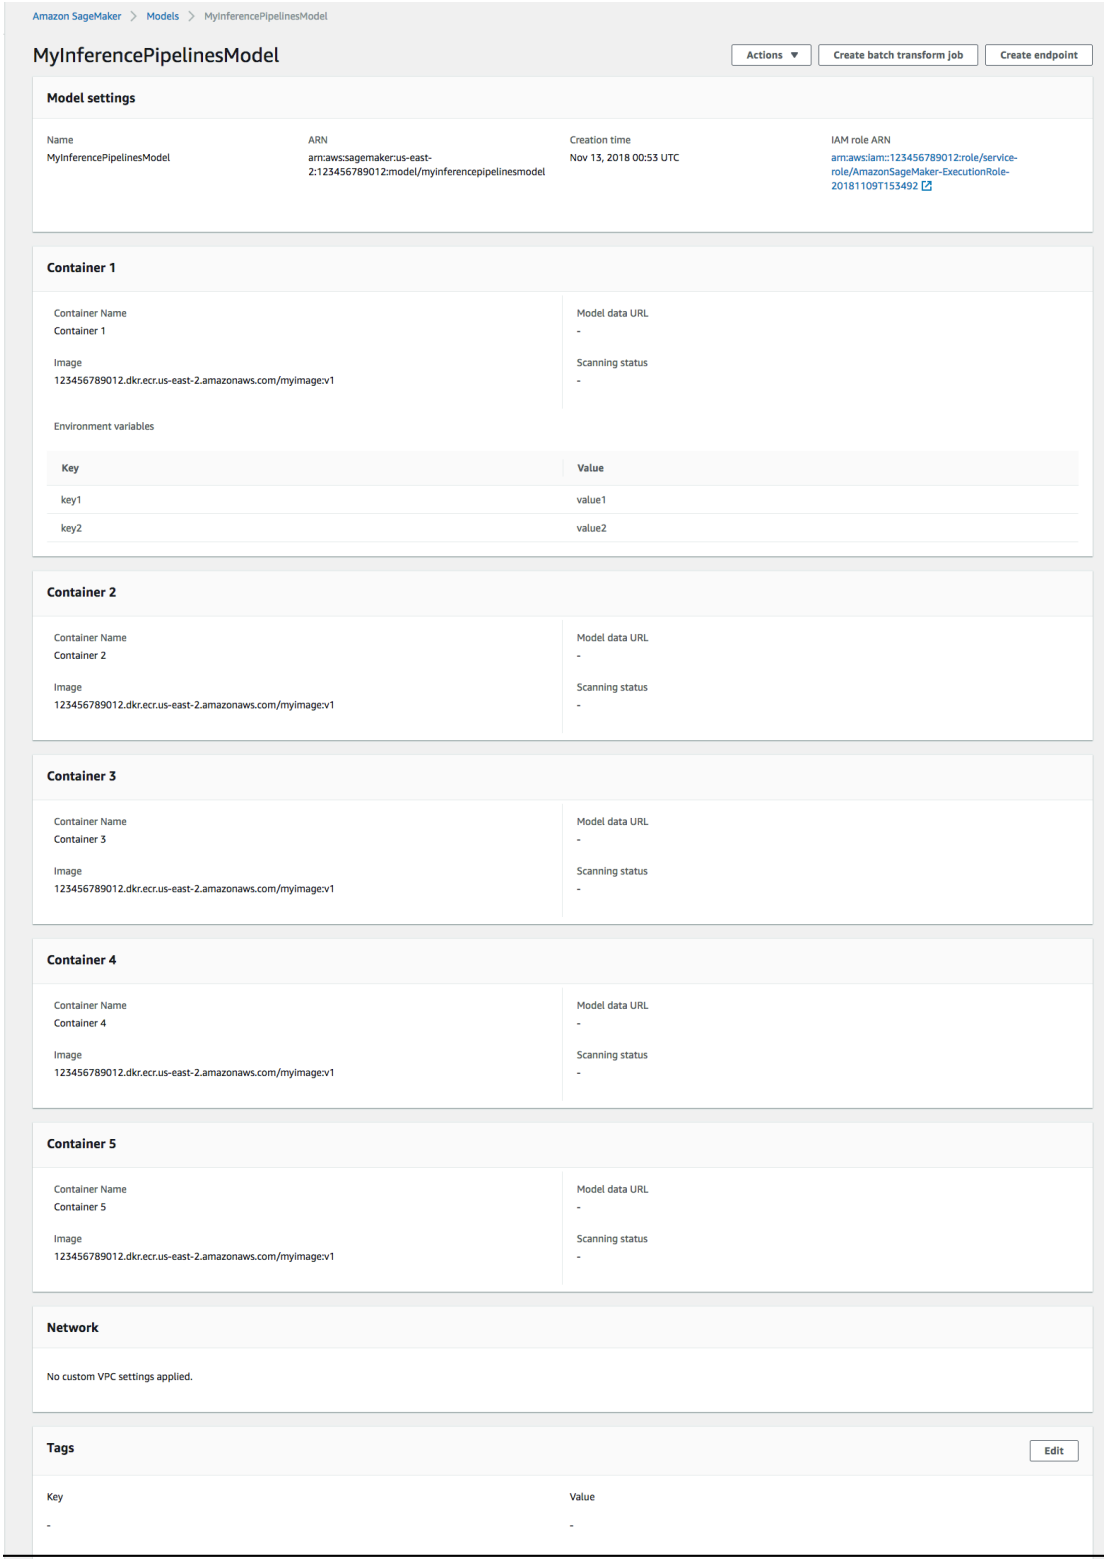
You can run and package scikit-learn jobs into containers directly in Amazon SageMaker AI. For an example of Python code for building a scikit-learn featurizer model that trains on Fisher's Iris flower data set and predicts the species of Iris based on morphological measurements, see IRIS Training and Prediction with Sagemaker Scikit-learn.

Create a Pipeline Model



To create a pipeline model that can be deployed to an endpoint or used for a batch transform job, use the Amazon SageMaker AI console or the `CreateModel` operation.

To create an inference pipeline (console)



1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. Choose **Models**, and then choose **Create models** from the **Inference** group.
3. On the **Create model** page, provide a model name, choose an IAM role, and, if you want to use a private VPC, specify VPC values.

4. To add information about the containers in the inference pipeline, choose **Add container**, then choose **Next**.
5. Complete the fields for each container in the order that you want to execute them, up to the maximum of fifteen. Complete the **Container input options**, , **Location of inference code image**, and, optionally, **Location of model artifacts**, **Container host name**, and **Environmental variables** fields. .

Container definition 1
Container input options
Provide model artifacts and inference image.
Provide model artifacts and inference image
Location of inference code image
The registry path where the inference code image is stored in Amazon ECR.

Add environment variable

The **MyInferencePipelineModel** page summarizes the settings for the containers that provide input for the model. If you provided the environment variables in a corresponding container definition, SageMaker AI shows them in the **Environment variables** field.

Run Real-time Predictions with an Inference Pipeline

You can use trained models in an inference pipeline to make real-time predictions directly without performing external preprocessing. When you configure the pipeline, you can choose to use the built-in feature transformers already available in Amazon SageMaker AI. Or, you can implement your own transformation logic using just a few lines of scikit-learn or Spark code.

MLeap, a serialization format and execution engine for machine learning pipelines, supports Spark, scikit-learn, and TensorFlow for training pipelines and exporting them to a serialized pipeline called an MLeap Bundle. You can deserialize Bundles back into Spark for batch-mode scoring or into the MLeap runtime to power real-time API services.

The containers in a pipeline listen on the port specified in the `SAGEMAKER_BIND_TO_PORT` environment variable (instead of 8080). When running in an inference pipeline, SageMaker AI automatically provides this environment variable to containers. If this environment variable isn't present, containers default to using port 8080. To indicate that your container complies with this requirement, use the following command to add a label to your Dockerfile:

```
LABEL com.amazonaws.sagemaker.capabilities.accept-bind-to-port=true
```

If your container needs to listen on a second port, choose a port in the range specified by the `SAGEMAKER_SAFE_PORT_RANGE` environment variable. Specify the value as an inclusive range in the format **"XXXX-YYYY"**, where XXXX and YYYY are multi-digit integers. SageMaker AI provides this value automatically when you run the container in a multicontainer pipeline.

> **Note**
>
> To use custom Docker images in a pipeline that includes SageMaker AI built-in algorithms, you need an Amazon Elastic Container Registry (Amazon ECR) policy. Your Amazon ECR repository must grant SageMaker AI permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines.

Create and Deploy an Inference Pipeline Endpoint

The following code creates and deploys a real-time inference pipeline model with SparkML and XGBoost models in series using the SageMaker AI SDK.

```
from sagemaker.serve import ModelBuilder
```

```
sparkml_data = 's3://{}/{}/{}'.format(s3_model_bucket, s3_model_key_prefix,
 'model.tar.gz')

model_name = 'serial-inference-' + timestamp_prefix
endpoint_name = 'serial-inference-ep-' + timestamp_prefix

model_builder = ModelBuilder(
    s3_model_data_url=sparkml_data,
    role_arn=role,
    instance_type='ml.c4.xlarge',
    pipeline_models=[sparkml_data, xgb_model.s3_model_data_url],
)
endpoint = model_builder.build().deploy(
    initial_instance_count=1,
    instance_type='ml.c4.xlarge',
    endpoint_name=endpoint_name
)
```

Request Real-Time Inference from an Inference Pipeline Endpoint

The following example shows how to make real-time predictions by calling an inference endpoint and passing a request payload in JSON format:

```
import json
from sagemaker.core.resources import Endpoint

payload = {
        "input": [
            {
                "name": "Pclass",
                "type": "float",
                "val": "1.0"
            },
            {
                "name": "Embarked",
                "type": "string",
                "val": "Q"
            },
            {
                "name": "Age",
                "type": "double",
                "val": "48.0"
```

```
            },
            {
                "name": "Fare",
                "type": "double",
                "val": "100.67"
            },
            {
                "name": "SibSp",
                "type": "double",
                "val": "1.0"
            },
            {
                "name": "Sex",
                "type": "string",
                "val": "male"
            }
        ],
        "output": {
            "name": "features",
            "type": "double",
            "struct": "vector"
        }
    }

endpoint = Endpoint(endpoint_name=endpoint_name)

response = endpoint.invoke(body=json.dumps(payload), content_type='application/json',
 accept='application/json')
print(response)
```

The response you get is the model's inference result.

Realtime inference pipeline example

You can run this example notebook using the SKLearn predictor that shows how to deploy an endpoint, run an inference request, then deserialize the response. Find this notebook and more examples in the Amazon SageMaker example GitHub repository.

Batch transforms with inference pipelines

To get inferences on an entire dataset you run a batch transform on a trained model. To run inferences on a full dataset, you can use the same inference pipeline model created and deployed to an endpoint for real-time processing in a batch transform job. To run a batch transform job

in a pipeline, you download the input data from Amazon S3 and send it in one or more HTTP requests to the inference pipeline model. For an example that shows how to prepare data for a batch transform, see "Section 2 - Preprocess the raw housing data using Scikit Learn" of the Amazon SageMaker Multi-Model Endpoints using Linear Learner sample notebook. For information about Amazon SageMaker AI batch transforms, see Batch transform for inference with Amazon SageMaker AI.

> **Note**
>
> To use custom Docker images in a pipeline that includes Amazon SageMaker AI built-in algorithms, you need an Amazon Elastic Container Registry (ECR) policy. Your Amazon ECR repository must grant SageMaker AI permission to pull the image. For more information, see Troubleshoot Amazon ECR Permissions for Inference Pipelines.

The following example shows how to run a transform job using the Amazon SageMaker Python SDK. In this example, `model_name` is the inference pipeline that combines SparkML and XGBoost models (created in previous examples). The Amazon S3 location specified by `input_data_path` contains the input data, in CSV format, to be downloaded and sent to the Spark ML model. After the transform job has finished, the Amazon S3 location specified by `output_data_path` contains the output data returned by the XGBoost model in CSV format.

```
from sagemaker.transform import TransformJob

input_data_path = 's3://{}/{}/{}'.format(default_bucket, 'key', 'file_name')
output_data_path = 's3://{}/{}'.format(default_bucket, 'key')
transform_job = TransformJob.create(
    model_name = model_name,
    transform_input = {
        'DataSource': {
            'S3DataSource': {
                'S3DataType': 'S3Prefix',
                'S3Uri': input_data_path
            }
        },
        'ContentType': CONTENT_TYPE_CSV,
        'SplitType': 'Line'
    },
    transform_output = {
        'S3OutputPath': output_data_path,
```

```
        'Accept': CONTENT_TYPE_CSV,
        'AssembleWith': 'Line'
    },
    transform_resources = {
        'InstanceType': 'ml.m4.xlarge',
        'InstanceCount': 1
    },
    transform_job_name = 'inference-pipelines-batch',
    batch_strategy = 'SingleRecord'
)
```

Inference Pipeline Logs and Metrics

Monitoring is important for maintaining the reliability, availability, and performance of Amazon SageMaker AI resources. To monitor and troubleshoot inference pipeline performance, use Amazon CloudWatch logs and error messages. For information about the monitoring tools that SageMaker AI provides, see Monitoring Amazon resources in Amazon SageMaker AI.

Use Metrics to Monitor Multi-container Models

To monitor the multi-container models in Inference Pipelines, use Amazon CloudWatch. CloudWatch collects raw data and processes it into readable, near real-time metrics. SageMaker AI training jobs and endpoints write CloudWatch metrics and logs in the `AWS/SageMaker` namespace.

The following tables list the metrics and dimensions for the following:

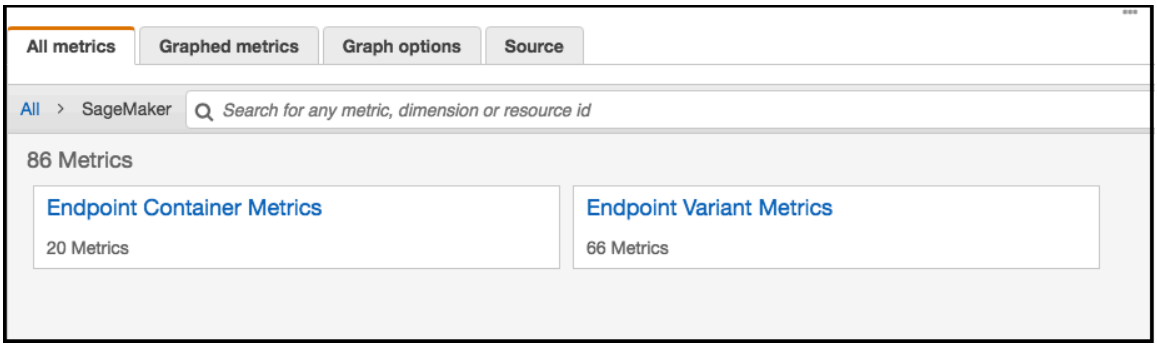
- Endpoint invocations
- Training jobs, batch transform jobs, and endpoint instances

A *dimension* is a name/value pair that uniquely identifies a metric. You can assign up to 10 dimensions to a metric. For more information on monitoring with CloudWatch, see Amazon SageMaker AI metrics in Amazon CloudWatch.

Endpoint Invocation Metrics

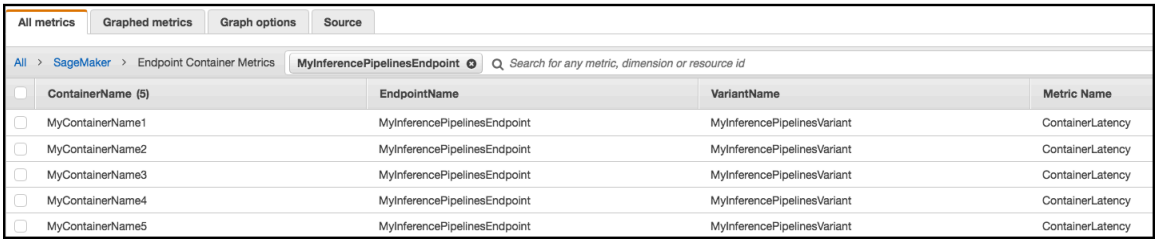
The `AWS/SageMaker` namespace includes the following request metrics from calls to `InvokeEndpoint`.

Metrics are reported at a 1-minute intervals.



Metric	Description
Invocation4XXErrors	The number of InvokeEndpoint requests that the model returned a 4xx HTTP response code for. For each 4xx response, SageMaker AI sends a 1. Units: None Valid statistics: Average, Sum
Invocation5XXErrors	The number of InvokeEndpoint requests that the model returned a 5xx HTTP response code for. For each 5xx response, SageMaker AI sends a 1. Units: None Valid statistics: Average, Sum
Invocations	The number of InvokeEndpoint requests sent to a model endpoint. To get the total number of requests sent to a model endpoint, use the Sum statistic. Units: None Valid statistics: Sum, Sample Count
InvocationsPerInstance	The number of endpoint invocations sent to a model, normalized by InstanceCount in each ProductionVariant . SageMaker AI sends 1/numberOfInstances as the value for each request, where numberOfInstances is the number of active instances for the ProductionVariant at the endpoint at the time of the request. Units: None Valid statistics: Sum
ModelLatency	The time the model or models took to respond. This includes the time it took to send the request, to fetch the response from the model

Metric	Description
	container, and to complete the inference in the container. `ModelLatency` is the total time taken by all containers in an inference pipeline. Units: Microseconds Valid statistics: `Average`, `Sum`, `Min`, `Max`, Sample Count
`OverheadLatency`	The time added to the time taken to respond to a client request by SageMaker AI for overhead. `OverheadLatency` is measured from the time that SageMaker AI receives the request until it returns a response to the client, minus the `ModelLatency` . Overhead latency can vary depending on request and response payload sizes, request frequency , and authentication or authorization of the request, among other factors. Units: Microseconds Valid statistics: `Average`, `Sum`, `Min`, `Max`, `Sample Count`
`ContainerLatency`	The time it took for an Inference Pipelines container to respond as viewed from SageMaker AI. `ContainerLatency` includes the time it took to send the request, to fetch the response from the model's container, and to complete inference in the container. Units: Microseconds Valid statistics: `Average`, `Sum`, `Min`, `Max`, `Sample Count`



Dimensions for Endpoint Invocation Metrics

Dimension	Description
`EndpointName`, `VariantName`, `ContainerName`	Filters endpoint invocation metrics for a `ProductionVariant` at the specified endpoint and for the specified variant.

For an inference pipeline endpoint, CloudWatch lists per-container latency metrics in your account as **Endpoint Container Metrics** and **Endpoint Variant Metrics** in the **SageMaker AI** namespace, as follows. The `ContainerLatency` metric appears only for inferences pipelines.

For each endpoint and each container, latency metrics display names for the container, endpoint, variant, and metric.

Training Job, Batch Transform Job, and Endpoint Instance Metrics

The namespaces `/aws/sagemaker/TrainingJobs`, `/aws/sagemaker/TransformJobs`, and `/aws/sagemaker/Endpoints` include the following metrics for training jobs and endpoint instances.

Metrics are reported at a 1-minute intervals.

Metric	Description
`CPUUtilization`	The percentage of CPU units that are used by the containers running on an instance. The value ranges from 0% to 100%, and is multiplied by the number of CPUs. For example, if there are four CPUs, `CPUUtilization` can range from 0% to 400%. For training jobs, `CPUUtilization` is the CPU utilization of the algorithm container running on the instance.

Metric	Description
	For batch transform jobs, `CPUUtilization` is the CPU utilization of the transform container running on the instance. For multi-container models, `CPUUtilization` is the sum of CPU utilization by all containers running on the instance. For endpoint variants, `CPUUtilization` is the sum of CPU utilization by all of the containers running on the instance. Units: Percent
`MemoryUtilization`	The percentage of memory that is used by the containers running on an instance. This value ranges from 0% to 100%. For training jobs, `MemoryUtilization` is the memory used by the algorithm container running on the instance. For batch transform jobs, `MemoryUtilization` is the memory used by the transform container running on the instance. For multi-container models, `MemoryUtilization` is the sum of memory used by all containers running on the instance. For endpoint variants, `MemoryUtilization` is the sum of memory used by all of the containers running on the instance. Units: Percent

Metric	Description
GPUUtilization	The percentage of GPU units that are used by the containers running on an instance. GPUUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUUtilization can range from 0% to 400%. For training jobs, GPUUtilization is the GPU used by the algorithm container running on the instance. For batch transform jobs, GPUUtilization is the GPU used by the transform container running on the instance. For multi-container models, GPUUtilization is the sum of GPU used by all containers running on the instance. For endpoint variants, GPUUtilization is the sum of GPU used by all of the containers running on the instance. Units: Percent
GPUMemory Utilization	The percentage of GPU memory used by the containers running on an instance. GPUMemoryUtilization ranges from 0% to 100% and is multiplied by the number of GPUs. For example, if there are four GPUs, GPUMemoryUtilization can range from 0% to 400%. For training jobs, GPUMemoryUtilization is the GPU memory used by the algorithm container running on the instance. For batch transform jobs, GPUMemoryUtilization is the GPU memory used by the transform container running on the instance. For multi-container models, GPUMemoryUtilization is sum of GPU used by all containers running on the instance. For endpoint variants, GPUMemoryUtilization is the sum of the GPU memory used by all of the containers running on the instance. Units: Percent

Metric	Description
DiskUtilization	The percentage of disk space used by the containers running on an instance. DiskUtilization ranges from 0% to 100%. This metric is not supported for batch transform jobs. For training jobs, DiskUtilization is the disk space used by the algorithm container running on the instance. For endpoint variants, DiskUtilization is the sum of the disk space used by all of the provided containers running on the instance. Units: Percent

Dimensions for Training Job, Batch Transform Job, and Endpoint Instance Metrics

Dimension	Description
Host	For training jobs, Host has the format [training-job-name]/algo-[instance-number-in-cluster] . Use this dimension to filter instance metrics for the specified training job and instance. This dimension format is present only in the /aws/sagemaker/TrainingJobs namespace. For batch transform jobs, Host has the format [transform-job-name]/[instance-id] . Use this dimension to filter instance metrics for the specified batch transform job and instance. This dimension format is present only in the /aws/sagemaker/TransformJobs namespace. For endpoints, Host has the format [endpoint-name]/[production-variant-name]/[instance-id] . Use this dimension to filter instance metrics for the specified endpoint, variant, and instance. This dimension format is present only in the /aws/sagemaker/Endpoints namespace.

To help you debug your training jobs, endpoints, and notebook instance lifecycle configurations, SageMaker AI also sends anything an algorithm container, a model container, or a notebook instance lifecycle configuration sends to `stdout` or `stderr` to Amazon CloudWatch Logs. You can use this information for debugging and to analyze progress.

Use Logs to Monitor an Inference Pipeline

The following table lists the log groups and log streams SageMaker AI. sends to Amazon CloudWatch

A *log stream* is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A *log group* is a group of log streams that share the same retention, monitoring, and access control settings.

Logs

Log Group Name	Log Stream Name
`/aws/sagemaker/TrainingJobs`	`[training-job-name]/algo-[instance-number-in-cluster]-[epoch_timestamp]`
`/aws/sagemaker/Endpoints/[EndpointName]`	`[production-variant-name]/[instance-id]`
	`[production-variant-name]/[instance-id]`
	`[production-variant-name]/[instance-id]/[container-name provided in the SageMaker AI model] (For Inference Pipelines)` For Inference Pipelines logs, if you don't provide container names, CloudWatch uses **container-1, container-2**, and so on, in the order that containers are provided in the model.
`/aws/sagemaker/NotebookInstances`	`[notebook-instance-name]/[LifecycleConfigHook]`
`/aws/sagemaker/TransformJobs`	`[transform-job-name]/[instance-id]-[epoch_timestamp]`
	`[transform-job-name]/[instance-id]-[epoch_timestamp]/data-log`

Log Group Name	Log Stream Name
	`[transform-job-name]/[instance-id]-[epoch_timestamp]/[container-name provided in the SageMaker AI model] (For Inference Pipelines)` For Inference Pipelines logs, if you don't provide container names, CloudWatch uses **container-1, container-2**, and so on, in the order that containers are provided in the model.

> **Note**
>
> SageMaker AI creates the `/aws/sagemaker/NotebookInstances` log group when you create a notebook instance with a lifecycle configuration. For more information, see Customization of a SageMaker notebook instance using an LCC script.

For more information about SageMaker AI logging, see CloudWatch Logs for Amazon SageMaker AI.

Troubleshoot Inference Pipelines

To troubleshoot inference pipeline issues, use CloudWatch logs and error messages. If you are using custom Docker images in a pipeline that includes Amazon SageMaker AI built-in algorithms, you might also encounter permissions problems. To grant the required permissions, create an Amazon Elastic Container Registry (Amazon ECR) policy.

Topics

- Troubleshoot Amazon ECR Permissions for Inference Pipelines
- Use CloudWatch Logs to Troubleshoot SageMaker AI Inference Pipelines
- Use Error Messages to Troubleshoot Inference Pipelines

Troubleshoot Amazon ECR Permissions for Inference Pipelines

When you use custom Docker images in a pipeline that includes SageMaker AI built-in algorithms, you need an Amazon ECR policy. The policy allows your Amazon ECR repository to grant permission for SageMaker AI to pull the image. The policy must add the following permissions:

JSON

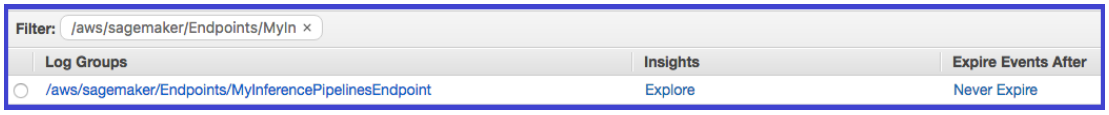
```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "allowSageMakerToPull",
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": [
                "ecr:GetDownloadUrlForLayer",
                "ecr:BatchGetImage",
                "ecr:BatchCheckLayerAvailability"
            ],
            "Resource": "*"
        }
    ]
}
```

Use CloudWatch Logs to Troubleshoot SageMaker AI Inference Pipelines

SageMaker AI publishes the container logs for endpoints that deploy an inference pipeline to Amazon CloudWatch at the following path for each container.

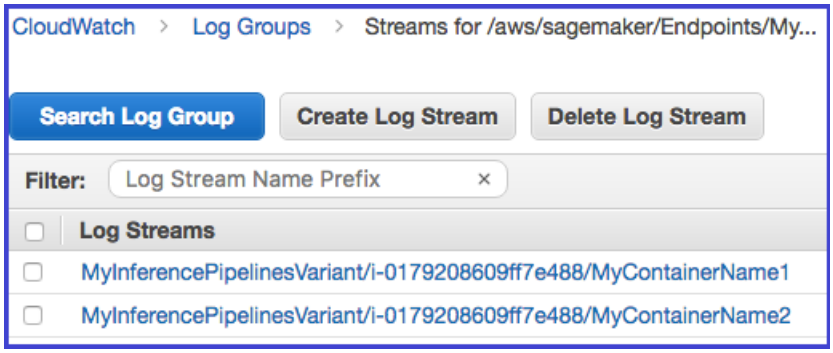
```
/aws/sagemaker/Endpoints/{EndpointName}/{Variant}/{InstanceId}/{ContainerHostname}
```

For example, logs for this endpoint are published to the following log groups and streams:



```
EndpointName: MyInferencePipelinesEndpoint
Variant: MyInferencePipelinesVariant
InstanceId: i-0179208609ff7e488
ContainerHostname: MyContainerName1 and MyContainerName2
```

```
logGroup: /aws/sagemaker/Endpoints/MyInferencePipelinesEndpoint
logStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName1
logStream: MyInferencePipelinesVariant/i-0179208609ff7e488/MyContainerName2
```



A *log stream* is a sequence of log events that share the same source. Each separate source of logs into CloudWatch makes up a separate log stream. A *log group* is a group of log streams that share the same retention, monitoring, and access control settings.

To see the log groups and streams

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation page, choose **Logs**.
3. In **Log Groups**. filter on **`MyInferencePipelinesEndpoint`**:

4. To see the log streams, on the CloudWatch **Log Groups** page, choose **`MyInferencePipelinesEndpoint`**, and then **Search Log Group**.

For a list of the logs that SageMaker AI publishes, see Inference Pipeline Logs and Metrics.

Use Error Messages to Troubleshoot Inference Pipelines

The inference pipeline error messages indicate which containers failed.

If an error occurs while SageMaker AI is invoking an endpoint, the service returns a `ModelError` (error code 424), which indicates which container failed. If the request payload (the response from the previous container) exceeds the limit of 5 MB, SageMaker AI provides a detailed error message, such as:

Received response from MyContainerName1 with status code 200. However, the request payload from MyContainerName1 to MyContainerName2 is 6000000 bytes, which has exceeded the maximum limit of 5 MB.

If a container fails the ping health check while SageMaker AI is creating an endpoint, it returns a `ClientError` and indicates all of the containers that failed the ping check in the last health check.

Delete Endpoints and Resources

Delete endpoints to stop incurring charges.

Delete Endpoint

Delete your endpoint programmatically using Amazon SDK for Python (Boto3), with the Amazon CLI, or interactively using the SageMaker AI console.

SageMaker AI frees up all of the resources that were deployed when the endpoint was created. Deleting an endpoint will not delete the endpoint configuration or the SageMaker AI model. See Delete Endpoint Configuration and Delete Model for information on how to delete your endpoint configuration and SageMaker AI model.

> **Delete inference components first**
>
> When you delete an endpoint from the SageMaker AI console, SageMaker AI first deletes the Inference Components that are attached to the endpoint. Then SageMaker AI deletes the endpoint. To delete a single Inference Component without deleting the endpoint, see the procedure that follows.

Amazon SDK for Python (Boto3)

Use the `DeleteEndpoint` API to delete your endpoint. Specify the name of your endpoint for the `EndpointName` field.

```
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)
```

```
# Delete endpoint
sagemaker_client.delete_endpoint(EndpointName=endpoint_name)
```

Amazon CLI

Use the `delete-endpoint` command to delete your endpoint. Specify the name of your endpoint for the `endpoint-name` flag.

```
aws sagemaker delete-endpoint --endpoint-name <endpoint-name>
```

SageMaker AI Console

Delete your endpoint interactively with the SageMaker AI console.

1. In the SageMaker AI console at https://console.amazonaws.cn/sagemaker/ navigation menu, choose **Inference**.
2. Choose **Endpoints** from the drop down menu. A list of endpoints created in you Amazon account will appear by name, Amazon Resource Name (ARN), creation time, status, and a time stamp of when the endpoint was last updated.
3. Select the endpoint you want to delete.
4. Select the **Actions** dropdown button in the top right corner.
5. Choose **Delete**.

To delete a single Inference Component from an endpoint without deleting the endpoint, use the **Inference components** tab.

> **Note**
>
> You can't delete the last Inference Component on an endpoint. To remove it, delete the endpoint instead.

To delete an Inference Component (console)

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, choose **Inference**, and then choose **Endpoints**.

3. Choose the endpoint.
4. Choose the **Inference components** tab.
5. Select the Inference Component that you want to delete.
6. Choose **Actions**, and then choose **Delete**.

> **Note**
>
> Deleting the Inference Component might take a few minutes.

Delete Endpoint Configuration

Delete your endpoint configuration programmaticially using Amazon SDK for Python (Boto3), with the Amazon CLI, or interactively using the SageMaker AI console. Deleting an endpoint configuration does not delete endpoints created using this configuration. See Delete Endpoint for information on how to delete your endpoint.

Do not delete an endpoint configuration in use by an endpoint that is live or while the endpoint is being updated or created. You might lose visibility into the instance type the endpoint is using if you delete the endpoint configuration of an endpoint that is active or being created or updated.

Amazon SDK for Python (Boto3)

Use the `DeleteEndpointConfig` API to delete your endpoint. Specify the name of your endpoint configuration for the `EndpointConfigName` field.

```
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint configuration
endpoint_config_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete endpoint configuration
sagemaker_client.delete_endpoint_config(EndpointConfigName=endpoint_config_name)
```

You can optionally use the DescribeEndpointConfig API to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the EndpointConfigName field.

```
# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Store DescribeEndpointConfig response into a variable that we can index in the
 next step.
response =
 sagemaker_client.describe_endpoint_config(EndpointConfigName=endpoint_name)

# Delete endpoint
endpoint_config_name = response['ProductionVariants'][0]['EndpointConfigName']

# Delete endpoint configuration
sagemaker_client.delete_endpoint_config(EndpointConfigName=endpoint_config_name)
```

For more information about other response elements returned by DescribeEndpointConfig, see DescribeEndpointConfig in the SageMaker API Reference guide.

Amazon CLI

Use the delete-endpoint-config command to delete your endpoint configuration. Specify the name of your endpoint configuration for the endpoint-config-name flag.

```
aws sagemaker delete-endpoint-config \
                        --endpoint-config-name <endpoint-config-name>
```

You can optionally use the describe-endpoint-config command to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the endpoint-config-name flag.

```
aws sagemaker describe-endpoint-config --endpoint-config-name <endpoint-config-name>
```

This will return a JSON response. You can copy and paste, use a JSON parser, or use a tool built for JSON parsing to obtain the endpoint configuration name associated with that endpoint.

SageMaker AI Console

Delete your endpoint configuration interactively with the SageMaker AI console.

1. In the SageMaker AI console at https://console.amazonaws.cn/sagemaker/ navigation menu, choose **Inference**.
2. Choose **Endpoint configurations** from the dropdown menu. A list of endpoint configurations created in you Amazon account will appear by name, Amazon Resource Name (ARN), and creation time.
3. Select the endpoint configuration you want to delete.
4. Select the **Actions** dropdown button in the top right corner.
5. Choose **Delete**.

Delete Model

Delete your SageMaker AI model programmaticially using Amazon SDK for Python (Boto3), with the Amazon CLI, or interactively using the SageMaker AI console. Deleting a SageMaker AI model only deletes the model entry that was created in SageMaker AI. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.

Amazon SDK for Python (Boto3)

Use the `DeleteModel` API to delete your SageMaker AI model. Specify the name of your model for the `ModelName` field.

```
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Specify the name of your endpoint configuration
model_name='<model_name>'
```

```
# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Delete model
sagemaker_client.delete_model(ModelName=model_name)
```

You can optionally use the DescribeEndpointConfig API to return information about the name of the your deployed models (production variants) such as the name of your model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the EndpointConfigName field.

```
# Specify the name of your endpoint
endpoint_name='<endpoint_name>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Store DescribeEndpointConfig response into a variable that we can index in the
 next step.
response =
 sagemaker_client.describe_endpoint_config(EndpointConfigName=endpoint_name)

# Delete endpoint
model_name = response['ProductionVariants'][0]['ModelName']
sagemaker_client.delete_model(ModelName=model_name)
```

For more information about other response elements returned by DescribeEndpointConfig, see DescribeEndpointConfig in the SageMaker API Reference guide.

Amazon CLI

Use the delete-model command to delete your SageMaker AI model. Specify the name of your model for the model-name flag.

```
aws sagemaker delete-model \
                        --model-name <model-name>
```

You can optionally use the describe-endpoint-config command to return information about the name of the your deployed models (production variants) such as the name of your

model and the name of the endpoint configuration associated with that deployed model. Provide the name of your endpoint for the `endpoint-config-name` flag.

```
aws sagemaker describe-endpoint-config --endpoint-config-name <endpoint-config-name>
```

This will return a JSON response. You can copy and paste, use a JSON parser, or use a tool built for JSON parsing to obtain the name of the model associated with that endpoint.

SageMaker AI Console

Delete your SageMaker AI model interactively with the SageMaker AI console.

1. In the SageMaker AI console at https://console.amazonaws.cn/sagemaker/ navigation menu, choose **Inference**.
2. Choose **Models** from the dropdown menu. A list of models created in you Amazon account will appear by name, Amazon Resource Name (ARN), and creation time.
3. Select the model you want to delete.
4. Select the **Actions** dropdown button in the top right corner.
5. Choose **Delete**.

Automatic scaling of Amazon SageMaker AI models

Amazon SageMaker AI supports automatic scaling (auto scaling) for your hosted models. *Auto scaling* dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. When the workload increases, auto scaling brings more instances online. When the workload decreases, auto scaling removes unnecessary instances so that you don't pay for provisioned instances that you aren't using. For more information about using per-instance metrics for scaling decisions, see Amazon SageMaker AI enhanced metrics for inference endpoints and Enhanced metrics for Amazon SageMaker AI endpoints.

- Delete endpoints configured for auto scaling

Auto scaling policy overview

To use auto scaling, you define a scaling policy that adds and removes the number of instances for your production variant in response to actual workloads.

To automatically scale as workload changes occur, you have two options: target tracking and step scaling policies.

In most cases, we recommend using target tracking scaling policies. With target tracking, you choose an Amazon CloudWatch metric and target value. Auto scaling creates and manages the CloudWatch alarms for the scaling policy and calculates the scaling adjustment based on the metric and the target value. The policy adds and removes the number of instances as required to keep the metric at, or close to, the specified target value. For example, a scaling policy that uses the predefined `InvocationsPerInstance` metric with a target value of 70 can keep `InvocationsPerInstance` at, or close to 70. For more information, see Target tracking scaling policies in the *Application Auto Scaling User Guide*.

You can use step scaling when you require an advanced configuration, such as specifying how many instances to deploy under what conditions. For example, you must use step scaling if you want to enable an endpoint to scale out from zero active instances. For an overview of step scaling policies and how they work, see Step scaling policies in the *Application Auto Scaling User Guide*.

To create a target tracking scaling policy, you specify the following:

- **Metric** — The CloudWatch metric to track, such as average number of invocations per instance.

- **Target value** — The target value for the metric, such as 70 invocations per instance per minute.

You can create target tracking scaling policies with either predefined metrics or custom metrics. A predefined metric is defined in an enumeration so that you can specify it by name in code or use it in the SageMaker AI console. Alternatively, you can use either the Amazon CLI or the Application Auto Scaling API to apply a target tracking scaling policy based on a predefined or custom metric.

Note that scaling activities are performed with cooldown periods between them to prevent rapid fluctuations in capacity. You can optionally configure the cooldown periods for your scaling policy.

For more information about the key concepts of auto scaling, see the following section.

Schedule-based scaling

You can also create scheduled actions to perform scaling activities at specific times. You can create scheduled actions that scale one time only or that scale on a recurring schedule. After a scheduled action runs, your scaling policy can continue to make decisions about whether to scale dynamically as workload changes occur. Scheduled scaling can be managed only from the Amazon CLI or the Application Auto Scaling API. For more information, see Scheduled scaling in the *Application Auto Scaling User Guide*.

Minimum and maximum scaling limits

When configuring auto scaling, you must specify your scaling limits before creating a scaling policy. You set limits separately for the minimum and maximum values.

The minimum value must be at least 1, and equal to or less than the value specified for the maximum value.

The maximum value must be equal to or greater than the value specified for the minimum value. SageMaker AI auto scaling does not enforce a limit for this value.

To determine the scaling limits that you need for typical traffic, test your auto scaling configuration with the expected rate of traffic to your model.

If a variant's traffic becomes zero, SageMaker AI automatically scales in to the minimum number of instances specified. In this case, SageMaker AI emits metrics with a value of zero.

There are three options for specifying the minimum and maximum capacity:

1. Use the console to update the **Minimum instance count** and **Maximum instance count** settings.

2. Use the Amazon CLI and include the `--min-capacity` and `--max-capacity` options when running the register-scalable-target command.
3. Call the RegisterScalableTarget API and specify the `MinCapacity` and `MaxCapacity` parameters.

> **Tip**
>
> You can manually scale out by increasing the minimum value, or manually scale in by decreasing the maximum value.

Cooldown period

A *cooldown period* is used to protect against over-scaling when your model is scaling in (reducing capacity) or scaling out (increasing capacity). It does this by slowing down subsequent scaling activities until the period expires. Specifically, it blocks the deletion of instances for scale-in requests, and limits the creation of instances for scale-out requests. For more information, see Define cooldown periods in the *Application Auto Scaling User Guide*.

You configure the cooldown period in your scaling policy.

If you don't specify a scale-in or a scale-out cooldown period, your scaling policy uses the default, which is 300 seconds for each.

If instances are being added or removed too quickly when you test your scaling configuration, consider increasing this value. You might see this behavior if the traffic to your model has a lot of spikes, or if you have multiple scaling policies defined for a variant.

If instances are not being added quickly enough to address increased traffic, consider decreasing this value.

- Application Auto Scaling API Reference
- Application Auto Scaling User Guide

> **Note**
>
> SageMaker AI recently introduced new inference capabilities built on real-time inference endpoints. You create a SageMaker AI endpoint with an endpoint configuration that defines the instance type and initial instance count for the endpoint. Then, create an inference component, which is a SageMaker AI hosting object that you can use to deploy a model to an endpoint. For information about scaling inference components, see SageMaker AI adds new inference capabilities to help reduce foundation model deployment costs and latency and Reduce model deployment costs by 50% on average using the latest features of SageMaker AI on the Amazon Blog.

Auto scaling prerequisites

Before you can use auto scaling, you must have already created an Amazon SageMaker AI model endpoint. You can have multiple model versions for the same endpoint. Each model is referred to as a production (model) variant. For more information about deploying a model endpoint, see Deploy the Model to SageMaker AI Hosting Services.

To activate auto scaling for a model, you can use the SageMaker AI console, the Amazon Command Line Interface (Amazon CLI), or an Amazon SDK through the Application Auto Scaling API.

- If this is your first time configuring scaling for a model, we recommend you Configure model auto scaling with the console.
- When using the Amazon CLI or the Application Auto Scaling API, the flow is to register the model as a scalable target, define the scaling policy, and then apply it. On the SageMaker AI console, under **Inference** in the navigation pane, choose **Endpoints**. Find your model's endpoint name and then choose it to find the variant name. You must specify both the endpoint name and the variant name to activate auto scaling for a model.

Auto scaling is made possible by a combination of the Amazon SageMaker AI, Amazon CloudWatch, and Application Auto Scaling APIs. For information about the minimum required permissions, see Application Auto Scaling identity-based policy examples in the *Application Auto Scaling User Guide*.

The `SagemakerFullAccessPolicy` IAM policy has all the IAM permissions required to perform auto scaling. For more information about SageMaker AI IAM permissions, see How to use SageMaker AI execution roles.

If you manage your own permission policy, you must include the following permissions:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "sagemaker:DescribeEndpoint",
        "sagemaker:DescribeEndpointConfig",
        "sagemaker:UpdateEndpointWeightsAndCapacities"
      ],
      "Resource": "*"
    },

      ],
      "Resource": "*"
    }
```

```
  ]
}
```

Service-linked role

Auto scaling uses the `AWSServiceRoleForApplicationAutoScaling_SageMakerEndpoint` service-linked role. This service-linked role grants Application Auto Scaling permission to describe the alarms for your policies, to monitor current capacity levels, and to scale the target resource. This role is created for you automatically. For automatic role creation to succeed, you must have permission for the `iam:CreateServiceLinkedRole` action. For more information, see Service-linked roles in the *Application Auto Scaling User Guide*.

Configure model auto scaling with the console

> **Note**
>
> You configure auto scaling differently depending on the endpoint type. For a Single Model Endpoint (SME), follow the next procedure, which scales the number of instances for the production variant. For an endpoint that hosts Inference Components, follow the Inference Component procedure later in this section, which scales the number of copies of each Inference Component.

To configure auto scaling for a model (console)

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. On the navigation pane, choose **Inference**, and then choose **Endpoints**.
3. Choose your endpoint, and then for **Endpoint runtime settings**, choose the variant.
4. Choose **Configure auto scaling**.
5. On the **Configure variant automatic scaling** page, for **Variant automatic scaling**, do the following:

   a. For **Minimum instance count**, type the minimum number of instances that you want the scaling policy to maintain. At least 1 instance is required.

   b. For **Maximum instance count**, type the maximum number of instances that you want the scaling policy to maintain.
6. For **Built-in scaling policy**, do the following:

a. For the **Target metric**, `SageMakerVariantInvocationsPerInstance` is automatically selected for the metric and cannot be changed.

b. For the **Target value**, type the average number of invocations per instance per minute for the model. To determine this value, follow the guidelines in Load testing.

c. (Optional) For **Scale-in cool down (seconds)** and **Scale-out cool down (seconds)**, enter the amount of time, in seconds, for each cool down period.

d. (Optional) Select **Disable scale in** if you don't want auto scaling to terminate instances when traffic decreases.

7. Choose **Save**.

This procedure registers a model as a scalable target with Application Auto Scaling. When you register a model, Application Auto Scaling performs validation checks to ensure the following:

- The model exists
- The permissions are sufficient
- You aren't registering a variant with an instance that is a burstable performance instance such as T2

> **Note**
>
> SageMaker AI doesn't support auto scaling for burstable instances such as T2, because they already allow for increased capacity under increased workloads. For information about burstable performance instances, see Amazon EC2 instance types.

For an endpoint that hosts Inference Components, you configure auto scaling for each Inference Component on the **Inference components** tab. Auto scaling adjusts the number of copies of the Inference Component in response to traffic.

To configure auto scaling for an Inference Component (console)

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the navigation pane, choose **Inference**, and then choose **Endpoints**.
3. Choose the endpoint.
4. Choose the **Inference components** tab.

5. Select the Inference Component, and then choose **Actions**.
6. Choose **Configure auto scaling**.
7. Set the minimum and maximum number of copies and the target value, and then choose **Save**.

Register a model

Before you add a scaling policy to your model, you first must register your model for auto scaling and define the scaling limits for the model.

The following procedures cover how to register a model (production variant) for auto scaling using the Amazon Command Line Interface (Amazon CLI) or Application Auto Scaling API.

Topics

- Register a model (Amazon CLI)
- Register a model (Application Auto Scaling API)

Register a model (Amazon CLI)

To register your production variant, use the register-scalable-target command with the following parameters:

- `--service-namespace`—Set this value to `sagemaker`.
- `--resource-id`—The resource identifier for the model (specifically, the production variant). For this parameter, the resource type is `endpoint` and the unique identifier is the name of the production variant. For example, `endpoint/`*`my-endpoint`*`/variant/`*`my-variant`*.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--min-capacity`—The minimum number of instances. This value must be set to at least 1 and must be equal to or less than the value specified for `max-capacity`.
- `--max-capacity`—The maximum number of instances. This value must be set to at least 1 and must be equal to or greater than the value specified for `min-capacity`.

Example

The following example shows how to register a variant named *`my-variant`*, running on the *`my-endpoint`* endpoint, that can be dynamically scaled to have one to eight instances.

```
aws application-autoscaling register-scalable-target \
  --service-namespace sagemaker \
  --resource-id endpoint/my-endpoint/variant/my-variant \
  --scalable-dimension sagemaker:variant:DesiredInstanceCount \
  --min-capacity 1 \
  --max-capacity 8
```

Register a model (Application Auto Scaling API)

To register your model with Application Auto Scaling, use the RegisterScalableTarget Application Auto Scaling API action with the following parameters:

- `ServiceNamespace`—Set this value to `sagemaker`.
- `ResourceID`—The resource identifier for the production variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/my-endpoint/variant/my-variant`.
- `ScalableDimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `MinCapacity`—The minimum number of instances. This value must be set to at least 1 and must be equal to or less than the value specified for `MaxCapacity`.
- `MaxCapacity`—The maximum number of instances. This value must be set to at least 1 and must be equal to or greater than the value specified for `MinCapacity`.

Example

The following example shows how to register a variant named *my-variant*, running on the *my-endpoint* endpoint, that can be dynamically scaled to use one to eight instances.

```
POST / HTTP/1.1
Host: application-autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.RegisterScalableTarget
X-Amz-Date: 20230506T182145Z
User-Agent: aws-cli/2.0.0 Python/3.7.5 Windows/10 botocore/2.0.0dev4
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "ServiceNamespace": "sagemaker",
```

```
    "ResourceId": "endpoint/my-endpoint/variant/my-variant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "MinCapacity": 1,
    "MaxCapacity": 8
}
```

Define a scaling policy

Before you add a scaling policy to your model, save your policy configuration as a JSON block in a text file. You use that text file when invoking the Amazon Command Line Interface (Amazon CLI) or the Application Auto Scaling API. You can optimize scaling by choosing an appropriate CloudWatch metric. However, before using a custom metric in production, you must test auto scaling with your custom metric.

Topics

- Specify a predefined metric (CloudWatch metric: InvocationsPerInstance)
- Specify a high-resolution predefined metric (CloudWatch metrics: ConcurrentRequestsPerModel and ConcurrentRequestsPerCopy)
- Define a custom metric (CloudWatch metric: CPUUtilization)
- Define a custom metric (CloudWatch metric: ExplanationsPerInstance)
- Specify cooldown periods

This section shows you example policy configurations for target tracking scaling policies.

Specify a predefined metric (CloudWatch metric: InvocationsPerInstance)

Example

The following is an example target tracking policy configuration for a variant that keeps the average invocations per instance at 70. Save this configuration in a file named `config.json`.

```
{
    "TargetValue": 70.0,
    "PredefinedMetricSpecification":
    {
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    }
}
```

For more information, see TargetTrackingScalingPolicyConfiguration in the *Application Auto Scaling API Reference*.

Specify a high-resolution predefined metric (CloudWatch metrics: ConcurrentRequestsPerModel and ConcurrentRequestsPerCopy)

With the following high-resolution CloudWatch metrics, you can set scaling policies for the volume of concurrent requests that your models receive:

ConcurrentRequestsPerModel

The number of concurrent requests being received by a model container.

ConcurrentRequestsPerCopy

The number of concurrent requests being received by an inference component.

These metrics track the number of simultaneous requests that your model containers handle, including the requests that are queued inside the containers. For models that send their inference response as a stream of tokens, these metrics track each request until the model sends the last token for the request.

As high-resolution metrics, they emit data more frequently than standard CloudWatch metrics. Standard metrics, such as the `InvocationsPerInstance` metric, emit data once every minute. However, these high-resolution metrics emit data every 10 seconds. Therefore, as the concurrent traffic to your models increases, your policy reacts by scaling out much more quickly than it would for standard metrics. However, as the traffic to your models decreases, your policy scales in at the same speed as it would for standard metrics.

The following is an example target tracking policy configuration that adds instances if the number of concurrent requests per model exceeds 5. Save this configuration in a file named `config.json`.

```
{
    "TargetValue": 5.0,
    "PredefinedMetricSpecification":
    {
        "PredefinedMetricType":
 "SageMakerVariantConcurrentRequestsPerModelHighResolution"
    }
}
```

If you use inference components to deploy multiple models to the same endpoint, you can create an equivalent policy. In that case, set `PredefinedMetricType` to `SageMakerInferenceComponentConcurrentRequestsPerCopyHighResolution`.

For more information, see TargetTrackingScalingPolicyConfiguration in the *Application Auto Scaling API Reference*.

Define a custom metric (CloudWatch metric: CPUUtilization)

To create a target tracking scaling policy with a custom metric, specify the metric's name, namespace, unit, statistic, and zero or more dimensions. A dimension consists of a dimension name and a dimension value. You can use any production variant metric that changes in proportion to capacity.

Example

The following example configuration shows a target tracking scaling policy with a custom metric. The policy scales the variant based on an average CPU utilization of 50 percent across all instances. Save this configuration in a file named `config.json`.

```
{
    "TargetValue": 50.0,
    "CustomizedMetricSpecification":
    {
        "MetricName": "CPUUtilization",
        "Namespace": "/aws/sagemaker/Endpoints",
        "Dimensions": [
            {"Name": "EndpointName", "Value": "my-endpoint" },
            {"Name": "VariantName","Value": "my-variant"}
        ],
        "Statistic": "Average",
        "Unit": "Percent"
    }
}
```

For more information, see CustomizedMetricSpecification in the *Application Auto Scaling API Reference*.

Define a custom metric (CloudWatch metric: ExplanationsPerInstance)

When the endpoint has online explainability activated, it emits a `ExplanationsPerInstance` metric that outputs the average number of records explained per minute, per instance, for a

variant. The resource utilization of explaining records can be more different than that of predicting records. We strongly recommend using this metric for target tracking scaling of endpoints with online explainability activated.

You can create multiple target tracking policies for a scalable target. Consider adding the `InvocationsPerInstance` policy from the Specify a predefined metric (CloudWatch metric: InvocationsPerInstance) section (in addition to the `ExplanationsPerInstance` policy). If most invocations don't return an explanation because of the threshold value set in the `EnableExplanations` parameter, then the endpoint can choose the `InvocationsPerInstance` policy. If there is a large number of explanations, the endpoint can use the `ExplanationsPerInstance` policy.

Example

The following example configuration shows a target tracking scaling policy with a custom metric. The policy scale adjusts the number of variant instances so that each instance has an `ExplanationsPerInstance` metric of 20. Save this configuration in a file named `config.json`.

```
{
    "TargetValue": 20.0,
    "CustomizedMetricSpecification":
    {
        "MetricName": "ExplanationsPerInstance",
        "Namespace": "AWS/SageMaker",
        "Dimensions": [
            {"Name": "EndpointName", "Value": "my-endpoint" },
            {"Name": "VariantName","Value": "my-variant"}
        ],
        "Statistic": "Sum"
    }
}
```

For more information, see CustomizedMetricSpecification in the *Application Auto Scaling API Reference*.

Specify cooldown periods

You can optionally define cooldown periods in your target tracking scaling policy by specifying the `ScaleOutCooldown` and `ScaleInCooldown` parameters.

Example

The following is an example target tracking policy configuration for a variant that keeps the average invocations per instance at 70. The policy configuration provides a scale-in cooldown period of 10 minutes (600 seconds) and a scale-out cooldown period of 5 minutes (300 seconds). Save this configuration in a file named `config.json`.

```
{
    "TargetValue": 70.0,
    "PredefinedMetricSpecification":
    {
        "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
    },
    "ScaleInCooldown": 600,
    "ScaleOutCooldown": 300
}
```

For more information, see TargetTrackingScalingPolicyConfiguration in the *Application Auto Scaling API Reference*.

Apply a scaling policy

After you register your model and define a scaling policy, apply the scaling policy to the registered model. This section shows how to apply a scaling policy using the the Amazon Command Line Interface (Amazon CLI) or the Application Auto Scaling API.

Topics

- Apply a target tracking scaling policy (Amazon CLI)
- Apply a scaling policy (Application Auto Scaling API)

Apply a target tracking scaling policy (Amazon CLI)

To apply a scaling policy to your model, use the put-scaling-policy Amazon CLI command with the following parameters:

- `--policy-name`—The name of the scaling policy.
- `--policy-type`—Set this value to `TargetTrackingScaling`.

- `--resource-id`—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example, `endpoint/`*`my-endpoint`*`/variant/`*`my-variant`*.
- `--service-namespace`—Set this value to `sagemaker`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `--target-tracking-scaling-policy-configuration`—The target-tracking scaling policy configuration to use for the model.

Example

The following example applies a target tracking scaling policy named *`my-scaling-policy`* to a variant named *`my-variant`*, running on the *`my-endpoint`* endpoint. For the `--target-tracking-scaling-policy-configuration` option, specify the `config.json` file that you created previously.

```
aws application-autoscaling put-scaling-policy \
  --policy-name my-scaling-policy \
  --policy-type TargetTrackingScaling \
  --resource-id endpoint/my-endpoint/variant/my-variant \
  --service-namespace sagemaker \
  --scalable-dimension sagemaker:variant:DesiredInstanceCount \
  --target-tracking-scaling-policy-configuration file://config.json
```

Apply a scaling policy (Application Auto Scaling API)

To apply a scaling policy to a variant with the Application Auto Scaling API, use the PutScalingPolicy Application Auto Scaling API action with the following parameters:

- `PolicyName`—The name of the scaling policy.
- `ServiceNamespace`—Set this value to `sagemaker`.
- `ResourceID`—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example, `endpoint/`*`my-endpoint`*`/variant/`*`my-variant`*.
- `ScalableDimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.
- `PolicyType`—Set this value to `TargetTrackingScaling`.
- `TargetTrackingScalingPolicyConfiguration`—The target-tracking scaling policy configuration to use for the variant.

Example

The following example applies a target tracking scaling policy named *my-scaling-policy* to a variant named *my-variant*, running on the *my-endpoint* endpoint. The policy configuration keeps the average invocations per instance at 70.

```
POST / HTTP/1.1
Host: application-autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.
X-Amz-Date: 20230506T182145Z
User-Agent: aws-cli/2.0.0 Python/3.7.5 Windows/10 botocore/2.0.0dev4
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "my-scaling-policy",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/my-endpoint/variant/my-variant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "PolicyType": "TargetTrackingScaling",
    "TargetTrackingScalingPolicyConfiguration": {
        "TargetValue": 70.0,
        "PredefinedMetricSpecification":
        {
            "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
        }
    }
}
```

Instructions for editing a scaling policy

After creating a scaling policy, you can edit any of its settings except the name.

To edit a target tracking scaling policy with the Amazon Web Services Management Console, use the same procedure that you used to Configure model auto scaling with the console.

You can use the Amazon CLI or the Application Auto Scaling API to edit a scaling policy in the same way that you create a new scaling policy. For more information, see Apply a scaling policy.

Temporarily turn off scaling policies

After you configure auto scaling, you have the following options if you need to investigate an issue without interference from scaling policies (dynamic scaling):

- Temporarily suspend and then resume scaling activities by calling the register-scalable-target CLI command or RegisterScalableTarget API action, specifying a Boolean value for both `DynamicScalingInSuspended` and `DynamicScalingOutSuspended`.

  Example

  The following example shows how to suspend scaling policies for a variant named *`my-variant`*, running on the *`my-endpoint`* endpoint.

  ```
  aws application-autoscaling register-scalable-target \
    --service-namespace sagemaker \
    --resource-id endpoint/my-endpoint/variant/my-variant \
    --scalable-dimension sagemaker:variant:DesiredInstanceCount \
    --suspended-
  state '{"DynamicScalingInSuspended":true,"DynamicScalingOutSuspended":true}'
  ```

- Prevent specific target tracking scaling policies from scaling in your variant by disabling the policy's scale-in portion. This method prevents the scaling policy from deleting instances, while still allowing it to create them as needed.

  Temporarily disable and then enable scale-in activities by editing the policy using the put-scaling-policy CLI command or the PutScalingPolicy API action, specifying a Boolean value for `DisableScaleIn`.

  Example

  The following is an example of a target tracking configuration for a scaling policy that will scale out but not scale in.

  ```
  {
      "TargetValue": 70.0,
      "PredefinedMetricSpecification":
      {
          "PredefinedMetricType": "SageMakerVariantInvocationsPerInstance"
      },
      "DisableScaleIn": true
  ```

```
}
```

Delete a scaling policy

If you no longer need a scaling policy, you can delete it at any time.

Topics

- Delete all scaling policies and deregister the model (console)
- Delete a scaling policy (Amazon CLI or Application Auto Scaling API)

Delete all scaling policies and deregister the model (console)

To delete all scaling policies and deregister the variant as a scalable target

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. On the navigation pane, choose **Endpoints**.
3. Choose your endpoint, and then for **Endpoint runtime settings**, choose the variant.
4. Choose **Configure auto scaling**.
5. Choose **Deregister auto scaling**.

Delete a scaling policy (Amazon CLI or Application Auto Scaling API)

You can use the Amazon CLI or the Application Auto Scaling API to delete a scaling policy from a variant.

Delete a scaling policy (Amazon CLI)

To delete a scaling policy from a variant, use the delete-scaling-policy command with the following parameters:

- `--policy-name`—The name of the scaling policy.
- `--resource-id`—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example, `endpoint/my-endpoint/variant/my-variant`.
- `--service-namespace`—Set this value to `sagemaker`.
- `--scalable-dimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.

Example

The following example deletes a target tracking scaling policy named *my-scaling-policy* from a variant named *my-variant*, running on the *my-endpoint* endpoint.

```
aws application-autoscaling delete-scaling-policy \
  --policy-name my-scaling-policy \
  --resource-id endpoint/my-endpoint/variant/my-variant \
  --service-namespace sagemaker \
  --scalable-dimension sagemaker:variant:DesiredInstanceCount
```

Delete a scaling policy (Application Auto Scaling API)

To delete a scaling policy from your variant, use the DeleteScalingPolicy Application Auto Scaling API action with the following parameters:

- `PolicyName`—The name of the scaling policy.
- `ServiceNamespace`—Set this value to `sagemaker`.
- `ResourceID`—The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example, `endpoint/`*my-endpoint*`/variant/`*my-variant*.
- `ScalableDimension`—Set this value to `sagemaker:variant:DesiredInstanceCount`.

Example

The following example deletes a target tracking scaling policy named *my-scaling-policy* from a variant named *my-variant*, running on the *my-endpoint* endpoint.

```
POST / HTTP/1.1
Host: application-autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
X-Amz-Date: 20230506T182145Z
User-Agent: aws-cli/2.0.0 Python/3.7.5 Windows/10 botocore/2.0.0dev4
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "my-scaling-policy",
```

```
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/my-endpoint/variant/my-variant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount"
}
```

Check the status of a scaling activity by describing scaling activities

You can check the status of a scaling activity for your auto scaled endpoint by describing scaling activities. Application Auto Scaling provides descriptive information about the scaling activities in the specified namespace from the previous six weeks. For more information, see Scaling activities for Application Auto Scaling in the *Application Auto Scaling User Guide*.

To check the status of a scaling activity, use the describe-scaling-activities command. You can't check the status of a scaling activity using the console.

Topics

- Describe scaling activities (Amazon CLI)
- Identify blocked scaling activities from instance quotas (Amazon CLI)

Describe scaling activities (Amazon CLI)

To describe scaling activities for all SageMaker AI resources that registered with Application Auto Scaling, use the describe-scaling-activities command, specifying `sagemaker` for the `--service-namespace` option.

```
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker
```

To describe scaling activities for a specific resource, include the `--resource-id` option.

```
aws application-autoscaling describe-scaling-activities \
  --service-namespace sagemaker \
  --resource-id endpoint/my-endpoint/variant/my-variant
```

The following example shows the output produced when you run this command.

```
{
    "ActivityId": "activity-id",
```

```
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/my-endpoint/variant/my-variant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "Description": "string",
    "Cause": "string",
    "StartTime": timestamp,
    "EndTime": timestamp,
    "StatusCode": "string",
    "StatusMessage": "string"
}
```

Identify blocked scaling activities from instance quotas (Amazon CLI)

When you scale out (add more instances), you might reach your account-level instance quota. You can use the describe-scaling-activities command to check whether you have reached your instance quota. When you exceed your quota, auto scaling is blocked.

To check if you have reached your instance quota, use the describe-scaling-activities command and specify the resource ID for the `--resource-id` option.

```
aws application-autoscaling describe-scaling-activities \
    --service-namespace sagemaker \
    --resource-id endpoint/my-endpoint/variant/my-variant
```

Within the return syntax, check the StatusCode and StatusMessage keys and their associated values. `StatusCode` returns `Failed`. Within `StatusMessage` there is a message indicating that the account-level service quota was reached. The following is an example of what that message might look like:

```
{
    "ActivityId": "activity-id",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/my-endpoint/variant/my-variant",
    "ScalableDimension": "sagemaker:variant:DesiredInstanceCount",
    "Description": "string",
    "Cause": "minimum capacity was set to 110",
    "StartTime": timestamp,
    "EndTime": timestamp,
    "StatusCode": "Failed",
    "StatusMessage": "Failed to set desired instance count to 110. Reason: The
    account-level service limit 'ml.xx.xxxxxx for endpoint usage' is 1000
```

```
    Instances, with current utilization of 997 Instances and a request delta
    of 20 Instances. Please contact Amazon support to request an increase for this
    limit. (Service: AmazonSageMaker; Status Code: 400;
    Error Code: ResourceLimitExceeded; Request ID: request-id)."
}
```

Scale an endpoint to zero instances

When you set up auto scaling for an endpoint, you can allow the scale-in process to reduce the number of in-service instances to zero. By doing so, you save costs during periods when your endpoint isn't serving inference requests and therefore doesn't require any active instances.

However, after scaling in to zero instances, your endpoint can't respond to any incoming inference requests until it provisions at least one instance. To automate the provisioning process, you create a step scaling policy with Application Auto Scaling. Then, you assign the policy to an Amazon CloudWatch alarm.

After you set up the step scaling policy and the alarm, your endpoint will automatically provision an instance soon after it receives an inference request that it can't respond to. Be aware that the provisioning process takes several minutes. During that time, any attempts to invoke the endpoint will produce an error.

The following procedures explain how to set up auto scaling for an endpoint so that it scales in to, and out from, zero instances. The procedures use commands with the Amazon CLI.

Before you begin

Before your endpoint can scale in to, and out from, zero instances, it must meet the following requirements:

- It is in service.
- It hosts one or more inference components. An endpoint can scale to and from zero instances only if it hosts inference components.

  For information about hosting inference components on SageMaker AI endpoints, see Deploy models for real-time inference.
- In the endpoint configuration, for the production variant `ManagedInstanceScaling` object, you've set the `MinInstanceCount` parameter to `0`.

  For reference information about this parameter, see ProductionVariantManagedInstanceScaling.

To enable an endpoint to scale in to zero instances (Amazon CLI)

For each inference component that the endpoint hosts, do the following:

1. Register the inference component as a scalable target. When you register it, set the minimum capacity to `0`, as shown by the following command:

   ```
   aws application-autoscaling register-scalable-target \
     --service-namespace sagemaker \
     --resource-id inference-component/inference-component-name \
     --scalable-dimension sagemaker:inference-component:DesiredCopyCount \
     --min-capacity 0 \
     --max-capacity n
   ```

   In this example, replace *inference-component-name* with the name of your inference component. Replace *n* with the maximum number of inference component copies to provision when scaling out.

   For more information about this command and each of its parameters, see register-scalable-target in the *Amazon CLI Command Reference*.

2. Apply a target tracking policy to the inference component, as shown by the following command:

   ```
   aws application-autoscaling put-scaling-policy \
     --policy-name my-scaling-policy \
     --policy-type TargetTrackingScaling \
     --resource-id inference-component/inference-component-name \
     --service-namespace sagemaker \
     --scalable-dimension sagemaker:inference-component:DesiredCopyCount \
     --target-tracking-scaling-policy-configuration file://config.json
   ```

   In this example, replace *inference-component-name* with the name of your inference component.

   In the example, the `config.json` file contains a target tracking policy configuration, such as the following:

   ```
   {
     "PredefinedMetricSpecification": {
         "PredefinedMetricType": "SageMakerInferenceComponentInvocationsPerCopy"
   ```

```
  },
  "TargetValue": 1,
  "ScaleInCooldown": 300,
  "ScaleOutCooldown": 300
}
```

For more example tracking policy configurations, see Define a scaling policy.

For more information about this command and each of its parameters, see put-scaling-policy in the *Amazon CLI Command Reference*.

To enable an endpoint to scale out from zero instances (Amazon CLI)

For each inference component that the endpoint hosts, do the following:

1. Apply a step scaling policy to the inference component, as shown by the following command:

```
aws application-autoscaling put-scaling-policy \
  --policy-name my-scaling-policy \
  --policy-type StepScaling \
  --resource-id inference-component/inference-component-name \
  --service-namespace sagemaker \
  --scalable-dimension sagemaker:inference-component:DesiredCopyCount \
  --step-scaling-policy-configuration file://config.json
```

In this example, replace *my-scaling-policy* with a unique name for your policy. Replace *inference-component-name* with the name of your inference component.

In the example, the `config.json` file contains a step scaling policy configuration, such as the following:

```
{
    "AdjustmentType": "ChangeInCapacity",
    "MetricAggregationType": "Maximum",
    "Cooldown": 60,
    "StepAdjustments":
      [
        {
          "MetricIntervalLowerBound": 0,
          "ScalingAdjustment": 1
        }
```

```
        ]
}
```

When this step scaling policy is triggered, SageMaker AI provisions the necessary instances to support the inference component copies.

After you create the step scaling policy, take note of its Amazon Resource Name (ARN). You need the ARN for the CloudWatch alarm in the next step.

For more information about step scaling polices, see Step scaling policies in the *Application Auto Scaling User Guide*.

2. Create a CloudWatch alarm and assign the step scaling policy to it, as shown by the following example:

```
aws cloudwatch put-metric-alarm \
--alarm-actions step-scaling-policy-arn \
--alarm-description "Alarm when SM IC endpoint invoked that has 0 instances." \
--alarm-name ic-step-scaling-alarm \
--comparison-operator GreaterThanThreshold  \
--datapoints-to-alarm 1 \
--dimensions "Name=InferenceComponentName,Value=inference-component-name" \
--evaluation-periods 1 \
--metric-name NoCapacityInvocationFailures \
--namespace AWS/SageMaker \
--period 60 \
--statistic Sum \
--threshold 1
```

In this example, replace *step-scaling-policy-arn* with the ARN of your step scaling policy. Replace *ic-step-scaling-alarm* with a name of your choice. Replace *inference-component-name* with the name of your inference component.

This example sets the `--metric-name` parameter to `NoCapacityInvocationFailures`. SageMaker AI emits this metric when an endpoint receives an inference request, but the endpoint has no active instances to serve the request. When that event occurs, the alarm initiates the step scaling policy in the previous step.

For more information about this command and each of its parameters, see put-metric-alarm in the *Amazon CLI Command Reference*.

Load testing your auto scaling configuration

Perform load tests to choose a scaling configuration that works the way you want.

The following guidelines for load testing assume you are using a scaling policy that uses the predefined target metric `SageMakerVariantInvocationsPerInstance`.

Topics

- Determine the performance characteristics
- Calculate the target load

Determine the performance characteristics

Perform load testing to find the peak `InvocationsPerInstance` that your model's production variant can handle, and the latency of requests, as concurrency increases.

This value depends on the instance type chosen, payloads that clients of your model typically send, and the performance of any external dependencies your model has.

To find the peak requests-per-second (RPS) your model's production variant can handle and latency of requests

1. Set up an endpoint with your model using a single instance. For information about how to set up an endpoint, see Deploy the Model to SageMaker AI Hosting Services.
2. Use a load testing tool to generate an increasing number of parallel requests, and monitor the RPS and model latency in the out put of the load testing tool.

   > **Note**
   >
   > You can also monitor requests-per-minute instead of RPS. In that case don't multiply by 60 in the equation to calculate `SageMakerVariantInvocationsPerInstance` shown below.

   When the model latency increases or the proportion of successful transactions decreases, this is the peak RPS that your model can handle.

Calculate the target load

After you find the performance characteristics of the variant, you can determine the maximum RPS we should allow to be sent to an instance. The threshold used for scaling must be less than this maximum value. Use the following equation in combination with load testing to determine the correct value for the `SageMakerVariantInvocationsPerInstance` target metric in your scaling configuration.

```
SageMakerVariantInvocationsPerInstance = (MAX_RPS * SAFETY_FACTOR) * 60
```

Where `MAX_RPS` is the maximum RPS that you determined previously, and `SAFETY_FACTOR` is the safety factor that you chose to ensure that your clients don't exceed the maximum RPS. Multiply by 60 to convert from RPS to invocations-per-minute to match the per-minute CloudWatch metric that SageMaker AI uses to implement auto scaling (you don't need to do this if you measured requests-per-minute instead of requests-per-second).

> **Note**
>
> SageMaker AI recommends that you start testing with a `SAFETY_FACTOR` of 0.5. Test your scaling configuration to ensure it operates in the way you expect with your model for both increasing and decreasing customer traffic on your endpoint.

Use Amazon CloudFormation to create a scaling policy

The following example shows how to configure model auto scaling on an endpoint using Amazon CloudFormation.

```
Endpoint:
  Type: "AWS::SageMaker::Endpoint"
  Properties:
    EndpointName: yourEndpointName
    EndpointConfigName: yourEndpointConfigName

ScalingTarget:
  Type: "AWS::ApplicationAutoScaling::ScalableTarget"
  Properties:
    MaxCapacity: 10
    MinCapacity: 2
```

```
      ResourceId: endpoint/my-endpoint/variant/my-variant
      RoleARN: arn
      ScalableDimension: sagemaker:variant:DesiredInstanceCount
      ServiceNamespace: sagemaker

  ScalingPolicy:
    Type: "AWS::ApplicationAutoScaling::ScalingPolicy"
    Properties:
      PolicyName: my-scaling-policy
      PolicyType: TargetTrackingScaling
      ScalingTargetId:
        Ref: ScalingTarget
      TargetTrackingScalingPolicyConfiguration:
        TargetValue: 70.0
        ScaleInCooldown: 600
        ScaleOutCooldown: 30
        PredefinedMetricSpecification:
          PredefinedMetricType: SageMakerVariantInvocationsPerInstance
```

For more information, see Create Application Auto Scaling resources with Amazon CloudFormation in the *Application Auto Scaling User Guide*.

Update endpoints that use auto scaling

When you update an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for auto scaling. If the update would change the instance type for any model that is a target for auto scaling, the update fails.

In the Amazon Web Services Management Console, you see a warning that you must deregister the model from auto scaling before you can update it. If you are trying to update the endpoint by calling the UpdateEndpoint API, the call fails. Before you update the endpoint, delete any scaling policies configured for it and deregister the variant as a scalable target by calling the DeregisterScalableTarget Application Auto Scaling API action. After you update the endpoint, you can register the updated variant as a scalable target and attach a scaling policy.

There is one exception. If you change the model for a variant that is configured for auto scaling, Amazon SageMaker AI auto scaling allows the update. This is because changing the model doesn't typically affect performance enough to change scaling behavior. If you do update a model for a variant configured for auto scaling, ensure that the change to the model doesn't significantly affect performance and scaling behavior.

When you update SageMaker AI endpoints that have auto scaling applied, complete the following steps:

To update an endpoint that has auto scaling applied

1. Deregister the endpoint as a scalable target by calling DeregisterScalableTarget.
2. Because auto scaling is blocked while the update operation is in progress (or if you turned off auto scaling in the previous step), you might want to take the additional precaution of increasing the number of instances for your endpoint during the update. To do this, update the instance counts for the production variants hosted at the endpoint by calling UpdateEndpointWeightsAndCapacities.
3. Call DescribeEndpoint repeatedly until the value of the `EndpointStatus` field of the response is `InService`.
4. Call DescribeEndpointConfig to get the values of the current endpoint config.
5. Create a new endpoint config by calling CreateEndpointConfig. For the production variants where you want to keep the existing instance count or weight, use the same variant name from the response from the call to DescribeEndpointConfig in the previous step. For all other values, use the values that you got as the response when you called DescribeEndpointConfig in the previous step.
6. Update the endpoint by calling UpdateEndpoint. Specify the endpoint config you created in the previous step as the `EndpointConfig` field. If you want to retain the variant properties like instance count or weight, set the value of the `RetainAllVariantProperties` parameter to `True`. This specifies that production variants with the same name will are updated with the most recent `DesiredInstanceCount` from the response from the call to `DescribeEndpoint`, regardless of the values of the `InitialInstanceCount` field in the new `EndpointConfig`.
7. (Optional) Re-activate auto scaling by calling RegisterScalableTarget and PutScalingPolicy.

> **Note**
>
> Steps 1 and 7 are required only if you are updating an endpoint with the following changes:
>
> - Changing the instance type for a production variant that has auto scaling configured
> - Removing a production variant that has auto scaling configured.

Delete endpoints configured for auto scaling

If you delete an endpoint, Application Auto Scaling checks to see whether any of the models on that endpoint are targets for auto scaling. If any are and you have permission to deregister the model, Application Auto Scaling deregisters those models as scalable targets without notifying you. If you use a custom permission policy that doesn't provide permission for the DeregisterScalableTarget action, you must request access to this action before deleting the endpoint.

> **Note**
>
> As an IAM user, you might not have sufficient permission to delete an endpoint if another user configured auto scaling for a variant on that endpoint.

Instance storage volumes

When you create an endpoint, Amazon SageMaker AI attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances that hosts the endpoint. The size of the storage volume is scalable, and storage options are divided into two categories: SSD-backed storage and HDD-backed storage.

For more information about Amazon EBS storages and features, see the following pages.

- Amazon EBS Features
- Amazon EBS User Guide

For a full list of the host instance storage volumes, see Host Instance Storage Volumes Table

> **Note**
>
> Amazon SageMaker AI attaches an Amazon Elastic Block Store (Amazon EBS) storage volume to Amazon EC2 instances only when you create Asynchronous inference or Real-time inference endpoint types. For more information on customizing Amazon EBS storage volume, see SageMaker AI endpoint parameters for large model inference.

Validation of models in production

With SageMaker AI, you can test multiple models or model versions behind the same endpoint using variants. A variant consists of an ML instance and the serving components specified in a SageMaker AI model. You can have multiple variants behind an endpoint. Each variant can have a different instance type or a SageMaker AI model that can be autoscaled independently of the others. The models within the variants can be trained using different datasets, different algorithms, different ML frameworks, or any combination of all of these. All the variants behind an endpoint share the same inference code. SageMaker AI supports two types of variants, production variants and shadow variants.

If you have multiple production variants behind an endpoint, then you can allocate a portion of your inference requests to each variant. Each request is routed to only one of the production variants. The production variant to which the request was routed provides the response to the caller. You can compare how the production variants perform relative to each other.

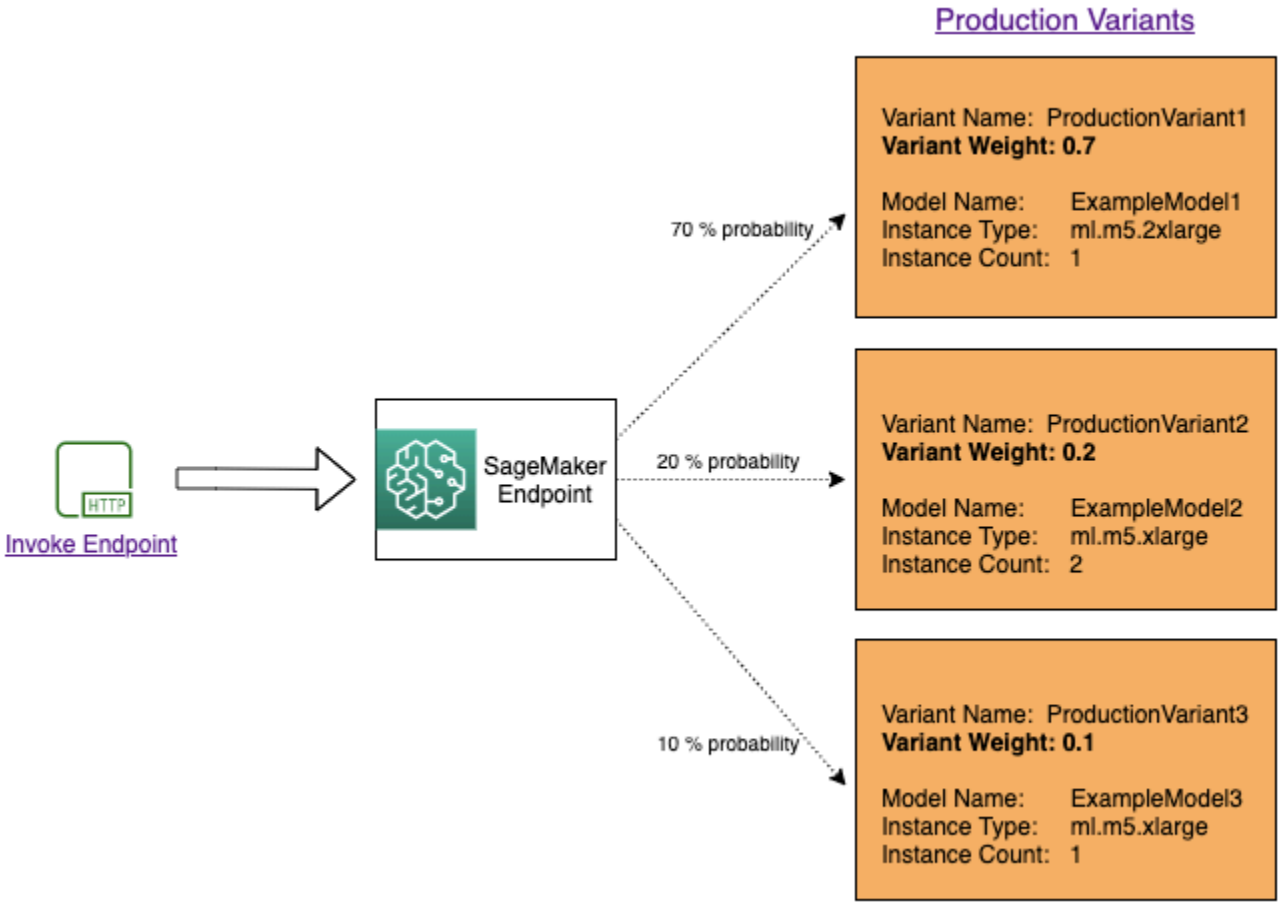
You can also have a shadow variant corresponding to a production variant behind an endpoint. A portion of the inference requests that goes to the production variant is replicated to the shadow variant. The responses of the shadow variant are logged for comparison and not returned to the caller. This lets you test the performance of the shadow variant without exposing the caller to the response produced by the shadow variant.

Topics

- Testing models with production variants
- Testing models with shadow variants

Testing models with production variants

In production ML workflows, data scientists and engineers frequently try to improve performance using various methods, such as Automatic model tuning with SageMaker AI, training on additional or more-recent data, improving feature selection, using better updated instances and serving containers. You can use production variants to compare your models, instances and containers, and choose the best performing candidate to respond to inference requests.

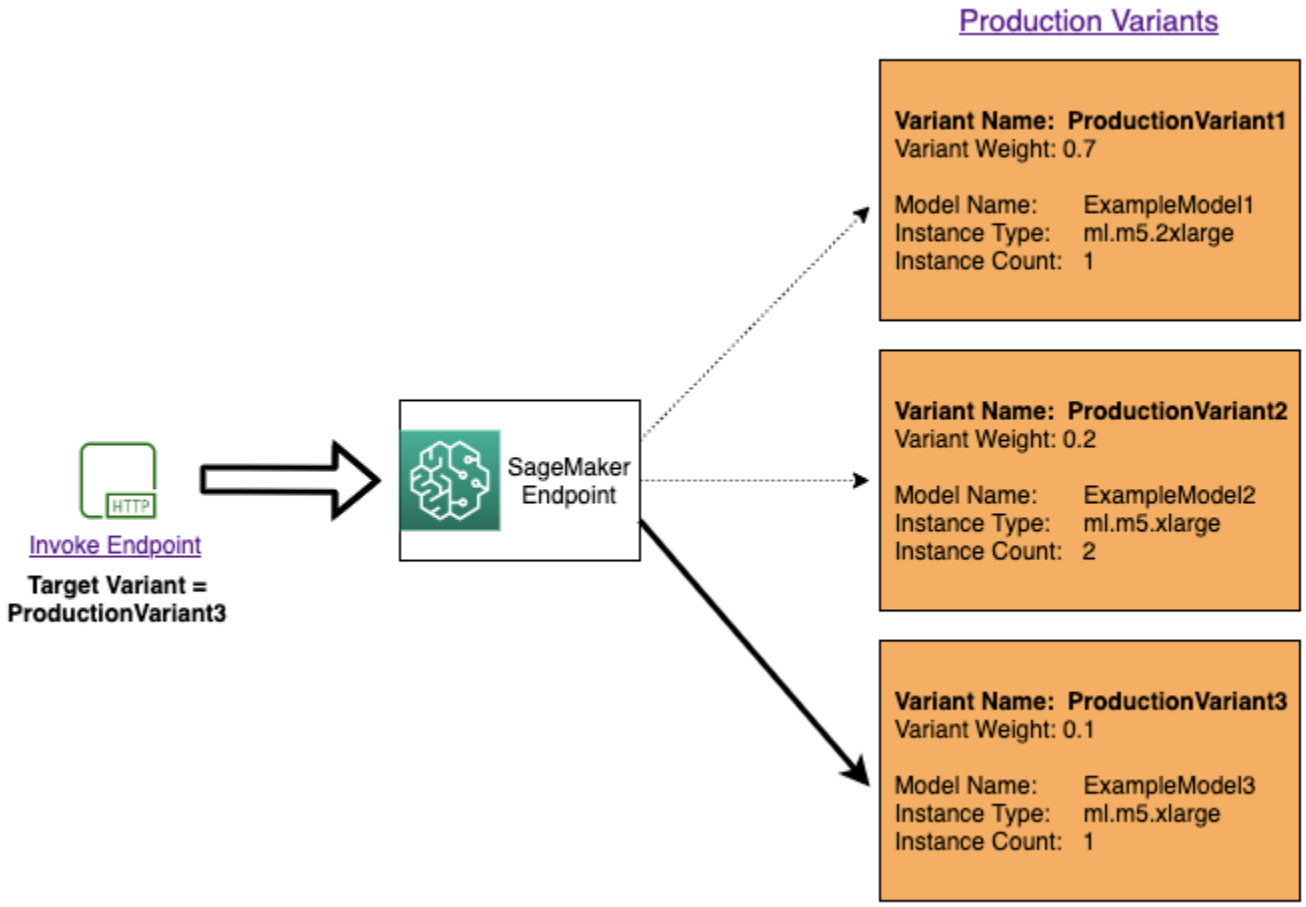


With SageMaker AI multi-variant endpoints you can distribute endpoint invocation requests across multiple production variants by providing the traffic distribution for each variant, or you can invoke a specific variant directly for each request. In this topic, we look at both methods for testing ML models.

Topics

- Test models by specifying traffic distribution
- Test models by invoking specific variants
- Model A/B test example

Test models by specifying traffic distribution



To test multiple models by distributing traffic between them, specify the percentage of the traffic that gets routed to each model by specifying the weight for each production variant in the endpoint configuration. For information, see CreateEndpointConfig. The following diagram shows how this works in more detail.

Test models by invoking specific variants

To test multiple models by invoking specific models for each request, specify the specific version of the model you want to invoke by providing a value for the `TargetVariant` parameter when

you call InvokeEndpoint. SageMaker AI ensures that the request is processed by the production variant you specify. If you have already provided traffic distribution and specify a value for the `TargetVariant` parameter, the targeted routing overrides the random traffic distribution. The following diagram shows how this works in more detail.

Model A/B test example

Performing A/B testing between a new model and an old model with production traffic can be an effective final step in the validation process for a new model. In A/B testing, you test different variants of your models and compare how each variant performs. If the newer version of the model delivers better performance than the previously existing version, replace the old version of the model with the new version in production.

The following example shows how to perform A/B model testing. For a sample notebook that implements this example, see "A/B Testing ML models in production.

Step 1: Create and deploy models

First, we define where our models are located in Amazon S3. These locations are used when we deploy our models in subsequent steps:

```
model_url = f"s3://{path_to_model_1}"
model_url2 = f"s3://{path_to_model_2}"
```

Next, we create the model objects with the image and model data. These model objects are used to deploy production variants on an endpoint. The models are developed by training ML models on different data sets, different algorithms or ML frameworks, and different hyperparameters:

```
from sagemaker.core import image_uris

model_name = f"DEMO-xgb-churn-pred-{datetime.now():%Y-%m-%d-%H-%M-%S}"
model_name2 = f"DEMO-xgb-churn-pred2-{datetime.now():%Y-%m-%d-%H-%M-%S}"
image_uri = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-1')
image_uri2 = get_image_uri(boto3.Session().region_name, 'xgboost', '0.90-2')

sm_session.create_model(
    name=model_name,
    role=role,
    container_defs={
        'Image': image_uri,
        'ModelDataUrl': model_url
    }
)

sm_session.create_model(
    name=model_name2,
    role=role,
    container_defs={
        'Image': image_uri2,
        'ModelDataUrl': model_url2
    }
)
```

We now create two production variants, each with its own different model and resource requirements (instance type and counts). This enables you to also test models on different instance types.

We set an initial_weight of 1 for both variants. This means that 50% of requests go to `Variant1`, and the remaining 50% of requests to `Variant2`. The sum of weights across both variants is 2 and each variant has weight assignment of 1. This means that each variant receives 1/2, or 50%, of the total traffic.

```
from sagemaker.session import production_variant

variant1 = production_variant(
               model_name=model_name,
               instance_type="ml.m5.xlarge",
               initial_instance_count=1,
               variant_name='Variant1',
               initial_weight=1,
           )

variant2 = production_variant(
               model_name=model_name2,
               instance_type="ml.m5.xlarge",
               initial_instance_count=1,
               variant_name='Variant2',
               initial_weight=1,
           )
```

Finally we're ready to deploy these production variants on a SageMaker AI endpoint.

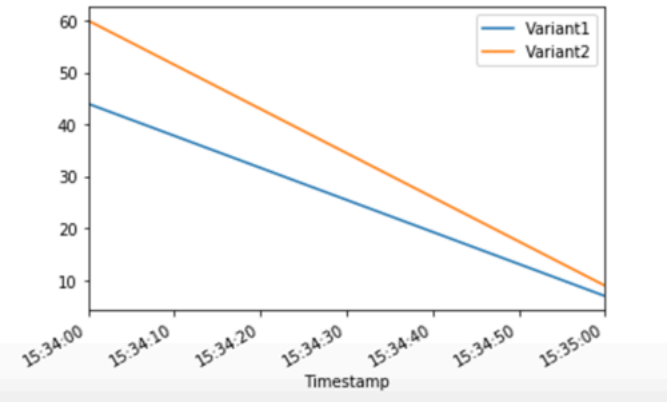
```
endpoint_name = f"DEMO-xgb-churn-pred-{datetime.now():%Y-%m-%d-%H-%M-%S}"
print(f"EndpointName={endpoint_name}")

sm_session.endpoint_from_production_variants(
    name=endpoint_name,
    production_variants=[variant1, variant2]
)
```

Step 2: Invoke the deployed models

Now we send requests to this endpoint to get inferences in real time. We use both traffic distribution and direct targeting.

First, we use traffic distribution that we configured in the previous step. Each inference response contains the name of the production variant that processes the request, so we can see that traffic to the two production variants is roughly equal.



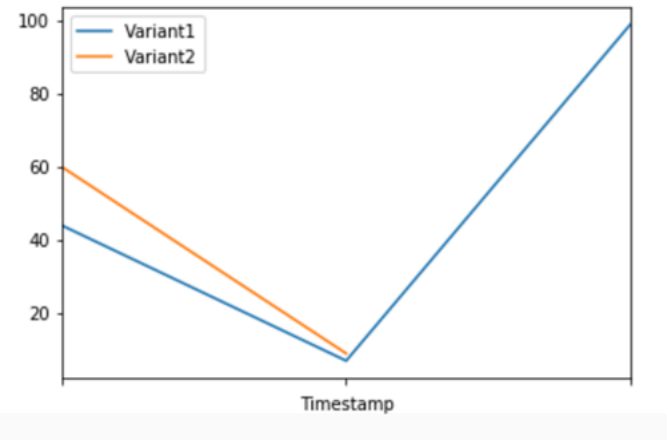
```
# get a subset of test data for a quick test
!tail -120 test_data/test-dataset-input-cols.csv > test_data/
test_sample_tail_input_cols.csv
print(f"Sending test traffic to the endpoint {endpoint_name}. \nPlease wait...")

with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print(".", end="", flush=True)
        payload = row.rstrip('\n')
        sm_runtime.invoke_endpoint(
            EndpointName=endpoint_name,
            ContentType="text/csv",
            Body=payload
        )
        time.sleep(0.5)

print("Done!")
```

SageMaker AI emits metrics such as `Latency` and `Invocations` for each variant in Amazon CloudWatch. For a complete list of metrics that SageMaker AI emits, see Amazon SageMaker AI metrics in Amazon CloudWatch. Let's query CloudWatch to get the number of invocations per variant, to show how invocations are split across variants by default:

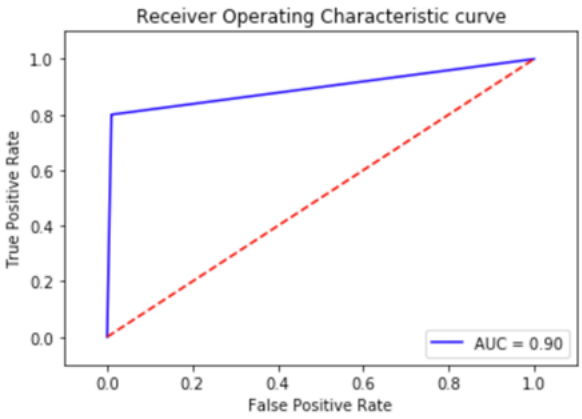
Timestamp	Variant1	Variant2
2020-06-05 15:34:00+00:00	44.0	60.0
2020-06-05 15:35:00+00:00	7.0	9.0



Now let's invoke a specific version of the model by specifying `Variant1` as the `TargetVariant` in the call to `invoke_endpoint`.

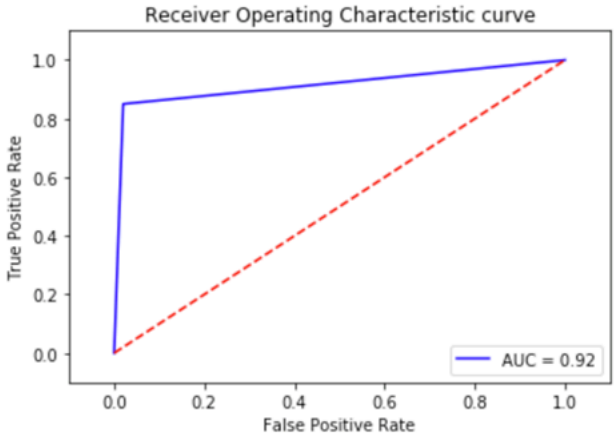
```
print(f"Sending test traffic to the endpoint {endpoint_name}. \nPlease wait...")
with open('test_data/test_sample_tail_input_cols.csv', 'r') as f:
    for row in f:
        print(".", end="", flush=True)
        payload = row.rstrip('\n')
        sm_runtime.invoke_endpoint(
            EndpointName=endpoint_name,
            ContentType="text/csv",
            Body=payload,
            TargetVariant="Variant1"
        )
        time.sleep(0.5)
```

To confirm that all new invocations were processed by `Variant1`, we can query CloudWatch to get the number of invocations per variant. We see that for the most recent invocations (latest timestamp), all requests were processed by `Variant1`, as we had specified. There were no invocations made for `Variant2`.



Timestamp	Variant1	Variant2
2020-06-05 15:34:00+00:00	44.0	60.0
2020-06-05 15:35:00+00:00	7.0	9.0
2020-06-05 15:36:00+00:00	99.0	NaN

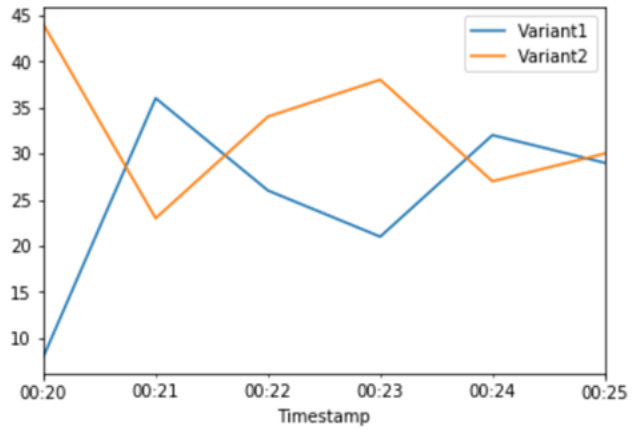
Step 3: Evaluate model performance



To see which model version performs better, let's evaluate the accuracy, precision, recall, F1 score, and Receiver operating charactersistic/Area under the curve for each variant. First, let's look at these metrics for `Variant1`:

```
Accuracy: 0.9583333333333334
Precision: 0.9411764705882353
Recall: 0.8
F1 Score: 0.8648648648648648
AUC is 0.895
```

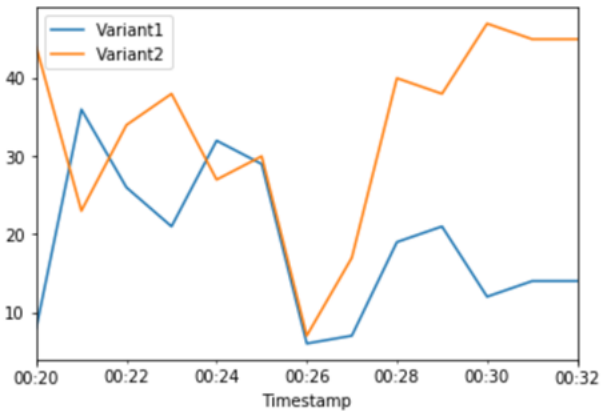
Now let's look at the metrics for `Variant2`:



```
Accuracy: 0.9583333333333334
Precision: 0.8947368421052632
Recall: 0.85
F1 Score: 0.8717948717948718
AUC is 0.915
```

For most of our defined metrics, `Variant2` is performing better, so this is the one that we want to use in production.

Step 4: Increase traffic to the best model

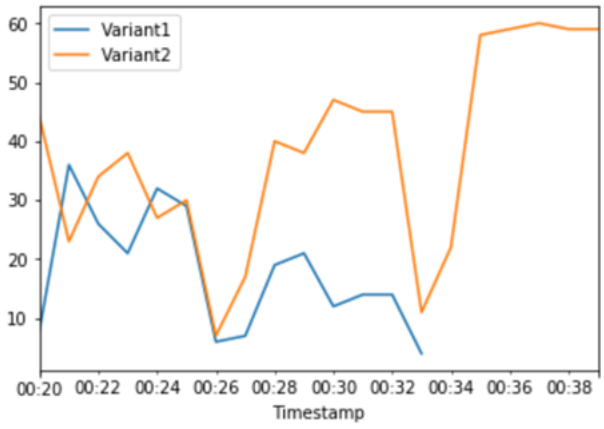


Now that we have determined that `Variant2` performs better than `Variant1`, we shift more traffic to it. We can continue to use `TargetVariant` to invoke a specific model variant, but a simpler approach is to update the weights assigned to each variant by calling UpdateEndpointWeightsAndCapacities. This changes the traffic distribution to your production variants without requiring updates to your endpoint. Recall from the setup section that we set variant weights to split traffic 50/50. The CloudWatch metrics for the total invocations for each variant below show us the invocation patterns for each variant:

Now we shift 75% of the traffic to `Variant2` by assigning new weights to each variant using `UpdateEndpointWeightsAndCapacities`. SageMaker AI now sends 75% of the inference requests to `Variant2` and remaining 25% of requests to `Variant1`.

```
sm.update_endpoint_weights_and_capacities(
    EndpointName=endpoint_name,
    DesiredWeightsAndCapacities=[
        {
            "DesiredWeight": 25,
            "VariantName": variant1["VariantName"]
        },
        {
            "DesiredWeight": 75,
            "VariantName": variant2["VariantName"]
        }
    ]
)
```

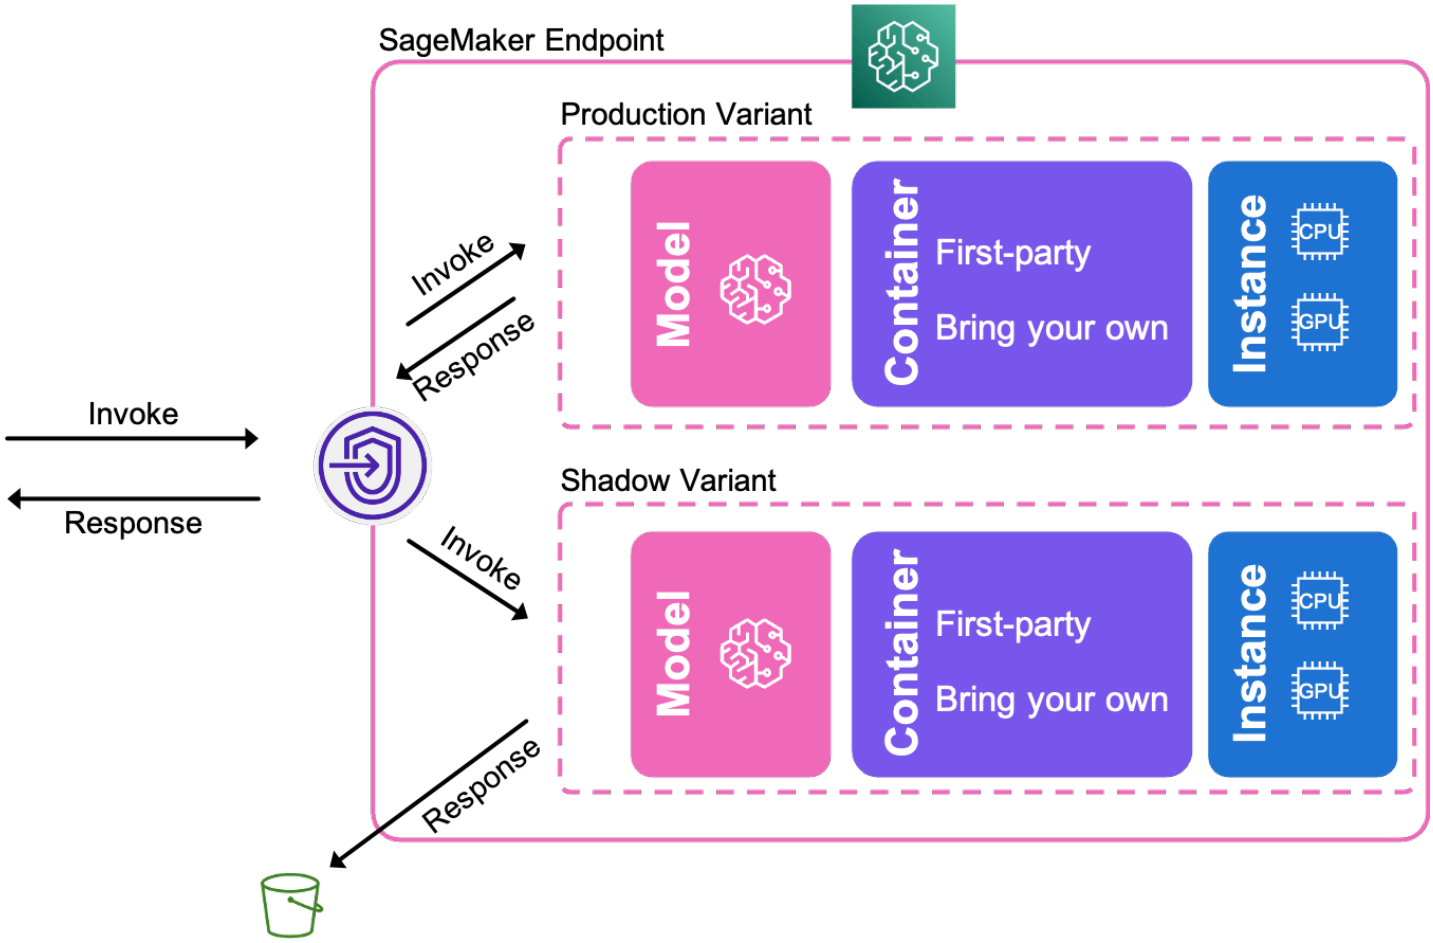
The CloudWatch metrics for total invocations for each variant shows us higher invocations for `Variant2` than for `Variant1`:



We can continue to monitor our metrics, and when we're satisfied with a variant's performance, we can route 100% of the traffic to that variant. We use `UpdateEndpointWeightsAndCapacities` to update the traffic assignments for the variants. The weight for `Variant1` is set to 0 and the weight for `Variant2` is set to 1. SageMaker AI now sends 100% of all inference requests to `Variant2`.

```
sm.update_endpoint_weights_and_capacities(
```

```
    EndpointName=endpoint_name,
    DesiredWeightsAndCapacities=[
        {
            "DesiredWeight": 0,
            "VariantName": variant1["VariantName"]
        },
        {
            "DesiredWeight": 1,
            "VariantName": variant2["VariantName"]
        }
    ]
)
```



The CloudWatch metrics for the total invocations for each variant show that all inference requests are being processed by `Variant2` and there are no inference requests processed by `Variant1`.

You can now safely update your endpoint and delete `Variant1` from your endpoint. You can also continue testing new models in production by adding new variants to your endpoint and following steps 2 - 4.

Testing models with shadow variants

You can use SageMaker AI Model Shadow Deployments to create long running shadow variants to validate any new candidate component of your model serving stack before promoting it to production. The following diagram shows how shadow variants work in more detail.

Deploy shadow variants

The following code example shows how you can programmatically deploy shadow variants. Replace the *`user placeholder text`* in the example with your own information.

1. Create two SageMaker AI models: one for your production variant, and one for your shadow variant.

```
import boto3
from sagemaker.core.helper.session_helper import get_execution_role, Session

aws_region = "aws-region"

boto_session = boto3.Session(region_name=aws_region)
sagemaker_client = boto_session.client("sagemaker")

role = get_execution_role()
```

```
bucket = Session(boto_session).default_bucket()

model_name1 = "name-of-your-first-model"
model_name2 = "name-of-your-second-model"

sagemaker_client.create_model(
    ModelName = model_name1,
    ExecutionRoleArn = role,
    Containers=[
        {
            "Image": "ecr-image-uri-for-first-model",
            "ModelDataUrl": "s3-location-of-trained-first-model"
        }
    ]
)

sagemaker_client.create_model(
    ModelName = model_name2,
    ExecutionRoleArn = role,
    Containers=[
        {
            "Image": "ecr-image-uri-for-second-model",
            "ModelDataUrl": "s3-location-of-trained-second-model"
        }
    ]
)
```

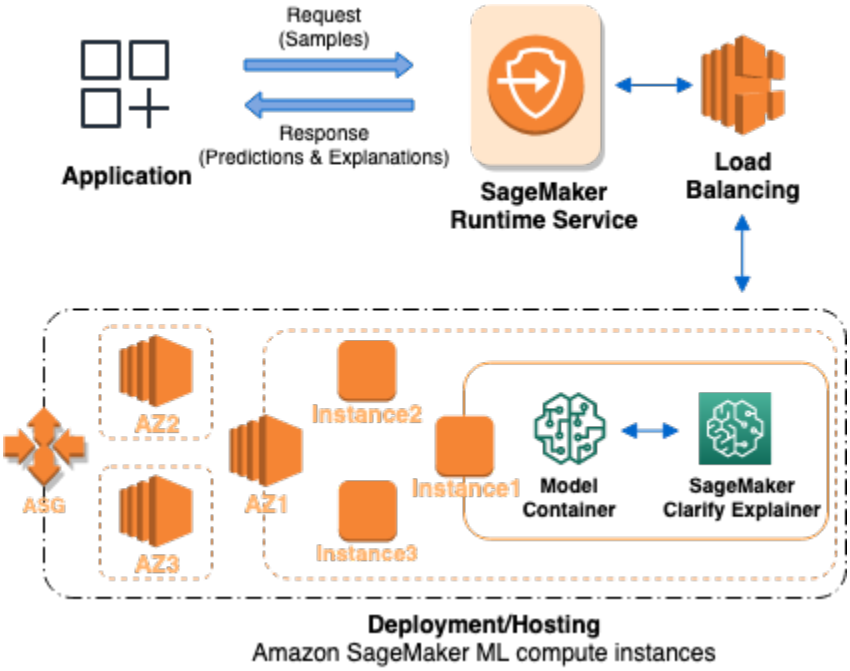
2. Create an endpoint configuration. Specify both your production and shadow variants in the configuration.

```
endpoint_config_name = name-of-your-endpoint-config

create_endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {
            "VariantName": name-of-your-production-variant,
            "ModelName": model_name1,
            "InstanceType": "ml.m5.xlarge",
            "InitialInstanceCount": 1,
            "InitialVariantWeight": 1,
        }
```

```
    ],
    ShadowProductionVariants=[
        {
            "VariantName": name-of-your-shadow-variant,
            "ModelName": model_name2,
            "InstanceType": "ml.m5.xlarge",
            "InitialInstanceCount": 1,
            "InitialVariantWeight": 1,
        }
   ]
)
```

3. Create an endpoint.



```
create_endpoint_response = sm.create_endpoint(
    EndpointName=name-of-your-endpoint,
    EndpointConfigName=endpoint_config_name,
)
```

Online explainability with SageMaker Clarify

This guide shows how to configure online explainability with SageMaker Clarify. With SageMaker AI real-time inference endpoints, you can analyze explainability in real time, continuously. The online explainability function fits into the **Deploy to production** part of the Amazon SageMaker AI Machine Learning workflow.

How Clarify Online Explainability Works

The following graphic depicts SageMaker AI architecture for hosting an endpoint that serves explainability requests. It depicts interactions between an endpoint, the model container, and the SageMaker Clarify explainer.

Here's how Clarify online explainability works. The application sends a REST-style `InvokeEndpoint` request to the SageMaker AI Runtime Service. The service routes this request to a SageMaker AI endpoint to obtain predictions and explanations. Then, the service receives the response from the endpoint. Lastly, the service sends the response back to the application.

To increase the endpoint availability, SageMaker AI automatically attempts to distribute endpoint instances in multiple Availability Zones, according to the instance count in the endpoint configuration. On an endpoint instance, upon a new explainability request, the SageMaker Clarify explainer calls the model container for predictions. Then it computes and returns the feature attributions.

Here are the four steps to create an endpoint that uses SageMaker Clarify online explainability:

1. Check if your pre-trained SageMaker AI model is compatible with online explainability by following the pre-check steps.
2. Create an endpoint configuration with the SageMaker Clarify explainer configuration using the `CreateEndpointConfig` API.
3. Create an endpoint and provide the endpoint configuration to SageMaker AI using the `CreateEndpoint` API. The service launches the ML compute instance and deploys the model as specified in the configuration.

4. Invoke the endpoint: After the endpoint is in service, call the SageMaker AI Runtime API `InvokeEndpoint` to send requests to the endpoint. The endpoint then returns explanations and predictions.

Pre-check the model container

This section shows how to pre-check the model container inputs and outputs for compatibility before configuring an endpoint. The SageMaker Clarify explainer is **model agnostic**, but it has requirements for model container input and output.

> **Note**
>
> You can increase efficiency by configuring your container to support batch requests, which support two or more records in a single request. For example, a single record is a single line of CSV data, or a single line of JSON Lines data. SageMaker Clarify will attempt to send a mini-batch of records to the model container first before falling back to single record requests.

Model container input

CSV

The model container supports input in CSV with MIME type:`text/csv`. The following table shows example inputs that SageMaker Clarify supports.

Model container input (string representation)	Comments
'1,2,3,4'	Single record that uses four numerical features.
'1,2,3,4\n5,6,7,8'	Two records, separated by line break '\n'.
'"This is a good product",5'	Single record that contains a text feature and a numerical feature.
'"This is a good product",5\n"Bad shopping experience",1'	Two records.

JSON Lines

SageMaker AI also supports input in JSON Lines dense format with MIME type:`application/jsonlines`, as shown in the following table.

Model container input	Comments
'{"data":{"features":[1,2,3,4]}}'	Single record; a list of features can be extracted by JMESPath expression `data.features` .
'{"data":{"features":[1,2,3,4]}}\n{"data":{"features":[5,6,7,8]}}'	Two records.
'{"features":["This is a good product",5]}'	Single record; a list of features can be extracted by JMESPath expression `features`.
'{"features":["This is a good product",5]}\n{"features":["Bad shopping experience",1]}'	Two records.

Model container output

Your model container output should also be in either CSV, or JSON Lines dense format. Additionally the model container should include the probabilities of the input records, which SageMaker Clarify uses to compute feature attributions.

The following data examples are for model container outputs in **CSV format**.

Probability only

For regression and binary classification problems, the model container outputs a single probability value (score) of the predicted label. These probabilities can be extracted using column index 0. For multi-class problems, the model container outputs a list of probabilities (scores). For multi-class problems, if no index is provided, all values are extracted.

Model container input	Model container output (string representation)
Single record	'0.6'
Two records (results in one line)	'0.6,0.3'
Two records (results in two lines)	'0.6\n0.3'
Single record of a multi-class model (three classes)	'0.1,0.6,0.3'
Two records of a multi-class model (three classes)	'0.1,0.6,0.3\n0.2,0.5,0.3'

Predicted label and probabilities

The model container outputs the predicted label followed by its probability in **CSV** format. The probabilities can be extracted using index 1.

Model container input	Model container output
Single record	'1,0.6'
Two records	'1,0.6\n0,0.3'

Predicted labels header and probabilities

A multi-class model container trained by Autopilot can be configured to output **the string representation** of the list of predicted labels and probabilities in **CSV** format. In the following example, the probabilities can be extracted by index 1. The label headers can be extracted by index 1, and the label headers can be extracted using index `0`.

Model container input	Model container output
Single record	'"[\'cat\',\'dog\',\'fish\']","[0.1,0.6,0.3]"'

Model container input	Model container output
Two records	'"[\'cat\',\'dog\',\'fish\']","[0.1,0.6,0.3]" \n"[\'cat\',\'dog\',\'fish\']","[0.2,0.5,0.3]"'

The following data examples are for model container outputs in **JSON Lines** format.

Probability only

In this example, the model container outputs the probability that can be extracted by `JMESPath` expression `score` in **JSON Lines** format.

Model container input	Model container output
Single record	'{"score":0.6}'
Two records	'{"score":0.6}\n{"score":0.3}'

Predicted label and probabilities

In this example, a multi-class model container outputs a list of label headers along with a list of probabilities in **JSON Lines** format. The probabilities can be extracted by `JMESPath` expression `probability`, and the label headers can be extracted by `JMESPath` expression `predicted labels`.

Model container input	Model container output
Single record	'{"predicted_labels":["cat","dog","fish"],"probabilities":[0.1,0.6,0.3]}'
Two records	'{"predicted_labels":["cat","dog","fish"],"probabilities":[0.1,0.6,0.3]}\n{"predicted_labels":["cat","dog","fish"],"probabilities":[0.2,0.5,0.3]}'

Predicted labels header and probabilities

In this example, a multi-class model container outputs a list of label headers and probabilities in **JSON Lines** format. The probabilities can be extracted by `JMESPath` expression `probability`, and the label headers can be extracted by `JMESPath` expression `predicted labels`.

Model container input	Model container output
Single record	'{"predicted_labels":["cat","dog","fish"],"probabilities":[0.1,0.6,0.3]}'
Two records	'{"predicted_labels":["cat","dog","fish"],"probabilities":[0.1,0.6,0.3]}\n{"predicted_labels":["cat","dog","fish"],"probabilities":[0.2,0.5,0.3]}'

Model container validation

We recommend that you deploy your model to a SageMaker AI real-time inference endpoint, and send requests to the endpoint. Manually examine the requests (model container inputs) and responses (model container outputs) to make sure that both are compliant with the requirements in the **Model Container Input** section and **Model Container Output** section. If your model container supports batch requests, you can start with a single record request, and then try two or more records.

The following commands show how to request a response using the Amazon CLI. The Amazon CLI is pre-installed in SageMaker Studio Classic, and SageMaker Notebook instances. If you need to install the Amazon CLI, follow this installation guide.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name $ENDPOINT_NAME \
  --content-type $CONTENT_TYPE \
  --accept $ACCEPT_TYPE \
  --body $REQUEST_DATA \
  $CLI_BINARY_FORMAT \
  /dev/stderr 1>/dev/null
```

The parameters are defined, as follows:

- `$ENDPOINT_NAME`: The name of the endpoint.
- `$CONTENT_TYPE`: The MIME type of the request (model container input).
- `$ACCEPT_TYPE`: The MIME type of the response (model container output).
- `$REQUEST_DATA`: The requested payload string.
- `$CLI_BINARY_FORMAT`: The format of the command line interface (CLI) parameter. For Amazon CLI v1, this parameter should remain blank. For v2, this parameter should be set to `--cli-binary-format raw-in-base64-out`.

> **Note**
>
> Amazon CLI v2 passes binary parameters as base64-encoded strings default.

The following examples use Amazon CLI v1:

Request and response in CSV format

- The request consists of a single record and the response is its probability value.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-sagemaker-xgboost-model \
  --content-type text/csv \
  --accept text/csv \
  --body '1,2,3,4' \
  /dev/stderr 1>/dev/null
```

  Output:

  `0.6`

- The request consists of two records, and the response includes their probabilities, and the model separates the probabilities by a comma. The `$'content'` expression in the `--body` tells the command to interpret `\n` in the content as a line break.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-sagemaker-xgboost-model \
  --content-type text/csv \
  --accept text/csv \
  --body $'1,2,3,4\n5,6,7,8' \
```

```
  /dev/stderr 1>/dev/null
```

Output:

```
0.6,0.3
```

- The request consists of two records, the response includes their probabilities, and the model separates the probabilities with a line break.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-1 \
  --content-type text/csv \
  --accept text/csv \
  --body $'1,2,3,4\n5,6,7,8' \
  /dev/stderr 1>/dev/null
```

Output:

```
0.6

0.3
```

- The request consists of a single record, and the response is probability values (multi-class model, three classes).

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-1 \
  --content-type text/csv \
  --accept text/csv \
  --body '1,2,3,4' \
  /dev/stderr 1>/dev/null
```

Output:

```
0.1,0.6,0.3
```

- The request consists of two records, and the response includes their probability values (multi-class model, three classes).

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-1 \
  --content-type text/csv \
  --accept text/csv \
```

```
  --body $'1,2,3,4\n5,6,7,8' \
  /dev/stderr 1>/dev/null
```

Output:

```
0.1,0.6,0.3

0.2,0.5,0.3
```

- The request consists of two records, and the response includes predicted label and probability.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-2 \
  --content-type text/csv \
  --accept text/csv \
  --body $'1,2,3,4\n5,6,7,8' \
  /dev/stderr 1>/dev/null
```

Output:

```
1,0.6

0,0.3
```

- The request consists of two records and the response includes label headers and probabilities.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-3 \
  --content-type text/csv \
  --accept text/csv \
  --body $'1,2,3,4\n5,6,7,8' \
  /dev/stderr 1>/dev/null
```

Output:

```
"['cat','dog','fish']","[0.1,0.6,0.3]"

"['cat','dog','fish']","[0.2,0.5,0.3]"
```

Request and response in JSON Lines format

- The request consists of a single record and the response is its probability value.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-jsonlines \
  --content-type application/jsonlines \
  --accept application/jsonlines \
  --body '{"features":["This is a good product",5]}' \
  /dev/stderr 1>/dev/null
```

  Output:

```
{"score":0.6}
```

- The request contains two records, and the response includes predicted label and probability.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-jsonlines-2 \
  --content-type application/jsonlines \
  --accept application/jsonlines \
  --body $'{"features":[1,2,3,4]}\n{"features":[5,6,7,8]}' \
  /dev/stderr 1>/dev/null
```

  Output:

```
{"predicted_label":1,"probability":0.6}

{"predicted_label":0,"probability":0.3}
```

- The request contains two records and the response includes label headers and probabilities.

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-jsonlines-3 \
  --content-type application/jsonlines \
  --accept application/jsonlines \
  --body $'{"data":{"features":[1,2,3,4]}}\n{"data":{"features":[5,6,7,8]}}' \
  /dev/stderr 1>/dev/null
```

  Output:

```
{"predicted_labels":["cat","dog","fish"],"probabilities":
[0.1,0.6,0.3]}

{"predicted_labels":["cat","dog","fish"],"probabilities":
[0.2,0.5,0.3]}
```

Request and response in different formats

- The request is in CSV format and the response is in JSON Lines format:

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-csv-in-jsonlines-out \
  --content-type text/csv \
  --accept application/jsonlines \
  --body $'1,2,3,4\n5,6,7,8' \
  /dev/stderr 1>/dev/null
```

  Output:

```
{"probability":0.6}

{"probability":0.3}
```

- The request is in JSON Lines format and the response is in CSV format:

```
aws sagemaker-runtime invoke-endpoint \
  --endpoint-name test-endpoint-jsonlines-in-csv-out \
  --content-type application/jsonlines \
  --accept text/csv \
  --body $'{"features":[1,2,3,4]}\n{"features":[5,6,7,8]}' \
  /dev/stderr 1>/dev/null
```

  Output:

```
0.6

0.3
```

After the validations are complete, delete the testing endpoint.

Configure and create an endpoint

Create a new endpoint configuration to fit your model, and use this configuration to create the endpoint. You can use the model container validated in the pre-check step to create an endpoint and enable the SageMaker Clarify online explainability feature.

Use the `sagemaker_client` object to create an endpoint using the CreateEndpointConfig API. Set the member `ClarifyExplainerConfig` inside the `ExplainerConfig` parameter as follows:

```
sagemaker_client.create_endpoint_config(
    EndpointConfigName='name-of-your-endpoint-config',
    ExplainerConfig={
        'ClarifyExplainerConfig': {
            'EnableExplanations': '`true`',
            'InferenceConfig': {
                ...
            },
            'ShapConfig': {
                ...
            }
        },
    },
    ProductionVariants=[{
        'VariantName': 'AllTraffic',
        'ModelName': 'name-of-your-model',
        'InitialInstanceCount': 1,
        'InstanceType': 'ml.m5.xlarge',
    }]
     ...
)
sagemaker_client.create_endpoint(
    EndpointName='name-of-your-endpoint',
    EndpointConfigName='name-of-your-endpoint-config'
)
```

The first call to the `sagemaker_client` object creates a new endpoint configuration with the explainability feature enabled. The second call uses the endpoint configuration to launch the endpoint.

> **Note**
>
> You can also host multiple models in one container behind a SageMaker AI real-time inference multi-model endpoint and configure online explainability with SageMaker Clarify.

The `EnableExplanations` expression

The `EnableExplanations` parameter is a `JMESPath` Boolean expression string. It is evaluated for **each record** in the explainability request. If this parameter is evaluated to be **true**, then the record will be explained. If this parameter is evaluated to be **false**, then explanations are not be generated.

SageMaker Clarify deserializes the model container output for each record into a JSON compatible data structure, and then uses the `EnableExplanations` parameter to evaluate the data.

> **Notes**
>
> There are two options for records depending on the format of the model container output.
>
> - If the model container output is in CSV format, then a record is loaded as a JSON array.
> - If the model container output is in JSON Lines format, then a record is loaded as a JSON object.

The `EnableExplanations` parameter is a JMESPath expression that can be passed either during the `InvokeEndpoint` or `CreateEndpointConfig` operations. If the JMESPath expression that you supplied is not valid, the endpoint creation will fail. If the expression is valid, but the expression evaluation result is unexpected, then the endpoint will be created successfully, but an error will be generated when the endpoint is invoked. Test your `EnableExplanations` expression by using the `InvokeEndpoint` API, and then apply it to the endpoint configuration.

The following are some examples of valid `EnableExplanations` expression. In the examples, a JMESPath expression encloses a literal using backtick characters. For example, `` `true` `` means true.

Expression (string representation)	Model container output (string representation)	Evaluation result (Boolean)	Meaning
'`true`'	(N/A)	True	Activate online explainability unconditionally.
'`false`'	(N/A)	False	Deactivate online explainability unconditionally.
'[1]>`0.5`'	'1,0.6'	True	For each record, the model container outputs its predicted label and probability. Explains a record if its probability (at index 1) is greater than 0.5.
'probability>`0.5`'	'{"predicted_label":1,"probability":0.6}'	True	For each record, the model container outputs JSON data. Explain a record if its probability is greater than 0.5.
'!contains(probabilities[:-1], max(probabilities))'	'{"probabilities": [0.4, 0.1, 0.4], "labels": ["cat","dog","fish"]}'	False	For a multi-class model: Explains a record if its predicted label (the class that has the max probability value) is the last class. Literally, the expression means that the max probability

Expression (string representation)	Model container output (string representation)	Evaluation result (Boolean)	Meaning
			value is not in the list of probabilities excluding the last one.

Synthetic dataset

SageMaker Clarify uses the Kernel SHAP algorithm. Given a record (also called a sample or an instance) and the SHAP configuration, the explainer first generates a synthetic dataset. SageMaker Clarify then queries the model container for the predictions of the dataset, and then computes and returns the feature attributions. The size of the synthetic dataset affects the runtime for the Clarify explainer. Larger synthetic datasets take more time to obtain model predictions than smaller ones.

The synthetic dataset size is determined by the following formula:

```
Synthetic dataset size = SHAP baseline size * n_samples
```

The SHAP baseline size is the number of records in the SHAP baseline data. This information is taken from the `ShapBaselineConfig`.

The size of `n_samples` is set by the parameter `NumberOfSamples` in the explainer configuration and the number of features. If the number of features is `n_features`, then `n_samples` is the following:

```
n_samples = MIN(NumberOfSamples, 2^n_features - 2)
```

The following shows `n_samples` if `NumberOfSamples` is not provided.

```
n_samples = MIN(2*n_features + 2^11, 2^n_features - 2)
```

For example, a tabular record with 10 features has a SHAP baseline size of 1. If `NumberOfSamples` is not provided, the synthetic dataset contains 1022 records. If the record has 20 features, the synthetic dataset contains 2088 records.

For NLP problems, `n_features` is equal to the number of non-text features plus the number of text units.

> **Note**
>
> The `InvokeEndpoint` API has a request timeout limit. If the synthetic dataset is too large, the explainer may not be able to complete the computation within this limit. If necessary, use the previous information to understand and reduce the SHAP baseline size and `NumberOfSamples`. If your model container is set up to handle batch requests, then you can also adjust the value of `MaxRecordCount`.

Invoke the endpoint

After the endpoint is running, use the SageMaker AI Runtime InvokeEndpoint API in the SageMaker AI Runtime service to send requests to, or invoke the endpoint. In response, the requests are handled as explainability requests by the SageMaker Clarify explainer.

> **Note**
>
> To invoke an endpoint, choose one of the following options:
>
> - For instructions to use Boto3 or the Amazon CLI to invoke an endpoint, see Invoke models for real-time inference.
> - To use the SageMaker SDK for Python to invoke an endpoint, see the Predictor API.

Request

The `InvokeEndpoint` API has an optional parameter `EnableExplanations`, which is mapped to the HTTP header `X-Amzn-SageMaker-Enable-Explanations`. If this parameter is provided, it overrides the `EnableExplanations` parameter of the `ClarifyExplainerConfig`.

> **Note**
>
> The `ContentType` and `Accept` parameters of the `InvokeEndpoint` API are required. Supported formats include MIME type `text/csv` and `application/jsonlines`.

Use the `sagemaker_runtime_client` to send a request to the endpoint, as follows:

```
response = sagemaker_runtime_client.invoke_endpoint(
    EndpointName='name-of-your-endpoint',
    EnableExplanations='`true`',
    ContentType='text/csv',
    Accept='text/csv',
    Body='1,2,3,4',  # single record (of four numerical features)
)
```

For multi-model endpoints, pass an additional `TargetModel` parameter in the previous example request to specifies which model to target at the endpoint. The multi-model endpoint dynamically loads target models as needed. For more information about multi-model endpoints, see Multi-model endpoints. See the SageMaker Clarify Online Explainability on Multi-Model Endpoint Sample Notebook for an example of how to set up and invoke multiple target models from a single endpoint.

Response

If the endpoint is created with `ExplainerConfig`, then a new response schema is used,
This new schema is different from, and is not compatible with, an endpoint that lacks the `ExplainerConfig` parameter provided.

The MIME type of the response is `application/json`, and the response payload can be decoded from UTF-8 bytes to a JSON object. The following shows the members of this JSON object are as follows:

- `version`: The version of the response schema in string format. For example, `1.0`.
- `predictions`: The predictions that the request makes have the following:
  - `content_type`: The MIME type of the predictions, referring to the `ContentType` of the model container response.
  - `data`: The predictions data string delivered as the payload of the model container response for the request.
- `label_headers`: The label headers from the `LabelHeaders` parameter. This is provided in either the explainer configuration or the model container output.
- `explanations`: The explanations provided in the request payload. If no records are explained, then this member returns the empty object `{}`.

- • `kernel_shap`: A key that refers to an array of Kernel SHAP explanations for each record in the request. If a record is not explained, the corresponding explanation is `null`.

The `kernel_shap` element has the following members:

- `feature_header`: The header name of the features provided by the `FeatureHeaders` parameter in the explainer configuration `ExplainerConfig`.
- `feature_type`: The feature type inferred by explainer or provided in the `FeatureTypes` parameter in the `ExplainerConfig`. This element is only available for NLP explainability problems.
- `attributions`: An array of attribution objects. Text features can have multiple attribution objects, each for a unit. The attribution object has the following members:
  - `attribution`: A list of probability values, given for each class.
  - `description`: The description of the text units, available only for NLP explainability problems.
    - `partial_text`: The portion of the text explained by the explainer.
    - `start_idx`: A zero-based index to identify the array location of the beginning of the partial text fragment.

Code examples: SDK for Python

This section provides sample code to create and invoke an endpoint that uses SageMaker Clarify online explainability. These code examples use the Amazon SDK for Python.

Tabular data

The following example uses tabular data and a SageMaker AI model called `model_name`. In this example, the model container accepts data in CSV format, and each record has four numerical features. In this minimal configuration, **for demonstration purposes only**, the SHAP baseline data is set to zero. Refer to SHAP Baselines for Explainability to learn how to choose more appropriate values for `ShapBaseline`.

Configure the endpoint, as follows:

```
endpoint_config_name = 'tabular_explainer_endpoint_config'
response = sagemaker_client.create_endpoint_config(
```

```
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[{
        'VariantName': 'AllTraffic',
        'ModelName': model_name,
        'InitialInstanceCount': 1,
        'InstanceType': 'ml.m5.xlarge',
    }],
    ExplainerConfig={
        'ClarifyExplainerConfig': {
            'ShapConfig': {
                'ShapBaselineConfig': {
                    'ShapBaseline': '0,0,0,0',
                },
            },
        },
    },
)
```

Use the endpoint configuration to create an endpoint, as follows:

```
endpoint_name = 'tabular_explainer_endpoint'
response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name,
)
```

Use the `DescribeEndpoint` API to inspect the progress of creating an endpoint, as follows:

```
response = sagemaker_client.describe_endpoint(
    EndpointName=endpoint_name,
)
response['EndpointStatus']
```

After the endpoint status is "InService", invoke the endpoint with a test record, as follows:

```
response = sagemaker_runtime_client.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType='text/csv',
    Accept='text/csv',
    Body='1,2,3,4',
)
```

> **Note**
>
> In the previous code example, for multi-model endpoints, pass an additional `TargetModel` parameter in the request to specify which model to target at the endpoint.

Assume that the response has a status code of 200 (no error), and load the response body, as follows:

```
import codecs
import json
json.load(codecs.getreader('utf-8')(response['Body']))
```

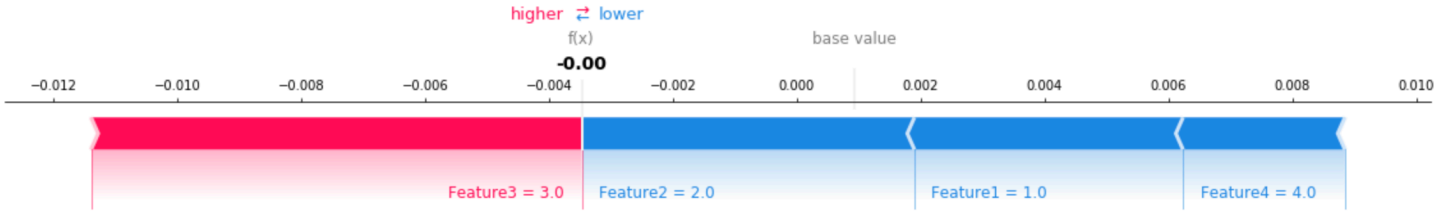
The default action for the endpoint is to explain the record. The following shows example output in the returned JSON object.

```
{
    "version": "1.0",
    "predictions": {
        "content_type": "text/csv; charset=utf-8",
        "data": "0.0006380207487381"
    },
    "explanations": {
        "kernel_shap": [
            [
                {
                    "attributions": [
                        {
                            "attribution": [-0.00433456]
                        }
                    ]
                },
                {
                    "attributions": [
                        {
                            "attribution": [-0.005369821]
                        }
                    ]
                },
                {
                    "attributions": [
                        {
```

```
                            "attribution": [0.007917749]
                        }
                    ]
                },
                {
                    "attributions": [
                        {
                            "attribution": [-0.00261214]
                        }
                    ]
                }
            ]
        ]
    }
}
```

Use the `EnableExplanations` parameter to enable on-demand explanations, as follows:

```
response = sagemaker_runtime_client.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType='text/csv',
    Accept='text/csv',
    Body='1,2,3,4',
    EnableExplanations='[0]>`0.8`',
)
```



> **Note**
>
> In the previous code example, for multi-model endpoints, pass an additional `TargetModel` parameter in the request to specify which model to target at the endpoint.

In this example, the prediction value is less than the threshold value of `0.8`, so the record is not explained:

```
{
    "version": "1.0",
    "predictions": {
        "content_type": "text/csv; charset=utf-8",
        "data": "0.6380207487381995"
    },
```

```
    "explanations": {}
}
```

Use visualization tools to help interpret the returned explanations. The following image shows how SHAP plots can be used to understand how each feature contributes to the prediction. The base value on the diagram, also called the expected value, is the mean predictions of the training dataset. Features that push the expected value higher are red, and features that push the expected value lower are blue. See SHAP additive force layout for additional information.

See the full example notebook for tabular data.

Text data

This section provides a code example to create and invoke an online explainability endpoint for text data. The code example uses SDK for Python.

The following example uses text data and a SageMaker AI model called `model_name`. In this example, the model container accepts data in CSV format, and each record is a single string.

```
endpoint_config_name = 'text_explainer_endpoint_config'
response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[{
        'VariantName': 'AllTraffic',
        'ModelName': model_name,
        'InitialInstanceCount': 1,
        'InstanceType': 'ml.m5.xlarge',
    }],
    ExplainerConfig={
        'ClarifyExplainerConfig': {
            'InferenceConfig': {
                'FeatureTypes': ['text'],
                'MaxRecordCount': 100,
            },
```

```
            'ShapConfig': {
                'ShapBaselineConfig': {
                    'ShapBaseline': '"<MASK>"',
                },
                'TextConfig': {
                    'Granularity': 'token',
                    'Language': 'en',
                },
                'NumberOfSamples': 100,
            },
        },
    },
)
```

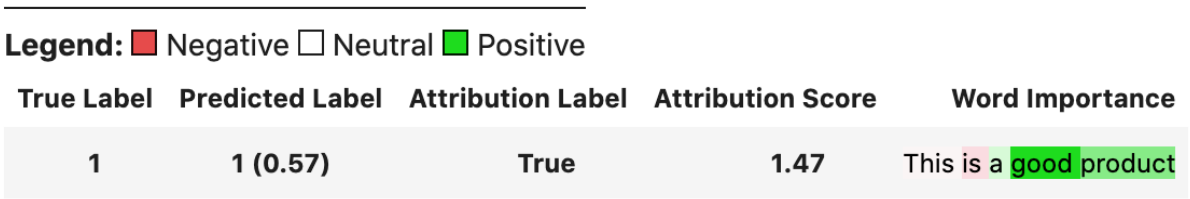
- `ShapBaseline`: A special token reserved for natural language processing (NLP) processing.
- `FeatureTypes`: Identifies the feature as text. If this parameter is not provided, the explainer will attempt to infer the feature type.
- `TextConfig`: Specifies the unit of granularity and language for the analysis of text features. In this example, the language is English, and granularity `token` means a word in English text.
- `NumberOfSamples`: A limit to set the upper bounds of the size of the synthetic dataset.
- `MaxRecordCount`: The maximum number of records in a request that the model container can handle. This parameter is set to stabilize performance.

Use the endpoint configuration to create the endpoint, as follows:

```
endpoint_name = 'text_explainer_endpoint'
response = sagemaker_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name,
)
```

After the status of the endpoint becomes `InService`, invoke the endpoint. The following code sample uses a test record as follows:

```
response = sagemaker_runtime_client.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType='text/csv',
    Accept='text/csv',
    Body='"This is a good product"',
```



```
)
```

If the request completes successfully, the response body will return a valid JSON object that's similar to the following:

```
{
    "version": "1.0",
    "predictions": {
        "content_type": "text/csv",
        "data": "0.9766594\n"
    },
    "explanations": {
        "kernel_shap": [
            [
                {
                    "attributions": [
                        {
                            "attribution": [
                                -0.007270948666666712
                            ],
                            "description": {
                                "partial_text": "This",
                                "start_idx": 0
                            }
                        },
                        {
                            "attribution": [
                                -0.018199033666666628
                            ],
                            "description": {
                                "partial_text": "is",
                                "start_idx": 5
                            }
                        },
                        {
                            "attribution": [
                                0.01970993241666666
                            ],
                            "description": {
                                "partial_text": "a",
                                "start_idx": 8
                            }
                        },
```

```
                        {
                            "attribution": [
                                0.1253469515833334
                            ],
                            "description": {
                                "partial_text": "good",
                                "start_idx": 10
                            }
                        },
                        {
                            "attribution": [
                                0.03291143366666657
                            ],
                            "description": {
                                "partial_text": "product",
                                "start_idx": 15
                            }
                        }
                    ],
                    "feature_type": "text"
                }
            ]
        ]
    }
}
```

Use visualization tools to help interpret the returned text attributions. The following image shows how the captum visualization utility can be used to understand how each word contributes to the prediction. The higher the color saturation, the higher the importance given to the word. In this example, a highly saturated bright red color indicates a strong negative contribution. A highly saturated green color indicates a strong positive contribution. The color white indicates that the word has a neutral contribution. See the captum library for additional information on parsing and rendering the attributions.

See the full example notebook for text data.

Troubleshooting guide

If you encounter errors using SageMaker Clarify online explainability, consult the topics in this section.

`InvokeEndpoint` API fails with the error "ReadTimeoutError:Read timeout on endpoint..."

This error means that the request could not be completed within the 60-second time limit set by the request timeout.

To reduce the request latency, try the following:

- Tune the model's performance during inference. For example, SageMaker AI Neo can optimize models for inference.
- Allow the model container to handle batch requests.
- Use a larger `MaxRecordCount` to reduce the number of calls from the explainer to the model container. This will reduce network latency and overhead.
- Use an instance type that has more resources allocated to it. Alternately, assign more instances to the endpoint to help balance the load.
- Reduce the number of records inside a single `InvokeEndpoint` request.
- Reduce the number of records in the baseline data.
- Use a smaller `NumberOfSamples` value to reduce the size of the synthetic dataset. For more information about how the number of samples affects your synthetic dataset, see Synthetic dataset.

Deploy to multiple instance types with instance pools

When you deploy a model to a SageMaker AI endpoint, you typically specify a single instance type for the production variant. If that instance type is unavailable in the target Availability Zone, the deployment fails with an insufficient capacity error (ICE), and you must manually retry with a different instance type.

With instance pools, you can specify an ordered list of up to five instance types for a production variant. SageMaker AI attempts to provision instances starting with the highest-priority type (priority 1) and automatically falls back to lower-priority types when capacity is unavailable. This eliminates the need for manual retry and improves endpoint availability.

Instance pools support both real-time and asynchronous inference endpoints. You can use them with single-model endpoints and with inference components.

The following steps describe how instance pool provisioning works:

1. SageMaker AI tries to provision instances from the highest-priority pool (priority 1).
2. If SageMaker AI encounters an insufficient capacity error (ICE) for the current instance type, it automatically falls back to the next pool in priority order.
3. This continues until the required number of instances is provisioned, all pools are exhausted, or the total provisioning timeout (`VariantInstanceProvisionTimeoutInSeconds`) is reached.

Topics

- Set up an endpoint with instance pools
- Monitor instance pools
- Auto-scaling with instance pools

Set up an endpoint with instance pools

To use instance pools, you replace the `InstanceType` parameter in your production variant with an `InstancePools` list. Each entry specifies an instance type and a priority (1 to 5, where 1 is the highest). You can optionally set `VariantInstanceProvisionTimeoutInSeconds` (300 to 3600 seconds) to control the total time SageMaker AI spends attempting to provision instances across all pools before the operation fails.

Real-time endpoint with a single model

The following example creates an endpoint configuration with two instance pools. If `ml.g6.2xlarge` instances are unavailable, SageMaker AI falls back to `ml.g6e.2xlarge`.

```
import boto3

sagemaker_client = boto3.client("sagemaker")

endpoint_config_name = "my-heterog-endpoint-config"

sagemaker_client.create_endpoint_config(
```

```
    EndpointConfigName=endpoint_config_name,
    ProductionVariants=[
        {
            "VariantName": "AllTraffic",
            "ModelName": "my-model",
            "InitialInstanceCount": 2,
            "InstancePools": [
                {
                    "InstanceType": "ml.g6.2xlarge",
                    "Priority": 1,
                },
                {
                    "InstanceType": "ml.g6e.2xlarge",
                    "Priority": 2,
                },
            ],
            "VariantInstanceProvisionTimeoutInSeconds": 600,
        }
    ],
)

sagemaker_client.create_endpoint(
    EndpointName="my-heterog-endpoint",
    EndpointConfigName=endpoint_config_name,
)
```

You can also use the `ModelNameOverride` parameter in each pool to specify a different model optimized for that instance type. For example, you might deploy a model compiled for GPU on one instance type and an uncompiled version on another.

Real-time endpoint with inference components

When you use inference components with instance pools, you have two options for defining specifications:

- **Single `Specification`** — Use the same model and resource configuration across all instance types in the endpoint's instance pools. This works when the model can run on any of the provisioned instance types with the same resource requirements.
- **Multiple `Specifications`** — Use the `Specifications` parameter (plural) to define different model or resource configurations for each instance type. Each specification includes an `InstanceType` field that maps it to an instance type in the endpoint's instance pools.

The following example creates an inference component with per-instance-type specifications:

```
sagemaker_client.create_inference_component(
    InferenceComponentName="my-ic",
    EndpointName="my-heterog-endpoint",
    VariantName="AllTraffic",
    Specifications=[
        {
            "InstanceType": "ml.g6.2xlarge",
            "ModelName": "my-model-g6",
            "Container": {
                "Image": "123456789012.dkr.ecr.us-west-2.amazonaws.com/my-
image:latest",
            },
            "ComputeResourceRequirements": {
                "NumberOfAcceleratorDevicesRequired": 1,
                "MinMemoryRequiredInMb": 4096,
            },
        },
        {
            "InstanceType": "ml.g6e.2xlarge",
            "ModelName": "my-model-g6e",
            "Container": {
                "Image": "123456789012.dkr.ecr.us-west-2.amazonaws.com/my-
image:latest",
            },
            "ComputeResourceRequirements": {
                "NumberOfAcceleratorDevicesRequired": 1,
                "MinMemoryRequiredInMb": 8192,
            },
        },
    ],
    RuntimeConfig={
        "CopyCount": 2,
    },
)
```

Monitor instance pools

Existing CloudWatch metrics that are aggregated across all instances in a variant — such as `Invocations`, `ModelLatency`, and `CPUUtilization` — continue to work the same way when

you use instance pools. In addition, CloudWatch publishes these metrics with an `InstanceType` dimension so you can monitor performance for each instance type separately.

Per-instance-type metrics

When a production variant uses instance pools, the following dimension combinations become available in CloudWatch for per-instance-type monitoring:

Dimension combination	Use case
`EndpointName` , `VariantName` , `InstanceType`	Filter endpoint-level and invocation metrics (such as `CPUUtilization` , `Invocations` , `ModelLatency`) for a specific instance type within the variant.
`InferenceComponentName` , `InstanceType`	Filter inference component metrics for a specific instance type. Use this to compare how the same inference component performs across different instance types.

These dimensions are available for both standard CloudWatch metrics and enhanced metrics. For the full list of available metrics, see Amazon SageMaker AI metrics in Amazon CloudWatch and Amazon SageMaker AI enhanced metrics for inference endpoints.

Check fleet distribution

To see the current instance count for each pool, call the `DescribeEndpoint` API. The `ProductionVariants` in the response include an `InstancePools` list with the current count for each instance type. This shows your fleet composition after provisioning, including any fallback instances from lower-priority pools.

If you use inference components, the `DescribeInferenceComponent` response includes a `PlacementStatus` field in the runtime configuration summary that shows the copy count per instance type. Use this to understand how inference component copies are distributed across the instance types in your fleet.

Auto-scaling with instance pools

Auto-scaling with instance pools follows the same process as standard endpoint auto-scaling. You register scalable targets, define scaling policies, and apply them to your endpoint. For general auto-scaling setup, see Automatic scaling of Amazon SageMaker AI models.

The key difference is how SageMaker AI provisions and releases instances when a scaling event triggers:

Scale out (adding instances)

SageMaker AI provisions instances starting with the highest-priority pool (lowest priority value). If SageMaker AI encounters an insufficient capacity error for the current instance type, it automatically falls back to the next pool in priority order. SageMaker AI continues retrying across pools until instances are provisioned or the total `VariantInstanceProvisionTimeoutInSeconds` is reached.

Scale in (removing instances)

SageMaker AI releases instances starting with the lowest-priority pool (highest priority value). Your preferred, higher-priority instance types are kept running as long as possible, and fallback instances are released first.

Use predefined scaling metrics

Predefined scaling metrics such as `SageMakerVariantInvocationsPerInstance` continue to work with instance pools. These metrics aggregate across all instance types in the variant, so the scaling behavior is the same as a standard endpoint. This is the simplest approach when all instance types in your pools have similar capacity.

For target tracking and step scaling policy setup, see Automatic scaling of Amazon SageMaker AI models.

Use weighted custom metrics for mixed fleets

When your instance pools contain instance types with different compute capacities, you can use CloudWatch metric math to create a weighted scaling signal. This lets you control how much each instance type's load contributes to the overall scaling decision.

The following example creates a target tracking policy that uses a weighted average of `ConcurrentRequestsPerModel` across two instance types. The weights determine how sensitive the scaling policy is to each type's load:

```
import boto3

aas_client = boto3.client("application-autoscaling")

# Register the scalable target
aas_client.register_scalable_target(
    ServiceNamespace="sagemaker",
    ResourceId="endpoint/my-heterog-endpoint/variant/AllTraffic",
    ScalableDimension="sagemaker:variant:DesiredInstanceCount",
    MinCapacity=1,
    MaxCapacity=10,
)

# Define target tracking policy with weighted metric math
aas_client.put_scaling_policy(
    PolicyName="weighted-concurrent-requests",
    ServiceNamespace="sagemaker",
    ResourceId="endpoint/my-heterog-endpoint/variant/AllTraffic",
    ScalableDimension="sagemaker:variant:DesiredInstanceCount",
    PolicyType="TargetTrackingScaling",
    TargetTrackingScalingPolicyConfiguration={
        "TargetValue": 10.0,
        "CustomizedMetricSpecification": {
            "Metrics": [
                {
                    "Id": "cr_g6",
                    "Label": "ConcurrentRequests-g6-2xlarge",
                    "MetricStat": {
                        "Metric": {
                            "Namespace": "AWS/SageMaker",
                            "MetricName": "ConcurrentRequestsPerModel",
                            "Dimensions": [
                                {"Name": "EndpointName", "Value": "my-heterog-
endpoint"},
                                {"Name": "VariantName", "Value": "AllTraffic"},
                                {"Name": "InstanceType", "Value": "ml.g6.2xlarge"},
                            ],
                        },
```

```
                        "Stat": "Average",
                    },
                    "ReturnData": False,
                },
                {
                    "Id": "cr_g6e",
                    "Label": "ConcurrentRequests-g6e-2xlarge",
                    "MetricStat": {
                        "Metric": {
                            "Namespace": "AWS/SageMaker",
                            "MetricName": "ConcurrentRequestsPerModel",
                            "Dimensions": [
                                {"Name": "EndpointName", "Value": "my-heterog-
endpoint"},
                                {"Name": "VariantName", "Value": "AllTraffic"},
                                {"Name": "InstanceType", "Value": "ml.g6e.2xlarge"},
                            ],
                        },
                        "Stat": "Average",
                    },
                    "ReturnData": False,
                },
                {
                    "Id": "weighted_avg",
                    "Label": "WeightedConcurrentRequests",
                    "Expression": "0.5 * cr_g6 + 0.5 * cr_g6e",
                    "ReturnData": True,
                },
            ],
        },
    },
)
```

In this example, `cr_g6` and `cr_g6e` fetch the per-instance-type `ConcurrentRequestsPerModel` metric. The `weighted_avg` expression combines them with equal weights (0.5 / 0.5). Adjust the weights to change how the policy responds to load on each instance type.

How weights affect scaling behavior: A higher weight on an instance type means the scaling policy is *more sensitive* to that type's load — not less. The lower-weighted type's signal is dampened, so it can run at higher utilization before triggering a scaling event.

Weight strategy	High-priority type tolerance	Low-priority type tolerance	Best for
Higher weight on high-priority (0.7 / 0.3)	Lower (protected)	Higher (runs hotter)	Protecting expensive or high-capacity instances from overload
Equal (0.5 / 0.5)	Balanced	Balanced	Default recommendation for most workloads
Higher weight on low-priority (0.3 / 0.7)	Higher (runs hotter)	Lower (protected)	Preventing smaller fallback instances from becoming saturated

For more information about custom metrics with auto-scaling, see Define a custom metric (CloudWatch metric: CPUUtilization).

Fine-tune models with adapter inference components

With Amazon SageMaker AI, you can host pre-trained foundation models without needing to create your own models from scratch. However, to tailor a general-purpose foundation model for the unique needs of your business, you must create a fine-tuned version of it. One cost-effective fine-tuning technique is Low-Rank Adaptation (LoRA). The principle behind LoRA is that only a small part of a large foundation model needs updating to adapt it to new tasks or domains. A LoRA adapter augments the inference from a base foundation model with just a few extra adapter layers.

If you host your base foundation model by using a SageMaker AI inference component, you can fine-tune that base model with LoRA adapters by creating *adapter inference components*. When you create an adapter inference component, you specify the following:

- The *base inference component* that is to contain the adapter inference component. The base inference component contains the foundation model that you want to adapt. The adapter inference component uses the compute resources that you assigned to the base inference component.
- The location where you've stored the LoRA adapter in Amazon S3.

After you create the adapter inference component, you can invoke it directly. When you do, SageMaker AI combines the adapter with the base model to augment the generated response.

Before you begin

Before you can create an adapter inference component, you must meet the following requirements:

- You have a base inference component that contains the foundation model to adapt. You've deployed this inference component to a SageMaker AI endpoint.

  For more information about deploying inference components to endpoints, see Deploy models for real-time inference.
- You have a LoRA adapter model, and you've stored the model artifacts as a `tar.gz` file in Amazon S3. You specify the S3 URI of the artifacts when you create the adapter inference component.

The following examples use the SDK for Python (Boto3) to create and invoke an adapter inference component.

Example `create_inference_component` call to create an adapter inference component

The following example creates an adapter inference component and assigns it to a base inference component:

```
sm_client.create_inference_component(
    InferenceComponentName = adapter_ic_name,
    EndpointName = endpoint_name,
    Specification={
        "BaseInferenceComponentName": base_inference_component_name,
        "Container": {
            "ArtifactUrl": adapter_s3_uri
        },
    },
)
```

When you use this example in your own code, replace the placeholder values as follows:

- *adapter_ic_name* – A unique name for your adapter inference component.
- *endpoint_name* – The name of the endpoint that hosts the base inference component.

- *base_inference_component_name* – The name of the base inference component that contains the foundation model to adapt.
- *adapter_s3_uri* – The S3 URI that locates the `tar.gz` file with your LoRA adapter artifacts.

You create an adapter inference component with code that is similar to the code for a normal inference component. One difference is that, for the `Specification` parameter, you omit the `ComputeResourceRequirements` key. When you invoke an adapter inference component, it is loaded by the base inference component. The adapter inference component uses the compute resources of the base inference component.

For more information about creating and deploying inference components with the SDK for Python (Boto3), see Deploy models with the Python SDKs.

After you create an adapter inference component, you invoke it by specifying its name in an `invoke_endpoint` request.

Example `invoke_endpoint` call to invoke an adapter inference component

The following example invokes an adapter inference component:

```
response = sm_rt_client.invoke_endpoint(
    EndpointName = endpoint_name,
    InferenceComponentName = adapter_ic_name,
    Body = json.dumps(
        {
            "inputs": prompt,
            "parameters": {"max_new_tokens": 100, "temperature":0.9}
        }
    ),
    ContentType = "application/json",
)

adapter_reponse = response["Body"].read().decode("utf8")["generated_text"]
```

When you use this example in your own code, replace the placeholder values as follows:

- *endpoint_name* – The name of the endpoint that hosts the base and adapter inference components.
- *adapter_ic_name* – The name of the adapter inference component.

- `prompt` – The prompt for the inference request.

For more information about invoking inference components with the SDK for Python (Boto3), see Invoke models for real-time inference.

Using GPU partitions on SageMaker AI real-time endpoints

Amazon SageMaker AI GPU partitioning (GPU partitioning) lets you run several models on one Graphics Processing Unit (GPU). GPU partitioning uses NVIDIA Multi-Instance GPU (MIG) to divide one physical GPU into multiple independent partitions. MIG gives each partition a fixed share of the GPU's compute slices and a dedicated block of its memory.

Use GPU partitioning when your models don't each need a whole GPU. Instead of one GPU per model, several inference components share one GPU, each in its own partition. For more information about inference components, see Inference components.

Benefits

Improved GPU utilization

Host several models on one GPU instead of dedicating a whole GPU to a model that can't fill it.

Hardware-enforced isolation

Each partition has its own compute slices and GPU memory, so one model can't read another model's GPU memory or take its throughput.

No change to invocation

You invoke a model by inference component name, as you do without partitioning. The partition doesn't appear in the request.

> **Note**
>
> GPU partitioning isolates the GPU's compute slices and memory. Models on the same instance still share host CPU, host memory, storage, and networking.

How GPU partitioning works

You turn on GPU partitioning with two optional API fields:

- `AcceleratorPartitionLayouts` on a production variant of an endpoint that hosts inference components. It declares how SageMaker AI partitions every accelerator on every instance in that variant.
- `AcceleratorPartitionType` on an inference component. It assigns the inference component to a partition type.

GPU partitioning adds no new API operations, resource types, or IAM actions. Endpoints that omit both fields behave as they do without partitioning.

A partition type states one partition's share of an accelerator. For example, `mig-4g.20gb` is 4 compute slices and 20 GB of GPU memory.

SageMaker AI partitions the accelerators while it launches the instances for the endpoint. When the endpoint is `InService`, every accelerator is partitioned and the partitions are empty. You then place models on the partitions by creating inference components.

> **Important**
>
> To use a different partition layout, create a new endpoint. You can't change the partition layout of a running endpoint. An `UpdateEndpoint` request to an endpoint configuration with a different layout returns a 400 error.

Monitor partitioned endpoints

To monitor with Amazon CloudWatch, use the invocation and latency metrics that the endpoint publishes. Partitioned endpoints and their inference components don't publish GPU, CPU, or memory utilization metrics.

Supported instances and Regions

GPU partitioning is supported on the following instance families:

- P4d, NVIDIA A100 (40 GB) accelerators
- P5, NVIDIA H100 (80 GB) accelerators
- G7, NVIDIA RTX PRO 4500 (32 GB) accelerators
- G7e, NVIDIA RTX PRO 6000 (96 GB) accelerators

GPU partitioning is available in the following Amazon Web Services Regions:

- US East (N. Virginia) `us-east-1`
- US East (Ohio) `us-east-2`
- US West (Oregon) `us-west-2`
- Asia Pacific (Singapore) `ap-southeast-1`
- Asia Pacific (Tokyo) `ap-northeast-1`
- Europe (Frankfurt) `eu-central-1`
- Europe (Ireland) `eu-west-1`

> **Note**
>
> Instance availability varies by Amazon Web Services Region. Confirm that your instance type is available in your Region, and that you have endpoint usage quota for it.

GPU partition types

The valid partition types depend on the instance's GPU. If you specify a partition type for a different GPU, SageMaker AI rejects the request with a 400 error that lists the valid values.

The **Partitions per GPU** column is the number of partitions of that type that fit on one GPU. To find the number of partitions on an instance, multiply by the number of GPUs on the instance. For example, an `ml.p4d.24xlarge` instance has 8 GPUs, so a layout of three `mig-1g.5gb` partitions provides 24 partitions on the instance.

P4d, NVIDIA A100 (40 GB)

Partition types for P4d instances

Partition type	GPU memory	Partitions per GPU
`mig-1g.5gb`	5 GB	7
`mig-1g.10gb`	10 GB	4
`mig-2g.10gb`	10 GB	3

Partition type	GPU memory	Partitions per GPU
mig-3g.20gb	20 GB	2
mig-4g.20gb	20 GB	1
mig-7g.40gb	40 GB	1

Important

On P4d instances, the `mig-1g.10gb` partition type requires a newer NVIDIA driver than the default image provides. If you request it on the default image, SageMaker AI accepts the request, and the host then fails to partition the accelerators without reporting which partition type caused the failure. To use `mig-1g.10gb` on a P4d instance, set `InferenceAmiVersion` to `al2023-ami-sagemaker-inference-gpu-4-1` on the production variant. For the driver version that each AMI version provides, see Current versions and supported instance families.

P5, NVIDIA H100 (80 GB)

Partition types for P5 instances

Partition type	GPU memory	Partitions per GPU
mig-1g.10gb	10 GB	7
mig-1g.20gb	20 GB	4
mig-2g.20gb	20 GB	3
mig-3g.40gb	40 GB	2
mig-4g.40gb	40 GB	1
mig-7g.80gb	80 GB	1

G7, NVIDIA RTX PRO 4500 (32 GB)

Partition types for G7 instances

Partition type	GPU memory	Partitions per GPU
`mig-1g.16gb`	16 GB	2
`mig-2g.32gb`	32 GB	1

G7e, NVIDIA RTX PRO 6000 (96 GB)

Partition types for G7e instances

Partition type	GPU memory	Partitions per GPU
`mig-1g.24gb`	24 GB	4
`mig-2g.48gb`	48 GB	2
`mig-4g.96gb`	96 GB	1

Resources

For more information about MIG, see the following NVIDIA documentation:

- NVIDIA Supported MIG Profiles

Topics

- Create an endpoint with GPU partitions
- Deploy models to GPU partitions with inference components
- Manage GPU partitioned endpoints
- Troubleshooting

Create an endpoint with GPU partitions

To create a partitioned endpoint, you declare a partition layout on the production variant of an endpoint configuration, and then create an endpoint from that configuration. SageMaker AI partitions the accelerators while it launches the instances for the endpoint.

Layout rules

You set the partition layout with the `AcceleratorPartitionLayouts` field on a production variant. The following rules apply to `AcceleratorPartitionLayouts`:

- `AcceleratorPartitionLayouts` must contain exactly 1 entry. That entry describes how to divide one accelerator, and SageMaker AI applies it to every accelerator on every instance in the variant.
- The requested partition types must fit on one accelerator. Otherwise, SageMaker AI returns a 400 error that states what the accelerator provides and what you requested. Each partition type is an NVIDIA MIG profile, and NVIDIA sets the number of compute and memory slices that it uses. For more information, see the NVIDIA Multi-Instance GPU User Guide on the NVIDIA website.
- To request multiple partitions of the same type, repeat the type. For example, `["mig-1g.5gb", "mig-1g.5gb", "mig-1g.5gb"]` requests three partitions per accelerator.
- SageMaker AI doesn't support the following NVIDIA profile references:
  - `+me`: Includes at least one media engine (NVDEC, NVENC, NVJPG, or OFA).
  - `+gfx`: Adds support for graphics APIs (new in GB20X).
  - `+me.all`: Allocates all available media engines to this instance, without graphics support.
  - `-me`: Excludes all media engines, for pure compute workloads.

For the partition types that each instance family provides, see GPU partition types.

> **Note**
>
> For more information about partition layouts, see Supported MIG Profiles in the NVIDIA Multi-Instance GPU User Guide on the NVIDIA website.

Create the endpoint config

The following procedure creates a partitioned endpoint on an `ml.p4d.24xlarge` instance in US West (Oregon). An `ml.p4d.24xlarge` instance has 8 NVIDIA A100 accelerators, and each A100 has 7 compute slices. The endpoint divides each A100 into three partitions, one of each of the types `mig-4g.20gb`, `mig-2g.10gb`, and `mig-1g.5gb`. This layout uses all 7 compute slices. The endpoint provides 24 partitions in total, 8 of each type.

> **Important**
>
> The `ml.p4d.24xlarge` instance incurs charges while the endpoint runs, whether or not inference components run on its partitions. To delete it, see Delete a partitioned endpoint. For pricing, see Amazon SageMaker AI pricing.

To create the endpoint config (Amazon CLI)

- Create an endpoint configuration that sets `AcceleratorPartitionLayouts` on the production variant. The following `create-endpoint-config` command creates the endpoint configuration `partition-demo-config`. Replace *`111122223333`* with your AWS account ID and *`my-execution-role`* with the name of an execution role that can pull the container image from Amazon ECR and write to Amazon CloudWatch Logs.

```
aws sagemaker create-endpoint-config \
  --region us-west-2 \
  --endpoint-config-name partition-demo-config \
  --execution-role-arn arn:aws:iam::111122223333:role/my-execution-role \
  --production-variants '[
    {
      "VariantName": "AllTraffic",
      "InstanceType": "ml.p4d.24xlarge",
      "InitialInstanceCount": 1,
      "AcceleratorPartitionLayouts": [
        {
          "AcceleratorPartitionTypes": ["mig-4g.20gb", "mig-2g.10gb", "mig-1g.5gb"]
        }
      ]
    }
  ]'
```

To confirm that SageMaker AI stored the layout, run the following `describe-endpoint-config` command:

```
aws sagemaker describe-endpoint-config \
  --region us-west-2 \
  --endpoint-config-name partition-demo-config \
  --query 'ProductionVariants[0].AcceleratorPartitionLayouts'
```

The output lists the partition types that you sent, in order. If the output is `null`, the endpoint won't be partitioned. For more information, see Troubleshooting.

Create the endpoint

After you create the endpoint config, create the endpoint from it.

To create a partitioned endpoint (Amazon CLI)

1. Create the endpoint, and wait for it to be in service. SageMaker AI partitions the accelerators while it launches the instances for the endpoint. Creating the endpoint can take some time. The following `create-endpoint` command creates the endpoint `partition-demo`, and the `wait endpoint-in-service` command waits until it's ready:

   ```
   aws sagemaker create-endpoint --region us-west-2 --endpoint-name partition-demo --
   endpoint-config-name partition-demo-config
   aws sagemaker wait endpoint-in-service --region us-west-2 --endpoint-name
    partition-demo
   ```

   If the waiter exits with an error, check the status in the next step instead of recreating the endpoint.

2. Describe the endpoint. The following `describe-endpoint` command returns the endpoint status, any failure reason, and the layout:

   ```
   aws sagemaker describe-endpoint \
     --region us-west-2 \
     --endpoint-name partition-demo \
     --query
    '[EndpointStatus,FailureReason,ProductionVariants[0].AcceleratorPartitionLayouts]'
   ```

The layout appears in the output only after the status is `InService`. While the status is `Creating` or `Failed`, the layout is `null`, which is expected and doesn't mean that the endpoint isn't partitioned. If the status is `Failed`, the failure reason explains why.

When the status is `InService`, the output echoes the layout that you sent, in order. Every accelerator is partitioned and the partitions are empty. An `InService` endpoint with no inference components is valid.

To place models on the partitions, see Deploy models to GPU partitions with inference components.

Deploy models to GPU partitions with inference components

After your partitioned endpoint is `InService`, you deploy a model to it by creating an inference component that requests a partition type. Each copy of the inference component occupies one partition of that type. To create the endpoint, see Create an endpoint with GPU partitions.

Inference component rules

The following rules apply to inference components on an endpoint with a partition layout:

- `AcceleratorPartitionType` is required. If you omit it, SageMaker AI returns a 400 error.
- The requested type must be one that the endpoint layout declares. Otherwise, SageMaker AI returns a 400 error that names the declared types.
- `NumberOfAcceleratorDevicesRequired` must be 1. It refers to one partition.
- `MinMemoryRequiredInMb` and `NumberOfCpuCoresRequired` describe host memory and CPU. The partition type sets the GPU memory.
- Each copy uses one partition. Increase `CopyCount` to place more copies on free partitions of the same type.

Create inference components

The following procedure deploys a model to the endpoint `partition-demo` on a `mig-4g.20gb` partition. The inference component defines its model inline with a Hugging Face inference container that downloads the `gpt2` model from Hugging Face at startup, so you don't need to run `create-model`.

To create inference components on partitions (Amazon CLI)

1. Create an inference component. Set `AcceleratorPartitionType` to select the partition type that the model runs on. The following `create-inference-component` command creates the inference component `demo-ic-4g` on a `mig-4g.20gb` partition:

```
aws sagemaker create-inference-component \
  --region us-west-2 \
  --inference-component-name demo-ic-4g \
  --endpoint-name partition-demo \
  --variant-name AllTraffic \
  --specification '{
    "Container": {
      "Image": "763104351884.dkr.ecr.us-west-2.amazonaws.com/huggingface-pytorch-
inference:1.10.2-transformers4.17.0-gpu-py38-cu113-ubuntu20.04",
      "Environment": {
        "HF_MODEL_ID": "gpt2",
        "HF_TASK": "text-generation"
      }
    },
    "ComputeResourceRequirements": {
      "AcceleratorPartitionType": "mig-4g.20gb",
      "NumberOfAcceleratorDevicesRequired": 1,
      "NumberOfCpuCoresRequired": 1,
      "MinMemoryRequiredInMb": 2048
    }
  }' \
  --runtime-config '{"CopyCount": 1}'
```

To place a model on each partition type in the layout, repeat the command for each type with a different inference component name and `AcceleratorPartitionType`.

The following list describes the fields in this example:

- `AcceleratorPartitionType` must be one of the types in the endpoint layout.
- `NumberOfAcceleratorDevicesRequired` must be 1. It refers to one partition.
- `NumberOfCpuCoresRequired` and `MinMemoryRequiredInMb` describe host CPU and memory. The partition type sets the GPU memory.

2. Describe the inference component. It takes a few minutes to create. The following `describe-inference-component` command returns the name, status, and any failure reason of the inference component:

```
aws sagemaker describe-inference-component --region us-west-2 --inference-
component-name demo-ic-4g \
  --query '[InferenceComponentName,InferenceComponentStatus,FailureReason]' --
output text
```

   An inference component is ready when its status is `InService`. If the status is `Failed`, the third column shows the failure reason. When the inference component is `InService`, the model runs on its own partition.

Partitioning doesn't affect invocation. Invoke the model as you would any inference component, by calling InvokeEndpoint with the inference component name. For more information, see Invoke models for real-time inference.

Manage GPU partitioned endpoints

After you deploy models to a partitioned endpoint, you can scale them, move them to a different partition type, or delete the endpoint. The examples in this topic use the resources from Create an endpoint with GPU partitions and Deploy models to GPU partitions with inference components.

Update partitioned resources

To serve more requests with a model, increase `CopyCount` on its inference component. SageMaker AI places each copy on a free partition of the same type. The following `update-inference-component` command scales `demo-ic-4g` to 2 copies:

```
aws sagemaker update-inference-component \
  --region us-west-2 \
  --inference-component-name demo-ic-4g \
  --runtime-config '{"CopyCount": 2}'
```

An endpoint has as many partitions of a type as the layout declares, multiplied by the number of accelerators and instances. To adjust the number of copies automatically, see Automatic scaling of Amazon SageMaker AI models.

Note

You can't change the partition type of an existing inference component. `UpdateInferenceComponent` rejects a change to `AcceleratorPartitionType`. To run a model on a different partition type, create a new inference component with the new type, wait until it's `InService`, move your clients to the new name, and then delete the old inference component. The new type must be one that the endpoint layout declares.

Note

You can't change the partition layout of a running endpoint. An `UpdateEndpoint` request to an endpoint configuration with a different layout, including the same types in a different order, returns a 400 error. To use a different layout, create a new endpoint configuration and endpoint with the new layout, create the inference components on it, move your traffic, and then delete the old endpoint.

Delete a partitioned endpoint

A partitioned endpoint incurs charges for its instances until you delete it. Delete the inference components first, and then the endpoint and the endpoint configuration. You can't delete an endpoint while its status is `Creating`. Wait until the status changes, and then delete it.

To delete a partitioned endpoint (Amazon CLI)

1. Delete the inference components. The following `delete-inference-component` command deletes `demo-ic-4g`. Repeat it for each inference component on the endpoint.

```
aws sagemaker delete-inference-component --region us-west-2 --inference-component-
name demo-ic-4g
```

2. Delete the endpoint, and wait until it's deleted. The following commands delete the endpoint `partition-demo` and wait for the deletion:

```
aws sagemaker delete-endpoint --region us-west-2 --endpoint-name partition-demo
aws sagemaker wait endpoint-deleted --region us-west-2 --endpoint-name partition-
demo
```

3. Delete the endpoint configuration. The following `delete-endpoint-config` command deletes `partition-demo-config`:

```
aws sagemaker delete-endpoint-config --region us-west-2 --endpoint-config-name
 partition-demo-config
```

After you delete a partitioned endpoint, its accelerators can take several minutes to become available again.

Troubleshooting

Use the following information to resolve common problems with partitioned endpoints.

`DescribeEndpointConfig` returns `null` for the layout

The `AcceleratorPartitionLayouts` field didn't reach the service, and an endpoint from this configuration won't be partitioned. Confirm that you call a supported Amazon Web Services Region and that your Amazon CLI or SDK version includes `AcceleratorPartitionLayouts`.

The endpoint configuration is rejected because the layout doesn't fit

The partition types in the layout need more compute slices or memory slices than one accelerator provides. The error states what the accelerator provides and what you requested. Remove a partition or choose smaller types. For the types that each instance family provides, see GPU partition types. For more information about the partitions that each GPU supports, see Supported MIG Profiles in the NVIDIA Multi-Instance GPU User Guide on the NVIDIA website.

A request is rejected with a 400 error that lists valid partition types

The partition type isn't valid for the instance's GPU. Partition types don't carry from one instance family to another. Use one of the types that the error lists.

The endpoint configuration is rejected because of the number of layouts

`AcceleratorPartitionLayouts` must contain exactly 1 entry. GPU partitioning also can't be combined with `ServerlessConfig` or instance pools on the same production variant.

The endpoint fails to partition the accelerators, and no error names a partition type

Some partition types require a newer NVIDIA driver than the default image provides. On P4d instances, `mig-1g.10gb` requires a newer driver. Set `InferenceAmiVersion` to `al2023-`

`ami-sagemaker-inference-gpu-4-1` on the production variant. For the driver version that each AMI version provides, see Current versions and supported instance families.

An inference component is rejected with a 400 error that names the declared partition types

The partition type that you requested isn't in the endpoint layout. There is no fallback to a whole accelerator. Request one of the declared types, or create a new endpoint with a layout that includes the type that you need.

An inference component is rejected because of `AcceleratorPartitionType` or `NumberOfAcceleratorDevicesRequired`

On an endpoint with a partition layout, every new inference component must set `AcceleratorPartitionType`, and `NumberOfAcceleratorDevicesRequired` must be 1. For the full list, see Inference component rules.

An inference component stays in `Failed` status

Check the `FailureReason` field from `DescribeInferenceComponent`. A common cause is a model that needs more GPU memory than the partition type provides. Choose a larger partition type, which requires a new inference component and, if the type isn't in the layout, a new endpoint.

Deploy models with Amazon SageMaker Serverless Inference

Amazon SageMaker Serverless Inference is a purpose-built inference option that enables you to deploy and scale ML models without configuring or managing any of the underlying infrastructure. On-demand Serverless Inference is ideal for workloads which have idle periods between traffic spurts and can tolerate cold starts. Serverless endpoints automatically launch compute resources and scale them in and out depending on traffic, eliminating the need to choose instance types or manage scaling policies. This takes away the undifferentiated heavy lifting of selecting and managing servers. Serverless Inference integrates with Amazon Lambda to offer you high availability, built-in fault tolerance and automatic scaling. With a pay-per-use model, Serverless Inference is a cost-effective option if you have an infrequent or unpredictable traffic pattern. During times when there are no requests, Serverless Inference scales your endpoint down to 0, helping you to minimize your costs. For more information about pricing for on-demand Serverless Inference, see Amazon SageMaker Pricing.

Optionally, you can also use Provisioned Concurrency with Serverless Inference. Serverless Inference with provisioned concurrency is a cost-effective option when you have predictable bursts

in your traffic. Provisioned Concurrency allows you to deploy models on serverless endpoints with predictable performance, and high scalability by keeping your endpoints warm. SageMaker AI ensures that for the number of Provisioned Concurrency that you allocate, the compute resources are initialized and ready to respond within milliseconds. For Serverless Inference with Provisioned Concurrency, you pay for the compute capacity used to process inference requests, billed by the millisecond, and the amount of data processed. You also pay for Provisioned Concurrency usage, based on the memory configured, duration provisioned, and the amount of concurrency enabled. For more information about pricing for Serverless Inference with Provisioned Concurrency, see Amazon SageMaker Pricing.

You can integrate Serverless Inference with your MLOps Pipelines to streamline your ML workflow, and you can use a serverless endpoint to host a model registered with Model Registry.

Serverless Inference is generally available in 21 Amazon Regions: US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon), Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Mumbai), Asia Pacific (Tokyo), Asia Pacific (Seoul), Asia Pacific (Osaka), Asia Pacific (Singapore), Asia Pacific (Sydney), Canada (Central), Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris), Europe (Stockholm), Europe (Milan), Middle East (Bahrain), South America (São Paulo). For more information about Amazon SageMaker AI regional availability, see the Amazon Regional Services List.

How it works

The following diagram shows the workflow of on-demand Serverless Inference and the benefits of using a serverless endpoint.

When you create an on-demand serverless endpoint, SageMaker AI provisions and manages the compute resources for you. Then, you can make inference requests to the endpoint and receive

model predictions in response. SageMaker AI scales the compute resources up and down as needed to handle your request traffic, and you only pay for what you use.

For Provisioned Concurrency, Serverless Inference also integrates with Application Auto Scaling, so that you can manage Provisioned Concurrency based on a target metric or on a schedule. For more information, see Automatically scale Provisioned Concurrency for a serverless endpoint.

The following sections provide additional details about Serverless Inference and how it works.

Topics

- Container support
- Memory size
- Concurrent invocations
- Minimizing cold starts
- Feature exclusions

Container support

For your endpoint container, you can choose either a SageMaker AI-provided container or bring your own. SageMaker AI provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a list of available SageMaker images, see Available Deep Learning Containers Images. If you are bringing your own container, you must modify it to work with SageMaker AI. For more information about bringing your own container, see Adapt your own inference container for Amazon SageMaker AI.

The maximum size of the container image you can use is 10 GB. For serverless endpoints, we recommend creating only one worker in the container and only loading one copy of the model. Note that this is unlike real-time endpoints, where some SageMaker AI containers may create a worker for each vCPU to process inference requests and load the model in each worker.

If you already have a container for a real-time endpoint, you can use the same container for your serverless endpoint, though some capabilities are excluded. To learn more about the container capabilities that are not supported in Serverless Inference, see Feature exclusions. If you choose to use the same container, SageMaker AI escrows (retains) a copy of your container image until you delete all endpoints that use the image. SageMaker AI encrypts the copied image at rest with a SageMaker AI-owned Amazon KMS key.

Memory size

Your serverless endpoint has a minimum RAM size of 1024 MB (1 GB), and the maximum RAM size you can choose is 6144 MB (6 GB). The memory sizes you can choose are 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB. Serverless Inference auto-assigns compute resources proportional to the memory you select. If you choose a larger memory size, your container has access to more vCPUs. Choose your endpoint's memory size according to your model size. Generally, the memory size should be at least as large as your model size. You may need to benchmark in order to choose the right memory selection for your model based on your latency SLAs. For a step by step guide to benchmark, see Introducing the Amazon SageMaker Serverless Inference Benchmarking Toolkit. The memory size increments have different pricing; see the Amazon SageMaker AI pricing page for more information.

Regardless of the memory size you choose, your serverless endpoint has 5 GB of ephemeral disk storage available. For help with container permissions issues when working with storage, see Troubleshooting.

Concurrent invocations

On-demand Serverless Inference manages predefined scaling policies and quotas for the capacity of your endpoint. Serverless endpoints have a quota for how many concurrent invocations can be processed at the same time. If the endpoint is invoked before it finishes processing the first request, then it handles the second request concurrently.

The total concurrency that you can share between all serverless endpoints in your account depends on your region:

- For the US East (Ohio), US East (N. Virginia), US West (Oregon), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo), Europe (Frankfurt), and Europe (Ireland) Regions, the total concurrency you can share between all serverless endpoints per Region in your account is 1000.
- For the US West (N. California), Africa (Cape Town), Asia Pacific (Hong Kong), Asia Pacific (Mumbai), Asia Pacific (Osaka), Asia Pacific (Seoul), Canada (Central), Europe (London), Europe (Milan), Europe (Paris), Europe (Stockholm), Middle East (Bahrain), and South America (São Paulo) Regions, the total concurrency per Region in your account is 500.

You can set the maximum concurrency for a single endpoint up to 200, and the total number of serverless endpoints you can host in a Region is 50. The maximum concurrency for an individual

endpoint prevents that endpoint from taking up all of the invocations allowed for your account, and any endpoint invocations beyond the maximum are throttled.

> **Note**
>
> Provisioned Concurrency that you assign to a serverless endpoint should always be less than or equal to the maximum concurrency that you assigned to that endpoint.

To learn how to set the maximum concurrency for your endpoint, see Create an endpoint configuration. For more information about quotas and limits, see Amazon SageMaker AI endpoints and quotas in the *Amazon Web Services General Reference*. To request a service limit increase, contact Amazon Support. For instructions on how to request a service limit increase, see Supported Regions and Quotas.

Minimizing cold starts

If your on-demand Serverless Inference endpoint does not receive traffic for a while and then your endpoint suddenly receives new requests, it can take some time for your endpoint to spin up the compute resources to process the requests. This is called a *cold start*. Since serverless endpoints provision compute resources on demand, your endpoint may experience cold starts. A cold start can also occur if your concurrent requests exceed the current concurrent request usage. The cold start time depends on your model size, how long it takes to download your model, and the start-up time of your container.

To monitor how long your cold start time is, you can use the Amazon CloudWatch metric `OverheadLatency` to monitor your serverless endpoint. This metric tracks the time it takes to launch new compute resources for your endpoint. To learn more about using CloudWatch metrics with serverless endpoints, see Alarms and logs for tracking metrics from serverless endpoints.

You can minimize cold starts by using Provisioned Concurrency. SageMaker AI keeps the endpoint warm and ready to respond in milliseconds, for the number of Provisioned Concurrency that you allocated.

Feature exclusions

Some of the features currently available for SageMaker AI Real-time Inference are not supported for Serverless Inference, including GPUs, Amazon marketplace model packages, private Docker registries, Multi-Model Endpoints, VPC configuration, network isolation, data capture, multiple production variants, Model Monitor, and inference pipelines.

You cannot convert your instance-based, real-time endpoint to a serverless endpoint. If you try to update your real-time endpoint to serverless, you receive a `ValidationError` message. You can convert a serverless endpoint to real-time, but once you make the update, you cannot roll it back to serverless.

Getting started

You can create, update, describe, and delete a serverless endpoint using the SageMaker AI console, the Amazon SDKs, the Amazon SageMaker Python SDK, and the Amazon CLI. You can invoke your endpoint using the Amazon SDKs, the Amazon SageMaker Python SDK, and the Amazon CLI.
For serverless endpoints with Provisioned Concurrency, you can use Application Auto Scaling to auto scale Provisioned Concurrency based on a target metric or a schedule. For more information about how to set up and use a serverless endpoint, read the guide Serverless endpoint operations.
For more information on auto scaling serverless endpoints with Provisioned Concurrency, see Automatically scale Provisioned Concurrency for a serverless endpoint.

> **Note**
>
> Application Auto Scaling for Serverless Inference with Provisioned Concurrency is currently not supported on Amazon CloudFormation.

Example notebooks and blogs

For Jupyter notebook examples that show end-to-end serverless endpoint workflows, see the Serverless Inference example notebooks.

Serverless endpoint operations

Unlike other SageMaker AI real-time endpoints, Serverless Inference manages compute resources for you, reducing complexity so you can focus on your ML model instead of on managing infrastructure. The following guide highlights the key capabilities of serverless endpoints: how to create, invoke, update, describe, or delete an endpoint. You can use the SageMaker AI console, the Amazon SDKs, the Amazon SageMaker Python SDK, or the Amazon CLI to manage your serverless endpoints.

Topics

- Complete the prerequisites

- Serverless endpoint creation
- Invoke a serverless endpoint
- Update a serverless endpoint
- Describe a serverless endpoint
- Delete a serverless endpoint

Complete the prerequisites

The following topic describes the prerequisites that you must complete before creating a serverless endpoint. These prerequisites include properly storing your model artifacts, configuring an Amazon IAM with the correct permissions, and selecting a container image.

To complete the prerequisites

1. **Set up an Amazon account.** You first need an Amazon account and an Amazon Identity and Access Management administrator user. For instructions on how to set up an Amazon account, see How do I create and activate a new Amazon account?. For instructions on how to secure your account with an IAM administrator user, see Creating your first IAM admin user and user group in the *IAM User Guide*.
2. **Create an Amazon S3 bucket.** You use an Amazon S3 bucket to store your model artifacts. To learn how to create a bucket, see Create your first S3 bucket in the *Amazon S3 User Guide*.
3. **Upload your model artifacts to your S3 bucket.** For instructions on how to upload your model to your bucket, see Upload an object to your bucket in the *Amazon S3 User Guide*.
4. **Create an IAM role for Amazon SageMaker AI.** Amazon SageMaker AI needs access to the S3 bucket that stores your model. Create an IAM role with a policy that gives SageMaker AI read access to your bucket. The following procedure shows how to create a role in the console, but you can also use the CreateRole API from the *IAM User Guide*. For information on giving your role more granular permissions based on your use case, see How to use SageMaker AI execution roles.

    a. Sign in to the IAM console.

    b. In the navigation tab, choose **Roles**.

    c. Choose **Create Role**.

    d. For **Select type of trusted entity**, choose **Amazon service** and then choose **SageMaker AI**.

    e. Choose **Next: Permissions** and then choose **Next: Tags**.

f. (Optional) Add tags as key-value pairs if you want to have metadata for the role.

g. Choose **Next: Review**.

h. For **Role name**, enter a name for the new role that is unique within your Amazon account. You cannot edit the role name after creating the role.

i. (Optional) For **Role description**, enter a description for the new role.

j. Choose **Create role**.

5. **Attach S3 bucket permissions to your SageMaker AI role.** After creating an IAM role, attach a policy that gives SageMaker AI permission to access the S3 bucket containing your model artifacts.

a. In the IAM console navigation tab, choose **Roles**.

b. From the list of roles, search for the role you created in the previous step by name.

c. Choose your role, and then choose **Attach policies**.

d. For **Attach permissions**, choose **Create policy**.

e. In the **Create policy** view, select the **JSON** tab.

f. Add the following policy statement into the JSON editor. Make sure to replace *<your-bucket-name>* with the name of the S3 bucket that stores your model artifacts. If you want to restrict the access to a specific folder or file in your bucket, you can also specify the Amazon S3 folder path, for example, *<your-bucket-name>*/*<model-folder>*.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "s3:GetObject",
            "Resource": "arn:aws-cn:s3:::<your-bucket-name>/*"
        }
    ]
}
```

g. Choose **Next: Tags**.

h. (Optional) Add tags in key-value pairs to the policy.

i. Choose **Next: Review**.

j. For **Name**, enter a name for the new policy.

k. (Optional) Add a **Description** for the policy.

l. Choose **Create policy**.

m. After creating the policy, return to **Roles** in the IAM console and select your SageMaker AI role.

n. Choose **Attach policies**.

o. For **Attach permissions**, search for the policy you created by name. Select it and choose **Attach policy**.

6. **Select a prebuilt Docker container image or bring your own.** The container you choose serves inference on your endpoint. SageMaker AI provides containers for built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker images, see Available Deep Learning Containers Images.

   If none of the existing SageMaker AI containers meet your needs, you may need to create your own Docker container. For information about how to create your Docker image and make it compatible with SageMaker AI, see Containers with custom inference code. To use your container with a serverless endpoint, the container image must reside in an Amazon ECR repository within the same Amazon account that creates the endpoint.

7. **(Optional) Register your model with Model Registry.** SageMaker Model Registry helps you catalog and manage versions of your models for use in ML pipelines. For more information about registering a version of your model, see Create a Model Group and Register a Model Version. For an example of a Model Registry and Serverless Inference workflow, see the following example notebook.

8. **(Optional) Bring an Amazon KMS key.** When setting up a serverless endpoint, you have the option to specify a KMS key that SageMaker AI uses to encrypt your Amazon ECR image. Note that the key policy for the KMS key must grant access to the IAM role you specify when setting up your endpoint. To learn more about KMS keys, see the Amazon Key Management Service Developer Guide.

Serverless endpoint creation

> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.
> Amazon managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

To create a serverless endpoint, you can use the Amazon SageMaker AI console, the APIs, or the Amazon CLI. You can create a serverless endpoint using a similar process as a real-time endpoint.

Topics

- Create a model
- Create an endpoint configuration
- Create an endpoint

Create a model

To create your model, you must provide the location of your model artifacts and container image. You can also use a model version from SageMaker Model Registry. The examples in the following sections show you how to create a model using the CreateModel API, Model Registry, and the Amazon SageMaker AI console.

To create a model (using Model Registry)

Model Registry is a feature of SageMaker AI that helps you catalog and manage versions of your model for use in ML pipelines. To use Model Registry with Serverless Inference, you must first register a model version in a Model Registry model group. To learn how to register a model in Model Registry, follow the procedures in Create a Model Group and Register a Model Version.

The following example requires you to have the ARN of a registered model version and uses the Amazon SDK for Python (Boto3) to call the CreateModel API. For Serverless Inference, Model Registry is currently only supported by the Amazon SDK for Python (Boto3). For the example, specify the following values:

- For `model_name`, enter a name for the model.
- For `sagemaker_role`, you can use the default SageMaker AI-created role or a customized SageMaker AI IAM role from Step 4 of the Complete the prerequisites section.
- For `ModelPackageName`, specify the ARN for your model version, which must be registered to a model group in Model Registry.

```
#Setup
import boto3
import sagemaker
from sagemaker.core.helper.session_helper import get_execution_role
region = boto3.Session().region_name
client = boto3.client("sagemaker", region_name=region)

#Role to give SageMaker AI permission to access Amazon services.
sagemaker_role = get_execution_role()

#Specify a name for the model
model_name = "<name-for-model>"

#Specify a Model Registry model version
container_list = [
    {
        "ModelPackageName": <model-version-arn>
     }
 ]

#Create the model
response = client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    container_list
)
```

To create a model (using API)

The following example uses the Amazon SDK for Python (Boto3) to call the CreateModel API. Specify the following values:

- For `sagemaker_role`, you can use the default SageMaker AI-created role or a customized SageMaker AI IAM role from Step 4 of the Complete the prerequisites section.
- For `model_url`, specify the Amazon S3 URI to your model.
- For `container`, retrieve the container you want to use by its Amazon ECR path. This example uses a SageMaker AI-provided XGBoost container. If you have not selected a SageMaker AI container or brought your own, see Step 6 of the Complete the prerequisites section for more information.
- For `model_name`, enter a name for the model.

```
#Setup
import boto3
import sagemaker
from sagemaker.core.helper.session_helper import get_execution_role
region = boto3.Session().region_name
client = boto3.client("sagemaker", region_name=region)

#Role to give SageMaker AI permission to access Amazon services.
sagemaker_role = get_execution_role()

#Get model from S3
model_url = "s3://amzn-s3-demo-bucket/models/model.tar.gz"

#Get container image (prebuilt example)
from sagemaker.core import image_uris
container = image_uris.retrieve("xgboost", region, "0.90-1")

#Create model
model_name = "<name-for-model>"

response = client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    Containers = [{
        "Image": container,
        "Mode": "SingleModel",
```

```
        "ModelDataUrl": model_url,
    }]
)
```

To create a model (using the console)

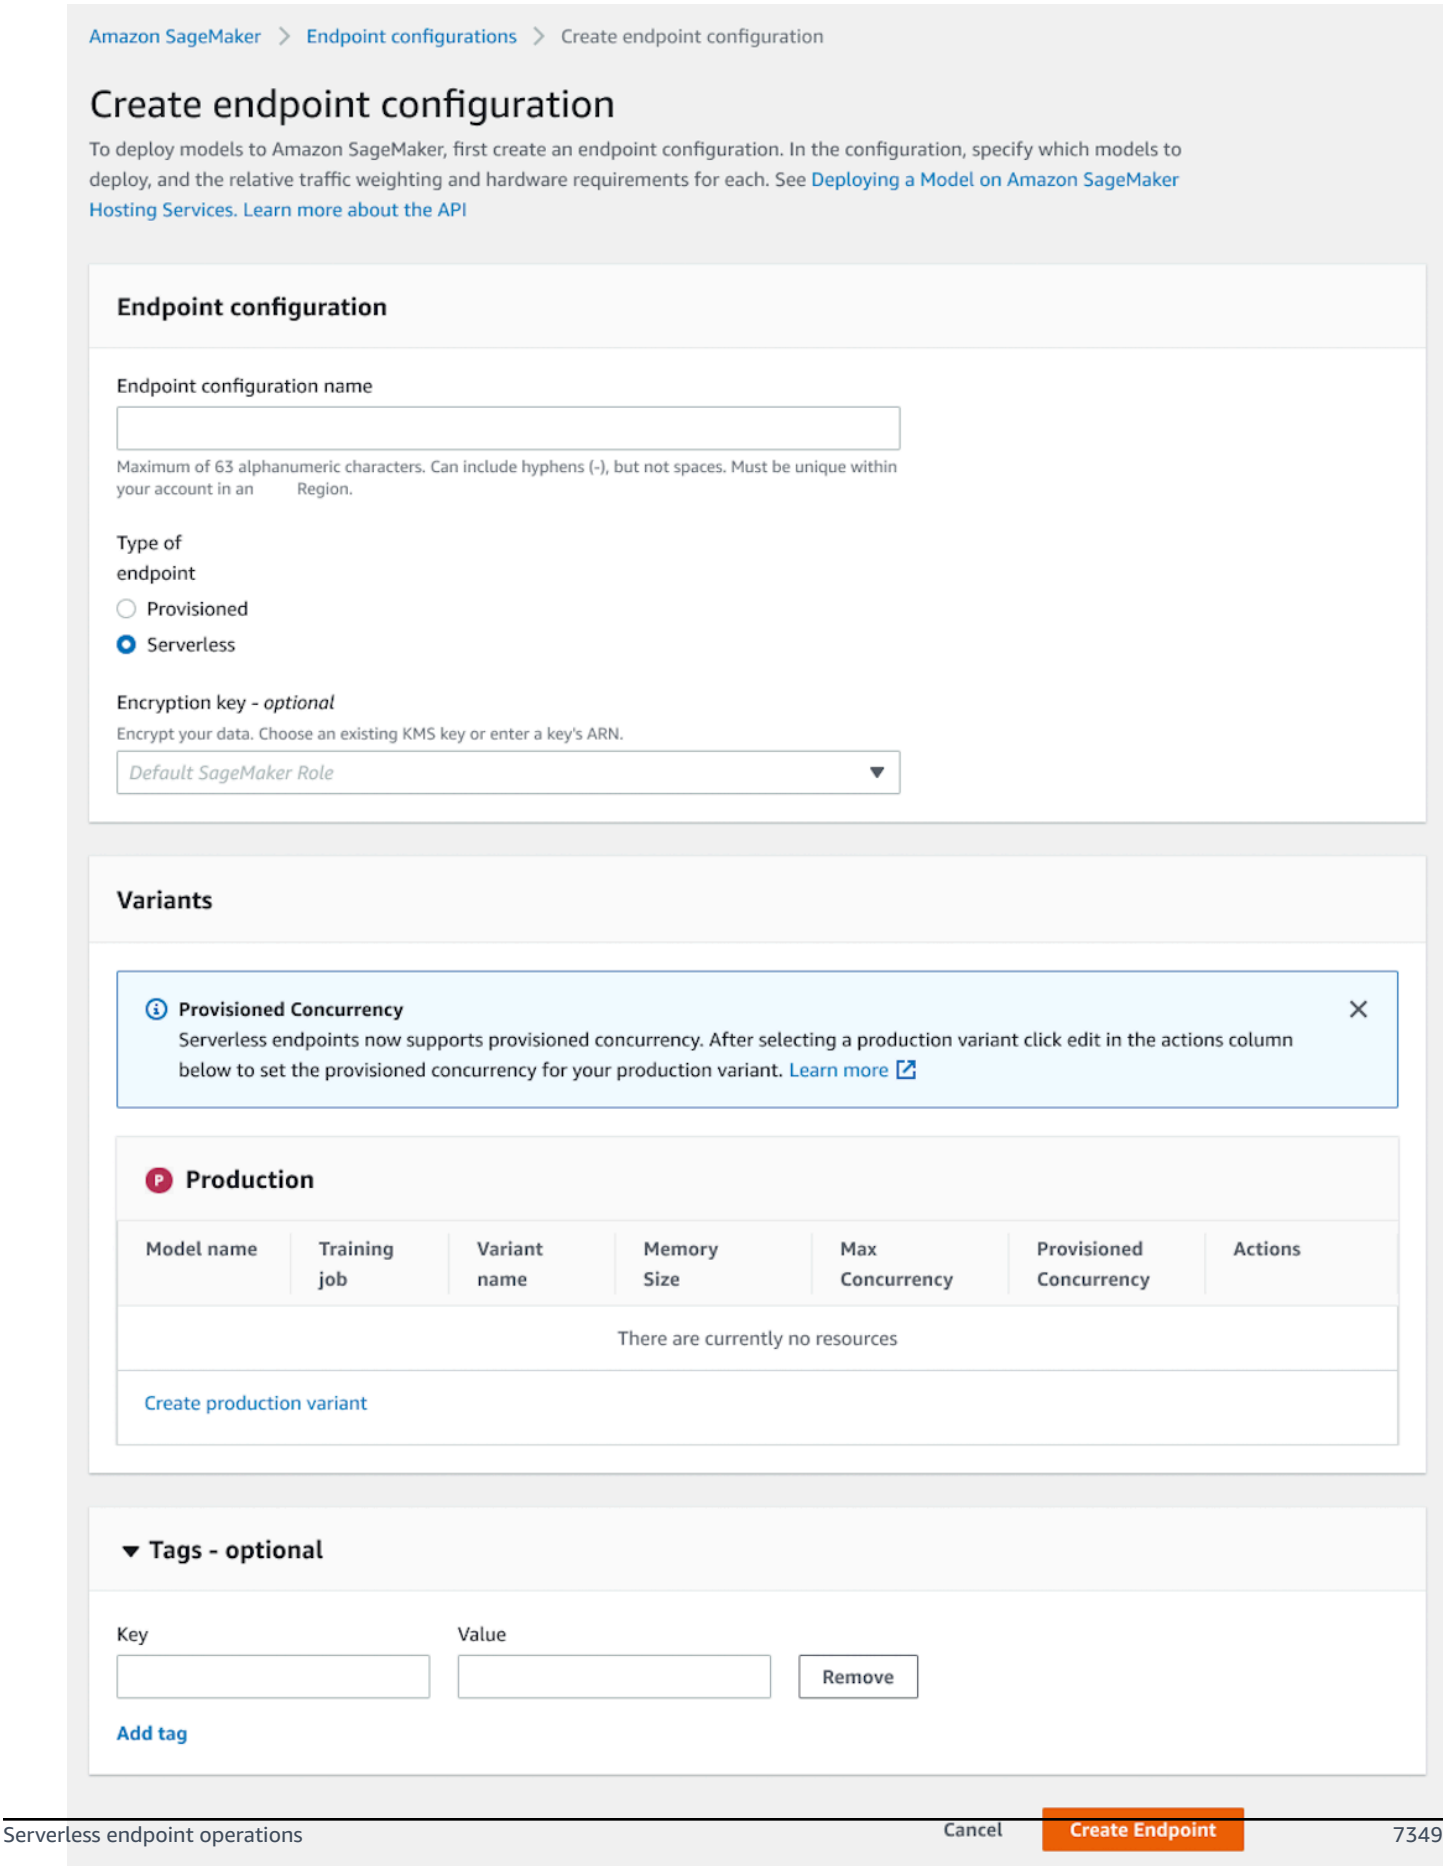
1. Sign in to the Amazon SageMaker AI console.
2. In the navigation tab, choose **Inference**.
3. Next, choose **Models**.
4. Choose **Create model**.
5. For **Model name**, enter a name for the model that is unique to your account and Amazon Web Services Region.
6. For **IAM role**, either select an IAM role you have already created (see Complete the prerequisites) or allow SageMaker AI to create one for you.
7. In **Container definition 1**, for **Container input options**, select **Provide model artifacts and input location**.
8. For **Provide model artifacts and inference image options**, select **Use a single model**.
9. For **Location of inference code image**, enter an Amazon ECR path to a container. The image must either be a SageMaker AI-provided first party image (e.g. TensorFlow, XGBoost) or an image that resides in an Amazon ECR repository within the same account in which you are creating the endpoint. If you do not have a container, go back to Step 6 of the Complete the prerequisites section for more information.
10. For **Location of model artifacts**, enter the Amazon S3 URI to your ML model. For example, *s3://amzn-s3-demo-bucket/models/model.tar.gz*.
11. (Optional) For **Tags**, add key-value pairs to create metadata for your model.
12. Choose **Create model**.

Create an endpoint configuration

After you create a model, create an endpoint configuration. You can then deploy your model using the specifications in your endpoint configuration. In the configuration, you specify whether you want a real-time or serverless endpoint. To create a serverless endpoint configuration, you can use the Amazon SageMaker AI console, the CreateEndpointConfig API, or the Amazon CLI. The API and console approaches are outlined in the following sections.

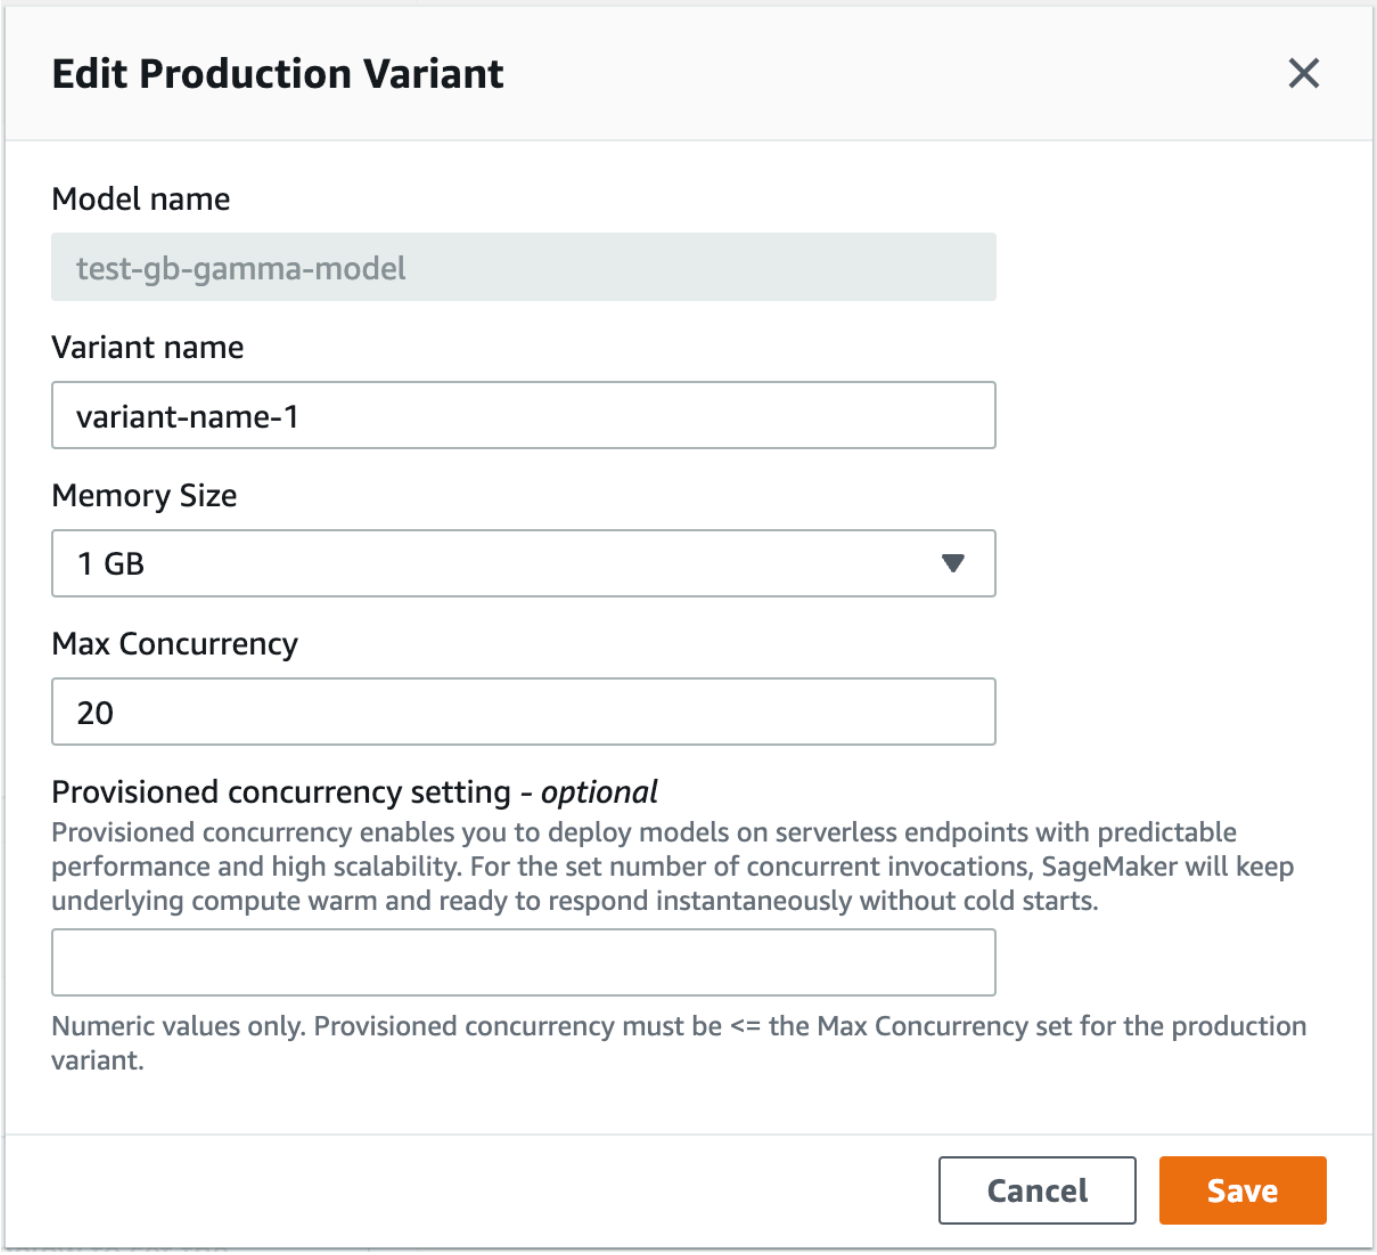
To create an endpoint configuration (using API)

The following example uses the Amazon SDK for Python (Boto3) to call the CreateEndpointConfig API. Specify the following values:



- For `EndpointConfigName`, choose a name for the endpoint configuration. The name should be unique within your account in a Region.
- (Optional) For `KmsKeyId`, use the key ID, key ARN, alias name, or alias ARN for an Amazon KMS key that you want to use. SageMaker AI uses this key to encrypt your Amazon ECR image.
- For `ModelName`, use the name of the model you want to deploy. It should be the same model that you used in the Create a model step.
- For `ServerlessConfig`:
  - Set `MemorySizeInMB` to `2048`. For this example, we set the memory size to 2048 MB, but you can choose any of the following values for your memory size: 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB.
  - Set `MaxConcurrency` to `20`. For this example, we set the maximum concurrency to 20. The maximum number of concurrent invocations you can set for a serverless endpoint is 200, and the minimum value you can choose is 1.
  - (Optional) To use Provisioned Concurrency, set `ProvisionedConcurrency` to 10. For this example, we set the Provisioned Concurrency to 10. The `ProvisionedConcurrency` number for a serverless endpoint must be lower than or equal to the `MaxConcurrency` number. You can leave it empty if you want to use on-demand Serverless Inference endpoint. You can dynamically scale Provision Concurrency. For more information, see Automatically scale Provisioned Concurrency for a serverless endpoint.

```
response = client.create_endpoint_config(
   EndpointConfigName="<your-endpoint-configuration>",
   KmsKeyId="arn:aws:kms:us-east-1:123456789012:key/143ef68f-76fd-45e3-abba-
ed28fc8d3d5e",
   ProductionVariants=[
        {
            "ModelName": "<your-model-name>",
            "VariantName": "AllTraffic",
            "ServerlessConfig": {
                "MemorySizeInMB": 2048,
                "MaxConcurrency": 20,
                "ProvisionedConcurrency": 10,
```



```
            }
        }
    ]
)
```

To create an endpoint configuration (using the console)

1. Sign in to the Amazon SageMaker AI console.
2. In the navigation tab, choose **Inference**.
3. Next, choose **Endpoint configurations**.
4. Choose **Create endpoint configuration**.
5. For **Endpoint configuration name**, enter a name that is unique within your account in a Region.
6. For **Type of endpoint**, select **Serverless**.

Amazon SageMaker > Endpoint configurations > Create endpoint configuration
Create endpoint configuration
To deploy models to Amazon SageMaker, first create an endpoint configuration. In the configuration, specify which models to deploy, and the relative traffic weighting and hardware requirements for each. See Deploying a Model on Amazon SageMaker Hosting Services. Learn more about the API
Endpoint configuration
Endpoint configuration name
Maximum of 63 alphanumeric characters. Can include hyphens (-), but not spaces. Must be unique within your account in an Region.
Type of endpoint
Provisioned
Serverless
Encryption key - optional
Encrypt your data. Choose an existing KMS key or enter a key's ARN.

Create Endpoint

7. For **Production variants**, choose **Add model**.
8. Under **Add model**, select the model you want to use from the list of models and then choose **Save**.
9. After adding your model, under **Actions**, choose **Edit**.
10. For **Memory size**, choose the memory size you want in GB.

11. For **Max Concurrency**, enter your desired maximum concurrent invocations for the endpoint. The maximum value you can enter is 200 and the minimum is 1.

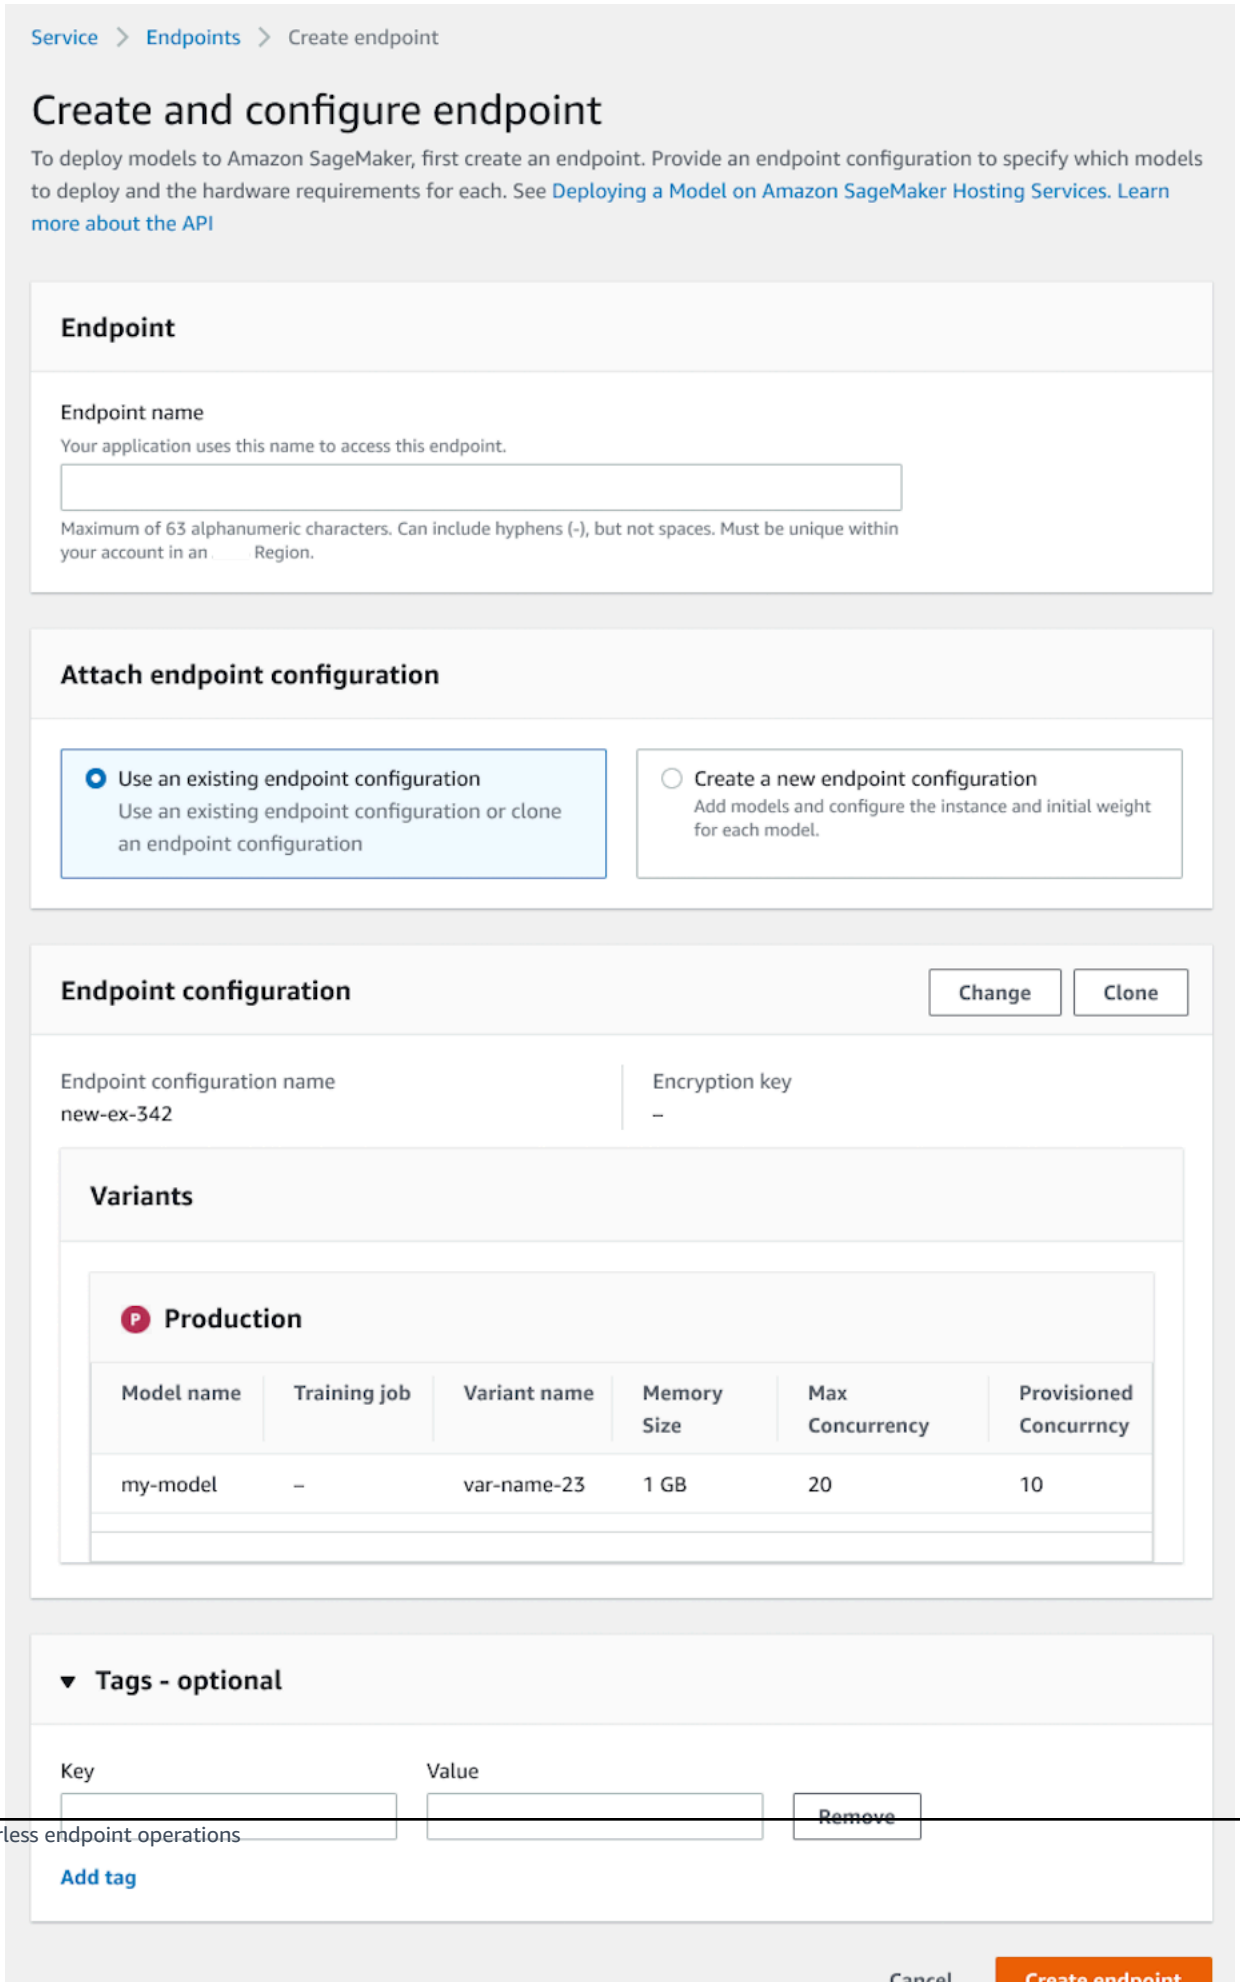
12. (Optional) To use Provisioned Concurrency, enter the desired number of concurrent invocations in the **Provisioned Concurrency setting** field. The number of provisioned concurrent invocations must be less than or equal to the number of maximum concurrent invocations.
13. Choose **Save**.
14. (Optional) For **Tags**, enter key-value pairs if you want to create metadata for your endpoint configuration.
15. Choose **Create endpoint configuration**.

Create an endpoint

To create a serverless endpoint, you can use the Amazon SageMaker AI console, the CreateEndpoint API, or the Amazon CLI. The API and console approaches are outlined in the following sections. Once you create your endpoint, it can take a few minutes for the endpoint to become available.

To create an endpoint (using API)

The following example uses the Amazon SDK for Python (Boto3) to call the CreateEndpoint API. Specify the following values:



- For `EndpointName`, enter a name for the endpoint that is unique within a Region in your account.
- For `EndpointConfigName`, use the name of the endpoint configuration that you created in the previous section.

```
response = client.create_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-endpoint-config>"
)
```

To create an endpoint (using the console)

1. Sign in to the Amazon SageMaker AI console.
2. In the navigation tab, choose **Inference**.
3. Next, choose **Endpoints**.
4. Choose **Create endpoint**.

5. For **Endpoint name**, enter a name than is unique within a Region in your account.
6. For **Attach endpoint configuration**, select **Use an existing endpoint configuration**.
7. For **Endpoint configuration**, select the name of the endpoint configuration you created in the previous section and then choose **Select endpoint configuration**.
8. (Optional) For **Tags**, enter key-value pairs if you want to create metadata for your endpoint.
9. Choose **Create endpoint**.

Create endpoint

Invoke a serverless endpoint

In order to perform inference using a serverless endpoint, you must send an HTTP request to the endpoint. You can use the InvokeEndpoint API or the Amazon CLI, which make a POST request to invoke your endpoint. The maximum request and response payload size for serverless invocations is 4 MB. For serverless endpoints:

- The model must download and the server must respond successfully to `/ping` within 3 minutes.
- The timeout for the container to respond to inference requests to `/invocations` is 1 minute.

To invoke an endpoint

The following example uses the Amazon SDK for Python (Boto3) to call the InvokeEndpoint API. Note that unlike the other API calls in this guide, for `InvokeEndpoint`, you must use SageMaker Runtime Runtime as the client. Specify the following values:

- For `endpoint_name`, use the name of the in-service serverless endpoint you want to invoke.
- For `content_type`, specify the MIME type of your input data in the request body (for example, `application/json`).
- For `payload`, use your request payload for inference. Your payload should be in bytes or a file-like object.

```
runtime = boto3.client("sagemaker-runtime")

endpoint_name = "<your-endpoint-name>"
content_type = "<request-mime-type>"
payload = <your-request-body>

response = runtime.invoke_endpoint(
    EndpointName=endpoint_name,
    ContentType=content_type,
    Body=payload
)
```

Update a serverless endpoint

Before updating your endpoint, create a new endpoint configuration or use an existing endpoint configuration. The endpoint configuration is where you specify the changes for your update. Then,

you can update your endpoint with the SageMaker AI console, the UpdateEndpoint API, or the Amazon CLI. The process for updating a serverless endpoint is the same as the process for updating a real-time endpoint. Note that when updating your endpoint, you can experience cold starts when making requests to the endpoint because SageMaker AI must re-initialize your container and model.

You may want to update an on-demand serverless endpoint to a serverless endpoint with provisioned concurrency or adjust the Provisioned Concurrency value for an existing serverless endpoint with provisioned concurrency. For both cases, you will have to create a new serverless endpoint configuration with the desired value for Provisioned Concurrency, and apply `UpdateEndpoint` to the existing serverless endpoint. For more information on creating a new serverless endpoint configuration with Provisioned Concurrency, see Create an endpoint configuration.

If you want to remove Provisioned Concurrency from a serverless endpoint, you will have to create a new endpoint configuration without specifying any value for Provisioned Concurrency, and then apply `UpdateEndpoint` to the endpoint.

> **Note**
>
> Updating a real-time inference endpoint to either an on-demand serverless endpoint or a serverless endpoint with Provisioned Concurrency is currently not supported.

Update the endpoint

After creating a new serverless endpoint configuration you can use the Amazon SDK for Python (Boto3) or the SageMaker AI console to update an existing serverless endpoint. Examples of how to update your endpoint using the Amazon SDK for Python (Boto3) and the SageMaker AI console are outlined in the following sections.

To update the endpoint (using Boto3)

The following example uses the Amazon SDK for Python (Boto3) to call the update_endpoint method. Specify at least the following parameters when calling the method:

- For `EndpointName`, use the name of the endpoint you're updating.
- For `EndpointConfigName`, use the name of the endpoint configuration that you want to use for the update.

```
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<new-endpoint-config>",
)
```

To update the endpoint (using the console)

1. Sign in to the Amazon SageMaker AI console.
2. In the navigation tab, choose **Inference**.
3. Next, choose **Endpoints**.
4. From the list of endpoints, select the endpoint you want to update.
5. Choose **Change** in **Endpoint configuration settings** section.
6. For **Change the Endpoint configuration**, choose **Use an existing endpoint configuration**.
7. From the list of endpoint configurations, select the one you want to use for your update.
8. Choose **Select endpoint configuration**.
9. Choose **Update endpoint**.

Describe a serverless endpoint

You might want to retrieve information about your endpoint, including details such as the endpoint's ARN, current status, deployment configuration, and failure reasons. You can find information about your endpoint using the SageMaker AI console, the DescribeEndpoint API, or the Amazon CLI.

To describe an endpoint (using API)

The following example uses the Amazon SDK for Python (Boto3) to call the DescribeEndpoint API. For `EndpointName`, use the name of the endpoint you want to check.

```
response = client.describe_endpoint(
    EndpointName="<your-endpoint-name>",
)
```

To describe an endpoint (using the console)

1. Sign in to the Amazon SageMaker AI console.

2. In the navigation tab, choose **Inference**.
3. Next, choose **Endpoints**.
4. From the list of endpoints, choose the endpoint you want to check.

The endpoint page contains the information about your endpoint.

Delete a serverless endpoint

You can delete your serverless endpoint using the SageMaker AI console, the DeleteEndpoint API, or the Amazon CLI. The following examples show you how to delete your endpoint through the API and the SageMaker AI console.

To delete an endpoint (using API)

The following example uses the Amazon SDK for Python (Boto3) to call the DeleteEndpoint API. For `EndpointName`, use the name of the serverless endpoint you want to delete.

```
response = client.delete_endpoint(
    EndpointName="<your-endpoint-name>",
)
```

To delete an endpoint (using the console)

1. Sign in to the Amazon SageMaker AI console.
2. In the navigation tab, choose **Inference**.
3. Next, choose **Endpoints**.
4. From the list of endpoints, select the endpoint you want to delete.
5. Choose the **Actions** drop-down list, and then choose **Delete**.
6. When prompted again, choose **Delete**.

Your endpoint should now begin the deletion process.

Alarms and logs for tracking metrics from serverless endpoints

To monitor your serverless endpoint, you can use Amazon CloudWatch alarms. CloudWatch is a service that collects metrics in real time from your Amazon applications and resources. An alarm watches metrics as they are collected and gives you the ability to pre-specify a threshold and the

actions to take if that threshold is breached. For example, your CloudWatch alarm can send you a notification if your endpoint breaches an error threshold. By setting up CloudWatch alarms, you gain visibility into the performance and functionality of your endpoint. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms in the *Amazon CloudWatch User Guide*.

Monitoring with CloudWatch

The metrics below are an exhaustive list of metrics for serverless endpoints. Any metric not listed below is not published for serverless endpoints. For information about the following metrics, see Monitor Amazon SageMaker AI with Amazon CloudWatch.

Common endpoint metrics

These CloudWatch metrics are the same as the metrics published for real-time endpoints.

The `OverheadLatency` metric tracks all additional latency that SageMaker AI added which includes the cold start time for launching new compute resources for your serverless endpoint. Compared to on-demand serverless endpoints, the `OverheadLatency` for serverless endpoints with provision concurrency is generally significantly less.

Serverless endpoints can also use the `Invocations4XXErrors`, `Invocations5XXErrors`, `Invocations`, `ModelLatency`, `ModelSetupTime` and `MemoryUtilization` metrics. To learn more about these metrics, see SageMaker AI endpoint invocation metrics.

Common serverless endpoint metrics

These CloudWatch metrics are published for both on-demand serverless endpoints and serverless endpoint with Provisioned Concurrency.

Metric Name	Description	Unit/Stats
`ServerlessConcurrentExecutionsUtilization`	The number of concurrent executions divided by the maximum concurrency.	Units: None Valid statistics: Average, Max, Min

Serverless endpoint with Provisioned Concurrency metrics

These CloudWatch metrics are published for serverless endpoints with Provisioned Concurrency.

Metric Name	Description	Unit/Stats
`ServerlessProvisionedConcurrencyExecutions`	The number of concurrent executions handled by the endpoint.	Units: Count Valid statistics: Average, Max, Min
`ServerlessProvisionedConcurrencyUtilization`	The number of concurrent executions divided by the allocated Provisioned Concurrency.	Units: None Valid statistics: Average, Max, Min
`ServerlessProvisionedConcurrencyInvocations`	The number of `InvokeEndpoint` requests handled by Provisioned Concurrency.	Units: Count Valid statistics: Average, Max, Min
`ServerlessProvisionedConcurrencySpilloverInvocations`	The number of `InvokeEndpoint` requests not handled by Provisioned Concurrency, that is handled by on-demand Serverless Inference.	Units: Count Valid statistics: Average, Max, Min

Logs

If you want to monitor the logs from your endpoint for debugging or progress analysis, you can use Amazon CloudWatch Logs. The SageMaker AI-provided log group that you can use for serverless endpoints is `/aws/sagemaker/Endpoints/[EndpointName]`. For more information about using CloudWatch Logs in SageMaker AI, see CloudWatch Logs for Amazon SageMaker AI. To learn more about CloudWatch Logs, see What is Amazon CloudWatch Logs? in the *Amazon CloudWatch Logs User Guide*.

Automatically scale Provisioned Concurrency for a serverless endpoint

Amazon SageMaker AI automatically scales in or out on-demand serverless endpoints. For serverless endpoints with Provisioned Concurrency you can use Application Auto Scaling to scale up or down the Provisioned Concurrency based on your traffic profile, thus optimizing costs.

The following are the prerequisites to autoscale Provisioned Concurrency on serverless endpoints:

- Register a model
- Define a scaling policy
- Apply a scaling policy

Before you can use autoscaling, you must have already deployed a model to a serverless endpoint with Provisioned Concurrency. Deployed models are referred to as production variants. See Create an endpoint configuration and Create an endpoint for more information about deploying a model to a serverless endpoint with Provisioned Concurrency. To specify the metrics and target values for a scaling policy, you must configure a scaling policy. For more information on how to define a scaling policy, see Define a scaling policy. After registering your model and defining a scaling policy, apply the scaling policy to the registered model. For information on how to apply the scaling policy, see Apply a scaling policy.

For details on other prerequisites and components used with autoscaling, see the Auto scaling prerequisites section in the SageMaker AI autoscaling documentation.

Register a model

To add autoscaling to a serverless endpoint with Provisioned Concurrency, you first must register your model (production variant) using Amazon CLI or Application Auto Scaling API.

Register a model (Amazon CLI)

To register your model, use the `register-scalable-target` Amazon CLI command with the following parameters:

- `--service-namespace` – Set this value to `sagemaker`.
- `--resource-id` – The resource identifier for the model (specifically the production variant). For this parameter, the resource type is `endpoint` and the unique identifier is the name of the production variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `--scalable-dimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.
- `--min-capacity` – The minimum number of Provisioned Concurrency for the model. Set `--min-capacity` to at least 1. It must be equal to or less than the value specified for `--max-capacity`.

- `--max-capacity` – The maximum number of Provisioned Concurrency that should be enabled through Application Auto Scaling. Set `--max-capacity` to a minimum of 1. It must be greater than or equal to the value specified for `--min-capacity`.

The following example shows how to register a model named `MyVariant` that is dynamically scaled to have 1 to 10 Provisioned Concurrency value:

```
aws application-autoscaling register-scalable-target \
    --service-namespace sagemaker \
    --scalable-dimension sagemaker:variant:DesiredProvisionedConcurrency \
    --resource-id endpoint/MyEndpoint/variant/MyVariant \
    --min-capacity 1 \
    --max-capacity 10
```

Register a model (Application Auto Scaling API)

To register your model, use the `RegisterScalableTarget` Application Auto Scaling API action with the following parameters:

- `ServiceNamespace` – Set this value to `sagemaker`.
- `ResourceId` – The resource identifier for the model (specifically the production variant). For this parameter, the resource type is `endpoint` and the unique identifier is the name of the production variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `ScalableDimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.
- `MinCapacity` – The minimum number of Provisioned Concurrency for the model. Set `MinCapacity` to at least 1. It must be equal to or less than the value specified for `MaxCapacity`.
- `MaxCapacity` – The maximum number of Provisioned Concurrency that should be enabled through Application Auto Scaling. Set `MaxCapacity` to a minimum of 1. It must be greater than or equal to the value specified for `MinCapacity`.

The following example shows how to register a model named `MyVariant` that is dynamically scaled to have 1 to 10 Provisioned Concurrency value:

```
POST / HTTP/1.1
```

```
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.RegisterScalableTarget
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndPoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredProvisionedConcurrency",
    "MinCapacity": 1,
    "MaxCapacity": 10
}
```

Define a scaling policy

To specify the metrics and target values for a scaling policy, you can configure a target-tracking scaling policy. Define the scaling policy as a JSON block in a text file. You can then use that text file when invoking the Amazon CLI or the Application Auto Scaling API. To quickly define a target-tracking scaling policy for a serverless endpoint, use the `SageMakerVariantProvisionedConcurrencyUtilization` predefined metric.

```
{
    "TargetValue": 0.5,
    "PredefinedMetricSpecification":
    {
        "PredefinedMetricType": "SageMakerVariantProvisionedConcurrencyUtilization"
    },
    "ScaleOutCooldown": 1,
    "ScaleInCooldown": 1
}
```

Apply a scaling policy

After registering your model, you can apply a scaling policy to your serverless endpoint with Provisioned Concurrency. See Apply a target-tracking scaling policy to apply a target-tracking scaling policy that you have defined. If the traffic flow to your serverless endpoint has a predictable routine then instead of applying a target-tracking scaling policy you might want to schedule

scaling actions at specific times. For more information on scheduling scaling actions, see Scheduled scaling.

Apply a target-tracking scaling policy

You can use the Amazon Web Services Management Console, Amazon CLI or the Application Auto Scaling API to apply a target-tracking scaling policy to your serverless endpoint with Provisioned Concurrency.

Apply a target-tracking scaling policy (Amazon CLI)

To apply a scaling policy to your model, use the `put-scaling-policy` Amazon CLI; command with the following parameters:

- `--policy-name` – The name of the scaling policy.
- `--policy-type` – Set this value to `TargetTrackingScaling`.
- `--resource-id` – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace` – Set this value to `sagemaker`.
- `--scalable-dimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.
- `--target-tracking-scaling-policy-configuration` – The target-tracking scaling policy configuration to use for the model.

The following example shows how to apply a target-tracking scaling policy named `MyScalingPolicy` to a model named `MyVariant`. The policy configuration is saved in a file named `scaling-policy.json`.

```
aws application-autoscaling put-scaling-policy \
    --policy-name MyScalingPolicy \
    --policy-type TargetTrackingScaling \
    --service-namespace sagemaker \
    --scalable-dimension sagemaker:variant:DesiredProvisionedConcurrency \
    --resource-id endpoint/MyEndpoint/variant/MyVariant \
    --target-tracking-scaling-policy-configuration file://[file-localtion]/scaling-
policy.json
```

Apply a target-tracking scaling policy (Application Auto Scaling API)

To apply a scaling policy to your model, use the `PutScalingPolicy` Application Auto Scaling API action with the following parameters:

- `PolicyName` – The name of the scaling policy.
- `PolicyType` – Set this value to `TargetTrackingScaling`.
- `ResourceId` – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `ServiceNamespace` – Set this value to `sagemaker`.
- `ScalableDimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.
- `TargetTrackingScalingPolicyConfiguration` – The target-tracking scaling policy configuration to use for the model.

The following example shows how to apply a target-tracking scaling policy named `MyScalingPolicy` to a model named `MyVariant`. The policy configuration is saved in a file named `scaling-policy.json`.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.PutScalingPolicy
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "MyScalingPolicy",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredProvisionedConcurrency",
    "PolicyType": "TargetTrackingScaling",
    "TargetTrackingScalingPolicyConfiguration":
    {
        "TargetValue": 0.5,
        "PredefinedMetricSpecification":
```

```
        {
            "PredefinedMetricType": "SageMakerVariantProvisionedConcurrencyUtilization"
        }
    }
}
```

Apply a target-tracking scaling policy (Amazon Web Services Management Console)

To apply a target-tracking scaling policy with the Amazon Web Services Management Console:

1. Sign in to the Amazon SageMaker AI console.
2. In the navigation panel, choose **Inference**.
3. Choose **Endpoints** to view a list of all of your endpoints.
4. Choose the endpoint to which you want to apply the scaling policy. A page with the settings of the endpoint will appear, with the models (production variant) listed under **Endpoint runtime settings section**.
5. Select the production variant to which you want to apply the scaling policy, and choose **Configure auto scaling**. The **Configure variant automatic scaling** dialog box appears.

Configure variant automatic scaling

There are no custom scaling policies for this variant.

Cancel Save

6. Enter the minimum and maximum Provisioned Concurrency values in the **Minimum provisioned concurrency** and **Maximum provisioned concurrency** fields, respectively, in the **Variant automatic scaling** section. Minimum Provisioned Concurrency must be less than or equal to maximum Provisioned Concurrency.
7. Enter the target value in the **Target value** field for the target metric, `SageMakerVariantProvisionedConcurrencyUtilization`.
8. (Optional) Enter scale in cool down and scale out cool down values (in seconds) in **Scale in cool down** and **Scale out cool down** fields respectively.
9. (Optional) Select **Disable scale in** if you don't want auto scaling to delete instance when traffic decreases.
10. Select **Save**.

Scheduled scaling

If the traffic to your serverless endpoint with Provisioned Concurrency follows a routine pattern you might want to schedule scaling actions at specific times, to scale in or scale out Provisioned Concurrency. You can use the Amazon CLI or the Application Auto Scaling to schedule scaling actions.

Scheduled scaling (Amazon CLI)

To apply a scaling policy to your model, use the `put-scheduled-action` Amazon CLI; command with the following parameters:

- `--schedule-action-name` – The name of the scaling action.
- `--schedule` – A cron expression that specifies the start and end times of the scaling action with a recurring schedule.
- `--resource-id` – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace` – Set this value to `sagemaker`.
- `--scalable-dimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.
- `--scalable-target-action` – The target of the scaling action.

The following example shows how to add a scaling action named `MyScalingAction` to a model named `MyVariant` on a recurring schedule. On the specified schedule (every day at 12:15 PM UTC), if the current Provisioned Concurrency is below the value specified for `MinCapacity`. Application Auto Scaling scales out the Provisioned Concurrency to the value specified by `MinCapacity`.

```
aws application-autoscaling put-scheduled-action \
    --scheduled-action-name 'MyScalingAction' \
    --schedule 'cron(15 12 * * ? *)' \
    --service-namespace sagemaker \
    --resource-id endpoint/MyEndpoint/variant/MyVariant \
    --scalable-dimension sagemaker:variant:DesiredProvisionedConcurrency \
    --scalable-target-action 'MinCapacity=10'
```

Scheduled scaling (Application Auto Scaling API)

To apply a scaling policy to your model, use the `PutScheduledAction` Application Auto Scaling API action with the following parameters:

- `ScheduleActionName` – The name of the scaling action.
- `Schedule` – A cron expression that specifies the start and end times of the scaling action with a recurring schedule.
- `ResourceId` – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `ServiceNamespace` – Set this value to `sagemaker`.
- `ScalableDimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.
- `ScalableTargetAction` – The target of the scaling action.

The following example shows how to add a scaling action named `MyScalingAction` to a model named `MyVariant` on a recurring schedule. On the specified schedule (every day at 12:15 PM UTC), if the current Provisioned Concurrency is below the value specified for `MinCapacity`. Application Auto Scaling scales out the Provisioned Concurrency to the value specified by `MinCapacity`.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.PutScheduledAction
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "ScheduledActionName": "MyScalingAction",
    "Schedule": "cron(15 12 * * ? *)",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredProvisionedConcurrency",
    "ScalableTargetAction": "MinCapacity=10"
        }
    }
}
```

Clean up

After you have finished using autoscaling for your serverless endpoint with Provisioned Concurrency, you should clean up the resources you created. This involves deleting the scaling policy and deregistering the model from Application Auto Scaling. Cleaning up ensures that you don't incur unnecessary costs for resources you're no longer using.

Delete a scaling policy

You can delete a scaling policy with the Amazon Web Services Management Console, the Amazon CLI, or the Application Auto Scaling API. For more information on deleting a scaling policy with the Amazon Web Services Management Console, see Delete a scaling policy in the SageMaker AI autoscaling documentation.

Delete a scaling policy (Amazon CLI)

To apply a scaling policy to your model, use the `delete-scaling-policy` Amazon CLI; command with the following parameters:

- `--policy-name` – The name of the scaling policy.

- `--resource-id` – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace` – Set this value to `sagemaker`.
- `--scalable-dimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.

The following example deletes scaling policy named `MyScalingPolicy` from a model named `MyVariant`.

```
aws application-autoscaling delete-scaling-policy \
    --policy-name MyScalingPolicy \
    --service-namespace sagemaker \
    --scalable-dimension sagemaker:variant:DesiredProvisionedConcurrency \
    --resource-id endpoint/MyEndpoint/variant/MyVariant
```

Delete a scaling policy (Application Auto Scaling API)

To delete a scaling policy to your model, use the `DeleteScalingPolicy` Application Auto Scaling API action with the following parameters:

- `PolicyName` – The name of the scaling policy.
- `ResourceId` – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `ServiceNamespace` – Set this value to `sagemaker`.
- `ScalableDimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.

The following example uses the Application Auto Scaling API to delete a scaling policy named `MyScalingPolicy` from a model named `MyVariant`.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.DeleteScalingPolicy
```

```
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "PolicyName": "MyScalingPolicy",
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredProvisionedConcurrency",
}
```

Deregister a model

You can deregister a model with the Amazon Web Services Management Console, the Amazon CLI, or the Application Auto Scaling API.

Deregister a model (Amazon CLI)

To deregister a model from Application Auto Scaling, use the `deregister-scalable-target` Amazon CLI; command with the following parameters:

- `--resource-id` – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `--service-namespace` – Set this value to `sagemaker`.
- `--scalable-dimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.

The following example deregisters a model named `MyVariant` from Application Auto Scaling.

```
aws application-autoscaling deregister-scalable-target \
    --service-namespace sagemaker \
    --scalable-dimension sagemaker:variant:DesiredProvisionedConcurrency \
    --resource-id endpoint/MyEndpoint/variant/MyVariant
```

Deregister a model (Application Auto Scaling API)

To deregister a model from Application Auto Scaling use the `DeregisterScalableTarget` Application Auto Scaling API action with the following parameters:

- `ResourceId` – The resource identifier for the variant. For this parameter, the resource type is `endpoint` and the unique identifier is the name of the variant. For example `endpoint/MyEndpoint/variant/MyVariant`.
- `ServiceNamespace` – Set this value to `sagemaker`.
- `ScalableDimension` – Set this value to `sagemaker:variant:DesiredProvisionedConcurrency`.

The following example uses the Application Auto Scaling API to deregister a model named `MyVariant` from Application Auto Scaling.

```
POST / HTTP/1.1
Host: autoscaling.us-east-2.amazonaws.com
Accept-Encoding: identity
X-Amz-Target: AnyScaleFrontendService.DeregisterScalableTarget
X-Amz-Date: 20160506T182145Z
User-Agent: aws-cli/1.10.23 Python/2.7.11 Darwin/15.4.0 botocore/1.4.8
Content-Type: application/x-amz-json-1.1
Authorization: AUTHPARAMS

{
    "ServiceNamespace": "sagemaker",
    "ResourceId": "endpoint/MyEndpoint/variant/MyVariant",
    "ScalableDimension": "sagemaker:variant:DesiredProvisionedConcurrency",
}
```

Deregister a model (Amazon Web Services Management Console)

To deregister a model (production variant) with the Amazon Web Services Management Console:

1. Open the Amazon SageMaker AI console.
2. In the navigational panel, choose **Inference**.
3. Choose **Endpoints** to view a list of your endpoints.

4. Choose the serverless endpoint hosting the production variant. A page with the settings of the endpoint will appear, with the production variants listed under **Endpoint runtime settings** section.
5. Select the production variant that you want to deregister, and choose **Configure auto scaling**. The **Configure variant automatic scaling** dialog box appears.
6. Choose **Deregister auto scaling**.

Troubleshooting

> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.
> Amazon managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

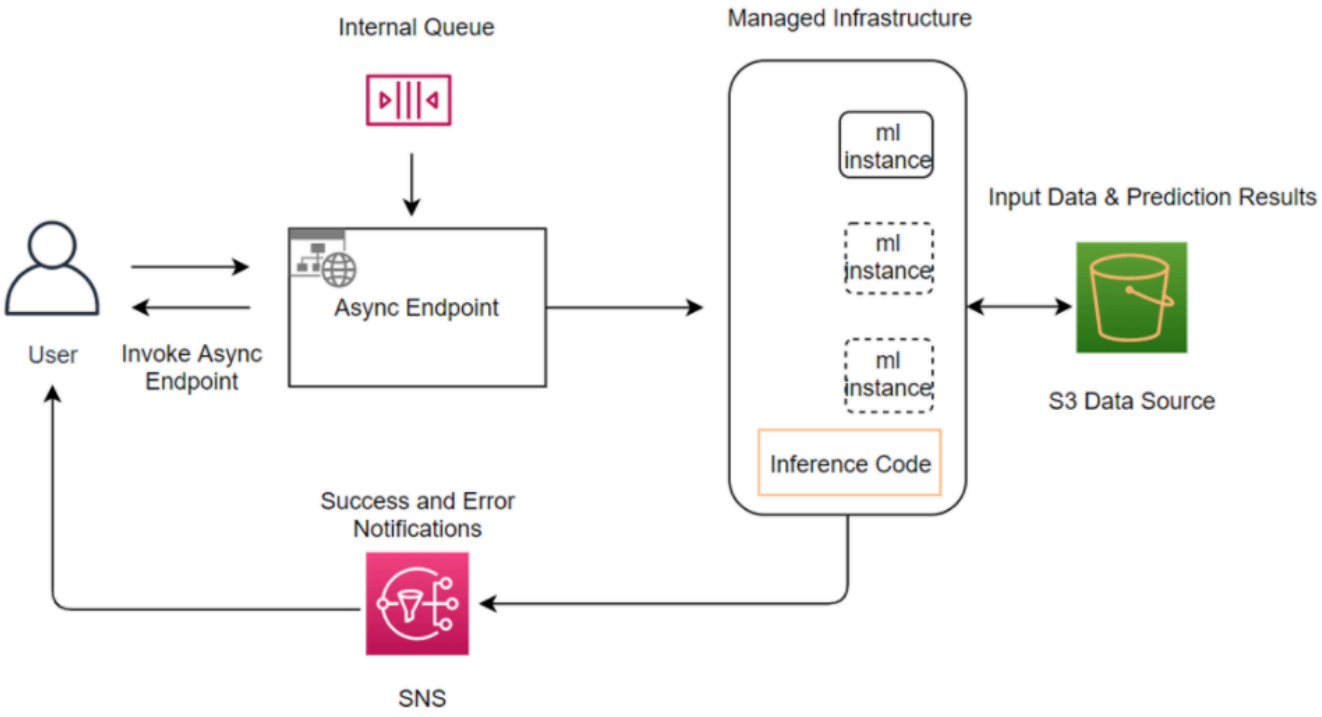
If you are having trouble with Serverless Inference, refer to the following troubleshooting tips.

Container issues

If the container you use for a serverless endpoint is the same one you used on an instance-based endpoint, your container may not have permissions to write files. This can happen for the following reasons:

- Your serverless endpoint fails to create or update due to a ping health check failure.
- The Amazon CloudWatch logs for the endpoint show that the container is failing to write to some file or directory due to a permissions error.

To fix this issue, you can try to add read, write, and execute permissions for `other` on the file or directory and then rebuild the container. You can perform the following steps to complete this process:



1. In the Dockerfile you used to build your container, add the following command: `RUN chmod o +rwX <file or directory name>`
2. Rebuild the container.
3. Upload the new container image to Amazon ECR.
4. Try to create or update the serverless endpoint again.

Asynchronous inference

Amazon SageMaker Asynchronous Inference is a capability in SageMaker AI that queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes (up to 1GB), long processing times (up to one hour), and near real-time latency requirements. Asynchronous Inference enables you to save on costs by autoscaling the instance count to zero when there are no requests to process, so you only pay when your endpoint is processing requests.

How It Works

Creating an asynchronous inference endpoint is similar to creating real-time inference endpoints. You can use your existing SageMaker AI models and only need to specify the `AsyncInferenceConfig` object while creating your endpoint configuration with the `EndpointConfig` field in the `CreateEndpointConfig` API. The following diagram shows the architecture and workflow of Asynchronous Inference.

To invoke the endpoint, you need to place the request payload in Amazon S3. You also need to provide a pointer to this payload as a part of the `InvokeEndpointAsync` request. Upon invocation, SageMaker AI queues the request for processing and returns an identifier and output location as a response. Upon processing, SageMaker AI places the result in the Amazon S3 location. You can optionally choose to receive success or error notifications with Amazon SNS. For more information about how to set up asynchronous notifications, see Check prediction results.

> **Note**
>
> The presence of an asynchronous inference configuration (`AsyncInferenceConfig`) object in the endpoint configuration implies that the endpoint can only receive asynchronous invocations.

How Do I Get Started?

If you are a first-time user of Amazon SageMaker Asynchronous Inference, we recommend that you do the following:

- Read Asynchronous endpoint operations for information on how to create, invoke, update, and delete an asynchronous endpoint.

- Explore the Asynchronous Inference example notebook in the aws/amazon-sagemaker-examples GitHub repository.

Note that if your endpoint uses any of the features listed in this Exclusions page, you cannot use Asynchronous Inference.

Asynchronous endpoint operations

This guide demonstrates the prerequisites you must satisfy to create an asynchronous endpoint, along with how to create, invoke, and delete your asynchronous endpoints. You can create, update, delete, and invoke asynchronous endpoints with the Amazon SDKs and the Amazon SageMaker Python SDK.

Topics

- Complete the prerequisites
- How to create an Asynchronous Inference Endpoint
- Invoke an Asynchronous Endpoint
- Update an Asynchronous Endpoint
- Delete an Asynchronous Endpoint

Complete the prerequisites

The following topic describes the prerequisites that you must complete before creating an asyncrhonous endpoint. These prerequisites include properly storing your model artifacts, configuring an Amazon IAM with the correct permissions, and selecting a container image.

To complete the prerequisites

1. **Create an IAM role for Amazon SageMaker AI.**

   Asynchronous Inference needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker AI and has permission to access Amazon S3 and Amazon SNS. Using this role, SageMaker AI can run under your account and access your Amazon S3 bucket and Amazon SNS topics.

You can create an IAM role by using the IAM console, Amazon SDK for Python (Boto3), or Amazon CLI. The following is an example of how to create an IAM role and attach the necessary policies with the IAM console.

a. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.

b. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.

c. For **Select type of trusted entity**, choose **Amazon service**.

d. Choose the service that you want to allow to assume this role. In this case, choose **SageMaker AI**. Then choose **Next: Permissions**.

   - This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.

e. Choose **Next: Tags**.

f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.

g. Choose **Next: Review**.

h. Type in a **Role name**.

i. If possible, type a role name or role name suffix. Role names must be unique within your Amazon account. They are not distinguished by case. For example, you cannot create roles named both `PRODROLE` and `prodrole`. Because other Amazon resources might reference the role, you cannot edit the name of the role after it has been created.

j. (Optional) For **Role description**, type a description for the new role.

k. Review the role and then choose **Create role**.

   Note the SageMaker AI role ARN. To find the role ARN using the console, do the following:

   i. Go to the IAM console: https://console.amazonaws.cn/iam/

   ii. Select **Roles**.

   iii. Search for the role you just created by typing in the name of the role in the search field.

   iv. Select the role.

   v. The role ARN is at the top of the **Summary** page.

2. **Add Amazon SageMaker AI, Amazon S3 and Amazon SNS Permissions to your IAM Role.**

Once the role is created, grant SageMaker AI, Amazon S3, and optionally Amazon SNS permissions to your IAM role.

Choose **Roles** in the IAM console. Search for the role you created by typing in your role name in the **Search** field.

a. Choose your role.

b. Next, choose **Attach Policies**.

c. Amazon SageMaker Asynchronous Inference needs permission to perform the following actions: `"sagemaker:CreateModel"`, `"sagemaker:CreateEndpointConfig"`, `"sagemaker:CreateEndpoint"`, and `"sagemaker:InvokeEndpointAsync"`.

   These actions are included in the `AmazonSageMakerFullAccess` policy. Add this policy to your IAM role. Search for `AmazonSageMakerFullAccess` in the **Search** field. Select `AmazonSageMakerFullAccess`.

d. Choose **Attach policy**.

e. Next, choose **Attach Policies** to add Amazon S3 permissions.

f. Select **Create policy**.

g. Select the `JSON` tab.

h. Add the following policy statement:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "s3:GetObject",
                "s3:PutObject",
                "s3:AbortMultipartUpload",
                "s3:ListBucket"
            ],
            "Effect": "Allow",
            "Resource": "arn:aws-cn:s3:::bucket_name/*"
        }
    ]
```

```
}
```

i. Choose **Next: Tags**.

j. Type in a **Policy name**.

k. Choose **Create policy**.

l. Repeat the same steps you completed to add Amazon S3 permissions in order to add Amazon SNS permissions. For the policy statement, attach the following:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "sns:Publish"
            ],
            "Effect": "Allow",
"Resource": "arn:aws-cn:sns:us-east-1:111122223333:SNS_Topic"
        }
    ]
}
```

3. **Upload your inference data (e.g., machine learning model, sample data) to Amazon S3.**

4. **Select a prebuilt Docker inference image or create your own Inference Docker Image.**

   SageMaker AI provides containers for its built-in algorithms and prebuilt Docker images for some of the most common machine learning frameworks, such as Apache MXNet, TensorFlow, PyTorch, and Chainer. For a full list of the available SageMaker AI images, see Available Deep Learning Containers Images. If you choose to use a SageMaker AI provided container, you can increase the endpoint timeout and payload sizes from the default by setting the environment variables in the container. To learn how to set the different environment variables for each framework, see the Create a Model step of creating an asynchronous endpoint.

   If none of the existing SageMaker AI containers meet your needs and you don't have an existing container of your own, you may need to create a new Docker container. See Containers with custom inference code for information on how to create your Docker image.

5. **Create an Amazon SNS topic (optional)**

Create an Amazon Simple Notification Service (Amazon SNS) topic that sends notifications about requests that have completed processing. Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. You can specify Amazon SNS topics when you create an `EndpointConfig` object when you specify `AsyncInferenceConfig` using the `EndpointConfig` API.

Follow the steps to create and subscribe to an Amazon SNS topic.

a. Using Amazon SNS console, create a topic. For instructions, see Creating an Amazon SNS topic in the *Amazon Simple Notification Service Developer Guide*.

b. Subscribe to the topic. For instructions, see Subscribing to an Amazon SNS topic in the *Amazon Simple Notification Service Developer Guide*.

c. When you receive email requesting that you confirm your subscription to the topic, confirm the subscription.

d. Note the topic Amazon Resource Name (ARN). The Amazon SNS topic you created is another resource in your Amazon account, and it has a unique ARN. The ARN is in the following format:

```
arn:aws:sns:aws-region:account-id:topic-name
```

For more information about Amazon SNS, see the Amazon SNS Developer Guide.

How to create an Asynchronous Inference Endpoint

Create an asynchronous endpoint the same way you would create an endpoint using SageMaker AI hosting services:

- Create a model in SageMaker AI with `CreateModel`.
- Create an endpoint configuration with `CreateEndpointConfig`.
- Create an HTTPS endpoint with `CreateEndpoint`.

To create an endpoint, you first create a model with `CreateModel`, where you point to the model artifact and a Docker registry path (Image). You then create a configuration using

`CreateEndpointConfig` where you specify one or more models that were created using the `CreateModel` API to deploy and the resources that you want SageMaker AI to provision. Create your endpoint with `CreateEndpoint` using the endpoint configuration specified in the request. You can update an asynchronous endpoint with the `UpdateEndpoint` API. Send and receive inference requests from the model hosted at the endpoint with `InvokeEndpointAsync`. You can delete your endpoints with the `DeleteEndpoint` API.

For a full list of the available SageMaker Images, see Available Deep Learning Containers Images. See Containers with custom inference code for information on how to create your Docker image.

Topics

- Create a Model
- Create an Endpoint Configuration
- Create Endpoint

Create a Model

The following example shows how to create a model using the Amazon SDK for Python (Boto3). The first few lines define:

- `sagemaker_client`: A low-level SageMaker AI client object that makes it easy to send and receive requests to Amazon services.
- `sagemaker_role`: A string variable with the SageMaker AI IAM role Amazon Resource Name (ARN).
- `aws_region`: A string variable with the name of your Amazon region.

```
import boto3

# Specify your AWS Region
aws_region='<aws_region>'

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# Role to give SageMaker permission to access Amazon services.
sagemaker_role= "arn:aws:iam::<account>:role/*"
```

Next, specify the location of the pre-trained model stored in Amazon S3. In this example, we use a pre-trained XGBoost model named `demo-xgboost-model.tar.gz`. The full Amazon S3 URI is stored in a string variable `model_url`:

```
#Create a variable w/ the model S3 URI
s3_bucket = '<your-bucket-name>' # Provide the name of your S3 bucket
bucket_prefix='saved_models'
model_s3_key = f"{bucket_prefix}/demo-xgboost-model.tar.gz"

#Specify S3 bucket w/ model
model_url = f"s3://{s3_bucket}/{model_s3_key}"
```

Specify a primary container. For the primary container, you specify the Docker image that contains inference code, artifacts (from prior training), and a custom environment map that the inference code uses when you deploy the model for predictions.

In this example, we specify an XGBoost built-in algorithm container image:

```
from sagemaker import image_uris

# Specify an AWS container image.
container = image_uris.retrieve(region=aws_region, framework='xgboost',
 version='0.90-1')
```

Create a model in Amazon SageMaker AI with `CreateModel`. Specify the following:

- `ModelName`: A name for your model (in this example it is stored as a string variable called `model_name`).
- `ExecutionRoleArn`: The Amazon Resource Name (ARN) of the IAM role that Amazon SageMaker AI can assume to access model artifacts and Docker images for deployment on ML compute instances or for batch transform jobs.
- `PrimaryContainer`: The location of the primary Docker image containing inference code, associated artifacts, and custom environment maps that the inference code uses when the model is deployed for predictions.

```
model_name = '<The_name_of_the_model>'

#Create model
```

```
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
    })
```

See `CreateModel` description in the SageMaker API Reference Guide for a full list of API parameters.

If you're using a SageMaker AI provided container, you can increase the model server timeout and payload sizes from the default values to the framework-supported maximums by setting environment variables in this step. You might not be able to leverage the maximum timeout and payload sizes that Asynchronous Inference supports if you don't explicitly set these variables. The following example shows how you can set the environment variables for a PyTorch Inference container based on TorchServe.

```
model_name = '<The_name_of_the_model>'

#Create model
create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url,
        'Environment': {
            'TS_MAX_REQUEST_SIZE': '100000000',
            'TS_MAX_RESPONSE_SIZE': '100000000',
            'TS_DEFAULT_RESPONSE_TIMEOUT': '1000'
        },
    })
```

After you finish creating your endpoint, you should test that you've set the environment variables correctly by printing them out from your `inference.py` script. The following table lists the environment variables for several frameworks that you can set to change the default values.

Framework	Environment variables
PyTorch 1.8 (based on TorchServe)	'TS_MAX_REQUEST_SIZE': '100000000'

Framework	Environment variables
	'TS_MAX_RESPONSE_SIZE': '100000000' 'TS_DEFAULT_RESPONSE_TIMEOUT': '1000'
PyTorch 1.4 (based on MMS)	'MMS_MAX_REQUEST_SIZE': '1000000000' 'MMS_MAX_RESPONSE_SIZE': '1000000000' 'MMS_DEFAULT_RESPONSE_TIMEOUT': '900'
HuggingFace Inference Container (based on MMS)	'MMS_MAX_REQUEST_SIZE': '2000000000' 'MMS_MAX_RESPONSE_SIZE': '2000000000' 'MMS_DEFAULT_RESPONSE_TIMEOUT': '900'

Create an Endpoint Configuration

Once you have a model, create an endpoint configuration with `CreateEndpointConfig`. Amazon SageMaker AI hosting services uses this configuration to deploy models. In the configuration, you identify one or more models, created using with `CreateModel`, to deploy the resources that you want Amazon SageMaker AI to provision. Specify the `AsyncInferenceConfig` object and provide an output Amazon S3 location for `OutputConfig`. You can optionally specify Amazon SNS topics on which to send notifications about prediction results. For more information about Amazon SNS topics, see Configuring Amazon SNS.

To improve endpoint availability and reduce insufficient capacity errors, you can configure *instance pools* in your production variant. Instance pools let you specify an ordered list of instance types so that SageMaker AI automatically falls back to lower-priority types when your preferred instance type is unavailable. For more information, see Deploy to multiple instance types with instance pools.

The following example shows how to create an endpoint configuration using Amazon SDK for Python (Boto3):

```
import datetime
from time import gmtime, strftime
```

```
# Create an endpoint config name. Here we create one based on the date
# so it we can search endpoints based on creation time.
endpoint_config_name = f"XGBoostEndpointConfig-{strftime('%Y-%m-%d-%H-%M-%S',
 gmtime())}"

# The name of the model that you want to host. This is the name that you specified when
 creating the model.
model_name='<The_name_of_your_model>'

create_endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name, # You will specify this name in a
 CreateEndpoint request.
    # List of ProductionVariant objects, one for each model that you want to host at
 this endpoint.
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": "ml.m5.xlarge", # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ],
    AsyncInferenceConfig={
        "OutputConfig": {
            # Location to upload response outputs when no location is provided in the
 request.
            "S3OutputPath": f"s3://{s3_bucket}/{bucket_prefix}/output"
            # (Optional) specify Amazon SNS topics
            "NotificationConfig": {
                "SuccessTopic": "arn:aws:sns:aws-region:account-id:topic-name",
                "ErrorTopic": "arn:aws:sns:aws-region:account-id:topic-name",
            }
        },
        "ClientConfig": {
            # (Optional) Specify the max number of inflight invocations per instance
            # If no value is provided, Amazon SageMaker will choose an optimal value
 for you
            "MaxConcurrentInvocationsPerInstance": 4
        }
    }
)
```

```
print(f"Created EndpointConfig:
 {create_endpoint_config_response['EndpointConfigArn']}")
```

In the aforementioned example, you specify the following keys for `OutputConfig` for the `AsyncInferenceConfig` field:

- `S3OutputPath`: Location to upload response outputs when no location is provided in the request.
- `NotificationConfig`: (Optional) SNS topics that post notifications to you when an inference request is successful (`SuccessTopic`) or if it fails (`ErrorTopic`).

You can also specify the following optional argument for `ClientConfig` in the `AsyncInferenceConfig` field:

- `MaxConcurrentInvocationsPerInstance`: (Optional) The maximum number of concurrent requests sent by the SageMaker AI client to the model container.

Create Endpoint

Once you have your model and endpoint configuration, use the `CreateEndpoint` API to create your endpoint. The endpoint name must be unique within an Amazon Region in your Amazon account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker AI uses the endpoint to provision resources and deploy models.

```
# The name of the endpoint. The name must be unique within an Amazon Web Services
 Region in your Amazon Web Services account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
                                            EndpointName=endpoint_name,
                                            EndpointConfigName=endpoint_config_name)
```

When you call the `CreateEndpoint` API, Amazon SageMaker Asynchronous Inference sends a test notification to check that you have configured an Amazon SNS topic. Amazon SageMaker

Asynchronous Inference also sends test notifications after calls to `UpdateEndpoint` and `UpdateEndpointWeightsAndCapacities`. This lets SageMaker AI check that you have the required permissions. The notification can simply be ignored. The test notification has the following form:

```
{
    "eventVersion":"1.0",
    "eventSource":"aws:sagemaker",
    "eventName":"TestNotification"
}
```

Invoke an Asynchronous Endpoint

Get inferences from the model hosted at your asynchronous endpoint with `InvokeEndpointAsync`.

> **Note**
>
> If you have not done so already, upload your inference data (e.g., machine learning model, sample data) to Amazon S3.

You can provide the request payload in one of two ways. These options are mutually exclusive; provide exactly one of them in a request:

- **Inline payload** — For payloads up to 128,000 bytes, pass the data directly in the request with the `Body` parameter. This avoids uploading the payload to Amazon S3 before each invocation.
- **Amazon S3 location** — For larger payloads, upload your inference data to Amazon S3 and pass its URI with the `InputLocation` parameter.

Specify the following fields in your request:

- For `Body`, provide the inference payload inline (up to 128,000 bytes). Use this *or* `InputLocation`, but not both.
- For `InputLocation`, specify the Amazon S3 location of your inference data. Use this *or* `Body`, but not both.
- For `EndpointName`, specify the name of your endpoint.

- (Optional) For `InvocationTimeoutSeconds`, you can set the max timeout for the requests. You can set this value to a maximum of 3600 seconds (one hour) on a per-request basis. If you don't specify this field in your request, by default the request times out at 15 minutes.

The following example sends the payload inline with the `Body` parameter, which does not require uploading the input to Amazon S3 first.

```
# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the inference payload inline (up to 128,000 bytes)
payload = b'{"inputs": "your inference data here"}'

# The name of the endpoint. The name must be unique within an Amazon Web Services
 Region in your Amazon Web Services account.
endpoint_name='<endpoint-name>'

# After you deploy a model into production using SageMaker AI hosting
# services, your client applications use this API to get inferences
# from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint_async(
                            EndpointName=endpoint_name,
                            Body=payload,
                            ContentType="application/json",
                            InvocationTimeoutSeconds=3600)
```

Alternatively, you can store the payload in Amazon S3 and pass its location with the `InputLocation` parameter. If you have not done so already, upload your inference data to Amazon S3 before invoking the endpoint.

```
# Create a low-level client representing Amazon SageMaker Runtime
sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the location of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

# The name of the endpoint. The name must be unique within an Amazon Web Services
 Region in your Amazon Web Services account.
endpoint_name='<endpoint-name>'

# After you deploy a model into production using SageMaker AI hosting
```

```
# services, your client applications use this API to get inferences
# from the model hosted at the specified endpoint.
response = sagemaker_runtime.invoke_endpoint_async(
                            EndpointName=endpoint_name,
                            InputLocation=input_location,
                            InvocationTimeoutSeconds=3600)
```

You receive a response as a JSON string with your request ID and the name of the Amazon S3 bucket that will have the response to the API call after it is processed.

Update an Asynchronous Endpoint

Update an asynchronous endpoint with the `UpdateEndpoint` API. When you update an endpoint, SageMaker AI first provisions and switches to the new endpoint configuration you specify before it deletes the resources that were provisioned in the previous endpoint configuration. Do not delete an `EndpointConfig` with an endpoint that is live or while the `UpdateEndpoint` or `CreateEndpoint` operations are being performed on the endpoint.

```
# The name of the endpoint. The name must be unique within an Amazon Region in your
 Amazon account.
endpoint_name='<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

sagemaker_client.update_endpoint(
                                EndpointConfigName=endpoint_config_name,
                                EndpointName=endpoint_name
                                )
```

When Amazon SageMaker AI receives the request, it sets the endpoint status to **Updating**. After updating the asynchronous endpoint, it sets the status to **InService**. To check the status of an endpoint, use the `DescribeEndpoint` API. For a full list of parameters you can specify when updating an endpoint, see the `UpdateEndpoint` API.

Delete an Asynchronous Endpoint

Delete an asynchronous endpoint in a similar manner to how you would delete a SageMaker AI hosted endpoint with the `DeleteEndpoint` API. Specify the name of the asynchronous endpoint you want to delete. When you delete an endpoint, SageMaker AI frees up all of the resources that

were deployed when the endpoint was created. Deleting a model does not delete model artifacts, inference code, or the IAM role that you specified when creating the model.

Delete your SageMaker AI model with the `DeleteModel` API or with the SageMaker AI console.

Boto3

```
import boto3

# Create a low-level SageMaker service client.
sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)
sagemaker_client.delete_endpoint(EndpointName='<endpoint-name>')
```

SageMaker AI console

1. Navigate to the SageMaker AI console at https://console.aws.amazon.com/sagemaker/.
2. Expand the **Inference** dropdown list.
3. Select **Endpoints**.
4. Search for endpoint in the **Search endpoints** search bar.
5. Select your endpoint.
6. Choose **Delete**.

In addition to deleting the asynchronous endpoint, you might want to clear up other resources that were used to create the endpoint, such as the Amazon ECR repository (if you created a custom inference image), the SageMaker AI model, and the asynchronous endpoint configuration itself.

Alarms and logs for tracking metrics from asynchronous endpoints

You can monitor SageMaker AI using Amazon CloudWatch, which collects raw data and processes it into readable, near real-time metrics. With Amazon CloudWatch, you can access historical information and gain a better perspective on how your web application or service is performing. For more information about Amazon CloudWatch, see What is Amazon CloudWatch?

Monitoring with CloudWatch

The metrics below are an exhaustive list of metrics for asynchronous endpoints and are in the the `AWS/SageMaker` namespace. Any metric not listed below is not published if the endpoint is enabled for asynchronous inference. Such metrics include (but are not limited to):

- OverheadLatency
- Invocations
- InvocationsPerInstance

Common Endpoint Metrics

These metrics are the same as the metrics published for real-time endpoints today. For more information about other metrics in Amazon CloudWatch, see Monitor SageMaker AI with Amazon CloudWatch.

Metric Name	Description	Unit/Stats
`Invocation4XXErrors`	The number of requests where the model returned a 4xx HTTP response code. For each 4xx response, 1 is sent; otherwise, 0 is sent.	Units: None Valid statistics: Average, Sum
`Invocation5XXErrors`	The number of InvokeEnd point requests where the model returned a 5xx HTTP response code. For each 5xx response, 1 is sent; otherwise , 0 is sent.	Units: None Valid statistics: Average, Sum
`ModelLatency`	The interval of time taken by a model to respond as viewed from SageMaker AI. This interval includes the local communication times taken to send the request and to fetch the response from the container of a model and the time taken to complete the inference in the container.	Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count

Asynchronous Inference Endpoint Metrics

These metrics are published for endpoints enabled for asynchronous inference. The following metrics are published with the `EndpointName` dimension:

Metric Name	Description	Unit/Stats
`ApproximateBacklogSize`	The number of items in the queue for an endpoint that are currently being processed or yet to be processed.	Units: Count Valid statistics: Average, Max, Min
`ApproximateBacklogSizePerInstance`	Number of items in the queue divided by the number of instances behind an endpoint. This metric is primarily used for setting up application autoscaling for an async-enabled endpoint.	Units: Count Valid statistics: Average, Max, Min
`ApproximateAgeOfOldestRequest`	Age of the oldest request in the queue.	Units: Seconds Valid statistics: Average, Max, Min
`HasBacklogWithoutCapacity`	The value of this metric is 1 when there are requests in the queue but zero instances behind the endpoint. The value is `0` at all other times. You can use this metric for autoscaling your endpoint up from zero instances upon receiving a new request in the queue.	Units: Count Valid statistics: Average

The following metrics are published with the `EndpointName` and `VariantName` dimensions:

Metric Name	Description	Unit/Stats
RequestDownloadFailures	When an inference failure occurs due to an issue downloading the request from Amazon S3.	Units: Count Valid statistics: Sum
ResponseUploadFailures	When an inference failure occurs due to an issue uploading the response to Amazon S3.	Units: Count Valid statistics: Sum
NotificationFailures	When an issue occurs publishing notifications.	Units: Count Valid statistics: Sum
RequestDownloadLatency	Total time to download the request payload.	Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count
ResponseUploadLatency	Total time to upload the response payload.	Units: Microseconds Valid statistics: Average, Sum, Min, Max, Sample Count
ExpiredRequests	Number of requests in the queue that fail due to reaching their specified request TTL.	Units: Count Valid statistics: Sum
InvocationFailures	If an invocation fails for any reason.	Units: Count Valid statistics: Sum
InvocationsProcessed	Number of async invocations processed by the endpoint.	Units: Count Valid statistics: Sum

Metric Name	Description	Unit/Stats
`TimeInBacklog`	Total time the request was queued before being processed. This does not include the actual processin g time (i.e. downloading time, uploading time, model latency).	Units: Milliseconds Valid statistics: Average, Sum, Min, Max, Sample Count
`TotalProcessingTime`	Time the inference request was recieved by SageMaker AI to the time the request finished processing. This includes time in backlog and time to upload and send response notifications, if any.	Units: Milliseconds Valid statistics: Average, Sum, Min, Max, Sample Count

Amazon SageMaker Asynchronous Inference also includes host-level metrics. For information on host-level metrics, see SageMaker AI Jobs and Endpoint Metrics.

Logs

In addition to the Model container logs that are published to Amazon CloudWatch in your account, you also get a new platform log for tracing and debugging inference requests.

The new logs are published under the Endpoint Log Group:

```
/aws/sagemaker/Endpoints/[EndpointName]
```

The log stream name consists of:

```
[production-variant-name]/[instance-id]/data-log.
```

Log lines contain the request's inference ID so that errors can be easily mapped to a particular request.

Check prediction results

There are several ways you can check predictions results from your asynchronous endpoint. Some options are:

1. Amazon SNS topics.
2. Check for outputs in your Amazon S3 bucket.

Amazon SNS Topics

Amazon SNS is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages via a choice of transport protocols, including HTTP, Amazon SQS, and email. Amazon SageMaker Asynchronous Inference posts notifications when you create an endpoint with `CreateEndpointConfig` and specify an Amazon SNS topic.

> **Note**
>
> In order to receive Amazon SNS notifications, your IAM role must have `sns:Publish` permissions. See the Complete the prerequisites for information on requirements you must satisfy to use Asynchronous Inference.

To use Amazon SNS to check prediction results from your asynchronous endpoint, you first need to create a topic, subscribe to the topic, confirm your subscription to the topic, and note the Amazon Resource Name (ARN) of that topic. For detailed information on how to create, subscribe, and find the Amazon ARN of an Amazon SNS topic, see Configuring Amazon SNS.

Provide the Amazon SNS topic ARN(s) in the `AsyncInferenceConfig` field when you create an endpoint configuration with `CreateEndpointConfig`. You can specify both an Amazon SNS `ErrorTopic` and an `SuccessTopic`.

```
import boto3

sagemaker_client = boto3.client('sagemaker', region_name=<aws_region>)

sagemaker_client.create_endpoint_config(
    EndpointConfigName=<endpoint_config_name>, # You specify this name in a
 CreateEndpoint request.
```

```
    # List of ProductionVariant objects, one for each model that you want to host at
 this endpoint.
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": "model_name",
            "InstanceType": "ml.m5.xlarge", # Specify the compute instance type.
            "InitialInstanceCount": 1 # Number of instances to launch initially.
        }
    ],
    AsyncInferenceConfig={
        "OutputConfig": {
            # Location to upload response outputs when no location is provided in the
 request.
            "S3OutputPath": "s3://<bucket>/<output_directory>"
            "NotificationConfig": {
                "SuccessTopic": "arn:aws:sns:aws-region:account-id:topic-name",
                "ErrorTopic": "arn:aws:sns:aws-region:account-id:topic-name",
            }
        }
    }
)
```

After creating your endpoint and invoking it, you receive a notification from your Amazon SNS topic. For example, if you subscribed to receive email notifications from your topic, you receive an email notification every time you invoke your endpoint. The following example shows the JSON content of a successful invocation email notification.

```
{
   "awsRegion":"us-east-1",
   "eventTime":"2022-01-25T22:46:00.608Z",
   "receivedTime":"2022-01-25T22:46:00.455Z",
   "invocationStatus":"Completed",
   "requestParameters":{
      "contentType":"text/csv",
      "endpointName":"<example-endpoint>",
      "inputLocation":"s3://<bucket>/<input-directory>/input-data.csv"
   },
   "responseParameters":{
      "contentType":"text/csv; charset=utf-8",
      "outputLocation":"s3://<bucket>/<output_directory>/prediction.out"
   },
   "inferenceId":"11111111-2222-3333-4444-555555555555",
```

```
    "eventVersion":"1.0",
    "eventSource":"aws:sagemaker",
    "eventName":"InferenceResult"
}
```

Check Your S3 Bucket

When you invoke an endpoint with `InvokeEndpointAsync`, it returns a response object. You can use the response object to get the Amazon S3 URI where your output is stored. With the output location, you can use a SageMaker Python SDK SageMaker AI session class to programmatically check for on an output.

The following stores the output dictionary of `InvokeEndpointAsync` as a variable named response. With the response variable, you then get the Amazon S3 output URI and store it as a string variable called `output_location`.

```
import uuid
import boto3

sagemaker_runtime = boto3.client("sagemaker-runtime", region_name=<aws_region>)

# Specify the S3 URI of the input. Here, a single SVM sample
input_location = "s3://bucket-name/test_point_0.libsvm"

response = sagemaker_runtime.invoke_endpoint_async(
    EndpointName='<endpoint-name>',
    InputLocation=input_location,
    InferenceId=str(uuid.uuid4()),
    ContentType="text/libsvm" #Specify the content type of your data
)

output_location = response['OutputLocation']
print(f"OutputLocation: {output_location}")
```

For information about supported content types, see Common data formats for inference.

With the Amazon S3 output location, you can then use a SageMaker Python SDK SageMaker AI Session Class to read in Amazon S3 files. The following code example shows how to create a function (`get_ouput`) that repeatedly attempts to read a file from the Amazon S3 output location:

```
from sagemaker.core.helper.session_helper import Session
import urllib, time
```

```
from botocore.exceptions import ClientError

sagemaker_session = Session()

def get_output(output_location):
    output_url = urllib.parse.urlparse(output_location)
    bucket = output_url.netloc
    key = output_url.path[1:]
    while True:
        try:
            return sagemaker_session.read_s3_file(
                                    bucket=output_url.netloc,
                                    key_prefix=output_url.path[1:])
        except ClientError as e:
            if e.response['Error']['Code'] == 'NoSuchKey':
                print("waiting for output...")
                time.sleep(2)
                continue
            raise

output = get_output(output_location)
print(f"Output: {output}")
```

Autoscale an asynchronous endpoint

Amazon SageMaker AI supports automatic scaling (autoscaling) your asynchronous endpoint. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. Unlike other hosted models Amazon SageMaker AI supports, with Asynchronous Inference you can also scale down your asynchronous endpoints instances to zero. Requests that are received when there are zero instances are queued for processing once the endpoint scales up.

To autoscale your asynchronous endpoint you must at a minimum:

- Register a deployed model (production variant).
- Define a scaling policy.
- Apply the autoscaling policy.

Before you can use autoscaling, you must have already deployed a model to a SageMaker AI endpoint. Deployed models are referred to as a production variant. See Deploy the Model to

SageMaker Hosting Services for more information about deploying a model to an endpoint. To specify the metrics and target values for a scaling policy, you configure a scaling policy. For information on how to define a scaling policy, see Define a scaling policy. After registering your model and defining a scaling policy, apply the scaling policy to the registered model. For information on how to apply the scaling policy, see Apply a scaling policy.

For more information on how to define an optional additional scaling policy that scales up your endpoint upon receiving a request after your endpoint has been scaled down to zero, see Optional: Define a scaling policy that scales up from zero for new requests. If you don't specify this optional policy, then your endpoint only initiates scaling up from zero after the number of backlog requests exceeds the target tracking value.

For details on other prerequisites and components used with autoscaling, see the Prerequisites section in the SageMaker AI autoscaling documentation.

> **Note**
>
> If you attach multiple scaling policies to the same autoscaling group, you might have scaling conflicts. When a conflict occurs, Amazon EC2 Auto Scaling chooses the policy that provisions the largest capacity for both scale out and scale in. For more information about this behavior, see Multiple dynamic scaling policies in the *Amazon EC2 Auto Scaling documentation*.

Define a scaling policy

To specify the metrics and target values for a scaling policy, you configure a target-tracking scaling policy. Define the scaling policy as a JSON block in a text file. You use that text file when invoking the Amazon CLI or the Application Auto Scaling API. For more information about policy configuration syntax, see `TargetTrackingScalingPolicyConfiguration` in the Application Auto Scaling API Reference.

For asynchronous endpoints SageMaker AI strongly recommends that you create a policy configuration for target-tracking scaling for a variant. In this configuration example, we use a custom metric, `CustomizedMetricSpecification`, called `ApproximateBacklogSizePerInstance`.

```
TargetTrackingScalingPolicyConfiguration={
```

```
        'TargetValue': 5.0, # The target value for the metric. Here the metric is:
 ApproximateBacklogSizePerInstance
        'CustomizedMetricSpecification': {
            'MetricName': 'ApproximateBacklogSizePerInstance',
            'Namespace': 'AWS/SageMaker',
            'Dimensions': [
                {'Name': 'EndpointName', 'Value': <endpoint_name> }
            ],
            'Statistic': 'Average',
        }
    }
```

Define a scaling policy that scales to zero

The following shows you how to both define and register your endpoint variant with application autoscaling using the Amazon SDK for Python (Boto3). After defining a low-level client object representing application autoscaling with Boto3, we use the `RegisterScalableTarget` method to register the production variant. We set `MinCapacity` to 0 because Asynchronous Inference enables you to autoscale to 0 when there are no requests to process.

```
# Common class representing application autoscaling for SageMaker
client = boto3.client('application-autoscaling')

# This is the format in which application autoscaling references the endpoint
resource_id='endpoint/' + <endpoint_name> + '/variant/' + <'variant1'>

# Define and register your endpoint variant
response = client.register_scalable_target(
    ServiceNamespace='sagemaker',
    ResourceId=resource_id,
    ScalableDimension='sagemaker:variant:DesiredInstanceCount', # The number of EC2
 instances for your Amazon SageMaker model endpoint variant.
    MinCapacity=0,
    MaxCapacity=5
)
```

For detailed description about the Application Autoscaling API, see the Application Scaling Boto3 documentation.

Optional: Define a scaling policy that scales up from zero for new requests

You might have a use case where you have sporadic requests or periods with low numbers of requests. If your endpoint has been scaled down to zero instances during these periods, then your endpoint won't scale up again until the number of requests in the queue exceeds the target specified in your scaling policy. This can result in long waiting times for requests in the queue. The following section shows you how to create an additional scaling policy that scales your endpoint up from zero instances after receiving any new request in the queue. Your endpoint will be able to respond to new requests more quickly instead of waiting for the queue size to exceed the target.

To create a scaling policy for your endpoint that scales up from zero instances, do the following:

1. Create a scaling policy that defines the desired behavior, which is to scale up your endpoint when it's at zero instances but has requests in the queue. The following shows you how to define a scaling policy called `HasBacklogWithoutCapacity-ScalingPolicy` using the Amazon SDK for Python (Boto3). When the queue is greater than zero and the current instance count for your endpoint is also zero, the policy scales your endpoint up. In all other cases, the policy does not affect scaling for your endpoint.

```
response = client.put_scaling_policy(
    PolicyName="HasBacklogWithoutCapacity-ScalingPolicy",
    ServiceNamespace="sagemaker",  # The namespace of the service that provides the
 resource.
    ResourceId=resource_id,  # Endpoint name
    ScalableDimension="sagemaker:variant:DesiredInstanceCount",  # SageMaker
 supports only Instance Count
    PolicyType="StepScaling",  # 'StepScaling' or 'TargetTrackingScaling'
    StepScalingPolicyConfiguration={
        "AdjustmentType": "ChangeInCapacity", # Specifies whether the
 ScalingAdjustment value in the StepAdjustment property is an absolute number or a
 percentage of the current capacity.
        "MetricAggregationType": "Average", # The aggregation type for the
 CloudWatch metrics.
        "Cooldown": 300, # The amount of time, in seconds, to wait for a previous
 scaling activity to take effect.
        "StepAdjustments": # A set of adjustments that enable you to scale based on
 the size of the alarm breach.
        [
            {
              "MetricIntervalLowerBound": 0,
              "ScalingAdjustment": 1
```

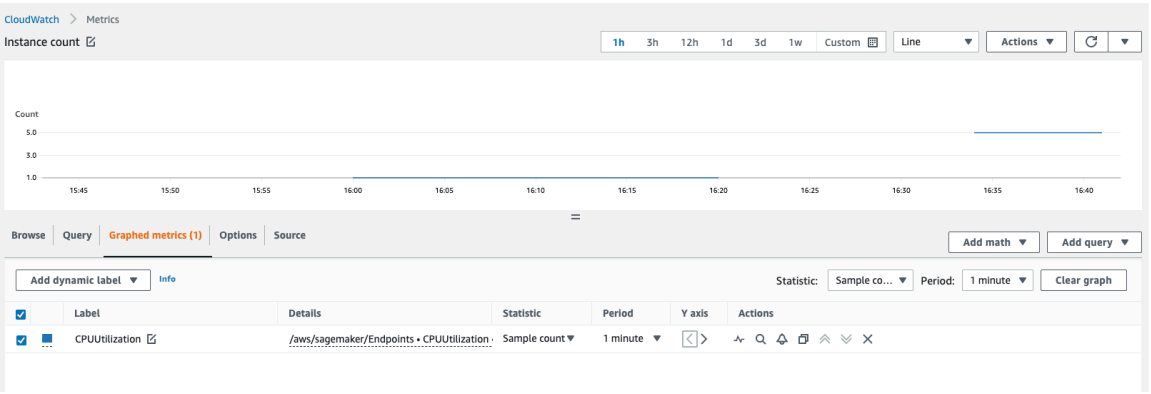
```
            }
        ]
    },
)
```

2. Create a CloudWatch alarm with the custom metric `HasBacklogWithoutCapacity`. When triggered, the alarm initiates the previously defined scaling policy. For more information about the `HasBacklogWithoutCapacity` metric, see Asynchronous Inference Endpoint Metrics.

```
response = cw_client.put_metric_alarm(
    AlarmName=step_scaling_policy_alarm_name,
    MetricName='HasBacklogWithoutCapacity',
    Namespace='AWS/SageMaker',
    Statistic='Average',
    EvaluationPeriods= 2,
    DatapointsToAlarm= 2,
    Threshold= 1,
    ComparisonOperator='GreaterThanOrEqualToThreshold',
    TreatMissingData='missing',
    Dimensions=[
        { 'Name':'EndpointName', 'Value':endpoint_name },
    ],
    Period= 60,
    AlarmActions=[step_scaling_policy_arn]
)
```

You should now have a scaling policy and CloudWatch alarm that scale up your endpoint from zero instances whenever your queue has pending requests.

Troubleshooting



The following FAQs can help you troubleshoot issues with your Amazon SageMaker Asynchronous Inference endpoints.

Q: I have autoscaling enabled. How can I find the instance count behind the endpoint at any given point?

You can use the following methods to find the instance count behind your endpoint:

- You can use the SageMaker AI DescribeEndpoint API to describe the number of instances behind the endpoint at any given point in time.

- You can get the instance count by viewing your Amazon CloudWatch metrics. View the metrics for your endpoint instances, such as `CPUUtilization` or `MemoryUtilization` and check the sample count statistic for a 1 minute period. The count should be equal to the number of active instances. The following screenshot shows the `CPUUtilization` metric graphed in the CloudWatch console, where the **Statistic** is set to `Sample count`, the **Period** is set to `1 minute`, and the resulting count is 5.

Q: What are the common tunable environment variables for SageMaker AI containers?

The following tables outline the common tunable environment variables for SageMaker AI containers by framework type.

TensorFlow

Environment variable	Description
`SAGEMAKER_TFS_INSTANCE_COUNT`	For TensorFlow-based models, the `tensorflow_model_server` binary is the operational piece that is responsible for loading a model in memory, running inputs against a model graph, and deriving outputs. Typically, a single instance of this binary is launched to serve models in an endpoint. This binary is internally multi-threaded and spawns multiple threads to respond to an inference request. In certain instances, if you observe that the CPU is respectably utilized (over 30% utilized) but the memory is underutilized (less than 10%

Environment variable	Description
	utilization), increasing this parameter might help. Increasing the number of `tensorflow_model_servers` available to serve typically increases the throughput of an endpoint.
`SAGEMAKER_TFS_FRACTIONAL_GPU_MEM_MARGIN`	This parameter governs the fraction of the available GPU memory to initialize CUDA/cuDNN and other GPU libraries. `0.2` means 20% of the available GPU memory is reserved for initializing CUDA/cuDNN and other GPU libraries, and 80% of the available GPU memory is allocated equally across the TF processes. GPU memory is pre-allocated unless the `allow_growth` option is enabled.
`SAGEMAKER_TFS_INTER_OP_PARALLELISM`	This ties back to the `inter_op_parallelism_threads` variable. This variable determines the number of threads used by independent non-blocking operations. `0` means that the system picks an appropriate number.
`SAGEMAKER_TFS_INTRA_OP_PARALLELISM`	This ties back to the `intra_op_parallelism_threads` variable. This determines the number of threads that can be used for certain operations like matrix multiplication and reductions for speedups. A value of `0` means that the system picks an appropriate number.

Environment variable	Description
SAGEMAKER_GUNICORN_WORKERS	This governs the number of worker processes that Gunicorn is requested to spawn for handling requests. This value is used in combination with other parameters to derive a set that maximizes inference throughput. In addition to this, the SAGEMAKER_GUNICORN_WORKER_CLASS governs the type of workers spawned, typically async or gevent.
SAGEMAKER_GUNICORN_WORKER_CLASS	This governs the number of worker processes that Gunicorn is requested to spawn for handling requests. This value is used in combination with other parameters to derive a set that maximizes inference throughput. In addition to this, the SAGEMAKER_GUNICORN_WORKER_CLASS governs the type of workers spawned, typically async or gevent.
OMP_NUM_THREADS	Python internally uses OpenMP for implementing multithreading within processes. Typically, threads equivalent to the number of CPU cores are spawned. But when implemented on top of Simultaneous Multi Threading (SMT), such Intel's HypeThreading, a certain process might oversubscribe a particular core by spawning twice as many threads as the number of actual CPU cores. In certain cases, a Python binary might end up spawning up to four times as many threads as available processor cores. Therefore, an ideal setting for this parameter, if you have oversubscribed available cores using worker threads, is 1, or half the number of CPU cores on a CPU with SMT turned on.

Environment variable	Description
TF_DISABLE_MKL TF_DISABLE_POOL_ALLOCATOR	In some cases, turning off MKL can speed up inference if TF_DISABLE_MKL and TF_DISABLE_POOL_ALLOCATOR are set to 1.

PyTorch

Environment variable	Description
SAGEMAKER_TS_MAX_BATCH_DELAY	This is the maximum batch delay time TorchServe waits to receive.
SAGEMAKER_TS_BATCH_SIZE	If TorchServe doesn't receive the number of requests specified in batch_size before the timer runs out, it sends the requests that were received to the model handler.
SAGEMAKER_TS_MIN_WORKERS	The minimum number of workers to which TorchServe is allowed to scale down.
SAGEMAKER_TS_MAX_WORKERS	The maximum number of workers to which TorchServe is allowed to scale up.
SAGEMAKER_TS_RESPONSE_TIMEOUT	The time delay, after which inference times out in absence of a response.
SAGEMAKER_TS_MAX_REQUEST_SIZE	The maximum payload size for TorchServe.
SAGEMAKER_TS_MAX_RESPONSE_SIZE	The maximum response size for TorchServe.

Multi Model Server (MMS)

Environment variable	Description
`job_queue_size`	This parameter is useful to tune when you have a scenario where the type of the inference request payload is large, and due to the size of payload being larger, you may have higher heap memory consumption of the JVM in which this queue is being maintaine d. Ideally you might want to keep the heap memory requirements of JVM lower and allow Python workers to allot more memory for actual model serving. JVM is only for receiving the HTTP requests, queuing them, and dispatching them to the Python-ba sed workers for inference. If you increase the `job_queue_size` , you might end up increasing the heap memory consumption of the JVM and ultimately taking away memory from the host that could have been used by Python workers. Therefore, exercise caution when tuning this parameter as well.
`default_workers_per_model`	This parameter is for the backend model serving and might be valuable to tune since this is the critical component of the overall model serving, based on which the Python processes spawn threads for each Model. If this component is slower (or not tuned properly), the front-end tuning might not be effective.

Q: How do I make sure my container supports Asynchronous Inference?

You can use the same container for Asynchronous Inference that you do for Real-Time Inference or Batch Transform. You should confirm that the timeouts and payload size limits on your container are set to handle larger payloads and longer timeouts.

Q: What are the limits specific to Asynchronous Inference, and can they be adjusted?

Refer to the following limits for Asynchronous Inference:

- Payload size limit: 1 GB
- Timeout limit: A request can take up to 60 minutes.
- Queue message TimeToLive (TTL): 6 hours
- Number of messages that can be put inside Amazon SQS: Unlimited. However, there is a quota of 120,000 for the number of in-flight messages for a standard queue, and 20,000 for a FIFO queue.

Q: What metrics are best to define for autoscaling on Asynchronous Inference? Can I have multiple scaling policies?

In general, with Asynchronous Inference, you can scale out based on invocations or instances. For invocation metrics, it's a good idea to look at your `ApproximateBacklogSize`, which is a metric that defines the number of items in your queue that have yet to been processed. You can utilize this metric or your `InvocationsPerInstance` metric to understand what TPS you may be getting throttled at. At the instance level, check your instance type and its CPU/GPU utilization to define when to scale out. If a singular instance is above 60-70% capacity, this is often a good sign that you are saturating your hardware.

We don't recommend having multiple scaling policies, as these can conflict and lead to confusion at the hardware level, causing delays when scaling out.

Q: Why is my asynchronous endpoint terminating an instance as `Unhealthy` and the update requests from autoscaling are failing?

Check if your container is able to handle ping and invoke requests concurrently. SageMaker AI invoke requests take approximately 3 minutes, and in this duration, usually multiple ping requests end up failing due to the timeout causing SageMaker AI to detect your container as `Unhealthy`.

Q: Can `MaxConcurrentInvocationsPerInstance` work for my BYOC model container with the ningx/gunicorn/flask settings?

Yes. `MaxConcurrentInvocationsPerInstance` is a feature of asynchronous endpoints. This does not depend on the custom container implementation. `MaxConcurrentInvocationsPerInstance` controls the rate at which invoke requests are sent

to the customer container. If this value is set as 1, then only 1 request is sent to the container at a time, no matter how many workers are on the customer container.

Q: How can I debug model server errors (500) on my asynchronous endpoint?

The error means that the customer container returned an error. SageMaker AI does not control the behavior of customer containers. SageMaker AI simply returns the response from the `ModelContainer` and does not retry. If you want, you can configure the invocation to retry on failure. We suggest that you turn on container logging and check your container logs to find the root cause of the 500 error from your model. Check the corresponding `CPUUtilization` and `MemoryUtilization` metrics at the point of failure as well. You can also configure the S3FailurePath to the model response in Amazon SNS as part of the Async Error Notifications to investiage failures.

Q: How can I know if `MaxConcurrentInvocationsPerInstance=1` takes effect? Are there any metrics that I can check?

You can check the metric `InvocationsProcesssed`, which should align with the number of invocations that you expect to be processed in a minute based on single concurrency.

Q: How can I track the success and failures of my invocation requests? What are the best practices?

The best practice is to enable Amazon SNS, which is a notification service for messaging-oriented applications, with multiple subscribers requesting and receiving "push" notifications of time-critical messages from a choice of transport protocols, including HTTP, Amazon SQS, and email. Asynchronous Inference posts notifications when you create an endpoint with `CreateEndpointConfig` and specify an Amazon SNS topic.

To use Amazon SNS to check prediction results from your asynchronous endpoint, you first need to create a topic, subscribe to the topic, confirm your subscription to the topic, and note the Amazon Resource Name (ARN) of that topic. For detailed information on how to create, subscribe, and find the Amazon ARN of an Amazon SNS topic, see Configuring Amazon SNS in the *Amazon SNS Developer Guide*. For more information about how to use Amazon SNS with Asynchronous Inference, see Check prediction results.

Q: Can I define a scaling policy that scales up from zero instances upon receiving a new request?

Yes. Asynchronous Inference provides a mechanism to scale down to zero instances when there are no requests. If your endpoint has been scaled down to zero instances during these periods, then

your endpoint won't scale up again until the number of requests in the queue exceeds the target specified in your scaling policy. This can result in long waiting times for requests in the queue. In such cases, if you want to scale up from zero instances for new requests less than the queue target specified, you can use an additional scaling policy called `HasBacklogWithoutCapacity`. For more information about how to define this scaling policy, see Autoscale an asynchronous endpoint.

Q: I'm getting an error that the instance type is not supported for Asynchronous Inference. What are the instance types Asynchronous Inference supports?

For an exhaustive list of instances supported by Asynchronous Inference per region, see SageMaker pricing. Check if the required instance is available in your region before proceeding.

Batch transform for inference with Amazon SageMaker AI

Use batch transform when you need to do the following:

- Preprocess datasets to remove noise or bias that interferes with training or inference from your dataset.
- Get inferences from large datasets.
- Run inference when you don't need a persistent endpoint.
- Associate input records with inferences to help with the interpretation of results.

To filter input data before performing inferences or to associate input records with inferences about those records, see Associate Prediction Results with Input Records. For example, you can filter input data to provide context for creating and interpreting reports about the output data.

- Troubleshooting

Use batch transform to get inferences from large datasets

Batch transform automatically manages the processing of large datasets within the limits of specified parameters. For example, having a dataset file, `input1.csv`, stored in an S3 bucket. The content of the input file might look like the following example.

```
Record1-Attribute1, Record1-Attribute2, Record1-Attribute3, ..., Record1-AttributeM
Record2-Attribute1, Record2-Attribute2, Record2-Attribute3, ..., Record2-AttributeM
Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM
...
RecordN-Attribute1, RecordN-Attribute2, RecordN-Attribute3, ..., RecordN-AttributeM
```

When a batch transform job starts, SageMaker AI starts compute instances and distributes the inference or preprocessing workload between them. Batch Transform partitions the Amazon S3 objects in the input by key and maps Amazon S3 objects to instances. When you have multiple files, one instance might process `input1.csv`, and another instance might process the file named `input2.csv`. If you have one input file but initialize multiple compute instances, only one instance processes the input file. The rest of the instances are idle.

You can also split input files into mini-batches. For example, you might create a mini-batch from `input1.csv` by including only two of the records.

```
Record3-Attribute1, Record3-Attribute2, Record3-Attribute3, ..., Record3-AttributeM
Record4-Attribute1, Record4-Attribute2, Record4-Attribute3, ..., Record4-AttributeM
```

> **Note**
>
> SageMaker AI processes each input file separately. It doesn't combine mini-batches from different input files to comply with the `MaxPayloadInMB` limit.

To split input files into mini-batches when you create a batch transform job, set the `SplitType` parameter value to `Line`. SageMaker AI uses the entire input file in a single request when:

- `SplitType` is set to None.
- An input file can't be split into mini-batches.

. Note that Batch Transform doesn't support CSV-formatted input that contains embedded newline characters. You can control the size of the mini-batches by using the `BatchStrategy` and `MaxPayloadInMB` parameters. `MaxPayloadInMB` must not be greater than 100 MB. If you specify the optional `MaxConcurrentTransforms` parameter, then the value of `(MaxConcurrentTransforms * MaxPayloadInMB)` must also not exceed 100 MB.

If the batch transform job successfully processes all of the records in an input file, it creates an output file. The output file has the same name and the `.out` file extension. For multiple input files, such as `input1.csv` and `input2.csv`, the output files are named `input1.csv.out` and `input2.csv.out`. The batch transform job stores the output files in the specified location in Amazon S3, such as `s3://amzn-s3-demo-bucket/output/`.

The predictions in an output file are listed in the same order as the corresponding records in the input file. The output file `input1.csv.out`, based on the input file shown earlier, would look like the following.

```
Inference1-Attribute1, Inference1-Attribute2, Inference1-Attribute3, ..., Inference1-
AttributeM
Inference2-Attribute1, Inference2-Attribute2, Inference2-Attribute3, ..., Inference2-
AttributeM
Inference3-Attribute1, Inference3-Attribute2, Inference3-Attribute3, ..., Inference3-
AttributeM
...
InferenceN-Attribute1, InferenceN-Attribute2, InferenceN-Attribute3, ..., InferenceN-
AttributeM
```

If you set `SplitType` to `Line`, you can set the `AssembleWith` parameter to `Line` to concatenate the output records with a line delimiter. This does not change the number of output files. The number of output files is equal to the number of input files, and using `AssembleWith` does not merge files. If you don't specify the `AssembleWith` parameter, the output records are concatenated in a binary format by default.

When the input data is very large and is transmitted using HTTP chunked encoding, to stream the data to the algorithm, set `MaxPayloadInMB` to `0`. Amazon SageMaker AI built-in algorithms don't support this feature.

For information about using the API to create a batch transform job, see the `CreateTransformJob` API. For more information about the relationship between batch transform input and output objects, see `OutputDataConfig`. For an example of how to use batch transform, see (Optional) Make Prediction with Batch Transform.

Speed up a batch transform job

If you are using the `CreateTransformJob` API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters. This includes parameters such as `MaxPayloadInMB`, `MaxConcurrentTransforms`, or `BatchStrategy`. The ideal value for `MaxConcurrentTransforms` is equal to the number of compute workers in the batch transform job.

If you are using the SageMaker AI console, specify these optimal parameter values in the **Additional configuration** section of the **Batch transform job configuration** page. SageMaker AI automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an execution-parameters endpoint.

Use batch transform to test production variants

To test different models or hyperparameter settings, create a separate transform job for each new model variant and use a validation dataset. For each transform job, specify a unique model name and location in Amazon S3 for the output file. To analyze the results, use Inference Pipeline Logs and Metrics.

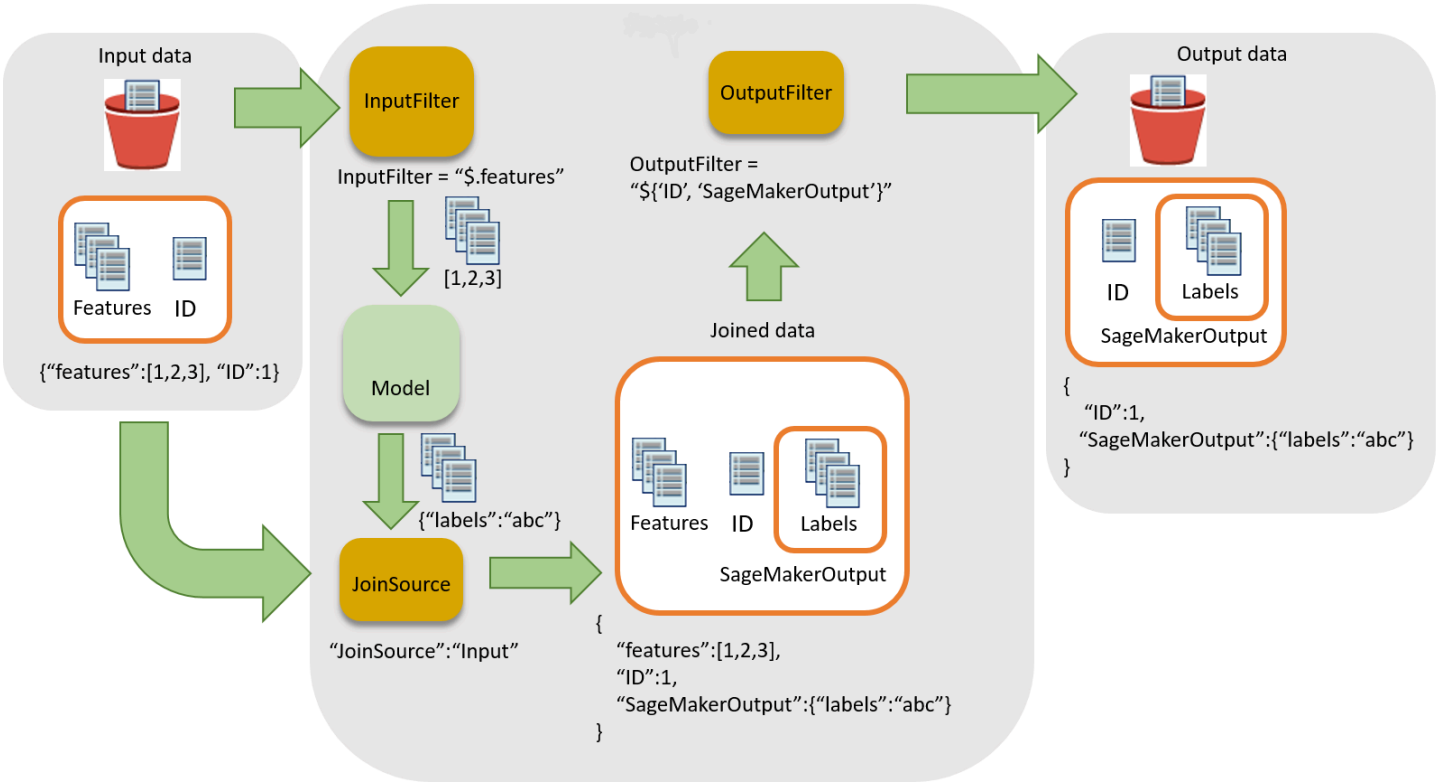
Batch transform sample notebooks

For sample notebook that uses batch transform, see Batch Transform with PCA and DBSCAN Movie Clusters. This notebook uses batch transform with a principal component analysis (PCA) model to reduce data in a user-item review matrix. It then shows the application of a density-based spatial clustering of applications with noise (DBSCAN) algorithm to cluster movies.

For instructions on creating and accessing Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After creating and opening a notebook instance, choose the **SageMaker Examples** tab to see a list of all the SageMaker AI examples. The topic modeling example notebooks that use the NTM algorithms are located in the **Advanced functionality** section. To open a notebook, choose its **Use** tab, then choose **Create copy**.

Associate Prediction Results with Input Records

When making predictions on a large dataset, you can exclude attributes that aren't needed for prediction. After the predictions have been made, you can associate some of the excluded attributes with those predictions or with other input data in your report. By using batch transform



to perform these data processing steps, you can often eliminate additional preprocessing or postprocessing. You can use input files in JSON and CSV format only.

- Supported JSONPath Operators
- Batch Transform Examples

Workflow for Associating Inferences with Input Records

The following diagram shows the workflow for associating inferences with input records.

To associate inferences with input data, there are three main steps:

1. Filter the input data that is not needed for inference before passing the input data to the batch transform job. Use the `InputFilter` parameter to determine which attributes to use as input for the model.
2. Associate the input data with the inference results. Use the `JoinSource` parameter to combine the input data with the inference.

3. Filter the joined data to retain the inputs that are needed to provide context for interpreting the predictions in the reports. Use `OutputFilter` to store the specified portion of the joined dataset in the output file.

Use Data Processing in Batch Transform Jobs

When creating a batch transform job with `CreateTransformJob` to process data:

1. Specify the portion of the input to pass to the model with the `InputFilter` parameter in the `DataProcessing` data structure.
2. Join the raw input data with the transformed data with the `JoinSource` parameter.
3. Specify which portion of the joined input and transformed data from the batch transform job to include in the output file with the `OutputFilter` parameter.
4. Choose either JSON- or CSV-formatted files for input:
   - For JSON- or JSON Lines-formatted input files, SageMaker AI either adds the `SageMakerOutput` attribute to the input file or creates a new JSON output file with the `SageMakerInput` and `SageMakerOutput` attributes. For more information, see `DataProcessing`.
   - For CSV-formatted input files, the joined input data is followed by the transformed data and the output is a CSV file.

If you use an algorithm with the `DataProcessing` structure, it must support your chosen format for *both* input and output files. For example, with the `TransformOutput` field of the `CreateTransformJob` API, you must set both the `ContentType` and `Accept` parameters to one of the following values: `text/csv`, `application/json`, or `application/jsonlines`. The syntax for specifying columns in a CSV file and specifying attributes in a JSON file are different. Using the wrong syntax causes an error. For more information, see Batch Transform Examples. For more information about input and output file formats for built-in algorithms, see Built-in algorithms and pretrained models in Amazon SageMaker.

The record delimiters for the input and output must also be consistent with your chosen file input. The `SplitType` parameter indicates how to split the records in the input dataset. The `AssembleWith` parameter indicates how to reassemble the records for the output. If you set input and output formats to `text/csv`, you must also set the `SplitType` and `AssembleWith` parameters to `line`. If you set the input and output formats to `application/jsonlines`, you can set both `SplitType` and `AssembleWith` to `line`.

For CSV files, you cannot use embedded newline characters. For JSON files, the attribute name `SageMakerOutput` is reserved for output. The JSON input file can't have an attribute with this name. If it does, the data in the input file might be overwritten.

Supported JSONPath Operators

To filter and join the input data and inference, use a JSONPath subexpression. SageMaker AI supports only a subset of the defined JSONPath operators. The following table lists the supported JSONPath operators. For CSV data, each row is taken as a JSON array, so only index based JSONPaths can be applied, e.g. `$[0]`, `$[1:]`. CSV data should also follow RFC format.

JSONPath Operator	Description	Example
$	The root element to a query. This operator is required at the beginning of all path expressions.	$
.*<name>*	A dot-notated child element.	$.id
*	A wildcard. Use in place of an attribute name or numeric value.	$.id.*
['*<name>*' (,'*<na*	A bracket-notated element or multiple child elements.	$['id','SageMakerOutput']
[*<number>* (,*<number>*)]	An index or array of indexes. Negative index values are also supported. A -1 index refers to the last element in an array.	$[1], $[1,3,5]
[*<start>*:*<end>*]	An array slice operator. The array slice() method extracts a section of an array and returns a new array. If you omit *<start>*, SageMaker AI uses the first element of the array. If you omit *<end>*, SageMaker AI uses the last element of the array.	$[2:5], $[:5], $[2:]

When using the bracket-notation to specify multiple child elements of a given field, additional nesting of children within brackets is not supported. For example, `$.field1.['child1','child2']` is supported while `$.field1.['child1','child2.grandchild']` is not.

For more information about JSONPath operators, see JsonPath on GitHub.

Batch Transform Examples

The following examples show some common ways to join input data with prediction results.

Topics

- Example: Output Only Inferences
- Example: Output Inferences Joined with Input Data
- Example: Output Inferences Joined with Input Data and Exclude the ID Column from the Input (CSV)
- Example: Output Inferences Joined with an ID Column and Exclude the ID Column from the Input (CSV)

Example: Output Only Inferences

By default, the `DataProcessing` parameter doesn't join inference results with input. It outputs only the inference results.

If you want to explicitly specify to not join results with input, use the Amazon SageMaker Python SDK and specify the following settings in a transformer call.

```
sm_transformer = sagemaker.transformer.Transformer(…)
sm_transformer.transform(…, input_filter="$", join_source= "None", output_filter="$")
```

To output inferences using the Amazon SDK for Python, add the following code to your CreateTransformJob request. The following code mimics the default behavior.

```
{
    "DataProcessing": {
        "InputFilter": "$",
        "JoinSource": "None",
        "OutputFilter": "$"
    }
```

```
}
```

Example: Output Inferences Joined with Input Data

If you're using the Amazon SageMaker Python SDK to combine the input data with the inferences in the output file, specify the `assemble_with` and `accept` parameters when initializing the transformer object. When you use the transform call, specify `Input` for the `join_source` parameter, and specify the `split_type` and `content_type` parameters as well. The `split_type` parameter must have the same value as `assemble_with`, and the `content_type` parameter must have the same value as `accept`. For more information about the parameters and their accepted values, see the Transformer page in the *Amazon SageMaker AI Python SDK*.

```
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line",
 accept="text/csv")
sm_transformer.transform(…, join_source="Input", split_type="Line", content_type="text/
csv")
```

If you're using the Amazon SDK for Python (Boto 3), join all input data with the inference by adding the following code to your `CreateTransformJob` request. The values for `Accept` and `ContentType` must match, and the values for `AssembleWith` and `SplitType` must also match.

```
{
    "DataProcessing": {
        "JoinSource": "Input"
    },
    "TransformOutput": {
        "Accept": "text/csv",
        "AssembleWith": "Line"
    },
    "TransformInput": {
        "ContentType": "text/csv",
        "SplitType": "Line"
    }
}
```

For JSON or JSON Lines input files, the results are in the `SageMakerOutput` key in the input JSON file. For example, if the input is a JSON file that contains the key-value pair `{"key":1}`, the data transform result might be `{"label":1}`.

SageMaker AI stores both in the input file in the `SageMakerInput` key.

```
{
    "key":1,
    "SageMakerOutput":{"label":1}
}
```

> **Note**
>
> The joined result for JSON must be a key-value pair object. If the input isn't a key-value pair object, SageMaker AI creates a new JSON file. In the new JSON file, the input data is stored in the `SageMakerInput` key and the results are stored as the `SageMakerOutput` value.

For a CSV file, for example, if the record is `[1,2,3]`, and the label result is `[1]`, then the output file would contain `[1,2,3,1]`.

Example: Output Inferences Joined with Input Data and Exclude the ID Column from the Input (CSV)

If you are using the Amazon SageMaker Python SDK to join your input data with the inference output while excluding an ID column from the transformer input, specify the same parameters from the preceding example as well as a JSONPath subexpression for the `input_filter` in your transformer call. For example, if your input data includes five columns and the first one is the ID column, use the following transform request to select all columns except the ID column as features. The transformer still outputs all of the input columns joined with the inferences. For more information about the parameters and their accepted values, see the Transformer page in the *Amazon SageMaker AI Python SDK*.

```
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line",
 accept="text/csv")
sm_transformer.transform(…, split_type="Line", content_type="text/csv",
 input_filter="$[1:]", join_source="Input")
```

If you are using the Amazon SDK for Python (Boto 3), add the following code to your `CreateTransformJob` request.

```
{
    "DataProcessing": {
        "InputFilter": "$[1:]",
```

```
        "JoinSource": "Input"
    },
    "TransformOutput": {
        "Accept": "text/csv",
        "AssembleWith": "Line"
    },
    "TransformInput": {
        "ContentType": "text/csv",
        "SplitType": "Line"
    }
}
```

To specify columns in SageMaker AI, use the index of the array elements. The first column is index 0, the second column is index 1, and the sixth column is index 5.

To exclude the first column from the input, set `InputFilter` to `"$[1:]"`. The colon (`:`) tells SageMaker AI to include all of the elements between two values, inclusive. For example, `$[1:4]` specifies the second through fifth columns.

If you omit the number after the colon, for example, `[5:]`, the subset includes all columns from the 6th column through the last column. If you omit the number before the colon, for example, `[:5]`, the subset includes all columns from the first column (index 0) through the sixth column.

Example: Output Inferences Joined with an ID Column and Exclude the ID Column from the Input (CSV)

If you are using the Amazon SageMaker Python SDK, you can specify the output to join only specific input columns (such as the ID column) with the inferences by specifying the `output_filter` in the transformer call. The `output_filter` uses a JSONPath subexpression to specify which columns to return as output after joining the input data with the inference results. The following request shows how you can make predictions while excluding an ID column and then join the ID column with the inferences. Note that in the following example, the last column (`-1`) of the output contains the inferences. If you are using JSON files, SageMaker AI stores the inference results in the attribute `SageMakerOutput`. For more information about the parameters and their accepted values, see the Transformer page in the *Amazon SageMaker AI Python SDK*.

```
sm_transformer = sagemaker.transformer.Transformer(…, assemble_with="Line",
 accept="text/csv")
sm_transformer.transform(…, split_type="Line", content_type="text/csv",
 input_filter="$[1:]", join_source="Input", output_filter="$[0,-1]")
```

If you are using the Amazon SDK for Python (Boto 3), join only the ID column with the inferences by adding the following code to your `CreateTransformJob` request.

```
{
    "DataProcessing": {
        "InputFilter": "$[1:]",
        "JoinSource": "Input",
        "OutputFilter": "$[0,-1]"
    },
    "TransformOutput": {
        "Accept": "text/csv",
        "AssembleWith": "Line"
    },
    "TransformInput": {
        "ContentType": "text/csv",
        "SplitType": "Line"
    }
}
```

Warning

If you are using a JSON-formatted input file, the file can't contain the attribute name `SageMakerOutput`. This attribute name is reserved for the inferences in the output file. If your JSON-formatted input file contains an attribute with this name, values in the input file might be overwritten with the inference.

Storage in Batch Transform

When you run a batch transform job, Amazon SageMaker AI attaches an Amazon Elastic Block Store storage volume to Amazon EC2 instances that process your job. The volume stores your model, and the size of the storage volume is fixed at 30 GB. You have the option to encrypt your model at rest in the storage volume.

Note

If you have a large model, you may encounter an `InternalServerError`.

For more information about Amazon EBS storage and features, see the following pages:

- Amazon EBS in the Amazon EC2 User Guide
- Amazon EBS volumes in the Amazon EC2 User Guide

> **Note**
>
> G4dn instances come with their own local SSD storage. To learn more about G4dn instances, see the Amazon EC2 G4 Instances page.

Troubleshooting

If you are having errors in Amazon SageMaker AI Batch Transform, refer to the following troubleshooting tips.

Max timeout errors

If you are getting max timeout errors when running batch transform jobs, try the following:

- Begin with the single-record `BatchStrategy`, a batch size of the default (6 MB) or smaller which you specify in the `MaxPayloadInMB` parameter, and a small sample dataset. Tune the maximum timeout parameter `InvocationsTimeoutInSeconds` (which has a maximum of 1 hour) until you receive a successful invocation response.
- After you receive a successful invocation response, increase the `MaxPayloadInMB` (which has a maximum of 100 MB) and the `InvocationsTimeoutInSeconds` parameters together to find the maximum batch size that can support your desired model timeout. You can use either the single-record or multi-record `BatchStrategy` in this step.

  > **Note**
  >
  > Exceeding the `MaxPayloadInMB` limit causes an error. This might happen with a large dataset if it can't be split, the `SplitType` parameter is set to none, or individual records within the dataset exceed the limit.

- (Optional) Tune the `MaxConcurrentTransforms` parameter, which specifies the maximum number of parallel requests that can be sent to each instance in a batch transform job. However, the value of `MaxConcurrentTransforms * MaxPayloadInMB` must not exceed 100 MB.

Incomplete output

SageMaker AI uses the Amazon S3 Multipart Upload API to upload results from a batch transform job to Amazon S3. If an error occurs, the uploaded results are removed from Amazon S3. In some cases, such as when a network outage occurs, an incomplete multipart upload might remain in Amazon S3. An incomplete upload might also occur if you have multiple input files but some of the files can't be processed by SageMaker AI Batch Transform. The input files that couldn't be processed won't have corresponding output files in Amazon S3.

To avoid incurring storage charges, we recommend that you add the S3 bucket policy to the S3 bucket lifecycle rules. This policy deletes incomplete multipart uploads that might be stored in the S3 bucket. For more information, see Object Lifecycle Management.

Job shows as `failed`

If a batch transform job fails to process an input file because of a problem with the dataset, SageMaker AI marks the job as `failed`. If an input file contains a bad record, the transform job doesn't create an output file for that input file because doing so prevents it from maintaining the same order in the transformed data as in the input file. When your dataset has multiple input files, a transform job continues to process input files even if it fails to process one. The processed files still generate useable results.

If you are using your own algorithms, you can use placeholder text, such as ERROR, when the algorithm finds a bad record in an input file. For example, if the last record in a dataset is bad, the algorithm places the placeholder text for that record in the output file.

Model parallelism and large model inference

Amazon SageMaker AI includes specialized deep learning containers (DLCs), libraries, and tooling for model parallelism and large model inference (LMI). In the following sections, you can find resources to get started with LMI on SageMaker AI.

Topics

- The large model inference (LMI) container documentation
- SageMaker AI endpoint parameters for large model inference
- Deploying uncompressed models
- Deploy large models for inference with TorchServe

The large model inference (LMI) container documentation

The Large Model Inference (LMI) container documentation is provided on the Deep Java Library documentation site.

The documentation is written for developers, data scientists, and machine learning engineers who need to deploy and optimize large language models (LLMs) on Amazon SageMaker AI. It helps you use LMI containers, which are specialized Docker containers for LLM inference, provided by Amazon. It provides an overview, deployment guides, user guides for supported inference libraries, and advanced tutorials.

By using the LMI container documentation, you can:

- Understand the components and architecture of LMI containers
- Learn how to select the appropriate instance type and backend for your use case
- Configure and deploy LLMs on SageMaker AI using LMI containers
- Optimize performance by using features like quantization, tensor parallelism, and continuous batching
- Benchmark and tune your SageMaker AI endpoints for optimal throughput and latency

SageMaker AI endpoint parameters for large model inference

You can customize the following parameters to facilitate low-latency large model inference (LMI) with SageMaker AI:

- **Maximum Amazon EBS volume size on the instance (`VolumeSizeInGB`)** – If the size of the model is larger than 30 GB and you are using an instance without a local disk, you should increase this parameter to be slightly larger than the size of your model.
- **Health check timeout quota (`ContainerStartupHealthCheckTimeoutInSeconds`)** – If your container is correctly set up and the CloudWatch logs indicate a health check timeout, you should increase this quota so the container has enough time to respond to health checks.
- **Model download timeout quota (`ModelDataDownloadTimeoutInSeconds`)** – If the size of your model is larger than 40 GB, then you should increase this quota to provide sufficient time to download the model from Amazon S3 to the instance.

The following code snippet demonstrates how to programatically configure the aforementioned parameters. Replace the *italicized placeholder text* in the example with your own information.

```
import boto3

aws_region = "aws-region"
sagemaker_client = boto3.client('sagemaker', region_name=aws_region)

# The name of the endpoint. The name must be unique within an Amazon Region in your
 Amazon account.
endpoint_name = "endpoint-name"

# Create an endpoint config name.
endpoint_config_name = "endpoint-config-name"

# The name of the model that you want to host.
model_name = "the-name-of-your-model"

instance_type = "instance-type"

sagemaker_client.create_endpoint_config(
    EndpointConfigName = endpoint_config_name
    ProductionVariants=[
        {
            "VariantName": "variant1", # The name of the production variant.
            "ModelName": model_name,
            "InstanceType": instance_type, # Specify the compute instance type.
            "InitialInstanceCount": 1, # Number of instances to launch initially.
            "VolumeSizeInGB": 256, # Specify the size of the Amazon EBS volume.
            "ModelDataDownloadTimeoutInSeconds": 1800, # Specify the model download
 timeout in seconds.
            "ContainerStartupHealthCheckTimeoutInSeconds": 1800, # Specify the health
 checkup timeout in seconds
        },
    ],
)

sagemaker_client.create_endpoint(EndpointName=endpoint_name,
 EndpointConfigName=endpoint_config_name)
```

For more information about the keys for `ProductionVariants`, see [ProductionVariant](#).

For examples that demonstrate how to achieve low latency inference with large models, see Generative AI Inference Examples on Amazon SageMaker AI in the aws-samples GitHub repository.

Deploying uncompressed models

When deploying ML models, one option is to archive and compress the model artifacts into a `tar.gz` format. Although this method works well for small models, compressing a large model artifact with hundreds of billions of parameters and then decompressing it on an endpoint can take a significant amount of time. For large model inference, we recommend that you deploy uncompressed ML model. This guide shows how you can deploy uncompressed ML model.

To deploy uncompressed ML models, upload all model artifacts to Amazon S3 and organize them under a common Amazon S3 prefix. A Amazon S3 prefix is a string of characters at the beginning of an Amazon S3 object key name, separated from the rest of the name by a delimiter. For more information on Amazon S3 prefix, see Organizing objects using prefixes.

For deploying with SageMaker AI, you must use slash (/) as the delimiter. You have to ensure that only artifacts associated with your ML model are organized with the prefix. For ML models with a single uncompressed artifact, the prefix will be identical to the key name. You can check which objects are associated with your prefix with the Amazon CLI:

```
aws s3 ls --recursive s3://bucket/prefix
```

After uploading the model artifacts to Amazon S3 and organizing them under a common prefix, you can specify their location as part of the ModelDataSource field when you invoke the CreateModel request. SageMaker AI will automatically download the uncompressed model artifacts to `/opt/ml/model` for inference. For more information about the rules that SageMaker AI uses when downloading the artifacts, see S3ModelDataSource.

The following code snippet shows how you can invoke the `CreateModel` API when deploying an uncompressed model. Replace the *`italicized user text`* with your own information.

```
model_name = "model-name"
sagemaker_role = "arn:aws:iam::123456789012:role/SageMakerExecutionRole"
container = "123456789012.dkr.ecr.us-west-2.amazonaws.com/inference-image:latest"

create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
```

```
        "Image": container,
        "ModelDataSource": {
            "S3DataSource": {
                "S3Uri": "s3://amzn-s3-demo-bucket/prefix/to/model/data/",
                "S3DataType": "S3Prefix",
                "CompressionType": "None",
            },
        },
    },
)
```

The aforementioned example assumes that your model artifacts are organized under a common prefix. If instead your model artifact is a single uncompressed Amazon S3 object, then change `"S3Uri"` to point to the Amazon S3 object, and change `"S3DataType"` to `"S3Object"`.

> **Note**
>
> Currently you cannot use `ModelDataSource` with Amazon Web Services Marketplace, SageMaker AI batch transform, SageMaker Serverless Inference endpoints, and SageMaker multi-model endpoints.

Deploy large models for inference with TorchServe

This tutorial demonstrates how to deploy large models and serve inference in Amazon SageMaker AI with TorchServe on GPUs. This example deploys the OPT-30b model to an `ml.g5` instance. You can modify this to work with other models and instance types. Replace the *`italicized placeholder text`* in the examples with your own information.

TorchServe is a powerful open platform for large distributed model inference. By supporting popular libraries like PyTorch, native PiPPy, DeepSpeed, and HuggingFace Accelerate, it offers uniform handler APIs that remain consistent across distributed large model and non-distributed model inference scenarios. For more information, see TorchServe's large model inference documentation.

Deep learning containers with TorchServe

To deploy a large model with TorchServe on SageMaker AI, you can use one of the SageMaker AI deep learning containers (DLCs). By default, TorchServe is installed in all Amazon PyTorch DLCs.

During model loading, TorchServe can install specialized libraries tailored for large models such as PiPPy, Deepspeed, and Accelerate.

The following table lists all of the SageMaker AI DLCs with TorchServe.

DLC cateogry	Framework	Hardware	Example URL
SageMaker AI Framework Containers	PyTorch 2.0.0+	CPU, GPU	763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-inference:2.0.1-gpu-py310-cu118-ubuntu20.04-sagemaker
SageMaker AI Framework Graviton Containers	PyTorch 2.0.0+	CPU	763104351884.dkr.ecr.us-east-1.amazonaws.com/pytorch-inference-graviton:2.0.1-cpu-py310-ubuntu20.04-sagemaker
StabilityAI Inference Containers	PyTorch 2.0.0+	GPU	763104351884.dkr.ecr.us-east-1.amazonaws.com/stabilityai-pytorch-inference:2.0.1-sgm0.1.0-gpu-py310-cu118-ubuntu20.04-sagemaker
Neuron Containers	PyTorch 1.13.1	Neuronx	763104351884.dkr.ecr.us-west-2.amazonaws.com/pytorch-inference-neuron:1.13.1-neuron-py310-sdk2.12.0-ubuntu20.04

Getting started

Before deploying your model, complete the prerequisites. You can also configure your model parameters and customize the handler code.

Prerequisites

To get started, ensure that you have the following prerequisites:

1. Ensure you have access to an Amazon account. Set up your environment so that the Amazon CLI can access your account through either an Amazon IAM user or an IAM role. We recommend using an IAM role. For the purposes of testing in your personal account, you can attach the following managed permissions policies to the IAM role:

   - AmazonEC2ContainerRegistryFullAccess
   - AmazonEC2FullAccess
   - AWSServiceRoleForAmazonEKSNodegroup
   - AmazonSageMakerFullAccess
   - AmazonS3FullAccess

   For more information about attaching IAM policies to a role, see Adding and removing IAM identity permissions in the *Amazon IAM User Guide*.
2. Locally configure your dependencies, as shown in the following examples.

   a. Install version 2 of the Amazon CLI:

   ```
   # Install the latest AWS CLI v2 if it is not installed
   !curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o
    "awscliv2.zip" !unzip awscliv2.zip
   #Follow the instructions to install v2 on the terminal
   !cat aws/README.md
   ```

   b. Install SageMaker AI and the Boto3 client:

   ```
   # If already installed, update your client
   #%pip install sagemaker pip --upgrade --quiet
   !pip install -U sagemaker
   !pip install -U boto
   !pip install -U botocore
   ```

```
!pip install -U boto3
```

Configure model settings and parameters

TorchServe uses `torchrun` to set up the distributed environment for model parallel processing. TorchServe has the capability to support multiple workers for a large model. By default, TorchServe uses a round-robin algorithm to assign GPUs to a worker on a host. In the case of large model inference, the number of GPUs assigned to each worker is automatically calculated based on the number of GPUs specified in the `model_config.yaml` file. The environment variable `CUDA_VISIBLE_DEVICES`, which specifies the GPU device IDs that are visible at a given time, is set based this number.

For example, suppose there are 8 GPUs on a node and one worker needs 4 GPUs on a node (`nproc_per_node=4`). In this case, TorchServe assigns four GPUs to the first worker (`CUDA_VISIBLE_DEVICES="0,1,2,3"`) and four GPUs to the second worker (`CUDA_VISIBLE_DEVICES="4,5,6,7”`).

In addition to this default behavior, TorchServe provides the flexibility for users to specify GPUs for a worker. For instance, if you set the variable `deviceIds: [2,3,4,5]` in the model config YAML file, and set `nproc_per_node=2`, then TorchServe assigns `CUDA_VISIBLE_DEVICES=”2,3”` to the first worker and `CUDA_VISIBLE_DEVICES="4,5”` to the second worker.

In the following `model_config.yaml` example, we configure both front-end and back-end parameters for the OPT-30b model. The configured front-end parameters are `parallelType`, `deviceType`, `deviceIds` and `torchrun`. For more detailed information about the front-end parameters you can configure, see the PyTorch GitHub documentation. The back-end configuration is based on a YAML map that allows for free-style customization. For the back-end parameters, we define the DeepSpeed configuration and additional parameters used by custom handler code.

```
# TorchServe front-end parameters
minWorkers: 1
maxWorkers: 1
maxBatchDelay: 100
responseTimeout: 1200
parallelType: "tp"
deviceType: "gpu"
# example of user specified GPU deviceIds
deviceIds: [0,1,2,3] # sets CUDA_VISIBLE_DEVICES
```

```
torchrun:
    nproc-per-node: 4

# TorchServe back-end parameters
deepspeed:
    config: ds-config.json
    checkpoint: checkpoints.json

handler: # parameters for custom handler code
    model_name: "facebook/opt-30b"
    model_path: "model/models--facebook--opt-30b/snapshots/
ceea0a90ac0f6fae7c2c34bcb40477438c152546"
    max_length: 50
    max_new_tokens: 10
    manual_seed: 40
```

Customize handlers

TorchServe offers base handlers and handler utilities for large model inference built with popular libraries. The following example demonstrates how the custom handler class TransformersSeqClassifierHandler extends BaseDeepSpeedHandler and uses the handler utilities. For a full code example, see the `custom_handler.py` code on the PyTorch GitHub documentation.

```
class TransformersSeqClassifierHandler(BaseDeepSpeedHandler, ABC):
    """
    Transformers handler class for sequence, token classification and question
 answering.
    """

    def __init__(self):
        super(TransformersSeqClassifierHandler, self).__init__()
        self.max_length = None
        self.max_new_tokens = None
        self.tokenizer = None
        self.initialized = False

    def initialize(self, ctx: Context):
        """In this initialize function, the HF large model is loaded and
        partitioned using DeepSpeed.
        Args:
            ctx (context): It is a JSON Object containing information
            pertaining to the model artifacts parameters.
```

```
        """
        super().initialize(ctx)
        model_dir = ctx.system_properties.get("model_dir")
        self.max_length = int(ctx.model_yaml_config["handler"]["max_length"])
        self.max_new_tokens = int(ctx.model_yaml_config["handler"]["max_new_tokens"])
        model_name = ctx.model_yaml_config["handler"]["model_name"]
        model_path = ctx.model_yaml_config["handler"]["model_path"]
        seed = int(ctx.model_yaml_config["handler"]["manual_seed"])
        torch.manual_seed(seed)

        logger.info("Model %s loading tokenizer", ctx.model_name)

        self.tokenizer = AutoTokenizer.from_pretrained(model_name)
        self.tokenizer.pad_token = self.tokenizer.eos_token
        config = AutoConfig.from_pretrained(model_name)
        with torch.device("meta"):
            self.model = AutoModelForCausalLM.from_config(
                config, torch_dtype=torch.float16
            )
        self.model = self.model.eval()

        ds_engine = get_ds_engine(self.model, ctx)
        self.model = ds_engine.module
        logger.info("Model %s loaded successfully", ctx.model_name)
        self.initialized = True

    def preprocess(self, requests):
        """
        Basic text preprocessing, based on the user's choice of application mode.
        Args:
            requests (list): A list of dictionaries with a "data" or "body" field, each
                            containing the input text to be processed.
        Returns:
            tuple: A tuple with two tensors: the batch of input ids and the batch of
                attention masks.
        """

    def postprocess(self, inference_output):
        """Post Process Function converts the predicted response into Torchserve
readable format.
        Args:
            inference_output (list): It contains the predicted response of the input
text.
        Returns:
            (list): Returns a list of the Predictions and Explanations.
        """
```

Prepare your model artifacts

Before deploying your model on SageMaker AI, you must package your model artifacts. For large models, we recommend that you use the PyTorch torch-model-archiver tool with the argument `--archive-format no-archive`, which skips compressing model artifacts. The following example saves all of the model artifacts to a new folder named `opt/`.

```
torch-model-archiver --model-name opt --version 1.0 --handler custom_handler.py --
extra-files ds-config.json -r requirements.txt --config-file opt/model-config.yaml --
archive-format no-archive
```

Once the `opt/` folder is created, download the OPT-30b model to the folder using the PyTorch Download_model tool.

```
cd opt
python path_to/Download_model.py --model_path model --model_name facebook/opt-30b --
revision main
```

Lastly, upload the model artifacts to an Amazon S3 bucket.

```
aws s3 cp opt {your_s3_bucket}/opt --recursive
```

You should now have model artifacts stored in Amazon S3 that are ready to deploy to a SageMaker AI endpoint.

Deploy the model using the SageMaker Python SDK

After preparing your model artifacts, you can deploy your model to a SageMaker AI Hosting endpoint. This section describes how to deploy a single large model to an endpoint and make streaming response predictions. For more information about streaming responses from endpoints, see Invoke real-time endpoints.

To deploy your model, complete the following steps:

1. Create a SageMaker AI session, as shown in the following example.

```
import boto3
import sagemaker
from sagemaker.core.resources import Model
from sagemaker.core import image_uris
from sagemaker.core.helper.session_helper import get_execution_role, Session

boto3_session=boto3.session.Session(region_name="us-west-2")
smr = boto3.client('sagemaker-runtime-demo')
sm = boto3.client('sagemaker')
role = get_execution_role()  # execution role for the endpoint
sess= Session(boto3_session, sagemaker_client=sm, sagemaker_runtime_client=smr)  #
 SageMaker AI session for interacting with different Amazon APIs
region = sess._region_name  # region name of the current SageMaker Studio Classic
 environment
account = sess.account_id()  # account_id of the current SageMaker Studio Classic
 environment

# Configuration:
bucket_name = sess.default_bucket()
prefix = "torchserve"
output_path = f"s3://{bucket_name}/{prefix}"
print(f'account={account}, region={region}, role={role},
 output_path={output_path}')
```

2. Create an uncompressed model in SageMaker AI, as shown in the following example.

```
from datetime import datetime

instance_type = "ml.g5.24xlarge"
```

```
endpoint_name = sagemaker.utils.name_from_base("ts-opt-30b")
s3_uri = {your_s3_bucket}/opt

model = Model(
    name="torchserve-opt-30b" + datetime.now().strftime("%Y-%m-%d-%H-%M-%S"),
    # Enable SageMaker uncompressed model artifacts
    model_data={
        "S3DataSource": {
                "S3Uri": s3_uri,
                "S3DataType": "S3Prefix",
                "CompressionType": "None",
        }
    },
    image_uri=container,
    role=role,
    sagemaker_session=sess,
    env={"TS_INSTALL_PY_DEP_PER_MODEL": "true"},
)
print(model)
```

3. Deploy the model to an Amazon EC2 instance, as shown in the following example.

```
model.deploy(
    initial_instance_count=1,
    instance_type=instance_type,
    endpoint_name=endpoint_name,
    volume_size_in_gb=512, # increase the size to store large model
    model_data_download_timeout=3600, # increase the timeout to download large
 model
    container_startup_health_check_timeout=600, # increase the timeout to load
 large model
)
```

4. Initialize a class to process the streaming response, as shown in the following example.

```
import io

class Parser:
    """
    A helper class for parsing the byte stream input.

    The output of the model will be in the following format:
    ```
```
```

```
   b'{"outputs": [" a"]}\n'
   b'{"outputs": [" challenging"]}\n'
   b'{"outputs": [" problem"]}\n'
   ...
   ```

   While usually each PayloadPart event from the event stream will contain a byte
array
   with a full json, this is not guaranteed and some of the json objects may be
split across
   PayloadPart events. For example:
   ```
   {'PayloadPart': {'Bytes': b'{"outputs": '}}
   {'PayloadPart': {'Bytes': b'[" problem"]}\n'}}
   ```

   This class accounts for this by concatenating bytes written via the 'write'
function
   and then exposing a method which will return lines (ending with a '\n'
character) within
   the buffer via the 'scan_lines' function. It maintains the position of the last
read
   position to ensure that previous bytes are not exposed again.
   """

   def __init__(self):
       self.buff = io.BytesIO()
       self.read_pos = 0

   def write(self, content):
       self.buff.seek(0, io.SEEK_END)
       self.buff.write(content)
       data = self.buff.getvalue()

   def scan_lines(self):
       self.buff.seek(self.read_pos)
       for line in self.buff.readlines():
           if line[-1] != b'\n':
               self.read_pos += len(line)
               yield line[:-1]

   def reset(self):
       self.read_pos = 0
```
```

5. Test a streaming response prediction, as shown in the following example.

```
import json

body = "Today the weather is really nice and I am planning on".encode('utf-8')
resp = smr.invoke_endpoint_with_response_stream(EndpointName=endpoint_name,
 Body=body, ContentType="application/json")
event_stream = resp['Body']
parser = Parser()
for event in event_stream:
    parser.write(event['PayloadPart']['Bytes'])
    for line in parser.scan_lines():
        print(line.decode("utf-8"), end=' ')
```

You have now deployed your model to a SageMaker AI endpoint and should be able to invoke it for responses. For more information about SageMaker AI real-time endpoints, see Single-model endpoints.

Deployment guardrails for updating models in production

Deployment guardrails are a set of model deployment options in Amazon SageMaker AI Inference to update your machine learning models in production. Using the fully managed deployment options, you can control the switch from the current model in production to a new one. Traffic shifting modes in blue/green deployments, such as canary and linear, give you granular control over the traffic shifting process from your current model to the new one during the course of the update. There are also built-in safeguards such as auto-rollbacks that help you catch issues early and automatically take corrective action before they significantly impact production.

Deployment guardrails provide the following benefits:

- **Deployment safety while updating production environments.** A regressive update to a production environment can cause unplanned downtime and business impact, such as increased model latency and high error rates. Deployment guardrails help you mitigate those risks by providing best practices and built-in operational safety guardrails.
- **Fully managed deployment.** SageMaker AI takes care of setting up and orchestrating these deployments and integrates them with endpoint update mechanisms. You do not need to build and maintain orchestration, monitoring, or rollback mechanisms. You can leverage SageMaker AI to set up and orchestrate these deployments and focus on leveraging ML for your applications.

- **Visibility.** You can track the progress of your deployment through the DescribeEndpoint API or through Amazon CloudWatch Events (for supported endpoints). To learn more about events in SageMaker AI, see the Endpoint deployment state change section in Events that Amazon SageMaker AI sends to Amazon EventBridge. Note that if your endpoint uses any of the features in the Exclusions page, you cannot use CloudWatch Events.

> **Note**
>
> Deployment guardrails only apply to Asynchronous inference and Real-time inference endpoint types.

How to get started

We support two types of deployments to update models in production: blue/green deployments and rolling deployments.

- Blue/Green Deployments: You can shift traffic from your old fleet (the blue fleet) to a new fleet (green fleet) with the updates. Blue/green deployments offer multiple traffic shifting modes. A traffic shifting mode is a configuration that specifies how SageMaker AI routes endpoint traffic to a new fleet containing your updates. The following traffic shifting modes provide you with different levels of control over the endpoint update process:
  - Use all at once traffic shifting shifts all of your endpoint traffic from the blue fleet to the green fleet. Once the traffic shifts to the green fleet, your pre-specified Amazon CloudWatch alarms begin monitoring the green fleet for a set amount of time (the *baking period*). If no alarms trip during the baking period, then SageMaker AI terminates the blue fleet.
  - Use canary traffic shifting shifts one small portion of your traffic (a *canary*) to the green fleet and monitor it for a baking period. If the canary succeeds on the green fleet, then SageMaker AI shifts the rest of the traffic from the blue fleet to the green fleet before terminating the blue fleet.
  - Use linear traffic shifting provides even more customization over the number of traffic-shifting steps and the percentage of traffic to shift for each step. While canary shifting lets you shift traffic in two steps, linear shifting extends this to *n* linearly spaced steps.
- Use rolling deployments: You can update your endpoint as SageMaker AI incrementally provisions capacity and shifts traffic to a new fleet in steps of a batch size that you specify. Instances on the new fleet are updated with the new deployment configuration, and if no

CloudWatch alarms trip during the baking period, then SageMaker AI cleans up instances on the old fleet. This option gives you granular control over the instance count or capacity percentage shifted during each step.

You can create and manage your deployment through the UpdateEndpoint and CreateEndpoint SageMaker API and Amazon Command Line Interface commands. See the individual deployment pages for more details on how to set up your deployment. Note that if your endpoint uses any of the features listed in the Exclusions page, you cannot use deployment guardrails.

To follow guided examples that shows how to use deployment guardrails, see our example Jupyter notebooks for the canary and linear traffic shifting modes.

Auto-Rollback Configuration and Monitoring

Amazon CloudWatch alarms are a prerequisite for using baking periods in deployment guardrails. You can only use the auto-rollback functionality in deployment guardrails if you set up CloudWatch alarms that can monitor an endpoint. If any of your alarms trip during the specified monitoring period, SageMaker AI initiates a complete rollback to the old endpoint to protect your application. If you do not have any CloudWatch alarms set up to monitor your endpoint, then the auto-rollback functionality does not work during your deployment.

To learn more about Amazon CloudWatch, see What is Amazon CloudWatch? in the *Amazon CloudWatch User Guide*.

> **Note**
>
> Ensure that your IAM execution role has permission to perform the `cloudwatch:DescribeAlarms` action on the auto-rollback alarms you specify.

Alarm Examples

To help you get started, we provide the following examples to demonstrate the capabilities of CloudWatch alarms. In addition to using or modifying the following examples, you can create your own alarms and configure the alarms to monitor various metrics on the specified fleets for a certain period of time. To see more SageMaker AI metrics and dimensions you can add to your alarms, see Amazon SageMaker AI metrics in Amazon CloudWatch.

Topics

- Monitor invocation errors on both old and new fleets
- Monitor model latency on the new fleet

Monitor invocation errors on both old and new fleets

The following CloudWatch alarm monitors an endpoint's average error rate. You can use this alarm with any deployment guardrails traffic shifting type to provide overall monitoring on both the old and new fleets. If the alarm trips, then SageMaker AI initiates a rollback to the old fleet.

Invocation errors coming from both the old fleet and new fleet contribute to the average error rate. If the average error rate exceeds the specified threshold, then the alarm trips. This particular example monitors the 4xx errors (client errors) on both the old and new fleets for the duration of a deployment. You can also monitor the 5xx errors (server errors) by using the metric `Invocation5XXErrors`.

> **Note**
>
> For this alarm type, if your old fleet trips the alarm during the deployment, SageMaker AI terminates your deployment. Therefore, if your current production fleet already causes errors, consider using or modifying one of the following examples that only monitors the new fleet for errors.

```
#Applied deployment type: all types
{
    "AlarmName": "EndToEndDeploymentHighErrorRateAlarm",
    "AlarmDescription": "Monitors the error rate of 4xx errors",
    "MetricName": "Invocation4XXErrors",
    "Namespace": "AWS/SageMaker",
    "Statistic": "Average",
    "Dimensions": [
        {
            "Name": "EndpointName",
            "Value": <your-endpoint-name>
        },
        {
            "Name": "VariantName",
            "Value": "AllTraffic"
        }
    ],
```

```
    "Period": 600,
    "EvaluationPeriods": 2,
    "Threshold": 1,
    "ComparisonOperator": "GreaterThanThreshold",
    "TreatMissingData": "notBreaching"
}
```

In the previous example, note the values for the following fields:

- For `AlarmName` and `AlarmDescription`, enter a name and description you choose for the alarm.
- For `MetricName`, use the value `Invocation4XXErrors` to monitor for 4xx errors on the endpoint
- For `Namespace`, use the value `AWS/SageMaker`. You can also specify your own custom metric, if applicable.
- For `Statistic`, use `Average`. This means that the alarm takes the average error rate over the evaluation periods when calculating whether the error rate has exceeded the threshold.
- For the dimension `EndpointName`, use the name of the endpoint you are updating as the value.
- For the dimension `VariantName`, use the value `AllTraffic` to specify all endpoint traffic.
- For `Period`, use `600`. This sets the alarm's evaluation periods to 10 minutes long.
- For `EvaluationPeriods`, use 2. This value tells the alarm to consider the two most recent evaluation periods when determining the alarm status.

Monitor model latency on the new fleet

The following CloudWatch alarm example monitors the new fleet's model latency during your deployment. You can use this alarm to monitor only the new fleet and exclude the old fleet. The alarm lasts for the entire deployment. This example gives you comprehensive, end-to-end monitoring of the new fleet and initiates a rollback to the old fleet if the new fleet has any response time issues.

CloudWatch publishes the metrics with the dimension `EndpointConfigName:{New-Ep-Config}` after the new fleet starts receiving traffic, and these metrics last even after the deployment is complete.

You can use the following alarm example with any deployment type.

```
#Applied deployment type: all types
{
    "AlarmName": "NewEndpointConfigVersionHighModelLatencyAlarm",
    "AlarmDescription": "Monitors the model latency on new fleet",
    "MetricName": "ModelLatency",
    "Namespace": "AWS/SageMaker",
    "Statistic": "Average",
    "Dimensions": [
        {
            "Name": "EndpointName",
            "Value": <your-endpoint-name>
        },
        {
            "Name": "VariantName",
            "Value": "AllTraffic"
        },
        {
            "Name": "EndpointConfigName",
            "Value": <your-config-name>
    ],
    "Period": 300,
    "EvaluationPeriods": 2,
    "Threshold": 100000, # 100ms
    "ComparisonOperator": "GreaterThanThreshold",
    "TreatMissingData": "notBreaching"
}
```

In the previous example, note the values for the following fields:

- For `MetricName`, use the value `ModelLatency` to monitor the model's response time.
- For `Namespace`, use the value `AWS/SageMaker`. You can also specify your own custom metric, if applicable.
- For the dimension `EndpointName`, use the name of the endpoint you are updating as the value.
- For the dimension `VariantName`, use the value `AllTraffic` to specify all endpoint traffic.
- For the dimension `EndpointConfigName`, the value should refer to the endpoint configuration name for your new or updated endpoint.

> **Note**
>
> If you want to monitor your old fleet instead of the new fleet, you can change the dimension `EndpointConfigName` to specify the name of your old fleet's configuration.

Blue/Green Deployments

When you update your endpoint, Amazon SageMaker AI automatically uses a blue/green deployment to maximize the availability of your endpoints. In a blue/green deployment, SageMaker AI provisions a new fleet with the updates (the green fleet). Then, SageMaker AI shifts traffic from the old fleet (the blue fleet) to the green fleet. Once the green fleet operates smoothly for a set evaluation period (called the baking period), SageMaker AI terminates the blue fleet. With the additional capabilities in blue/green deployments, you can utilize traffic shifting modes and auto-rollback monitoring to protect your endpoint from significant production impact.

The following list describes the key features of blue/green deployments in SageMaker AI:

- **Traffic shifting modes.** The traffic shifting modes for deployment guardrails let you control the volume of traffic and number of traffic-shifting steps between the blue fleet and the green fleet. This capability gives you the ability to progressively evaluate the performance of the green fleet without fully committing to a 100% traffic shift.
- **Baking period.** The baking period is a set amount of time to monitor the green fleet before proceeding to the next deployment stage. If any of the pre-specified alarms trip during any baking period, then all endpoint traffic rolls back to the blue fleet. The baking period helps you to build confidence in your update before making the traffic shift permanent.
- **Auto-rollbacks.** You can specify Amazon CloudWatch alarms that SageMaker AI uses to monitor the green fleet. If an issue with the updated code trips any of the alarms, SageMaker AI initiates an auto-rollback to the blue fleet in order to maintain availability thereby minimizing risk.

Traffic Shifting Modes

The various traffic shifting modes in blue/green deployments give you more granular control over traffic shifting between the blue fleet and the green fleet. The available traffic shifting modes for blue/green deployments are all at once, canary, and linear. The following table shows a comparison of the options.

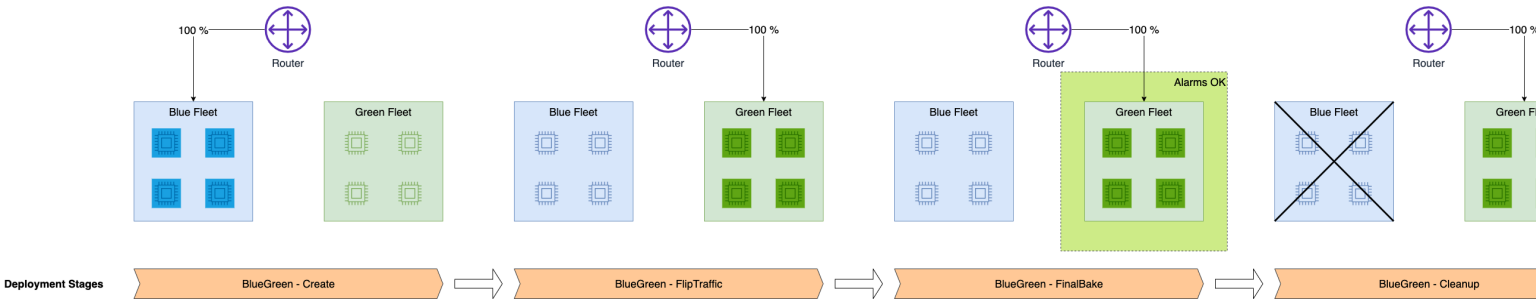
Important

For blue/green deployments that involve multiple stage traffic shifting or baking periods, you are billed for both the fleets for the duration of the update, irrespective of the traffic to the fleet. This is in contrast to blue/green deployments with all at once traffic shifting and no baking periods, where you are only billed for one fleet during the course of the update.

Name	What is it?	Pros	Cons	Recommendation
All at once	Shifts all of the traffic to the new fleet in a single step.	Minimizes the overall update duration.	Regressive updates affect 100% of the traffic.	Use this option to minimize update time and cost.
Canary	Traffic shifts in two steps. The first (canary) step shifts a small portion of the traffic followed by the second step, which shifts the remainder of the traffic.	Confines the blast radius of regressive updates to only the canary fleet.	Both fleets are operational in parallel for entire deployment.	Use this option to balance between minimizing the blast radius of regressive updates and minimizing the time that two fleets are operational.
Linear	A fixed portion of the traffic shifts in a pre-specified number of equally spaced steps.	Minimizes the risk of regressive updates by shifting traffic over several steps.	The update duration and cost are proportional to the number of steps.	Use this option to minimize risk by spreading out deployment across multiple steps.

Get Started

Once you specify your desired deployment configuration, SageMaker AI handles provisioning new instances, terminating old instances, and shifting traffic for you. You can create and manage your deployment through the existing UpdateEndpoint and CreateEndpoint SageMaker API and Amazon Command Line Interface commands. Note that if your endpoint uses any of the features listed in the Exclusions page, you cannot use deployment guardrails. See the individual deployment pages for more details on how to set up your deployment:



- Blue/Green Update with All At Once Traffic Shifting
- Blue/Green Update with Canary Traffic Shifting
- Blue/Green Update with Linear Traffic Shifting

To follow guided examples that show how to use deployment guardrails, see our example Jupyter notebooks for the canary and linear traffic shifting modes.

Use all at once traffic shifting

With all at once traffic shifting, you can quickly roll out an endpoint update using the safety guardrails of a blue/green deployment. You can use this traffic shifting option to minimize the update duration while still taking advantage of the availability guarantees of blue/green deployments. The baking period feature helps you to monitor the performance and functionality of your new instances before terminating your old instances, ensuring that your new fleet is fully operational.

The following diagram shows how all at once traffic shifting manages the old and new fleets.

When you use all at once traffic shifting, SageMaker AI routes 100% of the traffic to the new fleet (green fleet). Once the green fleet starts receiving traffic, the baking period begins. The baking period is a set amount of time in which pre-specified Amazon CloudWatch alarms monitor the performance of the green fleet. If no alarms trip during the baking period, SageMaker AI terminates the old fleet (blue fleet). If any alarms trip during the baking period, then an auto-rollback initiates and 100% of the traffic shifts back to the blue fleet.

Prerequisites

Before setting up a deployment with all at once traffic shifting, you must create Amazon CloudWatch alarms to watch metrics from your endpoint. If any of the alarms trip during the baking period, then the traffic rolls back to your blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring. To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the *Amazon CloudWatch User Guide*.

Configure All At Once Traffic Shifting

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use either the SageMaker AI UpdateEndpoint API or the update-endpoint command in the Amazon Command Line Interface to initiate the deployment.

Topics

- How to update an endpoint (API)
- How to update an endpoint with an existing blue/green update policy (API)
- How to update an endpoint (CLI)

How to update an endpoint (API)

The following example shows how you can update your endpoint with all at once traffic shifting using UpdateEndpoint in the Amazon SageMaker API.

```
import boto3
client = boto3.client("sagemaker")

response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "ALL_AT_ONCE"
            },
            "TerminationWaitInSeconds": 600,
            "MaximumExecutionTimeoutInSeconds": 1800
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {
                    "AlarmName": "<your-cw-alarm>"
                },
            ]
        }
    }
)
```

To configure the all at once traffic shifting option, do the following:

- For `EndpointName`, use the name of the existing endpoint you want to update.
- For `EndpointConfigName`, use the name of the endpoint configuration you want to use.
- Under `DeploymentConfig` and `BlueGreenUpdatePolicy`, in `TrafficRoutingConfiguration`, set the `Type` parameter to `ALL_AT_ONCE`. This specifies that the deployment uses the all at once traffic shifting mode.
- For `TerminationWaitInSeconds`, use `600`. This parameter tells SageMaker AI to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker AI waits for 10 minutes after the final baking period before terminating the blue fleet.
- For `MaximumExecutionTimeoutInSeconds`, use `1800`. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 30 minutes to finish.
- In `AutoRollbackConfiguration`, within the `Alarms` field, you can add your CloudWatch alarms by name. Create one `AlarmName: <your-cw-alarm>` entry for each alarm you want to use.

How to update an endpoint with an existing blue/green update policy (API)

When you use the CreateEndpoint API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same `DeploymentConfig` options as the previous UpdateEndpoint API example. There are no changes to the CreateEndpoint API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the UpdateEndpoint API to update your endpoint. When updating your endpoint, you can use the `RetainDeploymentConfig` option to keep the deployment configuration you specified when you created the endpoint.

When calling the UpdateEndpoint API, set `RetainDeploymentConfig` to `True` to keep the `DeploymentConfig` options from your original endpoint configuration.

```
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
```

```
)
```

How to update an endpoint (CLI)

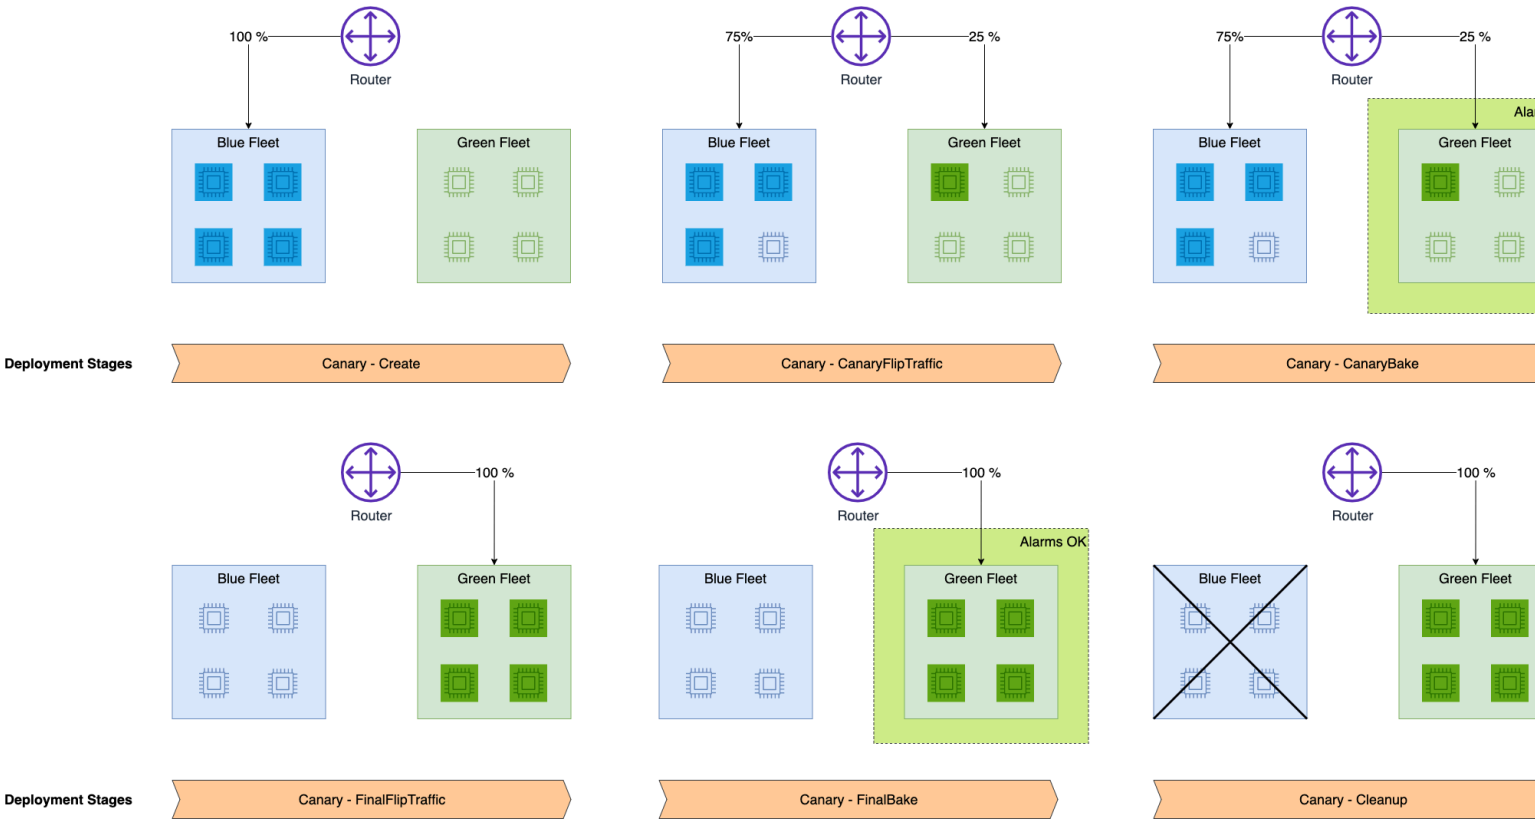
If you are using the Amazon CLI, the following example shows how to start a blue/green all at once deployment using the update-endpoint command.

```
update-endpoint
--endpoint-name <your-endpoint-name>
--endpoint-config-name <your-config-name>
--deployment-config '"BlueGreenUpdatePolicy": {"TrafficRoutingConfiguration": {"Type":
 "ALL_AT_ONCE"},
    "TerminationWaitInSeconds": 600, "MaximumExecutionTimeoutInSeconds": 1800},
    "AutoRollbackConfiguration": {"Alarms": [{"AlarmName": "<your-alarm>"}]}'
```

To configure the all at once traffic shifting option, do the following:

- For `endpoint-name`, use the name of the endpoint you want to update.
- For `endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `deployment-config`, use a BlueGreenUpdatePolicy JSON object.

> **Note**
>
> If you would rather save your JSON object in a file, see Generating Amazon CLI skeleton and input parameters in the *Amazon CLI User Guide*.



Use canary traffic shifting

With canary traffic shifting, you can test a portion of your endpoint traffic on the new fleet while the old fleet serves the remainder of the traffic. This testing step is a safety guardrail that validates the new fleet's functionality before shifting all of your traffic to the new fleet. You still have the benefits of a blue/green deployment, and the added canary feature lets you ensure that your new (green) fleet can serve inference before letting it handle 100% of the traffic.

The portion of your green fleet that turns on to receive traffic is called the canary, and you can choose the size of this canary. Note that the canary size should be less than or equal to 50% of the new fleet's capacity. Once the baking period finishes and no pre-specified Amazon CloudWatch

alarms trip, the rest of the traffic shifts from the old (blue) fleet to the green fleet. Canary traffic shifting provides you with more safety during your deployment since any issues with the updated model only impact the canary.

The following diagram shows how canary traffic shifting manages the distribution of traffic between the blue and green fleets.

Once SageMaker AI provisions the green fleet, SageMaker AI routes a portion of the incoming traffic (for example, 25%) to the canary. Then the baking period begins, during which your CloudWatch alarms monitor the performance of the green fleet. During this time, both the blue fleet and green fleet are partially active and receiving traffic. If any of the alarms trip during the baking period, then SageMaker AI initiates a rollback and all traffic returns to the blue fleet. If none of the alarms trip, then all of the traffic shifts to the green fleet and there is a final baking period. If the final baking period finishes without tripping any alarms, then the green fleet serves all traffic and SageMaker AI terminates the blue fleet.

Prerequisites

Before setting up a deployment with canary traffic shifting, you must create Amazon CloudWatch alarms to monitor metrics from your endpoint. The alarms are active during the baking period, and if any alarms trip, then all endpoint traffic rolls back to the blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring. To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the *Amazon CloudWatch User Guide*.

Configure Canary Traffic Shifting

Once you are ready for your deployment and have set up Amazon CloudWatch alarms for your endpoint, you can use either the Amazon SageMaker AI UpdateEndpoint API or the update-endpoint command in the Amazon CLI to initiate the deployment.

Topics

- How to update an endpoint (API)
- How to update an endpoint with an existing blue/green update policy (API)
- How to update an endpoint (CLI)

How to update an endpoint (API)

The following example of the UpdateEndpoint API shows how you can update an endpoint with canary traffic shifting.

```
import boto3
client = boto3.client("sagemaker")

response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
```

```
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "CANARY",
                "CanarySize": {
                    "Type": "CAPACITY_PERCENT",
                    "Value": 30
                },
                "WaitIntervalInSeconds": 600
            },
            "TerminationWaitInSeconds": 600,
            "MaximumExecutionTimeoutInSeconds": 1800
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {
                    "AlarmName": "<your-cw-alarm>"
                }
            ]
        }
    }
)
```

To configure the canary traffic shifting option, do the following:

- For `EndpointName`, use the name of the existing endpoint you want to update.
- For `EndpointConfigName`, use the name of the endpoint configuration you want to use.
- Under `DeploymentConfig` and `BlueGreenUpdatePolicy`, in `TrafficRoutingConfiguration`, set the `Type` parameter to `CANARY`. This specifies that the deployment uses canary traffic shifting.
- In the `CanarySize` field, you can change the size of the canary by modifying the `Type` and `Value` parameters. For `Type`, use `CAPACITY_PERCENT`, meaning the percentage of your green fleet you want to use as the canary, and then set `Value` to `30`. In this example, you use 30% of the green fleet's capacity as the canary. Note that the canary size should be equal to or less than 50% of the green fleet's capacity.
- For `WaitIntervalInSeconds`, use `600`. The parameter tells SageMaker AI to wait for the specified amount of time (in seconds) between each interval shift. This interval is the duration of the canary baking period. In the preceding example, SageMaker AI waits for 10 minutes after the canary shift and then completes the second and final traffic shift.

- For `TerminationWaitInSeconds`, use `600`. This parameter tells SageMaker AI to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker AI waits for 10 minutes after the final baking period before terminating the blue fleet.
- For `MaximumExecutionTimeoutInSeconds`, use `1800`. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 30 minutes to finish.
- In `AutoRollbackConfiguration`, within the `Alarms` field, you can add your CloudWatch alarms by name. Create one `AlarmName: <your-cw-alarm>` entry for each alarm you want to use.

How to update an endpoint with an existing blue/green update policy (API)

When you use the CreateEndpoint API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same `DeploymentConfig` options as the previous UpdateEndpoint API example. There are no changes to the CreateEndpoint API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the UpdateEndpoint API to update your endpoint. When updating your endpoint, you can use the `RetainDeploymentConfig` option to keep the deployment configuration you specified when you created the endpoint.

When calling the UpdateEndpoint API, set `RetainDeploymentConfig` to `True` to keep the `DeploymentConfig` options from your original endpoint configuration.

```
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

How to update an endpoint (CLI)

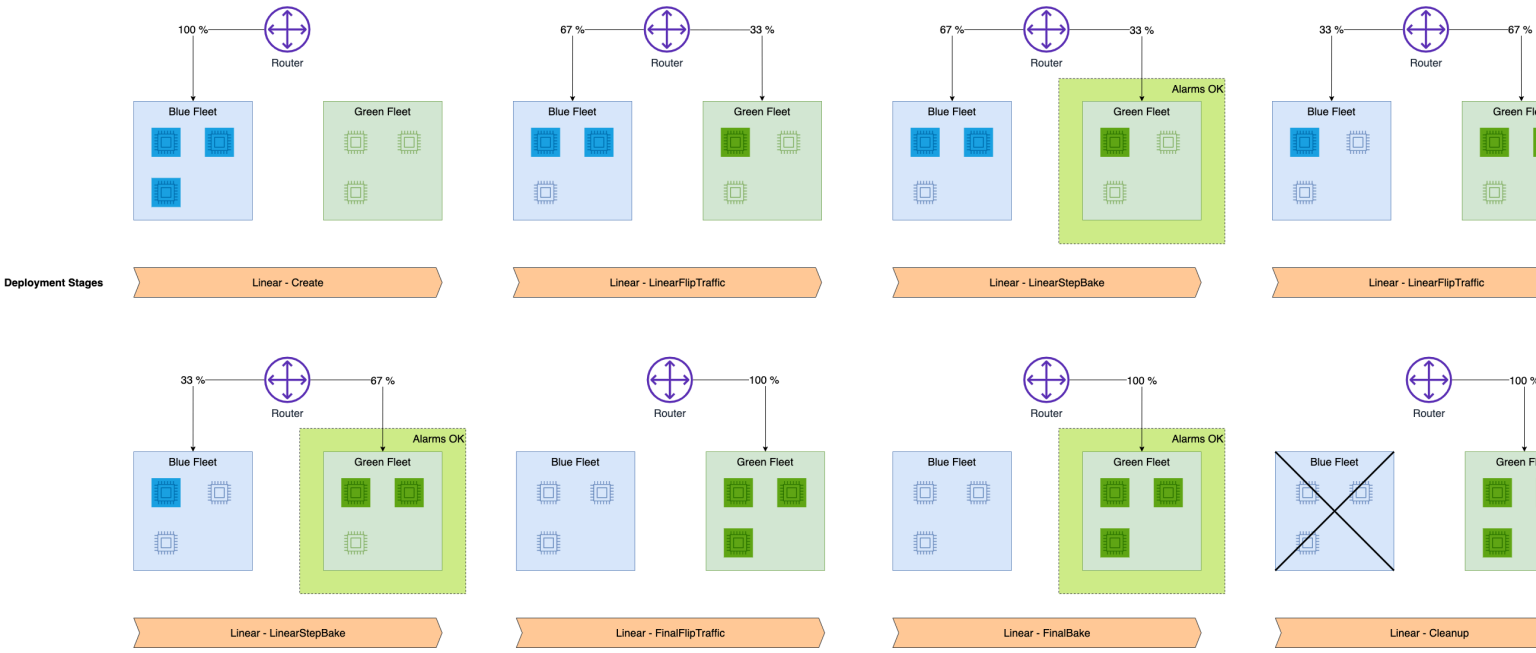
If you are using the Amazon CLI, the following example shows how to start a blue/green canary deployment using the update-endpoint command.

```
update-endpoint
```

```
--endpoint-name <your-endpoint-name>
--endpoint-config-name <your-config-name>
--deployment-config '"BlueGreenUpdatePolicy": {"TrafficRoutingConfiguration": {"Type":
 "CANARY",
    "CanarySize": {"Type": "CAPACITY_PERCENT", "Value": 30}, "WaitIntervalInSeconds":
 600},
    "TerminationWaitInSeconds": 600, "MaximumExecutionTimeoutInSeconds": 1800},
    "AutoRollbackConfiguration": {"Alarms": [{"AlarmName": "<your-alarm>"}]}'
```

To configure the canary traffic shifting option, do the following:

- For `endpoint-name`, use the name of the endpoint you want to update.
- For `endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `deployment-config`, use a BlueGreenUpdatePolicy JSON object.



> **Note**
>
> If you would rather save your JSON object in a file, see Generating Amazon CLI skeleton and input parameters in the *Amazon CLI User Guide*.

Use linear traffic shifting

Linear traffic shifting enables you to gradually shift traffic from your old fleet (blue fleet) to your new fleet (green fleet). With linear traffic shifting, you can shift traffic in multiple steps, minimizing the chance of a disruption to your endpoint. This blue/green deployment option gives you the most granular control over traffic shifting.

You can choose either the number of instances or the percentage of the green fleet's capacity to activate during each step. Each linear step should only be between 10-50% of the green fleet's capacity. For each step, there is a baking period during which your pre-specified Amazon CloudWatch alarms monitor metrics on the green fleet. Once the baking period finishes and no alarms trip, the active portion of your green fleet continues receiving traffic and a new step begins. If alarms trip during any of the baking periods, 100% of the endpoint traffic rolls back to the blue fleet.

The following diagram shows how linear traffic shifting routes traffic to the blue and green fleets.

100 %
Router
Blue Fleet
Green Fleet

33 %
Alarms OK
Deployment Stages
Linear - Create
Linear - LinearFlipTraffic
Linear - LinearStepBake
Linear - LinearFlipTraffic
Linear - LinearStepBake
Linear - FinalFlipTraffic
Linear - FinalBake
Linear - Cleanup

Once SageMaker AI provisions the new fleet, the first portion of the green fleet turns on and receives traffic. SageMaker AI deactivates the same size portion of the blue fleet, and the baking period begins. If any alarms trip, all of the endpoint traffic rolls back to the blue fleet. If the baking period finishes, then the next step begins. Another portion of the green fleet activates and receives traffic, part of the blue fleet deactivates, and another baking period begins. The same process repeats until the blue fleet is fully deactivated and the green fleet is fully active and receiving all traffic. If an alarm goes off at any point, SageMaker AI terminates the shifting process and 100% of the traffic rolls back to the blue fleet.

Prerequisites

Before setting up a deployment with linear traffic shifting, you must create CloudWatch alarms to monitor metrics from your endpoint. The alarms are active during the baking period, and if any alarms trip, then all endpoint traffic rolls back to the blue fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring. To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the *Amazon CloudWatch User Guide*.

Configure Linear Traffic Shifting

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use either the Amazon SageMaker AI UpdateEndpoint API or the update-endpoint command in the Amazon CLI to initiate the deployment.

Topics

- How to update an endpoint (API)
- How to update an endpoint with an existing blue/green update policy (API)
- How to update an endpoint (CLI)

How to update an endpoint (API)

The following example of the UpdateEndpoint API shows how you can update an endpoint with linear traffic shifting.

```
import boto3
client = boto3.client("sagemaker")

response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
```

```
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "BlueGreenUpdatePolicy": {
            "TrafficRoutingConfiguration": {
                "Type": "LINEAR",
                "LinearStepSize": {
                    "Type": "CAPACITY_PERCENT",
                    "Value": 20
                },
                "WaitIntervalInSeconds": 300
            },
            "TerminationWaitInSeconds": 300,
            "MaximumExecutionTimeoutInSeconds": 3600
        },
        "AutoRollbackConfiguration": {
            "Alarms": [
                {
                    "AlarmName": "<your-cw-alarm>"
                }
            ]
        }
    }
)
```

To configure the linear traffic shifting option, do the following:

- For `EndpointName`, use the name of the existing endpoint you want to update.
- For `EndpointConfigName`, use the name of the endpoint configuration you want to use.
- Under `DeploymentConfig` and `BlueGreenUpdatePolicy`, in `TrafficRoutingConfiguration`, set the `Type` parameter to `LINEAR`. This specifies that the deployment uses linear traffic shifting.
- In the `LinearStepSize` field, you can change the size of the steps by modifying the `Type` and `Value` parameters. For `Type`, use `CAPACITY_PERCENT`, meaning the percentage of your green fleet you want to use as the step size, and then set `Value` to `20`. In this example, you turn on 20% of the green fleet's capacity for each traffic shifting step. Note that when customizing your linear step size, you should only use steps that are 10-50% of the green fleet's capacity.
- For `WaitIntervalInSeconds`, use `300`. The parameter tells SageMaker AI to wait for the specified amount of time (in seconds) between each traffic shift. This interval is the duration of the baking period between each linear step. In the preceding example, SageMaker AI waits for 5 minutes between each traffic shift.

- For `TerminationWaitInSeconds`, use `300`. This parameter tells SageMaker AI to wait for the specified amount of time (in seconds) after your green fleet is fully active before terminating the instances in the blue fleet. In this example, SageMaker AI waits for 5 minutes after the final baking period before terminating the blue fleet.
- For `MaximumExecutionTimeoutInSeconds`, use `3600`. This parameter sets the maximum amount of time that the deployment can run before it times out. In the preceding example, your deployment has a limit of 1 hour to finish.
- In `AutoRollbackConfiguration`, within the `Alarms` field, you can add your CloudWatch alarms by name. Create one `AlarmName: <your-cw-alarm>` entry for each alarm you want to use.

How to update an endpoint with an existing blue/green update policy (API)

When you use the CreateEndpoint API to create an endpoint, you can optionally specify a deployment configuration to reuse for future endpoint updates. You can use the same `DeploymentConfig` options as the previous UpdateEndpoint API example. There are no changes to the CreateEndpoint API behavior. Specifying the deployment configuration does not automatically perform a blue/green update on your endpoint.

The option to use a previous deployment configuration happens when using the UpdateEndpoint API to update your endpoint. When updating your endpoint, you can use the `RetainDeploymentConfig` option to keep the deployment configuration you specified when you created the endpoint.

When calling the UpdateEndpoint API, set `RetainDeploymentConfig` to `True` to keep the `DeploymentConfig` options from your original endpoint configuration.

```
response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    RetainDeploymentConfig=True
)
```

How to update an endpoint (CLI)

If you are using the Amazon CLI, the following example shows how to start a blue/green linear deployment using the update-endpoint command.

```
update-endpoint
```

```
--endpoint-name <your-endpoint-name>
--endpoint-config-name <your-config-name>
--deployment-config '{"BlueGreenUpdatePolicy": {"TrafficRoutingConfiguration": {"Type":
 "LINEAR",
    "LinearStepSize": {"Type": "CAPACITY_PERCENT", "Value": 20},
 "WaitIntervalInSeconds": 300},
    "TerminationWaitInSeconds": 300, "MaximumExecutionTimeoutInSeconds": 3600},
    "AutoRollbackConfiguration": {"Alarms": [{"AlarmName": "<your-alarm>"}]}'
```

To configure the linear traffic shifting option, do the following:

- For `endpoint-name`, use the name of the endpoint you want to update.
- For `endpoint-config-name`, use the name of the endpoint configuration you want to use.
- For `deployment-config`, use a BlueGreenUpdatePolicy JSON object.

> **Note**
>
> If you would rather save your JSON object in a file, see Generating Amazon CLI skeleton and input parameters in the *Amazon CLI User Guide*.

Use rolling deployments

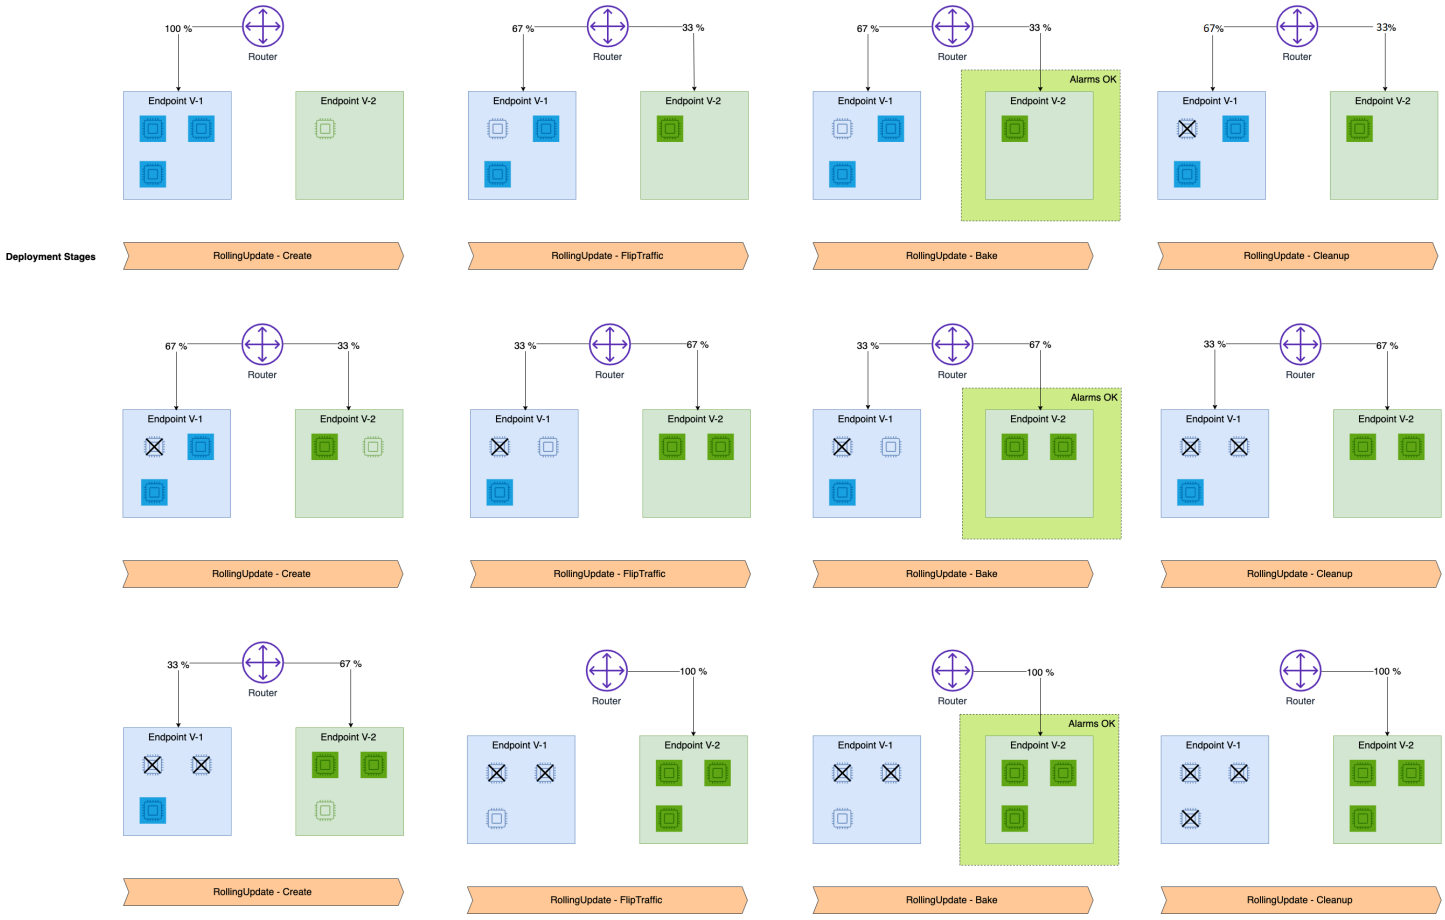
When you update your endpoint, you can specify a rolling deployment to gradually shift traffic from your old fleet to a new fleet. You can control the size of the traffic shifting steps, as well as specify an evaluation period to monitor the new instances for issues before terminating instances from the old fleet. With rolling deployments, instances on the old fleet are cleaned up after each traffic shift to the new fleet, reducing the amount of additional instances needed to update your endpoint. This is useful especially for accelerated instances that are in high demand.

Rolling deployments gradually replace the previous deployment of your model version with the new version by updating your endpoint in configurable batch sizes. The traffic shifting behavior of rolling deployments is similar to the linear traffic shifting mode in blue/green deployments, but rolling deployments provide you with the benefit of reduced capacity requirements when compared to blue/green deployments. With rolling deployments, fewer instances are active at a time, and you have more granular control over how many instances you want to update in the new fleet. You should consider using a rolling deployment instead of a blue/green deployment if you have large models or a large endpoint with many instances.

The following list describes the key features of rolling deployments in Amazon SageMaker AI:

- **Baking period.** The baking period is a set amount of time to monitor the new fleet before proceeding to the next deployment stage. If any of the pre-specified alarms trip during any baking period, then all endpoint traffic rolls back to the old fleet. The baking period helps you to build confidence in your update before making the traffic shift permanent.
- **Rolling batch size.** You have granular control over the size of each batch for traffic shifting, or the number of instances you want to update in each batch. This number can range for 5–50% of the size of your fleet. You can specify the batch size as a number of instances or as the overall percentage of your fleet.
- **Auto-rollbacks.** You can specify Amazon CloudWatch alarms that SageMaker AI uses to monitor the new fleet. If an issue with the updated code trips any of the alarms, SageMaker AI initiates an auto-rollback to the old fleet in order to maintain availability, thereby minimizing risk.

> **Note**
>
> If your endpoint uses any of the features listed in the Exclusions page, you cannot use rolling deployments.



How it works

During a rolling deployment, SageMaker AI provides the infrastructure to shift traffic from the old fleet to the new fleet without having to provision all of the new instances at once. SageMaker AI uses the following steps to shift traffic:

1. SageMaker AI provisions the first batch of instances in the new fleet.
2. A portion of traffic is shifted from the old instances to the first batch of new instances.
3. After the baking period, if no Amazon CloudWatch alarms are tripped, then SageMaker AI cleans up a batch of old instances.
4. SageMaker AI continues to provision, shift, and clean up instances in batches until the deployment is complete.

If an alarm is tripped during one of the baking periods, then traffic is rolled back to the old fleet in batches of a size that you specify. Alternatively, you can specify the rolling deployment to shift 100% of the traffic back to the old fleet if an alarm is tripped.

The following diagram shows the progression of a successful rolling deployment, as described in the previous steps.

To create a rolling deployment, you only have to specify your desired deployment configuration. Then SageMaker AI handles provisioning new instances, terminating old instances, and shifting traffic for you. You can create and manage your deployment through the existing UpdateEndpoint and CreateEndpoint SageMaker API and Amazon Command Line Interface commands.

Prerequisites

Before setting up a rolling deployment, you must create Amazon CloudWatch alarms to watch metrics from your endpoint. If any of the alarms trip during the baking period, then the traffic begins rolling back to your old fleet. To learn how to set up CloudWatch alarms on an endpoint, see the prerequisite page Auto-Rollback Configuration and Monitoring. To learn more about CloudWatch alarms, see Using Amazon CloudWatch alarms in the *Amazon CloudWatch User Guide*.

Also, review the Exclusions page to make sure that your endpoint meets the requirements for a rolling deployment.

Determine the rolling batch size

Before updating your endpoint, determine the batch size that you want to use for incrementally shifting traffic to the new fleet.

For rolling deployments, you can specify a batch size that is 5–50% of the capacity of your fleet. If you choose a large batch size, the deployment completes more quickly. However, keep in mind that the endpoint requires more capacity while updating, roughly the batch size overhead. If you choose a smaller batch size, the deployment takes longer, but you use less capacity during the deployment.

Configure a rolling deployment

Once you are ready for your deployment and have set up CloudWatch alarms for your endpoint, you can use the SageMaker AI UpdateEndpoint API or the update-endpoint command in the Amazon Command Line Interface to initiate the deployment.

How to update an endpoint

The following example shows how you can update your endpoint with a rolling deployment using the update_endpoint method of the Boto3 SageMaker AI client.

To configure a rolling deployment, use the following example and fields:

- For `EndpointName`, use the name of the existing endpoint you want to update.
- For `EndpointConfigName`, use the name of the endpoint configuration you want to use.
- In the `AutoRollbackConfiguration` object, within the `Alarms` field, you can add your CloudWatch alarms by name. Create one `AlarmName: <your-cw-alarm>` entry for each alarm you want to use.
- Under `DeploymentConfig`, for the `RollingUpdatePolicy` object, specify the following fields:
  - `MaximumExecutionTimeoutInSeconds` — The time limit for the total deployment. Exceeding this limit causes a timeout. The maximum value you can specify for this field is 28800 seconds, or 8 hours.
  - `WaitIntervalInSeconds` — The length of the baking period, during which SageMaker AI monitors alarms for each batch on the new fleet.
  - `MaximumBatchSize` — Specify the `Type` of batch you want to use (either instance count or overall percentage of your fleet) and the `Value`, or the size of each batch.

- `RollbackMaximumBatchSize` — Use this object to specify the rollback strategy in case an alarm trips. Specify the `Type` of batch you want to use (either instance count or overall percentage of your fleet), and the `Value`, or the size of each batch. If you don't specify these fields, or if you set the value to 100% of your endpoint, then SageMaker AI uses a blue/green rollback strategy and rolls all traffic back to the old fleet when an alarm trips.

```
import boto3
client = boto3.client("sagemaker")

response = client.update_endpoint(
    EndpointName="<your-endpoint-name>",
    EndpointConfigName="<your-config-name>",
    DeploymentConfig={
        "AutoRollbackConfiguration": {
            "Alarms": [
                {
                    "AlarmName": "<your-cw-alarm>"
                },
            ]
        },
        "RollingUpdatePolicy": {
            "MaximumExecutionTimeoutInSeconds": number,
            "WaitIntervalInSeconds": number,
            "MaximumBatchSize": {
                "Type": "INSTANCE_COUNT" | "CAPACITY_PERCENTAGE" (default),
                "Value": number
            },
            "RollbackMaximumBatchSize": {
                "Type": "INSTANCE_COUNT" | "CAPACITY_PERCENTAGE" (default),
                "Value": number
            },
        }
    }
)
```

After updating your endpoint, you might want to check the status of your rolling deployment and check the health of your endpoint. You can review your endpoint's status in the SageMaker AI console, or you can review the status of your endpoint by using the DescribeEndpoint API.

In the `VariantStatus` object returned by the `DescribeEndpoint` API, the `Status` field tells you the current deployment or operational status of your endpoint. For more information about the possible statuses and what they mean, see ProductionVariantStatus.

If you attempted to do a rolling deployment and the status of your endpoint is `UpdateRollbackFailed`, see the following section for troubleshooting help.

Failure handling

If your rolling deployments fails and the auto-rollback fails as well, your endpoint can be left with a status of `UpdateRollbackFailed`. This status means that different endpoint configurations are deployed to the instances behind your endpoint, and your endpoint is in service with a mix of old and new endpoint configurations.

You can make another call to the UpdateEndpoint API to return your endpoint to a healthy state. Specify your desired endpoint configuration and deployment configuration (either as a rolling deployment, a blue/green deployment, or neither) to update your endpoint.

You can call the DescribeEndpoint API to check the health of your endpoint again, which is returned in the `VariantStatus` object as the `Status` field. If your update is successful, your endpoint's `Status` returns to `InService`.

Exclusions

When doing a blue/green or rolling deployment, your new endpoint configuration must have the same variant name as the old endpoint configuration. There are also feature-based exclusions that make your endpoint incompatible with deployment guardrails at this time. If your endpoint uses any of the following features, you cannot use deployment guardrails on your endpoint, and your endpoint will fall back to using a blue/green deployment with all at once traffic shifting and no final baking period:

- Marketplace containers
- Endpoints that use Inf1 (Inferentia-based) instances

If you're doing a rolling deployment, there are additional feature-based exclusions:

- Serverless inference endpoints
- Multi-variant inference endpoints

Shadow tests

With Amazon SageMaker AI you can evaluate any changes to your model serving infrastructure by comparing its performance against the currently deployed infrastructure. This practice is known as shadow testing. Shadow testing can help you catch potential configuration errors and performance issues before they impact end users. With SageMaker AI, you don't need to invest in building your shadow testing infrastructure, so you can focus on model development.

You can use this capability to validate changes to any component of your production variant, namely the model, the container, or the instance, without any end user impact. It is useful in situations including but not limited to the following:

- You are considering promoting a new model that has been validated offline to production, but want to evaluate operational performance metrics such as latency and error rate before making this decision.
- You are considering changes to your serving infrastructure container, such as patching vulnerabilities or upgrading to newer versions, and want to assess the impact of these changes prior to promotion to production.
- You are considering changing your ML instance and want to evaluate how the new instance would perform with live inference requests.

The SageMaker AI console provides a guided experience to manage the workflow of shadow testing. You can set up shadow tests for a predefined duration of time, monitor the progress of the test through a live dashboard, clean up upon completion, and act on the results. Select a production variant you want to test against, and SageMaker AI automatically deploys the new variant in shadow mode and routes a copy of the inference requests to it in real time within the same endpoint. Only the responses of the production variant are returned to the calling application. You can choose to discard or log the responses of the shadow variant for offline comparison. For more information on production and shadow variants, see Validation of models in production.

See Create a shadow test for instructions on creating a shadow test.

Note

Certain endpoint features may make your endpoint incompatible with shadow tests. If your endpoint uses any of the following features, you cannot use shadow tests on your endpoint, and your request to set up shadow tests will lead to validation errors.

- Serverless inference
- Asynchronous inference
- Marketplace containers
- Multiple-container endpoints
- Multi-model endpoints
- Endpoints that use Inf1 (Inferentia-based) instances

Create a shadow test

You can create a shadow test to compare the performance of a shadow variant against a production variant. You can run the test on an existing endpoint that is serving inference requests or you can create a new endpoint on which to run the test.

To create a shadow test you need to specify the following:

- A *production variant* that receives and responds to 100 percent of the incoming inference requests.
- A *shadow variant* that receives a percentage of the incoming requests, replicated from the production variant, but does not return any responses.

For each variant, you can use SageMaker AI to control the model, instance type, and instance count. You can configure the percentage of incoming requests, known as the traffic sampling percentage, that you want replicated to your shadow variant. SageMaker AI manages the replication of requests to your shadow variant and you can modify the traffic sampling percentage when your test is scheduled or running. You can also optionally turn on Data Capture to log requests and responses of your production and shadow variants.

> **Note**
>
> SageMaker AI supports a maximum of one shadow variant per endpoint. For an endpoint with a shadow variant, there can be a maximum of one production variant.

You can schedule the test to start at any time and continue for a specified duration. The default duration is 7 days and the maximum is 30 days. After the test is complete, the endpoint reverts to the state it was in prior to starting the test. This ensures that you do not have to manually clean up resources upon the completion of the test.

You can monitor a test that is running through a dashboard in the SageMaker AI console. The dashboard provides a side by side comparison of invocation metrics and instance metrics between the production and shadow variants, along with a tabular view with relevant metric statistics. This dashboard is also available for completed tests. Once you have reviewed the metrics, you can either choose to promote the shadow variant to be the new production variant or retain the existing production variant. Once you promote the shadow variant, it responds to all incoming requests. For more information, see Promote a shadow variant.

The following procedure describes how to create a shadow test through the SageMaker AI console. There are variations in the workflow depending on whether you want to use an existing endpoint or to create a new endpoint for the shadow test.

Topics

- Prerequisites
- Enter shadow test details
- Enter shadow test settings

Prerequisites

Before creating a shadow test with the SageMaker AI console, you must have a SageMaker AI model ready to use. For more information about how to create a SageMaker AI model, see Deploy models for real-time inference.

You can get started with shadow tests with an existing endpoint with a production variant and a shadow variant, an existing endpoint with only a production variant, or just the SageMaker AI models you'd like to compare. Shadow tests support creating an endpoint and adding variants before your test begins.

Note

Certain endpoint features may make your endpoint incompatible with shadow tests. If your endpoint uses any of the following features, you cannot use shadow tests on your endpoint, and your request to set up shadow tests will lead to validation errors.

- Serverless inference
- Asynchronous inference
- Marketplace containers
- Multiple-container endpoints
- Multi-model endpoints
- Endpoints that use Inf1 (Inferentia-based) instances

Enter shadow test details

To start creating your shadow test, fill out the **Enter shadow test details** page by doing the following:

1. Open the SageMaker AI console.
2. In the left navigation panel, choose **Inference**, and then choose **Shadow tests**.
3. Choose **Create shadow test**.
4. Under **Name**, enter a name for the test.
5. (Optional) Under **Description**, enter a description for the test.
6. (Optional) Specify **Tags** using **Key** and **Value** pairs.
7. Choose **Next**.

Enter shadow test settings

After filling out the **Enter shadow test details** page, fill out the **Enter shadow test settings** page. If you already have a SageMaker AI Inference endpoint and a production variant, follow the **Use an existing endpoint** workflow. If you don't already have an endpoint, follow the **Create a new endpoint** workflow.

Use an existing endpoint

If you want to use an existing endpoint for your test, fill out the **Enter shadow test settings** page by doing the following:

1. Choose a role that has the `AmazonSageMakerFullAccess` IAM policy attached.
2. Choose **Use an existing endpoint**, and then choose one of the available endpoints.
3. (Optional) To encrypt the storage volume on your endpoint, either choose an existing KMS key or choose **Enter a KMS key ARN** from the dropdown list under **Encryption key**. If you choose the second option, a field to enter the KMS key ARN appears. Enter the KMS key ARN in that field.
4. If you have multiple production variants behind that endpoint, remove the ones you don't want to use for the test. You can remove a model variant by selecting it and then choosing **Remove**.
5. If you do not already have a shadow variant, add a shadow variant. To add a shadow variant, do the following:
    a. Choose **Add**.
    b. Choose **Shadow variant**.
    c. In the **Add model** dialog box, choose the model you want to use for your shadow variant.
    d. Choose **Save**.
6. (Optional) In the preceding step, the shadow variant is added with the default settings. To modify these settings, select the shadow variant and choose **Edit**. The **Edit shadow variant** dialog box appears. For more information on filling out this dialog box, see Edit a shadow test.
7. In the **Schedule** section, enter the duration of the test by doing the following:
    a. Choose the box under **Duration**. A popup calender appears.
    b. Select the start and end dates from the calender, or enter the start and end dates in the fields for **Start date** and **End date**, respectively.
    c. (Optional) For the fields **Start time** and **End time**, enter the start and end times, respectively, in the 24 hour format.
    d. Choose **Apply**.

The minimum duration is 1 hour, and the maximum duration is 30 days.

8. (Optional) Turn on **Enable data capture** to save inference request and response information from your endpoint to an Amazon S3 bucket, and then enter the location of the Amazon S3 bucket.
9. Choose **Create shadow test**.

Create a new endpoint

If you don't have an existing endpoint, or you want to create a new endpoint for your test, fill out the **Enter shadow test settings** page by doing the following:

1. Choose a role that has the `AmazonSageMakerFullAccess` IAM policy attached.
2. Choose **Create a new endpoint**.
3. Under **Name**, enter a name for the endpoint.
4. Add one production variant and one shadow variant to the endpoint:
   - To add a production variant choose **Add**, and then choose **Production variant**. In the **Add model** dialog box, choose the model you want to use for your production variant, and then choose **Save**.
   - To add a shadow variant choose **Add**, and then choose **Shadow variant**. In the **Add model** dialog box, choose the model you want to use for your shadow variant, and then choose **Save**.
5. (Optional) In the preceding step, the shadow variant is added with the default settings. To modify these settings, select the shadow variant and choose **Edit**. The **Edit shadow variant** dialog box appears. For more information on filling out this dialog box, see Edit a shadow test.
6. In the **Schedule** section, enter the duration of the test by doing the following:
   a. Choose the box under **Duration**. A popup calender appears.
   b. Select the start and end dates from the calender, or enter the start and end dates under **Start date** and **End date**, respectively.
   c. (Optional) Under **Start time** and **End time**, enter the start and end times, respectively, in the 24 hour format.
   d. Choose **Apply**.

The minimum duration is 1 hour, and the maximum duration is 30 days.

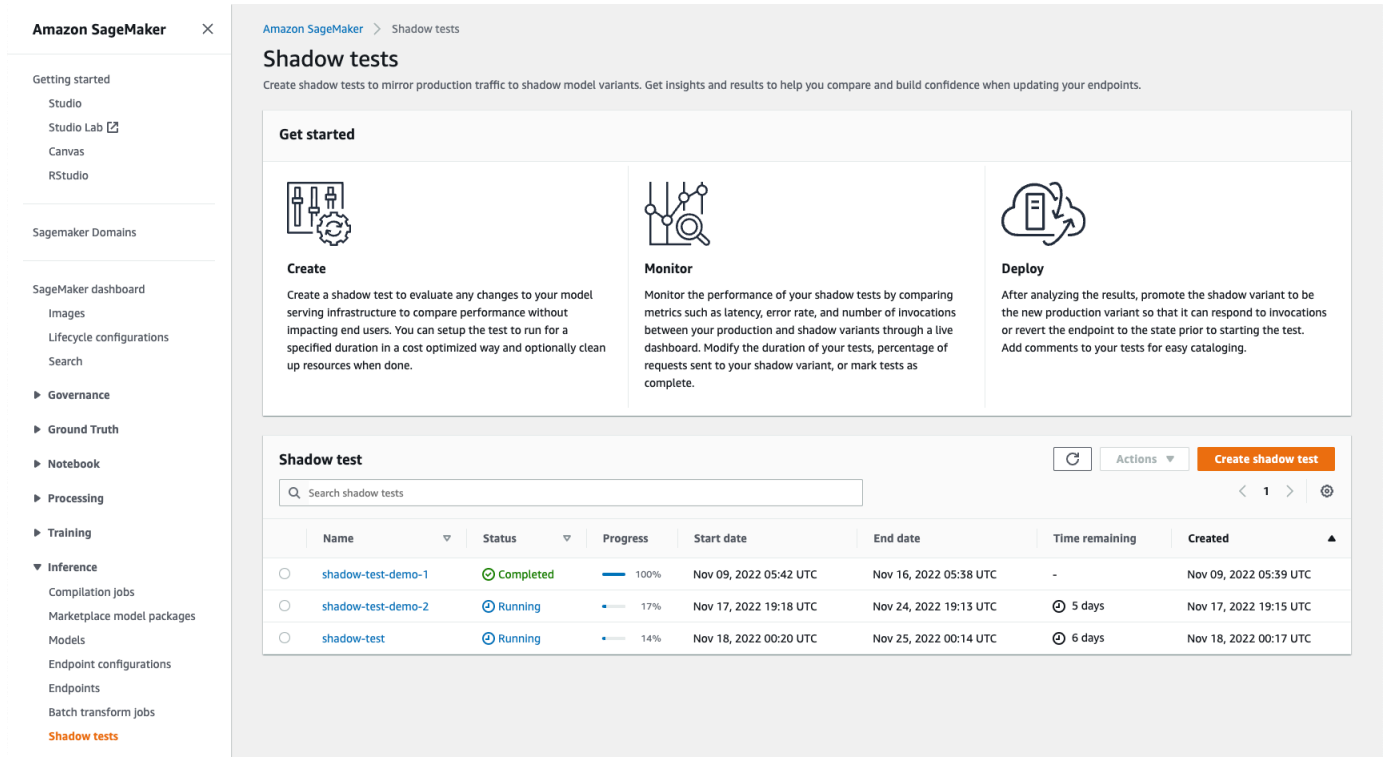
7. (Optional) Turn on **Enable data capture** to save inference request and response information from your endpoint to an Amazon S3 bucket, and then enter the location of the Amazon S3 bucket.
8. Choose **Create shadow test**.

After completing the preceding procedures, you should now have a test scheduled to begin at your specified start date and time. You can view the progress of the test from a dashboard. For more information about viewing your test and the actions you can take, see How to view, monitor, and edit shadow tests.

How to view, monitor, and edit shadow tests

You can view the statuses of your shadow tests, monitor their progress from a dashboard, and perform actions, such as starting or stopping an test early or deleting an test. The following topics show how you can view and modify your shadow tests using the SageMaker AI console.

Topics



- View shadow tests
- Monitor a shadow test
- Start a shadow test early
- Delete a shadow test
- Edit a shadow test

View shadow tests

You can view the statuses of all of your shadow tests on the **Shadow tests** page on the SageMaker AI console.

To view your tests in the console, do the following:

1. Open the SageMaker AI console.
2. In the navigation panel, choose **Inference**.
3. Choose **Shadow tests** to view the page that lists all of your shadow tests. The page should look like the following screenshot, with all the tests listed under the **Shadow test** section.

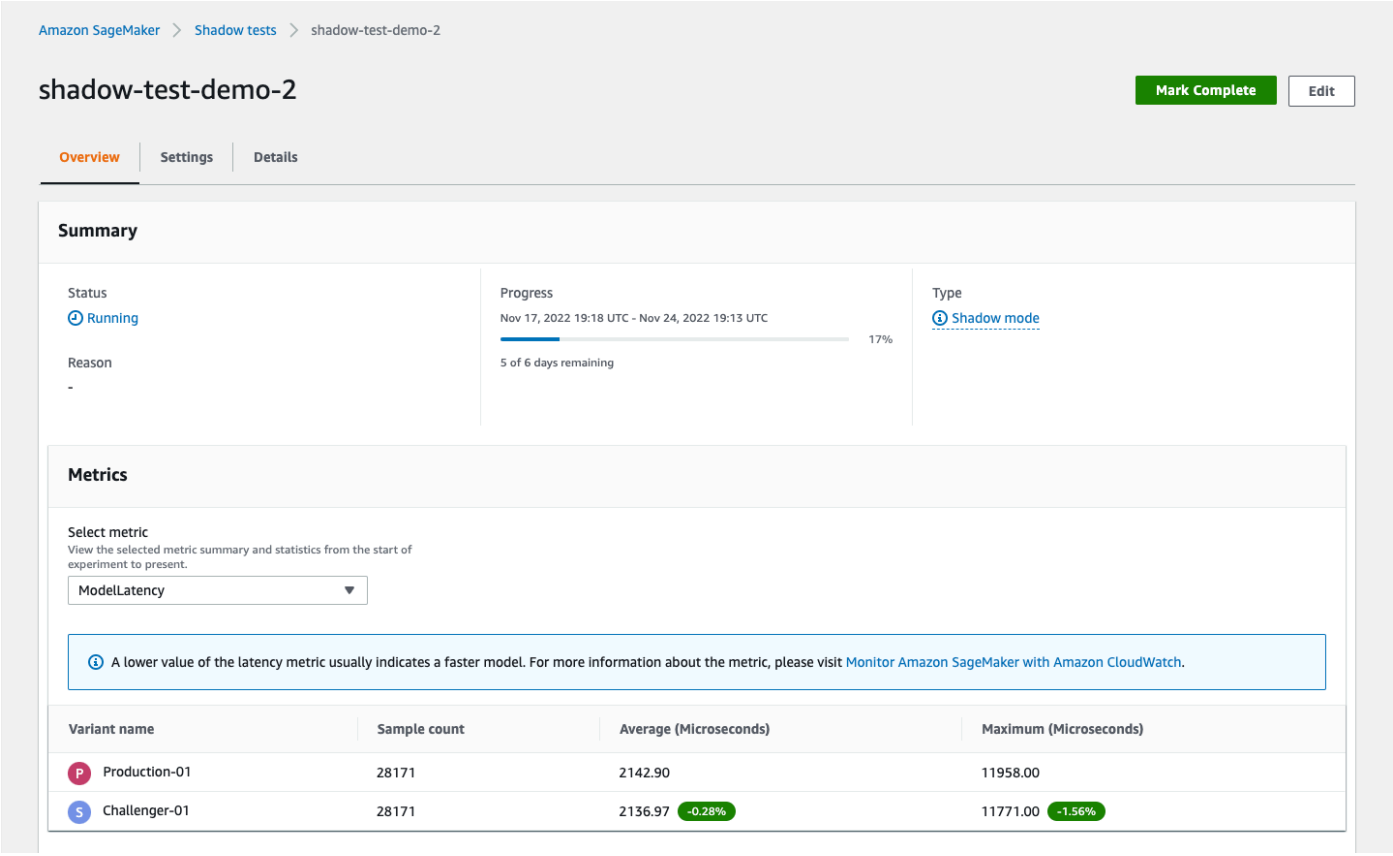
You can see the status of a test in the console on the **Shadow tests** page by checking the **Status** field for the test.

The following are the possible statuses for a test:

- `Creating` – SageMaker AI is creating your test.
- `Created` – SageMaker AI has finished creating your test, and it will begin at the scheduled time.
- `Updating` – When you make changes to your test, your test shows as updating.
- `Starting` – SageMaker AI is beginning your test.
- `Running` – Your test is in progress.
- `Stopping` – SageMaker AI is stopping your test.
- `Completed` – Your test has completed.
- `Cancelled` – When you conclude your test early, it shows as cancelled.

Monitor a shadow test

You can view the details of a shadow test and monitor it while it is in progress or after it has completed. SageMaker AI presents a live dashboard comparing the operational metrics like model latency, and error rate aggregated, of the production and shadow variants.



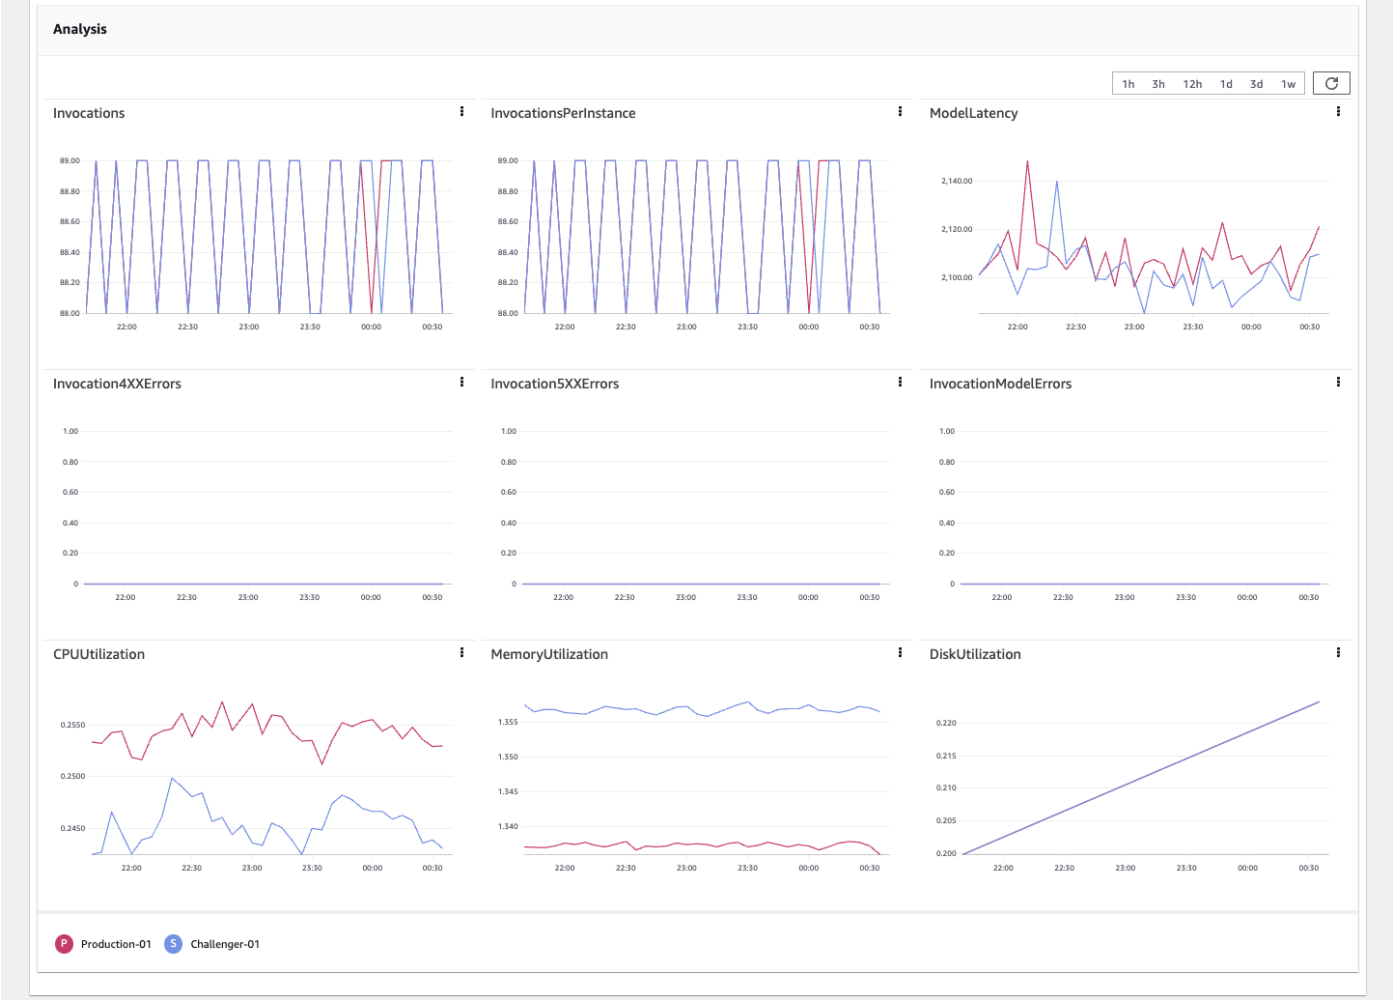
To view the details of an individual test in the console, do the following:

1. Select the test you want to monitor from the **Shadow test** section on the **Shadow tests** page.
2. From the **Actions** dropdown list, choose **View**. An overview page with the details of the test and a metrics dashboard appears.

The overview page has the following three sections.

Summary

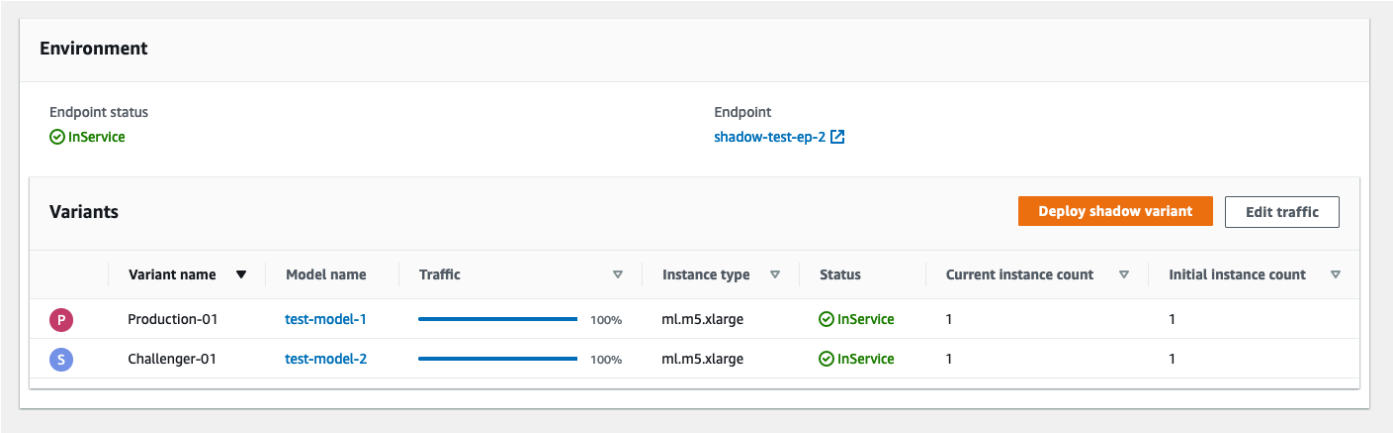
This section summarizes the progress and status of the test. It also shows the summary statistics of the metric chosen from the **Select metric** dropdown list in the **Metrics** subsection. The following screenshot shows this section.



In the preceding screenshot, the **Settings**, and **Details** tabs show the settings that you selected, and the details that you entered when creating the test.

Analysis

This section shows a metrics dashboard with separate graphs for the following metrics:



- `Invocations`
- `InvocationsPerInstance`
- `ModelLatency`
- `Invocation4XXErrors`
- `Invocation5XXErrors`
- `InvocationModelErrors`
- `CPUUtilization`
- `MemoryUtilization`
- `DiskUtilization`

The last three metrics monitor the model container runtime resource usage. The rest are CloudWatch metrics that you can use to analyse the performance of your variant. In general, fewer errors indicate a more stable model. A lower latency indicates either a faster model or a faster infrastructure. For more information about CloudWatch metrics, see SageMaker AI endpoint invocation metrics. The following screenshot shows the metrics dashboard.

Environment

This section shows the variants that you compared in the test. If you are satisfied by the performance of the shadow variant, based on the aforementioned metrics, you can promote the shadow variant to production, by choosing **Deploy shadow variant**. For more details about deploying a shadow variant, see Promote a shadow variant. You can also change the traffic sampling percentage, and continue testing, by choosing **Edit traffic**. For more details about editing a shadow variant, see Edit a shadow test. The following screenshot shows this section.

Start a shadow test early

You can start your test before its scheduled start time. If the new duration of the test exceeds 30 days, SageMaker AI automatically sets the end of the test to 30 days after the new start time. This action starts the test immediately. If you want to change the start or end time of the test, see Edit a shadow test.

To immediately start your test, before its scheduled start time, through the console, do the following:

1. Select the test you want to start immediately from the **Shadow test** section on the **Shadow tests** page.
2. From the **Actions** dropdown list, choose **Start**. The **Start shadow test?** dialog box appears.
3. Choose **Start now**.

Delete a shadow test

You can delete a test that you no longer need. Deleting your test only deletes the test metadata and not your endpoint, variants, or data captured in Amazon S3. If you want your endpoint to stop running, you must delete your endpoint. For more information about deleting an endpoint, see Delete Endpoints and Resources

To delete a test through the console, do the following:

1. Select the test you want to delete from the **Shadow test** section on the **Shadow tests** page.
2. From the **Actions** dropdown list, choose **Delete**. The **Delete shadow test** dialog box appears.

3. In the **To confirm deletion, type *delete* in the field.** text box, enter **`delete`**.
4. Choose **Delete**.

Edit a shadow test

You can modify both scheduled and in-progress tests. Before your test starts, you can change the description, the shadow variant configuration, the start date, and the end date of the test. You can also turn on or turn off data capture.

After your test starts, you can only change the description, the traffic sampling percentage for the shadow variant, and the end date.

To edit the details of your test through the console, do the following:

1. Select the test you want to edit from the **Shadow test** section on the **Shadow tests** page.
2. From the **Actions** dropdown list, choose **Edit**. The **Enter shadow test details** page appears.
3. (Optional) Under **Description**, enter a description of your test.
4. Choose **Next**. The **Enter shadow test settings** page appears.
5. (Optional) To edit your shadow variant, do the following:

    a. Select the shadow variant and choose **Edit**. The **Edit shadow variant** dialog box appears. If your test has already started, then you can only change the traffic sampling percentage.
    b. (Optional) Under **Name**, enter the new name to replace the old name.
    c. (Optional) Under **Traffic sample**, enter the new traffic sampling percentage to replace the old traffic sampling percentage.
    d. (Optional) Under **Instance type**, select the new instance type from the dropdown list.
    e. (Optional) Under **Instance count**, enter the new instance count to replace the old instance count.
    f. Choose **Apply**.

    You cannot change the model in your shadow variant using the above procedure. If you want to change the model, first remove the shadow variant by selecting it and choosing **Remove**. Then add a new shadow variant.
6. (Optional) To edit the duration of the test, do the following:

    a. Choose the box under **Duration** in the **Schedule** section. A popup calender appears.

b. If your test is yet to start, you can change both the start and end dates. Select the new start and end dates from the calender, or enter the new start and end dates under **Start date** and **End date**, respectively.

   If your test has already started, you can only change the end date. Enter the new end date under **End date**.

c. (Optional) If your test is yet to start, you can change both the start and end times. Enter the new start and end times under **Start time**, and **End time**, respectively, in the 24 hour format.

   If your test has already started, you can only change the end time. Enter the new end time under **End time**, in the 24 hour format.

d. Choose **Apply**.

7. (Optional) Turn on or turn off **Enable data capture**.
8. Choose **Update shadow test**.

Complete a shadow test

Your test automatically completes at the end of the scheduled duration, or you can stop an in-progress test early. After your test has completed, the test's status in the **Shadow tests** section on the **Shadow tests** page shows as **Complete**. Then you can review and analyze the final metrics of your test.

You can use the metrics dashboard to decide whether to promote the shadow variant to production. For more information about analyzing the metrics dashboard of your test, see Monitor a shadow test.

For instructions on how to complete your test before the end of its scheduled completion time, see Complete a shadow test early.

For instructions on promoting your shadow variant to production, see Promote a shadow variant.

Complete a shadow test early

One reason you might want to complete an in-progress shadow test is if you've decided that the metrics for your shadow variant look good and you want to promote it to production. You might also decide to complete the test if one or more of the variants aren't performing well.

To complete your test before its scheduled end date, do the following:

1. Select the test you want to mark complete from the **Shadow tests** section on the **Shadow tests** page.
2. From the **Actions** dropdown list, choose **Complete**, and the **Complete shadow test** dialog box appears.
3. In the dialog box, choose one of the following options:
   - **Yes, deploy shadow variant**
   - **No, remove shadow variant**
4. (Optional) In the **Comment** text box, enter your reason for completing the test before its scheduled end time.
5. 1. If you decided to deploy the shadow variant, choose **Complete and proceed to deploy**. The **Deploy shadow variant** page appears. For instructions on how to fill out this page, see Promote a shadow variant.
   2. If you decide to remove the shadow variant, choose **Confirm**.

Promote a shadow variant

If you've decided that you want to replace your production variant with your shadow variant, you can update your endpoint and promote your shadow variant to respond to inference requests. This removes your current production variant from production and replaces it with your shadow variant.

If your shadow test is still in-progress, you must first complete your test. To complete your shadow test before its scheduled end, follow the instructions in Complete a shadow test early before continuing with this section.

When you promote a shadow variant to production, you have the following options for the instance count of the shadow variant.

- You can retain the instance count and type from the production variant. If you select this option, then your shadow variant launches in production with the current instance count, ensuring that your model can continue to process request traffic at the same scale.
- You can retain the instance count and type of your shadow variant. If you want to use this option, we recommend that you shadow test with 100 percent traffic sampling to ensure that the shadow variant can process request traffic at the current scale.

- You can use custom values for the instance count and type. If you want to use this option, we recommend that you shadow test with 100 percent traffic sampling to ensure that the shadow variant can process request traffic at the current scale.

Unless you are validating the instance type or count or both of the shadow variant, we highly recommend that you retain the instance count and type from the production variant when promoting your shadow variant.

To promote your shadow variant, do the following:

1. If your test has completed, do the following:

   a. Select the test from the **Shadow test** section on the **Shadow tests** page.

   b. From the **Actions** dropdown list, choose **View**. The dashboard appears.

   c. Choose **Deploy shadow variant** in the **Environment** section. The **Deploy shadow variant** page appears.

   If your test has not completed, see Complete a shadow test early to complete it.
2. In the **Variant settings** section, select one of the following options:

   - **Retain production settings**
   - **Retain shadow settings**
   - **Custom instance settings**

   If you selected **Custom instance settings**, do the following:

   a. Select the instance type from the **Instance type** dropdown list.

   b. Under **Instance count**, enter the number of instances.
3. In **Enter 'deploy' to confirm deployment** text box, enter **`deploy`**.
4. Choose **Deploy shadow variant**.

Your SageMaker AI Inference endpoint is now using the shadow variant as your production variant, and your production variant has been removed from the endpoint.

Best practices

When creating an inference experiment, keep the following information in mind:

- **Traffic sampling percentage** – Sampling 100 percent of the inference requests lets you validate that your shadow variant can handle production traffic when promoted. You may start off with a lower traffic sampling percentage and dial up as you gain confidence in your variant, but it is best practice to ensure that you've increased the traffic to 100 percent prior to promotion.
- **Instance type** – Unless you are using shadow variants to evaluate alternate instance types or sizes, we recommend that you use the same instance type, size, and count so that you can be certain that your shadow variant can handle the volume of inference requests after you promote it.
- **Auto scaling** – To ensure that your shadow variant can respond to spikes in the number of inference requests or changes in inference requests patterns, we highly recommend that you configure autoscaling on your shadow variants. To learn how to configure autoscaling, see Automatic scaling of Amazon SageMaker AI models. If you have configured autoscaling, you can also validate changes to autoscaling policies without causing impact to users.
- **Metrics monitoring** – After you initiate a shadow experiment and have sufficient invocations, monitor the metrics dashboard to ensure that the metrics such as latency and error rate are within acceptable bounds. This helps you catch misconfigurations early and take corrective action. For information about how to monitor the metrics of an in-progress inference experiment, see How to view, monitor, and edit shadow tests.

Access containers through SSM

Amazon SageMaker AI allows you to securely connect to the Docker containers on which your models are deployed on for Inference using Amazon Systems Manager (SSM). This gives you shell level access to the container so that you can debug the processes running within the container and log commands and responses with Amazon CloudWatch. You can also set up an Amazon PrivateLink connection to the ML instances that host your containers for accessing the containers via SSM privately.

> **Warning**
>
> Enabling SSM access can impact the performance of your endpoint. We recommend using this feature with your dev or test endpoints and not with the endpoints in production.

Also, SageMaker AI automatically applies security patches, and replaces or terminates faulty endpoint instances within 10 minutes. However for endpoints with SSM enabled production variants, SageMaker AI delays security patching and replacing or terminating faulty endpoint instances by a day, to allow you to debug.

The following sections detail how you can use this feature.

Allowlist

You have to contact customer support, and get your account allowlisted, to use this feature. You cannot create an endpoint with SSM access enabled, if your account is not allow listed for this access.

Enable SSM access

To enable SSM access for an existing container on an endpoint, update the endpoint with a new endpoint configuration, with the `EnableSSMAccess` parameter set to `true` The following example provides a sample endpoint configuration.

```
{
    "EndpointConfigName": "endpoint-config-name",
    "ProductionVariants": [
        {
            "InitialInstanceCount": 1,
            "InitialVariantWeight": 1.0,
            "InstanceType": "ml.t2.medium",
            "ModelName": model-name,
            "VariantName": variant-name,
            "EnableSSMAccess": true,
        },
    ]
}
```

For more information on enabling SSM access, see EnableSSMAccess.

IAM configuration

Endpoint IAM permissions

If you have enabled SSM access for an endpoint instance, SageMaker AI starts and manages the SSM agent when it initiates the endpoint instance. To allow the SSM agent to communicate with the SSM services, add the following policy to the execution role that the endpoint runs under.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssmmessages:CreateControlChannel",
                "ssmmessages:CreateDataChannel",
                "ssmmessages:OpenControlChannel",
                "ssmmessages:OpenDataChannel"
            ],
            "Resource": "*"
        }
    ]
 }
```

User IAM permissions

Add the following policy to give an IAM user SSM session permissions to connect to a SSM target.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession",
```

```
                "ssm:TerminateSession"
            ],
            "Resource": "*"
        }
    ]
}
```

You can restrict the endpoints that an IAM user can connect to, with the following policy. Replace the *italicized placeholder text* with your own information.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:StartSession"
            ],
            "Resource": "arn:aws-cn:sagemaker:us-
west-2:111122223333:endpoint/endpoint-name"
        }
    ]
}
```

SSM access with Amazon PrivateLink

If your endpoints run within a virtual private cloud (VPC) that is not connected to the public internet, you can use Amazon PrivateLink to enable SSM. Amazon PrivateLink restricts all network traffic between your endpoint instances, SSM, and Amazon EC2 to the Amazon network. For more information on how to setup SSM access with Amazon PrivateLink, see Set up a VPC endpoint for Session Manager.

Logging with Amazon CloudWatch Logs

For SSM access enabled endpoints, you can log errors from the SSM agent with Amazon CloudWatch Logs. For more information on how to log errors with CloudWatch Logs, see Logging

session activity. The log is available at the SSM log stream, *variant-name*/*ec2-instance-id*/ssm, under the endpoint log group /aws/sagemaker/endpoints/*endpoint-name*. For more information on how to view the log, see View log data sent to CloudWatch Logs.

Production variants behind your endpoint can have multiple model containers. The log for each model container is recorded in the log stream. Each log is preceded by [sagemaker ssm logs] [container-name], where container-name is either the name that you gave to the container, or the default name, such as container_0, and container_1.

Accessing model containers

To access a model container on your endpoint instance, you need its target ID. The target ID is in one of the following formats:

- sagemaker-endpoint:*endpoint-name*_*variant-name*_*ec2-instance-id* for containers on single container endpoints
- sagemaker-endpoint:*endpoint-name*_*variant-name*_*ec2-instance-id*_*container-name* for containers on multi-container endpoints

The following example shows how you can use the Amazon CLI to access a model container using its target ID.

```
aws ssm start-session --target sagemaker-endpoint:prod-image-
classifier_variant1_i-003a121c1b21a90a9_container_1
```

If you enable logging, as mentioned in Logging with Amazon CloudWatch Logs, you can find the target IDs for all the containers listed at the beginning of the SSM log stream.

Note

- You cannot connect to 1P algorithm containers or containers of models obtained from SageMaker AI MarketPlace with SSM. However you can connect to deep learning containers (DLCs) provided by Amazon or any custom container that you own.
- If you have enabled network isolation for a model container that prevents it from making outbound network calls, you cannot start an SSM session for that container.

- You can only access one container from one SSM session. To access another container, even if it is behind the same endpoint, start a new SSM session with the target ID of that endpoint.

Model servers for model deployment with Amazon SageMaker AI

You can use popular model servers, such as TorchServe, DJL Serving, and Triton Inference Server, to deploy your models on SageMaker AI. The following topics explain how.

Topics

- Deploy models with TorchServe
- Deploy models with DJL Serving
- Model deployment with Triton Inference Server

Deploy models with TorchServe

TorchServe is the recommended model server for PyTorch, preinstalled in the Amazon PyTorch Deep Learning Container (DLC). This powerful tool offers customers a consistent and user-friendly experience, delivering high performance in deploying multiple PyTorch models across various Amazon instances, including CPU, GPU, Neuron, and Graviton, regardless of the model size or distribution.

TorchServe supports a wide array of advanced features, including dynamic batching, microbatching, model A/B testing, streaming, torch XLA, tensorRT, ONNX and IPEX. Moreover, it seamlessly integrates PyTorch's large model solution, PiPPy, enabling efficient handling of large models. Additionally, TorchServe extends its support to popular open-source libraries like DeepSpeed, Accelerate, Fast Transformers, and more, expanding its capabilities even further. With TorchServe, Amazon users can confidently deploy and serve their PyTorch models, taking advantage of its versatility and optimized performance across various hardware configurations and model types. For more detailed information, you can refer to the PyTorch documentation and TorchServe on GitHub.

The following table lists the Amazon PyTorch DLCs supported by TorchServe.

Instance type	SageMaker AI PyTorch DLC link
CPU and GPU	SageMaker AI PyTorch containers
Neuron	PyTorch Neuron containers
Graviton	SageMaker AI PyTorch Graviton containers

The following sections describe the setup to build and test PyTorch DLCs on Amazon SageMaker AI.

Getting started

To get started, ensure that you have the following prerequisites:

1. Ensure that you have access to an Amazon account. Set up your environment so that the Amazon CLI can access your account through either an Amazon IAM user or an IAM role. We recommend using an IAM role. For the purposes of testing in your personal account, you can attach the following managed permissions policies to the IAM role:
   - AmazonEC2ContainerRegistryFullAccess
   - AmazonEC2FullAccess
   - AmazonServiceRoleForAmazonEKSNodegroup
   - AmazonSageMakerFullAccess
   - AmazonS3FullAccess
2. Locally configure your dependencies, as shown in the following example:

```
from datetime import datetime
    import os
    import json
    import logging
    import time

    # External Dependencies:
    import boto3
    from botocore.exceptions import ClientError
    import sagemaker

    sess = boto3.Session()
    sm = sess.client("sagemaker")
```

```
    region = sess.region_name
    account = boto3.client("sts").get_caller_identity().get("Account")

    smsess = sagemaker.Session(boto_session=sess)
    role = sagemaker.get_execution_role()

    # Configuration:
    bucket_name = smsess.default_bucket()
    prefix = "torchserve"
    output_path = f"s3://{bucket_name}/{prefix}/models"
    print(f"account={account}, region={region}, role={role}")
```

3. Retrieve the PyTorch DLC image, as shown in the following example.

   SageMaker AI PyTorch DLC images are available in all Amazon regions. For more information, see the list of DLC container images.

```
baseimage = sagemaker.image_uris.retrieve(
        framework="pytorch",
        region="<region>",
        py_version="py310",
        image_scope="inference",
        version="2.0.1",
        instance_type="ml.g4dn.16xlarge",
    )
```

4. Create a local workspace.

```
mkdir -p workspace/
```

Adding a package

The following sections describe how to add and preinstall packages to your PyTorch DLC image.

BYOC use cases

The following steps outline how to add a package to your PyTorch DLC image. For more information about customizing your container, see Building Amazon Deep Learning Containers Custom Images.

1. Suppose you want to add a package to the PyTorch DLC docker image. Create a Dockerfile under the `docker` directory, as shown in the following example:

```
mkdir -p workspace/docker
    cat workspace/docker/Dockerfile

    ARG BASE_IMAGE

    FROM $BASE_IMAGE

    #Install any additional libraries
    RUN pip install transformers==4.28.1
```

2. Build and publish the customized docker image by using the following build_and_push.sh script.

```
# Download script build_and_push.sh to workspace/docker
    ls workspace/docker
    build_and_push.sh  Dockerfile

    # Build and publish your docker image
    reponame = "torchserve"
    versiontag = "demo-0.1"

    ./build_and_push.sh {reponame} {versiontag} {baseimage} {region} {account}
```

SageMaker AI preinstall use cases

The following example shows you how to preinstall a package to your PyTorch DLC container. You must create a `requirements.txt` file locally under the directory `workspace/code`.

```
mkdir -p workspace/code
    cat workspace/code/requirements.txt

    transformers==4.28.1
```

Create TorchServe model artifacts

In the following example, we use the pre-trained MNIST model. We create a directory `workspace/mnist`, implement mnist_handler.py by following the TorchServe custom service instructions, and configure the model parameters (such as batch size and workers) in model-

config.yaml. Then, we use the TorchServe tool `torch-model-archiver` to build the model artifacts and upload to Amazon S3.

1. Configure the model parameters in `model-config.yaml`.

```
ls -al workspace/mnist-dev

    mnist.py
    mnist_handler.py
    mnist_cnn.pt
    model-config.yaml

    # config the model
    cat workspace/mnist-dev/model-config.yaml
    minWorkers: 1
    maxWorkers: 1
    batchSize: 4
    maxBatchDelay: 200
    responseTimeout: 300
```

2. Build the model artifacts by using torch-model-archiver .

```
torch-model-archiver --model-name mnist --version 1.0 --model-file workspace/
mnist-dev/mnist.py --serialized-file workspace/mnist-dev/mnist_cnn.pt --handler
 workspace/mnist-dev/mnist_handler.py --config-file workspace/mnist-dev/model-
config.yaml --archive-format tgz
```

   If you want to preinstall a package, you must include the code directory in the `tar.gz` file.

```
cd workspace
    torch-model-archiver --model-name mnist --version 1.0 --model-file mnist-
dev/mnist.py --serialized-file mnist-dev/mnist_cnn.pt --handler mnist-dev/
mnist_handler.py --config-file mnist-dev/model-config.yaml --archive-format no-
archive

    cd mnist
    mv ../code .
    tar cvzf mnist.tar.gz .
```

3. Upload `mnist.tar.gz` to Amazon S3.

```
# upload mnist.tar.gz to S3
```

```
    output_path = f"s3://{bucket_name}/{prefix}/models"
    aws s3 cp mnist.tar.gz {output_path}/mnist.tar.gz
```

Using single model endpoints to deploy with TorchServe

The following example shows you how to create a single model real-time inference endpoint, deploy the model to the endpoint, and test the endpoint by using the Amazon SageMaker Python SDK.

```
from sagemaker.serve import ModelBuilder
from sagemaker.core.resources import Endpoint

# Create a ModelBuilder for the single model endpoint and deploy it on SageMaker AI
model_builder = ModelBuilder(
    s3_model_data_url=f'{output_path}/mnist.tar.gz',
    image_uri=baseimage,
    role_arn=role,
    model_server='TORCHSERVE'
)

model_builder.build()

endpoint_name = 'torchserve-endpoint-' + time.strftime("%Y-%m-%d-%H-%M-%S",
 time.gmtime())
endpoint = model_builder.deploy(
    instance_type='ml.g4dn.xlarge',
    initial_instance_count=1,
    endpoint_name=endpoint_name
)

# test the endpoint
import random
import json
import numpy as np
dummy_data = {"inputs": np.random.rand(16, 1, 28, 28).tolist()}

response = endpoint.invoke(
    body=json.dumps(dummy_data),
    content_type='application/json'
)
res = json.loads(response.body.read().decode('utf-8'))
```

Using multi-model endpoints to deploy with TorchServe

Multi-model endpoints are a scalable and cost-effective solution to hosting large numbers of models behind one endpoint. They improve endpoint utilization by sharing the same fleet of resources and serving container to host all of your models. They also reduce deployment overhead because SageMaker AI manages dynamically loading and unloading models, as well as scaling resources based on traffic patterns. Multi-model endpoints are particularly useful for deep learning and generative AI models that require accelerated compute power.

By using TorchServe on SageMaker AI multi-model endpoints, you can speed up your development by using a serving stack that you are familiar with while leveraging the resource sharing and simplified model management that SageMaker AI multi-model endpoints provide.

The following example shows you how to create a multi-model endpoint, deploy the model to the endpoint, and test the endpoint by using the Amazon SageMaker Python SDK. Additional details can be found in this notebook example.

```
from sagemaker.serve import ModelBuilder

# Create a ModelBuilder for the multi-model endpoint and deploy it on SageMaker AI
model_builder = ModelBuilder(
    s3_model_data_url=f'{output_path}/mnist.tar.gz',
    image_uri=baseimage,
    role_arn=role,
    model_server='TORCHSERVE'
)

endpoint_name = 'torchserve-endpoint-' + time.strftime("%Y-%m-%d-%H-%M-%S",
 time.gmtime())
model_builder.build()
endpoint = model_builder.deploy(
    initial_instance_count=1,
    instance_type="ml.g4dn.xlarge",
    endpoint_name=endpoint_name,
    model_data_download_timeout=1200
)

# test the endpoint
import random
import json
import numpy as np
dummy_data = {"inputs": np.random.rand(16, 1, 28, 28).tolist()}
```

```
response = endpoint.invoke(
    body=json.dumps(dummy_data),
    content_type='application/json',
    target_model="mnist.tar.gz"
)
res = json.loads(response.body.read().decode('utf-8'))
```

Metrics

TorchServe supports both system level and model level metrics. You can enable metrics in either log format mode or Prometheus mode through the environment variable `TS_METRICS_MODE`. You can use the TorchServe central metrics config file `metrics.yaml` to specify the types of metrics to be tracked, such as request counts, latency, memory usage, GPU utilization, and more. By referring to this file, you can gain insights into the performance and health of the deployed models and effectively monitor the TorchServe server's behavior in real-time. For more detailed information, see the TorchServe metrics documentation.

You can access TorchServe metrics logs that are similar to the StatsD format through the Amazon CloudWatch log filter. The following is an example of a TorchServe metrics log:

```
CPUUtilization.Percent:0.0|#Level:Host|#hostname:my_machine_name,timestamp:1682098185
    DiskAvailable.Gigabytes:318.0416717529297|#Level:Host|
#hostname:my_machine_name,timestamp:1682098185
```

Deploy models with DJL Serving

DJL Serving is a high performance universal stand-alone model serving solution. It takes a deep learning model, several models, or workflows and makes them available through an HTTP endpoint.

You can use one of the DJL Serving Deep Learning Containers (DLCs) to serve your models on Amazon. To learn about the supported model types and frameworks, see the DJL Serving GitHub repository.

DJL Serving offers many features that help you to deploy your models with high performance:

- Ease of use – DJL Serving can serve most models without any modifications. You bring your model artifacts, and DJL Serving can host them.

- Multiple device and accelerator support – DJL Serving supports deploying models on CPUs, GPUs, and Amazon Inferentia.
- Performance – DJL Serving runs multithreaded inference in a single Java virtual machine (JVM) to boost throughput.
- Dynamic batching – DJL Serving supports dynamic batching to increase throughput.
- Auto scaling – DJL Serving automatically scales workers up or down based on the traffic load.
- Multi-engine support – DJL Serving can simultaneously host models using different frameworks (for example, PyTorch and TensorFlow).
- Ensemble and workflow models – DJL Serving supports deploying complex workflows comprised of multiple models and can execute parts of the workflow on CPUs and other parts on GPUs. Models within a workflow can leverage different frameworks.

The following sections describe how to set up an endpoint with DJL Serving on SageMaker AI.

Getting started

To get started, ensure that you have the following prerequisites:

1. Ensure that you have access to an Amazon account. Set up your environment so that the Amazon CLI can access your account through either an Amazon IAM user or an IAM role. We recommend using an IAM role. For the purposes of testing in your personal account, you can attach the following managed permissions policies to the IAM role:
   - AmazonEC2ContainerRegistryFullAccess
   - AmazonEC2FullAccess
   - AmazonSageMakerFullAccess
   - AmazonS3FullAccess
2. Ensure that you have the docker client set up on your system.
3. Log in to Amazon Elastic Container Registry and set the following environment variables:

```
export ACCOUNT_ID=<your_account_id>
export REGION=<your_region>
aws ecr get-login-password --region $REGION | docker login --username Amazon --
password-stdin $ACCOUNT_ID.dkr.ecr.$REGION.amazonaws.com
```

4. Pull the docker image.

```
docker pull 763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:0.22.1-
deepspeed0.9.2-cu118
```

For all of the available DJL Serving container images, see the large model inference containers and the DJL Serving CPU inference containers. When choosing an image from the tables in the preceding links, replace the Amazon region in the example URL column with the region you are in. The DLCs are available in the regions listed in the table at the top of the Available Deep Learning Containers Images page.

Customize your container

You can add packages to the base DLC images to customize your container. Suppose you want to add a package to the `763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:0.22.1-deepspeed0.9.2-cu118` docker image. You must create a dockerfile with your desired image as the base image, add the required packages, and push the image to Amazon ECR.

To add a package, complete the following steps:

1. Specify instructions for running your desired libraries or packages in the base image's dockerfile.

   ```
   FROM 763104351884.dkr.ecr.us-west-2.amazonaws.com/djl-inference:0.22.1-
   deepspeed0.9.2-cu118

   ## add custom packages/libraries
   RUN git clone https://github.com/awslabs/amazon-sagemaker-examples
   ```

2. Build the Docker image from the dockerfile. Specify your Amazon ECR repository, the name of the base image, and a tag for the image. If you don't have an Amazon ECR repository, see Using Amazon ECR with the Amazon CLI in the *Amazon ECR User Guide* for instructions on how to create one.

   ```
   docker build -f Dockerfile -t <registry>/<image_name>:<image_tag>
   ```

3. Push the Docker image to your Amazon ECR repository.

   ```
   docker push $ACCOUNT_ID.dkr.ecr.$REGION.amazonaws.com/<image_name>:<image_tag>
   ```

You should now have a customized container image that you can use for model serving. For more examples of customizing your container, see Building Amazon Deep Learning Containers Custom Images.

Prepare your model artifacts

Before deploying your model on SageMaker AI, you must package your model artifacts in a `.tar.gz` file. DJL Serving accepts the following artifacts in your archive:

- Model checkpoint: Files that store your model weights.
- `serving.properties`: A configuration file that you can add for each model. Place `serving.properties` in the same directory as your model file.
- `model.py`: The inference handler code. This is only applicable when using Python mode. If you don't specify `model.py`, djl-serving uses one of the default handlers.

The following is an example of a `model.tar.gz` structure:

```
- model_root_dir # root directory
   - serving.properties
   - model.py # your custom handler file for Python, if you choose not to use the
default handlers provided by DJL Serving
   - model binary files # used for Java mode, or if you don't want to use
option.model_id and option.s3_url for Python mode
```

DJL Serving supports Java engines powered by DJL or Python engines. Not all of the preceding artifacts are required; the required artifacts vary based on the mode you choose. For example, in Python mode, you only need to specify `option.model_id` in the `serving.properties` file; you don't need to specify the model checkpoint inside LMI containers. In Java mode, you are required to package the model checkpoint. For more details on how to configure `serving.properties` and operate with different engines, see DJL Serving Operation Modes.

Use single model endpoints to deploy with DJL Serving

After preparing your model artifacts, you can deploy your model to a SageMaker AI endpoint. This section describes how to deploy a single model to an endpoint with DJL Serving. If you're deploying multiple models, skip this section and go to Use multi-model endpoints to deploy with DJL Serving.

The following example shows you a method to create a model object using the Amazon SageMaker Python SDK. You'll need to specify the following fields:

- `image_uri`: You can either retrieve one of the base DJL Serving images as shown in this example, or you can specify a custom Docker image from your Amazon ECR repository, if you followed the instructions in Customize your container.
- `model_s3_url`: This should an Amazon S3 URI that points to your `.tar.gz`file.
- `model_name`: Specify a name for the model object.

```
import boto3
 import sagemaker
from sagemaker.model import Model
from sagemaker import image_uris, get_execution_role

aws_region = "aws-region"
sagemaker_session =
 sagemaker.Session(boto_session=boto3.Session(region_name=aws_region))
role = get_execution_role()

def create_model(model_name, model_s3_url):
    # Get the DJL DeepSpeed image uri
    image_uri = image_uris.retrieve(
        framework="djl-deepspeed",
        region=sagemaker_session.boto_session.region_name,
        version="0.20.0"
    )
    model = Model(
        image_uri=image_uri,
        model_data=model_s3_url,
        role=role,
        name=model_name,
        sagemaker_session=sagemaker_session,
    )
    return model
```

Use multi-model endpoints to deploy with DJL Serving

If you want to deploy multiple models to an endpoint, SageMaker AI offers multi-model endpoints, which are a scalable and cost-effective solution to deploying large numbers of models. DJL Serving also supports loading multiple models simultaneously and running inference on each of the

models concurrently. DJL Serving containers adhere to the SageMaker AI multi-model endpoints contracts and can be used to deploy multi-model endpoints.

Each individual model artifact needs to be packaged in the same way as described in the previous section Prepare your model artifacts. You can set model-specific configurations in the `serving.properties` file and model-specific inference handler code in `model.py`. For a multi-model endpoint, models need to be arranged in the following way:

```
root_dir
       |-- model_1.tar.gz
       |-- model_2.tar.gz
       |-- model_3.tar.gz
           .
           .
           .
```

The Amazon SageMaker Python SDK uses the MultiDataModel object to instantiate a multi-model endpoint. The Amazon S3 URI for the root directory should be passed as the `model_data_prefix` argument to the `MultiDataModel` constructor.

DJL Serving also provides several configuration parameters to manage model memory requirements, such as `required_memory_mb` and `reserved_memory_mb`, that can be configured for each model in the serving.properties file. These parameters are useful to handle out of memory errors more gracefully. For all of the configurable parameters, see OutofMemory handling in djl-serving.

The auto scaling feature of DJL Serving makes it easy to ensure that the models are scaled appropriately for incoming traffic. By default, DJL Serving determines the maximum number of workers for a model that can be supported based on the hardware available (such as CPU cores or GPU devices). You can set lower and upper bounds for each model to ensure that a minimum traffic level can always be served, and that a single model does not consume all available resources. You can set the following properties in the serving.properties file:

- `gpu.minWorkers`: Minimum number of workers for GPUs.
- `gpu.maxWorkers`: Maximum number of workers for GPUs.
- `cpu.minWorkers`: Minimum number of workers for CPUs.
- `cpu.maxWorkers`: Maximum number of workers for CPUs.

For an end-to-end example of how to deploy a multi-model endpoint on SageMaker AI using a DJL Serving container, see the example notebook Multi-Model-Inference-Demo.ipynb.

Model deployment with Triton Inference Server

Triton Inference Server is an open source inference serving software that streamlines AI inference. With Triton, you can deploy any model built with multiple deep learning and machine learning frameworks, including TensorRT, TensorFlow, PyTorch, ONNX, OpenVINO, Python, RAPIDS FIL, and more.

The SageMaker AI Triton containers help you deploy Triton Inference Server on the SageMaker AI Hosting platform to serve trained models in production. It supports the different modes in which SageMaker AI operates. For a list of available Triton Inference Server containers available on SageMaker AI, see NVIDIA Triton Inference Containers (SM support only).

For end-to-end notebook examples, we recommend taking a look at the amazon-sagemaker-examples repository.

Hosting modes

The following SageMaker AI Hosting modes are supported by Triton containers:

- Single model endpoints
  - This is SageMaker AI's default mode of operation. In this mode, the Triton container can load a single model, or a single ensemble model.
  - The name of the model must be passed as as a property of the container environment, which is part of the `CreateModel` SageMaker AI API call. The environment variable used to pass in the model name is `SAGEMAKER_TRITON_DEFAULT_MODEL_NAME`.
- Single model endpoints with ensemble
  - Triton Inference Server supports *ensemble*, which is a pipeline, or a DAG (directed acyclic graph) of models. While an ensemble technically comprises of multiple models, in the default single model endpoint mode, SageMaker AI can treat the *ensemble proper* (the meta-model that represents the pipeline) as the main model to load, and can subsequently load the associated models.
  - The ensemble proper's model name must be used to load the model. It must be passed as a property of the container environment, which is part of the `CreateModel` SageMaker API call. The environment variable used to pass in the model name is `SAGEMAKER_TRITON_DEFAULT_MODEL_NAME`.

- Multi-model endpoints
  - In this mode, SageMaker AI can serve multiple models on a single endpoint. You can use this mode by specifying the environment variable `'MultiModel': true` as a property of the container environment, which is part of the `CreateModel` SageMaker API call.
  - By default, no model is loaded when the instance starts. To run an inference request against a particular model, specify the corresponding model's `*.tar.gz` file as an argument to the `TargetModel` property of the `InvokeEndpoint` SageMaker API call.
- Multi-model endpoints with ensemble
  - In this mode, SageMaker AI functions as described for multi-model endpoints. However, the SageMaker AI Triton container can load multiple ensemble models, meaning that multiple model pipelines can run on the same instance. SageMaker AI treats every ensemble as one model, and the ensemble proper of each model can be invoked by specifying the corresponding `*.tar.gz` archive as the `TargetModel`.
  - For better memory management during dynamic memory `LOAD` and `UNLOAD`, we recommend that you keep the ensemble size small.

Inference payload types

Triton supports two methods of sending an inference payload over the network – `json` and `binary+json` (or binary encoded json). The JSON payload in both cases includes the datatype, shape and the actual inference request tensor. The request tensor must be a binary tensor.

With the `binary+json` format, you must specify the length of the request metadata in the header to allow Triton to correctly parse the binary payload. In the SageMaker AI Triton container, this is done using a custom `Content-Type` header: `application/vnd.sagemaker-triton.binary+json;json-header-size={}`. This is different from using the `Inference-Header-Content-Length` header on a stand-alone Triton Inference Server because custom headers are not allowed in SageMaker AI.

Using config.pbtxt to set the model config

For Triton Inference Servers on SageMaker AI, each model must include a `config.pbtxt` file that specifies, at a minimum, the following configurations for the model:

- `name`: While this is optional for models running outside of SageMaker AI, we recommend that you always provide a name for the models to be run in Triton on SageMaker AI.

- platform and/or backend: Setting a backend is essential to specify the type of the model. Some backends have further classification, such as tensorflow_savedmodel or tensorflow_graphdef. Such options can be specified as part of the platform key in addition to the backend key. The most common backends are tensorrt, onnxruntime, tensorflow, pytorch, python, dali, fil, and openvino.
- input: Specify three attributes for the input: name, data_type and dims (the shape).
- output: Specify three attributes for the output: name, data_type and dims (the shape).
- max_batch_size: Set the batch size to a value greater than or equal to 1 that indicates the maximum batch size that Triton should use with the model.

For more details on configuring config.pbtxt, see Triton's GitHub repository. Triton provides several configurations for tweaking model behavior. Some of the most common and important configuration options are:

- instance_groups: Instance groups help with specifying the number and location for a given model. They have the attributes count, kind, and gpus (used when kind is KIND_GPU). The count attribute is equivalent to the number of workers. For regular model serving, each worker has its own copy of the model. Similarly, in Triton, the count specifies the number of model copies per device. For example, if the instance_group type is KIND_CPU, then the CPU has count number of model copies.

  > **Note**
  >
  > On a GPU instance, the instance_group configuration applies per GPU device. For example, count number of model copies are placed on each GPU device unless you explicitly specify which GPU devices should load the model.

- dynamic_batching and sequence_batching: Dynamic batching is used for stateless models, and sequence batching is used for stateful models (where you want to route a request to the same model instance every time). Batching schedulers enable a per-model queue, which help in increasing throughput, depending on the batching configuration.
- ensemble: An ensemble model represents a *pipeline* of one or more models and the connection of input and output tensors between those models. It can be configured by specifying platform as ensemble. The ensemble configuration is just a representation of the model pipeline. On SageMaker AI, all the models under an ensemble are treated as dependents of

the ensemble model and are counted as a single model for SageMaker AI metrics, such as `LoadedModelCount`.

Publishing default Triton metrics to Amazon CloudWatch

The NVIDIA Triton Inference Container exposes metrics at port 8002 (configurable) for the different models and GPUs that are utilized in the Triton Inference Server. For full details of the default metrics that are available, see the GitHub page for the Triton Inference Server metrics. These metrics are in Prometheus format and can be scraped using a Prometheus scraper configuration.

Starting with version v23.07 onwards, the SageMaker AI Triton container supports publishing these metrics to Amazon CloudWatch by specifying a few environment variables. In order to scrape the Prometheus metrics, the SageMaker AI Triton container leverages the Amazon CloudWatch agent.

The required environment variables that you must specify to collect metrics are as follows:

Environment variable	Description	Example value
`SAGEMAKER_TRITON_ALLOW_METRICS`	Specify this option to allow Triton to publish metrics to its Prometheus endpoint.	"true"
`SAGEMAKER_TRITON_PUBLISH_METRICS_TO_CLOUDWATCH`	Specify this option to start the pre-checks necessary to publish metrics to Amazon CloudWatch.	"true"
`SAGEMAKER_TRITON_CLOUDWATCH_LOG_GROUP`	Specify this option to point to the log group to which metrics are written.	"/aws/SageMaker AI/Endpoints/TritonMetrics/SageMakerTwoEnsemblesTest"
`SAGEMAKER_TRITON_CLOUDWATCH_METRIC_NAMESPACE`	Specify this option to point to the metric namespace where you want to see and plot the metrics.	"/aws/SageMaker AI/Endpoints/TritonMetrics/SageMakerTwoEnsemblesPublicTest"
`SAGEMAKER_TRITON_METRICS_PORT`	Specify this as 8002, or any other port. If SageMaker AI has not blocked the specified	"8002"

Environment variable	Description	Example value
	port, it is used. Otherwise, another non-blocked port is chosen automatically.	

When publishing metrics with Triton on SageMaker AI, keep in mind the following limitations:

- While you can generate custom metrics through the C-API and Python backend (v23.05 onwards), these are currently not supported for publishing to Amazon CloudWatch.
- In SageMaker AI multi-model endpoints (MME) mode, Triton runs in an environment that requires model namespacing to be enabled because each model (except ensemble models) are treated as if they are in their own model repository. Currently, this creates a limitation for metrics. When model namespacing is enabled, Triton does not distinguish the metrics between two models with the same name belonging to different ensembles. As a workaround, make sure that every model being deployed has a unique name. This also makes it easier to look up your metrics in CloudWatch.

Environment variables

The following table lists the supported environment variables for Triton on SageMaker AI.

Environment variable	Description	Type	Possible values
`SAGEMAKER_MULTI_MODEL`	Allows Triton to operate in SageMaker AI multi-model endpoints mode.	Boolean	`true`, `false`
`SAGEMAKER_TRITON_DEFAULT_MODEL_NAME`	Specify the model to be loaded in the SageMaker AI single model (default) mode. For ensemble mode,	String	*`<model_name>`* as specified in config.pbtxt

Environment variable	Description	Type	Possible values
	specify the name of the ensemble proper.		
SAGEMAKER_TRITON_PING_MODE	`'ready'` is the default mode in SageMaker AI's single model mode, and `'live'` is the default in SageMaker AI's multi-model endpoints mode.	String	`ready`, `live`
SAGEMAKER_TRITON_DISABLE_MODEL_NAMESPACING	In the SageMaker AI Triton container, this is set to `true` by default.	Boolean	`true`, `false`
SAGEMAKER_BIND_TO_PORT	While on SageMaker AI, the default port is 8080. You can customize to a different port in multi-container scenarios.	String	*<port_number>*
SAGEMAKER_SAFE_PORT_RANGE	This is set by the SageMaker AI platform when using multi-container mode.	String	*<port_1>*–*<port_2>*

Environment variable	Description	Type	Possible values
SAGEMAKER_TRITON_ALLOW_GRPC	While SageMaker AI doesn't support GRPC currently, if you're using Triton in front of a custom reverse proxy, you may choose to enable GRPC.	Boolean	true, false
SAGEMAKER_TRITON_GRPC_PORT	The default port for GRPC is 8001, but you can change it.	String	*<port_number>*
SAGEMAKER_TRITON_THREAD_COUNT	You can set the number of default HTTP request handler threads.	String	*<number>*
SAGEMAKER_TRITON_LOG_VERBOSE	true by default on SageMaker AI, but you can selectively turn this option off.	Boolean	true, false
SAGEMAKER_TRITON_LOG_INFO	false by default on SageMaker AI.	Boolean	true, false
SAGEMAKER_TRITON_LOG_WARNING	false by default on SageMaker AI.	Boolean	true, false
SAGEMAKER_TRITON_LOG_ERROR	false by default on SageMaker AI.	Boolean	true, false

Environment variable	Description	Type	Possible values
SAGEMAKER_TRITON_SHM_DEFAULT_BYTE_SIZE	Specify the shm size for the Python backend, in bytes. The default value is 16 MB but can be increased.	String	*<number>*
SAGEMAKER_TRITON_SHM_GROWTH_BYTE_SIZE	Specify the shm growth size for the Python backend, in bytes. The default value is 1 MB but can be increased to allow greater increments.	String	*<number>*
SAGEMAKER_TRITON_TENSORFLOW_VERSION	The default value is 2. Triton no longer supports Tensorflow 2 from Triton v23.04. You can configure this variable for previous versions.	String	*<number>*
SAGEMAKER_TRITON_MODEL_LOAD_GPU_LIMIT	Restrict the maximum GPU memory percentage which is used for model loading, allowing the remainder to be used for the inference requests.	String	*<number>*

Environment variable	Description	Type	Possible values
SAGEMAKER_TRITON_ALLOW_METRICS	false by default on SageMaker AI.	Boolean	true, false
SAGEMAKER_TRITON_METRICS_PORT	The default port is 8002.	String	*<number>*
SAGEMAKER_TRITON_PUBLISH_METRICS_TO_CLOUDWATCH	false by default on SageMaker AI. Set this variable to true to allow pushing Triton default metrics to Amazon CloudWatch. If this option is enabled, you are responsible for CloudWatch costs when metrics are published to your account.	Boolean	true, false
SAGEMAKER_TRITON_CLOUDWATCH_LOG_GROUP	Required if you've enabled metrics publishing to CloudWatch.	String	*<cloudwatch_log_group_name>*
SAGEMAKER_TRITON_CLOUDWATCH_METRIC_NAMESPACE	Required if you've enabled metrics publishing to CloudWatch.	String	*<cloudwatch_metric_namespace>*

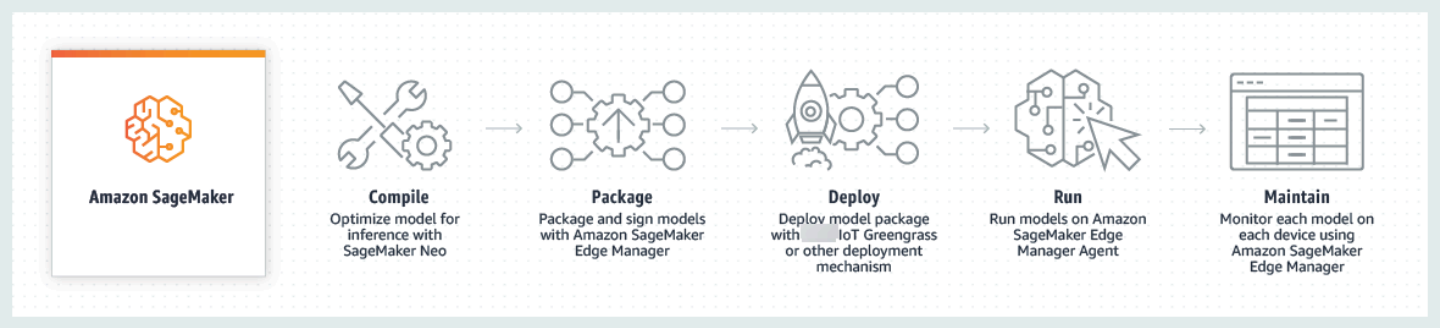
Environment variable	Description	Type	Possible values
SAGEMAKER_TRITON_ADDITIONAL_ARGS	Appends any additional arguments when starting the Triton Server.	String	*<additional_args>*

Model deployment at the edge with SageMaker Edge Manager

> **Warning**
>
> SageMaker Edge Manager is being discontinued on April 26th, 2024. For more information about continuing to deploy your models to edge devices, see SageMaker Edge Manager end of life.

Amazon SageMaker Edge Manager provides model management for edge devices so you can optimize, secure, monitor, and maintain machine learning models on fleets of edge devices such as smart cameras, robots, personal computers, and mobile devices.

Why Use Edge Manager?



Many machine learning (ML) use cases require running ML models on a fleet of edge devices, which allows you to get predictions in real-time, preserves the privacy of the end users, and lowers the cost of network connectivity. With the increasing availability of low-power edge hardware designed for ML, it is now possible to run multiple complex neural network models on edge devices.

However, operating ML models on edge devices is challenging, because devices, unlike cloud instances, have limited compute, memory, and connectivity. After the model is deployed, you need to continuously monitor the models, because model drift can cause the quality of model to decay overtime. Monitoring models across your device fleets is difficult because you need to write custom code to collect data samples from your device and recognize skew in predictions. In addition, models are often hard-coded into the application. To update the model, you must rebuild and update the entire application or device firmware, which can disrupt your operations.

With SageMaker Edge Manager, you can optimize, run, monitor, and update machine learning models across fleets of devices at the edge.

How Does it Work?

At a high level, there are five main components in the SageMaker Edge Manager workflow: compiling models with SageMaker Neo, packaging Neo-compiled models, deploying models to your devices, running models on the SageMaker AI inference engine (Edge Manager agent), and maintaining models on the devices.

SageMaker Edge Manager uses SageMaker Neo to optimize your models for the target hardware in one click, then to cryptographically sign your models before deployment. Using SageMaker Edge Manager, you can sample model input and output data from edge devices and send it to the cloud for monitoring and analysis, and view a dashboard that tracks and visually reports on the operation of the deployed models within the SageMaker AI console.

SageMaker Edge Manager extends capabilities that were previously only available in the cloud to the edge, so developers can continuously improve model quality by using Amazon SageMaker Model Monitor for drift detection, then relabel the data with SageMaker AI Ground Truth and retrain the models in SageMaker AI.

How Do I Use SageMaker Edge Manager?

If you are a first time user of SageMaker Edge Manager, we recommend that you do the following:

1. **Read the Getting Started section** - This section walks you through setting up your first edge packaging job and creating your first fleet.
2. **Explore Edge Manager Jupyter notebook examples** - Example notebooks are stored in the amazon-sagemaker-examples GitHub repository in the sagemaker_edge_manager folder.

First Steps with Amazon SageMaker AI Edge Manager

This guide demonstrates how to complete the necessary steps to register, deploy, and manage a fleet of devices, and how to satisfy Amazon SageMaker AI Edge Manager prerequisites.

Topics

- Setting Up
- Prepare Your Model for Deployment
- Register and Authenticate Your Device Fleet
- Download and Set Up Edge Manager
- Run Agent

Setting Up

Before you begin using SageMaker Edge Manager to manage models on your device fleets, you must first create IAM Roles for both SageMaker AI and Amazon IoT. You will also want to create at least one Amazon S3 bucket where you will store your pre-trained model, the output of your SageMaker Neo compilation job, as well as input data from your edge devices.

Sign up for an Amazon Web Services account

If you do not have an Amazon Web Services account, use the following procedure to create one.

To sign up for Amazon Web Services

1. Open http://www.amazonaws.cn/ and choose **Sign Up**.
2. Follow the on-screen instructions.

Amazon sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to http://www.amazonaws.cn/ and choosing **My Account**.

Secure IAM users

After you sign up for an Amazon Web Services account, safeguard your administrative user by turning on multi-factor authentication (MFA). For instructions, see Enable a virtual MFA device for an IAM user (console) in the *IAM User Guide*.

To give other users access to your Amazon Web Services account resources, create IAM users. To secure your IAM users, turn on MFA and only give the IAM users the permissions needed to perform their tasks.

For more information about creating and securing IAM users, see the following topics in the *IAM User Guide*:

- Creating an IAM user in your Amazon Web Services account
- Access management for Amazon resources
- Example IAM identity-based policies

Create roles and storage

SageMaker Edge Manager needs access to your Amazon S3 bucket URI. To facilitate this, create an IAM role that can run SageMaker AI and has permission to access Amazon S3. Using this role, SageMaker AI can run under your account and access to your Amazon S3 bucket.

You can create an IAM role by using the IAM console, Amazon SDK for Python (Boto3), or Amazon CLI. The following is an example of how to create an IAM role, attach the necessary policies with the IAM console, and create an Amazon S3 bucket.

1. **Create an IAM role for Amazon SageMaker AI.**

    a. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.

    b. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.

    c. For **Select type of trusted entity**, choose **Amazon service**.

    d. Choose the service that you want to allow to assume this role. In this case, choose **SageMaker AI**. Then choose **Next: Permissions**.

        - This automatically creates an IAM policy that grants access to related services such as Amazon S3, Amazon ECR, and CloudWatch Logs.

    e. Choose **Next: Tags**.

    f. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.

    g. Choose **Next: Review**.

    h. Type in a **Role name**.

i. If possible, type a role name or role name suffix. Role names must be unique within your Amazon account. They are not distinguished by case. For example, you cannot create roles named both `PRODROLE` and `prodrole`. Because other Amazon resources might reference the role, you cannot edit the name of the role after it has been created.

j. (Optional) For **Role description**, type a description for the new role.

k. Review the role and then choose **Create role**.

Note the SageMaker AI Role ARN, which you use to create a compilation job with SageMaker Neo and a packaging job with Edge Manager. To find out the role ARN using the console, do the following:

i. Go to the IAMconsole: https://console.amazonaws.cn/iam/

ii. Select **Roles**.

iii. Search for the role you just created by typing in the name of the role in the search field.

iv. Select the role.

v. The role ARN is at the top of the **Summary** page.

2. **Create an IAM role for Amazon IoT.**

The Amazon IoT IAM role you create is used to authorize your thing objects. You also use the IAM role ARN to create and register device fleets with a SageMaker AI client object.

Configure an IAM role in your Amazon account for the credentials provider to assume on behalf of the devices in your device fleet. Then, attach a policy to authorize your devices to interact with Amazon IoT services.

Create a role for Amazon IoT either programmatically or with the IAM console, similar to what you did when you created a role for SageMaker AI.

a. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.

b. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.

c. For **Select type of trusted entity**, choose **Amazon service**.

d. Choose the service that you want to allow to assume this role. In this case, choose **IoT**. Select **IoT** as the **Use Case**.

e. Choose **Next: Permissions**.

f. Choose **Next: Tags**.

g. (Optional) Add metadata to the role by attaching tags as key–value pairs. For more information about using tags in IAM, see Tagging IAM resources.

h. Choose **Next: Review**.

i. Type in a **Role name**. The role name must start with `SageMaker AI`.

j. (Optional) For **Role description**, type a description for the new role.

k. Review the role and then choose **Create role**.

l. Once the role is created, choose **Roles** in the IAM console. Search for the role you created by typing in role name in the **Search** field.

m. Choose your role.

n. Next, choose **Attach Policies**.

o. Search for `AmazonSageMakerEdgeDeviceFleetPolicy` in the **Search** field. Select `AmazonSageMakerEdgeDeviceFleetPolicy`.

p. Choose **Attach policy**.

q. Add the following policy statement to the trust relationship:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
      {
        "Effect": "Allow",
        "Principal": {"Service": "credentials.iot.amazonaws.com"},
        "Action": "sts:AssumeRole"
      },
      {
        "Effect": "Allow",
        "Principal": {"Service": "sagemaker.amazonaws.com"},
        "Action": "sts:AssumeRole"
      }
  ]
}
```

A trust policy is a JSON policy document in which you define the principals that you trust to assume the role. For more information about trust policies, see Roles terms and concepts.

r. Note the Amazon IoT role ARN. You use the Amazon IoT Role ARN to create and register the device fleet. To find the IAM role ARN with the console:

i. Go to the IAM console: https://console.amazonaws.cn/iam/

ii. Choose **Roles**.

iii. Search for the role you created by typing in the name of the role in the **Search** field.

iv. Select the role.

v. The role ARN is on the Summary page.

3. **Create an Amazon S3 bucket.**

SageMaker Neo and Edge Manager access your pre-compiled model and compiled model from an Amazon S3 bucket. Edge Manager also stores sample data from your device fleet in Amazon S3.

a. Open the Amazon S3 console at https://console.amazonaws.cn/s3/.

b. Choose **Create bucket**.

c. In **Bucket name**, enter a name for your bucket.

d. In **Region**, choose the Amazon Region where you want the bucket to reside.

e. In **Bucket settings for Block Public Access**, choose the settings that you want to apply to the bucket.

f. Choose **Create bucket**.

For more information about creating Amazon S3 buckets, see Getting started with Amazon S3.

Prepare Your Model for Deployment

In this section you will create SageMaker AI and Amazon IoT client objects, download a pre-trained machine learning model, upload your model to your Amazon S3 bucket, compile your model for your target device with SageMaker Neo, and package your model so that it can be deployed with the Edge Manager agent.

1. **Import libraries and create client objects.**

   This tutorial uses the Amazon SDK for Python (Boto3) to create clients to interact with SageMaker AI, Amazon S3, and Amazon IoT.

   Import Boto3, specify your Region, and initialize the client objects you need as shown in the following example:

   ```
   import boto3
   import json
   import time

   AWS_REGION = 'us-west-2'# Specify your Region
   bucket = 'bucket-name'

   sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)
   iot_client = boto3.client('iot', region_name=AWS_REGION)
   ```

   Define variables and assign them the role ARN you created for SageMaker AI and Amazon IoT as strings:

   ```
   # Replace with the role ARN you created for SageMaker
   sagemaker_role_arn = "arn:aws:iam::<account>:role/*"

   # Replace with the role ARN you created for Amazon IoT.
   # Note: The name must start with 'SageMaker'
   iot_role_arn = "arn:aws:iam::<account>:role/SageMaker*"
   ```

2. **Train a machine learning model.**

   See Train a Model with Amazon SageMaker for more information on how to train a machine learning model using SageMaker AI. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

   If you do not have a model yet, you can use a pre-trained model for the next steps in this tutorial. For example, you can save the MobileNet V2 models from the TensorFlow framework. MobileNet V2 is an image classification model optimized for mobile applications. For more information about MobileNet V2, see the MobileNet GitHub README.

   Type the following into your Jupyter Notebook to save the pre-trained MobileNet V2 model:

```
# Save the MobileNet V2 model to local storage
   import tensorflow as tf
   model = tf.keras.applications.MobileNetV2()
   model.save("mobilenet_v2.h5")
```

> **Note**
>
> - If you do not have TensorFlow installed, you can do so by running `pip install tensorflow=2.4`
> - Use TensorFlow version 2.4 or lower for this tutorial.

The model will be saved into the `mobilenet_v2.h5` file. Before packaging the model, you will need to first compile your model using SageMaker Neo. See Supported Frameworks, Devices, Systems, and Architectures to check if your version of TensorFlow (or other framework of choice) is currently supported by SageMaker Neo.

SageMaker Neo requires models to be stored as a compressed TAR file. Repackage it as a compressed TAR file (*.tar.gz):

```
# Package MobileNet V2 model into a TAR file
   import tarfile

   tarfile_name='mobilenet-v2.tar.gz'

   with tarfile.open(tarfile_name, mode='w:gz') as archive:
       archive.add('mobilenet-v2.h5')
```

3. **Upload your model to Amazon S3.**

   Once you have a machine learning model, store it in an Amazon S3 bucket. The following example uses an Amazon CLI command to upload the model the to the Amazon S3 bucket you created earlier in a directory called *models*. Type in the following into your Jupyter Notebook:

   ```
   !aws s3 cp mobilenet-v2.tar.gz s3://{bucket}/models/
   ```

4. **Compile your model with SageMaker Neo.**

Compile your machine learning model with SageMaker Neo for an edge device. You need to know your Amazon S3 bucket URI where you stored the trained model, the machine learning framework you used to train your model, the shape of your model's input, and your target device.

For the MobileNet V2 model, use the following:

```
framework = 'tensorflow'
target_device = 'jetson_nano'
data_shape = '{"data":[1,3,224,224]}'
```

SageMaker Neo requires a specific model input shape and model format based on the deep learning framework you use. For more information about how to save your model, see What input data shapes does SageMaker Neo expect?. For more information about devices and frameworks supported by Neo, see Supported Frameworks, Devices, Systems, and Architectures.

Use the `CreateCompilationJob` API to create a compilation job with SageMaker Neo. Provide a name to the compilation job, the SageMaker AI Role ARN, the Amazon S3 URI where your model is stored, the input shape of the model, the name of the framework, the Amazon S3 URI where you want SageMaker AI to store your compiled model, and your edge device target.

```
# Specify the path where your model is stored
model_directory = 'models'
s3_model_uri = 's3://{}/{}/{}'.format(bucket, model_directory, tarfile_name)

# Store compiled model in S3 within the 'compiled-models' directory
compilation_output_dir = 'compiled-models'
s3_output_location = 's3://{}/{}/'.format(bucket, compilation_output_dir)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'

sagemaker_client.create_compilation_job(CompilationJobName=compilation_job_name,
                                        RoleArn=sagemaker_role_arn,
                                        InputConfig={
                                            'S3Uri': s3_model_uri,
                                            'DataInputConfig': data_shape,
                                            'Framework' : framework.upper()},
```

```
                                        OutputConfig={
                                            'S3OutputLocation': s3_output_location,
                                            'TargetDevice': target_device},
                                        StoppingCondition={'MaxRuntimeInSeconds':
 900})
```

5. **Package your compiled model.**

   Packaging jobs take SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent. To package your model, create an edge packaging job with the `create_edge_packaging` API or the SageMaker AI console.

   You need to provide the name that you used for your Neo compilation job, a name for the packaging job, a role ARN (see Setting Up section), a name for the model, a model version, and the Amazon S3 bucket URI for the output of the packaging job. Note that Edge Manager packaging job names are case-sensitive. The following is an example of how to create a packaging job using the API.

```
edge_packaging_name='edge-packaging-demo'
model_name="sample-model"
model_version="1.1"
```

   Define the Amazon S3 URI where you want to store the packaged model.

```
# Output directory where you want to store the output of the packaging job
packaging_output_dir = 'packaged_models'
packaging_s3_output = 's3://{}/{}'.format(bucket, packaging_output_dir)
```

   Use `CreateEdgePackagingJob` to package your Neo-compiled model. Provide a name for your edge packaging job and the name you provided for your compilation job (in this example, it was stored in the variable `compilation_job_name`). Also provide a name for your model, a version for your model (this is used to help you keep track of what model version you are using), and the S3 URI where you want SageMaker AI to store the packaged model.

```
sagemaker_client.create_edge_packaging_job(
                    EdgePackagingJobName=edge_packaging_name,
                    CompilationJobName=compilation_job_name,
                    RoleArn=sagemaker_role_arn,
```

```
                    ModelName=model_name,
                    ModelVersion=model_version,
                    OutputConfig={
                        "S3OutputLocation": packaging_s3_output
                        }
                    )
```

Register and Authenticate Your Device Fleet

In this section you will create your Amazon IoT thing object, create a device fleet, register your device fleet so it can interact with the cloud, create X.509 certificates to authenticate your devices to Amazon IoT Core, associate the role alias with Amazon IoT that was generated when you created your fleet, get your Amazon account-specific endpoint for the credentials provider, get an official Amazon Root CA file, and upload the Amazon CA file to Amazon S3.

1. **Create Amazon IoT things.**

   SageMaker Edge Manager takes advantage of the Amazon IoT Core services to facilitate the connection between the edge devices and endpoints in the Amazon cloud. You can take advantage of existing Amazon IoT functionality after you set up your devices to work with Edge Manager.

   To connect your device to Amazon IoT, you need to create Amazon IoT *thing objects*, create and register a client certificate with Amazon IoT, and create and configure the IAM role for your devices.

   First, create Amazon IoT thing objects with the Amazon IoT client (`iot_client`) you created earlier with Boto3. The following example shows how to create two thing objects:

```
iot_thing_name = 'sample-device'
iot_thing_type = 'getting-started-demo'

iot_client.create_thing_type(
    thingTypeName=iot_thing_type
)

# Create an Amazon IoT thing objects
iot_client.create_thing(
    thingName=iot_thing_name,
    thingTypeName=iot_thing_type
```

```
)
```

2. **Create your device fleet.**

   Create a device fleet with the SageMaker AI client object defined in a previous step. You can also use the SageMaker AI console to create a device fleet.

   ```
   import time
   device_fleet_name="demo-device-fleet" + str(time.time()).split('.')[0]
   device_name="sagemaker-edge-demo-device" + str(time.time()).split('.')[0]
   ```

   Specify your IoT role ARN. This lets Amazon IoT grant temporary credentials to devices.

   ```
   device_model_directory='device_output'
   s3_device_fleet_output = 's3://{}/{}'.format(bucket, device_model_directory)

   sagemaker_client.create_device_fleet(
       DeviceFleetName=device_fleet_name,
       RoleArn=iot_role_arn, # IoT Role ARN specified in previous step
       OutputConfig={
           'S3OutputLocation': s3_device_fleet_output
       }
   )
   ```

   An Amazon IoT role alias is created when you create a device fleet. This role alias is associated with Amazon IoT using the `iot_client` object in a later step.

3. **Register your device fleet.**

   To interact with the cloud, you need to register your device with SageMaker Edge Manager. In this example, you register a single device with the fleet you created. To register the device, you need to provide a device name and the Amazon IoT thing name as shown in the following example:

   ```
   # Device name should be 36 characters
   device_name = "sagemaker-edge-demo-device" + str(time.time()).split('.')[0]

   sagemaker_client.register_devices(
       DeviceFleetName=device_fleet_name,
       Devices=[
           {
               "DeviceName": device_name,
   ```

```
            "IotThingName": iot_thing_name
        }
    ]
)
```

4. **Create X.509 certificates.**

   After creating the Amazon IoT thing object, you must create a X.509 device certificate for your thing object. This certificate authenticates your device to Amazon IoT Core.

   Use the following to create a private key, public key, and a X.509 certificate file using the Amazon IoT client defined (`iot_client`) earlier.

```
# Creates a 2048-bit RSA key pair and issues an X.509 # certificate
# using the issued public key.
create_cert = iot_client.create_keys_and_certificate(
    setAsActive=True
)

# Get certificate from dictionary object and save in its own
with open('./device.pem.crt', 'w') as f:
    for line in create_cert['certificatePem'].split('\n'):
        f.write(line)
        f.write('\n')
# Get private key from dictionary object and save in its own
with open('./private.pem.key', 'w') as f:
    for line in create_cert['keyPair']['PrivateKey'].split('\n'):
        f.write(line)
        f.write('\n')
# Get a private key from dictionary object and save in its own
with open('./public.pem.key', 'w') as f:
    for line in create_cert['keyPair']['PublicKey'].split('\n'):
        f.write(line)
        f.write('\n')
```

5. **Associate the role alias with Amazon IoT.**

   When you create a device fleet with SageMaker AI (`sagemaker_client.create_device_fleet()`), a role alias is generated for you. An Amazon IoT role alias provides a mechanism for connected devices to authenticate to Amazon IoT using X.509 certificates, and then obtain short-lived Amazon credentials from an IAM role that is associated with an Amazon IoT role alias. The role alias allows you to change the role of

the device without having to update the device. Use `DescribeDeviceFleet` to get the role alias name and ARN.

```
# Print Amazon Resource Name (ARN) and alias that has access
# to Amazon Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)

# Store iot role alias string in a variable
# Grabs role ARN
full_role_alias_name =
 sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)
['IotRoleAlias']
start_index = full_role_alias_name.find('SageMaker') # Find beginning of role name

role_alias_name = full_role_alias_name[start_index:]
```

Use the `iot_client` to facilitate associating the role alias generated from creating the device fleet with Amazon IoT:

```
role_alias = iot_client.describe_role_alias(
                    roleAlias=role_alias_name)
```

For more information about IAM role alias, see Role alias allows access to unused services .

You created and registered a certificate with Amazon IoT earlier for successful authentication of your device. Now, you need to create and attach a policy to the certificate to authorize the request for the security token.

```
alias_policy = {
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "iot:AssumeRoleWithCertificate",
    "Resource": role_alias['roleAliasDescription']['roleAliasArn']
  }
}

policy_name = 'aliaspolicy-'+ str(time.time()).split('.')[0]
aliaspolicy = iot_client.create_policy(policyName=policy_name,
                                       policyDocument=json.dumps(alias_policy))
```

```
# Attach policy
iot_client.attach_policy(policyName=policy_name,
                         target=create_cert['certificateArn'])
```

6. **Get your Amazon account-specific endpoint for the credentials provider.**

   Edge devices need an endpoint in order to assume credentials. Obtain your Amazon account-specific endpoint for the credentials provider.

```
# Get the unique endpoint specific to your Amazon account that is making the call.
iot_endpoint = iot_client.describe_endpoint(
    endpointType='iot:CredentialProvider'
)

endpoint="https://{}/role-aliases/{}/
credentials".format(iot_endpoint['endpointAddress'],role_alias_name)
```

7. **Get the official Amazon root CA file and upload it to the Amazon S3 bucket.**

   Use the following in your Jupyter Notebook or Amazon CLI (if you use your terminal, remove the '!' magic function):

```
!wget https://www.amazontrust.com/repository/AmazonRootCA1.pem
```

   Use the endpoint to make an HTTPS request to the credentials provider to return a security token. The following example command uses `curl`, but you can use any HTTP client.

```
!curl --cert device.pem.crt --key private.pem.key --cacert AmazonRootCA1.pem
 $endpoint
```

   If the certificate is verified, upload the keys and certificate to your Amazon S3 bucket URI:

```
!aws s3 cp private.pem.key s3://{bucket}/authorization-files/
!aws s3 cp device.pem.crt s3://{bucket}/authorization-files/
!aws s3 cp AmazonRootCA1.pem s3://{bucket}/authorization-files/
```

   Clean your working directory by moving your keys and certificate to a different directory:

```
# Optional - Clean up working directory
!mkdir authorization-files
```

```
!mv private.pem.key device.pem.crt AmazonRootCA1.pem authorization-files/
```

Download and Set Up Edge Manager

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals.

In this section you will set up your device with the agent. To do so, first copy a release artifact and signing root certificate from the release bucket locally to your machine. After you unzip the release artifact, upload it to Amazon S3. Next, define and save a configuration file for the agent. A template is provided for you to copy and paste. Finally, copy the release artifacts, configuration file, and credentials to your device.

1. **Download the SageMaker Edge Manager agent.**

   The agent is released in binary format for supported operating systems. This example runs inference on a Jetson Nano which uses a Linux operating system and has an ARM64 architecture. For more information about what operating system and architecture supported devices use, see Supported Devices, Chip Architectures, and Systems.

   Fetch the latest version of binaries from the SageMaker Edge Manager release bucket from the us-west-2 Region.

   ```
   !aws s3 ls s3://sagemaker-edge-release-store-us-west-2-linux-armv8/Releases/ | sort
    -r
   ```

   This returns release artifacts sorted by their version.

   ```
                              PRE 1.20210512.96da6cc/
                              PRE 1.20210305.a4bc999/
                              PRE 1.20201218.81f481f/
                              PRE 1.20201207.02d0e97/
   ```

   The version has the following format: `<MAJOR_VERSION>.<YYYY-MM-DD>.<SHA-7>`. It consists of three components:

   - `<MAJOR_VERSION>`: The release version. The release version is currently set to 1.

- <YYYY-MM-DD>: The time stamp of the artifact release.
- <SHA-7>: The repository commit ID from which the release is built.

Copy the zipped TAR file locally or to your device directly. The following example shows how to copy the latest release artifact at the time this document was released.

```
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/
Releases/1.20201218.81f481f/1.20201218.81f481f.tgz ./
```

Once you have the artifact, unzip the zipped TAR file. The following unzips the TAR file and stores it in a directory called `agent_demo`:

```
!mkdir agent_demo
!tar -xvzf 1.20201218.81f481f.tgz -C ./agent_demo
```

Upload the agent release artifacts to your Amazon S3 bucket. The following code example copies the content within `agent_demo` and uploads it to a directory within your Amazon S3 bucket called `agent_demo`:

```
!aws s3 cp --recursive ./agent_demo s3://{bucket}/agent_demo
```

You also need the signing root certificates from the release bucket:

```
!aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Certificates/us-
west-2/us-west-2.pem ./
```

Upload the signing root certificate to your Amazon S3 bucket:

```
!aws s3 cp us-west-2.pem s3://{bucket}/authorization-files/
```

2. **Define a SageMaker Edge Manager agent configuration file.**

   First, define the agent configuration file as follows:

```
sagemaker_edge_config = {
    "sagemaker_edge_core_device_name": "device_name",
    "sagemaker_edge_core_device_fleet_name": "device_fleet_name",
    "sagemaker_edge_core_capture_data_buffer_size": 30,
```

```
    "sagemaker_edge_core_capture_data_push_period_seconds": 4,
    "sagemaker_edge_core_folder_prefix": "demo_capture",
    "sagemaker_edge_core_region": "us-west-2",
    "sagemaker_edge_core_root_certs_path": "/agent_demo/certificates",
    "sagemaker_edge_provider_aws_ca_cert_file": "/agent_demo/iot-credentials/
AmazonRootCA1.pem",
    "sagemaker_edge_provider_aws_cert_file": "/agent_demo/iot-credentials/
device.pem.crt",
    "sagemaker_edge_provider_aws_cert_pk_file": "/agent_demo/iot-credentials/
private.pem.key",
    "sagemaker_edge_provider_aws_iot_cred_endpoint": "endpoint",
    "sagemaker_edge_provider_provider": "Aws",
    "sagemaker_edge_provider_s3_bucket_name": bucket,
    "sagemaker_edge_core_capture_data_destination": "Cloud"
}
```

Replace the following:

- `"device_name"` with the name of your device (this string was stored in an earlier step in a variable named `device_name`).
- `"device_fleet_name"` with the name of your device fleet (this string was stored an earlier step in a variable named `device_fleet_name`)
- `"endpoint"` with your Amazon account-specific endpoint for the credentials provider (this string was stored in an earlier step in a variable named `endpoint`).

Next, save it as a JSON file:

```
edge_config_file = open("sagemaker_edge_config.json", "w")
json.dump(sagemaker_edge_config, edge_config_file, indent = 6)
edge_config_file.close()
```

Upload the configuration file to your Amazon S3 bucket:

```
!aws s3 cp sagemaker_edge_config.json s3://{bucket}/
```

3. **Copy the release artifacts, configuration file, and credentials to your device.**

   The following instructions are performed on the edge device itself.

> **Note**
>
> You must first install Python, the Amazon SDK for Python (Boto3), and the Amazon CLI on your edge device.

Open a terminal on your device. Create a folder to store the release artifacts, your credentials, and the configuration file.

```
mkdir agent_demo
cd agent_demo
```

Copy the contents of the release artifacts that you stored in your Amazon S3 bucket to your device:

```
# Copy release artifacts
aws s3 cp s3://<bucket-name>/agent_demo/ ./ --recursive
```

(The contents of the release artifact was stored in a directory called `agent_demo` in a previous step). Replace `<bucket-name>` and `agent_demo` with the name of your Amazon S3 bucket and the file path to your release artifacts, respectively.

Go the `/bin` directory and make the binary files executable:

```
cd bin

chmod +x sagemaker_edge_agent_binary
chmod +x sagemaker_edge_agent_client_example

cd agent_demo
```

Make a directory to store your Amazon IoT credentials and copy your credentials from your Amazon S3 bucket to your edge device (use the same on you define in the variable `bucket`:

```
mkdir iot-credentials
cd iot-credentials

aws s3 cp s3://<bucket-name>/authorization-files/AmazonRootCA1.pem ./
```

```
aws s3 cp s3://<bucket-name>/authorization-files/device.pem.crt ./
aws s3 cp s3://<bucket-name>/authorization-files/private.pem.key ./

cd ../
```

Make a directory to store your model signing root certificates:

```
mkdir certificates

cd certificates

aws s3 cp s3://<bucket-name>/authorization-files/us-west-2.pem ./

cd agent_demo
```

Copy your configuration file to your device:

```
#Download config file from S3
aws s3 cp s3://<bucket-name>/sagemaker_edge_config.json ./

cd agent_demo
```

Your `agent_demo` directory on your edge device should look similar to the following:

```
###agent_demo
|    ### bin
|        ### sagemaker_edge_agent_binary
|        ### sagemaker_edge_agent_client_example
|    ### sagemaker_edge_config.json
|    ### certificates
|        ###us-west-2.pem
|    ### iot-credentials
|        ### AmazonRootCA1.pem
|        ### device.pem.crt
|        ### private.pem.key
|    ### docs
|        ### api
|        ### examples
|    ### ATTRIBUTIONS.txt
|    ### LICENSE.txt
|    ### RELEASE_NOTES.md
```

Run Agent

In this section you will run the agent as a binary using gRPC, and check that both your device and fleet are working and collecting sample data.

1. **Launch the agent.**

   The SageMaker Edge Manager agent can be run as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or can be linked against as a Dynamic Shared Object (.dll). Running as a standalone executable binary is the preferred mode and is supported on Linux.

   This example uses gRPC to run the agent. gRPC is an open source high-performance Remote Procedure Call (RPC) framework that can run in any environment. For more information about gRPC, see the gRPC documentation.

   To use gRPC, perform the following steps:

   a. Define a service in a .proto file.

   b. Generate server and client code using the protocol buffer compiler.

   c. Use the Python (or other languages supported by gRPC) gRPC API to write the server for your service.

   d. Use the Python (or other languages supported by gRPC) gRPC API to write a client for your service.

   The release artifact you downloaded contains a gRPC application ready for you to run the agent. The example is located within the `/bin` directory of your release artifact. The `sagemaker_edge_agent_binary` binary executable is in this directory.

   To run the agent with this example, provide the path to your socket file (.sock) and JSON .config file:

   ```
   ./bin/sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c
    sagemaker_edge_config.json
   ```

2. **Check your device.**

   Check that your device is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

Provide the name of the fleet to which the device belongs and the unique device identifier. From your local machine, run the following:

```
sagemaker_client.describe_device(
    DeviceName=device_name,
    DeviceFleetName=device_fleet_name
)
```

For the given model, you can see the name, model version, latest sample time, and when the last inference was made.

```
{
  "DeviceName": "sample-device",
  "DeviceFleetName": "demo-device-fleet",
  "IoTThingName": "sample-thing-name-1",
  "RegistrationTime": 1600977370,
  "LatestHeartbeat": 1600977370,
  "Models":[
    {
        "ModelName": "mobilenet_v2.tar.gz",
        "ModelVersion": "1.1",
        "LatestSampleTime": 1600977370,
        "LatestInference": 1600977370
    }
  ]
}
```

The timestamp provided by `LastetHeartbeat` indicates the last signal that was received from the device. `LatestSampleTime` and `LatestInference` describe the time stamp of the last data sample and inference, respectively.

3. **Check your fleet.**

   Check that your fleet is working with `GetDeviceFleetReport`. Provide the name of the fleet the device belongs to.

```
sagemaker_client.get_device_fleet_report(
    DeviceFleetName=device_fleet_name
)
```

For a given model, you can see the name, model version, latest sample time, and when the last inference was made, along with the Amazon S3 bucket URI where the data samples are stored.

```
# Sample output
{
 "DeviceFleetName": "sample-device-fleet",
 "DeviceFleetArn": "arn:aws:sagemaker:us-west-2:9999999999:device-fleet/sample-
fleet-name",
 "OutputConfig": {
              "S3OutputLocation": "s3://fleet-bucket/package_output",
  },
 "AgentVersions":[{"Version": "1.1", "AgentCount": 2}]}
 "DeviceStats": {"Connected": 2, "Registered": 2},
 "Models":[{
            "ModelName": "sample-model",
            "ModelVersion": "1.1",
            "OfflineDeviceCount": 0,
            "ConnectedDeviceCount": 2,
            "ActiveDeviceCount": 2,
            "SamplingDeviceCount": 100
            }]
}
```

Setup for Devices and Fleets in SageMaker Edge Manager

Fleets are collections of logically grouped devices you can use to collect and analyze data. You can use SageMaker Edge Manager to operate machine learning models on a fleet of smart cameras, smart speakers, robots, and other edge devices.

Create a fleet and register your devices either programmatically with the Amazon SDK for Python (Boto3) or through the SageMaker AI console.

Topics

- Create a Fleet
- Register a Device
- Check Status

Create a Fleet

You can create a fleet programmatically with the Amazon SDK for Python (Boto3) or through the SageMaker AI console https://console.amazonaws.cn/sagemaker.

Create a Fleet (Boto3)

Use the `CreateDeviceFleet` API to create a fleet. Specify a name for the fleet, your Amazon IoT Role ARN for the `RoleArn` field, as well as an Amazon S3 URI where you want the device to store sampled data.

You can optionally include a description of the fleet, tags, and an Amazon KMS Key ID.

```
import boto3

# Create SageMaker client so you can interact and manage SageMaker resources
sagemaker_client = boto3.client("sagemaker", region_name="aws-region")

sagemaker_client.create_device_fleet(
    DeviceFleetName="sample-fleet-name",
    RoleArn="arn:aws:iam::999999999:role/rolename", # IoT Role ARN
    Description="fleet description",
    OutputConfig={
        S3OutputLocation="s3://bucket/",
        KMSKeyId: "1234abcd-12ab-34cd-56ef-1234567890ab",
    },
        Tags=[
        {
            "Key": "string",
            "Value" : "string"
         }
     ],
)
```

An Amazon IoT Role Alias is created for you when you create a device fleet. The Amazon IoT role alias provides a mechanism for connected devices to authenticate to Amazon IoT using X.509 certificates and then obtain short-lived Amazon credentials from an IAM role that is associated with the Amazon IoT role alias.

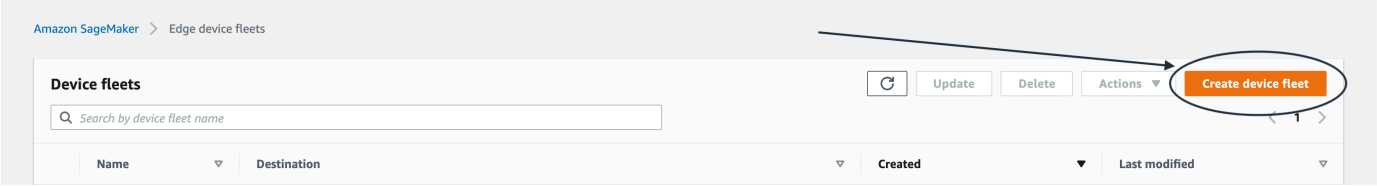
Use `DescribeDeviceFleet` to get the role alias name and ARN.

```
# Print Amazon Resource Name (ARN) and alias that has access
```

```
# to Amazon Internet of Things (IoT).
sagemaker_client.describe_device_fleet(DeviceFleetName=device_fleet_name)
['IotRoleAlias']
```

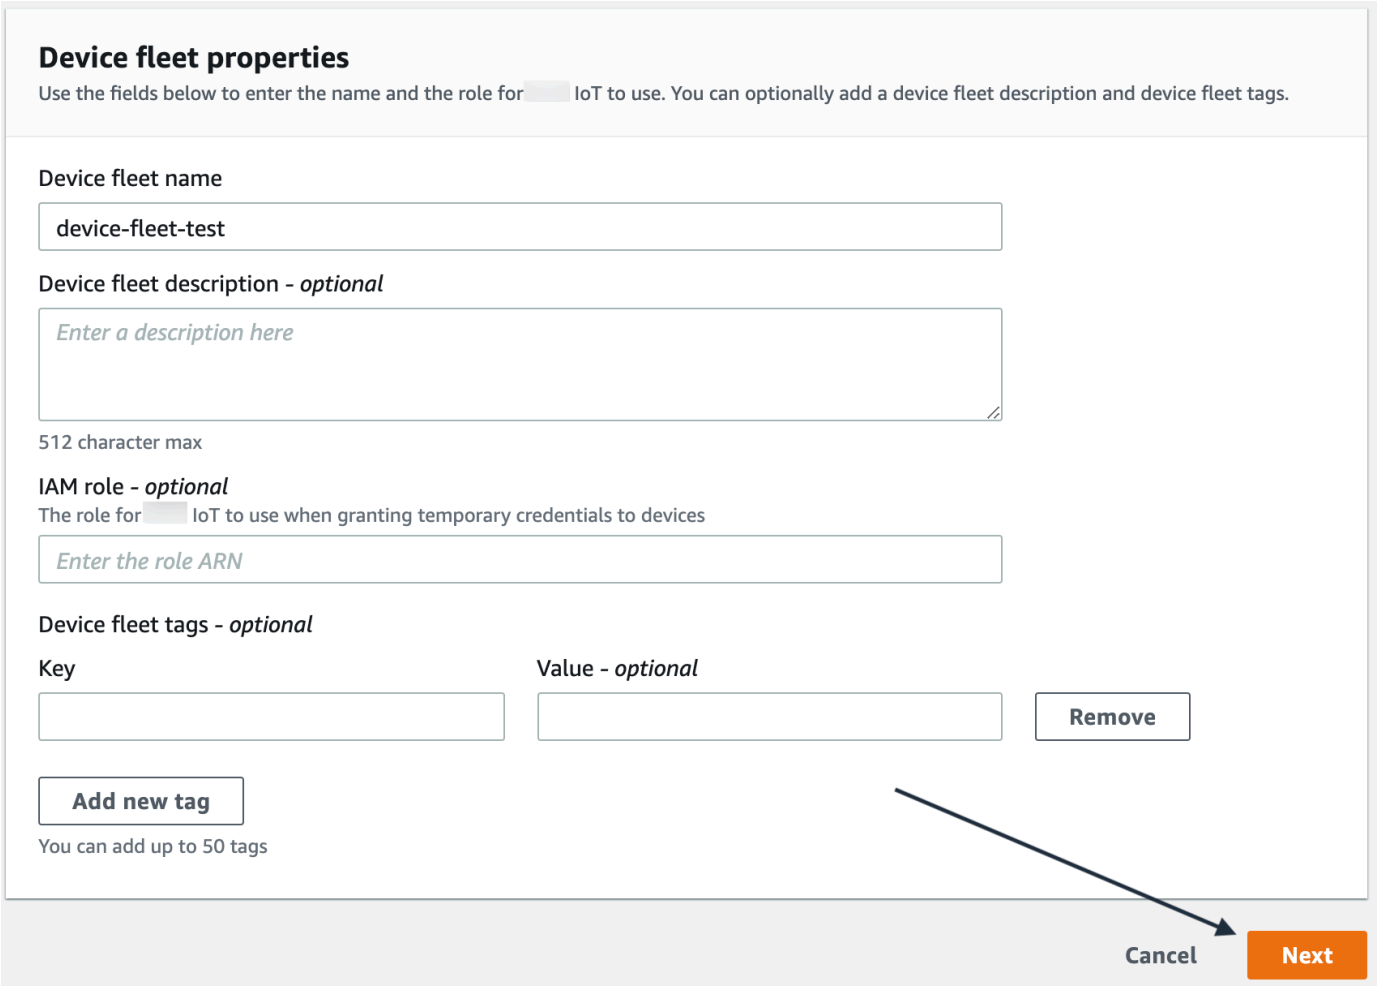
Use `DescribeDeviceFleet` API to get a description of fleets you created.

```
sagemaker_client.describe_device_fleet(
    DeviceFleetName="sample-fleet-name"
)
```



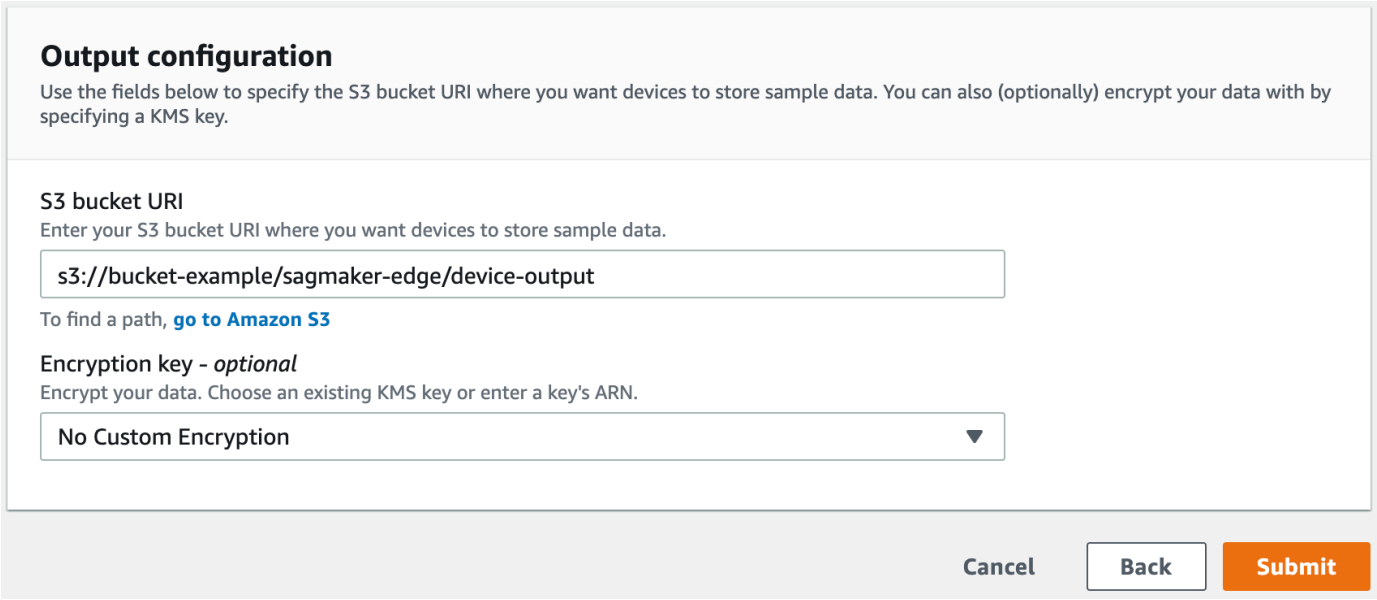
By default, it returns the name of the fleet, the device fleet ARN, the Amazon S3 bucket URI, the IAM role, the role alias created in Amazon IoT, a timestamp of when the fleet was created, and a timestamp of when the fleet was last modified.

```
{ "DeviceFleetName": "sample-fleet-name",
  "DeviceFleetArn": "arn:aws:sagemaker:us-west-2:9999999999:device-fleet/sample-fleet-
name",
  "IAMRole": "arn:aws:iam::999999999:role/rolename",
  "Description": "this is a sample fleet",
  "IoTRoleAlias": "arn:aws:iot:us-west-2:9999999999:rolealias/SagemakerEdge-sample-
fleet-name"
  "OutputConfig": {
              "S3OutputLocation": "s3://bucket/folder",
              "KMSKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab"
   },
   "CreationTime": "1600977370",
   "LastModifiedTime": "1600977370"}
```



Create a Fleet (Console)

You can create a Edge Manager packaging job using the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker.



1. In the SageMaker AI console, choose **Edge Manager** and then choose **Edge device fleets**.
2. Choose **Create device fleet**.

3. Enter a name for the device fleet in the **Device fleet name** field. Choose **Next**.

4. On the **Output configuration** page, specify the Amazon S3 bucket URI where you want to store sample data from your device fleet. You can optionally add an encryption key as well by electing an existing Amazon KMS key from the dropdown list or by entering a key's ARN. Choose **Submit**.

5. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, Amazon KMS key ID (if provided), Amazon IoT alias (if provided), and IAM role. If you added tags, they appear in the **Device fleet tags** section.

Register a Device

> **Important**
>
> Device registration is required to use any part of SageMaker Edge Manager.

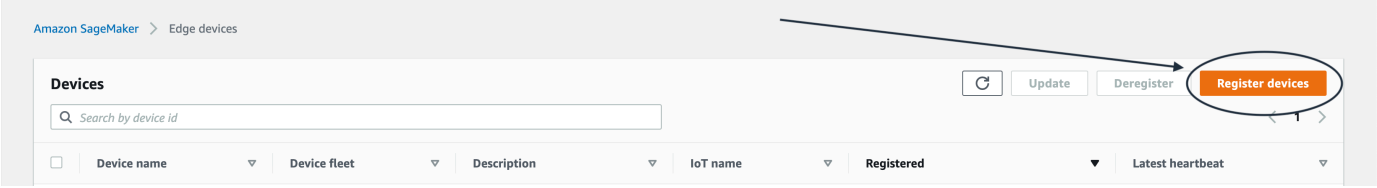
You can create a fleet programmatically with the Amazon SDK for Python (Boto3) or through the SageMaker AI console at https://console.amazonaws.cn/sagemaker.

Register a Device (Boto3)

To register your device, first create and register an Amazon IoT thing object and configure an IAM role. SageMaker Edge Manager takes advantage of the Amazon IoT Core services to facilitate the connection between the edge devices and the cloud. You can take advantage of existing Amazon IoT functionality after you set up your devices to work with Edge Manager.

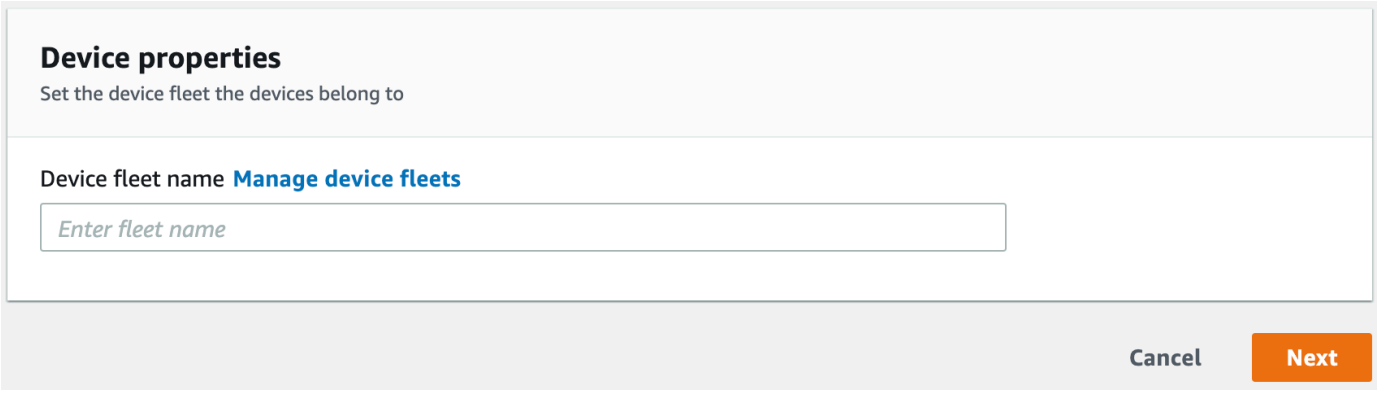
To connect your device to Amazon IoT you need to create Amazon IoT thing objects, create and register a client certificate with Amazon IoT, and create and configure IAM role for your devices.

See the Getting Started Guide for an in-depth example or the Explore Amazon IoT Core services in hands-on tutorial.



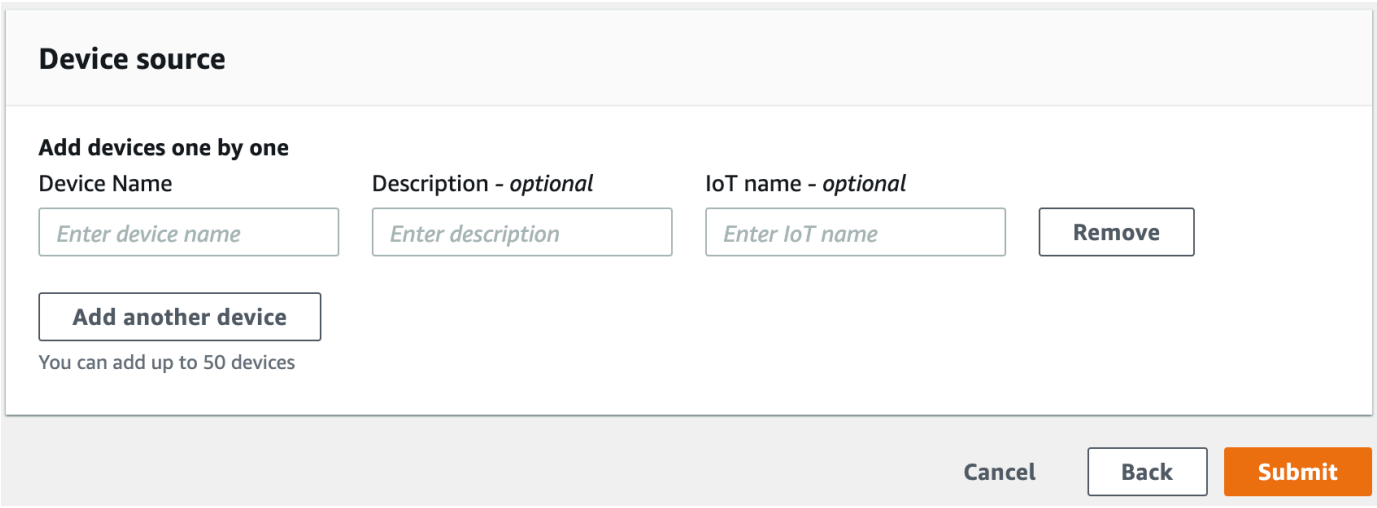
Use the `RegisterDevices` API to register your device. Provide the name of the fleet of which you want the devices to be a part, as well as a name for the device. You can optionally add a description to the device, tags, and Amazon IoT thing name associated with the device.

```
sagemaker_client.register_devices(
    DeviceFleetName="sample-fleet-name",
    Devices=[
        {
            "DeviceName": "sample-device-1",
            "IotThingName": "sample-thing-name-1",
            "Description": "Device #1"
        }
     ],
     Tags=[
        {
            "Key": "string",
            "Value" : "string"
         }
     ],
)
```



Register a Device (Console)

You can register your device using the SageMaker AI console at https://console.amazonaws.cn/sagemaker.



1. In the SageMaker AI console, choose **Edge Inference** and then choose **Edge devices**.
2. Choose **Register devices**.

3. In the **Device properties** section, enter the name of the fleet the device belongs to under the **Device fleet name** field. Choose **Next**.

4. In the **Device source** section, add your devices one by one. You must include a **Device Name** for each device in your fleet. You can optionally provide a description (in the **Description** field) and an Internet of Things (IoT) object name (in the **IoT name** field). Choose **Submit** once you have added all your devices.

The **Devices** page displays the name of the device you have added, the fleet to which it belongs, when it was registered, the last heartbeat, and the description and Amazon IoT name, if you provided one.

Choose a device to view the device's details, including the device name, fleet, ARN, description, IoT Thing name, when the device was registered, and the last heartbeat.

Check Status

Check that your device or fleet is connected and sampling data. Making periodic checks, manually or automatically, allows you to check that your device or fleet is working properly.

Use the Amazon S3 console at https://console.amazonaws.cn/s3/ to interactively choose a fleet for a status check. You can also use the Amazon SDK for Python (Boto3). The following describes different APIs from Boto3 you can use to check the status of your device or fleet. Use the API that best fits your use case.

- **Check an individual device.**

  To check the status of an individual device, use `DescribeDevice` API. A list containing one or more models is provided if a models have been deployed to the device.

```
sagemaker_client.describe_device(
    DeviceName="sample-device-1",
    DeviceFleetName="sample-fleet-name"
)
```

  Running `DescribeDevice` returns:

```
{ "DeviceName": "sample-device".
  "Description": "this is a sample device",
  "DeviceFleetName": "sample-device-fleet",
  "IoTThingName": "SampleThing",
  "RegistrationTime": 1600977370,
  "LatestHeartbeat": 1600977370,
  "Models":[
        {
         "ModelName": "sample-model",
         "ModelVersion": "1.1",
         "LatestSampleTime": 1600977370,
         "LatestInference": 1600977370
        }
   ]
}
```

- **Check a fleet of devices.**

  To check the status of the fleet, use the `GetDeviceFleetReport` API. Provide the name of the device fleet to get a summary of the fleet.

```
sagemaker_client.get_device_fleet_report(
    DeviceFleetName="sample-fleet-name"
)
```

- **Check for a heartbeat.**

  Each device within a fleet periodically generates a signal, or “heartbeat”. The heartbeat can be used to check that the device is communicating with Edge Manager. If the timestamp of the last heartbeat is not being updated, the device may be failing.

  Check the last heartbeat with made by a device with the `DescribeDevice` API. Specify the name of the device and the fleet to which the edge device belongs.

```
sagemaker_client.describe_device(
    DeviceName="sample-device-1",
    DeviceFleetName="sample-fleet-name"
)
```

How to Package Model

SageMaker Edge Manager packaging jobs take Amazon SageMaker Neo–compiled models and make any changes necessary to deploy the model with the inference engine, Edge Manager agent.

Topics

- Complete prerequisites
- Package a Model (Amazon SageMaker AI Console)
- Package a Model (Boto3)

Complete prerequisites

To package a model, you must do the following:

1. **Compile your machine learning model with SageMaker AI Neo.**

   If you have not already done so, compile your model with SageMaker Neo. For more information on how to compile your model, see Compile and Deploy Models with Neo. If you are first-time user of SageMaker Neo, go through Getting Started with Neo Edge Devices.

2. **Get the name of your compilation job.**

   Provide the name of the compilation job name you used when you compiled your model with SageMaker Neo. Open the SageMaker AI console at https://console.amazonaws.cn/sagemaker/ and choose **Compilation jobs** to find a list of compilations that have been

submitted to your Amazon account. The names of submitted compilation jobs are in the **Name** column.

3. **Get your IAM ARN.**

   You need an Amazon Resource Name (ARN) of an IAM role that you can use to download and upload the model and contact SageMaker Neo.

   Use one of the following methods to get your IAM ARN:

   - **Programmatically with the SageMaker AI Python SDK**

     ```
     from sagemaker.core.helper.session_helper import Session, get_execution_role

     # Initialize SageMaker Session object so you can interact with Amazon resources
     sess = Session()

     # Get the role ARN
     role = get_execution_role()

     print(role)
     >> arn:aws:iam::<your-aws-account-id>:role/<your-role-name>
     ```

     For more information about using the SageMaker Python SDK, see the SageMaker AI Python SDK API.

   - **Using the Amazon Identity and Access Management (IAM) console**

     Navigate to the IAM console at https://console.amazonaws.cn/iam/. In the IAM **Resources** section, choose **Roles** to view a list of roles in your Amazon account. Select or create a role that has `AmazonSageMakerFullAccess`, `AWSIoTFullAccess`, and `AmazonS3FullAccess`.

     For more information on IAM, see What is IAM?

4. **Have an S3 bucket URI.**

   You need to have at least one Amazon Simple Storage Service (Amazon S3) bucket URI to store your Neo-compiled model, the output of the Edge Manager packaging job, and sample data from your device fleet.

   Use one of the following methods to create an Amazon S3 bucket:

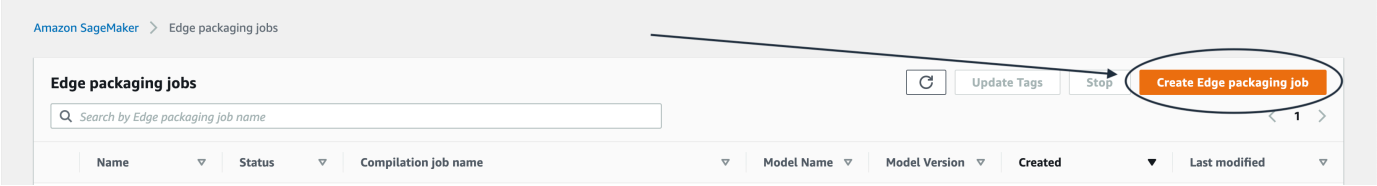
- **Programmatically with the SageMaker AI Python SDK**

  You can use the default Amazon S3 bucket during a session. A default bucket is created based on the following format: `sagemaker-{region}-{aws-account-id}`. To create a default bucket with the SageMaker Python SDK, use the following:

  ```
  import sagemaker

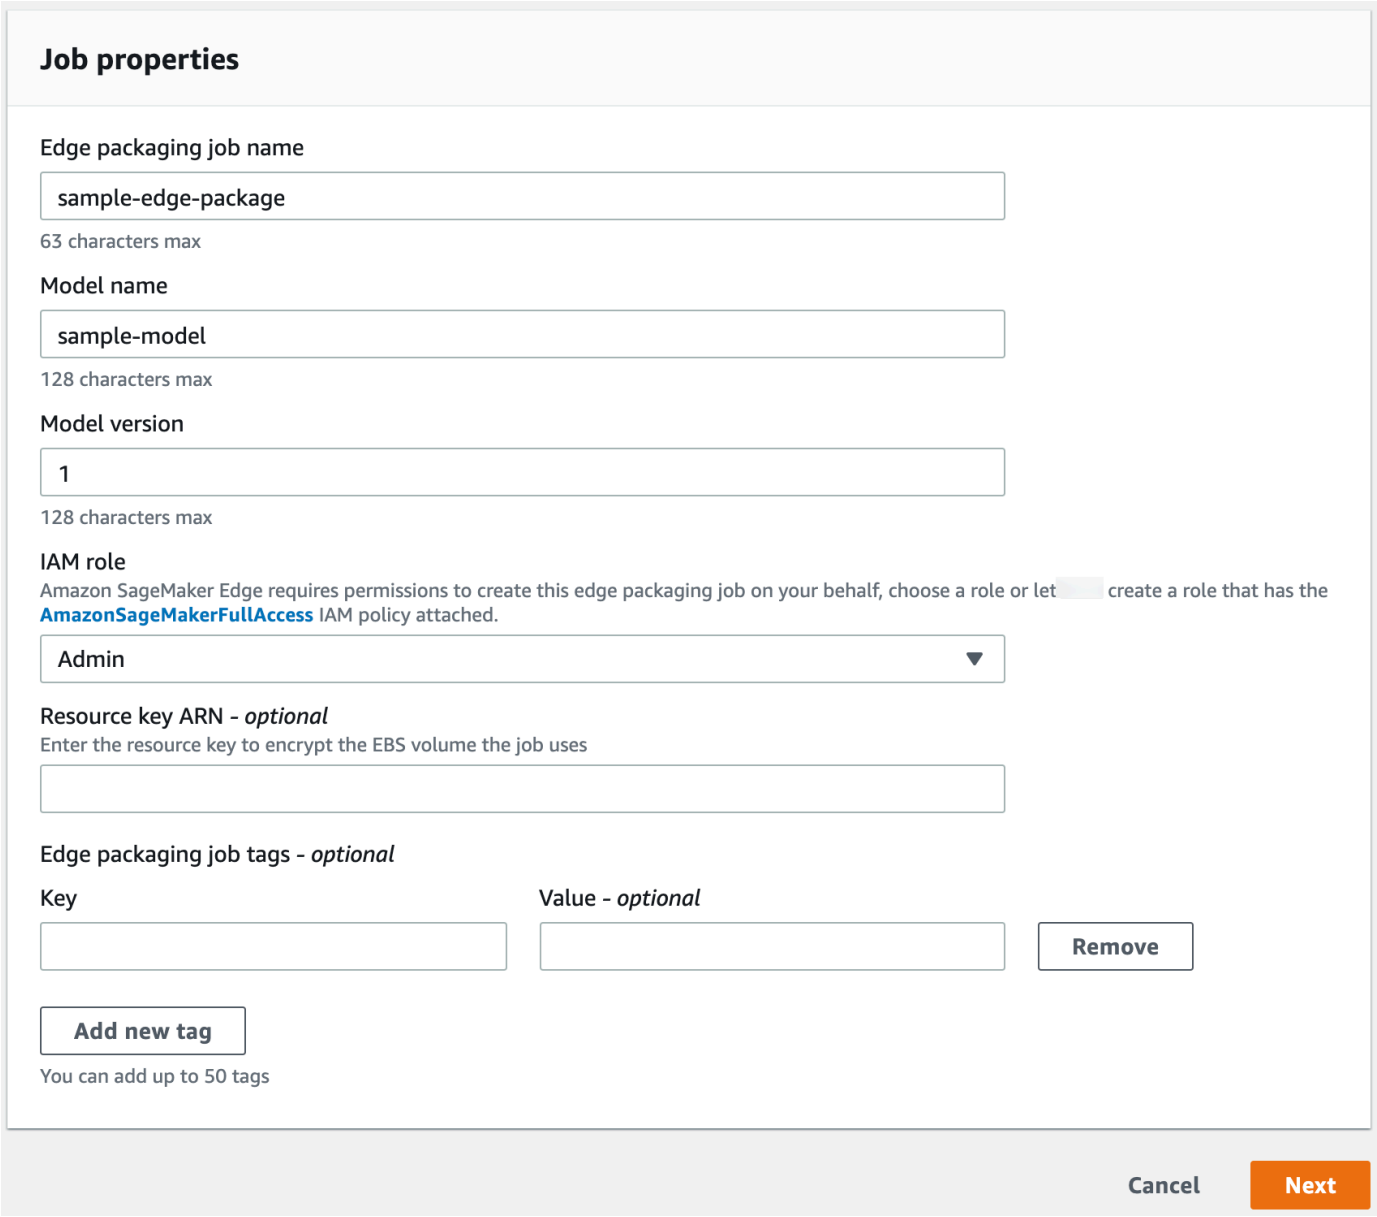
  session=sagemaker.create_session()

  bucket=session.default_bucket()
  ```



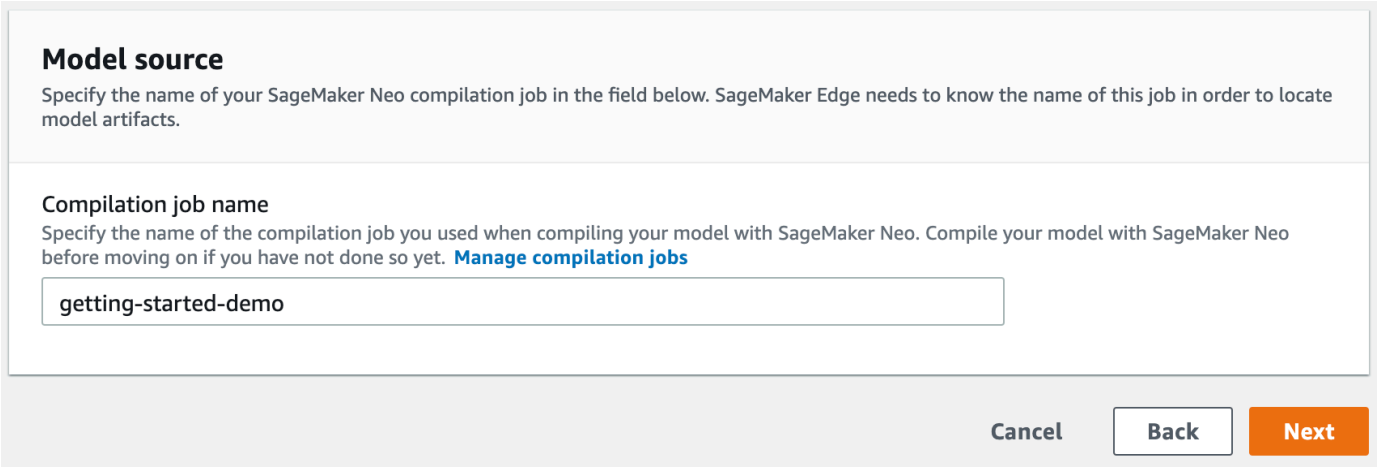
- **Using the Amazon S3 console**

  Open the Amazon S3 console at https://console.amazonaws.cn/s3/ and see How do I create an S3 Bucket? for step-by-step instructions.

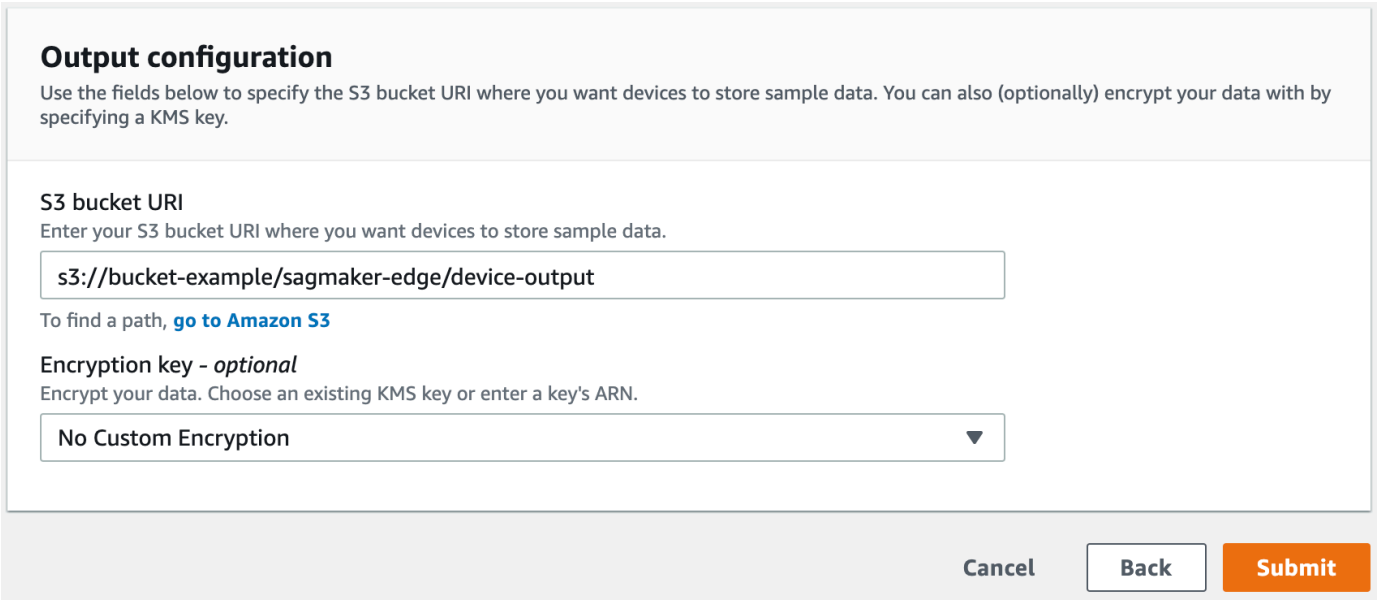


Package a Model (Amazon SageMaker AI Console)

You can create a SageMaker Edge Manager packaging job using the SageMaker AI console at https://console.amazonaws.cn/sagemaker/. Before continuing, make sure you have satisfied the Complete prerequisites.



1. In the SageMaker AI console, choose **Edge Inference** and then choose **Create edge packaging jobs**, as shown in the following image.



2. On the **Job properties** page, enter a name for your packaging job under **Edge packaging job name**. Note that Edge Manager packaging job names are case-sensitive. Name your model and give it a version: enter this under **Model name** and **Model version**, respectively.
3. Next, select an **IAM role**. You can chose a role or let Amazon create a role for you. You can optionally specify a **resource key ARN** and **job tags**.
4. Choose **Next**.

5. Specify the name of the compilation job you used when compiling your model with SageMaker Neo in the **Compilation job name** field. Choose **Next**.

6. On the **Output configuration** page, enter the Amazon S3 bucket URI in which you want to store the output of the packaging job.

The **Status** column on the **Edge packaging** jobs page should read **IN PROGRESS**. Once the packaging job is complete, the status updates to **COMPLETED**.

Selecting a packaging job directs you to that job's settings. The **Job settings** section displays the job name, ARN, status, creation time, last modified time, duration of the packaging job, and role ARN.

The **Input configuration** section displays the location of the model artifacts, the data input configuration, and the machine learning framework of the model.

The **Output configuration** section displays the output location of the packaging job, the target device for which the model was compiled, and any tags you created.

7. Choose the name of your device fleet to be redirected to the device fleet details. This page displays the name of the device fleet, ARN, description (if you provided one), date the fleet was created, last time the fleet was modified, Amazon S3 bucket URI, Amazon KMS key ID (if provided), Amazon IoT alias (if provided), and IAM role. If you added tags, they appear in the **Device fleet tags** section.

Package a Model (Boto3)

You can create a SageMaker Edge Manager packaging job with the Amazon SDK for Python (Boto3). Before continuing, make sure you have satisfied the Complete prerequisites.

To request an edge packaging job, use `CreateEdgePackagingJob`. You need to provide a name to your edge packaging job, the name of your SageMaker Neo compilation job, your role Amazon resource name (ARN), a name for your model, a version for your model, and the Amazon S3 bucket URI where you want to store the output of your packaging job. Note that Edge Manager packaging job names and SageMaker Neo compilation job names are case-sensitive.

```
# Import Amazon SDK for Python (Boto3)
import boto3

# Create Edge client so you can submit a packaging job
sagemaker_client = boto3.client("sagemaker", region_name='aws-region')

sagemaker_client.create_edge_packaging_job(
    EdgePackagingJobName="edge-packaging-name",
    CompilationJobName="neo-compilation-name",
    RoleArn="arn:aws:iam::99999999999:role/rolename",
    ModelName="sample-model-name",
    ModelVersion="model-version",
    OutputConfig={
        "S3OutputLocation": "s3://your-bucket/",
    }
)
```

You can check the status of an edge packaging job using `DescribeEdgePackagingJob` and providing the case-sensitive edge packaging job name:

```
response = sagemaker_client.describe_edge_packaging_job(
                                       EdgePackagingJobName="edge-packaging-name")
```

This returns a dictionary that can be used to poll the status of the packaging job:

```
# Optional - Poll every 30 sec to check completion status
import time

while True:
    response = sagemaker_client.describe_edge_packaging_job(
                                           EdgePackagingJobName="edge-packaging-name")

    if response['EdgePackagingJobStatus'] == 'Completed':
        break
    elif response['EdgePackagingJobStatus'] == 'Failed':
        raise RuntimeError('Packaging job failed')
    print('Packaging model...')
    time.sleep(30)
print('Done!')
```

For a list of packaging jobs, use `ListEdgePackagingJobs`. You can use this API to search for a specific packaging job. Provide a partial name to filter packaging job names for `NameContains`, a partial name for `ModelNameContains` to filter for jobs in which the model name contains the name you provide. Also specify with which column to sort with `SortBy`, and by which direction to sort for `SortOrder` (either `Ascending` or `Descending`).

```
sagemaker_client.list_edge_packaging_jobs(
    "NameContains": "sample",
    "ModelNameContains": "sample",
    "SortBy": "column-name",
    "SortOrder": "Descending"
)
```

To stop a packaging job, use `StopEdgePackagingJob` and provide the name of your edge packaging job.

```
sagemaker_client.stop_edge_packaging_job(
        EdgePackagingJobName="edge-packaging-name"
)
```

For a full list of Edge Manager APIs, see the Boto3 documentation.

The Edge Manager Agent

The Edge Manager agent is an inference engine for your edge devices. Use the agent to make predictions with models loaded onto your edge devices. The agent also collects model metrics and captures data at specific intervals. Sample data is stored in your Amazon S3 bucket.

There are two methods of installing and deploying the Edge Manager agent onto your edge devices:

1. Download the agent as a binary from the Amazon S3 release bucket. For more information, see Download and Set Up the Edge Manager Agent Manually.
2. Use the Amazon IoT Greengrass V2 console or the Amazon CLI to deploy `aws.greengrass.SageMakerEdgeManager`. See Create the Amazon IoT Greengrass V2 Components.

Download and Set Up the Edge Manager Agent Manually

Download the Edge Manager agent based on your operating system, architecture, and Amazon Region. The agent is periodically updated, so you have the option to choose your agent based on release dates and versions. Once you have the agent, create a JSON configuration file. Specify the device IoT thing name, fleet name, device credentials, and other key-value pairs. See Running the Edge Manager agent for full a list of keys you must specify in the configuration file. You can run the agent as an executable binary or link against it as a dynamic shared object (DSO).

How the agent works

The agent runs on the CPU of your devices. The agent runs inference on the framework and hardware of the target device you specified during the compilation job. For example, if you compiled your model for the Jetson Nano, the agent supports the GPU in the provided Deep Learning Runtime (DLR).

The agent is released in binary format for supported operating systems. Check that your operating system is supported and meets the minimum OS requirement in the following table:

Linux

Version: Ubuntu 18.04

Supported Binary Formats: x86-64 bit (ELF binary) and ARMv8 64 bit (ELF binary)

Windows

Version: Windows 10 version 1909

Supported Binary Formats: x86-32 bit (DLL) and x86-64 bit (DLL)

Installing the Edge Manager agent

To use the Edge Manager agent, you first must obtain the release artifacts and a root certificate. The release artifacts are stored in an Amazon S3 bucket in the `us-west-2` Region. To download the artifacts, specify your operating system (`<OS>`) and the `<VERSION>`.

Based on your operating system, replace `<OS>` with one of the following:

Windows 32-bit	Windows 64-bit	Linux x86-64	Linux ARMv8
windows-x86	windows-x64	linux-x64	linux-armv8

The `VERSION` is broken into three components: `<MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>`, where:

- `<MAJOR_VERSION>`: The release version. The release version is currently set to 1.
- `<YYYY-MM-DD>`: The time stamp of the artifacts release.
- `<SHA-7>`: The repository commit ID from which the release is built.

You must provide the `<MAJOR_VERSION>` and the time stamp in `YYYY-MM-DD` format. We suggest you use the latest artifact release time stamp.

Run the following in your command line to get the latest time stamp. Replace `<OS>` with your operating system:

```
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-<OS>/Releases/ | sort -r
```

For example, if you have a Windows 32-bit OS, run:

```
aws s3 ls s3://sagemaker-edge-release-store-us-west-2-windows-x86/Releases/ | sort -r
```

This returns:

```
2020-12-01 23:33:36 0

                   PRE 1.20201218.81f481f/
                   PRE 1.20201207.02d0e97/
```

The return output in this example shows two release artifacts. The first release artifact file notes that the release version has a major release version of 1, a time stamp of 20201218 (in YYYY-MM-DD format), and a 81f481f SHA-7 commit ID.

> **Note**
>
> The preceding command assumes you have configured the Amazon Command Line Interface. For more information, about how to configure the settings that the Amazon CLI uses to interact with Amazon, see Configuring the Amazon CLI.

Based on your operating system, use the following commands to install the artifacts:

Windows 32-bit

```
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x86/
Releases/<VERSION>/<VERSION>.zip .
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x86/
Releases/<VERSION>/sha256_hex.shasum .
```

Windows 64-bit

```
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x64/
Releases/<VERSION>/<VERSION>.zip .
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-windows-x64/
Releases/<VERSION>/sha256_hex.shasum .
```

Linux x86-64

```
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/
Releases/<VERSION>/<VERSION>.tgz .
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-x64/Releases/<VERSION>/
sha256_hex.shasum .
```

Linux ARMv8

```
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-armv8/
Releases/<VERSION>/<VERSION>.tgz .
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-linux-armv8/
Releases/<VERSION>/sha256_hex.shasum .
```

You also must download a root certificate. This certificate validates model artifacts signed by Amazon before loading them onto your edge devices.

Replace <OS> corresponding to your platform from the list of supported operation systems and replace <REGION> with your Amazon Region.

```
aws s3 cp s3://sagemaker-edge-release-store-us-west-2-<OS>/
Certificates/<REGION>/<REGION>.pem .
```

Running the Edge Manager agent

You can run the SageMaker AI Edge Manager agent as a standalone process in the form of an Executable and Linkable Format (ELF) executable binary or you can link against it as a dynamic shared object (.dll). Linux supports running it as a standalone executable binary and is the preferred mode. Windows supports running it as a shared object (.dll).

On Linux, we recommend that you run the binary via a service that's a part of your initialization (`init`) system. If you want to run the binary directly, you can do so in a terminal as shown in the following example. If you have a modern OS, there are no other installations necessary prior to running the agent, since all the requirements are statically built into the executable. This gives you flexibility to run the agent on the terminal, as a service, or within a container.

To run the agent, first create a JSON configuration file. Specify the following key-value pairs:

- `sagemaker_edge_core_device_name`: The name of the device. This device name needs to be registered along with the device fleet in the SageMaker Edge Manager console.
- `sagemaker_edge_core_device_fleet_name`: The name of the fleet to which the device belongs.
- `sagemaker_edge_core_region`: The Amazon Region associated with the device, the fleet and the Amazon S3 buckets. This corresponds to the Region where the device is registered and where the Amazon S3 bucket is created (they are expected to be the same). The models themselves can

be compiled with SageMaker Neo in a different Region, this configuration is not related to model compilation Region.

- `sagemaker_edge_core_root_certs_path`: The absolute folder path to root certificates. This is used to validate the device with the relevant Amazon account.
- `sagemaker_edge_provider_aws_ca_cert_file`: The absolute path to Amazon Root CA certificate (AmazonRootCA1.pem). This is used to validate the device with the relevant Amazon account. `AmazonCA` is a certificate owned by Amazon.
- `sagemaker_edge_provider_aws_cert_file`: The absolute path to Amazon IoT signing root certificate (`*.pem.crt`).
- `sagemaker_edge_provider_aws_cert_pk_file`: The absolute path to Amazon IoT private key. (`*.pem.key`).
- `sagemaker_edge_provider_aws_iot_cred_endpoint`: The Amazon IoT credentials endpoint (*`identifier`*.iot.*`region`*.amazonaws.com). This endpoint is used for credential validation. See Connecting devices to Amazon IoT for more information.
- `sagemaker_edge_provider_provider`: This indicates the implementation of the provider interface being used. The provider interface communicates with the end network services for uploads, heartbeats and registration validation. By default this is set to `"Aws"`. We allow custom implementations of the provider interface. It can be set to `None` for no provider or `Custom` for custom implementation with the relevant shared object path provided.
- `sagemaker_edge_provider_provider_path`: Provides the absolute path to the provider implementation shared object. (.so or .dll file). The `"Aws"` provider .dll or .so file is provided with the agent release. This field is mandatory.
- `sagemaker_edge_provider_s3_bucket_name`: The name of your Amazon S3 bucket (not the Amazon S3 bucket URI). The bucket must have a `sagemaker` string within its name.
- `sagemaker_edge_log_verbose` (Boolean.): Optional. This sets the debug log. Select either `True` or `False`.
- `sagemaker_edge_telemetry_libsystemd_path`: For Linux only, `systemd` implements the agent crash counter metric. Set the absolute path of libsystemd to turn on the crash counter metric. You can find the default libsystemd path can be found by running `whereis libsystemd` in the device terminal.
- `sagemaker_edge_core_capture_data_destination`: The destination for uploading capture data. Choose either `"Cloud"` or `"Disk"`. The default is set to `"Disk"`. Setting it to `"Disk"` writes the input and output tensor(s) and auxiliary data to the local file system at your

preferred location of. When writing to `"Cloud"` use the Amazon S3 bucket name provided in the `sagemaker_edge_provider_s3_bucket_name` configuration.

- `sagemaker_edge_core_capture_data_disk_path`: Set the absolute path in the local file system, into which capture data files are written when `"Disk"` is the destination. This field is not used when `"Cloud"` is specified as the destination.
- `sagemaker_edge_core_folder_prefix`: The parent prefix in Amazon S3 where captured data is stored when you specify `"Cloud"` as the capture data destination (`sagemaker_edge_core_capture_data_disk_path`). Captured data is stored in a sub-folder under `sagemaker_edge_core_capture_data_disk_path` if `"Disk"` is set as the data destination.
- `sagemaker_edge_core_capture_data_buffer_size` (Integer value) : The capture data circular buffer size. It indicates the maximum number of requests stored in the buffer.
- `sagemaker_edge_core_capture_data_batch_size` (Integer value): The capture data batch size. It indicates the size of a batch of requests that are handled from the buffer. This value must to be less than `sagemaker_edge_core_capture_data_buffer_size`. A maximum of half the size of the buffer is recommended for batch size.
- `sagemaker_edge_core_capture_data_push_period_seconds` (Integer value): The capture data push period in seconds. A batch of requests in the buffer is handled when there are batch size requests in the buffer, or when this time period has completed (whichever comes first). This configuration sets that time period.
- `sagemaker_edge_core_capture_data_base64_embed_limit`: The limit for uploading capture data in bytes. Integer value.

Your configuration file should look similar to the following example(with your specific values specified). This example uses the default Amazon provider(`"Aws"`) and does not specify a periodic upload.

```
{
    "sagemaker_edge_core_device_name": "device-name",
    "sagemaker_edge_core_device_fleet_name": "fleet-name",
    "sagemaker_edge_core_region": "region",
    "sagemaker_edge_core_root_certs_path": "<Absolute path to root certificates>",
    "sagemaker_edge_provider_provider": "Aws",
    "sagemaker_edge_provider_provider_path" : "/path/to/libprovider_aws.so",
    "sagemaker_edge_provider_aws_ca_cert_file": "<Absolute path to Amazon Root CA
 certificate>/AmazonRootCA1.pem",
```

```
    "sagemaker_edge_provider_aws_cert_file": "<Absolute path to Amazon IoT signing root
 certificate>/device.pem.crt",
    "sagemaker_edge_provider_aws_cert_pk_file": "<Absolute path to Amazon IoT private
 key.>/private.pem.key",
    "sagemaker_edge_provider_aws_iot_cred_endpoint": "https://<Amazon IoT Endpoint
 Address>",
    "sagemaker_edge_core_capture_data_destination": "Cloud",
    "sagemaker_edge_provider_s3_bucket_name": "sagemaker-bucket-name",
    "sagemaker_edge_core_folder_prefix": "Amazon S3 folder prefix",
    "sagemaker_edge_core_capture_data_buffer_size": 30,
    "sagemaker_edge_core_capture_data_batch_size": 10,
    "sagemaker_edge_core_capture_data_push_period_seconds": 4000,
    "sagemaker_edge_core_capture_data_base64_embed_limit": 2,
    "sagemaker_edge_log_verbose": false
}
```

The release artifact includes a binary executable called `sagemaker_edge_agent_binary` in the `/bin` directory. To run the binary, use the `-a` flag to create a socket file descriptor (.sock) in a directory of your choosing and specify the path of the agent JSON config file you created with the `-c` flag.

```
./sagemaker_edge_agent_binary -a <ADDRESS_TO_SOCKET> -c <PATH_TO_CONFIG_FILE>
```

The following example shows the code snippet with a directory and file path specified:

```
./sagemaker_edge_agent_binary -a /tmp/sagemaker_edge_agent_example.sock -c
 sagemaker_edge_config.json
```

In this example, a socket file descriptor named `sagemaker_edge_agent_example.sock` is created in the `/tmp` directory and points to a configuration file that is in the same working directory as the agent called `sagemaker_edge_config.json`.

Model Package and Edge Manager Agent Deployment with Amazon IoT Greengrass

SageMaker Edge Manager integrates Amazon IoT Greengrass version 2 to simplify accessing, maintaining, and deploying the Edge Manager agent and model to your devices. Without Amazon IoT Greengrass V2, setting up your devices and fleets to use SageMaker Edge Manager requires you to manually copy the Edge Manager agent from an Amazon S3 release bucket. You use the agent

to make predictions with models loaded onto your edge devices. With Amazon IoT Greengrass V2 and SageMaker Edge Manager integration, you can use Amazon IoT Greengrass V2 components. Components are pre-built software modules that can connect your edge devices to Amazon services or third-party service via Amazon IoT Greengrass.

You must install the Amazon IoT Greengrass Core software onto your device(s) if you want to use Amazon IoT Greengrass V2 to deploy the Edge Manager agent and your model. For more information about device requirements and how to set up your devices, see Setting up Amazon IoT Greengrass core devices in the Amazon IoT Greengrass documentation.

You use the following three components to deploy the Edge Manager agent:

- *A pre-built public component*: SageMaker AI maintains the public Edge Manager component.
- *A autogenerated private component*: The private component is autogenerated when you package your machine learning model with the `CreateEdgePackagingJob` API and specify `GreengrassV2Component` for the Edge Manager API field `PresetDeploymentType`.
- *A custom component*: This is the inference application that is responsible for preprocessing and making inferences on your device. You must create this component. See either Create a Hello World custom component in the SageMaker Edge Manager documentation or Create custom Amazon IoT Greengrass components in the Amazon IoT Greengrass documentation for more information on how to create custom components.

Complete prerequisites to deploy the Edge Manager agent

SageMaker Edge Manager uses Amazon IoT Greengrass V2 to simplify the deployment of the Edge Manager agent, your machine learning models, and your inference application to your devices with the use of components. To make it easier to maintain your Amazon IAM roles, Edge Manager allows you to reuse your existing Amazon IoT role alias. If you do not have one yet, Edge Manager generates a role alias as part of the Edge Manager packaging job. You no longer need to associate a role alias generated from the SageMaker Edge Manager packaging job with your Amazon IoT role.

Before you start, you must complete the following prerequisites:

1. Install the Amazon IoT Greengrass Core software. For detailed information, see Install the Amazon IoT Greengrass Core software.
2. Set up Amazon IoT Greengrass V2. For more information, see Install Amazon IoT Greengrass Core software with manual resource provisioning.

> **Note**
>
> - Make sure the Amazon IoT thing name is all lowercase and does not contain characters except (optionally) dashes (-).
> - The IAM Role must start with `SageMaker*`

3. Attach the following permission and inline policy to the IAM role created during Amazon IoT Greengrass V2 setup.
   - Navigate to the IAM console https://console.amazonaws.cn/iam/.
   - Search for the role you created by typing in rhe role name in the **Search** field.
   - Choose your role.
   - Next, choose **Attach policies**.
   - Search for **AmazonSageMakerEdgeDeviceFleetPolicy**.
   - Select **AmazonSageMakerFullAccess** (This is an optional step that makes it easier for you to reuse this IAM role in model compilation and packaging).
   - Add required permissions to a role's permissions policy, don't attach inline policies to IAM users.

     JSON

     ```
     {
         "Version":"2012-10-17",
         "Statement":[
           {
             "Sid":"GreengrassComponentAccess",
             "Effect":"Allow",
             "Action":[
                 "greengrass:CreateComponentVersion",
                 "greengrass:DescribeComponent"
             ],
             "Resource":"*"
            }
         ]
     }
     ```

   - Choose **Attach policy**.
   - Choose **Trust relationship**.

- Choose **Edit trust relationship**.
- Replace the content with the following.

  JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "credentials.iot.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    },
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

4. Create an Edge Manager device fleet. For information on how to create a fleet, see Setup for Devices and Fleets in SageMaker Edge Manager.
5. Register your device with the same name as your Amazon IoT thing name created during the Amazon IoT Greengrass V2 setup.
6. Create at least one custom private Amazon IoT Greengrass component. This component is the application that runs inference on the device. For more information, see Create a Hello World custom component

Note

- The SageMaker Edge Manager and Amazon IoT Greengrass integration only works for Amazon IoT Greengrass v2.
- Both your Amazon IoT thing name and Edge Manager device name must be the same.

- SageMaker Edge Manager does not load local Amazon IoT certificates and call the Amazon IoT credential provider endpoint directly. Instead, SageMaker Edge Manager uses the Amazon IoT Greengrass v2 TokenExchangeService and it fetches a temporary credential from a TES endpoint.

Create the Amazon IoT Greengrass V2 Components

Amazon IoT Greengrass uses *components*, a software module that is deployed to and runs on a Amazon IoT Greengrass core device. You need (at a minimum) three components:

1. *A public Edge Manager Agent Amazon IoT Greengrass component* which deploys the Edge Manager agentbinary.
2. *A model component* that is autogenerated when you package your machine learning model with either the Amazon SDK for Python (Boto3) API or with the SageMaker AI console. For information, see Create an autogenerated component.
3. *A private, custom component* to implement the Edge Manager agent client application, and do any preprocessing and post-processing of the inference results. For more information about how to create a custom component, see Create an autogenerated component or Create custom Amazon IoT Greengrass components.

Create an autogenerated component

Generate the model component with the `CreateEdgePackagingJob` API and specify `GreengrassV2Component` for the SageMaker Edge Manager packaging job API field `PresetDeploymentType`. When you call the `CreateEdgePackagingJob` API, Edge Manager takes your SageMaker AI Neo–compiled model in Amazon S3 and creates a model component. The model component is automatically stored in your account. You can view any of your components by navigating to the Amazon IoT console https://console.amazonaws.cn/iot/. Select **Greengrass** and then select **Core** devices. The page has a list of Amazon IoT Greengrass core devices associated with your account. If a model component name is not specified in `PresetDeploymentConfig`, the default name generated consists of `"SagemakerEdgeManager"` and the name of your Edge Manager agent packaging job. The following example demonstrates how to specify to Edge Manager to create a Amazon IoT Greengrass V2 component with the `CreateEdgePackagingJob` API.

```
import sagemaker
```

```
import boto3

# Create a SageMaker client object to make it easier to interact with other AWS
 services.
sagemaker_client = boto3.client('sagemaker', region=<YOUR_REGION>)

# Replace with your IAM Role ARN
sagemaker_role_arn = "arn:aws:iam::<account>:role/*"

# Replace string with the name of your already created S3 bucket.
bucket = 'amzn-s3-demo-bucket-edge-manager'

# Specify a name for your edge packaging job.
edge_packaging_name = "edge_packag_job_demo"

# Replace the following string with the name you used for the SageMaker Neo compilation
 job.
compilation_job_name = "getting-started-demo"

# The name of the model and the model version.
model_name = "sample-model"
model_version = "1.1"

# Output directory in S3 where you want to store the packaged model.
packaging_output_dir = 'packaged_models'
packaging_s3_output = 's3://{}/{}'.format(bucket, packaging_output_dir)

# The name you want your Greengrass component to have.
component_name = "SagemakerEdgeManager" + edge_packaging_name

sagemaker_client.create_edge_packaging_job(
                    EdgePackagingJobName=edge_packaging_name,
                    CompilationJobName=compilation_job_name,
                    RoleArn=sagemaker_role_arn,
                    ModelName=model_name,
                    ModelVersion=model_version,
                    OutputConfig={
                        "S3OutputLocation": packaging_s3_output,
                        "PresetDeploymentType":"GreengrassV2Component",
                        "PresetDeploymentConfig":"{\"ComponentName\":\"sample-
component-name\", \"ComponentVersion\":\"1.0.2\"}"
                        }
                    )
```

You can also create the autogenerated component with the SageMaker AI console. Follow steps 1-6 in Package a Model (Amazon SageMaker AI Console)

Enter the Amazon S3 bucket URI where you want to store the output of the packaging job and optional encrytion key.

Complete the following to create the model component:

1. Choose **Preset deployment**.
2. Specify the name of the component for the **Component name** field.
3. Optionally, provide a description of the component, a component version, the platform OS, or the platform architecture for the **Component description**, **Component version**, **Platform OS**, and **Platform architecture**, respectively.
4. Choose **Submit**.

Create a Hello World custom component

The custom application component is used to perform inference on the edge device. The component is responsible for loading models to SageMaker Edge Manager, invoking the Edge Manager agent for inference, and unloading the model when the component is shut down. Before you create your component, ensure the agent and application can communicate with Edge Manager. To do this, configure gRPC. The Edge Manager agent uses methods defined in Protobuf Buffers and the gRPC server to establish communication with the client application on the edge device and the cloud.

To use gRPC, you must:

1. Create a gRPC stub using the .proto file provided when you download the Edge Manager agent from Amazon S3 release bucket.
2. Write client code with the language you prefer.

You do not need to define the service in a .proto file. The service .proto files are included in the compressed TAR file when you download the Edge Manager agent release binary from the Amazon S3 release bucket.

Install gRPC and other necessary tools on your host machine and create the gRPC stubs `agent_pb2_grpc.py` and `agent_pb2.py` in Python. Make sure you have `agent.proto` in your local directory.

```
%%bash
pip install grpcio
pip install grpcio-tools
python3 -m grpc_tools.protoc --proto_path=. --python_out=. --grpc_python_out=.
 agent.proto
```

The preceding code generates the gRPC client and server interfaces from your .proto service definition. In other words, it creates the gRPC model in Python. The API directory contains the Protobuf specification for communicating with the agent.

Next, use the gRPC API to write a client and server for your service (2). The following example script, `edge_manager_python_example.py`, uses Python to load, list, and unload a `yolov3` model to the edge device.

```
import grpc
from PIL import Image
import agent_pb2
import agent_pb2_grpc
import os

model_path = '<PATH-TO-SagemakerEdgeManager-COMPONENT>'

agent_socket = 'unix:///tmp/aws.greengrass.SageMakerEdgeManager.sock'

agent_channel = grpc.insecure_channel(agent_socket, options=(('grpc.enable_http_proxy',
 0),))

agent_client = agent_pb2_grpc.AgentStub(agent_channel)

def list_models():
    return agent_client.ListModels(agent_pb2.ListModelsRequest())

def list_model_tensors(models):
    return {
        model.name: {
            'inputs': model.input_tensor_metadatas,
            'outputs': model.output_tensor_metadatas
        }
        for model in list_models().models
```

```
    }

def load_model(model_name, model_path):
    load_request = agent_pb2.LoadModelRequest()
    load_request.url = model_path
    load_request.name = model_name
    return agent_client.LoadModel(load_request)

def unload_model(name):
    unload_request = agent_pb2.UnLoadModelRequest()
    unload_request.name = name
    return agent_client.UnLoadModel(unload_request)

def predict_image(model_name, image_path):
    image_tensor = agent_pb2.Tensor()
    image_tensor.byte_data = Image.open(image_path).tobytes()
    image_tensor_metadata = list_model_tensors(list_models())[model_name]['inputs'][0]
    image_tensor.tensor_metadata.name = image_tensor_metadata.name
    image_tensor.tensor_metadata.data_type = image_tensor_metadata.data_type
    for shape in image_tensor_metadata.shape:
        image_tensor.tensor_metadata.shape.append(shape)
    predict_request = agent_pb2.PredictRequest()
    predict_request.name = model_name
    predict_request.tensors.append(image_tensor)
    predict_response = agent_client.Predict(predict_request)
    return predict_response

def main():
    try:
        unload_model('your-model')
    except:
        pass

    print('LoadModel...', end='')
    try:
        load_model('your-model', model_path)
        print('done.')
    except Exception as e:
        print()
        print(e)
        print('Model already loaded!')
```

```
    print('ListModels...', end='')
    try:
        print(list_models())
        print('done.')

    except Exception as e:
        print()
        print(e)
        print('List model failed!')

    print('Unload model...', end='')
    try:
        unload_model('your-model')
        print('done.')
    except Exception as e:
        print()
        print(e)
        print('unload model failed!')

if __name__ == '__main__':
    main()
```

Ensure `model_path` points to the name of the Amazon IoT Greengrass component containing the model if you use the same client code example.

You can create your Amazon IoT Greengrass V2 Hello World component once you have generated your gRPC stubs and you have your Hello World code ready. To do so:

- Upload your `edge_manager_python_example.py`, `agent_pb2_grpc.py`, and `agent_pb2.py` to your Amazon S3 bucket and note down their Amazon S3 path.
- Create a private component in the Amazon IoT Greengrass V2 console and define the recipe for your component. Specify the Amazon S3 URI to your Hello World application and gRPC stub in the following recipe.

```
---
RecipeFormatVersion: 2020-01-25
ComponentName: com.sagemaker.edgePythonExample
ComponentVersion: 1.0.0
ComponentDescription: Sagemaker Edge Manager Python example
ComponentPublisher: Amazon Web Services, Inc.
ComponentDependencies:
```

```
  aws.greengrass.SageMakerEdgeManager:
    VersionRequirement: '>=1.0.0'
    DependencyType: HARD
Manifests:
  - Platform:
      os: linux
      architecture: "/amd64|x86/"
    Lifecycle:
      install: |-
        apt-get install python3-pip
        pip3 install grpcio
        pip3 install grpcio-tools
        pip3 install protobuf
        pip3 install Pillow
      run:
        script: |-
          python3 {artifacts:path}/edge_manager_python_example.py
    Artifacts:
      - URI: <code-s3-path>
      - URI: <pb2-s3-path>
      - URI: <pb2-grpc-s3-path>
```

For detailed information about creating a Hello World recipe, see Create your first component in the Amazon IoT Greengrass documentation.

Deploy the components to your device

Deploy your components with the Amazon IoT console or with the Amazon CLI.

To deploy your components (console)

Deploy your Amazon IoT Greengrass components with the Amazon IoT console.

1. In the Amazon IoT Greengrass console at https://console.amazonaws.cn/iot/ navigation menu, choose **Deployments**.
2. On the **Components** page, on the **Public components** tab, choose `aws.greengrass.SageMakerEdgeManager`.
3. On the `aws.greengrass.SageMakerEdgeManager` page, choose **Deploy**.
4. From `Add to deployment`, choose one of the following:
   a. To merge this component to an existing deployment on your target device, choose **Add to existing deployment**, and then select the deployment that you want to revise.

b. To create a new deployment on your target device, choose **Create new deployment**. If you have an existing deployment on your device, choosing this step replaces the existing deployment.

5. On the **Specify target** page, do the following:

   a. Under **Deployment information**, enter or modify the friendly name for your deployment.

   b. Under **Deployment targets**, select a target for your deployment, and choose **Next**. You cannot change the deployment target if you are revising an existing deployment.

6. On the **Select components** page, under **My components**, choose:

   - com.*<CUSTOM-COMPONENT-NAME>*
   - `aws.greengrass.SageMakerEdgeManager`
   - SagemakerEdgeManager.*<YOUR-PACKAGING-JOB>*

7. On the **Configure components** page, choose **com.greengrass.SageMakerEdgeManager**, and do the following.

   a. Choose **Configure component**.

   b. Under **Configuration update**, in **Configuration to merge**, enter the following configuration.

```
{
    "DeviceFleetName": "device-fleet-name",
    "BucketName": "bucket-name"
}
```

   Replace *device-fleet-name* with the name of the edge device fleet that you created, and replace *bucket-name* with the name of the Amazon S3 bucket that is associated with your device fleet.

   c. Choose **Confirm**, and then choose **Next**.

8. On the **Configure advanced settings** page, keep the default configuration settings, and choose **Next**.

9. On the **Review** page, choose **Deploy**.

To deploy your components (Amazon CLI)

1. Create a `deployment.json` file to define the deployment configuration for your SageMaker Edge Manager components. This file should look like the following example.

```
{
  "targetArn":"targetArn",
  "components": {
    "aws.greengrass.SageMakerEdgeManager": {
      "componentVersion": 1.0.0,
      "configurationUpdate": {
        "merge": {
          "DeviceFleetName": "device-fleet-name",
          "BucketName": "bucket-name"
        }
      }
    },
    "com.greengrass.SageMakerEdgeManager.ImageClassification": {
      "componentVersion": 1.0.0,
      "configurationUpdate": {
      }
    },
    "com.greengrass.SageMakerEdgeManager.ImageClassification.Model": {
      "componentVersion": 1.0.0,
      "configurationUpdate": {
      }
    },
  }
}
```

- In the `targetArn` field, replace *`targetArn`* with the Amazon Resource Name (ARN) of the thing or thing group to target for the deployment, in the following format:
  - Thing: `arn:aws:iot:`*`region`*`:`*`account-id`*`:thing/`*`thingName`*
  - Thing group: `arn:aws:iot:`*`region`*`:`*`account-id:`*`thinggroup/`*`thingGroupName`*
- In the `merge` field, replace *`device-fleet-name`* with the name of the edge device fleet that you created, and replace *`bucket-name`* with the name of the Amazon S3 bucket that is associated with your device fleet.
- Replace the component versions for each component with the latest available version.

2. Run the following command to deploy the components on the device:

```
aws greengrassv2 create-deployment \
    --cli-input-json file://path/to/deployment.json
```

The deployment can take several minutes to complete. In the next step, check the component log to verify that the deployment completed successfully and to view the inference results.

For more information about deploying components to individual devices or groups of devices, see Deploy Amazon IoT Greengrass components to devices.

Deploy the Model Package Directly with SageMaker Edge Manager Deployment API

SageMaker Edge Manager provides a deployment API that you can use to deploy models to device targets without Amazon IoT Greengrass. It is useful in situations where you want to update models independently of firmware updates or application deployment mechanisms. You can use the API to integrate your edge deployments into a CI/CD workflow to automatically deploy models once you have validated your model for accuracy. The API also has convenient rollback and staged rollout options for you to ensure models work well in a particular environment before wider rollout.

To use the Edge Manager deployment API first compile and package your model. For information on how to compile and package your model, see Prepare Your Model for Deployment. The following sections of this guide show how you can create edge deployments using SageMaker API, after you have compiled and packaged your models.

Topics

- Create an edge deployment plan
- Start the edge deployment
- Check the status of the deployment

Create an edge deployment plan

You can create an edge deployment plan with the `CreateEdgeDeploymentPlan` API. The deployment plan can have multiple stages. You can configure each stage to rollout the deployment to a subset of edge devices (by percentage, or by device name). You can also configure how rollout failures are handled at each stage.

The following code snippet shows how you can create an edge deployment plan with 1 stage to deploy a compiled and package model to 2 specific edge devices:

```
import boto3
```

```
client = boto3.client("sagemaker")

client.create_edge_deployment_plan(
    EdgeDeploymentPlanName="edge-deployment-plan-name",
    DeviceFleetName="device-fleet-name",
    ModelConfigs=[
        {
            "EdgePackagingJobName": "edge-packaging-job-name",
            "ModelHandle": "model-handle"
        }
    ],
    Stages=[
        {
            "StageName": "stage-name",
            "DeviceSelectionConfig": {
                "DeviceSubsetType": "SELECTION",
                "DeviceNames": ["device-name-1", "device-name-2"]
            },
            "DeploymentConfig": {
                "FailureHandlingPolicy": "ROLLBACK_ON_FAILURE"
            }
        }
    ]
)
```

Instead of specific devices, if you want to deploy to the model to a percentage of devices in your fleet, then set the value of `DeviceSubsetType` to `"PERCENTAGE"` and replace `"DeviceNames": ["device-name-1", "device-name-2"]` with `"Percentage": desired-percentage` in the above example.

Stages can be added after the deployment plan has been created with the CreateEdgeDeploymentStage API, in case you want to start rolling out new stages after validating your test rollout success. For more information about deployment stages see DeploymentStage.

Start the edge deployment

After creating the deployment plan and the deployment stages, you can start the deployment with the `StartEdgeDeploymentStage` API.

```
client.start_edge_deployment_stage(
```

```
    EdgeDeploymentPlanName="edge-deployment-plan-name",
    StageName="stage-name"
)
```

Check the status of the deployment

You can check the status of the edge deployment with the DescribeEdgeDeploymentPlan API.

```
client.describe_edge_deployment_plan(
    EdgeDeploymentPlanName="edge-deployment-plan-name"
)
```

Manage Model

The Edge Manager agent can load multiple models at a time and make inference with loaded models on edge devices. The number of models the agent can load is determined by the available memory on the device. The agent validates the model signature and loads into memory all the artifacts produced by the edge packaging job. This step requires all the required certificates described in previous steps to be installed along with rest of the binary installation. If the model's signature cannot be validated, then loading of the model fails with appropriate return code and reason.

SageMaker Edge Manager agent provides a list of Model Management APIs that implement control plane and data plane APIs on edge devices. Along with this documentation, we recommend going through the sample client implementation which shows canonical usage of the below described APIs.

The `proto` file is available as a part of the release artifacts (inside the release tarball). In this doc, we list and describe the usage of APIs listed in this `proto` file.

> **Note**
>
> There is one-to-one mapping for these APIs on Windows release and a sample code for an application implement in C# is shared with the release artifacts for Windows. Below instructions are for running the Agent as a standalone process, applicable for to the release artifacts for Linux.

Extract the archive based on your OS. Where `VERSION` is broken into three components: `<MAJOR_VERSION>.<YYYY-MM-DD>-<SHA-7>`. See Installing the Edge Manager agent for information on how to obtain the release version (`<MAJOR_VERSION>`), time stamp of the release artifact (`<YYYY-MM-DD>`), and the repository commit ID (`SHA-7`)

Linux

The zip archive can be extracted with the command:

```
tar -xvzf <VERSION>.tgz
```

Windows

The zip archive can be extracted with the UI or command:

```
unzip <VERSION>.tgz
```

The release artifact hierarchy (after extracting the `tar/zip` archive) is shown below. The agent `proto` file is available under `api/`.

```

Topics

- Load Model
- Unload Model
- List Models
- Describe Model
- Capture Data
- Get Capture Status
- Predict

Load Model

The Edge Manager agent supports loading multiple models. This API validates the model signature and loads into memory all the artifacts produced by the `EdgePackagingJob` operation. This step requires all the required certificates to be installed along with rest of the agent binary installation. If the model's signature cannot be validated then this step fails with appropriate return code and error messages in the log.

```
// perform load for a model
// Note:
// 1. currently only local filesystem paths are supported for loading models.
// 2. multiple models can be loaded at the same time, as limited by available device
 memory
// 3. users are required to unload any loaded model to load another model.
// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn't exist at the url
// 5. ALREADY_EXISTS - model with the same name is already loaded
// 6. RESOURCE_EXHAUSTED - memory is not available to load the model
// 7. FAILED_PRECONDITION - model is not compiled for the machine.
//
rpc LoadModel(LoadModelRequest) returns (LoadModelResponse);
```

Input

```
//
// request for LoadModel rpc call
```

```
//
message LoadModelRequest {
  string url = 1;
  string name = 2;  // Model name needs to match regex "^[a-zA-Z0-9](-*[a-zA-Z0-9])*
$"
}
```

Output

```
//
//
// response for LoadModel rpc call
//
message LoadModelResponse {
  Model model = 1;
}

//
// Model represents the metadata of a model
//  url - url representing the path of the model
//  name - name of model
//  input_tensor_metadatas - TensorMetadata array for the input tensors
//  output_tensor_metadatas - TensorMetadata array for the output tensors
//
// Note:
//  1. input and output tensor metadata could empty for dynamic models.
//
message Model {
  string url = 1;
  string name = 2;
  repeated TensorMetadata input_tensor_metadatas = 3;
  repeated TensorMetadata output_tensor_metadatas = 4;
}
```

Unload Model

Unloads a previously loaded model. It is identified via the model alias which was provided during `loadModel`. If the alias is not found or model is not loaded then returns error.

```
//
// perform unload for a model
// Status Codes:
```

```
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn't exist
//
rpc UnLoadModel(UnLoadModelRequest) returns (UnLoadModelResponse);
```

Input

```
//
// request for UnLoadModel rpc call
//
message UnLoadModelRequest {
 string name = 1; // Model name needs to match regex "^[a-zA-Z0-9](-*[a-zA-Z0-9])*$"
}
```

Output

```
//
// response for UnLoadModel rpc call
//
message UnLoadModelResponse {}
```

List Models

Lists all the loaded models and their aliases.

```
//
// lists the loaded models
// Status Codes:
// 1. OK - unload is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
//
rpc ListModels(ListModelsRequest) returns (ListModelsResponse);
```

Input

```
//
// request for ListModels rpc call
```

```
//
message ListModelsRequest {}
```

Output

```
//
// response for ListModels rpc call
//
message ListModelsResponse {
 repeated Model models = 1;
}
```

Describe Model

Describes a model that is loaded on the agent.

```
//
// Status Codes:
// 1. OK - load is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - model doesn't exist at the url
//
rpc DescribeModel(DescribeModelRequest) returns (DescribeModelResponse);
```

Input

```
//
// request for DescribeModel rpc call
//
message DescribeModelRequest {
  string name = 1;
}
```

Output

```
//
// response for DescribeModel rpc call
//
message DescribeModelResponse {
  Model model = 1;
```

```
}
```

Capture Data

Allows the client application to capture input and output tensors in Amazon S3 bucket, and optionally the auxiliary. The client application is expected to pass a unique capture ID along with each call to this API. This can be later used to query status of the capture.

```
//
// allows users to capture input and output tensors along with auxiliary data.
// Status Codes:
// 1. OK - data capture successfully initiated
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 5. ALREADY_EXISTS - capture initiated for the given capture_id
// 6. RESOURCE_EXHAUSTED - buffer is full cannot accept any more requests.
// 7. OUT_OF_RANGE - timestamp is in the future.
// 8. INVALID_ARGUMENT - capture_id is not of expected format.
//
rpc CaptureData(CaptureDataRequest) returns (CaptureDataResponse);
```

Input

```
enum Encoding {
 CSV = 0;
 JSON = 1;
 NONE = 2;
 BASE64 = 3;
}

//
// AuxilaryData represents a payload of extra data to be capture along with inputs
 and outputs of inference
// encoding - supports the encoding of the data
// data - represents the data of shared memory, this could be passed in two ways:
// a. send across the raw bytes of the multi-dimensional tensor array
// b. send a SharedMemoryHandle which contains the posix shared memory segment id
 and
// offset in bytes to location of multi-dimensional tensor array.
//
message AuxilaryData {
```

```
 string name = 1;
 Encoding encoding = 2;
 oneof data {
 bytes byte_data = 3;
 SharedMemoryHandle shared_memory_handle = 4;
 }
}

//
// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
// tensor_metadata - represents metadata of the shared memory segment
// data_or_handle - represents the data of shared memory, this could be passed in
 two ways:
// a. send across the raw bytes of the multi-dimensional tensor array
// b. send a SharedMemoryHandle which contains the posix shared memory segment
// id and offset in bytes to location of multi-dimensional tensor array.
//
message Tensor {
 TensorMetadata tensor_metadata = 1; //optional in the predict request
 oneof data {
 bytes byte_data = 4;
 // will only be used for input tensors
 SharedMemoryHandle shared_memory_handle = 5;
 }
}

//
// request for CaptureData rpc call
//
message CaptureDataRequest {
 string model_name = 1;
 string capture_id = 2; //uuid string
 Timestamp inference_timestamp = 3;
 repeated Tensor input_tensors = 4;
 repeated Tensor output_tensors = 5;
 repeated AuxilaryData inputs = 6;
 repeated AuxilaryData outputs = 7;
}
```

Output

```
//
// response for CaptureData rpc call
```

```
//
message CaptureDataResponse {}
```

Get Capture Status

Depending on the models loaded the input and output tensors can be large (for many edge devices). Capture to the cloud can be time consuming. So the `CaptureData()` is implemented as an asynchronous operation. A capture ID is a unique identifier that the client provides during capture data call, this ID can be used to query the status of the asynchronous call.

```
//
// allows users to query status of capture data operation
// Status Codes:
// 1. OK - data capture successfully initiated
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - given capture id doesn't exist.
//
rpc GetCaptureDataStatus(GetCaptureDataStatusRequest) returns
 (GetCaptureDataStatusResponse);
```

Input

```
//
// request for GetCaptureDataStatus rpc call
//
message GetCaptureDataStatusRequest {
  string capture_id = 1;
}
```

Output

```
enum CaptureDataStatus {
  FAILURE = 0;
  SUCCESS = 1;
  IN_PROGRESS = 2;
  NOT_FOUND = 3;
}

//
// response for GetCaptureDataStatus rpc call
```

```
//
message GetCaptureDataStatusResponse {
  CaptureDataStatus status = 1;
}
```

Predict

The `predict` API performs inference on a previously loaded model. It accepts a request in the form of a tensor that is directly fed into the neural network. The output is the output tensor (or scalar) from the model. This is a blocking call.

```
//
// perform inference on a model.
//
// Note:
// 1. users can chose to send the tensor data in the protobuf message or
// through a shared memory segment on a per tensor basis, the Predict
// method with handle the decode transparently.
// 2. serializing large tensors into the protobuf message can be quite expensive,
// based on our measurements it is recommended to use shared memory of
// tenors larger than 256KB.
// 3. SMEdge IPC server will not use shared memory for returning output tensors,
// i.e., the output tensor data will always send in byte form encoded
// in the tensors of PredictResponse.
// 4. currently SMEdge IPC server cannot handle concurrent predict calls, all
// these call will be serialized under the hood. this shall be addressed
// in a later release.
// Status Codes:
// 1. OK - prediction is successful
// 2. UNKNOWN - unknown error has occurred
// 3. INTERNAL - an internal error has occurred
// 4. NOT_FOUND - when model not found
// 5. INVALID_ARGUMENT - when tenors types mismatch
//
rpc Predict(PredictRequest) returns (PredictResponse);
```

Input

```
// request for Predict rpc call
//
message PredictRequest {
```

```
string name = 1;
repeated Tensor tensors = 2;
}

//
// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
//    tensor_metadata - represents metadata of the shared memory segment
//    data_or_handle - represents the data of shared memory, this could be passed in
 two ways:
//                        a. send across the raw bytes of the multi-dimensional
 tensor array
//                        b. send a SharedMemoryHandle which contains the posix
 shared memory segment
//                            id and offset in bytes to location of multi-
dimensional tensor array.
//
message Tensor {
  TensorMetadata tensor_metadata = 1; //optional in the predict request
  oneof data {
    bytes byte_data = 4;
    // will only be used for input tensors
    SharedMemoryHandle shared_memory_handle = 5;
  }
}

//
// Tensor represents a tensor, encoded as contiguous multi-dimensional array.
//    tensor_metadata - represents metadata of the shared memory segment
//    data_or_handle - represents the data of shared memory, this could be passed in
 two ways:
//                        a. send across the raw bytes of the multi-dimensional
 tensor array
//                        b. send a SharedMemoryHandle which contains the posix
 shared memory segment
//                            id and offset in bytes to location of multi-
dimensional tensor array.
//
message Tensor {
  TensorMetadata tensor_metadata = 1; //optional in the predict request
  oneof data {
    bytes byte_data = 4;
    // will only be used for input tensors
    SharedMemoryHandle shared_memory_handle = 5;
  }
```

```
}

//
// TensorMetadata represents the metadata for a tensor
//    name - name of the tensor
//    data_type  - data type of the tensor
//    shape - array of dimensions of the tensor
//
message TensorMetadata {
  string name = 1;
  DataType data_type = 2;
  repeated int32 shape = 3;
}

//
// SharedMemoryHandle represents a posix shared memory segment
//    offset - offset in bytes from the start of the shared memory segment.
//    segment_id - shared memory segment id corresponding to the posix shared memory
 segment.
//    size - size in bytes of shared memory segment to use from the offset position.
//
message SharedMemoryHandle {
  uint64 size = 1;
  uint64 offset = 2;
  uint64 segment_id = 3;
}
```

Output

> **Note**
>
> The `PredictResponse` only returns `Tensors` and not `SharedMemoryHandle`.

```
// response for Predict rpc call
//
message PredictResponse {
   repeated Tensor tensors = 1;
}
```

SageMaker Edge Manager end of life

Starting in April 26, 2024, you can no longer access Amazon SageMaker Edge Manager through the Amazon management console, make edge packaging jobs, and manage edge device fleets.

FAQs

Use the following sections to get answers to commonly asked questions about the SageMaker Edge Manager end of life (EOL).

Q: What happens to my Amazon SageMaker Edge Manager after the EOL date?

A: After April 26, 2024, all references to edge packaging jobs, devices, and device fleets are deleted from the Edge Manager service. You can no longer discover or access the Edge Manager service from your Amazon console and applications that call on the Edge Manager service APIs no longer work.

Q: Will I be billed for Edge Manager resources remaining in my account after the EOL date?

A: Resources created by Edge Manager, such as edge packages inside Amazon S3 buckets, Amazon IoT things, and Amazon IAM roles, continue to exist on their respective services after April 26, 2024. To avoid being billed after Edge Manager is no longer supported, delete your resources. For more information on deleting your resources, see Delete Edge Manager resources.

Q: How do I delete my Amazon SageMaker Edge Manager resources?

A: Resources created by Edge Manager, such as edge packages inside Amazon S3 buckets, Amazon IoT things, and Amazon IAM roles, continue to exist on their respective services after April 26, 2024. To avoid being billed after Edge Manager is no longer supported, delete your resources. For more information on deleting your resources, see Delete Edge Manager resources.

Q: How can I continue deploying models on the edge?

A: We suggest you try one the following machine learning tools. For a cross-platform edge runtime, use ONNX. ONNX is a popular, well-maintained open-source solution that translates your models into instructions that many types of hardware can run, and is compatible with the latest ML frameworks. ONNX can be integrated into your SageMaker AI workflows as an automated step for your edge deployments.

For edge deployments and monitoring use Amazon IoT Greengrass V2. Amazon IoT Greengrass V2 has an extensible packaging and deployment mechanism that can fit models and applications

at the edge. You can use the built-in MQTT channels to send model telemetry back for Amazon SageMaker Model Monitor or use the built-in permissions system to send data captured from the model back to Amazon Simple Storage Service (Amazon S3). If you don't or can't use Amazon IoT Greengrass V2, we suggest using MQTT and IoT Jobs (C/C++ library) to create a lightweight OTA mechanism to deliver models.

We have prepared sample code available at this GitHub repository to help you transition to these suggested tools.

Delete Edge Manager resources

Resources created by Edge Manager continue to exist after April 26, 2024. To avoid billing, delete these resources.

To delete Amazon IoT Greengrass resources, do the following:

1. In the Amazon IoT Core console, choose **Greengrass devices** under **Manage**.
2. Choose **Components**.
3. Under **My components**, Edge Manager created components are in the format *SageMaker AIEdge (EdgePackagingJobName)*. Select the component you want to delete.
4. Then choose **Delete version**.

To delete a Amazon IoT role alias, do the following:

1. In the Amazon IoT Core console, choose **Security** under **Manage**.
2. Choose **Role aliases**.
3. Edge Manager created role aliases are in the format *SageMaker AIEdge-{DeviceFleetName}*. Select the role you want to delete.
4. Choose **Delete**.

To delete packaging jobs in Amazon S3 buckets, do the following:

1. In the SageMaker AI console, choose **Edge Inference**.
2. Choose **Edge packaging jobs**.
3. Select one of the edge packaging jobs. Copy the Amazon S3 URI under **Model artifact** in the **Output configuration** section.

4. In the Amazon S3 console, navigate to the corresponding location, and check if you need to delete the model artifact. To delete the model artifact, select the Amazon S3 object and choose **Delete**.

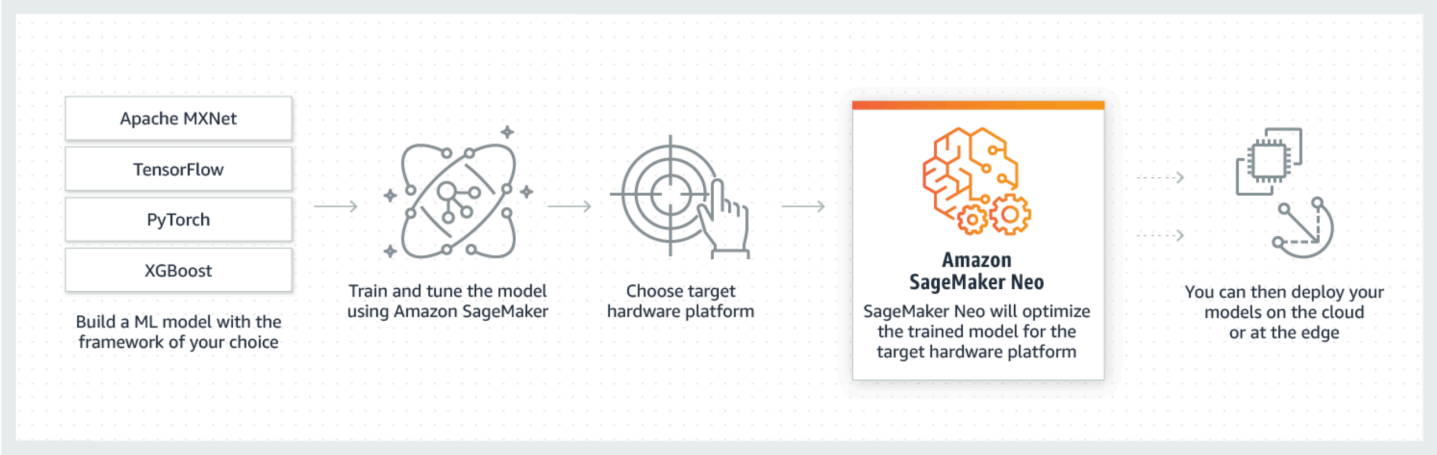
Model performance optimization with SageMaker Neo

Neo is a capability of Amazon SageMaker AI that enables machine learning models to train once and run anywhere in the cloud and at the edge.

If you are a first time user of SageMaker Neo, we recommend you check out the Getting Started with Edge Devices section to get step-by-step instructions on how to compile and deploy to an edge device.

What is SageMaker Neo?

Generally, optimizing machine learning models for inference on multiple platforms is difficult because you need to hand-tune models for the specific hardware and software configuration of each platform. If you want to get optimal performance for a given workload, you need to know the hardware architecture, instruction set, memory access patterns, and input data shapes, among other factors. For traditional software development, tools such as compilers and profilers simplify the process. For machine learning, most tools are specific to the framework or to the hardware. This forces you into a manual trial-and-error process that is unreliable and unproductive.



Neo automatically optimizes Gluon, Keras, MXNet, PyTorch, TensorFlow, TensorFlow-Lite, and ONNX models for inference on Android, Linux, and Windows machines based on processors from Ambarella, ARM, Intel, Nvidia, NXP, Qualcomm, Texas Instruments, and Xilinx. Neo is tested with computer vision models available in the model zoos across the frameworks. SageMaker Neo supports compilation and deployment for two main platforms: cloud instances (including Inferentia) and edge devices.

For more information about supported frameworks and cloud instance types you can deploy to, see Supported Instance Types and Frameworks for cloud instances.

For more information about supported frameworks, edge devices, operating systems, chip architectures, and common machine learning models tested by SageMaker AI Neo for edge devices, see Supported Frameworks, Devices, Systems, and Architectures for edge devices.

How it Works

Neo consists of a compiler and a runtime. First, the Neo compilation API reads models exported from various frameworks. It converts the framework-specific functions and operations into a framework-agnostic intermediate representation. Next, it performs a series of optimizations. Then it generates binary code for the optimized operations, writes them to a shared object library, and saves the model definition and parameters into separate files. Neo also provides a runtime for each target platform that loads and executes the compiled model.

You can create a Neo compilation job from either the SageMaker AI console, the Amazon Command Line Interface (Amazon CLI), a Python notebook, or the SageMaker AI SDK.For information on how to compile a model, see Model Compilation with Neo. With a few CLI commands, an API invocation, or a few clicks, you can convert a model for your chosen platform. You can deploy the model to a SageMaker AI endpoint or on an Amazon IoT Greengrass device quickly.

Neo can optimize models with parameters either in FP32 or quantized to INT8 or FP16 bit-width.

Model Compilation with Neo

This section shows how to create, describe, stop, and list compilation jobs. The following options are available in Amazon SageMaker Neo for managing the compilation jobs for machine learning

models: the Amazon Command Line Interface, the Amazon SageMaker AI console, or the Amazon SageMaker SDK.

Topics

- Prepare Model for Compilation
- Compile a Model (Amazon Command Line Interface)
- Compile a Model (Amazon SageMaker AI Console)
- Compile a Model (Amazon SageMaker AI SDK)

Prepare Model for Compilation

SageMaker Neo requires machine learning models to satisfy specific input data shapes. The input shape required for compilation depends on the deep learning framework you use. Once your model input shape is correctly formatted, save your model according to the requirements below. Once you have a saved model, compress the model artifacts.

Topics

- What input data shapes does SageMaker Neo expect?
- Saving Models for SageMaker Neo

What input data shapes does SageMaker Neo expect?

Before you compile your model, make sure your model is formatted correctly. Neo expects the name and shape of the expected data inputs for your trained model with JSON format or list format. The expected inputs are framework specific.

Below are the input shapes SageMaker Neo expects:

Keras

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Note that while Keras model artifacts should be uploaded in NHWC (channel-last) format, DataInputConfig should be specified in NCHW (channel-first) format. The dictionary formats required are as follows:

- For one input: `{'input_1':[1,3,224,224]}`
- For two inputs: `{'input_1': [1,3,224,224], 'input_2':[1,3,224,224]}`

MXNet/ONNX

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{'data':[1,3,1024,1024]}`
- For two inputs: `{'var1': [1,1,28,28], 'var2':[1,1,28,28]}`

PyTorch

For a PyTorch model, you don't need to provide the name and shape of the expected data inputs if you meet both of the following conditions:

- You created your model definition file by using PyTorch 2.0 or later. For more information about how to create the definition file, see the PyTorch section under *Saving Models for SageMaker Neo*.
- You are compiling your model for a cloud instance. For more information about the instance types that SageMaker Neo supports, see Supported Instance Types and Frameworks.

If you meet these conditions, SageMaker Neo gets the input configuration from the model definition file (.pt or .pth) that you create with PyTorch.

Otherwise, you must do the following:

Specify the name and shape (NCHW format) of the expected data inputs using a dictionary format for your trained model. Alternatively, you can specify the shape only using a list format. The dictionary formats required are as follows:

- For one input in dictionary format: `{'input0':[1,3,224,224]}`
- For one input in list format: `[[1,3,224,224]]`
- For two inputs in dictionary format: `{'input0':[1,3,224,224], 'input1':[1,3,224,224]}`
- For two inputs in list format: `[[1,3,224,224], [1,3,224,224]]`

TensorFlow

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{'input':[1,1024,1024,3]}`
- For two inputs: `{'data1': [1,28,28,1], 'data2':[1,28,28,1]}`

TFLite

Specify the name and shape (NHWC format) of the expected data inputs using a dictionary format for your trained model. The dictionary formats required are as follows:

- For one input: `{'input':[1,224,224,3]}`

> **Note**
>
> SageMaker Neo only supports TensorFlow Lite for edge device targets. For a list of supported SageMaker Neo edge device targets, see the SageMaker Neo Devices page. For a list of supported SageMaker Neo cloud instance targets, see the SageMaker Neo Supported Instance Types and Frameworks page.

XGBoost

An input data name and shape are not needed.

Saving Models for SageMaker Neo

The following code examples show how to save your model to make it compatible with Neo. Models must be packaged as compressed tar files (`*.tar.gz`).

Keras

Keras models require one model definition file (`.h5`).

There are two options for saving your Keras model in order to make it compatible for SageMaker Neo:

1. Export to `.h5` format with `model.save("<model-name>", save_format="h5")`.
2. Freeze the `SavedModel` after exporting.

Below is an example of how to export a `tf.keras` model as a frozen graph (option two):

```
import os
import tensorflow as tf
from tensorflow.keras.applications.resnet50 import ResNet50
from tensorflow.keras import backend

tf.keras.backend.set_learning_phase(0)
model = tf.keras.applications.ResNet50(weights='imagenet', include_top=False,
 input_shape=(224, 224, 3), pooling='avg')
model.summary()

# Save as a SavedModel
export_dir = 'saved_model/'
model.save(export_dir, save_format='tf')

# Freeze saved model
input_node_names = [inp.name.split(":")[0] for inp in model.inputs]
output_node_names = [output.name.split(":")[0] for output in model.outputs]
print("Input names: ", input_node_names)
with tf.Session() as sess:
    loaded = tf.saved_model.load(sess, export_dir=export_dir, tags=["serve"])
    frozen_graph = tf.graph_util.convert_variables_to_constants(sess,

 sess.graph.as_graph_def(),
                                                                 output_node_names)
    tf.io.write_graph(graph_or_graph_def=frozen_graph, logdir=".",
 name="frozen_graph.pb", as_text=False)

import tarfile
tar = tarfile.open("frozen_graph.tar.gz", "w:gz")
tar.add("frozen_graph.pb")
tar.close()
```

Warning

Do not export your model with the `SavedModel` class using `model.save(<path>, save_format='tf')`. This format is suitable for training, but it is not suitable for inference.

MXNet

MXNet models must be saved as a single symbol file `*-symbol.json` and a single parameter `*.params files`.

Gluon Models

Define the neural network using the `HybridSequential` Class. This will run the code in the style of symbolic programming (as opposed to imperative programming).

```
from mxnet import nd, sym
from mxnet.gluon import nn

def get_net():
    net = nn.HybridSequential()  # Here we use the class HybridSequential.
    net.add(nn.Dense(256, activation='relu'),
            nn.Dense(128, activation='relu'),
            nn.Dense(2))
    net.initialize()
    return net

# Define an input to compute a forward calculation.
x = nd.random.normal(shape=(1, 512))
net = get_net()

# During the forward calculation, the neural network will automatically infer
# the shape of the weight parameters of all the layers based on the shape of
# the input.
net(x)

# hybridize model
net.hybridize()
net(x)

# export model
net.export('<model_name>') # this will create model-symbol.json and
 model-0000.params files

import tarfile
tar = tarfile.open("<model_name>.tar.gz", "w:gz")
for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
    tar.add(name)
tar.close()
```

For more information about hybridizing models, see the MXNet hybridize documentation.

Gluon Model Zoo (GluonCV)

GluonCV model zoo models come pre-hybridized. So you can just export them.

```
import numpy as np
import mxnet as mx
import gluoncv as gcv
from gluoncv.utils import export_block
import tarfile

net = gcv.model_zoo.get_model('<model_name>', pretrained=True) # For example, choose
 <model_name> as resnet18_v1
export_block('<model_name>', net, preprocess=True, layout='HWC')

tar = tarfile.open("<model_name>.tar.gz", "w:gz")

for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
    tar.add(name)
tar.close()
```

Non Gluon Models

All non-Gluon models when saved to disk use `*-symbol` and `*.params` files. They are therefore already in the correct format for Neo.

```
# Pass the following 3 parameters: sym, args, aux
mx.model.save_checkpoint('<model_name>',0,sym,args,aux) # this will create
 <model_name>-symbol.json and <model_name>-0000.params files

import tarfile
tar = tarfile.open("<model_name>.tar.gz", "w:gz")

for name in ["<model_name>-0000.params", "<model_name>-symbol.json"]:
    tar.add(name)
tar.close()
```

PyTorch

PyTorch models must be saved as a definition file (`.pt` or `.pth`) with input datatype of `float32`.

To save your model, use the `torch.jit.trace` method followed by the `torch.save` method. This process saves an object to a disk file and by default uses python pickle (`pickle_module=pickle`) to save the objects and some metadata. Next, convert the saved model to a compressed tar file.

```
import torchvision
import torch

model = torchvision.models.resnet18(pretrained=True)
model.eval()
inp = torch.rand(1, 3, 224, 224)
model_trace = torch.jit.trace(model, inp)

# Save your model. The following code saves it with the .pth file extension
model_trace.save('model.pth')

# Save as a compressed tar file
import tarfile
with tarfile.open('model.tar.gz', 'w:gz') as f:
    f.add('model.pth')
f.close()
```

If you save your model with PyTorch 2.0 or later, SageMaker Neo derives the input configuration for the model (the name and shape for its input) from the definition file. In that case, you don't need to specify the data input configuration to SageMaker AI when you compile the model.

If you want to prevent SageMaker Neo from deriving the input configuration, you can set the `_store_inputs` parameter of `torch.jit.trace` to `False`. If you do this, you must specify the data input configuration to SageMaker AI when you compile the model.

For more information about the `torch.jit.trace` method, see TORCH.JIT.TRACE in the PyTorch documentation.

TensorFlow

TensorFlow requires one `.pb` or one `.pbtxt` file and a variables directory that contains variables. For frozen models, only one `.pb` or `.pbtxt` file is required.

The following code example shows how to use the tar Linux command to compress your model. Run the following in your terminal or in a Jupyter notebook (if you use a Jupyter notebook, insert the `!` magic command at the beginning of the statement):

```
# Download SSD_Mobilenet trained model
!wget http://download.tensorflow.org/models/object_detection/
ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# unzip the compressed tar file
!tar xvf ssd_mobilenet_v2_coco_2018_03_29.tar.gz

# Compress the tar file and save it in a directory called 'model.tar.gz'
!tar czvf model.tar.gz ssd_mobilenet_v2_coco_2018_03_29/frozen_inference_graph.pb
```

The command flags used in this example accomplish the following:

- c: Create an archive
- z: Compress the archive with gzip
- v: Display archive progress
- f: Specify the filename of the archive

Built-In Estimators

Built-in estimators are either made by framework-specific containers or algorithm-specific containers. Estimator objects for both the built-in algorithm and framework-specific estimator saves the model in the correct format for you when you train the model using the built-in `.fit` method.

For example, you can use a `sagemaker.TensorFlow` to define a TensorFlow estimator:

```
from sagemaker.train import ModelTrainer
from sagemaker.train.configs import Compute, SourceCode

model_trainer = ModelTrainer(
    training_image='insert appropriate TensorFlow training image URI',
    role=role,  #param role can be arn of a sagemaker execution role
    compute=Compute(instance_type='ml.c4.xlarge', instance_count=2),
    hyperparameters={
        'training_steps': '1000',
        'evaluation_steps': '100',
    },
    source_code=SourceCode(entry_script='mnist.py'),
)
```

Then train the model with the `.train` method:

```
model_trainer.train(inputs)
```

Before finally compiling model with the build in `compile_model` method:

```
# Neo compilation in V3 uses ModelBuilder.optimize() with compilation_config
from sagemaker.serve import ModelBuilder

# Specify output path of the compiled model
output_path = '/'.join(model_trainer.output_path.split('/')[:-1])

model_builder = ModelBuilder(
    model=model_trainer,
    role_arn=role,
    instance_type='ml.c5.xlarge',
)
optimized_model = model_builder.optimize(
    instance_type='ml.c5.xlarge',
    output_path=output_path,
    compilation_config={
        'OverrideEnvironment': {
            'OPTION_TARGET_INSTANCE_FAMILY': 'ml_c5',
            'OPTION_FRAMEWORK': 'tensorflow',
            'OPTION_FRAMEWORK_VERSION': '1.15.3',
        },
    },
)
```

You can also use the `sagemaker.estimator.Estimator` Class to initialize an estimator object for training and compiling a built-in algorithm with the `compile_model` method from the SageMaker Python SDK:

```
from sagemaker.core import image_uris
from sagemaker.core.helper.session_helper import Session
from sagemaker.train import ModelTrainer
from sagemaker.train.configs import Compute, InputData

sagemaker_session = Session()
aws_region = sagemaker_session.boto_region_name

# Specify built-in algorithm training image
```

```
training_image = image_uris.retrieve(framework='image-classification',
                          region=aws_region, image_scope='training')

# Create ModelTrainer object for training
model_trainer = ModelTrainer(training_image=training_image,
                                          role=role,  #param role can be arn of a
 sagemaker execution role
                                          compute=Compute(
                                              instance_count=1,
                                              instance_type='ml.p3.8xlarge',
                                              volume_size_in_gb=50,
                                          ),
                                          output_data_config={'s3_output_path':
 s3_training_output_location},
                                          base_job_name='image-classification-training'
                                          )

# Setup the input data_channels to be used later for training.

train_data = InputData(channel_name='train', data_source=s3_training_data_location)
validation_data = InputData(channel_name='validation',
 data_source=s3_validation_data_location)
data_channels = [train_data, validation_data]

# Train model
model_trainer.train(inputs=data_channels)

# Neo compilation in V3 uses ModelBuilder.optimize() with compilation_config
from sagemaker.serve import ModelBuilder

model_builder = ModelBuilder(
    model=model_trainer,
    role_arn=role,
    instance_type='ml.c5.xlarge',
)
optimized_model = model_builder.optimize(
    instance_type='ml.c5.xlarge',
    output_path=s3_compilation_output_location,
    compilation_config={
        'OverrideEnvironment': {
            'OPTION_TARGET_INSTANCE_FAMILY': 'ml_c5',
            'OPTION_FRAMEWORK': 'mxnet',
            'OPTION_FRAMEWORK_VERSION': '1.7',
        },
```

```
    },
)
```

For more information about compiling models with the SageMaker Python SDK, see Compile a Model (Amazon SageMaker AI SDK).

Compile a Model (Amazon Command Line Interface)

This section shows how to manage Amazon SageMaker Neo compilation jobs for machine learning models using Amazon Command Line Interface (CLI). You can create, describe, stop, and list the compilation jobs.

1. Create a Compilation Job

   With the CreateCompilationJob API operation, you can specify the data input format, the S3 bucket in which to store your model, the S3 bucket to which to write the compiled model, and the target hardware device or platform.

   The following table demonstrates how to configure `CreateCompilationJob` API based on whether your target is a device or a platform.

   Device Example

```
{
    "CompilationJobName": "neo-compilation-job-demo",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-
ExecutionRole-yyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/
train",
        "DataInputConfig":  "{'data': [1,3,1024,1024]}",
        "Framework": "MXNET"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-
demo-data/compile",
        # A target device specification example for a ml_c5 instance family
        "TargetDevice": "ml_c5"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
```

```
}
```

You can optionally specify the framework version you used with the `FrameworkVersion` field if you used the PyTorch framework to train your model and your target device is a `ml_*` target.

```
{
    "CompilationJobName": "neo-compilation-job-demo",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-
ExecutionRole-yyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/
train",
        "DataInputConfig":  "{'data': [1,3,1024,1024]}",
        "Framework": "PYTORCH",
        "FrameworkVersion": "1.6"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-
demo-data/compile",
        # A target device specification example for a ml_c5 instance family
        "TargetDevice": "ml_c5",
        # When compiling for ml_* instances using PyTorch framework, use the
 "CompilerOptions" field in
        # OutputConfig to provide the correct data type ("dtype") of the model's
 input. Default assumed is "float32"
        "CompilerOptions": "{'dtype': 'long'}"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

Notes:

- If you saved your model by using PyTorch version 2.0 or later, the `DataInputConfig` field is optional. SageMaker AI Neo gets the input configuration from the model definition file that you create with PyTorch. For more information about how to create the definition file, see the PyTorch section under *Saving Models for SageMaker AI Neo*.

- This API field is only supported for PyTorch.

Platform Example

```
{
    "CompilationJobName": "neo-test-compilation-job",
    "RoleArn": "arn:aws:iam::<your-account>:role/service-role/AmazonSageMaker-
ExecutionRole-yyyymmddThhmmss",
    "InputConfig": {
        "S3Uri": "s3://<your-bucket>/sagemaker/neo-compilation-job-demo-data/
train",
        "DataInputConfig":  "{'data': [1,3,1024,1024]}",
        "Framework": "MXNET"
    },
    "OutputConfig": {
        "S3OutputLocation": "s3://<your-bucket>/sagemaker/neo-compilation-job-
demo-data/compile",
        # A target platform configuration example for a p3.2xlarge instance
        "TargetPlatform": {
            "Os": "LINUX",
            "Arch": "X86_64",
            "Accelerator": "NVIDIA"
        },
        "CompilerOptions": "{'cuda-ver': '10.0', 'trt-ver': '6.0.1', 'gpu-code':
 'sm_70'}"
    },
    "StoppingCondition": {
        "MaxRuntimeInSeconds": 300
    }
}
```

Note

For the `OutputConfig` API operation, the `TargetDevice` and `TargetPlatform` API operations are mutually exclusive. You have to choose one of the two options.

To find the JSON string examples of `DataInputConfig` depending on frameworks, see What input data shapes Neo expects.

For more information about setting up the configurations, see the InputConfig, OutputConfig, and TargetPlatform API operations in the SageMaker API reference.

2. After you configure the JSON file, run the following command to create the compilation job:

```
aws sagemaker create-compilation-job \
--cli-input-json file://job.json \
--region us-west-2

# You should get CompilationJobArn
```

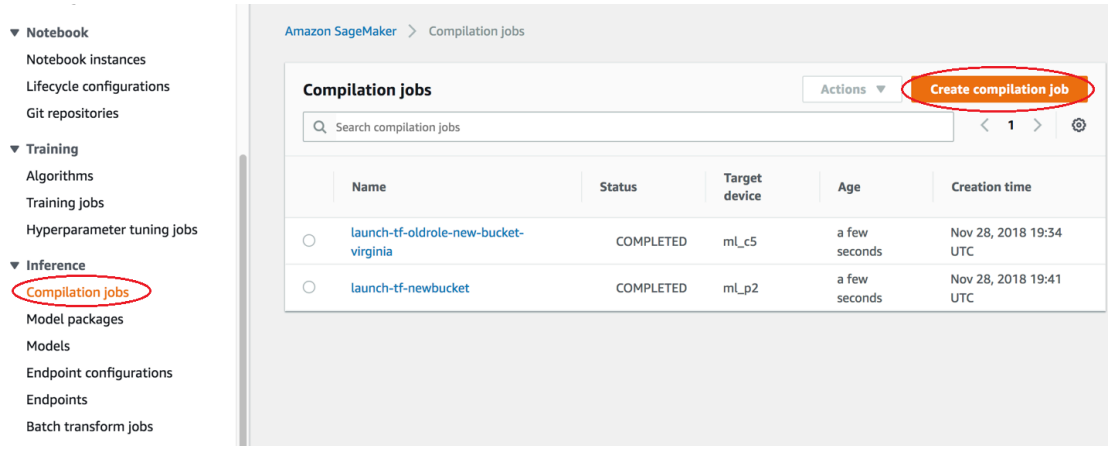
3. Describe the compilation job by running the following command:

```
aws sagemaker describe-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2
```

4. Stop the compilation job by running the following command:

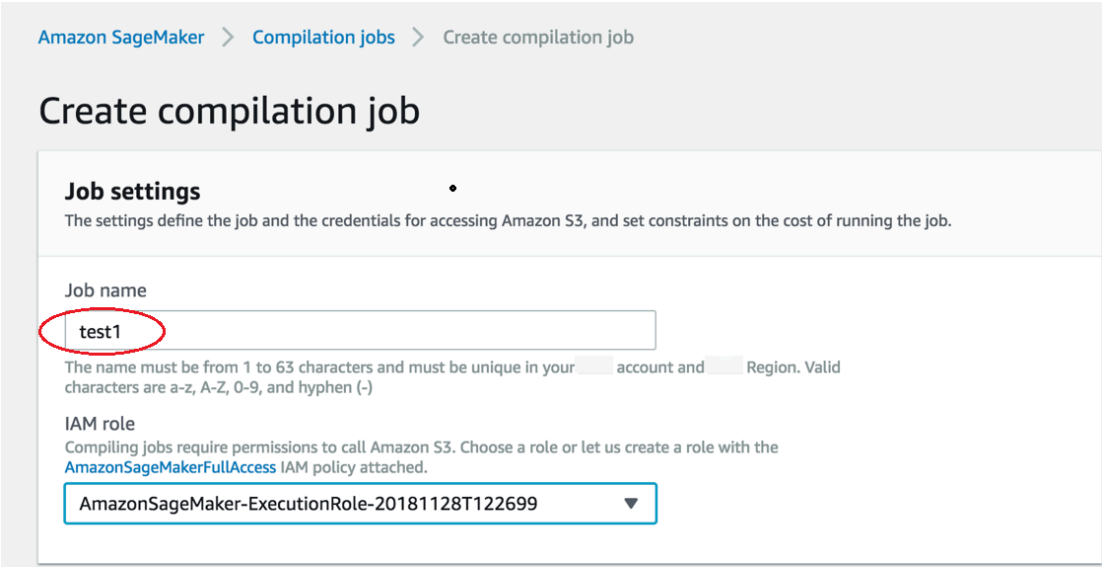
```
aws sagemaker stop-compilation-job \
--compilation-job-name $JOB_NM \
--region us-west-2

# There is no output for compilation-job operation
```



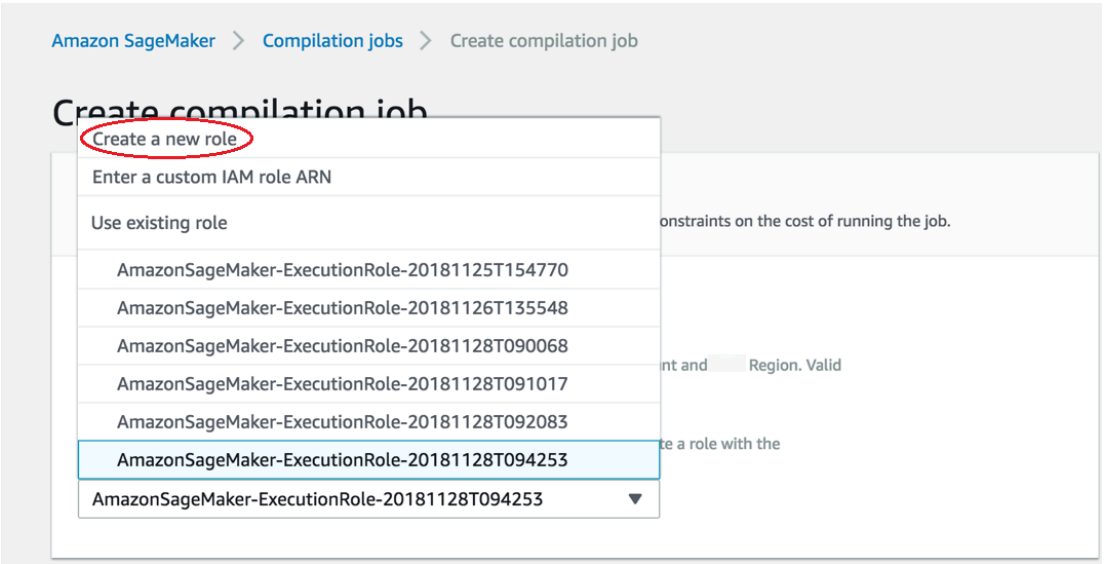
5. List the compilation job by running the following command:

```
aws sagemaker list-compilation-jobs \
--region us-west-2
```

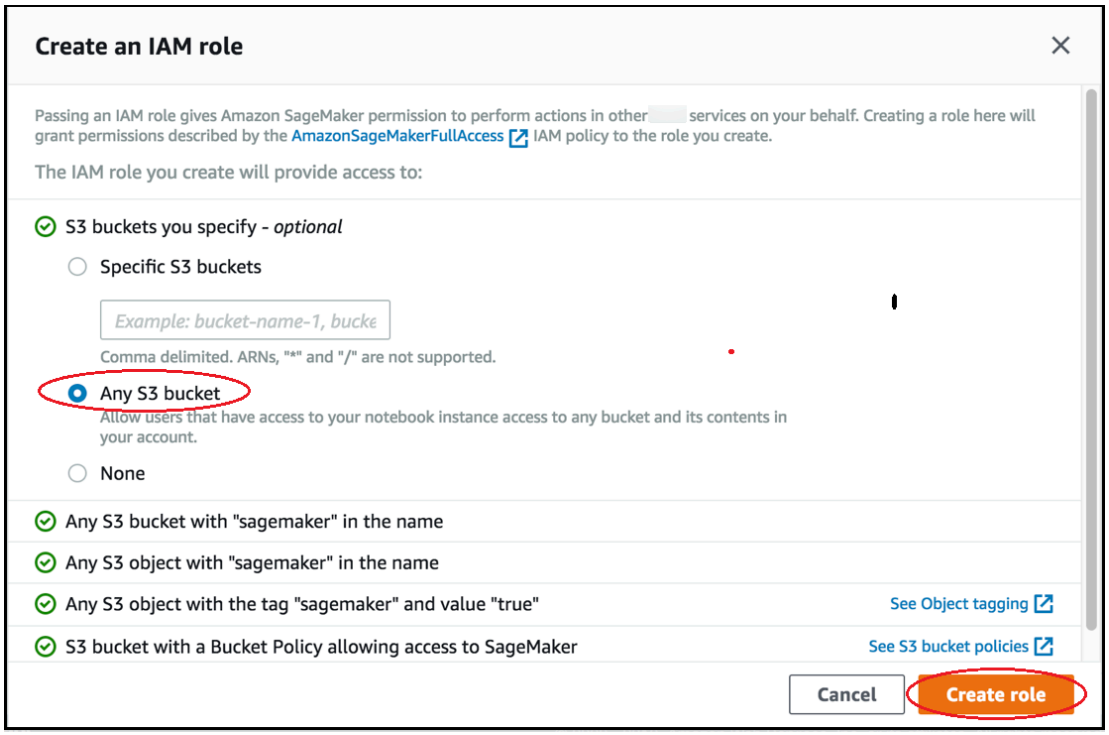


Compile a Model (Amazon SageMaker AI Console)

You can create an Amazon SageMaker Neo compilation job in the Amazon SageMaker AI console.



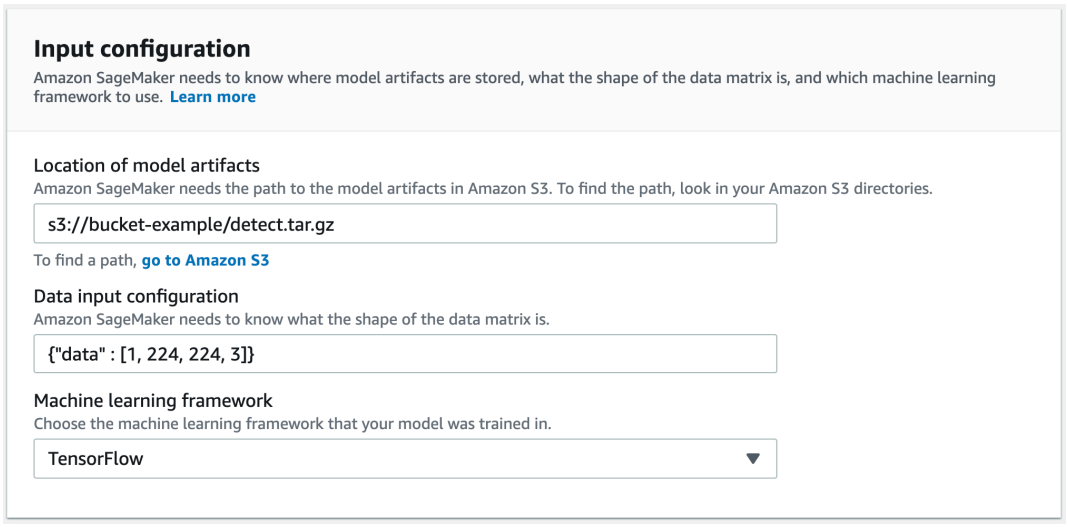
1. In the **Amazon SageMaker AI** console, choose **Compilation jobs**, and then choose **Create compilation job**.



2. On the **Create compilation job** page, under **Job name**, enter a name. Then select an **IAM role**.

3. If you don't have an IAM role, choose **Create a new role**.

4. On the **Create an IAM role** page, choose **Any S3 bucket**, and choose **Create role**.



5. Non PyTorch Frameworks

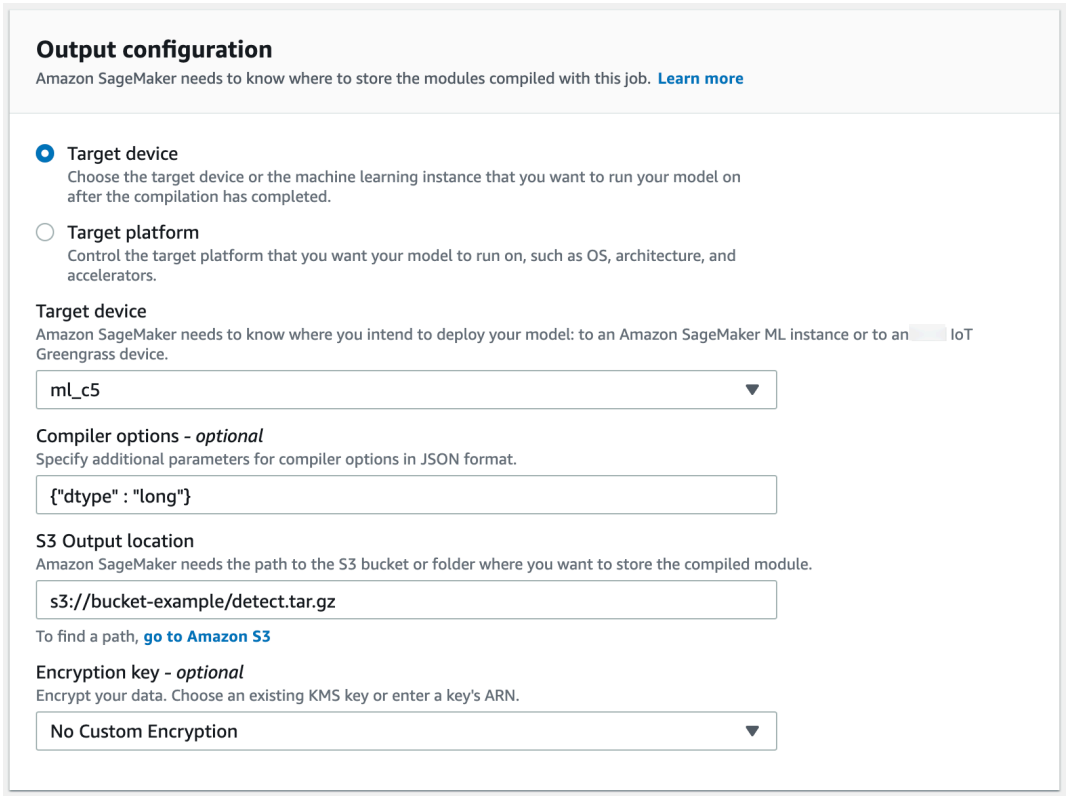
   Within the **Input configuration** section, enter the full path of the Amazon S3 bucket URI that contains your model artifacts in the **Location of model artifacts** input field. Your model artifacts must be in a compressed tarball file format (`.tar.gz`).

   For the **Data input configuration** field, enter the JSON string that specifies the shape of the input data.

   For **Machine learning framework**, choose the framework of your choice.

To find the JSON string examples of input data shapes depending on frameworks, see What input data shapes Neo expects.

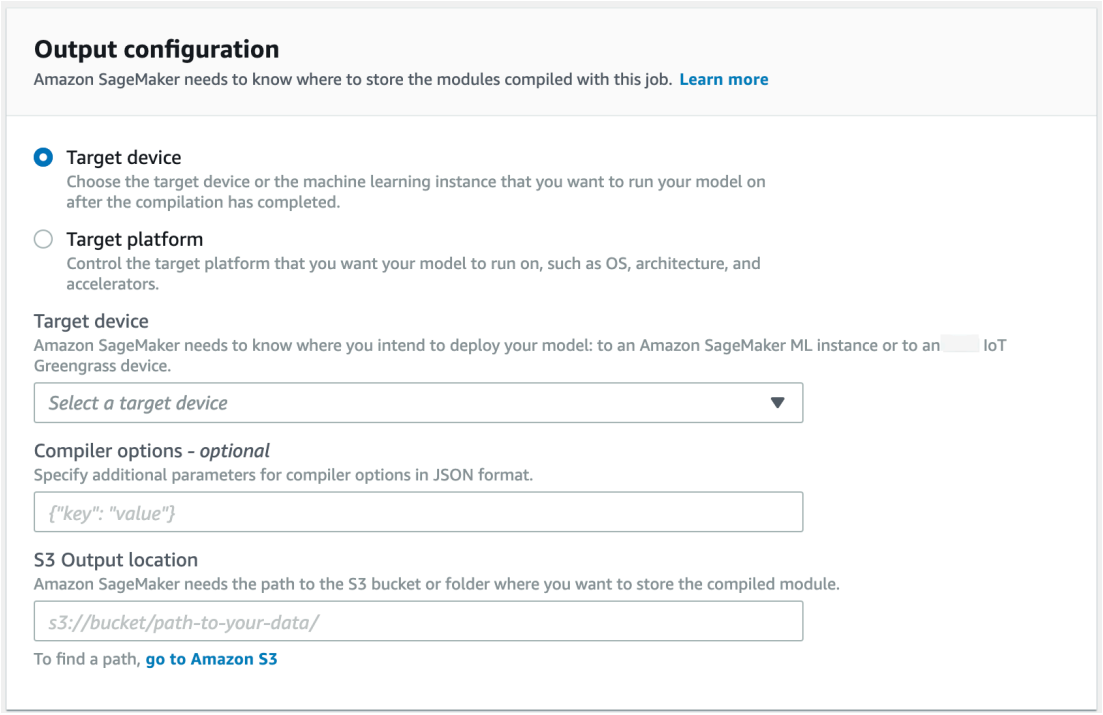
PyTorch Framework



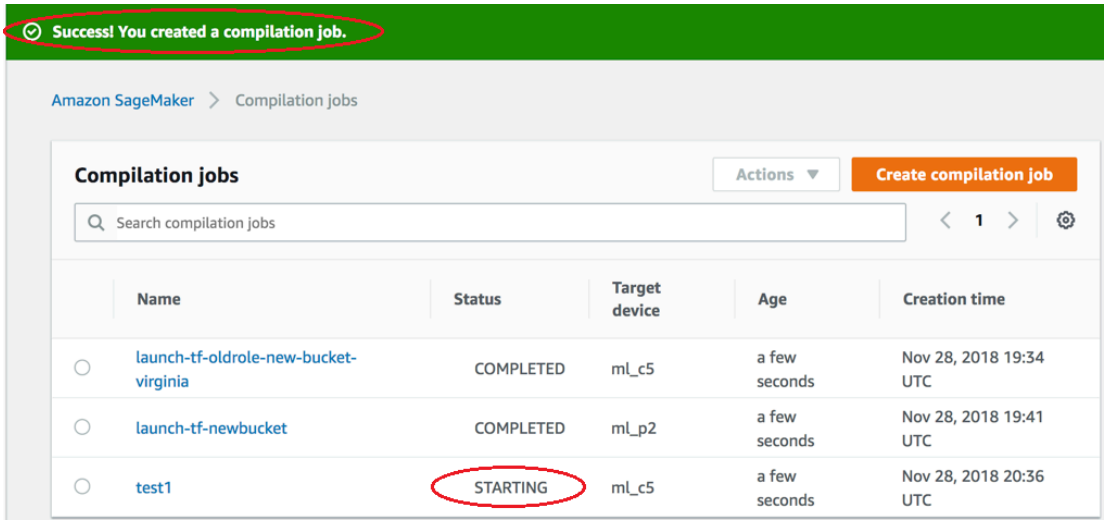
Similar instructions apply for compiling PyTorch models. However, if you trained with PyTorch and are trying to compile the model for `ml_*` (except `ml_inf`) target, you can optionally specify the version of PyTorch you used.

To find the JSON string examples of input data shapes depending on frameworks, see What input data shapes Neo expects.

Notes



- If you saved your model by using PyTorch version 2.0 or later, the **Data input configuration field** is optional. SageMaker Neo gets the input configuration from the model definition file that you create with PyTorch. For more information about how to create the definition file, see the PyTorch section under *Saving Models for SageMaker AI Neo*.
- When compiling for `ml_*` instances using PyTorch framework, use **Compiler options** field in **Output Configuration** to provide the correct data type (`dtype`) of the model's input. The default is set to `"float32"`.



> **Warning**
>
> If you specify a Amazon S3 bucket URI path that leads to `.pth` file, you will receive the following error after starting compilation: `ClientError: InputConfiguration: Unable to untar input model.Please confirm the model is a tar.gz file`

6. Go to the **Output configuration** section. Choose where you want to deploy your model. You can deploy your model to a **Target device** or a **Target platform**. Target devices include cloud and edge devices. Target platforms refer to specific OS, architecture, and accelerators you want your model to run on.

   For **S3 Output location**, enter the path to the S3 bucket where you want to store the model. You can optionally add compiler options in JSON format under the **Compiler options** section.

7. Check the status of the compilation job when started. This status of the job can be found at the top of the **Compilation Job** page, as shown in the following screenshot. You can also check the status of it in the **Status** column.

8. Check the status of the compilation job when completed. You can check the status in the **Status** column as shown in the following screenshot.

Compile a Model (Amazon SageMaker AI SDK)

You can use the `compile_model` API in the Amazon SageMaker Python SDK to compile a trained model and optimize it for specific target hardware. The API should be invoked on the estimator object used during model training.

> **Note**
>
> You must set `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable to `500` when compiling the model with MXNet or PyTorch. The environment variable is not needed for TensorFlow.

The following is an example of how you can compile a model using the `trained_model_estimator` object:

```
# Neo compilation in V3 uses ModelBuilder.optimize() with compilation_config
from sagemaker.serve import ModelBuilder

# Replace the value of expected_trained_model_input below and
# specify the name & shape of the expected inputs for your trained model
# in json dictionary form
expected_trained_model_input = {'data':[1, 784]}

# Replace the example target_instance_family below to your preferred
 target_instance_family
model_builder = ModelBuilder(
    model=trained_model,
    role_arn=role,
    instance_type='ml.c5.xlarge',
)
optimized_model = model_builder.optimize(
    instance_type='ml.c5.xlarge',
    output_path='insert s3 output path',
    compilation_config={
        'OverrideEnvironment': {
            'OPTION_TARGET_INSTANCE_FAMILY': 'ml_c5',
            'MMS_DEFAULT_RESPONSE_TIMEOUT': '500',
        },
    },
)
```

The code compiles the model, saves the optimized model at `output_path`, and creates a SageMaker AI model that can be deployed to an endpoint.

Cloud Instances

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks such as TensorFlow, PyTorch, MXNet, and more. You can deploy your compiled model to cloud instances and Amazon Inferentia instances. For a full list of supported frameworks and instances types, see Supported Instances Types and Frameworks.

You can compile your model in one of three ways: through the Amazon CLI, the SageMaker AI Console, or the SageMaker Python SDK. See, Use Neo to Compile a Model for more information. Once compiled, your model artifacts are stored in the Amazon S3 bucket URI you specified

during the compilation job. You can deploy your compiled model to cloud instances and Amazon Inferentia instances using the SageMaker Python SDK, Amazon SDK for Python (Boto3), Amazon CLI, or the Amazon console.

If you deploy your model using Amazon CLI, the console, or Boto3, you must select a Docker image Amazon ECR URI for your primary container. See Neo Inference Container Images for a list of Amazon ECR URIs.

- Inference Requests With a Deployed Service
- Inference Container Images

Supported Instance Types and Frameworks

Amazon SageMaker Neo supports popular deep learning frameworks for both compilation and deployment. You can deploy your model to cloud instances or Amazon Inferentia instance types.

The following describes frameworks SageMaker Neo supports and the target cloud instances you can compile and deploy to. For information on how to deploy your compiled model to a cloud or Inferentia instance, see Deploy a Model with Cloud Instances.

Cloud Instances

SageMaker Neo supports the following deep learning frameworks for CPU and GPU cloud instances:

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
MXNet	1.8.0	Supports 1.8.0 or earlier	Image Classification, Object Detection, Semantic	One symbol file (.json) and one parameter file (.params)	GluonCV v0.8.0

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
			Segmentation, Pose Estimation, Activity Recognition		
ONNX	1.7.0	Supports 1.7.0 or earlier	Image Classification, SVM	One model file (.onnx)	
Keras	2.2.4	Supports 2.2.4 or earlier	Image Classification	One model definition file (.h5)	
PyTorch	1.4, 1.5, 1.6, 1.7, 1.8, 1.12, 1.13, or 2.0	Supports 1.4, 1.5, 1.6, 1.7, 1.8, 1.12, 1.13, and 2.0	Image Classification Versions 1.13 and 2.0 support Object Detection, Vision Transformer, and HuggingFace	One model definition file (.pt or .pth) with input dtype of float32	

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
TensorFlow	1.15.3 or 2.9	Supports 1.15.3 and 2.9	Image Classification	For saved models, one .pb or one .pbtxt file and a variables directory that contains variables For frozen models, only one .pb or .pbtxt file	
XGBoost	1.3.3	Supports 1.3.3 or earlier	Decision Trees	One XGBoost model file (.model) where the number of nodes in a tree is less than 2^31	

Note

"Model Version" is the version of the framework used to train and export the model.

Instance Types

You can deploy your SageMaker AI compiled model to one of the cloud instances listed below:

Instance	Compute Type				
ml_c4	Standard				
ml_c5	Standard				
ml_m4	Standard				
ml_m5	Standard				
ml_p2	Accelerated computing				
ml_p3	Accelerated computing				
ml_g4dn	Accelerated computing				

For information on the available vCPU, memory, and price per hour for each instance type, see Amazon SageMaker Pricing.

Note

When compiling for `ml_*` instances using PyTorch framework, use **Compiler options** field in **Output Configuration** to provide the correct data type (`dtype`) of the model's input. The default is set to `"float32"`.

Amazon Inferentia

SageMaker Neo supports the following deep learning frameworks for Inf1:

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
MXNet	1.5 or 1.8	Supports 1.8, 1.5 and earlier	Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition	One symbol file (.json) and one parameter file (.params)	GluonCV v0.8.0
PyTorch	1.7, 1.8 or 1.9	Supports 1.9 and earlier	Image Classification	One model definition file (.pt or .pth) with input dtype of float32	
TensorFlow	1.15 or 2.5	Supports 2.5, 1.15 and earlier	Image Classification	For saved models, one .pb or one .pbtxt file and a variables directory that contains variables For frozen models, only one .pb or .pbtxt file	

> **Note**
>
> "Model Version" is the version of the framework used to train and export the model.

You can deploy your SageMaker Neo-compiled model to Amazon Inferentia-based Amazon EC2 Inf1 instances. Amazon Inferentia is Amazon's first custom silicon chip designed to accelerate deep learning. Currently, you can use the `ml_inf1` instance to deploy your compiled models.

Amazon Inferentia2 and Amazon Trainium

Currently, you can deploy your SageMaker Neo-compiled model to Amazon Inferentia2-based Amazon EC2 Inf2 instances (in US East (Ohio) Region), and to Amazon Trainium-based Amazon EC2 Trn1 instances (in US East (N. Virginia) Region). For more information about supported models on these instances, see Model Architecture Fit Guidelines in the Amazon Neuron documentation, and the examples in the Neuron Github repository.

Deploy a Model

To deploy an Amazon SageMaker Neo-compiled model to an HTTPS endpoint, you must configure and create the endpoint for the model using Amazon SageMaker AI hosting services. Currently, developers can use Amazon SageMaker APIs to deploy modules on to ml.c5, ml.c4, ml.m5, ml.m4, ml.p3, ml.p2, and ml.inf1 instances.

For Inferentia and Trainium instances, models need to be compiled specifically for those instances. Models compiled for other instance types are not guaranteed to work with Inferentia or Trainium instances.

When you deploy a compiled model, you need to use the same instance for the target that you used for compilation. This creates a SageMaker AI endpoint that you can use to perform inferences. You can deploy a Neo-compiled model using any of the following: Amazon SageMaker Python SDK, SDK for Python (Boto3), Amazon Command Line Interface, and the SageMaker AI console.

> **Note**
>
> For deploying a model using Amazon CLI, the console, or Boto3, see Neo Inference Container Images to select the inference image URI for your primary container.

Topics

- Prerequisites
- Deploy a Compiled Model Using SageMaker SDK
- Deploy a Compiled Model Using Boto3
- Deploy a Compiled Model Using the Amazon CLI
- Deploy a Compiled Model Using the Console

Prerequisites

> **Note**
>
> Follow the instructions in this section if you compiled your model using Amazon SDK for Python (Boto3), Amazon CLI, or the SageMaker AI console.

To create a SageMaker Neo-compiled model, you need the following:

1. A Docker image Amazon ECR URI. You can select one that meets your needs from this list.
2. An entry point script file:

    a. **For PyTorch and MXNet models:**

    If you trained your model using SageMaker AI, the training script must implement the functions described below. The training script serves as the entry point script during inference. In the example detailed in MNIST Training, Compilation and Deployment with MXNet Module and SageMaker Neo, the training script (`mnist.py`) implements the required functions.

    If you did not train your model using SageMaker AI, you need to provide an entry point script (`inference.py`) file that can be used at the time of inference. Based on the framework—MXNet or PyTorch—the inference script location must conform to the SageMaker Python SDK Model Directory Structure for MxNet or Model Directory Structure for PyTorch.

    When using Neo Inference Optimized Container images with **PyTorch** and **MXNet** on CPU and GPU instance types, the inference script must implement the following functions:

    - `model_fn`: Loads the model. (Optional)

- `input_fn`: Converts the incoming request payload into a numpy array.
- `predict_fn`: Performs the prediction.
- `output_fn`: Converts the prediction output into the response payload.
- Alternatively, you can define `transform_fn` to combine `input_fn`, `predict_fn`, and `output_fn`.

The following are examples of `inference.py` script within a directory named `code` (`code/inference.py`) for **PyTorch and MXNet (Gluon and Module).** The examples first load the model and then serve it on image data on a GPU:

MXNet Module

```
import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401
from collections import namedtuple

Batch = namedtuple('Batch', ['data'])

# Change the context to mx.cpu() if deploying to a CPU endpoint
ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    sym, arg_params, aux_params = mx.model.load_checkpoint('compiled', 0)
    mod = mx.mod.Module(symbol=sym, context=ctx, label_names=None)
    exe = mod.bind(for_training=False,
                   data_shapes=[('data', (1,3,224,224))],
                   label_shapes=mod._label_shapes)
    mod.set_params(arg_params, aux_params, allow_missing=True)

    # Run warm-up inference on empty data during model load (required for
 GPU)
    data = mx.nd.empty((1,3,224,224), ctx=ctx)
    mod.forward(Batch([data]))
    return mod

def transform_fn(mod, image, input_content_type, output_content_type):
```

```
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
                                  mean=mx.nd.array([0.485, 0.456, 0.406]),
                                  std=mx.nd.array([0.229, 0.224, 0.225]))
    transposed = normalized.transpose((2, 0, 1))
    batchified = transposed.expand_dims(axis=0)
    casted = batchified.astype(dtype='float32')
    processed_input = casted.as_in_context(ctx)

    # prediction/inference
    mod.forward(Batch([processed_input]))

    # post-processing
    prob = mod.get_outputs()[0].asnumpy().tolist()
    prob_json = json.dumps(prob)
    return prob_json, output_content_type
```

MXNet Gluon

```
import numpy as np
import json
import mxnet as mx
import neomx  # noqa: F401

# Change the context to mx.cpu() if deploying to a CPU endpoint
ctx = mx.gpu()

def model_fn(model_dir):
    # The compiled model artifacts are saved with the prefix 'compiled'
    block = mx.gluon.nn.SymbolBlock.imports('compiled-symbol.json',
['data'],'compiled-0000.params', ctx=ctx)

    # Hybridize the model & pass required options for Neo: static_alloc=True
 & static_shape=True
    block.hybridize(static_alloc=True, static_shape=True)

    # Run warm-up inference on empty data during model load (required for
 GPU)
    data = mx.nd.empty((1,3,224,224), ctx=ctx)
    warm_up = block(data)
```

```
    return block

def input_fn(image, input_content_type):
    # pre-processing
    decoded = mx.image.imdecode(image)
    resized = mx.image.resize_short(decoded, 224)
    cropped, crop_info = mx.image.center_crop(resized, (224, 224))
    normalized = mx.image.color_normalize(cropped.astype(np.float32) / 255,
                                   mean=mx.nd.array([0.485, 0.456, 0.406]),
                                   std=mx.nd.array([0.229, 0.224, 0.225]))
    transposed = normalized.transpose((2, 0, 1))
    batchified = transposed.expand_dims(axis=0)
    casted = batchified.astype(dtype='float32')
    processed_input = casted.as_in_context(ctx)
    return processed_input

def predict_fn(processed_input_data, block):
    # prediction/inference
    prediction = block(processed_input_data)
    return prediction

def output_fn(prediction, output_content_type):
    # post-processing
    prob = prediction.asnumpy().tolist()
    prob_json = json.dumps(prob)
    return prob_json, output_content_type
```

PyTorch 1.4 and Older

```
import os
import torch
import torch.nn.parallel
import torch.optim
import torch.utils.data
import torch.utils.data.distributed
import torchvision.transforms as transforms
from PIL import Image
import io
import json
import pickle
```

```
def model_fn(model_dir):
    """Load the model and return it.
    Providing this function is optional.
    There is a default model_fn available which will load the model
    compiled using SageMaker Neo. You can override it here.

    Keyword arguments:
    model_dir -- the directory path where the model artifacts are present
    """

    # The compiled model is saved as "compiled.pt"
    model_path = os.path.join(model_dir, 'compiled.pt')

    # preprocess
    decoded = Image.open(io.BytesIO(request_body))
    preprocess = transforms.Compose([
                               transforms.Resize(256),
                               transforms.CenterCrop(224),
                               transforms.ToTensor(),
                               transforms.Normalize(
                                   mean=[
                                       0.485, 0.456, 0.406], std=[
                                       0.229, 0.224, 0.225]),
                                   ])
    normalized = preprocess(decoded)
    batchified = normalized.unsqueeze(0)

    # predict
    device = torch.device("cuda" if torch.cuda.is_available() else "cpu")
    batchified = batchified.to(device)
    output = model.forward(batchified)
    return json.dumps(output.cpu().numpy().tolist()), response_content_type
```

b. **For inf1 instances or onnx, xgboost, keras container images**

For all other Neo Inference-optimized container images, or inferentia instance types, the entry point script must implement the following functions for Neo Deep Learning Runtime:

- `neo_preprocess`: Converts the incoming request payload into a numpy array.
- `neo_postprocess`: Converts the prediction output from Neo Deep Learning Runtime into the response body.

> **Note**
>
> The preceding two functions do not use any of the functionalities of MXNet, PyTorch, or TensorFlow.

For examples of how to use these functions, see Neo Model Compilation Sample Notebooks.

c. **For TensorFlow models**

If your model requires custom pre- and post-processing logic before data is sent to the model, then you must specify an entry point script `inference.py` file that can be used at the time of inference. The script should implement either a either a pair of `input_handler` and `output_handler` functions or a single handler function.

> **Note**
>
> Note that if handler function is implemented, `input_handler` and `output_handler` are ignored.

The following is a code example of `inference.py` script that you can put together with the compile model to perform custom pre- and post-processing on an image classification model. The SageMaker AI client sends the image file as an `application/x-image` content type to the `input_handler` function, where it is converted to JSON. The converted image file is then sent to the Tensorflow Model Server (TFX) using the REST API.

```
import json
```

```
import numpy as np
import json
import io
from PIL import Image

def input_handler(data, context):
    """ Pre-process request input before it is sent to TensorFlow Serving REST
 API

    Args:
    data (obj): the request data, in format of dict or string
    context (Context): an object containing request and configuration details

    Returns:
    (dict): a JSON-serializable dict that contains request body and headers
    """
    f = data.read()
    f = io.BytesIO(f)
    image = Image.open(f).convert('RGB')
    batch_size = 1
    image = np.asarray(image.resize((512, 512)))
    image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
    body = json.dumps({"signature_name": "serving_default", "instances":
 image.tolist()})
    return body

def output_handler(data, context):
    """Post-process TensorFlow Serving output before it is returned to the
 client.

    Args:
    data (obj): the TensorFlow serving response
    context (Context): an object containing request and configuration details

    Returns:
    (bytes, string): data to return to client, response content type
    """
    if data.status_code != 200:
        raise ValueError(data.content.decode('utf-8'))

    response_content_type = context.accept_header
    prediction = data.content
    return prediction, response_content_type
```

If there is no custom pre- or post-processing, the SageMaker AI client converts the file image to JSON in a similar way before sending it over to the SageMaker AI endpoint.

For more information, see the Deploying to TensorFlow Serving Endpoints in the SageMaker Python SDK.

3. The Amazon S3 bucket URI that contains the compiled model artifacts.

Deploy a Compiled Model Using SageMaker SDK

You must satisfy the prerequisites section if the model was compiled using Amazon SDK for Python (Boto3), Amazon CLI, or the Amazon SageMaker AI console. Follow one of the following use cases to deploy a model compiled with SageMaker Neo based on how you compiled your model.

Topics

- If you compiled your model using the SageMaker SDK
- If you compiled your model using MXNet or PyTorch
- If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow

If you compiled your model using the SageMaker SDK

The sagemaker.Model object handle for the compiled model supplies the deploy() function, which enables you to create an endpoint to serve inference requests. The function lets you set the number and type of instances that are used for the endpoint. You must choose an instance for which you have compiled your model. For example, in the job compiled in Compile a Model (Amazon SageMaker SDK) section, this is `ml_c5`.

```
from sagemaker.serve import ModelBuilder

model_builder = ModelBuilder(
    model=compiled_model,
    role_arn=role,
    instance_type='ml.c5.4xlarge',
)
endpoint = model_builder.build().deploy(
    initial_instance_count=1,
    instance_type='ml.c5.4xlarge'
)
```

```
# Print the name of newly created endpoint
print(endpoint.endpoint_name)
```

If you compiled your model using MXNet or PyTorch

Create and deploy the SageMaker AI model using `ModelBuilder`. Specify the `s3_model_data_url` parameter as the S3 path to your compiled model archive, the `role_arn` parameter as your execution role, and the `instance_type` parameter for your target instance. You must also set the `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable to `500`.

The following example shows how to use these functions to deploy a compiled model using the SageMaker Python SDK:

```
from sagemaker.serve import ModelBuilder

# V3 uses a unified ModelBuilder approach for all frameworks
model_builder = ModelBuilder(
    s3_model_data_url='insert S3 path of compiled model archive',
    role_arn='AmazonSageMaker-ExecutionRole',
    instance_type='ml.p3.2xlarge',
    env={'MMS_DEFAULT_RESPONSE_TIMEOUT': '500'},
)
endpoint = model_builder.build().deploy(
    initial_instance_count=1,
    instance_type='ml.p3.2xlarge'
)

# Print the name of newly created endpoint
print(endpoint.endpoint_name)
```

Note

The `AmazonSageMakerFullAccess` and `AmazonS3ReadOnlyAccess` policies must be attached to the `AmazonSageMaker-ExecutionRole` IAM role.

If you compiled your model using Boto3, SageMaker console, or the CLI for TensorFlow

Construct a model object, then call deploy:

```
from sagemaker.serve import ModelBuilder
```

```
model_builder = ModelBuilder(
    s3_model_data_url='S3 path for model file',
    role_arn=role,
    instance_type='ml.c5.xlarge',
)
endpoint = model_builder.build().deploy(
    initial_instance_count=1,
    instance_type='ml.c5.xlarge'
)
```

See Deploying directly from model artifacts for more information.

You can select a Docker image Amazon ECR URI that meets your needs from this list.

For more information on how to construct a `TensorFlowModel` object, see the SageMaker SDK.

> **Note**
>
> Your first inference request might have high latency if you deploy your model on a GPU. This is because an optimized compute kernel is made on the first inference request. We recommend that you make a warm-up file of inference requests and store that alongside your model file before sending it off to a TFX. This is known as “warming up” the model.

The following code snippet demonstrates how to produce the warm-up file for image classification example in the prerequisites section:

```
import tensorflow as tf
from tensorflow_serving.apis import classification_pb2
from tensorflow_serving.apis import inference_pb2
from tensorflow_serving.apis import model_pb2
from tensorflow_serving.apis import predict_pb2
from tensorflow_serving.apis import prediction_log_pb2
from tensorflow_serving.apis import regression_pb2
import numpy as np

with tf.python_io.TFRecordWriter("tf_serving_warmup_requests") as writer:
    img = np.random.uniform(0, 1, size=[224, 224, 3]).astype(np.float32)
    img = np.expand_dims(img, axis=0)
    test_data = np.repeat(img, 1, axis=0)
    request = predict_pb2.PredictRequest()
```

```
    request.model_spec.name = 'compiled_models'
    request.model_spec.signature_name = 'serving_default'
    request.inputs['Placeholder:0'].CopyFrom(tf.compat.v1.make_tensor_proto(test_data,
 shape=test_data.shape, dtype=tf.float32))
    log = prediction_log_pb2.PredictionLog(
    predict_log=prediction_log_pb2.PredictLog(request=request))
    writer.write(log.SerializeToString())
```

For more information on how to “warm up” your model, see the TensorFlow TFX page.

Deploy a Compiled Model Using Boto3

You must satisfy the prerequisites section if the model was compiled using Amazon SDK for Python (Boto3), Amazon CLI, or the Amazon SageMaker AI console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using Amazon Web Services SDK for Python (Boto3).

Topics

- Deploy the Model

Deploy the Model

After you have satisfied the prerequisites, use the `create_model`, `create_enpoint_config`, and `create_endpoint` APIs.

The following example shows how to use these APIs to deploy a model compiled with Neo:

```
import boto3
client = boto3.client('sagemaker')

# create sagemaker model
create_model_api_response = client.create_model(
                                    ModelName='my-sagemaker-model',
                                    PrimaryContainer={
                                        'Image': <insert the ECR Image URI>,
                                        'ModelDataUrl': 's3://path/to/model/artifact/
model.tar.gz',
                                        'Environment': {}
                                    },
                                    ExecutionRoleArn='ARN for AmazonSageMaker-
ExecutionRole'
```

```
                            )

print ("create_model API response", create_model_api_response)

# create sagemaker endpoint config
create_endpoint_config_api_response = client.create_endpoint_config(
                                            EndpointConfigName='sagemaker-neomxnet-
endpoint-configuration',
                                            ProductionVariants=[
                                                {
                                                    'VariantName': <provide your
 variant name>,
                                                    'ModelName': 'my-sagemaker-model',
                                                    'InitialInstanceCount': 1,
                                                    'InstanceType': <provide your
 instance type here>
                                                },
                                            ]
                                        )

print ("create_endpoint_config API response", create_endpoint_config_api_response)

# create sagemaker endpoint
create_endpoint_api_response = client.create_endpoint(
                                    EndpointName='provide your endpoint name',
                                    EndpointConfigName=<insert your endpoint config
 name>,
                                )

print ("create_endpoint API response", create_endpoint_api_response)
```

> **Note**
>
> The `AmazonSageMakerFullAccess` and `AmazonS3ReadOnlyAccess` policies must be attached to the `AmazonSageMaker-ExecutionRole` IAM role.

For full syntax of `create_model`, `create_endpoint_config`, and `create_endpoint` APIs, see `create_model`, `create_endpoint_config`, and `create_endpoint`, respectively.

If you did not train your model using SageMaker AI, specify the following environment variables:

MXNet and PyTorch

```
"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region",
    "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}
```

TensorFlow

```
"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region"
}
```

If you trained your model using SageMaker AI, specify the environment variable `SAGEMAKER_SUBMIT_DIRECTORY` as the full Amazon S3 bucket URI that contains the training script.

Deploy a Compiled Model Using the Amazon CLI

You must satisfy the prerequisites section if the model was compiled using Amazon SDK for Python (Boto3), Amazon CLI, or the Amazon SageMaker AI console. Follow the steps below to create and deploy a SageMaker Neo-compiled model using the Amazon CLI.

Topics

- Deploy the Model

Deploy the Model

After you have satisfied the prerequisites, use the `create-model`, `create-enpoint-config`, and `create-endpoint` Amazon CLI commands. The following steps explain how to use these commands to deploy a model compiled with Neo:

Create a Model

From Neo Inference Container Images, select the inference image URI and then use `create-model` API to create a SageMaker AI model. You can do this with two steps:

1. Create a `create_model.json` file. Within the file, specify the name of the model, the image URI, the path to the `model.tar.gz` file in your Amazon S3 bucket, and your SageMaker AI execution role:

```
{
    "ModelName": "insert model name",
    "PrimaryContainer": {
        "Image": "insert the ECR Image URI",
        "ModelDataUrl": "insert S3 archive URL",
        "Environment": {"See details below"}
    },
    "ExecutionRoleArn": "ARN for AmazonSageMaker-ExecutionRole"
}
```

   If you trained your model using SageMaker AI, specify the following environment variable:

```
"Environment": {
    "SAGEMAKER_SUBMIT_DIRECTORY" : "[Full S3 path for *.tar.gz file containing the
 training script]"
}
```

   If you did not train your model using SageMaker AI, specify the following environment variables:

   MXNet and PyTorch

```
"Environment": {
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region",
    "MMS_DEFAULT_RESPONSE_TIMEOUT": "500"
}
```

   TensorFlow

```
"Environment": {
```

```
    "SAGEMAKER_PROGRAM": "inference.py",
    "SAGEMAKER_SUBMIT_DIRECTORY": "/opt/ml/model/code",
    "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
    "SAGEMAKER_REGION": "insert your region"
}
```

> **Note**
>
> The AmazonSageMakerFullAccess and AmazonS3ReadOnlyAccess policies must be attached to the AmazonSageMaker-ExecutionRole IAM role.

2. Run the following command:

```
aws sagemaker create-model --cli-input-json file://create_model.json
```

For the full syntax of the create-model API, see create-model.

Create an Endpoint Configuration

After creating a SageMaker AI model, create the endpoint configuration using the create-endpoint-config API. To do this, create a JSON file with your endpoint configuration specifications. For example, you can use the following code template and save it as create_config.json:

```
{
    "EndpointConfigName": "<provide your endpoint config name>",
    "ProductionVariants": [
        {
            "VariantName": "<provide your variant name>",
            "ModelName": "my-sagemaker-model",
            "InitialInstanceCount": 1,
            "InstanceType": "<provide your instance type here>",
            "InitialVariantWeight": 1.0
        }
    ]
}
```

Now run the following Amazon CLI command to create your endpoint configuration:

```
aws sagemaker create-endpoint-config --cli-input-json file://create_config.json
```

For the full syntax of the `create-endpoint-config` API, see `create-endpoint-config`.

Create an Endpoint

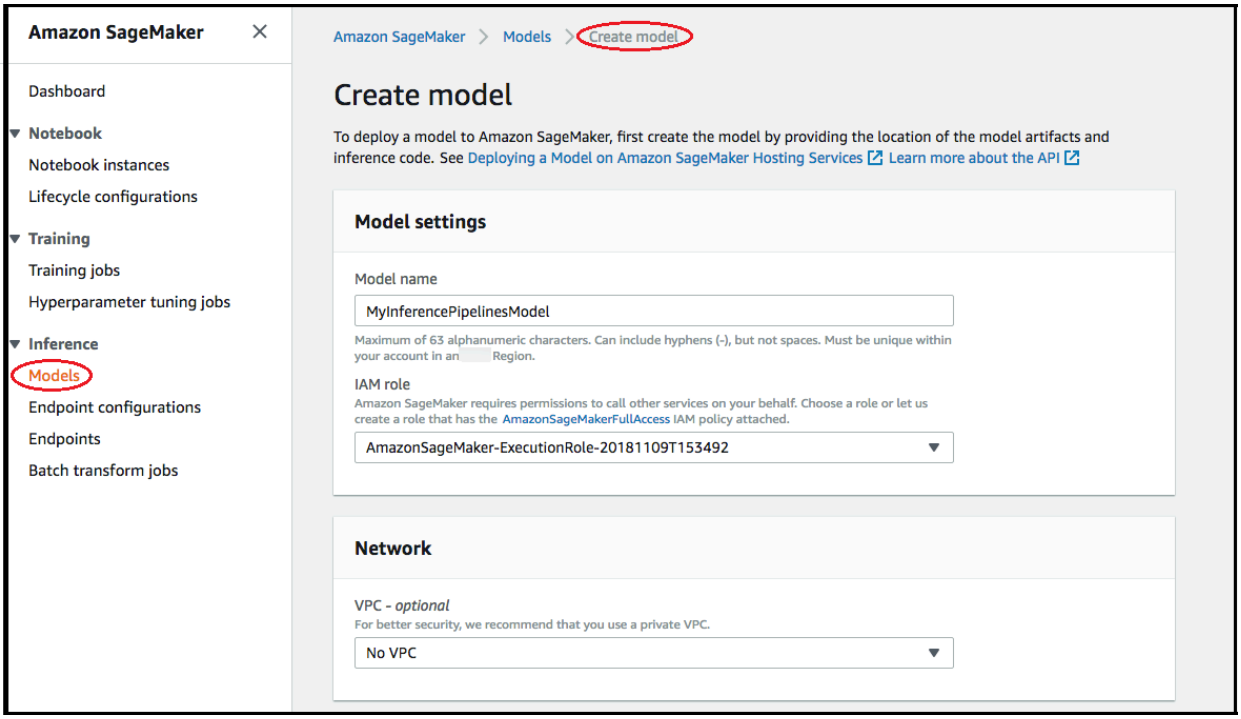
After you have created your endpoint configuration, create an endpoint using the `create-endpoint` API:

```
aws sagemaker create-endpoint --endpoint-name '<provide your endpoint name>' --
endpoint-config-name '<insert your endpoint config name>'
```

For the full syntax of the `create-endpoint` API, see `create-endpoint`.

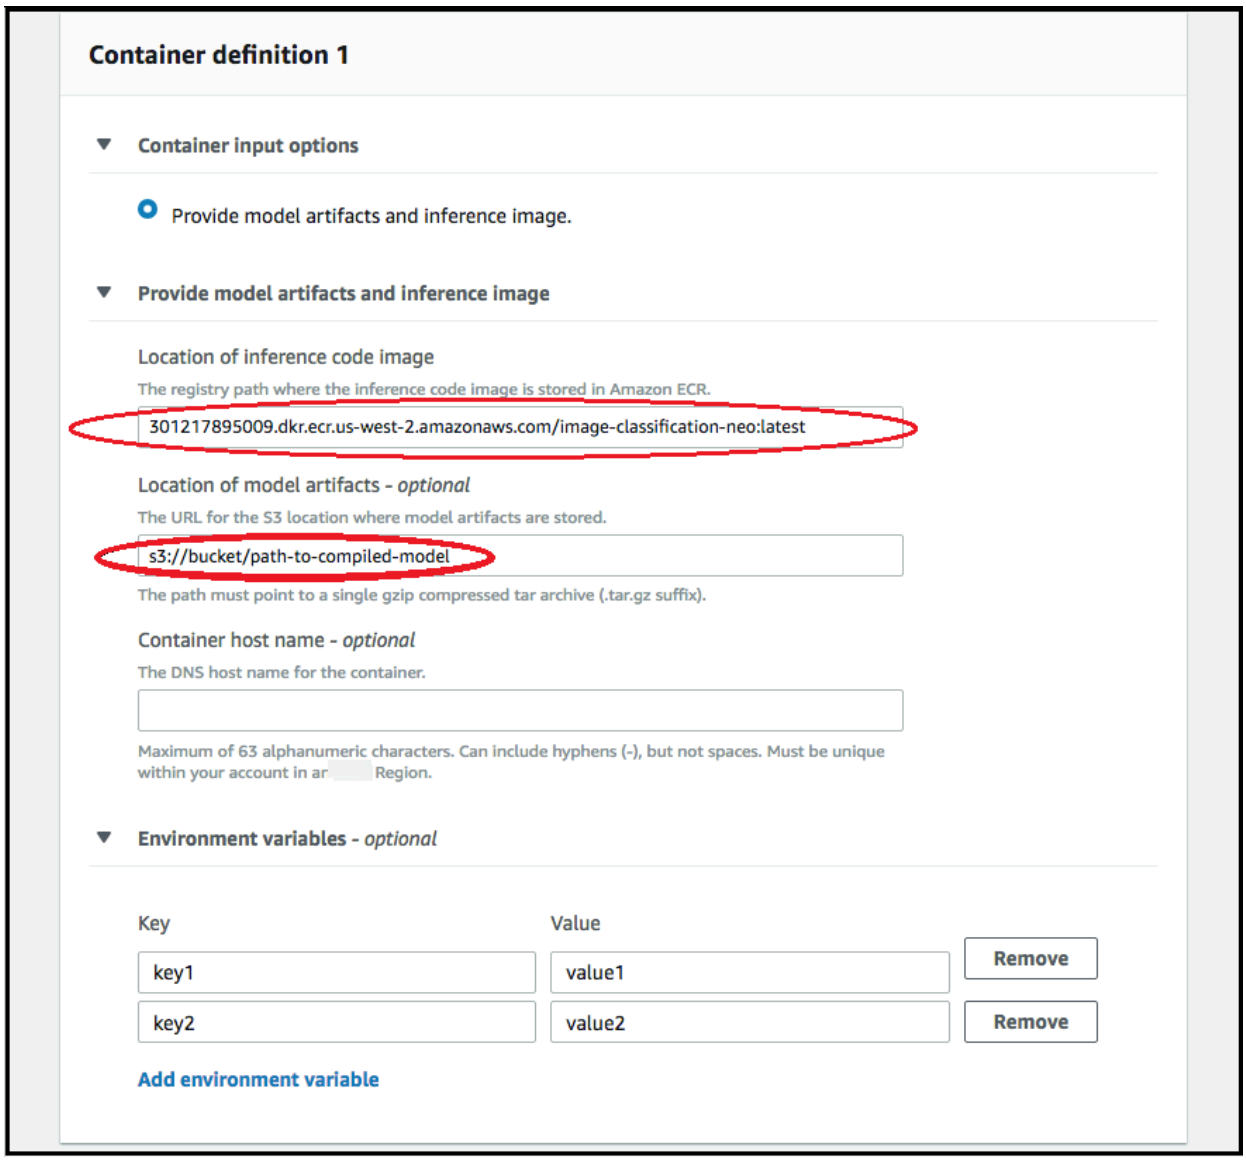
Deploy a Compiled Model Using the Console

You must satisfy the prerequisites section if the model was compiled using Amazon SDK for Python (Boto3), the Amazon CLI, or the Amazon SageMaker AI console. Follow the steps below to create and deploy a SageMaker AI Neo-compiled model using the SageMaker AI consolehttps://console.amazonaws.cn/ SageMaker AI.



Topics

- Deploy the Model

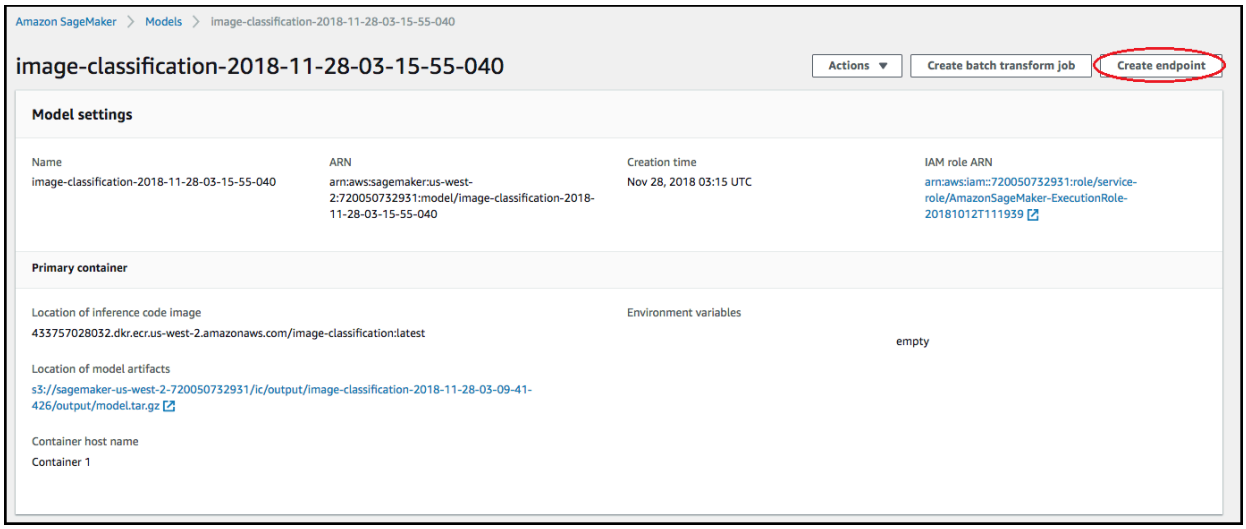


Deploy the Model

After you have satisfied the prerequisites, use the following steps to deploy a model compiled with Neo:

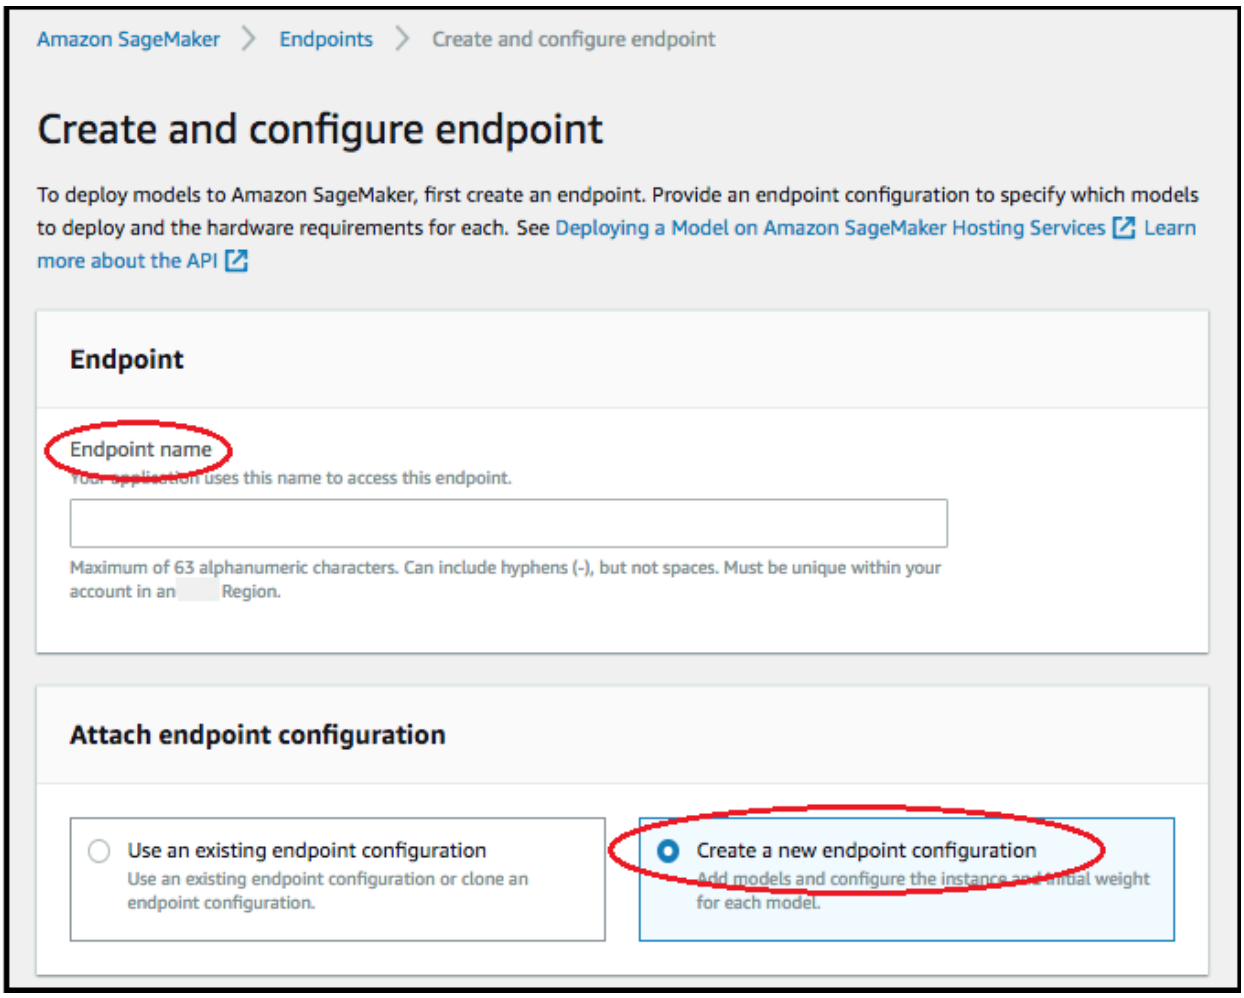
1. Choose **Models**, and then choose **Create models** from the **Inference** group. On the **Create model** page, complete the **Model name**, **IAM role**, and **VPC** fields (optional), if needed.

2. To add information about the container used to deploy your model, choose **Add container** container, then choose **Next**. Complete the **Container input options**, **Location of inference code image**, and **Location of model artifacts**, and optionally, **Container host name**, and **Environmental variables** fields.



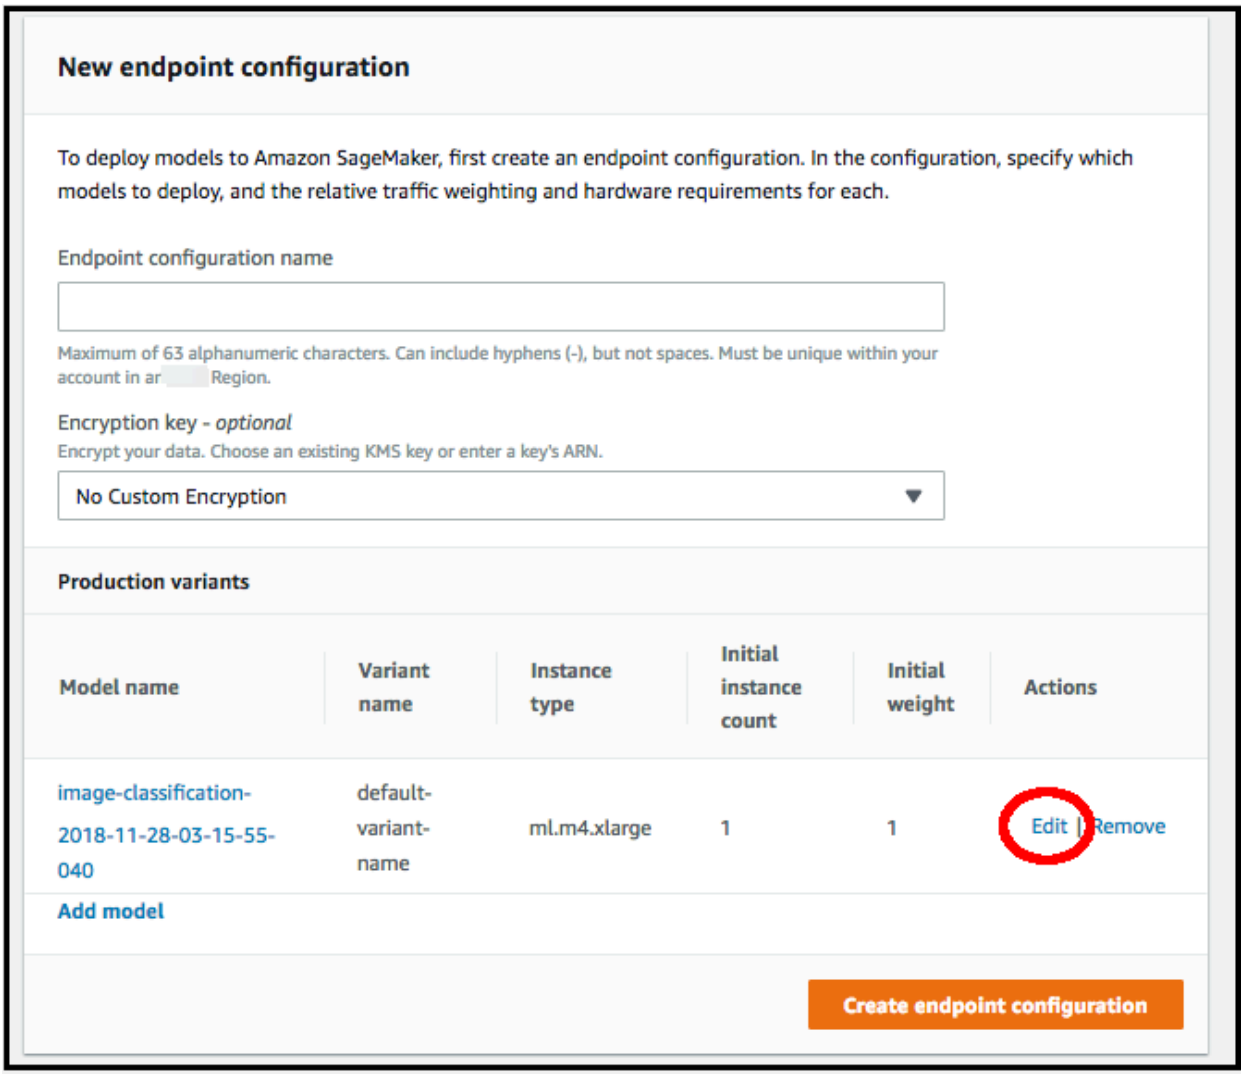
3. To deploy Neo-compiled models, choose the following:

   - **Container input options**: Choose **Provide model artifacts and inference image**.
   - **Location of inference code image**: Choose the inference image URI from Neo Inference Container Images, depending on the Amazon Region and kind of application.
   - **Location of model artifact**: Enter the Amazon S3 bucket URI of the compiled model artifact generated by the Neo compilation API.
   - **Environment variables**:
     - Leave this field blank for **SageMaker XGBoost**.

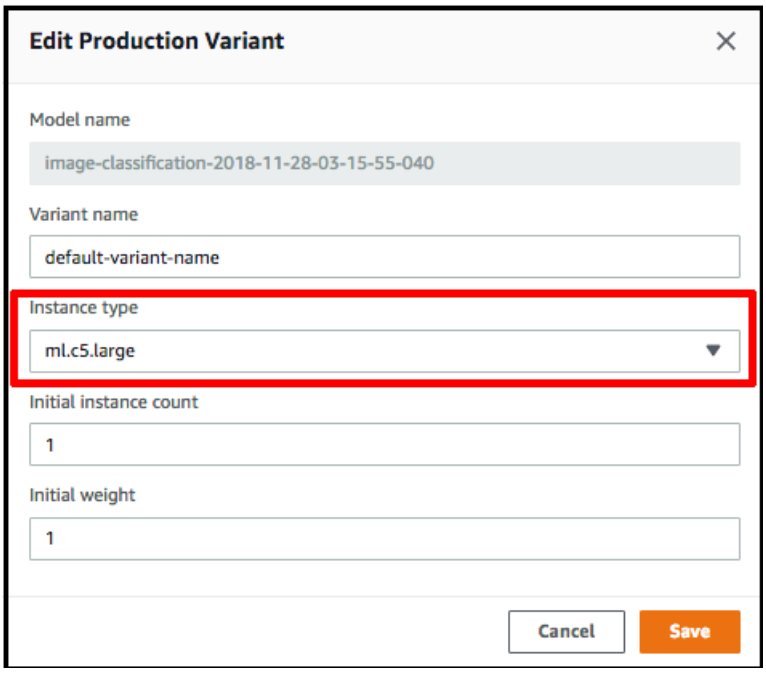


- If you trained your model using SageMaker AI, specify the environment variable `SAGEMAKER_SUBMIT_DIRECTORY` as the Amazon S3 bucket URI that contains the training script.
- If you did not train your model using SageMaker AI, specify the following environment variables:

Key	Values for MXNet and PyTorch	Values TensorFlow
SAGEMAKER_PROGRAM	inference.py	inference.py
SAGEMAKER_SUBMIT_DIRECTORY	/opt/ml/model/code	/opt/ml/model/code
SAGEMAKER_CONTAINER_LOG_LEVEL	20	20
SAGEMAKER_REGION	<your region>	<your region>
MMS_DEFAULT_RESPONSE_TIMEOUT	500	Leave this field blank for TF



4. Confirm that the information for the containers is accurate, and then choose **Create model**. On the **Create model landing page**, choose **Create endpoint**.



5. In **Create and configure endpoint** diagram, specify the **Endpoint name**. For **Attach endpoint configuration**, choose **Create a new endpoint configuration**.

6. In **New endpoint configuration** page, specify the **Endpoint configuration name**.

7. Choose **Edit** next to the name of the model and specify the correct **Instance type** on the **Edit Production Variant** page. It is imperative that the **Instance type** value match the one specified in your compilation job.

8. Choose **Save**.
9. On the **New endpoint configuration** page, choose **Create endpoint configuration**, and then choose **Create endpoint**.

Inference Requests With a Deployed Service

If you have followed instructions in Deploy a Model, you should have a SageMaker AI endpoint set up and running. Regardless of how you deployed your Neo-compiled model, there are three ways you can submit inference requests:

Topics

- Request Inferences from a Deployed Service (Amazon SageMaker SDK)
- Request Inferences from a Deployed Service (Boto3)
- Request Inferences from a Deployed Service (Amazon CLI)

Request Inferences from a Deployed Service (Amazon SageMaker SDK)

Use the following the code examples to request inferences from your deployed service based on the framework you used to train your model. The code examples for the different frameworks are similar. The main difference is that TensorFlow requires `application/json` as the content type.

PyTorch and MXNet

If you are using **PyTorch v1.4 or later** or **MXNet 1.7.0 or later** and you have an Amazon SageMaker AI endpoint `InService`, you can make inference requests using the `predictor` package of the SageMaker Python SDK.

> **Note**
>
> The API varies based on the SageMaker Python SDK version:
>
> - For version 1.x, use the `RealTimePredictor` and `Predict` API.
> - For version 3.x, use the `Endpoint` and the `invoke` API.

The following code example shows how to use these APIs to send an image for inference:

```
from sagemaker.core.resources import Endpoint

endpoint_name = 'insert name of your endpoint here'

# Read image into memory
payload = None
with open("image.jpg", 'rb') as f:
    payload = f.read()

endpoint = Endpoint(endpoint_name=endpoint_name)
inference_response = endpoint.invoke(body=payload, content_type='application/x-image')
print(inference_response.body.read().decode('utf-8'))
```

TensorFlow

The following code example shows how to use the SageMaker Python SDK API to send an image for inference:

```
from sagemaker.core.resources import Endpoint
from PIL import Image
import numpy as np
import json

endpoint_name = 'insert the name of your endpoint here'
```

```
# Read image into memory
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({"instances": image.tolist()})

endpoint = Endpoint(endpoint_name=endpoint_name)
inference_response = endpoint.invoke(body=body, content_type='application/json')
print(inference_response)
```

Request Inferences from a Deployed Service (Boto3)

You can submit inference requests using SageMaker AI SDK for Python (Boto3) client and `invoke_endpoint()` API once you have an SageMaker AI endpoint `InService`. The following code example shows how to send an image for inference:

PyTorch and MXNet

```
import boto3

import json

endpoint = 'insert name of your endpoint here'

runtime = boto3.Session().client('sagemaker-runtime')

# Read image into memory
with open(image, 'rb') as f:
    payload = f.read()
# Send image via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='application/
x-image', Body=payload)

# Unpack response
result = json.loads(response['Body'].read().decode('utf-8'))
```

TensorFlow

For TensorFlow submit an input with `application/json` for the content type.

```
from PIL import Image
```

```
import numpy as np
import json
import boto3

client = boto3.client('sagemaker-runtime')
input_file = 'path/to/image'
image = Image.open(input_file)
batch_size = 1
image = np.asarray(image.resize((224, 224)))
image = image / 128 - 1
image = np.concatenate([image[np.newaxis, :, :]] * batch_size)
body = json.dumps({"instances": image.tolist()})
ioc_predictor_endpoint_name = 'insert name of your endpoint here'
content_type = 'application/json'
ioc_response = client.invoke_endpoint(
    EndpointName=ioc_predictor_endpoint_name,
    Body=body,
    ContentType=content_type
 )
```

XGBoost

For an XGBoost application, you should submit a CSV text instead:

```
import boto3
import json

endpoint = 'insert your endpoint name here'

runtime = boto3.Session().client('sagemaker-runtime')

csv_text = '1,-1.0,1.0,1.5,2.6'
# Send CSV text via InvokeEndpoint API
response = runtime.invoke_endpoint(EndpointName=endpoint, ContentType='text/csv',
 Body=csv_text)
# Unpack response
result = json.loads(response['Body'].read().decode('utf-8'))
```

Note that BYOM allows for a custom content type. For more information, see runtime_InvokeEndpoint.

Request Inferences from a Deployed Service (Amazon CLI)

Inference requests can be made with the `sagemaker-runtime invoke-endpoint` once you have an Amazon SageMaker AI endpoint `InService`. You can make inference requests with the Amazon Command Line Interface (Amazon CLI). The following example shows how to send an image for inference:

```
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint
 here' --body fileb://image.jpg --content-type=application/x-image output_file.txt
```

An `output_file.txt` with information about your inference requests is made if the inference was successful.

For TensorFlow submit an input with `application/json` as the content type.

```
aws sagemaker-runtime invoke-endpoint --endpoint-name 'insert name of your endpoint
 here' --body fileb://input.json --content-type=application/json output_file.txt
```

Inference Container Images

SageMaker Neo now provides inference image URI information for `ml_*` targets. For more information see DescribeCompilationJob.

Based on your use case, replace the highlighted portion in the inference image URI template provided below with appropriate values.

Amazon SageMaker AI XGBoost

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/xgboost-neo:latest
```

Replace *aws_account_id* from the table at the end of this page based on the *aws_region* you used.

Keras

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-keras:fx_version-
instance_type-py3
```

Replace *aws_account_id* from the table at the end of this page based on the *aws_region* you used.

Replace *fx_version* with 2.2.4.

Replace *instance_type* with either cpu or gpu.

MXNet

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-
mxnet:fx_version-instance_type-py3
```

Replace *aws_account_id* from the table at the end of this page based on the *aws_region* you used.

Replace *fx_version* with 1.8.0.

Replace *instance_type* with either cpu or gpu.

Inferentia1

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-
mxnet:fx_version-instance_type-py3
```

Replace *aws_region* with either us-east-1 or us-west-2.

Replace *aws_account_id* from the table at the end of this page based on the *aws_region* you used.

Replace *fx_version* with 1.5.1.

Replace *instance_type* with inf.

ONNX

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-onnx:fx_version-
instance_type-py3
```

Replace *aws_account_id* from the table at the end of this page based on the *aws_region* you used.

Replace *fx_version* with 1.5.0.

Replace *instance_type* with either cpu or gpu.

PyTorch

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-
pytorch:fx_version-instance_type-py3
```

Replace *aws_account_id* from the table at the end of this page based on the *aws_region* you used.

Replace *fx_version* with `1.4`, `1.5`, `1.6`, `1.7`, `1.8`, `1.12`, `1.13`, or `2.0`.

Replace *instance_type* with either `cpu` or `gpu`.

Inferentia1

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-
pytorch:fx_version-instance_type-py3
```

Replace *aws_region* with either `us-east-1` or `us-west-2`.

Replace *aws_account_id* from the table at the end of this page based on the *aws_region* you used.

Replace *fx_version* with `1.5.1`.

Replace *instance_type* with `inf`.

Inferentia2 and Trainium1

```
763104351884.dkr.ecr.aws_region.amazonaws.com/pytorch-inference-neuronx:1.13.1-
neuronx-py38-sdk2.10.0-ubuntu20.04
```

Replace *aws_region* with `us-east-2` for Inferentia2, and `us-east-1` for Trainium1.

TensorFlow

CPU or GPU instance types

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-inference-
tensorflow:fx_version-instance_type-py3
```

Replace *aws_account_id* from the table at the end of this page based on the *aws_region* you used.

Replace *fx_version* with `1.15.3` or `2.9`.

Replace *instance_type* with either cpu or gpu.

Inferentia1

```
aws_account_id.dkr.ecr.aws_region.amazonaws.com/sagemaker-neo-
tensorflow:fx_version-instance_type-py3
```

Replace *aws_account_id* from the table at the end of this page based on the *aws_region* you used. Note that for instance type `inf` only `us-east-1` and `us-west-2` are supported.

Replace *fx_version* with `1.15.0`

Replace *instance_type* with `inf`.

Inferentia2 and Trainium1

```
763104351884.dkr.ecr.aws_region.amazonaws.com/tensorflow-inference-neuronx:2.10.1-
neuronx-py38-sdk2.10.0-ubuntu20.04
```

Replace *aws_region* with `us-east-2` for Inferentia2, and `us-east-1` for Trainium1.

The following table maps *aws_account_id* with *aws_region*. Use this table to find the correct inference image URI you need for your application.

aws_account_id	aws_region
785573368785	us-east-1
007439368137	us-east-2
710691900526	us-west-1
301217895009	us-west-2
802834080501	eu-west-1
205493899709	eu-west-2

aws_account_id	aws_region
254080097072	eu-west-3
601324751636	eu-north-1
966458181534	eu-south-1
746233611703	eu-central-1
110948597952	ap-east-1

756306329178	sa-east-1
464438896020	ca-central-1
836785723513	me-south-1
774647643957	af-south-1
275950707576	il-central-1

Edge Devices

Amazon SageMaker Neo provides compilation support for popular machine learning frameworks. You can deploy your Neo-compiled edge devices such as the Raspberry Pi 3, Texas Instruments' Sitara, Jetson TX1, and more. For a full list of supported frameworks and edge devices, see Supported Frameworks, Devices, Systems, and Architectures.

You must configure your edge device so that it can use Amazon services. One way to do this is to install DLR and Boto3 to your device. To do this, you must set up the authentication credentials. See Boto3 Amazon Configuration for more information. Once your model is compiled and your edge device is configured, you can download the model from Amazon S3 to your edge device. From there, you can use the Deep Learning Runtime (DLR) to read the compiled model and make inferences.

For first-time users, we recommend you check out the Getting Started guide. This guide walks you through how to set up your credentials, compile a model, deploy your model to a Raspberry Pi 3, and make inferences on images.

Topics

- Supported Frameworks, Devices, Systems, and Architectures
- Deploy Models
- Set up Neo on Edge Devices

Supported Frameworks, Devices, Systems, and Architectures

Amazon SageMaker Neo supports common machine learning frameworks, edge devices, operating systems, and chip architectures. Find out if Neo supports your framework, edge device, OS, and chip architecture by selecting one of the topics below.

You can find a list of models that have been tested by the Amazon SageMaker Neo Team in the Tested Models section.

Note

- Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation. For more information, see Troubleshoot Ambarella Errors.

- TIM-VX (libtim-vx.so) is required for i.MX 8M Plus. For information on how to build TIM-VX, see the TIM-VX GitHub repository.

Topics

- Supported Frameworks
- Supported Devices, Chip Architectures, and Systems
- Tested Models

Supported Frameworks

Amazon SageMaker Neo supports the following frameworks.

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
MXNet	1.8	Supports 1.8 or earlier	Image Classification, Object Detection, Semantic Segmentation, Pose Estimation, Activity Recognition	One symbol file (.json) and one parameter file (.params)	GluonCV v0.8.0
ONNX	1.7	Supports 1.7 or earlier	Image Classification, SVM	One model file (.onnx)	
Keras	2.2	Supports 2.2 or earlier	Image Classification	One model definition file (.h5)	

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
PyTorch	1.7, 1.8	Supports 1.7, 1.8 or earlier	Image Classification, Object Detection	One model definition file (.pth)	
TensorFlow	1.15, 2.4, 2.5 (only for ml.inf1.* instances)	Supports 1.15, 2.4, 2.5 (only for ml.inf1.* instances) or earlier	Image Classification, Object Detection	*For saved models, one .pb or one .pbtxt file and a variables directory that contains variables *For frozen models, only one .pb or .pbtxt file	
TensorFlow-Lite	1.15	Supports 1.15 or earlier	Image Classification, Object Detection	One model definition flatbuffer file (.tflite)	
XGBoost	1.3	Supports 1.3 or earlier	Decision Trees	One XGBoost model file (.model) where the number of nodes in a tree is less than 2^31	

Framework	Framework Version	Model Version	Models	Model Formats (packaged in *.tar.gz)	Toolkits
DARKNET			Image Classific ation, Object Detection (Yolo model is not supported)	One config (.cfg) file and one weights (.weights) file	

Supported Devices, Chip Architectures, and Systems

Amazon SageMaker Neo supports the following devices, chip architectures, and operating systems.

Devices

You can select a device using the dropdown list in the Amazon SageMaker AI console or by specifying the `TargetDevice` in the output configuration of the `CreateCompilationJob` API.

You can choose from one of the following edge devices:

Device List	System on a Chip (SoC)	Operating System	Architecture	Accelerator	Compiler Options Example
aisage	*None*	Linux	ARM64	Mali	*None*
amba_cv2	CV2	Arch Linux	ARM64	cvflow	*None*
amba_cv22	CV22	Arch Linux	ARM64	cvflow	*None*
amba_cv25	CV25	Arch Linux	ARM64	cvflow	*None*
coreml	*None*	iOS, macOS	*None*	*None*	`{"class_labels": "imagenet`

Device List	System on a Chip (SoC)	Operating System	Architecture	Accelerator	Compiler Options Example
					`_labels_1000.txt"}`

Deploy Models

You can deploy the compute module to resource-constrained edge devices by: downloading the compiled model from Amazon S3 to your device and using DLR, or you can use Amazon IoT Greengrass.

Before moving on, make sure your edge device must be supported by SageMaker Neo. See, Supported Frameworks, Devices, Systems, and Architectures to find out what edge devices are supported. Make sure that you specified your target edge device when you submitted the compilation job, see Use Neo to Compile a Model.

Deploy a Compiled Model (DLR)

DLR is a compact, common runtime for deep learning models and decision tree models. DLR uses the TVM runtime, Treelite runtime, NVIDIA TensorRT™, and can include other hardware-specific runtimes. DLR provides unified Python/C++ APIs for loading and running compiled models on various devices.

You can install latest release of DLR package using the following pip command:

```
pip install dlr
```

For installation of DLR on GPU targets or non-x86 edge devices, please refer to Releases for prebuilt binaries, or Installing DLR for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

```
pip install https://neo-ai-dlr-release.s3-us-west-2.amazonaws.com/v1.3.0/pi-armv7l-
raspbian4.14.71-glibc2_24-libstdcpp3_4/dlr-1.3.0-py3-none-any.whl
```

Deploy a Model (Amazon IoT Greengrass)

Amazon IoT Greengrass extends cloud capabilities to local devices. It enables devices to collect and analyze data closer to the source of information, react autonomously to local events, and communicate securely with each other on local networks. With Amazon IoT Greengrass, you can perform machine learning inference at the edge on locally generated data using cloud-trained models. Currently, you can deploy models on to all Amazon IoT Greengrass devices based on ARM Cortex-A, Intel Atom, and Nvidia Jetson series processors. For more information on deploying a Lambda inference application to perform machine learning inferences with Amazon IoT Greengrass, see How to configure optimized machine learning inference using the Amazon Management Console.

Set up Neo on Edge Devices

This guide to getting started with Amazon SageMaker Neo shows you how to compile a model, set up your device, and make inferences on your device. Most of the code examples use Boto3. We provide commands using Amazon CLI where applicable, as well as instructions on how to satisfy prerequisites for Neo.

> **Note**
>
> You can run the following code snippets on your local machine, within a SageMaker notebook, within Amazon SageMaker Studio, or (depending on your edge device) on your edge device. The setup is similar; however, there are two main exceptions if you run this guide within a SageMaker notebook instance or SageMaker Studio session:
>
> - You do not need to install Boto3.
> - You do not need to add the `'AmazonSageMakerFullAccess'` IAM policy

This guide assumes you are running the following instructions on your edge device.

Prerequisites

SageMaker Neo is a capability that allows you to train machine learning models once and run them anywhere in the cloud and at the edge. Before you can compile and optimize your models with Neo, there are a few prerequisites you need to set up. You must install the necessary Python libraries, configure your Amazon credentials, create an IAM role with the required permissions, and

set up an S3 bucket for storing model artifacts. You must also have a trained machine learning model ready. The following steps guide you through the setup:

1. **Install Boto3**

   If you are running these commands on your edge device, you must install the Amazon SDK for Python (Boto3). Within a Python environment (preferably a virtual environment), run the following locally on your edge device's terminal or within a Jupyter notebook instance:

   Terminal

   ```
   pip install boto3
   ```

   Jupyter Notebook

   ```
   !pip install boto3
   ```

2. **Set Up Amazon Credentials**

   You need to set up Amazon Web Services credentials on your device in order to run SDK for Python (Boto3). By default, the Amazon credentials should be stored in the file `~/.aws/credentials` on your edge device. Within the credentials file, you should see two environment variables: `aws_access_key_id` and `aws_secret_access_key`.

   In your terminal, run:

   ```
   $ more ~/.aws/credentials

   [default]
   aws_access_key_id = YOUR_ACCESS_KEY
   aws_secret_access_key = YOUR_SECRET_KEY
   ```

   The Amazon General Reference Guide has instructions on how to get the necessary `aws_access_key_id` and `aws_secret_access_key`. For more information on how to set up credentials on your device, see the Boto3 documentation.

3. **Set up an IAM Role and attach policies.**

   Neo needs access to your S3 bucket URI. Create an IAM role that can run SageMaker AI and has permission to access the S3 URI. You can create an IAM role either by using SDK for Python

(Boto3), the console, or the Amazon CLI. The following example illustrates how to create an IAM role using SDK for Python (Boto3):

```
import boto3

AWS_REGION = 'aws-region'

# Create an IAM client to interact with IAM
iam_client = boto3.client('iam', region_name=AWS_REGION)
role_name = 'role-name'
```

For more information on how to create an IAM role with the console, Amazon CLI, or through the Amazon API, see Creating an IAM user in your Amazon account.

Create a dictionary describing the IAM policy you are attaching. This policy is used to create a new IAM role.

```
policy = {
    'Statement': [
        {
            'Action': 'sts:AssumeRole',
            'Effect': 'Allow',
            'Principal': {'Service': 'sagemaker.amazonaws.com'},
        }],
     'Version': '2012-10-17       '
}
```

Create a new IAM role using the policy you defined above:

```
import json

new_role = iam_client.create_role(
    AssumeRolePolicyDocument=json.dumps(policy),
    Path='/',
    RoleName=role_name
)
```

You need to know what your Amazon Resource Name (ARN) is when you create a compilation job in a later step, so store it in a variable as well.

```
role_arn = new_role['Role']['Arn']
```

Now that you have created a new role, attach the permissions it needs to interact with Amazon SageMaker AI and Amazon S3:

```
iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonSageMakerFullAccess'
)

iam_client.attach_role_policy(
    RoleName=role_name,
    PolicyArn='arn:aws:iam::aws:policy/AmazonS3FullAccess'
);
```

4. **Create an Amazon S3 bucket to store your model artifacts**

   SageMaker Neo will access your model artifacts from Amazon S3

   Boto3

   ```
   # Create an S3 client
   s3_client = boto3.client('s3', region_name=AWS_REGION)

   # Name buckets
   bucket='name-of-your-bucket'

   # Check if bucket exists
   if boto3.resource('s3').Bucket(bucket) not in
    boto3.resource('s3').buckets.all():
       s3_client.create_bucket(
           Bucket=bucket,
           CreateBucketConfiguration={
               'LocationConstraint': AWS_REGION
           }
       )
   else:
       print(f'Bucket {bucket} already exists. No action needed.')
   ```

CLI

```
aws s3 mb s3://'name-of-your-bucket' --region specify-your-region

# Check your bucket exists
aws s3 ls s3://'name-of-your-bucket'/
```

5. **Train a machine learning model**

   See Train a Model with Amazon SageMaker AI for more information on how to train a machine learning model using Amazon SageMaker AI. You can optionally upload your locally trained model directly into an Amazon S3 URI bucket.

   > **Note**
   >
   > Make sure the model is correctly formatted depending on the framework you used. See What input data shapes does SageMaker Neo expect?

   If you do not have a model yet, use the `curl` command to get a local copy of the `coco_ssd_mobilenet` model from TensorFlow's website. The model you just copied is an object detection model trained from the COCO dataset. Type the following into your Jupyter notebook:

```
model_zip_filename = './coco_ssd_mobilenet_v1_1.0.zip'
!curl http://storage.googleapis.com/download.tensorflow.org/models/tflite/
coco_ssd_mobilenet_v1_1.0_quant_2018_06_29.zip \
    --output {model_zip_filename}
```

   Note that this particular example was packaged in a .zip file. Unzip this file and repackage it as a compressed tarfile (`.tar.gz`) before using it in later steps. Type the following into your Jupyter notebook:

```
# Extract model from zip file
!unzip -u {model_zip_filename}

model_filename = 'detect.tflite'
model_name = model_filename.split('.')[0]
```

```
# Compress model into .tar.gz so SageMaker Neo can use it
model_tar = model_name + '.tar.gz'
!tar -czf {model_tar} {model_filename}
```

6. **Upload trained model to an S3 bucket**

   Once you have trained your machine learning mode, store it in an S3 bucket.

   Boto3

   ```
   # Upload model
   s3_client.upload_file(Filename=model_filename, Bucket=bucket,
    Key=model_filename)
   ```

   CLI

   Replace `your-model-filename` and `amzn-s3-demo-bucket` with the name of your S3 bucket.

   ```
   aws s3 cp your-model-filename s3://amzn-s3-demo-bucket
   ```

Compile the Model

Once you have satisfied the Prerequisites, you can compile your model with Amazon SageMaker AI Neo. You can compile your model using the Amazon CLI, the console or the Amazon Web Services SDK for Python (Boto3), see Use Neo to Compile a Model. In this example, you will compile your model with Boto3.

To compile a model, SageMaker Neo requires the following information:

1. **The Amazon S3 bucket URI where you stored the trained model.**

   If you followed the prerequisites, the name of your bucket is stored in a variable named `bucket`. The following code snippet shows how to list all of your buckets using the Amazon CLI:

   ```
   aws s3 ls
   ```

   For example:

```
$ aws s3 ls
2020-11-02 17:08:50 bucket
```

2. **The Amazon S3 bucket URI where you want to save the compiled model.**

   The code snippet below concatenates your Amazon S3 bucket URI with the name of an output directory called `output`:

   ```
   s3_output_location = f's3://{bucket}/output'
   ```

3. **The machine learning framework you used to train your model.**

   Define the framework you used to train your model.

   ```
   framework = 'framework-name'
   ```

   For example, if you wanted to compile a model that was trained using TensorFlow, you could either use `tflite` or `tensorflow`. Use `tflite` if you want to use a lighter version of TensorFlow that uses less storage memory.

   ```
   framework = 'tflite'
   ```

   For a complete list of Neo-supported frameworks, see Supported Frameworks, Devices, Systems, and Architectures.

4. **The shape of your model's input.**

   Neo requires the name and shape of your input tensor. The name and shape are passed in as key-value pairs. `value` is a list of the integer dimensions of an input tensor and `key` is the exact name of an input tensor in the model.

   ```
   data_shape = '{"name": [tensor-shape]}'
   ```

   For example:

   ```
   data_shape = '{"normalized_input_image_tensor":[1, 300, 300, 3]}'
   ```

> **Note**
>
> Make sure the model is correctly formatted depending on the framework you used. See What input data shapes does SageMaker Neo expect? The key in this dictionary must be changed to the new input tensor's name.

5. **Either the name of the target device to compile for or the general details of the hardware platform**

```
target_device = 'target-device-name'
```

For example, if you want to deploy to a Raspberry Pi 3, use:

```
target_device = 'rasp3b'
```

You can find the entire list of supported edge devices in Supported Frameworks, Devices, Systems, and Architectures.

Now that you have completed the previous steps, you can submit a compilation job to Neo.

```
# Create a SageMaker client so you can submit a compilation job
sagemaker_client = boto3.client('sagemaker', region_name=AWS_REGION)

# Give your compilation job a name
compilation_job_name = 'getting-started-demo'
print(f'Compilation job for {compilation_job_name} started')

response = sagemaker_client.create_compilation_job(
    CompilationJobName=compilation_job_name,
    RoleArn=role_arn,
    InputConfig={
        'S3Uri': s3_input_location,
        'DataInputConfig': data_shape,
        'Framework': framework.upper()
    },
    OutputConfig={
        'S3OutputLocation': s3_output_location,
        'TargetDevice': target_device
    },
```

```
    StoppingCondition={
        'MaxRuntimeInSeconds': 900
    }
)

# Optional - Poll every 30 sec to check completion status
import time

while True:
    response =
 sagemaker_client.describe_compilation_job(CompilationJobName=compilation_job_name)
    if response['CompilationJobStatus'] == 'COMPLETED':
        break
    elif response['CompilationJobStatus'] == 'FAILED':
        raise RuntimeError('Compilation failed')
    print('Compiling ...')
    time.sleep(30)
print('Done!')
```

If you want additional information for debugging, include the following print statement:

```
print(response)
```

If the compilation job is successful, your compiled model isstored in the output Amazon S3 bucket you specified earlier (`s3_output_location`). Download your compiled model locally:

```
object_path = f'output/{model}-{target_device}.tar.gz'
neo_compiled_model = f'compiled-{model}.tar.gz'
s3_client.download_file(bucket, object_path, neo_compiled_model)
```

Set Up Your Device

You will need to install packages on your edge device so that your device can make inferences. You will also need to either install Amazon IoT Greengrass core or Deep Learning Runtime (DLR). In this example, you will install packages required to make inferences for the `coco_ssd_mobilenet` object detection algorithm and you will use DLR.

1. **Install additional packages**

   In addition to Boto3, you must install certain libraries on your edge device. What libraries you install depends on your use case.

For example, for the `coco_ssd_mobilenet` object detection algorithm you downloaded earlier, you need to install NumPy for data manipulation and statistics, PIL to load images, and Matplotlib to generate plots. You also need a copy of TensorFlow if you want to gauge the impact of compiling with Neo versus a baseline.

```
!pip3 install numpy pillow tensorflow matplotlib
```

2. **Install inference engine on your device**

   To run your Neo-compiled model, install the Deep Learning Runtime (DLR) on your device. DLR is a compact, common runtime for deep learning models and decision tree models. On x86_64 CPU targets running Linux, you can install the latest release of the DLR package using the following `pip` command:

   ```
   !pip install dlr
   ```

   For installation of DLR on GPU targets or non-x86 edge devices, refer to Releases for prebuilt binaries, or Installing DLR for building DLR from source. For example, to install DLR for Raspberry Pi 3, you can use:

   ```
   !pip install https://neo-ai-dlr-release.s3-us-west-2.amazonaws.com/v1.3.0/pi-
   armv7l-raspbian4.14.71-glibc2_24-libstdcpp3_4/dlr-1.3.0-py3-none-any.whl
   ```

Make Inferences on Your Device

In this example, you will use Boto3 to download the output of your compilation job onto your edge device. You will then import DLR, download an example images from the dataset, resize this image to match the model's original input, and then you will make a prediction.

1. **Download your compiled model from Amazon S3 to your device and extract it from the compressed tarfile.**

   ```
   # Download compiled model locally to edge device
   object_path = f'output/{model_name}-{target_device}.tar.gz'
   neo_compiled_model = f'compiled-{model_name}.tar.gz'
   s3_client.download_file(bucket_name, object_path, neo_compiled_model)

   # Extract model from .tar.gz so DLR can use it
   ```

```
!mkdir ./dlr_model # make a directory to store your model (optional)
!tar -xzvf ./compiled-detect.tar.gz --directory ./dlr_model
```

2. **Import DLR and an initialized `DLRModel` object.**

```
import dlr

device = 'cpu'
model = dlr.DLRModel('./dlr_model', device)
```

3. **Download an image for inferencing and format it based on how your model was trained**.

   For the `coco_ssd_mobilenet` example, you can download an image from the COCO dataset and then reform the image to `300x300`:

```
from PIL import Image

# Download an image for model to make a prediction
input_image_filename = './input_image.jpg'
!curl https://farm9.staticflickr.com/8325/8077197378_79efb4805e_z.jpg --output
 {input_image_filename}

# Format image so model can make predictions
resized_image = image.resize((300, 300))

# Model is quantized, so convert the image to uint8
x = np.array(resized_image).astype('uint8')
```

4. **Use DLR to make inferences**.

   Finally, you can use DLR to make a prediction on the image you just downloaded:

```
out = model.run(x)
```

For more examples using DLR to make inferences from a Neo-compiled model on an edge device, see the neo-ai-dlr Github repository.

Troubleshoot Errors

This section contains information about how to understand and prevent common errors, the error messages they generate, and guidance on how to resolve these errors. Before moving on, ask yourself the following questions:

Did you encounter an error before you deployed your model? If yes, see Troubleshoot Neo Compilation Errors.

Did you encounter an error after you compiled your model? If yes, see Troubleshoot Neo Inference Errors.

Did you encounter an error trying to compile your model for Ambarella devices? If yes, see Troubleshoot Ambarella Errors.

Error Classification Types

This list classifies the *user errors* you can receive from Neo. These include access and permission errors and load errors for each of the supported frameworks. All other errors are *system errors*.

Client permission error

Neo passes the errors for these straight through from the dependent service.

- *Access Denied* when calling sts:AssumeRole
- *Any 400* error when calling Amazon S3 to download or upload a client model
- *PassRole* error

Load error

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, check whether the tarball contains the necessary files for compilation. The checking criteria is framework-specific:

- **TensorFlow**: Expects only protobuf file (*.pb or *.pbtxt). For saved models, expects one variables folder.
- **Pytorch**: Expect only one pytorch file (*.pth).
- **MXNET**: Expect only one symbol file (*.json) and one parameter file (*.params).
- **XGBoost**: Expect only one XGBoost model file (*.model). The input model has size limitation.

Compilation error

Assuming that the Neo compiler successfully loaded .tar.gz from Amazon S3, and that the tarball contains necessary files for compilation. The checking criteria is:

- **OperatorNotImplemented**: An operator has not been implemented.
- **OperatorAttributeNotImplemented**: The attribute in the specified operator has not been implemented.
- **OperatorAttributeRequired**: An attribute is required for an internal symbol graph, but it is not listed in the user input model graph.
- **OperatorAttributeValueNotValid**: The value of the attribute in the specific operator is not valid.

Troubleshoot Neo Compilation Errors

This section contains information about how to understand and prevent common compilation errors, the error messages they generate, and guidance on how to resolve these errors.

Topics

- How to Use This Page
- Framework-Related Errors
- Infrastructure-Related Errors
- Check your compilation log

How to Use This Page

Attempt to resolve your error by the going through these sections in the following order:

1. Check that the input of your compilation job satisfies the input requirements. See What input data shapes does SageMaker Neo expect?
2. Check common framework-specific errors.

3. Check if your error is an infrastructure error.
4. Check your compilation log.

Framework-Related Errors

Keras

Error	Solution
`InputConfiguration: No h5 file provided in <model path>`	Check your h5 file is in the Amazon S3 URI you specified. *Or* Check that the h5 file is correctly formatted.
`InputConfiguration: Multiple h5 files provided, <model path>, when only one is allowed`	Check you are only providing one h5 file.
`ClientError: InputConfiguration: Unable to load provided Keras model. Error: 'sample_weight_mode'`	Check the Keras version you specified is supported. See, supported frameworks for cloud instances and edge devices.
`ClientError: InputConfiguration: Input input has wrong shape in Input Shape dictionary. Input shapes should be provided in NCHW format.`	Check that your model input follows NCHW format. See What input data shapes does SageMaker Neo expect?

MXNet

Error	Solution
`ClientError: InputConfiguration: Only one parameter file is allowed for MXNet model. Please make sure the framework you select is correct.`	SageMaker Neo will select the first parameter file given for compilation.

TensorFlow

Error	Solution
`InputConfiguration: Exactly one .pb file is allowed for TensorFlow models.`	Make sure you only provide one .pb or .pbtxt file.
`InputConfiguration: Exactly one .pb or .pbtxt file is allowed for TensorFlow models.`	Make sure you only provide one .pb or .pbtxt file.
`ClientError: InputConfiguration: TVM cannot convert <model zoo> model. Please make sure the framework you selected is correct. The following operators are not implemented: {<operator name>}`	Check the operator you chose is supported. See SageMaker Neo Supported Frameworks and Operators.

PyTorch

Error	Solution
`InputConfiguration: We are unable to extract DataInputConfig from the model due to` *`input_config_derivation_error`* `. Please override by providing a DataInputConfig during compilation job creation.`	Do either of the following: • Specify the name and shape of the expected inputs by providing a `DataInputConfig`

Error	Solution
	definition in your compilation request. • Investigate the error in Amazon CloudWatch Logs. Check the `/aws/sagemaker/CompilationJobs` log group and look for a log stream named *`compilationJobName`*`/model-info-extraction .`

Infrastructure-Related Errors

Error	Solution
`ClientError: InputConfiguration: S3 object does not exist. Bucket: <bucket>, Key: <bucket key>`	Check the Amazon S3 URI your provided.
`ClientError: InputConfiguration: Bucket <bucket name> is in region <region name> which is different from Amazon Sagemaker service region <service region>`	Create an Amazon S3 bucket that is in the same region as the service.
`ClientError: InputConfiguration: Unable to untar input model. Please confirm the model is a tar.gz file`	Check that your model in Amazon S3 is compressed into a `tar.gz` file.

Check your compilation log

1. Navigate to Amazon CloudWatch at https://console.amazonaws.cn/cloudwatch/.
2. Select the region you created the compilation job from the **Region** dropdown list in the top right.

3. In the navigation pane of the Amazon CloudWatch, choose **Logs**. Select **Log groups**.
4. Search for the log group called `/aws/sagemaker/CompilationJobs`. Select the log group.
5. Search for the logstream named after the compilation job name. Select the log stream.

Troubleshoot Neo Inference Errors

This section contains information about how to prevent and resolve some of the common errors you might encounter upon deploying and/or invoking the endpoint. This section applies to **PyTorch 1.4.0 or later** and **MXNet v1.7.0 or later**.

- Make sure the first inference (warm-up inference) on a valid input data is done in `model_fn()`, if you defined a `model_fn` in your inference script, otherwise the following error message may be seen on the terminal when `predict API` is called:

```
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received
 server error (0) from <users-sagemaker-endpoint> with message "Your invocation timed
 out while waiting for a response from container model. Review the latency metrics
 for each container in Amazon CloudWatch, resolve the issue, and try again."
```

- Make sure that the environment variables in the following table are set. If they are not set, the following error message might show up:

  On the terminal:

```
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received
 server error (503) from <users-sagemaker-endpoint> with message "{ "code": 503,
 "type": "InternalServerException", "message": "Prediction failed" } ".
```

  In CloudWatch:

```
W-9001-model-stdout com.amazonaws.ml.mms.wlm.WorkerLifeCycle - AttributeError:
 'NoneType' object has no attribute 'transform'
```

Key	Value
SAGEMAKER_PROGRAM	inference.py

Key	Value
SAGEMAKER_SUBMIT_DIRECTORY	/opt/ml/model/code
SAGEMAKER_CONTAINER_LOG_LEVEL	20
SAGEMAKER_REGION	<your region>

- Make sure that the `MMS_DEFAULT_RESPONSE_TIMEOUT` environment variable is set to 500 or a higher value while creating the Amazon SageMaker AI model; otherwise, the following error message may be seen on the terminal:

```
An error occurred (ModelError) when calling the InvokeEndpoint operation: Received
 server error (0) from <users-sagemaker-endpoint> with message "Your invocation timed
 out while waiting for a response from container model. Review the latency metrics
 for each container in Amazon CloudWatch, resolve the issue, and try again."
```

Troubleshoot Ambarella Errors

SageMaker Neo requires models to be packaged in a compressed TAR file (`*.tar.gz`). Ambarella devices require additional files to be included within the compressed TAR file before it is sent for compilation. Include the following files within your compressed TAR file if you want to compile a model for Ambarella targets with SageMaker Neo:

- A trained model using a framework supported by SageMaker Neo
- A JSON configuration file
- Calibration images

For example, the contents of your compressed TAR file should look similar to the following example:

```
###amba_config.json
###calib_data
|    ### data1
|    ### data2
|    ### .
|    ### .
|    ### .
|    ### data500
```

```
###mobilenet_v1_1.0_0224_frozen.pb
```

The directory is configured as follows:

- `amba_config.json` : Configuration file
- `calib_data` : Folder containing calibration images
- `mobilenet_v1_1.0_0224_frozen.pb` : TensorFlow model saved as a frozen graph

For information about frameworks supported by SageMaker Neo, see Supported Frameworks.

Setting up the Configuration File

The configuration file provides information required by the Ambarella toolchain to compile the model. The configuration file must be saved as a JSON file and the name of the file must end with `*config.json`. The following chart shows the contents of the configuration file.

Key	Description	Example
inputs	Dictionary mapping input layers to attribute.	`{inputs:{"data":{...},"data1":{...}}}`
"data"	Input layer name. Note: "data" is an example of the name you can use to label the input layer.	"data"
shape	Describes the shape of the input to the model. This follows the same conventions that SageMaker Neo uses.	"shape": "1,3,224,224"
filepath	Relative path to the directory containing calibration images. These can be binary or image files like JPG or PNG.	"filepath": "calib_data/"
colorformat	Color format that model expects. This will be used	"colorformat":"RGB"

Key	Description	Example
	while converting images to binary. Supported values: [RGB, BGR]. Default is RGB.	
mean	Mean value to be subtracted from the input. Can be a single value or a list of values. When the mean is given as a list the number of entries must match the channel dimension of the input.	"mean":128.0
scale	Scale value to be used for normalizing the input. Can be a single value or a list of values. When the scale is given as a list, the number of entries must match the channel dimension of the input.	"scale": 255.0

The following is a sample configuration file:

```
{
    "inputs": {
        "data": {
                "shape": "1, 3, 224, 224",
                "filepath": "calib_data/",
                "colorformat": "RGB",
                "mean":[128,128,128],
                "scale":[128.0,128.0,128.0]
        }
    }
}
```

Calibration Images

Quantize your trained model by providing calibration images. Quantizing your model improves the performance of the CVFlow engine on an Ambarella System on a Chip (SoC). The Ambarella toolchain uses the calibration images to determine how each layer in the model should be quantized to achieve optimal performance and accuracy. Each layer is quantized independently to INT8 or INT16 formats. The final model has a mix of INT8 and INT16 layers after quantization.

How many images should you use?

It is recommended that you include between 100–200 images that are representative of the types of scenes the model is expected to handle. The model compilation time increases linearly to the number of calibration images in the input file.

What are the recommended image formats?

Calibration images can be in a raw binary format or image formats such as JPG and PNG.

Your calibration folder can contain a mixture of images and binary files. If the calibration folder contains both images and binary files, the toolchain first converts the images to binary files. Once the conversion is complete, it uses the newly generated binary files along with the binary files that were originally in the folder.

Can I convert the images into binary format first?

Yes. You can convert the images to the binary format with open-source packages such as OpenCV or PIL. Crop and resize the images so they satisfy the input layer of your trained model.

Mean and Scale

You can specify mean and scaling pre-processing options to the Amberalla toolchain. These operations are embedded into the network and are applied during inference on each input. Do not provide processed data if you specify the mean or scale. More specifically, do not provide data you have subtracted the mean from or have applied scaling to.

Check your compilation log

For information on checking compilation log for Ambarella devices, see Check your compilation log.

Stateful sessions with Amazon SageMaker AI models

When you send requests to an Amazon SageMaker AI inference endpoint, you can choose to route the requests to a *stateful session*. During a stateful session, you send multiple inference requests to the same ML instance, and the instance facilitates the session.

Normally, when you invoke an inference endpoint, Amazon SageMaker AI routes your request to any one ML instance among the multiple instances that the endpoint hosts. This routing behavior helps minimize latency by evenly distributing your inference traffic. However, one outcome of the routing behavior is that you can't predict which instance will serve your request.

This unpredictability is a limitation if you intend to send your request to a *stateful model*. A stateful model has a container that caches the context data that it receives from inference requests. Because the data is cached, you can interact with the container by sending multiple requests, and with each request, you don't need to include the full context of the interaction. Instead, the model draws from the cached context data to inform its prediction.

Stateful models are ideal when the context data for the interaction is very large, such as when it includes the following:

- Large text files
- Long chat histories
- Multimedia data (images, video, and audio) for multimodal models

In these cases, if you pass the full context with every prompt, the network latency of your requests is slowed, and responsiveness of your application is diminished.

Before your inference endpoint can support a stateful session, it must host a stateful model. The implementation of the stateful model is owned by you. Amazon SageMaker AI makes it possible for you to route your requests to a stateful session, but it doesn't provide stateful models that you can deploy and use.

For an example notebook and model container that demonstrates how stateful interactions are implemented, see Example implementation.

For information about implementing stateful models with TorchServe, see Stateful Inference in the TorchServe GitHub repository.

How stateful sessions work

During a stateful session, your application interacts with your model container in the following ways.

To start a stateful session

1. To start a session with a stateful model that's hosted by Amazon SageMaker AI, your client sends an `InvokeEndpoint` request with the SageMaker API. For the `SessionID` request parameter, the client tells SageMaker AI to start a new session by specifying the value `NEW_SESSION`. In the request payload, the client also tells the container to start a new session. The syntax of this statement varies based on your container implementation. It depends on how your container code handles the request payload.

   The following example starts a new session by using the SDK for Python (Boto3):

   ```
   import boto3
   import sagemaker
   import json

   payload = {
   "requestType":"NEW_SESSION"
   }
   payload = json.dumps(payload)

   smr = boto3.client(
       'sagemaker-runtime',
       region_name="region_name",
       endpoint_url="endoint_url")

   create_session_response = smr.invoke_endpoint(
       EndpointName="endpoint_name",
       Body=payload,
       ContentType="application/json",
       SessionId="NEW_SESSION")
   ```

2. Your model container handles your client's request by starting a new session. For the session, it caches the data that the client sends in the request payload. It also creates a session ID, and it sets a time to live (TTL) timestamp. This timestamp indicates when the session expires. The container must provide the session ID and timestamp to Amazon SageMaker AI by setting the following HTTP header in the response:

```
X-Amzn-SageMaker-Session-Id: session_id; Expires=yyyy-mm-ddThh:mm:ssZ
```

3. In the response to the `InvokeEndpoint` request, Amazon SageMaker AI provides the session ID and TTL timestamp for the `NewSessionID` response parameter.

   The following example extracts the session ID from the `invoke_endpoint` response:

```
session_id = create_session_response['ResponseMetadata']['HTTPHeaders']['x-amzn-
sagemaker-new-session-id'].split(';')[0]
```

To continue a stateful session

- To use the same session for a subsequent inference request, your client sends another `InvokeEndpoint` request. For the `SessionID` request parameter, it specifies the ID of the session. With this ID, SageMaker AI routes the request to the same ML instance where the session was started. Because your container has already cached the original request payload, your client doesn't need to pass the same context data that was in the original request.

  The following example continues a session by passing the session ID with the `SessionId` request parameter:

```
smr.invoke_endpoint(
    EndpointName="endpoint_name",
    Body=payload,
    ContentType="application/json",
    SessionId=session_id)
```

To close a stateful session

1. To close a session, your client sends a final `InvokeEndpoint` request. For the `SessionID` request parameter, the client provides the ID of the session. In the payload in the request body, your client states that the container should close the session. The syntax of this statement varies based on your container implementation.

   The following example closes a session:

```
payload = {
```

```
    "requestType":"CLOSE"
}
payload = json.dumps(payload)

closeSessionResponse = smr.invoke_endpoint(
    EndpointName="endpoint_name",
    Body=payload,
    ContentType="application/json",
    SessionId=session_id)
```

2. When it closes the session, the container returns the session ID to SageMaker AI by setting the following HTTP header in the response:

```
X-Amzn-SageMaker-Closed-Session-Id: session_id
```

3. In the response to the `InvokeEndpoint` request from the client, SageMaker AI provides the session ID for the `ClosedSessionId` response parameter.

   The following example extracts the closed session ID from the `invoke_endpoint` response:

```
closed_session_id = closeSessionResponse['ResponseMetadata']['HTTPHeaders']['x-
amzn-sagemaker-closed-session-id'].split(';')[0]
```

Example implementation

The following example notebook demonstrates how to implement the container for a stateful model. It also demonstrates how a client application starts, continues, and closes a stateful session.

LLaVA stateful inference with SageMaker AI

The notebook uses the LLaVA: Large Language and Vision Assistant model, which accepts images and text prompts. The notebook uploads an image to the model, and then it asks questions about the image without having to resend the image for every request. The model container uses the TorchServe framework. It caches the image data in GPU memory.

Best practices

The following topics provide guidance on best practices for deploying machine learning models in Amazon SageMaker AI.

Topics

- Best practices for deploying models on SageMaker AI Hosting Services
- Monitor Security Best Practices
- Low latency real-time inference with Amazon PrivateLink
- Migrate inference workload from x86 to Amazon Graviton
- Troubleshoot Amazon SageMaker AI model deployments
- Inference cost optimization best practices
- Best practices to minimize interruptions during GPU driver upgrades
- Best practices for endpoint security and health with Amazon SageMaker AI
- Updating inference containers to comply with the NVIDIA Container Toolkit

Best practices for deploying models on SageMaker AI Hosting Services

When hosting models using SageMaker AI hosting services, consider the following:

- Typically, a client application sends requests to the SageMaker AI HTTPS endpoint to obtain inferences from a deployed model. You can also send requests to this endpoint from your Jupyter notebook during testing.
- You can deploy a model trained with SageMaker AI to your own deployment target. To do that, you need to know the algorithm-specific format of the model artifacts that were generated by model training. For more information about output formats, see the section corresponding to the algorithm you are using in Common Data Formats for Training.
- You can deploy multiple variants of a model to the same SageMaker AI HTTPS endpoint. This is useful for testing variations of a model in production. For example, suppose that you've deployed a model into production. You want to test a variation of the model by directing a small amount of traffic, say 5%, to the new model. To do this, create an endpoint configuration that describes both variants of the model. You specify the `ProductionVariant` in your request to the `CreateEndPointConfig`. For more information, see `ProductionVariant`.
- You can configure a `ProductionVariant` to use Application Auto Scaling. For information about configuring automatic scaling, see Automatic scaling of Amazon SageMaker AI models.
- You can modify an endpoint without taking models that are already deployed into production out of service. For example, you can add new model variants, update the ML Compute instance configurations of existing model variants, or change the distribution of traffic among model variants. To modify an endpoint, you provide a new endpoint configuration. SageMaker AI

implements the changes without any downtime. For more information see, `UpdateEndpoint` and `UpdateEndpointWeightsAndCapacities`.

- Changing or deleting model artifacts or changing inference code after deploying a model produces unpredictable results. If you need to change or delete model artifacts or change inference code, modify the endpoint by providing a new endpoint configuration. Once you provide the new endpoint configuration, you can change or delete the model artifacts corresponding to the old endpoint configuration.
- If you want to get inferences on entire datasets, consider using batch transform as an alternative to hosting services. For information, see Batch transform for inference with Amazon SageMaker AI

Deploy Multiple Instances Across Availability Zones

Create robust endpoints when hosting your model. SageMaker AI endpoints can help protect your application from Availability Zone outages and instance failures. If an outage occurs or an instance fails, SageMaker AI automatically attempts to distribute your instances across Availability Zones. For this reason, we strongly recommend that you deploy multiple instances for each production endpoint.

If you are using an Amazon Virtual Private Cloud (VPC), configure the VPC with at least two `Subnets`, each in a different Availability Zone. If an outage occurs or an instance fails, Amazon SageMaker AI automatically attempts to distribute your instances across Availability Zones.

In general, to achieve more reliable performance, use more small Instance Types in different Availability Zones to host your endpoints.

Deploy inference components for high availability. In addition to the above recommendation for instance numbers, to achieve 99.95% availability, ensure that your inference components are configured to have more than two copies. In addition, in your managed auto scaling policy, set the minimum number of instances to two as well.

Monitor Security Best Practices

Monitor your usage of SageMaker AI as it relates to security best practices by using Amazon Security Hub CSPM. Security Hub CSPM uses security controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub CSPM to evaluate SageMaker AI resources, see Amazon SageMaker AI controls in the *Amazon Security Hub CSPM User Guide*.

Low latency real-time inference with Amazon PrivateLink

Amazon SageMaker AI provides low latency for real-time inferences while maintaining high availability and resiliency using multi-AZ deployment. The application latency is made up of two primary components: infrastructure or overhead latency and model inference latency. Reduction of overhead latency opens up new possibilities such as deploying more complex, deep, and accurate models or splitting monolithic applications into scalable and maintainable microservice modules. You can reduce the latency for real-time inferences with SageMaker AI using an Amazon PrivateLink deployment. With Amazon PrivateLink, you can privately access all SageMaker API operations from your Virtual Private Cloud (VPC) in a scalable manner by using interface VPC endpoints. An interface VPC endpoint is an elastic network interface in your subnet with private IP addresses that serves as an entry point for all SageMaker API calls.

By default, a SageMaker AI endpoint with 2 or more instances is deployed in at least 2 Amazon Availability Zones (AZs) and instances in any AZ can process invocations. This results in one or more AZ “hops” that contribute to the overhead latency. An Amazon PrivateLink deployment with the `privateDNSEnabled` option set as `true` alleviates this by achieving two objectives:

- It keeps all inference traffic within your VPC.
- It keeps invocation traffic in the same AZ as the client that originated it when using SageMaker Runtime. This avoids the “hops” between AZs reducing the overhead latency.

The following sections of this guide demonstrate how you can reduce the latency for real-time inferences with Amazon PrivateLink deployment.

Topics

- Deploy Amazon PrivateLink
- Deploy SageMaker AI endpoint in a VPC
- Invoke the SageMaker AI endpoint

Deploy Amazon PrivateLink

To deploy Amazon PrivateLink, first create an interface endpoint for the VPC from which you connect to the SageMaker AI endpoints. Please follow the steps in Access an Amazon service using an interface VPC endpoint to create the interface endpoint. While creating the endpoint, select the following settings in the console interface:

- Select the **Enable DNS name** checkbox under **Additional Settings**
- Select the appropriate security groups and the subnets to be used with the SageMaker AI endpoints.

Also make sure that the VPC has DNS hostnames turned on. For more information on how to change DNS attributes for your VPC, see View and update DNS attributes for your VPC.

Deploy SageMaker AI endpoint in a VPC

To achieve low overhead latency, create a SageMaker AI endpoint using the same subnets that you specified when deploying Amazon PrivateLink. These subnets should match the AZs of your client application, as shown in the following code snippet.

```
model_name = '<the-name-of-your-model>'

vpc = 'vpc-0123456789abcdef0'
subnet_a = 'subnet-0123456789abcdef0'
subnet_b = 'subnet-0123456789abcdef1'
security_group = 'sg-0123456789abcdef0'

create_model_response = sagemaker_client.create_model(
    ModelName = model_name,
    ExecutionRoleArn = sagemaker_role,
    PrimaryContainer = {
        'Image': container,
        'ModelDataUrl': model_url
    },
    VpcConfig = {
        'SecurityGroupIds': [security_group],
        'Subnets': [subnet_a, subnet_b],
    },
)
```

The aforementioned code snippet assumes that you have followed the steps in Before you begin.

Invoke the SageMaker AI endpoint

Finally, specify the SageMaker Runtime client and invoke the SageMaker AI endpoint as shown in the following code snippet.

```
endpoint_name = '<endpoint-name>'

runtime_client = boto3.client('sagemaker-runtime')
response = runtime_client.invoke_endpoint(EndpointName=endpoint_name,
                                          ContentType='text/csv',
                                          Body=payload)
```

For more information on endpoint configuration, see Deploy models for real-time inference.

Migrate inference workload from x86 to Amazon Graviton

Amazon Graviton is a series of ARM-based processors designed by Amazon. They are more energy efficient than x86-based processors and offer a compelling price-performance ratio. Amazon SageMaker AI offers Graviton-based instances so that you can take advantage of these advanced processors for your inference needs.

You can migrate your existing inference workloads from x86-based instances to Graviton-based instances, by using either ARM compatible container images or multi-architecture container images. This guide assumes that you are either using Amazon Deep Learning container images, or your own ARM compatible container images. For more information on building your own images, check Building your image.

At a high level, migrating inference workload from x86-based instances to Graviton-based instances is a four-step process:

1. Push container images to Amazon Elastic Container Registry (Amazon ECR), an Amazon managed container registry.
2. Create a SageMaker AI Model.
3. Create an endpoint configuration.
4. Create an endpoint.

The following sections of this guide provide more details regarding the above steps. Replace the *`user placeholder text`* in the code examples with your own information.

Topics

- Push container images to Amazon ECR

- Create a SageMaker AI Model
- Create an endpoint configuration
- Create an endpoint

Push container images to Amazon ECR

You can push your container images to Amazon ECR with the Amazon CLI. When using an ARM compatible image, verify that it supports ARM architecture:

```
docker inspect deep-learning-container-uri
```

The response `"Architecture": "arm64"` indicates that the image supports ARM architecture. You can push it to Amazon ECR with the `docker push` command. For more information, check Pushing a Docker image.

Multi-architecture container images are fundamentally a set of container images supporting different architectures or operating systems, that you can refer to by a common manifest name. If you are using multi-architecture container images, then in addition to pushing the images to Amazon ECR, you will also have to push a manifest list to Amazon ECR. A manifest list allows for the nested inclusion of other image manifests, where each included image is specified by architecture, operating system and other platform attributes. The following example creates a manifest list, and pushes it to Amazon ECR.

1. Create a manifest list.

```
docker manifest create aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-
repository \
  aws-account-id.dkr.ecr.aws-account-id.amazonaws.com/my-repository:amd64 \
 aws-account-id.dkr.ecr.aws-account-id.amazonaws.com/my-repository:arm64 \
```

2. Annotate the manifest list, so that it correctly identifies which image is for which architecture.

```
docker manifest annotate --arch arm64 aws-account-id.dkr.ecr.aws-
region.amazonaws.com/my-repository \
  aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-repository:arm64
```

3. Push the manifest.

```
docker manifest push aws-account-id.dkr.ecr.aws-region.amazonaws.com/my-repository
```

For more information on creating and pushing manifest lists to Amazon ECR, check Introducing multi-architecture container images for Amazon ECR, and Pushing a multi-architecture image.

Create a SageMaker AI Model

Create a SageMaker AI Model by calling the `CreateModel` API.

```
import boto3
from sagemaker.core.helper.session_helper import get_execution_role

aws_region = "aws-region"
sagemaker_client = boto3.client("sagemaker", region_name=aws_region)

role = get_execution_role()

sagemaker_client.create_model(
    ModelName = "model-name",
    PrimaryContainer = {
        "Image": "deep-learning-container-uri",
        "ModelDataUrl": "model-s3-location",
        "Environment": {
            "SAGEMAKER_PROGRAM": "inference.py",
            "SAGEMAKER_SUBMIT_DIRECTORY": "inference-script-s3-location",
            "SAGEMAKER_CONTAINER_LOG_LEVEL": "20",
            "SAGEMAKER_REGION": aws_region,
        }
    },
    ExecutionRoleArn = role
)
```

Create an endpoint configuration

Create an endpoint configuration by calling the `CreateEndpointConfig` API. For a list of Graviton-based instances, check Compute optimized instances.

```
sagemaker_client.create_endpoint_config(
    EndpointConfigName = "endpoint-config-name",
    ProductionVariants = [
        {
            "VariantName": "variant-name",
            "ModelName": "model-name",
            "InitialInstanceCount": 1,
            "InstanceType": "ml.c7g.xlarge", # Graviton-based instance
       }
    ]
)
```

Create an endpoint

Create an endpoint by calling the `CreateEndpoint` API.

```
sagemaker_client.create_endpoint(
    EndpointName = "endpoint-name",
    EndpointConfigName = "endpoint-config-name"
)
```

Troubleshoot Amazon SageMaker AI model deployments

If you encounter an issue when deploying machine learning models in Amazon SageMaker AI, see the following guidance.

Topics

- Detection Errors in the Active CPU Count
- Issues with deploying a model.tar.gz file
- Primary container did not pass ping health checks

Detection Errors in the Active CPU Count

If you deploy a SageMaker AI model with a Linux Java Virtual Machine (JVM), you might encounter detection errors that prevent using available CPU resources. This issue affects some JVMs that support Java 8 and Java 9, and most that support Java 10 and Java 11. These JVMs implement a mechanism that detects and handles the CPU count and the maximum memory available when

running a model in a Docker container, and, more generally, within Linux `taskset` commands or control groups (cgroups). SageMaker AI deployments take advantage of some of the settings that the JVM uses for managing these resources. Currently, this causes the container to incorrectly detect the number of available CPUs.

SageMaker AI doesn't limit access to CPUs on an instance. However, the JVM might detect the CPU count as 1 when more CPUs are available for the container. As a result, the JVM adjusts all of its internal settings to run as if only 1 CPU core is available. These settings affect garbage collection, locks, compiler threads, and other JVM internals that negatively affect the concurrency, throughput, and latency of the container.

For an example of the misdetection, in a container configured for SageMaker AI that is deployed with a JVM that is based on Java8_191 and that has four available CPUs on the instance, run the following command to start your JVM:

```
java -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: determined by OSContainer: 1
openjdk version "1.8.0_191"
OpenJDK Runtime Environment (build 1.8.0_191-8u191-b12-2ubuntu0.16.04.1-b12)
OpenJDK 64-Bit Server VM (build 25.191-b12, mixed mode)
```

Many of the JVMs affected by this issue have an option to disable this behavior and reestablish full access to all of the CPUs on the instance. Disable the unwanted behavior and establish full access to all instance CPUs by including the `-XX:-UseContainerSupport` parameter when starting Java applications. For example, run the `java` command to start your JVM as follows:

```
java -XX:-UseContainerSupport -XX:+UnlockDiagnosticVMOptions -XX:+PrintActiveCpus -
version
```

This generates the following output:

```
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: sched_getaffinity processor count: 4
active_processor_count: sched_getaffinity processor count: 4
openjdk version "1.8.0_191"
OpenJDK Runtime Environment (build 1.8.0_191-8u191-b12-2ubuntu0.16.04.1-b12)
OpenJDK 64-Bit Server VM (build 25.191-b12, mixed mode)
```

Check whether the JVM used in your container supports the `-XX:-UseContainerSupport` parameter. If it does, always pass the parameter when you start your JVM. This provides access to all of the CPUs in your instances.

You might also encounter this issue when indirectly using a JVM in SageMaker AI containers. For example, when using a JVM to support SparkML Scala. The `-XX:-UseContainerSupport` parameter also affects the output returned by the Java `Runtime.getRuntime().availableProcessors()` API .

Issues with deploying a model.tar.gz file

When you deploy a model using a `model.tar.gz` file, the model tarball should not include any symlinks. Symlinks cause the model creation to fail. Also, we recommend that you do not include any unnecessary files in the tarball.

Primary container did not pass ping health checks

If your primary container fails ping health checks with the following error message, it indicates that there is an issue with your container or script:

```
The primary container for production variant beta did not pass the ping health check.
 Please check CloudWatch Logs logs for this endpoint.
```

To troubleshoot this issue, you should check the CloudWatch Logs logs for the endpoint in question to see if there are any errors or issues that are preventing the container from responding to `/ping` or `/invocations`. The logs may provide an error message that could point to the issue. Once you have identified the error and failure reason you should resolve the error.

It is also good practice to test the model deployment locally before creating an endpoint.

- Use local mode in the SageMaker SDK to imitate the hosted environment by deploying the model to a local endpoint. For more information, see Local Mode.

- Use vanilla docker commands to test the container responds to /ping and /invocations. For more information, see local_test.

Inference cost optimization best practices

The following content provides techniques and considerations for optimizing the cost of endpoints. You can use these recommendations to optimize the cost for both new and existing endpoints.

Best practices

To optimize your SageMaker AI Inference costs, follow these best practices.

Pick the best inference option for the job.

SageMaker AI offers 4 different inference options to provide the best inference option for the job. You may be able to save on costs by picking the inference option that best matches your workload.

- Use real-time inference for low latency workloads with predictable traffic patterns that need to have consistent latency characteristics and are always available. You pay for using the instance.
- Use serverless inference for synchronous workloads that have a spiky traffic pattern and can accept variations in the p99 latency. Serverless inference automatically scales to meet your workload traffic so you don't pay for any idle resources. You only pay for the duration of the inference request. The same model and containers can be used with both real-time and serverless inference so you can switch between these two modes if your needs change.
- Use asynchronous inference for asynchronous workloads that process up to 1 GB of data (such as text corpus, image, video, and audio) that are latency insensitive and cost sensitive. With asynchronous inference, you can control costs by specifying a fixed number of instances for the optimal processing rate instead of provisioning for the peak. You can also scale down to zero to save additional costs.
- Use batch inference for workloads for which you need inference for a large set of data for processes that happen offline (that is, you don't need a persistent endpoint). You pay for the instance for the duration of the batch inference job.

Opt in to a SageMaker AI Savings Plan.

- If you have a consistent usage level across all SageMaker AI services, you can opt in to a SageMaker AI Savings Plan to help reduce your costs by up to 64%.

- Amazon SageMaker AI Savings Plans provide a flexible pricing model for Amazon SageMaker AI, in exchange for a commitment to a consistent amount of usage (measured in $/hour) for a one-year or three-year term. These plans automatically apply to eligible SageMaker AI ML instance usages including SageMaker Studio Classic Notebook, SageMaker On-Demand Notebook, SageMaker Processing, SageMaker Data Wrangler, SageMaker Training, SageMaker Real-Time Inference, and SageMaker Batch Transform regardless of instance family, size, or Region. For example, you can change usage from a CPU ml.c5.xlarge instance running in US East (Ohio) to a ml.Inf1 instance in US West (Oregon) for inference workloads at any time and automatically continue to pay the Savings Plans price.

Optimize your model to run better.

- Unoptimized models can lead to longer run times and use more resources. You may choose to use more or bigger instances to improve performance; however, this leads to higher costs.
- By optimizing your models to be more performant, you may be able to lower costs by using fewer or smaller instances while keeping the same or better performance characteristics. You can use SageMaker Neo with SageMaker AI Inference to automatically optimize models. For more details and samples, see Model performance optimization with SageMaker Neo.

Use the most optimal instance type and size for real-time inference.

- SageMaker Inference has over 70 instance types and sizes that can be used to deploy ML models including Amazon Inferentia and Graviton chipsets that are optimized for ML. Choosing the right instance for your model helps ensure you have the most performant instance at the lowest cost for your models.

- By using Inference Recommender, you can quickly compare different instances to understand the performance of the model and the costs. With these results, you can choose the instance to deploy with the best return on investment.

Improve efficiency and costs by combining multiple endpoints into a single endpoint for real-time inference.

- Costs can quickly add up when you deploy multiple endpoints, especially if the endpoints don't fully utilize the underlying instances. To understand if the instance is under-utilized, check the utilization metrics (CPU, GPU, etc) in Amazon CloudWatch for your instances. If you have

more than one of these endpoints, you can combine the models or containers on these multiple endpoints into a single endpoint.

- Using Multi-model endpoints (MME) or Multi-container endpoints (MCE), you can deploy multiple ML models or containers in a single endpoint to share the instance across multiple models or containers and improve your return on investment. To learn more, see this Save on inference costs by using Amazon SageMaker AI multi-model endpoints or Deploy multiple serving containers on a single instance using Amazon SageMaker AI multi-container endpoints on the Amazon Machine Learning blog.

Set up autoscaling to match your workload requirements for real-time and asynchronous inference.

- Without autoscaling, you need to provision for peak traffic or risk model unavailability. Unless the traffic to your model is steady throughout the day, there will be excess unused capacity. This leads to low utilization and wasted resources.
- Autoscaling is an out-of-the-box feature that monitors your workloads and dynamically adjusts the capacity to maintain steady and predictable performance at the possible lowest cost. When the workload increases, autoscaling brings more instances online. When the workload decreases, autoscaling removes unnecessary instances, helping you reduce your compute cost. To learn more, see Configuring autoscaling inference endpoints in Amazon SageMaker AI on the Amazon Machine Learning blog.

Best practices to minimize interruptions during GPU driver upgrades

SageMaker AI Model Deployment upgrades GPU drivers on the ML instances for Real-time, Batch, and Asynchronous Inference options over time to provide customers access to improvements from the driver providers. Below you can see the GPU version supported for each Inference option. Different driver versions can change how your model interacts with the GPUs. Below are some strategies to help you understand how your application works with different driver versions.

Current versions and supported instance families

The following table lists the GPU drivers and instance families that Amazon SageMaker AI Inference supports. For Real-time, Batch, and Asynchronous Inference services, an AMI override is an explicit AMI version specified in the inference endpoint or batch transform job configuration.

For inference endpoints, set the `InferenceAmiVersion` parameter on the applicable `ProductionVariant` when calling CreateEndpointConfig API. For batch transform jobs, set the `TransformAmiVersion` parameter when calling CreateTransformJob API. The compatible instance types column identifies additional instance families that support this AMI version. SageMaker AI does not automatically apply the AMI override.

Service	GPU	Driver version	CUDA version	AMI version	Instance types (default)	Compatible instance types with AMI version overrides
Real-time	NVIDIA	470	CUDA 11.4		ml.p4d.*, ml.p4de.*, ml.g4dn.*, ml.g5.*	
		535	CUDA 12.2	al2-ami-sagemaker-inference-gpu-2, al2-ami-sagemaker-inference-gpu-2-1	ml.p5.*, ml.g6.*, ml.g6e.*	ml.p4d.*, ml.p4de.*, ml.g4dn.*, ml.g5.*
		550	CUDA 12.4	al2-ami-sagemaker-inference-gpu-3-1	ml.p5e.*, ml.p5en.*	ml.p4d.*, ml.p4de.*, ml.p5.*, ml.g4dn.*, ml.g5.*, ml.g6.*, ml.g6e.*
		580	CUDA 13.0	al2023-ami-sagemaker-infere	ml.p6.*, ml.g7.*, ml.g7e.*	ml.p4d.*, ml.p4de.*, ml.p5.*,

Service	GPU	Driver version	CUDA version	AMI version	Instance types (default)	Compatible instance types with AMI version overrides
				nce-gpu-4-1		ml.p5e.*, ml.p5en.*, ml.g4dn.*, ml.g5.*, ml.g6.*, ml.g6e.*
535	CUDA 12.2	al2-ami-sagemaker-inference-gpu-2, al2-ami-sagemaker-inference-gpu-2-1	ml.p5.*, ml.g6.*, ml.g6e.*	ml.p4d.*, ml.p4de.*, ml.g4dn.*, ml.g5.*		
550	CUDA 12.4	al2-ami-sagemaker-inference-gpu-3-1	ml.p5e.*, ml.p5en.*	ml.p4d.*, ml.p4de.*, ml.p5.*, ml.g4dn.*, ml.g5.*, ml.g6.*, ml.g6e.*		

Service	GPU	Driver version	CUDA version	AMI version	Instance types (default)	Compatible instance types with AMI version overrides
580	CUDA 13.0	al2023-ami-sagemaker-inference-gpu-4-1	ml.p6.*, ml.g7.*, ml.g7e.*	ml.p4d.*, ml.p4de.*, ml.p5.*, ml.p5e.*, ml.p5en.*, ml.g4dn.*, ml.g5.*, ml.g6.*, ml.g6e.*		
Batch	NVIDIA	470	CUDA 11.4	al2-ami-sagemaker-batch-gpu-470	ml.g4dn.*, ml.g5.*	
		535	CUDA 12.2	al2-ami-sagemaker-batch-gpu-535	ml.g6.*, ml.g6e.*	ml.g4dn.*, ml.g5.*

Troubleshoot your model container with GPU capabilities

If you encounter an issue when running your GPU workload, see the following guidance:

GPU card detection failure or NVIDIA initialization error

Run the `nvidia-smi` (NVIDIA System Management Interface) command from within the Docker container. If the NVIDIA System Management Interface detects a GPU detection error or NVIDIA initialization error, it will return the following error message:

```
Failed to initialize NVML: Driver/library version mismatch
```

Based on your use case, follow these best practices to resolve the failure or error:

- Follow the best practice recommendation described in the If you bring your own (BYO) model containers dropdown.
- Follow the best practice recommendation described in the If you use a CUDA compatibility layer dropdown.

Refer to the NVIDIA System Management Interface page on the NVIDIA website for more information.

`CannotStartContainerError`

If your GPU instance uses NVIDIA driver versions that are not compatible with the CUDA version in the Docker container, then deploying an endpoint will fail with the following error message:

```
Failure reason CannotStartContainerError. Please ensure the model container for
variant <variant_name> starts correctly when invoked with 'docker run <image> serve'
```

Based on your use case, follow these best practices to resolve the failure or error:

- Follow the best practice recommendation described in the The driver my container depends on is greater than the version on the ML GPU instances dropdown.
- Follow the best practice recommendation described in the If you use a CUDA compatibility layer dropdown.

Best practices for working with mismatched driver versions

The following provides information on how to update your GPU driver:

The driver my container depends on is lower than the version on the ML GPU instance

No action is required. NVIDIA provides backwards compatibility.

The driver my container depends on is greater than the version on the ML GPU instances

If it is a minor version difference, no action is required. NVIDIA provides minor version forward compatibility.

If it is a major version difference, the CUDA Compatibility Package will need to be installed. Please refer to CUDA Compatibility Package in the NVIDIA documentation.

> **Important**
>
> The CUDA Compatibility Package is not backwards compatible so it needs to be disabled if the driver version on the instance is greater than the CUDA Compatibility Package version.

If you bring your own (BYO) model containers

Ensure no NVIDIA driver packages are bundled in the image which could cause conflict with on host NVIDIA driver version.

If you use a CUDA compatibility layer

To verify if the platform Nvidia driver version supports the CUDA Compatibility Package version installed in the model container, see the CUDA documentation. If the platform Nvidia driver version does not support the CUDA Compatibility Package version, you can disable or remove the CUDA Compatibility Package from the model container image. If the CUDA compatibility libs version is supported by the latest Nvidia driver version, we suggest that you enable the CUDA Compatibility Package based on the detected Nvidia driver version for future compatibility by adding the code snippet below into the container start up shell script (at the `ENTRYPOINT` script).

The script demonstrates how to dynamically switch the use of the CUDA Compatibility Package based on the detected Nvidia driver version on the deployed host for your model container. When SageMaker releases a newer Nvidia driver version, the installed CUDA Compatibility Package can be turned off automatically if the CUDA application is supported natively on the new driver.

```
#!/bin/bash

verlt() {
    [ "$1" = "$2" ] && return 1 || [ "$1" = "$(echo -e "$1\n$2" | sort -V | head -
n1)" ]
}

if [ -f /usr/local/cuda/compat/libcuda.so.1 ]; then
    CUDA_COMPAT_MAX_DRIVER_VERSION=$(readlink /usr/local/cuda/compat/libcuda.so.1 | cut
 -d'.' -f 3-)
    echo "CUDA compat package should be installed for NVIDIA driver smaller than
 ${CUDA_COMPAT_MAX_DRIVER_VERSION}"
```

```
    NVIDIA_DRIVER_VERSION=$(sed -n 's/^NVRM.*Kernel Module *\([0-9.]*\).*$/\1/p' /proc/
driver/nvidia/version 2>/dev/null || true)
    echo "Current installed NVIDIA driver version is ${NVIDIA_DRIVER_VERSION}"
    if verlt $NVIDIA_DRIVER_VERSION $CUDA_COMPAT_MAX_DRIVER_VERSION; then
        echo "Adding CUDA compat to LD_LIBRARY_PATH"
        export LD_LIBRARY_PATH=/usr/local/cuda/compat:$LD_LIBRARY_PATH
        echo $LD_LIBRARY_PATH
    else
        echo "Skipping CUDA compat setup as newer NVIDIA driver is installed"
    fi
else
    echo "Skipping CUDA compat setup as package not found"
fi
```

Best practices for endpoint security and health with Amazon SageMaker AI

To address the latest security issues, Amazon SageMaker AI automatically patches endpoints to the latest and most secure software. However, if you incorrectly modify your endpoint dependencies, Amazon SageMaker AI can't automatically patch your endpoints or replace your unhealthy instances. To ensure your endpoints remain eligible for automatic updates, apply the following best practices.

Don't delete resources while your endpoints use them

Avoid deleting any of the following resources if you have existing endpoints that use them:

- The model definition that you create with the CreateModel action in the Amazon SageMaker API.
- Any model artifacts that you specify for the `ModelDataUrl` parameter.
- The IAM role and permissions that you specify for the `ExecutionRoleArn` parameter.

> **Reminder**
>
> In the model definition that your endpoint uses, ensure that the IAM role that you specified has the correct permissions. For more information about the required permissions for Amazon SageMaker AI endpoints, see CreateModel API: Execution Role Permissions.

- The inference images that you specify for the `Image` parameter, if you use your own inference code.

> **Reminder**
>
> If you use the private registry feature, ensure that Amazon SageMaker AI can access the private registry as long as you're using the endpoint.

- The Amazon VPC subnets and security groups that you specify for the `VpcConfig` parameter.
- The endpoint configuration that you create with the CreateEndpointConfig action in the Amazon SageMaker API.
- Any KMS keys or Amazon S3 buckets that you specify in the endpoint configuration.

> **Reminder**
>
> Ensure you don't disable these KMS keys.

Follow these procedures to update your endpoints

When you update your Amazon SageMaker AI endpoints, use any of the following procedures that apply to your needs.

To update your model definition settings

1. Create a new model definition with your updated settings by using the CreateModel action in the Amazon SageMaker API.
2. Create a new endpoint configuration that uses the new model definition. To do this, use the CreateEndpointConfig action in the Amazon SageMaker API.
3. Update your endpoint with the new endpoint configuration so that your updated model definition settings take effect.
4. (Optional) Delete the old endpoint configuration if you're not using it with any other endpoints. You can also delete the resources that you specified in the model definition if you're not using them with any other endpoints. These resources include model artifacts in Amazon S3 and inference images.

To update your endpoint configuration

1. Create a new endpoint configuration with your updated settings.

2. Update your endpoint with the new configuration so that your updates take effect.
3. (Optional) Delete the old endpoint configuration if you're not using it with any other endpoints. You can also delete the resources that you specified in the model definition if you're not using them with any other endpoints. These resources include model artifacts in Amazon S3 and inference images.

Whenever you create a new model definition or endpoint configuration, we recommend that you use a unique name. If you want to update these resources and retain their original names, use the following procedures.

To update your model settings and retain the original model name

1. Delete the existing model definition. At this point, any endpoint that uses the model is broken, but you fix this in the following steps.
2. Create the model definition again with your updated settings, and use the same model name.
3. Create a new endpoint configuration that uses the updated model definition.
4. Update your endpoint with the new endpoint configuration so that your updates take effect.

To update your endpoint configuration and retain the original configuration name

1. Delete the existing endpoint configuration.
2. Create a new endpoint configuration with your updated settings, and use the original name.
3. Update your endpoint with the new configuration so that your updates take effect.

Updating inference containers to comply with the NVIDIA Container Toolkit

As of versions 1.17.4 and higher, the NVIDIA Container Toolkit no longer mounts CUDA compatibility libraries automatically. This change in behavior could affect your SageMaker AI inference workloads. Your SageMaker AI endpoints and batch transform jobs might use containers that are incompatible with the latest versions of the NVIDIA Container Toolkit. To ensure that your workloads comply with the latest requirements, you might need to update your endpoints or configure your batch transform jobs.

Updating SageMaker AI endpoints for compliance

We recommend that you update your existing SageMaker AI endpoints or create new ones that support the latest default behavior.

To ensure your endpoint is compatible with latest versions of the NVIDIA Container Toolkit, follow these steps:

1. Update how you set up the CUDA compatibility libraries if you bring your own container.
2. Specify an inference Amazon Machine Image (AMI) that supports the latest NVIDIA Container Toolkit behavior. You specify an AMI when you update an existing endpoint or create a new one.

Updating the CUDA compatibility setup if you bring your own container

The CUDA compatibility libraries enable forward compatibility. This compatibility applies to any CUDA toolkit versions that are newer than the NVIDIA driver provided by the SageMaker AI instance.

You must enable the CUDA compatibility libraries only when the NVIDIA driver that the SageMaker AI instance uses has an older version than the CUDA toolkit in the model container. If your model container does not require CUDA compatibility, you can skip this step. For example, you can skip this step if you don't plan to use a newer CUDA toolkit than those provided by SageMaker AI instances.

Because of the changes introduced in the NVIDIA Container Toolkit version 1.17.4, you can explicitly enable CUDA compatibility libraries, if needed, by adding them to `LD_LIBRARY_PATH` in the container.

We suggest that you enable the CUDA compatibility based on the detected NVIDIA driver version. To enable it, add the code snippet below to the container startup shell script. Add this code at the `ENTRYPOINT` script.

The following script demonstrates how to dynamically switch the use of the CUDA compatibility based on the detected NVIDIA driver version on the deployed host for your model container.

```
#!/bin/bash

verlt() {
    [ "$1" = "$2" ] && return 1 || [ "$1" = "$(echo -e "$1\n$2" | sort -V | head -
n1)" ]
```

```
}

if [ -f /usr/local/cuda/compat/libcuda.so.1 ]; then
    CUDA_COMPAT_MAX_DRIVER_VERSION=$(readlink /usr/local/cuda/compat/libcuda.so.1 | cut
 -d'.' -f 3-)
    echo "CUDA compat package should be installed for NVIDIA driver smaller than
 ${CUDA_COMPAT_MAX_DRIVER_VERSION}"
    NVIDIA_DRIVER_VERSION=$(sed -n 's/^NVRM.*Kernel Module *\([0-9.]*\).*$/\1/p' /proc/
driver/nvidia/version 2>/dev/null || true)
    echo "Current installed NVIDIA driver version is ${NVIDIA_DRIVER_VERSION}"

        echo "Skipping CUDA compat setup as newer NVIDIA driver is installed"
    fi
else
    echo "Skipping CUDA compat setup as package not found"
fi
```

Specifying an Inference AMI that complies with the NVIDIA Container Toolkit

In the `InferenceAmiVersion` parameter of the `ProductionVariant` data type, you can select the AMI for a SageMaker AI endpoint. Each of the supported AMIs is a preconfigured image. Each image is configured by Amazon with a set of software and driver versions.

By default, the SageMaker AI AMIs follow the legacy behavior. They automatically mount CUDA compatibility libraries in the container. To make an endpoint use the new behavior, you must specify an inference AMI version that is configured for the new behavior.

The following inference AMI versions currently follow the new behavior. They don't mount CUDA compatibility libraries automatically.

al2-ami-sagemaker-inference-gpu-2-1

- NVIDIA driver version: 535.54.03
- CUDA version: 12.2

al2-ami-sagemaker-inference-gpu-3-1

- NVIDIA driver version: 550.144.01
- CUDA version: 12.4

Updating an existing endpoint

Use the following example to update an existing endpoint. The example uses an inference AMI version that disables automatic mounting of CUDA compatibility libraries.

```
ENDPOINT_NAME="<endpoint name>"
INFERENCE_AMI_VERSION="al2-ami-sagemaker-inference-gpu-3-1"

# Obtaining current endpoint configuration
CURRENT_ENDPOINT_CFG_NAME=$(aws sagemaker describe-endpoint --endpoint-name
 "$ENDPOINT_NAME" --query "EndpointConfigName" --output text)
NEW_ENDPOINT_CFG_NAME="${CURRENT_ENDPOINT_CFG_NAME}new"

# Copying Endpoint Configuration with AMI version specified
aws sagemaker describe-endpoint-config \
    --endpoint-config-name ${CURRENT_ENDPOINT_CFG_NAME} \
    --output json | \
jq "del(.EndpointConfigArn, .CreationTime) | . + {
    EndpointConfigName: \"${NEW_ENDPOINT_CFG_NAME}\",
    ProductionVariants: (.ProductionVariants | map(.InferenceAmiVersion =
 \"${INFERENCE_AMI_VERSION}\"))
}" > /tmp/new_endpoint_config.json

# Make sure all fields in the new endpoint config look as expected
cat /tmp/new_endpoint_config.json

# Creating new endpoint config
aws sagemaker create-endpoint-config \
   --cli-input-json file:///tmp/new_endpoint_config.json

# Updating the endpoint
aws sagemaker update-endpoint \
    --endpoint-name "$ENDPOINT_NAME" \
    --endpoint-config-name "$NEW_ENDPOINT_CFG_NAME" \
    --retain-all-variant-properties
```

Creating a new endpoint

Use the following example to create a new endpoint. The example uses an inference AMI version that disables automatic mounting of CUDA compatibility libraries.

```
INFERENCE_AMI_VERSION="al2-ami-sagemaker-inference-gpu-3-1"
```

```
aws sagemakercreate-endpoint-config \
 --endpoint-config-name "<endpoint_config>" \
 --production-variants '[{ \
    ....
    "InferenceAmiVersion":  "${INFERENCE_AMI_VERSION}", \
    ...
    "}]'

aws sagemaker create-endpoint \
--endpoint-name "<endpoint_name>" \
--endpoint-config-name "<endpoint_config>"
```

Running compliant batch transform jobs

Batch transform is the inference option that's best suited for requests to process large amounts of data offline. To create batch transform jobs, you use the `CreateTransformJob` API action. For more information, see the section called “Batch transform”.

The changed behavior of the NVIDIA Container Toolkit affects batch transform jobs. To run a batch transform that complies with the NVIDIA Container Toolkit requirements, do the following:

1. If you want to run batch transform with a model for which you've brought your own container, first, update the container for CUDA compatibility. To update it, follow the process in the section called “Updating the CUDA compatibility setup if you bring your own container”.
2. Use the `CreateTransformJob` API action to create the batch transform job. In your request, set the `SAGEMAKER_CUDA_COMPAT_DISABLED` environment variable to `true`. This parameter instructs to the container not to automatically mount CUDA compatibility libraries.

   For example, when you create a batch transform job by using the Amazon CLI, you set the environment variable with the `--environment` parameter:

   ```
   aws sagemaker create-transform-job \
       --environment '{"SAGEMAKER_CUDA_COMPAT_DISABLED": "true"}'\
       . . .
   ```

Supported features

Amazon SageMaker AI offers the following four options to deploy models for inference.

- Real-time inference for inference workloads with real-time, interactive, low latency requirements.
- Batch transform for offline inference with large datasets.
- Asynchronous inference for near-real-time inference with large inputs that require longer preprocessing times.
- Serverless inference for inference workloads that have idle periods between traffic spurts.

The following table summarizes the core platform features that are supported by each inference option. It does not show features that can be provided by frameworks, custom Docker containers, or through chaining different Amazon services.

Feature	Real-time inference	Batch transform	Asynchronous inference	Serverless inference	Docker containers
Autoscaling support	✓	N/A	✓	✓	N/A
GPU support	✓[1]	✓[1]	✓[1]		1P, pre-built, BYOC
Single model	✓	✓	✓	✓	N/A
Multi-model endpoint	✓				k-NN, XGBoost, Linear Learner, RCF, TensorFlow, Apache MXNet, PyTorch, scikit-learn [2]
Multi-container endpoint	✓				1P, pre-built, Extend pre-built, BYOC

Feature	Real-time inference	Batch transform	Asynchronous inference	Serverless inference	Docker containers

[1] Availability of the Amazon EC2 instance types depends on the Amazon Region. For availability of instances specific to Amazon, see Amazon SageMaker AI Pricing.

[2] To use any other framework or algorithm, use the SageMaker AI Inference toolkit to build a container that supports multi-model endpoints.

[3] With SageMaker AI, you can deploy large models (up to 500 GB) for inference. You can configure the container health check and download timeout quotas, up to 60 minutes. This will allow you to have more time to download and load your model and associated resources. For more information, see SageMaker AI endpoint parameters for large model inference. You can use SageMaker AI compatible large model Inference containers. You can also use third-party model parallelization libraries, such as Triton with FasterTransformer and DeepSpeed. You have to ensure that they are compatible with SageMaker AI.

Blogs, example notebooks, and additional resources

The following sections contain examples and additional resources for you to learn more about Amazon SageMaker AI.

Blogs and case studies

See the following table for lists of blogs and case studies for various features within SageMaker AI Inference. You can use the blogs to help put together solutions that work for your use case.

Feature	Resources
Real-Time Inference	• Getting started with deploying real-time models on Amazon SageMaker AI

Feature	Resources
	• Deploy BLOOM-176B and OPT-30B on Amazon SageMaker AI with large model inference Deep Learning Containers and DeepSpeed • Creating a machine learning-powered REST API with Amazon API Gateway mapping templates and Amazon SageMaker AI
Autoscaling	• Configuring autoscaling inference endpoints in Amazon SageMaker AI
Serverless Inference	• Amazon SageMaker Serverless Inference – Machine Learning Inference without Worrying about Servers • Host Hugging Face transformer models using Amazon SageMaker Serverless Inference • Introducing the Amazon SageMaker Serverless Inference Benchmarking Toolkit
Asynchronous Inference	• Run computer vision inference on large videos with Amazon SageMaker AI asynchronous endpoints • Build a predictive maintenance solution with Amazon Kinesis, Amazon Glue, and Amazon SageMaker AI • Improve high-value research with Hugging Face and Amazon SageMaker Asynchronous Inference endpoints
Batch Transform	• Associating prediction results with input data using Amazon SageMaker AI Batch Transform

Feature	Resources
Multi-Model Endpoints	• Save on inference costs by using Amazon SageMaker AI multi-model endpoints • Run multiple deep learning models on GPU with Amazon SageMaker AI multi-model endpoints • How to scale machine learning inference for multi-tenant SaaS use cases • Run and optimize multi-model inference with Amazon SageMaker AI multi-model endpoints
Serial Inference Pipelines	• Design patterns for serial inference on Amazon SageMaker AI
Multi-Container Endpoints	• Cost efficient ML inference with multi-framework models on Amazon SageMaker AI
Running Model Ensembles	• Run ensemble ML models on Amazon SageMaker AI
Inference Recommender	• SageMaker Inference Recommender example notebook • SageMaker Inference Recommender for HuggingFace BERT Sentiment Analysis example notebook • Achieve hyperscale performance for model serving using NVIDIA Triton Inference Server on Amazon SageMaker AI

Feature	Resources
Advanced model hosting blog series	• Part 1: Common design patterns for building ML application on Amazon SageMaker AI • Part 2: Getting started with deploying real time models on SageMaker AI • Part 3: Run and optimize multi-model inference with Amazon SageMaker AI multi-model endpoints • Part 4: Design patterns for serial inference on Amazon SageMaker AI • Part 5: Cost efficient ML inference with multi-framework models on Amazon SageMaker AI • Part 6: Best practices in testing and updating models on SageMaker AI • Part 7: Run ensemble ML models on Amazon SageMaker AI

Example notebooks

Feature	Example notebooks
Inference Recommender	• SageMaker Inference Recommender example notebook • SageMaker Inference Recommender for HuggingFace BERT Sentiment Analysis example notebook
Optimize large language models (LLMs) for SageMaker AI	Generative AI LLMs workshop

Additional resources

For more information about each SageMaker AI Inference option in detail, you can watch the following video.

Deploy ML models for inference at high performance and low cost

Troubleshooting and reference

You can use the following resources and reference documentation to understand best practices when using SageMaker AI Inference and to troubleshoot issues with model deployments:

- For troubleshooting model deployments, see Troubleshoot Amazon SageMaker AI model deployments.
- For model deployment best practices, see Best practices.
- For reference information about the size of storage volumes provided for different sizes of hosting instances, see Instance storage volumes.
- For reference information about SageMaker AI limits and quotas, see Amazon SageMaker AI endpoints and quotas.
- For frequently asked questions about SageMaker AI, see Model Hosting FAQs.

Model Hosting FAQs

Refer to the following FAQ items for answers to commonly asked questions about SageMaker AI Inference Hosting.

General Hosting

The following FAQ items answer common general questions for SageMaker AI Inference.

Q: What deployment options does Amazon SageMaker AI provide?

A: After you build and train models, Amazon SageMaker AI provides four options to deploy them so you can start making predictions. Real-Time Inference is suitable for workloads with millisecond latency requirements, payload sizes up to 25 MB, and processing times of up to 60 seconds for regular responses and 8 minutes for streaming responses. Batch Transform is ideal for offline predictions on large batches of data that are available up front. Asynchronous Inference is designed for workloads that do not have sub-second latency requirements, payload sizes up to 1

GB, and processing times of up to 60 minutes. With Serverless Inference, you can quickly deploy machine learning models for inference without having to configure or manage the underlying infrastructure, and you pay only for the compute capacity used to process inference requests, which is ideal for intermittent workloads.

Q: How do I choose a model deployment option in SageMaker AI?

If you want to process requests in batches, you might want to choose Batch Transform. Otherwise, if you want to receive inference for each request to your model, you might want to choose Asynchronous Inference, Serverless Inference, or Real-Time Inference. You can choose Asynchronous Inference if you have long processing times or large payloads and want to queue requests. You can choose Serverless Inference if your workload has unpredictable or intermittent traffic. You can choose Real-Time Inference if you have sustained traffic and need lower and consistent latency for your requests.

Q: I've heard SageMaker AI Inference is expensive. What's the best way to optimize my cost when hosting models?

A: To optimize your costs with SageMaker AI Inference, you should choose the right hosting option for your use case. You can also use Inference features such as Amazon SageMaker AI Savings Plans, model optimization with SageMaker Neo, Multi-Model Endpoints and Multi-Container Endpoints, or autoscaling. For tips on how to optimize your Inference costs, see Inference cost optimization best practices.

Q: Why should I use Amazon SageMaker Inference Recommender?

A: You should use Amazon SageMaker Inference Recommender if you need recommendations for the right endpoint configuration to improve performance and reduce costs. Previously, data scientists who wanted to deploy their models had to run manual benchmarks to select the right endpoint configuration. First, they had to select the right machine learning instance type out of more than 70 available instance types based on the resource requirements of their models and sample payloads, and then optimize the model to account for differing hardware. Then, they had to conduct extensive load tests to validate that latency and throughput requirements were met and that the costs were low. Inference Recommender eliminates this complexity by helping you do the following:

- Get started in minutes with an instance recommendation.
- Conduct load tests across instance types to get recommendations on your endpoint configuration within hours.

- Automatically tune container and model server parameters as well as perform model optimizations for a given instance type.

Q: What is a model server?

A: SageMaker AI endpoints are HTTP REST endpoints that use a containerized web server, which includes a model server. These containers are responsible for loading up and serving requests for a machine learning model. They implement a web server that responds to `/invocations` and `/ping` on port 8080.

Common model servers include TensorFlow Serving, TorchServe and Multi Model Server. SageMaker AI framework containers have these model servers built in.

Q: What is Bring Your Own Container with Amazon SageMaker AI?

A: Everything in SageMaker AI Inference is containerized. SageMaker AI provides managed containers for popular frameworks such as TensorFlow, SKlearn, and HuggingFace. For a comprehensive updated list of those images, see Available Images.

Sometimes there are custom frameworks for which you might need to build a container. This approach is known as *Bring Your Own Container* or *BYOC*. With the BYOC approach, you provide the Docker image to set up your framework or library. Then, you push the image to Amazon Elastic Container Registry (Amazon ECR) so that you can use the image with SageMaker AI.

Alternatively, instead of building an image from scratch, you can extend a container. You can take one of the base images that SageMaker AI provides and add your dependencies on top of it in your Dockerfile.

Q: Do I need to train my models on SageMaker AI to host them on SageMaker AI endpoints?

A: SageMaker AI offers the capacity to bring your own trained framework model that you've trained outside of SageMaker AI and deploy it on any of the SageMaker AI hosting options.

SageMaker AI requires you to package the model in a `model.tar.gz` file and have a specific directory structure. Each framework has its own model structure (see the following question for example structures). For more information, see the SageMaker Python SDK documentation for TensorFlow, PyTorch, and MXNet.

While you can choose from prebuilt framework images such as TensorFlow, PyTorch, and MXNet to host your trained model, you can also build your own container to host your trained models on

SageMaker AI endpoints. For a walkthrough, see the example Jupyter notebook Building your own algorithm container.

Q: How should I structure my model if I want to deploy on SageMaker AI but not train on SageMaker AI?

A: SageMaker AI requires your model artifacts to be compressed in a `.tar.gz` file, or a *tarball*. SageMaker AI automatically extracts this `.tar.gz` file into the `/opt/ml/model/` directory in your container. The tarball shouldn't contain any symlinks or unncessary files. If you are making use of one of the framework containers, such as TensorFlow, PyTorch, or MXNet, the container expects your TAR structure to be as follows:

TensorFlow

```
model.tar.gz/
             |--[model_version_number]/
                                      |--variables
                                      |--saved_model.pb
            code/
                |--inference.py
                |--requirements.txt
```

PyTorch

```
model.tar.gz/
             |- model.pth
             |- code/
                    |- inference.py
                    |- requirements.txt  # only for versions 1.3.1 and higher
```

MXNet

```
model.tar.gz/
            |- model-symbol.json
            |- model-shapes.json
            |- model-0000.params
            |- code/
                   |- inference.py
                   |- requirements.txt # only for versions 1.6.0 and higher
```

Q: When invoking a SageMaker AI endpoint, I can provide a `ContentType` and `Accept` MIME Type. Which one is used to identify the data type being sent and received?

A: `ContentType` is the MIME type of the input data in the request body (the MIME type of the data you are sending to your endpoint). The model server uses the `ContentType` to determine if it can handle the type provided or not.

`Accept` is the MIME type of the inference response (the MIME type of the data your endpoint returns). The model server uses the `Accept` type to determine if it can handle returning the type provided or not.

Common MIME types include `text/csv`, `application/json`, and `application/jsonlines`.

Q: What are the supported data formats for SageMaker AI Inference?

A: SageMaker AI passes any request onto the model container without modification. The container must contain the logic to deserialize the request. For information about the formats defined for built-in algorithms, see Common Data Formats for Inference. If you are building your own container or using a SageMaker AI Framework container, you can include the logic to accept a request format of your choice.

Similarly, SageMaker AI also returns the response without modification, and then the client must deserialize the response. In case of the built-in algorithms, they return responses in specific formats. If you are building your own container or using a SageMaker AI Framework container, you can include the logic to return a response in the format you choose.

Q: How do I invoke my endpoint with binary data such as videos or images?

Use the Invoke Endpoint API call to make inference against your endpoint.

When passing your input as a payload to the `InvokeEndpoint` API, you must provide the correct type of input data that your model expects. When passing a payload in the `InvokeEndpoint` API call, the request bytes are forwarded directly to the model container. For example, for an image, you may use `application/jpeg` for the `ContentType`, and make sure that your model can perform inference on this type of data. This applies for JSON, CSV, video, or any other type of input with which you may be dealing.

Another factor to consider is payload size limits. The payload limits are 25 MB for real-time endpoints and 4 MB for serverless endpoints. You can split your video into multiple frames and invoke the endpoint with each frame individually. Alternatively, if your use case permits, you can

send the whole video in the payload using an asynchronous endpoint, which supports up to 1 GB payloads.

For an example that showcases how to run computer vision inference on large videos with Asynchronous Inference, see this blog post.

Real-Time Inference

The following FAQ items answer common questions for SageMaker AI Real-Time Inference.

Q: How do I create a SageMaker AI endpoint?

A: You can create a SageMaker AI endpoint through Amazon-supported tooling such as the Amazon SDKs, the SageMaker Python SDK, the Amazon Web Services Management Console, Amazon CloudFormation, and the Amazon Cloud Development Kit (Amazon CDK).

There are three key entities in endpoint creation: a SageMaker AI model, a SageMaker AI endpoint configuration, and a SageMaker AI endpoint. The SageMaker AI model points towards the model data and image you are using. The endpoint configuration defines your production variants, which might include the instance type and instance count. You can then use either the create_endpoint API call or the .deploy() call for SageMaker AI to create an endpoint using the metadata from your model and endpoint configuration.

Q: Do I need to use the SageMaker Python SDK to create/invoke endpoints?

A: No, you can use the various Amazon SDKs (see Invoke/Create for available SDKs) or even call the corresponding web APIs directly.

Q: What is the difference between Multi-Model Endpoints (MME) and Multi Model Server (MMS)?

A: A Multi-Model Endpoint is a Real-Time Inference option that SageMaker AI provides. With Multi-Model Endpoints, you can host thousands of models behind one endpoint. Multi Model Server is an open-source framework for serving machine learning models. It provides the HTTP front-end and model management capabilities required by multi-model endpoints to host multiple models within a single container, load models into and unload models out of the container dynamically, and perform inference on a specified loaded model.

Q: What are the different model deployment architectures supported by Real-Time Inference?

A: SageMaker AI Real-Time Inference supports various model deployment architecture such as Multi-Model Endpoints, Multi-Container Endpoints, and Serial Inference Pipelines.

Multi-Model Endpoints (MME) – MME allows customers to deploy 1000s of hyper-personalized models in a cost effective way. All the models are deployed on a shared-resource fleet. MME works best when the models are of similar size and latency and belong to the same ML framework. These endpoints are ideal for when you have don't need to call the same model at all times. You can dynamically load respective models onto the SageMaker AI endpoint to serve your request.

Multi-Container Endpoints (MCE) – MCE allows customers to deploy 15 different containers with diverse ML frameworks and functionalities with no cold starts while only using one SageMaker endpoint. You can directly invoke these containers. MCE is best for when you want to keep all the models in memory.

Serial Inference Pipelines (SIP) – You can use SIP to chain together 2-15 containers on a single endpoint. SIP is mostly suitable for combining preprocessing and model inference in one endpoint and for low latency operations.

Serverless Inference

The following FAQ items answer common questions for Amazon SageMaker Serverless Inference.

Q: What is Amazon SageMaker Serverless Inference?

A: Deploy models with Amazon SageMaker Serverless Inference is a purpose-built serverless model serving option that makes it easy to deploy and scale ML models. Serverless Inference endpoints automatically start compute resources and scale them in and out depending on traffic, eliminating the need for you to choose instance type, run provisioned capacity, or manage scaling. You can optionally specify the memory requirements for your serverless endpoint. You pay only for the duration of running the inference code and the amount of data processed, not for idle periods.

Q: Why should I use Serverless Inference?

A: Serverless Inference simplifies the developer experience by eliminating the need to provision capacity up front and manage scaling policies. Serverless Inference can scale instantly from tens to thousands of inferences within seconds based on the usage patterns, making it ideal for ML applications with intermittent or unpredictable traffic. For example, a chatbot service used by a payroll processing company experiences an increase in inquiries at the end of the month while traffic is intermittent for rest of the month. Provisioning instances for the entire month in such scenarios is not cost-effective, as you end up paying for idle periods.

Serverless Inference helps address these types of use cases by providing you automatic and fast scaling out of the box without the need for you to forecast traffic up front or manage scaling

policies. Additionally, you pay only for the compute time to run your inference code and for data processing, making it ideal for workloads with intermittent traffic.

Q: How do I choose the right memory size for my serverless endpoint?

A: Your serverless endpoint has a minimum RAM size of 1024 MB (1 GB), and the maximum RAM size you can choose is 6144 MB (6 GB). The memory sizes you can choose are 1024 MB, 2048 MB, 3072 MB, 4096 MB, 5120 MB, or 6144 MB. Serverless Inference auto-assigns compute resources proportional to the memory you select. If you choose a larger memory size, your container has access to more vCPUs.

Choose your endpoint's memory size according to your model size. Generally, the memory size should be at least as large as your model size. You may need to benchmark in order to choose the right memory selection for your model based on your latency SLAs. The memory size increments have different pricing; see the Amazon SageMaker pricing page for more information.

Batch Transform

The following FAQ items answer common questions for SageMaker AI Batch Transform.

Q: How does Batch Transform split my data?

A: For specific file formats such as CSV, RecordIO and TFRecord, SageMaker AI can split your data into single-record or multi-record mini batches and send this as a payload to your model container. When the value of `BatchStrategy` is `MultiRecord`, SageMaker AI sends the maximum number of records in each request, up to the `MaxPayloadInMB` limit. When the value of `BatchStrategy` is `SingleRecord`, SageMaker AI sends individual records in each request.

Q: What is the maximum timeout for Batch Transform and payload limit for a single record?

A: The maximum timeout for Batch Transform is 3600 seconds. The maximum payload size for a record (per mini batch) is 100 MB.

Q: How do I speed up a Batch Transform job?

A: If you are using the `CreateTransformJob` API, you can reduce the time it takes to complete batch transform jobs by using optimal values for parameters such as `MaxPayloadInMB`, `MaxConcurrentTransforms`, or `BatchStrategy`. The ideal value for `MaxConcurrentTransforms` is equal to the number of compute workers in the batch transform job. If you are using the SageMaker AI console, you can specify these optimal parameter values in

the **Additional configuration** section of the **Batch transform job configuration** page. SageMaker AI automatically finds the optimal parameter settings for built-in algorithms. For custom algorithms, provide these values through an execution-parameters endpoint.

Q: What are the data formats natively supported in Batch Transform?

A: Batch Transform supports CSV and JSON.

Asynchronous Inference

The following FAQ items answer common general questions for SageMaker AI Asynchronous Inference.

Q: What is Amazon SageMaker Asynchronous Inference?

A: Asynchronous Inference queues incoming requests and processes them asynchronously. This option is ideal for requests with large payload sizes or long processing times that need to be processed as they arrive. Optionally, you can configure auto-scaling settings to scale down the instance count to zero when not actively processing requests.

Q: How do I scale my endpoints to 0 when there's no traffic?

A: Amazon SageMaker AI supports automatic scaling (autoscaling) your asynchronous endpoint. Autoscaling dynamically adjusts the number of instances provisioned for a model in response to changes in your workload. Unlike other hosted models SageMaker AI supports, with Asynchronous Inference you can also scale down your asynchronous endpoints instances to zero. Requests that are received when there are zero instances are queued for processing once the endpoint scales up. For more information, see Autoscale an asynchronous endpoint.

Amazon SageMaker Serverless Inference also automatically scales down to zero. You won't see this because SageMaker AI manages scaling your serverless endpoints, but if you are not experiencing any traffic, the same infrastructure applies.

Implement MLOps

Amazon SageMaker AI supports features to implement machine learning models in production environments with continuous integration and deployment. The following topics give information about how to set up MLOps infrastructure when using SageMaker AI.

Topics

- Why Should You Use MLOps?
- SageMaker Experiments
- SageMaker AI Workflows
- Amazon SageMaker ML Lineage Tracking
- Model Registration Deployment with Model Registry
- Model Deployment in SageMaker AI
- SageMaker Model Monitor
- MLOps Automation With SageMaker Projects
- Amazon SageMaker AI MLOps troubleshooting

Why Should You Use MLOps?

As you move from running individual artificial intelligence and machine learning (AI/ML) projects to using AI/ML to transform your business at scale, the discipline of ML Operations (MLOps) can help. MLOps accounts for the unique aspects of AI/ML projects in project management, CI/CD, and quality assurance, helping you improve delivery time, reduce defects, and make data science more productive. MLOps refers to a methodology that is built on applying DevOps practices to machine learning workloads. For a discussion of DevOps principles, see the white paper Introduction to DevOps on Amazon. To learn more about implementation using Amazon services, see Practicing CI/CD on Amazon and Infrastructure as Code.

Like DevOps, MLOps relies on a collaborative and streamlined approach to the machine learning development lifecycle where the intersection of people, process, and technology optimizes the end-to-end activities required to develop, build, and operate machine learning workloads.

MLOps focuses on the intersection of data science and data engineering in combination with existing DevOps practices to streamline model delivery across the machine learning development lifecycle. MLOps is the discipline of integrating ML workloads into release management, CI/CD, and

operations. MLOps requires the integration of software development, operations, data engineering, and data science.

Challenges with MLOps

Although MLOps can provide valuable tools to help you scale your business, you might face certain issues as you integrate MLOps into your machine learning workloads.

Project management

- ML projects involve data scientists, a relatively new role, and one not often integrated into cross-functional teams. These new team members often speak a very different technical language than product owners and software engineers, compounding the usual problem of translating business requirements into technical requirements.

Communication and collaboration

- Building visibility on ML projects and enabling collaboration across different stakeholders such as data engineers, data scientists, ML engineers, and DevOps is becoming increasingly important to ensure successful outcomes.

Everything is code

- Use of production data in development activities, longer experimentation lifecycles, dependencies on data pipelines, retraining deployment pipelines, and unique metrics in evaluating the performance of a model.
- Models often have a lifecycle independent of the applications and systems integrating with those models.
- The entire end-to-end system is reproducible through versioned code and artifacts. DevOps projects use Infrastructure-as-Code (IaC) and Configuration-as-Code (CaC) to build environments, and Pipelines-as-Code (PaC) to ensure consistent CI/CD patterns. The pipelines have to integrate with Big Data and ML training workflows. That often means that the pipeline is a combination of a traditional CI/CD tool and another workflow engine. There are important policy concerns for many ML projects, so the pipeline may also need to enforce those policies. Biased input data produces biased results, an increasing concern for business stakeholders.

CI/CD

- In MLOps, the source data is a first-class input, along with source code. That's why MLOps calls for versioning the source data and initiating pipeline runs when the source or inference data changes.
- Pipelines must also version the ML models, along with inputs and other outputs, in order to provide for traceability.
- Automated testing must include proper validation of the ML model during build phases and when the model is in production.
- Build phases may include model training and retraining, a time-consuming and resource-intensive process. Pipelines must be granular enough to only perform a full training cycle when the source data or ML code changes, not when related components change.
- Because machine learning code is typically a small part of an overall solution, a deployment pipeline may also incorporate the additional steps required to package a model for consumption as an API by other applications and systems.

Monitoring and logging

- The feature engineering and model training phases needed to capture model training metrics as well as model experiments. Tuning an ML model requires manipulating the form of the input data as well as algorithm hyperparameters, and systematically capture those experiments. Experiment tracking helps data scientists work more effectively and gives a reproducible snapshot of their work.
- Deployed ML models require monitoring of the data passed to the model for inference, along with the standard endpoint stability and performance metrics. The monitoring system must also capture the quality of model output, as evaluated by an appropriate ML metric.

Benefits of MLOps

Adopting MLOps practices gives you faster time-to-market for ML projects by delivering the following benefits.

- **Productivity**: Providing self-service environments with access to curated data sets lets data engineers and data scientists move faster and waste less time with missing or invalid data.
- **Repeatability**: Automating all the steps in the MLDC helps you ensure a repeatable process, including how the model is trained, evaluated, versioned, and deployed.

- **Reliability**: Incorporating CI/CD practices allows for the ability to not only deploy quickly but with increased quality and consistency.
- **Auditability**: Versioning all inputs and outputs, from data science experiments to source data to trained model, means that we can demonstrate exactly how the model was built and where it was deployed.
- **Data and model quality**: MLOps lets us enforce policies that guard against model bias and track changes to data statistical properties and model quality over time.

SageMaker Experiments

ML model building requires many iterations of training as you tune the algorithm, model architecture, and parameters to achieve high prediction accuracy. You can track the inputs and outputs across these training iterations to improve repeatability of trials and collaboration within your team using Amazon SageMaker Experiments. You can also track parameters, metrics, datasets, and other artifacts related to your model training jobs. SageMaker Experiments offers a single interface where you can visualize your in-progress training jobs, share experiments within your team, and deploy models directly from an experiment.

To learn about SageMaker Experiments, see Amazon SageMaker Experiments in Studio Classic.

SageMaker AI Workflows

As you scale your machine learning (ML) operations, you can use Amazon SageMaker AI fully managed workflow services to implement continuous integration and deployment (CI/CD) practices for your ML lifecycle. With the Pipelines SDK, you choose and integrate pipeline steps into a unified solution that automates the model-building process from data preparation to model deployment. For Kubernetes based architectures, you can install SageMaker AI Operators on your Kubernetes cluster to create SageMaker AI jobs natively using the Kubernetes API and command-line Kubernetes tools such as `kubectl`. With SageMaker AI components for Kubeflow pipelines, you can create and monitor native SageMaker AI jobs from your Kubeflow Pipelines. The job parameters, status, and outputs from SageMaker AI are accessible from the Kubeflow Pipelines UI. Lastly, if you want to schedule batch jobs, you can use either the Amazon Batch job queue integration or the Jupyter notebook-based workflows service to initiate standalone or regular runs on a schedule you define.

In summary, SageMaker AI offers the following workflow technologies:

- Pipelines: Tool for building and managing ML pipelines.
- Kubernetes Orchestration: SageMaker AI custom operators for your Kubernetes cluster and components for Kubeflow Pipelines.
- SageMaker Notebook Jobs: On demand or scheduled non-interactive batch runs of your Jupyter notebook.

You can also leverage other services that integrate with SageMaker AI to build your workflow. Options include the following services:

- Airflow Workflows: SageMaker APIs to export configurations for creating and managing Airflow workflows.
- Amazon Step Functions: Multi-step ML workflows in Python that orchestrate SageMaker AI infrastructure without having to provision your resources separately.
- Amazon Batch: Submit SageMaker AI training jobs to an Amazon Batch job queue, where you can prioritize and schedule jobs to run in a compute environment.

For more information on managing SageMaker training and inference, see Amazon SageMaker Python SDK Workflows.

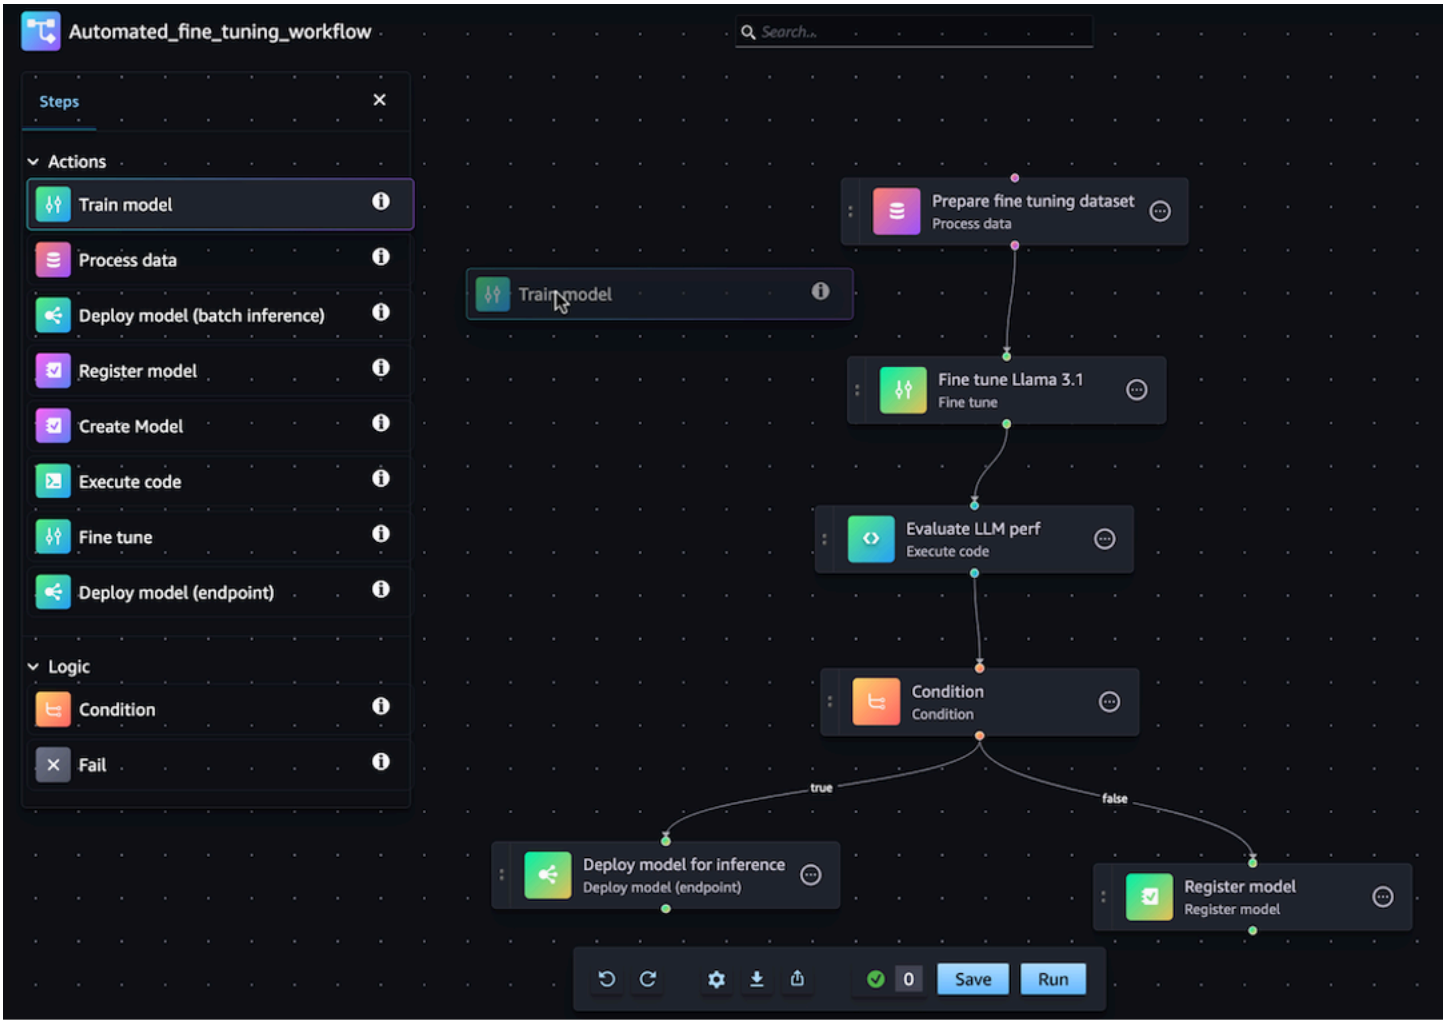
Pipelines



Amazon SageMaker Pipelines is a purpose-built workflow orchestration service to automate machine learning (ML) development.

Pipelines provide the following advantages over other Amazon workflow offerings:

Auto-scaling serverless infrastructure You don't need to manage the underlying orchestration infrastructure to run Pipelines, which allows you to focus on core ML tasks. SageMaker AI

automatically provisions, scales, and shuts down the pipeline orchestration compute resources as your ML workload demands.

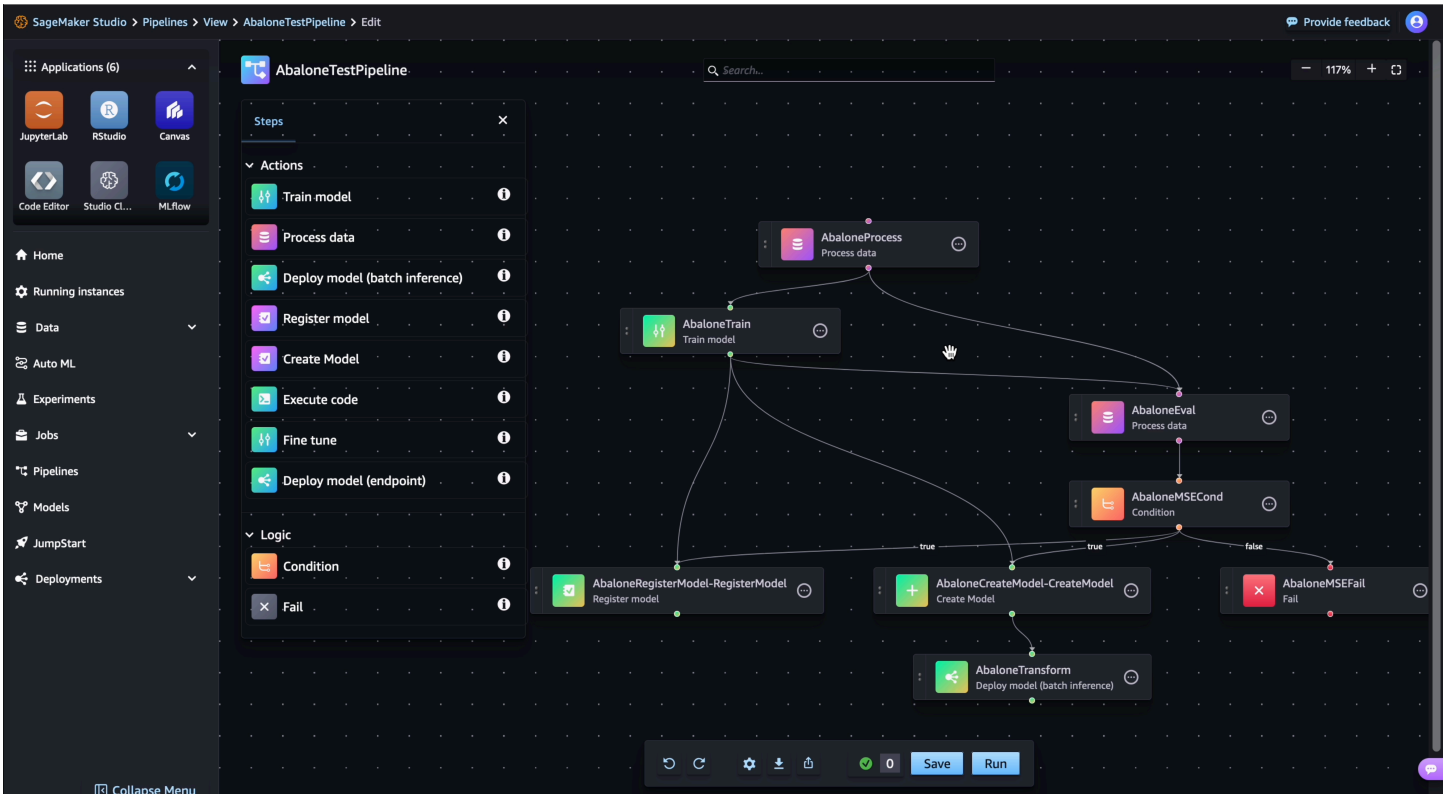
Intuitive user experience Pipelines can be created and managed through your interface of choice: visual editor, SDK, APIs, or JSON. You can drag-and-drop the various ML steps to author your pipelines in the Amazon SageMaker Studio visual interface. The following screenshot shows the Studio visual editor for pipelines.

If you prefer managing your ML workflows programmatically, the SageMaker Python SDK offers advanced orchestration features. For more information, see Amazon SageMaker Pipelines in the SageMaker Python SDK documentation.

Amazon integrations Pipelines provide seamless integration with all SageMaker AI features and other Amazon services to automate data processing, model training, fine-tuning, evaluation, deployment, and monitoring jobs. You can incorporate the SageMaker AI features in your Pipelines

and navigate across them using deep links to create, monitor, and debug your ML workflows at scale.

Reduced costs With Pipelines, you only pay for the SageMaker Studio environment and the underlying jobs that are orchestrated by Pipelines (for example, SageMaker Training, SageMaker Processing, SageMaker AI Inference, and Amazon S3 data storage).



Auditability and lineage tracking With Pipelines, you can track the history of pipeline updates and executions using built-in versioning. Amazon SageMaker ML Lineage Tracking helps you analyze the data sources and data consumers in the end-to-end ML development lifecycle.

Pipelines overview

An Amazon SageMaker AI pipeline is a series of interconnected steps in directed acyclic graph (DAG) that are defined using the drag-and-drop UI or Pipelines SDK. You can also build your pipeline using the pipeline definition JSON schema. This DAG JSON definition gives information on the requirements and relationships between each step of your pipeline. The structure of a pipeline's DAG is determined by the data dependencies between steps. These data dependencies are created when the properties of a step's output are passed as the input to another step. The following image is an example of a pipeline DAG:

The example DAG includes the following steps:

1. `AbaloneProcess`, an instance of the Processing step, runs a preprocessing script on the data used for training. For example, the script could fill in missing values, normalize numerical data, or split data into the train, validation, and test datasets.
2. `AbaloneTrain`, an instance of the Training step, configures hyperparameters and trains a model from the preprocessed input data.
3. `AbaloneEval`, another instance of the Processing step, evaluates the model for accuracy. This step shows an example of a data dependency—this step uses the test dataset output of the `AbaloneProcess`.
4. `AbaloneMSECond` is an instance of a Condition step which, in this example, checks to make sure the mean-square-error result of model evaluation is below a certain limit. If the model does not meet the criteria, the pipeline run stops.
5. The pipeline run proceeds with the following steps:

    a. `AbaloneRegisterModel`, where SageMaker AI calls a RegisterModel step to register the model as a versioned model package group into the Amazon SageMaker Model Registry.

b. `AbaloneCreateModel`, where SageMaker AI calls a CreateModel step to create the model in preparation for batch transform. In `AbaloneTransform`, SageMaker AI calls a Transform step to generate model predictions on a dataset you specify.

The following topics describe fundamental Pipelines concepts. For a tutorial describing the implementation of these concepts, see Pipelines actions.

Pipeline Structure and Execution

Topics

- Pipeline Structure
- Pipeline Execution using Parallelism Configuration

Pipeline Structure

An Amazon SageMaker Pipelines instance is composed of a `name`, `parameters`, and `steps`. Pipeline names must be unique within an `(account, region)` pair. All parameters used in step definitions must be defined in the pipeline. Pipeline steps listed automatically determine their order of execution by their data dependencies on one another. The Pipelines service resolves the relationships between steps in the data dependency DAG to create a series of steps that the execution completes. The following is an example of a pipeline structure.

> **Warning**
>
> When building a pipeline through the visual editor or SageMaker AI Python SDK, do not include sensitive information in pipeline parameters or any step definition field (such as environment variables). These fields will be visible in the future when returned in a `DescribePipeline` request.

```
from sagemaker.workflow.pipeline import Pipeline

  pipeline_name = f"AbalonePipeline"
  pipeline = Pipeline(
      name=pipeline_name,
      parameters=[
          processing_instance_type,
          processing_instance_count,
          training_instance_type,
          model_approval_status,
          input_data,
          batch_data,
      ],
      steps=[step_process, step_train, step_eval, step_cond],
  )
```

Pipeline Execution using Parallelism Configuration

By default, a pipeline performs all steps that are available to run in parallel. You can control this behavior by using the `ParallelismConfiguration` property when creating or updating a pipeline, as well as when starting or retrying a pipeline execution.

Parallelism configurations are applied per execution. For example, if two executions are started they can each run a maximum of 50 steps concurrently, for a total of 100 concurrently running steps. Also, `ParallelismConfiguration`(s) specified when starting, retrying or updating an execution take precedence over parallelism configurations defined in the pipeline.

Example Creating a pipeline execution with `ParallelismConfiguration`

```
pipeline = Pipeline(
        name="myPipeline",
        steps=[step_process, step_train]
    )

  pipeline.create(role, parallelism_config={"MaxParallelExecutionSteps": 50})
```

IAM Access Management

The following sections describe the Amazon Identity and Access Management (IAM) requirements for Amazon SageMaker Pipelines. For an example of how you can implement these permissions, see Prerequisites.

Topics

- Pipeline Role Permissions
- Pipeline Step Permissions
- CORS configuration with Amazon S3 buckets
- Customize access management for Pipelines jobs
- Customize access to pipeline versions
- Service Control Policies with Pipelines

Pipeline Role Permissions

Your pipeline requires an IAM pipeline execution role that is passed to Pipelines when you create a pipeline. The role for the SageMaker AI instance you're using to create the pipeline must have a policy with the `iam:PassRole` permission that specifies the pipeline execution role. This is because the instance needs permission to pass your pipeline execution role to the Pipelines service for use in creating and running pipelines. For more information on IAM roles, see IAM Roles.

Your pipeline execution role requires the following permissions:

- You can use a unique or customized role for any of the SageMaker AI job steps in your pipeline (rather than the pipeline execution role, which is used by default). Make sure that your pipeline execution role has added a policy with the `iam:PassRole` permission that specifies each of these roles.
- `Create` and `Describe` permissions for each of the job types in the pipeline.
- Amazon S3 permissions to use the `JsonGet` function. You control access to your Amazon S3 resources using resource-based policies and identity-based policies. A resource-based policy is applied to your Amazon S3 bucket and grants Pipelines access to the bucket. An identity-based policy gives your pipeline the ability to make Amazon S3 calls from your account. For more information on resource-based policies and identity-based policies, see Identity-based policies and resource-based policies.

```
{
    "Action": [
        "s3:GetObject"
    ],
    "Resource": "arn:aws:s3:::<your-bucket-name>/*",
    "Effect": "Allow"
}
```

Pipeline Step Permissions

Pipelines include steps that run SageMaker AI jobs. In order for the pipeline steps to run these jobs, they require an IAM role in your account that provides access for the needed resource. This role is passed to the SageMaker AI service principal by your pipeline. For more information on IAM roles, see IAM Roles.

By default, each step takes on the pipeline execution role. You can optionally pass a different role to any of the steps in your pipeline. This ensures that the code in each step does not have the ability to impact resources used in other steps unless there is a direct relationship between the two steps specified in the pipeline definition. You pass these roles when defining the processor or estimator for your step. For examples of how to include these roles in these definitions, see the SageMaker AI Python SDK documentation.

CORS configuration with Amazon S3 buckets

To ensure your images are imported into your Pipelines from an Amazon S3 bucket in a predictable manner, a CORS configuration must be added to Amazon S3 buckets where images are imported

from. This section provides instructions on how to set the required CORS configuration to your Amazon S3 bucket. The XML `CORSConfiguration` required for Pipelines differs from the one in CORS Requirement for Input Image Data, otherwise you can use the information there to learn more about the CORS requirement with Amazon S3 buckets.

Use the following CORS configuration code for the Amazon S3 buckets that host your images. For instructions on configuring CORS, see Configuring cross-origin resource sharing (CORS) in the Amazon Simple Storage Service User Guide. If you use the Amazon S3 console to add the policy to your bucket, you must use the JSON format.

JSON

```
[
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
            "PUT"
        ],
        "AllowedOrigins": [
            "*"
        ],
        "ExposeHeaders": [
            "Access-Control-Allow-Origin"
        ]
    }
]
```

XML

```
<CORSConfiguration>
 <CORSRule>
   <AllowedHeader>*</AllowedHeader>
   <AllowedOrigin>*</AllowedOrigin>
   <AllowedMethod>PUT</AllowedMethod>
   <ExposeHeader>Access-Control-Allow-Origin</ExposeHeader>
 </CORSRule>
</CORSConfiguration>
```

Customize access management for Pipelines jobs

You can further customize your IAM policies so selected members in your organization can run any or all pipeline steps. For example, you can give certain users permission to create training jobs, and another group of users permission to create processing jobs, and all of your users permission to run the remaining steps. To use this feature, you select a custom string which prefixes your job name. Your admin prepends the permitted ARNs with the prefix while your data scientist includes this prefix in pipeline instantiations. Because the IAM policy for permitted users contains a job ARN with the specified prefix, subsequent jobs of your pipeline step have necessary permissions to proceed. Job prefixing is off by default—you must toggle on this option in your `Pipeline` class to use it.

For jobs with prefixing turned off, the job name is formatted as shown and is a concatenation of fields described in the following table:

`pipelines-<executionId>-<stepNamePrefix>-<entityToken>-<failureCount>`

Field	Definition
pipelines	A static string always prepended. This string identifies the pipeline orchestration service as the job's source.
executionId	A randomized buffer for the running instance of the pipeline.
stepNamePrefix	The user-specified step name (given in the `name` argument of the pipeline step), limited to the first 20 characters.
entityToken	A randomized token to ensure idempotency of the step entity.

Field	Definition
failureCount	The current number of retries attempted to complete the job.

In this case, no custom prefix is prepended to the job name, and the corresponding IAM policy must match this string.

For users who turn on job prefixing, the underlying job name takes the following form, with the custom prefix specified as `MyBaseJobName`:

<MyBaseJobName>-*<executionId>*-*<entityToken>*-*<failureCount>*

The custom prefix replaces the static `pipelines` string to help you narrow the selection of users who can run the SageMaker AI job as a part of a pipeline.

Prefix length restrictions

The job names have internal length constraints specific to individual pipeline steps. This constraint also limits the length of the allowed prefix. The prefix length requirements are as follows:

Pipeline step	Prefix length
TrainingStep, ModelStep, TransformStep, ProcessingStep, ClarifyCheckStep, QualityCheckStep, RegisterModelStep	38
TuningStep, AutoML	6

Apply job prefixes to an IAM policy

Your admin creates IAM policies allowing users of specific prefixes to create jobs. The following example policy permits data scientists to create training jobs if they use the `MyBaseJobName` prefix.

```
{
```

```
    "Action": "sagemaker:CreateTrainingJob",
    "Effect": "Allow",
    "Resource": [
        "arn:aws:sagemaker:region:account-id:*/MyBaseJobName-*"
    ]
}
```

Apply job prefixes to pipeline instantiations

You specify your prefix with the `*base_job_name` argument of the job instance class.

> **Note**
>
> You pass your job prefix with the `*base_job_name` argument to the job instance before creating a pipeline step. This job instance contains the necessary information for the job to run as a step in a pipeline. This argument varies depending upon the job instance used. The following list shows which argument to use for each pipeline step type:
>
> - `base_job_name` for the `Estimator` (`TrainingStep`), `Processor` (`ProcessingStep`), and `AutoML` (`AutoMLStep`) classes
> - `tuning_base_job_name` for the `Tuner` class (`TuningStep`)
> - `transform_base_job_name` for the `Transformer` class (`TransformStep`)
> - `base_job_name` of `CheckJobConfig` for the `QualityCheckStep` (Quality Check) and `ClarifyCheckstep` (Clarify Check) classes
> - For the `Model` class, the argument used depends on if you run `create` or `register` on your model before passing the result to `ModelStep`
>   - If you call `create`, the custom prefix comes from the `name` argument when you construct your model (i.e., `Model(name=)`)
>   - If you call `register`, the custom prefix comes from the `model_package_name` argument of your call to `register` (i.e., *`my_model`*`.register(model_package_name=)`)

The following example shows how to specify a prefix for a new training job instance.

```
# Create a job instance
xgb_train = Estimator(
    image_uri=image_uri,
```

```
    instance_type="ml.m5.xlarge",
    instance_count=1,
    output_path=model_path,
    role=role,
    subnets=["subnet-0ab12c34567de89f0"],
    base_job_name="MyBaseJobName"
    security_group_ids=["sg-1a2bbcc3bd4444e55"],
    tags = [ ... ]
    encrypt_inter_container_traffic=True,
)

# Attach your job instance to a pipeline step
step_train = TrainingStep(
    name="TestTrainingJob",
    estimator=xgb_train,
    inputs={
        "train": TrainingInput(...),
        "validation": TrainingInput(...)
    }
)
```

Job prefixing is off by default. To opt into this feature, use the `use_custom_job_prefix` option of `PipelineDefinitionConfig` as shown in the following snippet:

```
from sagemaker.workflow.pipeline_definition_config import PipelineDefinitionConfig

# Create a definition configuration and toggle on custom prefixing
definition_config = PipelineDefinitionConfig(use_custom_job_prefix=True);

# Create a pipeline with a custom prefix
 pipeline = Pipeline(
     name="MyJobPrefixedPipeline",
     parameters=[...]
     steps=[...]
     pipeline_definition_config=definition_config
)
```

Create and run your pipeline. The following example creates and runs a pipeline, and also demonstrates how you can turn off job prefixing and rerun your pipeline.

```
pipeline.create(role_arn=sagemaker.get_execution_role())
```

```
# Optionally, call definition() to confirm your prefixed job names are in the built
 JSON
pipeline.definition()
pipeline.start()

# To run a pipeline without custom-prefixes, toggle off use_custom_job_prefix, update
 the pipeline
# via upsert() or update(), and start a new run
definition_config = PipelineDefinitionConfig(use_custom_job_prefix=False)
pipeline.pipeline_definition_config = definition_config
pipeline.update()
execution = pipeline.start()
```

Similarly, you can toggle the feature on for existing pipelines and start a new run which uses job prefixes.

```
definition_config = PipelineDefinitionConfig(use_custom_job_prefix=True)
pipeline.pipeline_definition_config = definition_config
pipeline.update()
execution = pipeline.start()
```

Finally, you can view your custom-prefixed job by calling `list_steps` on the pipeline execution.

```
steps = execution.list_steps()

prefixed_training_job_name = steps['PipelineExecutionSteps'][0]['Metadata']
['TrainingJob']['Arn']
```

Customize access to pipeline versions

You can grant customized access to specific versions of Amazon SageMaker Pipelines by using the `sagemaker:PipelineVersionId` condition key. For example, the policy below grants access to start executions or update pipeline version only for version ID 6 and above.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": {
        "Sid": "AllowStartPipelineExecution",
```

```
        "Effect": "Allow",
        "Action": [
            "sagemaker:StartPipelineExecution",
            "sagemaker:UpdatePipelineVersion"
        ],
        "Resource": "*",
        "Condition": {
            "NumericGreaterThanEquals": {
                "sagemaker:PipelineVersionId": 6
            }
        }
    }
}
```

For more information about supported condition keys, see Condition keys for Amazon SageMaker AI.

Service Control Policies with Pipelines

Service control policies (SCPs) are a type of organization policy that you can use to manage permissions in your organization. SCPs offer central control over the maximum available permissions for all accounts in your organization. By using Pipelines within your organization, you can ensure that data scientists manage your pipeline executions without having to interact with the Amazon console.

If you're using a VPC with your SCP that restricts access to Amazon S3, you need to take steps to allow your pipeline to access other Amazon S3 resources.

To allow Pipelines to access Amazon S3 outside of your VPC with the `JsonGet` function, update your organization's SCP to ensure that the role using Pipelines can access Amazon S3. To do this, create an exception for roles that are being used by the Pipelines executor via the pipeline execution role using a principal tag and condition key.

To allow Pipelines to access Amazon S3 outside of your VPC

1. Create a unique tag for your pipeline execution role following the steps in Tagging IAM users and roles.
2. Grant an exception in your SCP using the `Aws:PrincipalTag IAM` condition key for the tag you created. For more information, see Creating, updating, and deleting service control policies.

Set up cross-account support for Pipelines

Cross-account support for Amazon SageMaker Pipelines enables you to collaborate on machine learning pipelines with other teams or organizations that operate in different Amazon accounts. By setting up cross-account pipeline sharing, you can grant controlled access to pipelines, allow other accounts to view pipeline details, trigger executions, and monitor runs. The following topic covers how to set up cross-account pipeline sharing, the different permission policies available for shared resources, and how to access and interact with shared pipeline entities through direct API calls to SageMaker AI.

Set up cross-account pipeline sharing

SageMaker AI uses Amazon Resource Access Manager (Amazon RAM) to help you securely share your pipeline entities across accounts.

Create a resource share

1. Select **Create a resource share** through the Amazon RAM console.
2. When specifying resource share details, choose the Pipelines resource type and select one or more pipelines that you want to share. When you share a pipeline with any other account, all of its executions are also shared implicitly.
3. Associate permissions with your resource share. Choose either the default read-only permission policy or the extended pipeline execution permission policy. For more detailed information, see Permission policies for Pipelines resources.

   > **Note**
   >
   > If you select the extended pipeline execution policy, note that any start, stop, and retry commands called by shared accounts use resources in the Amazon account that shared the pipeline.

4. Use Amazon account IDs to specify the accounts to which you want to grant access to your shared resources.
5. Review your resource share configuration and select **Create resource share**. It may take a few minutes for the resource share and principal associations to complete.

For more information, see Sharing your Amazon resources in the *Amazon Resource Access Manager User Guide*.

Get responses to your resource share invitation

Once the resource share and principal associations are set, the specified Amazon accounts receive an invitation to join the resource share. The Amazon accounts must accept the invite to gain access to any shared resources.

For more information on accepting a resource share invite through Amazon RAM, see Using shared Amazon resources in the *Amazon Resource Access Manager User Guide*.

Permission policies for Pipelines resources

When creating your resource share, choose one of two supported permission policies to associate with the SageMaker AI pipeline resource type. Both policies grant access to any selected pipeline and all of its executions.

Default read-only permissions

The `AWSRAMDefaultPermissionSageMakerPipeline` policy allows the following read-only actions:

```
"sagemaker:DescribePipeline"
"sagemaker:DescribePipelineDefinitionForExecution"
"sagemaker:DescribePipelineExecution"
"sagemaker:ListPipelineExecutions"
"sagemaker:ListPipelineExecutionSteps"
"sagemaker:ListPipelineParametersForExecution"
"sagemaker:Search"
```

Extended pipeline execution permissions

The `AWSRAMPermissionSageMakerPipelineAllowExecution` policy includes all of the read-only permissions from the default policy and also allows shared accounts to start, stop, and retry pipeline executions.

> **Note**
>
> Be mindful of Amazon resource usage when using the extended pipeline execution permission policy. With this policy, shared accounts are allowed to start, stop, and retry pipeline executions. Any resources used for shared pipeline executions are consumed by the owner account.

The extended pipeline execution permission policy allows the following actions:

```
"sagemaker:DescribePipeline"
"sagemaker:DescribePipelineDefinitionForExecution"
"sagemaker:DescribePipelineExecution"
"sagemaker:ListPipelineExecutions"
"sagemaker:ListPipelineExecutionSteps"
"sagemaker:ListPipelineParametersForExecution"
"sagemaker:StartPipelineExecution"
"sagemaker:StopPipelineExecution"
"sagemaker:RetryPipelineExecution"
"sagemaker:Search"
```

Access shared pipeline entities through direct API calls

Once cross-account pipeline sharing is set up, you can call the following SageMaker API actions using a pipeline ARN:

> **Note**
>
> You can only call API commands if they are included in the permissions associated with your resource share. If you select the `AWSRAMPermissionSageMakerPipelineAllowExecution` policy, then the start, stop, and retry commands use resources in the Amazon account that shared the pipeline.

- DescribePipelineExecution
- ListPipelineExecutions
- ListPipelineExecutionSteps
- ListPipelineParametersForExecution
- StartPipelineExecution
- StopPipelineExecution
- RetryPipelineExecution

Pipeline parameters

You can introduce variables into your pipeline definition using parameters. You can reference parameters that you define throughout your pipeline definition. Parameters have a default value, which you can override by specifying parameter values when starting a pipeline execution. The default value must be an instance matching the parameter type. All parameters used in step definitions must be defined in your pipeline definition. This topic describes the parameters that you can define and how to implement them.

Amazon SageMaker Pipelines supports the following parameter types:

- `ParameterString` – Representing a string parameter.
- `ParameterInteger` – Representing an integer parameter.
- `ParameterFloat` – Representing a float parameter.
- `ParameterBoolean` – Representing a Boolean Python type.

Parameters take the following format:

```
<parameter> = <parameter_type>(
    name="<parameter_name>",
    default_value=<default_value>
)
```

The following example shows a sample parameter implementation.

```
from sagemaker.workflow.parameters import (
    ParameterInteger,
    ParameterString,
    ParameterFloat,
    ParameterBoolean
)

processing_instance_count = ParameterInteger(
    name="ProcessingInstanceCount",
    default_value=1
)
```

You pass the parameter when creating your pipeline as shown in the following example.

```
pipeline = Pipeline(
```

```
    name=pipeline_name,
    parameters=[
        processing_instance_count
    ],
    steps=[step_process]
)
```

You can also pass a parameter value that differs from the default value to a pipeline execution, as shown in the following example.

```
execution = pipeline.start(
    parameters=dict(
        ProcessingInstanceCount="2",
        ModelApprovalStatus="Approved"
    )
)
```

You can manipulate parameters with SageMaker Python SDK functions like `sagemaker.workflow.functions.Join`. For more information on parameters, see SageMaker Pipelines Parameters.

For known limitations of Pipelines Parameters, see *Limitations - Parameterization* in the Amazon SageMaker Python SDK.

Pipelines steps

Pipelines are composed of steps. These steps define the actions that the pipeline takes and the relationships between steps using properties. The following page describes the types of steps, their properties, and the relationships between them.

Topics

- Add a step
- Add integration
- Step properties
- Step parallelism
- Data dependency between steps
- Custom dependency between steps
- Custom images in a step

Add a step

The following describes the requirements of each step type and provides an example implementation of the step, as well as how to add the step to a Pipelines. These are not working implementations because they don't provide the resource and inputs needed. For a tutorial that implements these steps, see Pipelines actions.

> **Note**
>
> You can also create a step from your local machine learning code by converting it to a Pipelines step with the `@step` decorator. For more information, see @step decorator.

Amazon SageMaker Pipelines support the following step types:

- Execute code

  Processing
- Training
- Tuning
- AutoML
- `Model`
- `Create model`
- `Register model`
- `Deploy model (endpoint)`
- Transform
- Condition
- `Callback`
- Lambda
- `ClarifyCheck`
- `QualityCheck`
- EMR
- Notebook Job

- Fail

@step decorator

If you want to orchestrate a custom ML job that leverages advanced SageMaker AI features or other Amazon services in the drag-and-drop Pipelines UI, use the Execute code step.

You can create a step from local machine learning code using the `@step` decorator. After you test your code, you can convert the function to a SageMaker AI pipeline step by annotating it with the `@step` decorator. Pipelines creates and runs a pipeline when you pass the output of the `@step`-decorated function as a step to your pipeline. You can also create a multi-step DAG pipeline that includes one or more `@step`-decorated functions as well as traditional SageMaker AI pipeline steps. For more details about how to create a step with `@step` decorator, see Lift-and-shift Python code with the @step decorator.

Execute code step

In the Pipelines drag-and-drop UI, you can use an **Execute code** step to run your own code as a pipeline step. You can upload a Python function, script, or notebook to be executed as part of your pipeline. You should use this step if you want to orchestrate a custom ML job that leverages advanced SageMaker AI features or other Amazon services.

The **Execute Code** step uploads files to your default Amazon S3 bucket for Amazon SageMaker AI. This bucket might not have the required Cross-Origin Resource Sharing (CORS) permissions set. To learn more about configuring CORS permissions, see CORS Requirement for Input Image Data.

The **Execute Code** step uses an Amazon SageMaker training job to run your code. Ensure that your IAM role has the `sagemaker:DescribeTrainingJob` and `sagemaker:CreateTrainingJob` API permissions. To learn more about all the required permissions for Amazon SageMaker AI and how to set them up, see Amazon SageMaker AI API Permissions: Actions, Permissions, and Resources Reference.

To add an execute code step to a pipeline using the Pipeline Designer, do the following:

1. Open the Amazon SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.

4. Choose **Blank**.
5. In the left sidebar, choose **Execute code** and drag it to the canvas.
6. In the canvas, choose the **Execute code** step you added.
7. In the right sidebar, complete the forms in the **Setting** and **Details** tabs.
8. You can upload a single file to execute or upload a compressed folder containing multiple artifacts.
9. For single file uploads, you can provide optional parameters for notebooks, python functions, or scripts.
10. When providing Python functions, a handler must be provided in the format `file.py:<function_name>`
11. For compressed folder uploads, relative paths to your code must be provided, and you can optionally provide paths to a `requirements.txt` file or initialization script inside the compressed folder.
12. If the canvas includes any step that immediately precedes the **Execute code** step you added, click and drag the cursor from the step to the **Execute code** step to create an edge.
13. If the canvas includes any step that immediately succeeds the **Execute code** step you added, click and drag the cursor from the **Execute code** step to the step to create an edge. Outputs from **Execute code** steps can be referenced for Python functions.

Processing step

Use a processing step to create a processing job for data processing. For more information on processing jobs, see Process Data and Evaluate Models.

Pipeline Designer

To add a processing step to a pipeline using the Pipeline Designer, do the following:

1. Open the Amazon SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.
4. In the left sidebar, choose **Process data** and drag it to the canvas.
5. In the canvas, choose the **Process data** step you added.

6. In the right sidebar, complete the forms in the **Setting** and **Details** tabs. For information about the fields in these tabs, see sagemaker.workflow.steps.ProcessingStep.
7. If the canvas includes any step that immediately precedes the **Process data** step you added, click and drag the cursor from the step to the **Process data** step to create an edge.
8. If the canvas includes any step that immediately succeeds the **Process data** step you added, click and drag the cursor from the **Process data** step to the step to create an edge.

SageMaker Python SDK

A processing step requires a processor, a Python script that defines the processing code, outputs for processing, and job arguments. The following example shows how to create a `ProcessingStep` definition.

```
from sagemaker.core.processing import Processor, ProcessingInput, ProcessingOutput

processor = Processor(
    image_uri='sklearn-processing-image-uri',
    role=<role>,
    instance_type='ml.m5.xlarge',
    instance_count=1
)
```

```
from sagemaker.mlops.workflow.steps import ProcessingStep

inputs = [
    ProcessingInput(source=<input_data>, destination="/opt/ml/processing/input"),
]

outputs = [
    ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
    ProcessingOutput(output_name="validation", source="/opt/ml/processing/
validation"),
    ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
]

step_process = ProcessingStep(
    name="AbaloneProcess",
    step_args = processor.run(inputs=inputs, outputs=outputs,
        code="abalone/preprocessing.py")
)
```

Pass runtime parameters

The following example shows how to pass runtime parameters from a PySpark processor to a `ProcessingStep`.

```
from sagemaker.core.workflow.pipeline_context import PipelineSession
from sagemaker.core.processing import Processor, ProcessingInput, ProcessingOutput
from sagemaker.mlops.workflow.steps import ProcessingStep

pipeline_session = PipelineSession()

pyspark_processor = Processor(
    image_uri='pyspark-processing-image-uri',
    role=<role>,
    instance_type='ml.m5.xlarge',
    instance_count=1,
    sagemaker_session=pipeline_session,
)

step_args = pyspark_processor.run(
    inputs=[ProcessingInput(source=<input_data>, destination="/opt/ml/processing/
input"),],
    outputs=[
        ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
        ProcessingOutput(output_name="validation", source="/opt/ml/processing/
validation"),
        ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
    ],
    code="preprocess.py",
    arguments=None,
)

step_process = ProcessingStep(
    name="AbaloneProcess",
    step_args=step_args,
)
```

For more information on processing step requirements, see the sagemaker.workflow.steps.ProcessingStep documentation. For an in-depth example, see the Orchestrate Jobs to Train and Evaluate Models with Amazon SageMaker Pipelines

example notebook. The *Define a Processing Step for Feature Engineering* section includes more information.

Training step

You use a training step to create a training job to train a model. For more information on training jobs, see Train a Model with Amazon SageMaker AI.

A training step requires a ModelTrainer, as well as training and validation data inputs.

Pipeline Designer

To add a training step to a pipeline using the Pipeline Designer, do the following:

1. Open the Amazon SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.
4. Choose **Blank**.
5. In the left sidebar, choose **Train model** and drag it to the canvas.
6. In the canvas, choose the **Train model** step you added.
7. In the right sidebar, complete the forms in the **Setting** and **Details** tabs. For information about the fields in these tabs, see sagemaker.workflow.steps.TrainingStep.
8. If the canvas includes any step that immediately precedes the **Train model** step you added, click and drag the cursor from the step to the **Train model** step to create an edge.
9. If the canvas includes any step that immediately succeeds the **Train model** step you added, click and drag the cursor from the **Train model** step to the step to create an edge.

SageMaker Python SDK

The following example shows how to create a `TrainingStep` definition. For more information about training step requirements, see the sagemaker.workflow.steps.TrainingStep documentation.

```
from sagemaker.core.workflow.pipeline_context import PipelineSession
from sagemaker.train import ModelTrainer
from sagemaker.train.configs import InputData, Compute
```

```
from sagemaker.mlops.workflow.steps import TrainingStep
from sagemaker.core import image_uris

pipeline_session = PipelineSession()

training_image = image_uris.retrieve("xgboost", region, "1.7-1")

model_trainer = ModelTrainer(
    training_image=training_image,
    role=role,
    compute=Compute(instance_type="ml.m5.xlarge", instance_count=1),
    hyperparameters={...}
)

step_args = model_trainer.train(
    input_data_config=[
        InputData(
            channel_name="train",
            data_source=step_process.properties.ProcessingOutputConfig.Outputs[
                "train"
            ].S3Output.S3Uri,
        ),
        InputData(
            channel_name="validation",
            data_source=step_process.properties.ProcessingOutputConfig.Outputs[
                "validation"
            ].S3Output.S3Uri,
        )
    ]
)

step_train = TrainingStep(
    name="TrainAbaloneModel",
    step_args=step_args,
)
```

Tuning step

You use a tuning step to create a hyperparameter tuning job, also known as hyperparameter optimization (HPO). A hyperparameter tuning job runs multiple training jobs, with each job producing a model version. For more information on hyperparameter tuning, see Automatic model tuning with SageMaker AI.

The tuning job is associated with the SageMaker AI experiment for the pipeline, with the training jobs created as trials. For more information, see Experiments Integration.

A tuning step requires a HyperparameterTuner and training inputs. You can retrain previous tuning jobs by specifying the `warm_start_config` parameter of the `HyperparameterTuner`. For more information on hyperparameter tuning and warm start, see Run a Warm Start Hyperparameter Tuning Job.

You use the get_top_model_s3_uri method of the sagemaker.workflow.steps.TuningStep class to get the model artifact from one of the top-performing model versions. For a notebook that shows how to use a tuning step in a SageMaker AI pipeline, see sagemaker-pipelines-tuning-step.ipynb.

> **Important**
>
> Tuning steps were introduced in Amazon SageMaker Python SDK v2.48.0 and Amazon SageMaker Studio Classic v3.8.0. You must update Studio Classic before you use a tuning step or the pipeline DAG doesn't display. To update Studio Classic, see Shut Down and Update Amazon SageMaker Studio Classic.

The following example shows how to create a `TuningStep` definition.

```
from sagemaker.workflow.pipeline_context import PipelineSession

from sagemaker.tuner import HyperparameterTuner
from sagemaker.inputs import TrainingInput
from sagemaker.workflow.steps import TuningStep

tuner = HyperparameterTuner(..., sagemaker_session=PipelineSession())

step_tuning = TuningStep(
    name = "HPTuning",
    step_args = tuner.fit(inputs=TrainingInput(s3_data="s3://amzn-s3-demo-bucket/my-data"))
)
```

Get the best model version

The following example shows how to get the best model version from the tuning job using the `get_top_model_s3_uri` method. At most, the top 50 performing versions are available ranked

according to HyperParameterTuningJobObjective. The `top_k` argument is an index into the versions, where `top_k=0` is the best-performing version and `top_k=49` is the worst-performing version.

```
best_model = Model(
    image_uri=image_uri,
    model_data=step_tuning.get_top_model_s3_uri(
        top_k=0,
        s3_bucket=sagemaker_session.default_bucket()
    ),
    ...
)
```

For more information on tuning step requirements, see the sagemaker.workflow.steps.TuningStep documentation.

Fine-tuning step

Fine-tuning trains a pretrained foundation model from Amazon SageMaker JumpStart on a new dataset. This process, also known as transfer learning, can produce accurate models with smaller datasets and less training time. When you fine-tune a model, you can use the default dataset or choose your own data. To learn more about fine-tuning a foundation model from JumpStart, see Fine-Tune a Model.

The fine-tuning step uses an Amazon SageMaker training job to customize your model. Ensure that your IAM role has the `sagemaker:DescribeTrainingJob` and `sagemaker:CreateTrainingJob` API permissions to execute the fine-tuning job in your pipeline. To learn more about the required permissions for Amazon SageMaker AI and how to set them up, see Amazon SageMaker AI API Permissions: Actions, Permissions, and Resources Reference.

To add a **Fine-tune model** step to your pipeline using the drag-and-drop editor, follow these steps:

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.
4. Choose **Blank**.
5. In the left sidebar, choose **Fine-tune model** and drag it to the canvas.
6. In the canvas, choose the **Fine-tune model** step you added.
7. In the right sidebar, complete the forms in the **Setting** and **Details** tabs.

8. If the canvas includes any step that immediately precedes the **Fine-tune model** step you added, click and drag the cursor from the step to the **Fine-tune model** step to create an edge.
9. If the canvas includes any step that immediately succeeds the **Fine-tune model** step you added, click and drag the cursor from the **Fine-tune model** step to the step to create an edge.

AutoML step

Use the AutoML API to create an AutoML job to automatically train a model. For more information on AutoML jobs, see Automate model development with Amazon SageMaker Autopilot.

> **Note**
>
> Currently, the AutoML step supports only ensembling training mode.

The following example shows how to create a definition using `AutoMLStep`.

```
from sagemaker.workflow.pipeline_context import PipelineSession
from sagemaker.workflow.automl_step import AutoMLStep

pipeline_session = PipelineSession()

auto_ml = AutoML(...,
    role="<role>",
    target_attribute_name="my_target_attribute_name",
    mode="ENSEMBLING",
    sagemaker_session=pipeline_session)

input_training = AutoMLInput(
    inputs="s3://amzn-s3-demo-bucket/my-training-data",
    target_attribute_name="my_target_attribute_name",
    channel_type="training",
)
input_validation = AutoMLInput(
    inputs="s3://amzn-s3-demo-bucket/my-validation-data",
    target_attribute_name="my_target_attribute_name",
    channel_type="validation",
)

step_args = auto_ml.fit(
    inputs=[input_training, input_validation]
```

```
)

step_automl = AutoMLStep(
    name="AutoMLStep",
    step_args=step_args,
)
```

Get the best model version

The AutoML step automatically trains several model candidates. Get the model with the best objective metric from the AutoML job using the `get_best_auto_ml_model` method as follows. You must also use an IAM `role` to access model artifacts.

```
best_model = step_automl.get_best_auto_ml_model(role=<role>)
```

For more information, see the AutoML step in the SageMaker Python SDK.

Model step

Use a `ModelStep` to create or register a SageMaker AI model. For more information on `ModelStep` requirements, see the sagemaker.workflow.model_step.ModelStep documentation.

Create a model

You can use a `ModelStep` to create a SageMaker AI model. A `ModelStep` requires model artifacts and information about the SageMaker AI instance type that you need to use to create the model. For more information about SageMaker AI models, see Train a Model with Amazon SageMaker AI.

The following example shows how to create a `ModelStep` definition.

```
from sagemaker.core.workflow.pipeline_context import PipelineSession
from sagemaker.core.resources import Model
from sagemaker.mlops.workflow.model_step import ModelStep

step_train = TrainingStep(...)
model = Model(
    image_uri=pytorch_estimator.training_image_uri(),
    model_data=step_train.properties.ModelArtifacts.S3ModelArtifacts,
    sagemaker_session=PipelineSession(),
    role=role,
)
```

```
step_model_create = ModelStep(
   name="MyModelCreationStep",
   step_args=model.create(instance_type="ml.m5.xlarge"),
)
```

Register a model

You can use a `ModelStep` to register a `sagemaker.model.Model` or a `sagemaker.pipeline.PipelineModel` with the Amazon SageMaker Model Registry. A `PipelineModel` represents an inference pipeline, which is a model composed of a linear sequence of containers that process inference requests. For more information about how to register a model, see Model Registration Deployment with Model Registry.

The following example shows how to create a `ModelStep` that registers a `PipelineModel`.

```
import time

from sagemaker.core.workflow.pipeline_context import PipelineSession
from sagemaker.core.resources import Model
from sagemaker.core import image_uris

pipeline_session = PipelineSession()

code_location = 's3://{0}/{1}/code'.format(bucket_name, prefix)

sklearn_model = SKLearnModel(

 model_data=processing_step.properties.ProcessingOutputConfig.Outputs['model'].S3Output.S3Uri,
   entry_point='inference.py',
   source_dir='sklearn_source_dir/',
   code_location=code_location,
   framework_version='1.0-1',
   role=role,
   sagemaker_session=pipeline_session,
   py_version='py3'
)

xgboost_model = XGBoostModel(
   model_data=training_step.properties.ModelArtifacts.S3ModelArtifacts,
   entry_point='inference.py',
   source_dir='xgboost_source_dir/',
   code_location=code_location,
```

```
   framework_version='0.90-2',
   py_version='py3',
   sagemaker_session=pipeline_session,
   role=role
)

from sagemaker.mlops.workflow.model_step import ModelStep
from sagemaker.core.pipeline_model import PipelineModel

pipeline_model = PipelineModel(
   models=[sklearn_model, xgboost_model],
   role=role,sagemaker_session=pipeline_session,
)

register_model_step_args = pipeline_model.register(
    content_types=["application/json"],
   response_types=["application/json"],
   inference_instances=["ml.t2.medium", "ml.m5.xlarge"],
   transform_instances=["ml.m5.xlarge"],
   model_package_group_name='sipgroup',
)

step_model_registration = ModelStep(
   name="AbaloneRegisterModel",
   step_args=register_model_step_args,
)
```

Create model step

You use a Create model step to create a SageMaker AI model. For more information on SageMaker AI models, see Train a Model with Amazon SageMaker.

A create model step requires model artifacts and information about the SageMaker AI instance type that you need to use to create the model. The following examples show how to create a Create model step definition. For more information about Create model step requirements, see the sagemaker.workflow.steps.CreateModelStep documentation.

Pipeline Designer

To add a create model step to your pipeline, do the following:

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.

2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.
4. Choose **Blank**.
5. In the left sidebar, choose **Create model** and drag it to the canvas.
6. In the canvas, choose the **Create model** step you added.
7. In the right sidebar, complete the forms in the **Setting** and **Details** tabs. For information about the fields in these tabs, see sagemaker.workflow.steps.CreateModelStep.
8. If the canvas includes any step that immediately precedes the **Create model** step you added, click and drag the cursor from the step to the **Create model** step to create an edge.
9. If the canvas includes any step that immediately succeeds the **Create model** step you added, click and drag the cursor from the **Create model** step to the step to create an edge.

SageMaker Python SDK

> **Important**
>
> We recommend using Model step to create models as of v2.90.0 of the SageMaker AI Python SDK. `CreateModelStep` will continue to work in previous versions of the SageMaker Python SDK, but is no longer actively supported.

```
from sagemaker.workflow.steps import CreateModelStep

step_create_model = CreateModelStep(
    name="AbaloneCreateModel",
    model=best_model,
    inputs=inputs
)
```

Register model step

The Register model step registers a model into the SageMaker Model Registry.

Pipeline Designer

To register a model from a pipeline using the Pipeline Designer, do the following:

1. Open the Amazon SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.
4. Choose **Blank**.
5. In the left sidebar, choose **Register model** and drag it to the canvas.
6. In the canvas, choose the **Register model** step you added.
7. In the right sidebar, complete the forms in the **Setting** and **Details** tabs. For information about the fields in these tabs, see sagemaker.workflow.step_collections.RegisterModel.
8. If the canvas includes any step that immediately precedes the **Register model** step you added, click and drag the cursor from the step to the **Register model** step to create an edge.
9. If the canvas includes any step that immediately succeeds the **Register model** step you added, click and drag the cursor from the **Register model** step to the step to create an edge.

SageMaker Python SDK

> **Important**
>
> We recommend using Model step to register models as of v2.90.0 of the SageMaker AI Python SDK. `RegisterModel` will continue to work in previous versions of the SageMaker Python SDK, but is no longer actively supported.

You use a `RegisterModel` step to register a sagemaker.model.Model or a sagemaker.pipeline.PipelineModel with the Amazon SageMaker Model Registry. A `PipelineModel` represents an inference pipeline, which is a model composed of a linear sequence of containers that process inference requests.

For more information about how to register a model, see Model Registration Deployment with Model Registry. For more information on `RegisterModel` step requirements, see the sagemaker.workflow.step_collections.RegisterModel documentation.

The following example shows how to create a `RegisterModel` step that registers a `PipelineModel`.

```
import time
from sagemaker.sklearn import SKLearnModel
from sagemaker.xgboost import XGBoostModel

code_location = 's3://{0}/{1}/code'.format(bucket_name, prefix)

sklearn_model =
 SKLearnModel(model_data=processing_step.properties.ProcessingOutputConfig.Outputs['model'].
 entry_point='inference.py',
 source_dir='sklearn_source_dir/',
 code_location=code_location,
 framework_version='1.0-1',
 role=role,
 sagemaker_session=sagemaker_session,
 py_version='py3')

xgboost_model =
 XGBoostModel(model_data=training_step.properties.ModelArtifacts.S3ModelArtifacts,
 entry_point='inference.py',
 source_dir='xgboost_source_dir/',
 code_location=code_location,
 framework_version='0.90-2',
 py_version='py3',
 sagemaker_session=sagemaker_session,
 role=role)

from sagemaker.workflow.step_collections import RegisterModel
from sagemaker import PipelineModel
pipeline_model =
 PipelineModel(models=[sklearn_model,xgboost_model],role=role,sagemaker_session=sagemaker_se

step_register = RegisterModel(
 name="AbaloneRegisterModel",
 model=pipeline_model,
 content_types=["application/json"],
 response_types=["application/json"],
 inference_instances=["ml.t2.medium", "ml.m5.xlarge"],
 transform_instances=["ml.m5.xlarge"],
 model_package_group_name='sipgroup',
)
```

If `model` isn't provided, the register model step requires an estimator as shown in the following example.

```
from sagemaker.workflow.step_collections import RegisterModel

step_register = RegisterModel(
    name="AbaloneRegisterModel",
    estimator=xgb_train,
    model_data=step_train.properties.ModelArtifacts.S3ModelArtifacts,
    content_types=["text/csv"],
    response_types=["text/csv"],
    inference_instances=["ml.t2.medium", "ml.m5.xlarge"],
    transform_instances=["ml.m5.xlarge"],
    model_package_group_name=model_package_group_name,
    approval_status=model_approval_status,
    model_metrics=model_metrics
)
```

Deploy model (endpoint) step

In the Pipeline Designer, use the Deploy model (endpoint) step to deploy your model to an endpoint. You can create a new endpoint or use an existing endpoint. Real-time inference is ideal for inference workloads where you have real-time, interactive, low latency requirements. You can deploy your model to SageMaker AI Hosting services and get a real-time endpoint that can be used for inference. These endpoints are fully managed and support auto-scaling. To learn more about real-time inference in SageMaker AI, see Real-time inference.

Before adding a deploy model step to your pipeline, make sure that your IAM role has the following permissions:

- `sagemaker:CreateModel`
- `sagemaker:CreateEndpointConfig`
- `sagemaker:CreateEndpoint`
- `sagemaker:UpdateEndpoint`
- `sagemaker:DescribeModel`
- `sagemaker:DescribeEndpointConfig`
- `sagemaker:DescribeEndpoint`

To learn more about all the required permissions for SageMaker AI and how to set them up, see Amazon SageMaker AI API Permissions: Actions, Permissions, and Resources Reference.

To add a model deployment step to your Pipeline in the drag-and-drop editor, complete the following steps:

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.
4. Choose **Blank**.
5. In the left sidebar, choose **Deploy model (endpoint)** and drag it to the canvas.
6. In the canvas, choose the **Deploy model (endpoint)** step you added.
7. In the right sidebar, complete the forms in the **Setting** and **Details** tabs.
8. If the canvas includes any step that immediately precedes the **Deploy model (endpoint)** step you added, click and drag the cursor from the step to the **Deploy model (endpoint)** step to create an edge.
9. If the canvas includes any step that immediately succeeds the **Deploy model (endpoint)** step you added, click and drag the cursor from the **Deploy model (endpoint)** step to the step to create an edge.

Transform step

You use a transform step for batch transformation to run inference on an entire dataset. For more information about batch transformation, see Batch transforms with inference pipelines.

A transform step requires a transformer and the data on which to run batch transformation. The following example shows how to create a Transform step definition. For more information on Transform step requirements, see the sagemaker.workflow.steps.TransformStep documentation.

Pipeline Designer

To add a batch transform step to your pipeline using the drag-and-drop visual editor, do the following:

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.

4. Choose **Blank**.
5. In the left sidebar, choose **Deploy model (batch transform)** and drag it to the canvas.
6. In the canvas, choose the **Deploy model (batch transform)** step you added.
7. In the right sidebar, complete the forms in the **Setting** and **Details** tabs. For information about the fields in these tabs, see sagemaker.workflow.steps.TransformStep.
8. If the canvas includes any step that immediately precedes the **Deploy model (batch transform)** step you added, click and drag the cursor from the step to the **Deploy model (batch transform)** step to create an edge.
9. If the canvas includes any step that immediately succeeds the **Deploy model (batch transform)** step you added, click and drag the cursor from the **Deploy model (batch transform)** step to the step to create an edge.

SageMaker Python SDK

```
from sagemaker.core.workflow.pipeline_context import PipelineSession

from sagemaker.core.transformer import Transformer
from sagemaker.train.configs import TransformInput
from sagemaker.mlops.workflow.steps import TransformStep

transformer = Transformer(..., sagemaker_session=PipelineSession())

step_transform = TransformStep(
    name="AbaloneTransform",
    step_args=transformer.transform(data="s3://amzn-s3-demo-bucket/my-data"),
)
```

Condition step

You use a condition step to evaluate the condition of step properties to assess which action should be taken next in the pipeline.

A condition step requires:

- A list of conditions.
- A list of steps to run if the condition evaluates to `true`.
- A list of steps to run if the condition evaluates to `false`.

Pipeline Designer

To add a condition step to a pipeline using the Pipeline Designer, do the following:

1. Open the Amazon SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.
4. Choose **Blank**.
5. In the left sidebar, choose **Condition** and drag it to the canvas.
6. In the canvas, choose the **Condition** step you added.
7. In the right sidebar, complete the forms in the **Setting** and **Details** tabs. For information about the fields in these tabs, see sagemaker.workflow.condition_step.ConditionStep.
8. If the canvas includes any step that immediately precedes the **Condition** step you added, click and drag the cursor from the step to the **Condition** step to create an edge.
9. If the canvas includes any step that immediately succeeds the **Condition** step you added, click and drag the cursor from the **Condition** step to the step to create an edge.

SageMaker Python SDK

The following example shows how to create a `ConditionStep` definition.

Limitations

- Pipelines doesn't support the use of nested condition steps. You can't pass a condition step as the input for another condition step.
- A condition step can't use identical steps in both branches. If you need the same step functionality in both branches, duplicate the step and give it a different name.

```
from sagemaker.core.workflow.conditions import ConditionLessThanOrEqualTo
from sagemaker.mlops.workflow.condition_step import ConditionStep
from sagemaker.core.workflow.functions import JsonGet

cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step_name=step_eval.name,
```

```
        property_file=evaluation_report,
        json_path="regression_metrics.mse.value"
    ),
    right=6.0
)

step_cond = ConditionStep(
    name="AbaloneMSECond",
    conditions=[cond_lte],
    if_steps=[step_register, step_create_model, step_transform],
    else_steps=[]
)
```

For more information on `ConditionStep` requirements, see the sagemaker.workflow.condition_step.ConditionStep API reference. For more information on supported conditions, see *Amazon SageMaker Pipelines - Conditions* in the SageMaker AI Python SDK documentation.

Callback step

Use a `Callback` step to add additional processes and Amazon services into your workflow that aren't directly provided by Amazon SageMaker Pipelines. When a `Callback` step runs, the following procedure occurs:

- Pipelines sends a message to a customer-specified Amazon Simple Queue Service (Amazon SQS) queue. The message contains a Pipelines–generated token and a customer-supplied list of input parameters. After sending the message, Pipelines waits for a response from the customer.
- The customer retrieves the message from the Amazon SQS queue and starts their custom process.
- When the process finishes, the customer calls one of the following APIs and submits the Pipelines–generated token:
  - SendPipelineExecutionStepSuccess, along with a list of output parameters
  - SendPipelineExecutionStepFailure, along with a failure reason
- The API call causes Pipelines to either continue the pipeline process or fail the process.

For more information on `Callback` step requirements, see the sagemaker.workflow.callback_step.CallbackStep documentation. For a complete solution, see Extend SageMaker Pipelines to include custom steps using callback steps.

Important

`Callback` steps were introduced in Amazon SageMaker Python SDK v2.45.0 and Amazon SageMaker Studio Classic v3.6.2. You must update Studio Classic before you use a `Callback` step or the pipeline DAG doesn't display. To update Studio Classic, see Shut Down and Update Amazon SageMaker Studio Classic.

The following sample shows an implementation of the preceding procedure.

```
from sagemaker.mlops.workflow.callback_step import CallbackStep

step_callback = CallbackStep(
    name="MyCallbackStep",
    sqs_queue_url="https://sqs.us-east-2.amazonaws.com/012345678901/MyCallbackQueue",
    inputs={...},
    outputs=[...]
)

callback_handler_code = '
    import boto3
    import json

    def handler(event, context):
        sagemaker_client=boto3.client("sagemaker")

        for record in event["Records"]:
            payload=json.loads(record["body"])
            token=payload["token"]

            # Custom processing

            # Call SageMaker AI to complete the step
            sagemaker_client.send_pipeline_execution_step_success(
                CallbackToken=token,
                OutputParameters={...}
            )
'
```

> **Note**
>
> Output parameters for `CallbackStep` should not be nested. For example, if you use a nested dictionary as your output parameter, then the dictionary is treated as a single string (ex. `{"output1": "{\"nested_output1\":\"my-output\"}"}`). If you provide a nested value, then when you try to refer to a particular output parameter, SageMaker AI throws a non-retryable client error.

Stopping behavior

A pipeline process doesn't stop while a `Callback` step is running.

When you call StopPipelineExecution on a pipeline process with a running `Callback` step, Pipelines sends an Amazon SQS message to the SQS queue. The body of the SQS message contains a **Status** field, which is set to `Stopping`. The following shows an example SQS message body.

```
{
  "token": "26vcYbeWsZ",
  "pipelineExecutionArn": "arn:aws:sagemaker:us-east-2:012345678901:pipeline/callback-
pipeline/execution/7pinimwddh3a",
  "arguments": {
    "number": 5,
    "stringArg": "some-arg",
    "inputData": "s3://sagemaker-us-west-2-012345678901/abalone/abalone-dataset.csv"
  },
  "status": "Stopping"
}
```

You should add logic to your Amazon SQS message consumer to take any needed action (for example, resource cleanup) upon receipt of the message. Then add a call to `SendPipelineExecutionStepSuccess` or `SendPipelineExecutionStepFailure`.

Only when Pipelines receives one of these calls does it stop the pipeline process.

Lambda step

You use a Lambda step to run an Amazon Lambda function. You can run an existing Lambda function, or SageMaker AI can create and run a new Lambda function. If you choose to use an existing Lambda function, it must be in the same Amazon Web Services Region as the SageMaker

AI pipeline. For a notebook that shows how to use a Lambda step in a SageMaker AI pipeline, see sagemaker-pipelines-lambda-step.ipynb.

> **Important**
>
> Lambda steps were introduced in Amazon SageMaker Python SDK v2.51.0 and Amazon SageMaker Studio Classic v3.9.1. You must update Studio Classic before you use a Lambda step or the pipeline DAG doesn't display. To update Studio Classic, see Shut Down and Update Amazon SageMaker Studio Classic.

SageMaker AI provides the sagemaker.lambda_helper.Lambda class to create, update, invoke, and delete Lambda functions. `Lambda` has the following signature.

```
Lambda(
    function_arn,       # Only required argument to invoke an existing Lambda function

    # The following arguments are required to create a Lambda function:
    function_name,
    execution_role_arn,
    zipped_code_dir,    # Specify either zipped_code_dir and s3_bucket, OR script
    s3_bucket,          # S3 bucket where zipped_code_dir is uploaded
    script,             # Path of Lambda function script
    handler,            # Lambda handler specified as "lambda_script.lambda_handler"
    timeout,            # Maximum time the Lambda function can run before the lambda
 step fails
    ...
)
```

The sagemaker.workflow.lambda_step.LambdaStep class has a `lambda_func` argument of type `Lambda`. To invoke an existing Lambda function, the only requirement is to supply the Amazon Resource Name (ARN) of the function to `function_arn`. If you don't supply a value for `function_arn`, you must specify `handler` and one of the following:

- `zipped_code_dir` – The path of the zipped Lambda function

  `s3_bucket` – Amazon S3 bucket where `zipped_code_dir` is to be uploaded
- `script` – The path of the Lambda function script file

The following example shows how to create a Lambda step definition that invokes an existing Lambda function.

```
from sagemaker.mlops.workflow.lambda_step import LambdaStep
from sagemaker.lambda_helper import Lambda

step_lambda = LambdaStep(
    name="ProcessingLambda",
    lambda_func=Lambda(
        function_arn="arn:aws:lambda:us-west-2:012345678910:function:split-dataset-
lambda"
    ),
    inputs={
        s3_bucket = s3_bucket,
        data_file = data_file
    },
    outputs=[
        "train_file", "test_file"
    ]
)
```

The following example shows how to create a Lambda step definition that creates and invokes a Lambda function using a Lambda function script.

```
from sagemaker.workflow.lambda_step import LambdaStep
from sagemaker.lambda_helper import Lambda

step_lambda = LambdaStep(
    name="ProcessingLambda",
    lambda_func=Lambda(
      function_name="split-dataset-lambda",
      execution_role_arn=execution_role_arn,
      script="lambda_script.py",
      handler="lambda_script.lambda_handler",
      ...
    ),
    inputs={
        s3_bucket = s3_bucket,
        data_file = data_file
    },
    outputs=[
        "train_file", "test_file"
    ]
```

```
)
```

Inputs and outputs

If your `Lambda` function has inputs or outputs, these must also be defined in your `Lambda` step.

> **Note**
>
> Input and output parameters should not be nested. For example, if you use a nested dictionary as your output parameter, then the dictionary is treated as a single string (ex. `{"output1": "{\"nested_output1\":\"my-output\"}"}`). If you provide a nested value and try to refer to it later, a non-retryable client error is thrown.

When defining the `Lambda` step, `inputs` must be a dictionary of key-value pairs. Each value of the `inputs` dictionary must be a primitive type (string, integer, or float). Nested objects are not supported. If left undefined, the `inputs` value defaults to `None`.

The `outputs` value must be a list of keys. These keys refer to a dictionary defined in the output of the `Lambda` function. Like `inputs`, these keys must be primitive types, and nested objects are not supported.

Timeout and stopping behavior

The `Lambda` class has a `timeout` argument that specifies the maximum time that the Lambda function can run. The default value is 120 seconds with a maximum value of 10 minutes. If the Lambda function is running when the timeout is met, the Lambda step fails; however, the Lambda function continues to run.

A pipeline process can't be stopped while a Lambda step is running because the Lambda function invoked by the Lambda step can't be stopped. If you stop the process while the Lambda function is running, the pipeline waits for the function to finish or until the timeout is hit. This depends on whichever occurs first. The process then stops. If the Lambda function finishes, the pipeline process status is `Stopped`. If the timeout is hit the pipeline process status is `Failed`.

ClarifyCheck step

You can use the `ClarifyCheck` step to conduct baseline drift checks against previous baselines for bias analysis and model explainability. You can then generate and register your baselines

with the `model.register()` method and pass the output of that method to Model step using `step_args`. These baselines for drift check can be used by Amazon SageMaker Model Monitor for your model endpoints. As a result, you don't need to do a baseline suggestion separately.

The `ClarifyCheck` step can also pull baselines for drift check from the model registry. The `ClarifyCheck` step uses the SageMaker Clarify prebuilt container. This container provides a range of model monitoring capabilities, including constraint suggestion and constraint validation against a given baseline. For more information, see Prebuilt SageMaker Clarify Containers.

Configuring the ClarifyCheck step

You can configure the `ClarifyCheck` step to conduct only one of the following check types each time it's used in a pipeline.

- Data bias check
- Model bias check
- Model explainability check

To do this, set the `clarify_check_config` parameter with one of the following check type values:

- `DataBiasCheckConfig`
- `ModelBiasCheckConfig`
- `ModelExplainabilityCheckConfig`

The `ClarifyCheck` step launches a processing job that runs the SageMaker AI Clarify prebuilt container and requires dedicated configurations for the check and the processing job. `ClarifyCheckConfig` and `CheckJobConfig` are helper functions for these configurations. These helper functions are aligned with how the SageMaker Clarify processing job computes for checking model bias, data bias, or model explainability. For more information, see Run SageMaker Clarify Processing Jobs for Bias Analysis and Explainability.

Controlling step behaviors for drift check

The `ClarifyCheck` step requires the following two boolean flags to control its behavior:

- `skip_check`: This parameter indicates if the drift check against the previous baseline is skipped or not. If it is set to `False`, the previous baseline of the configured check type must be available.

- `register_new_baseline`: This parameter indicates if a newly calculated baseline can be accessed though step property `BaselineUsedForDriftCheckConstraints`. If it is set to `False`, the previous baseline of the configured check type also must be available. This can be accessed through the `BaselineUsedForDriftCheckConstraints` property.

For more information, see Baseline calculation, drift detection and lifecycle with ClarifyCheck and QualityCheck steps in Amazon SageMaker Pipelines.

Working with baselines

You can optionally specify the `model_package_group_name` to locate the existing baseline. Then, the `ClarifyCheck` step pulls the `DriftCheckBaselines` on the latest approved model package in the model package group.

Or, you can provide a previous baseline through the `supplied_baseline_constraints` parameter. If you specify both the `model_package_group_name` and the `supplied_baseline_constraints`, the `ClarifyCheck` step uses the baseline specified by the `supplied_baseline_constraints` parameter.

For more information on using the `ClarifyCheck` step requirements, see the sagemaker.workflow.steps.ClarifyCheckStep in the *Amazon SageMaker AI SageMaker AI SDK for Python (Boto)*. For an Amazon SageMaker Studio Classic notebook that shows how to use `ClarifyCheck` step in Pipelines, see sagemaker-pipeline-model-monitor-clarify-steps.ipynb.

Example Create a `ClarifyCheck` step for data bias check

```
from sagemaker.workflow.check_job_config import CheckJobConfig
from sagemaker.mlops.workflow.clarify_check_step import DataBiasCheckConfig,
 ClarifyCheckStep
from sagemaker.workflow.execution_variables import ExecutionVariables
from sagemaker.core.clarify import DataConfig, BiasConfig
from sagemaker.core.workflow.functions import Join

check_job_config = CheckJobConfig(
    role=role,
    instance_count=1,
    instance_type="ml.c5.xlarge",
    volume_size_in_gb=120,
    sagemaker_session=sagemaker_session,
)
```

```
data_bias_data_config = DataConfig(

 s3_data_input_path=step_process.properties.ProcessingOutputConfig.Outputs["train"].S3Output.S3
    s3_output_path=Join(on='/', values=['s3:/', your_bucket, base_job_prefix,
 ExecutionVariables.PIPELINE_EXECUTION_ID, 'databiascheckstep']),
    label=0,
    dataset_type="text/csv",
    s3_analysis_config_output_path=data_bias_analysis_cfg_output_path,
)

data_bias_config = BiasConfig(
    label_values_or_threshold=[15.0], facet_name=[8], facet_values_or_threshold=[[0.5]]

)

data_bias_check_config = DataBiasCheckConfig(
    data_config=data_bias_data_config,
    data_bias_config=data_bias_config,
)

data_bias_check_step = ClarifyCheckStep(
    name="DataBiasCheckStep",
    clarify_check_config=data_bias_check_config,
    check_job_config=check_job_config,
    skip_check=False,
    register_new_baseline=False,
    supplied_baseline_constraints="s3://sagemaker-us-west-2-111122223333/baseline/
analysis.json",
    model_package_group_name="MyModelPackageGroup"
)
```

QualityCheck step

Use the `QualityCheck` step to conduct baseline suggestions and drift checks against a previous baseline for data quality or model quality in a pipeline. You can then generate and register your baselines with the `model.register()` method and pass the output of that method to Model step using `step_args`.]

Model Monitor can use these baselines for drift check for your model endpoints so that you don't need to do a baseline suggestion separately. The `QualityCheck` step can also pull baselines for drift check from the model registry. The `QualityCheck` step leverages the Amazon SageMaker AI Model Monitor prebuilt container. This container has a range of model monitoring capabilities

including constraint suggestion, statistics generation, and constraint validation against a baseline. For more information, see Amazon SageMaker Model Monitor prebuilt container.

Configuring the QualityCheck step

You can configure the `QualityCheck` step to run only one of the following check types each time it's used in a pipeline.

- Data quality check
- Model quality check

You do this by setting the `quality_check_config` parameter with one of the following check type values:

- `DataQualityCheckConfig`
- `ModelQualityCheckConfig`

The `QualityCheck` step launches a processing job that runs the Model Monitor prebuilt container and requires dedicated configurations for the check and the processing job. The `QualityCheckConfig` and `CheckJobConfig` are helper functions for these configurations. These helper functions are aligned with how Model Monitor creates a baseline for the model quality or data quality monitoring. For more information on the Model Monitor baseline suggestions, see Create a Baseline and Create a model quality baseline.

Controlling step behaviors for drift check

The `QualityCheck` step requires the following two Boolean flags to control its behavior:

- `skip_check`: This parameter indicates if the drift check against the previous baseline is skipped or not. If it is set to `False`, the previous baseline of the configured check type must be available.
- `register_new_baseline`: This parameter indicates if a newly calculated baseline can be accessed through step properties `BaselineUsedForDriftCheckConstraints` and `BaselineUsedForDriftCheckStatistics`. If it is set to `False`, the previous baseline of the configured check type must also be available. These can be accessed through the `BaselineUsedForDriftCheckConstraints` and `BaselineUsedForDriftCheckStatistics` properties.

For more information, see Baseline calculation, drift detection and lifecycle with ClarifyCheck and QualityCheck steps in Amazon SageMaker Pipelines.

Working with baselines

You can specify a previous baseline directly through the `supplied_baseline_statistics` and `supplied_baseline_constraints` parameters. You can also specify the `model_package_group_name` and the `QualityCheck` step pulls the `DriftCheckBaselines` on the latest approved model package in the model package group.

When you specify the following, the `QualityCheck` step uses the baseline specified by `supplied_baseline_constraints` and `supplied_baseline_statistics` on the check type of the `QualityCheck` step.

- `model_package_group_name`
- `supplied_baseline_constraints`
- `supplied_baseline_statistics`

For more information on using the `QualityCheck` step requirements, see the sagemaker.workflow.steps.QualityCheckStep in the *Amazon SageMaker AI SageMaker AI SDK for Python (Boto)*. For an Amazon SageMaker Studio Classic notebook that shows how to use `QualityCheck` step in Pipelines, see sagemaker-pipeline-model-monitor-clarify-steps.ipynb.

Example Create a `QualityCheck` step for data quality check

```
from sagemaker.workflow.check_job_config import CheckJobConfig
from sagemaker.mlops.workflow.quality_check_step import DataQualityCheckConfig,
 QualityCheckStep
from sagemaker.workflow.execution_variables import ExecutionVariables
from sagemaker.core.model_monitor.dataset_format import DatasetFormat
from sagemaker.core.workflow.functions import Join

check_job_config = CheckJobConfig(
    role=role,
    instance_count=1,
    instance_type="ml.c5.xlarge",
    volume_size_in_gb=120,
    sagemaker_session=sagemaker_session,
)
```

```
data_quality_check_config = DataQualityCheckConfig(

 baseline_dataset=step_process.properties.ProcessingOutputConfig.Outputs["train"].S3Output.S3Ur
    dataset_format=DatasetFormat.csv(header=False, output_columns_position="START"),
    output_s3_uri=Join(on='/', values=['s3:/', your_bucket, base_job_prefix,
 ExecutionVariables.PIPELINE_EXECUTION_ID, 'dataqualitycheckstep'])
)

data_quality_check_step = QualityCheckStep(
    name="DataQualityCheckStep",
    skip_check=False,
    register_new_baseline=False,
    quality_check_config=data_quality_check_config,
    check_job_config=check_job_config,
    supplied_baseline_statistics="s3://sagemaker-us-west-2-555555555555/baseline/
statistics.json",
    supplied_baseline_constraints="s3://sagemaker-us-west-2-555555555555/baseline/
constraints.json",
    model_package_group_name="MyModelPackageGroup"
)
```

EMR step

Use the Amazon SageMaker Pipelines EMR step to:

- Process Amazon EMR steps on a running Amazon EMR cluster.
- Have the pipeline create and manage an Amazon EMR cluster for you.

For more information about Amazon EMR, see Getting started with Amazon EMR.

The EMR step requires that `EMRStepConfig` include the location of the JAR file used by the Amazon EMR cluster and any arguments to be passed. You also provide the Amazon EMR cluster ID if you want to run the step on a running EMR cluster. You can also pass the cluster configuration to run the EMR step on a cluster that it creates, manages, and terminates for you. The following sections include examples and links to sample notebooks demonstrating both methods.

> **Note**
>
> - EMR steps require that the role passed to your pipeline has additional permissions. Attach the Amazon managed policy: `AmazonSageMakerPipelinesIntegrations` to your pipeline role, or ensure that the role includes the permissions in that policy.

- If you process an EMR step on a running cluster, you can only use a cluster that is in one of the following states:
  - `STARTING`
  - `BOOTSTRAPPING`
  - `RUNNING`
  - `WAITING`
- If you process EMR steps on a running cluster, you can have at most 256 EMR steps in a `PENDING` state on an EMR cluster. EMR steps submitted beyond this limit result in pipeline execution failure. You may consider using Retry Policy for Pipeline Steps.
- You can specify either cluster ID or cluster configuration, but not both.
- The EMR step relies on Amazon EventBridge to monitor changes in the EMR step or cluster state. If you process your Amazon EMR job on a running cluster, the EMR step uses the `SageMakerPipelineExecutionEMRStepStatusUpdateRule` rule to monitor EMR step state. If you process your job on a cluster that the EMR step creates, the step uses the `SageMakerPipelineExecutionEMRClusterStatusRule` rule to monitor changes in cluster state. If you see either of these EventBridge rules in your Amazon account, do not delete them or else your EMR step may not complete.

Add an Amazon EMR step to your pipeline

To add an EMR step to your pipeline, do the following:

- Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
- In the left navigation pane, select **Pipelines**.
- Choose **Create**.
- Choose **Blank**.
- In the left sidebar, choose **Process data** and drag it to the canvas.
- In the canvas, choose the **Process data** step you added.
- In the right sidebar, under mode, choose **EMR (managed)**.
- In the right sidebar, complete the forms in the **Setting and Details** tabs. For information about the fields in these tabs, see sagemaker.workflow.fail_step.EMRstep.

Launch a new job on a running Amazon EMR cluster

To launch a new job on a running Amazon EMR cluster, pass the cluster ID as a string to the `cluster_id` argument of `EMRStep`. The following example demonstrates this procedure.

```
from sagemaker.workflow.emr_step import EMRStep, EMRStepConfig

emr_config = EMRStepConfig(
    jar="jar-location", # required, path to jar file used
    args=["--verbose", "--force"], # optional list of arguments to pass to the jar
    main_class="com.my.Main1", # optional main class, this can be omitted if jar above
 has a manifest
    properties=[ # optional list of Java properties that are set when the step runs
    {
        "key": "mapred.tasktracker.map.tasks.maximum",
        "value": "2"
    },
    {
        "key": "mapreduce.map.sort.spill.percent",
        "value": "0.90"
   },
   {
       "key": "mapreduce.tasktracker.reduce.tasks.maximum",
       "value": "5"
    }
  ]
)

step_emr = EMRStep (
    name="EMRSampleStep", # required
    cluster_id="j-1ABCDEFG2HIJK", # include cluster_id to use a running cluster
    step_config=emr_config, # required
    display_name="My EMR Step",
    description="Pipeline step to execute EMR job"
)
```

For a sample notebook that guides you through a complete example, see Pipelines EMR Step With Running EMR Cluster.

Launch a new job on a new Amazon EMR cluster

To launch a new job on a new cluster that `EMRStep` creates for you, provide your cluster configuration as a dictionary. The dictionary must have the same structure as a RunJobFlow request. However, do not include the following fields in your cluster configuration:

- [Name]
- [Steps]
- [AutoTerminationPolicy]
- [Instances][KeepJobFlowAliveWhenNoSteps]
- [Instances][TerminationProtected]

All other RunJobFlow arguments are available for use in your cluster configuration. For details about the request syntax, see RunJobFlow.

The following example passes a cluster configuration to an EMR step definition. This prompts the step to launch a new job on a new EMR cluster. The EMR cluster configuration in this example includes specifications for primary and core EMR cluster nodes. For more information about Amazon EMR node types, see Understand node types: primary, core, and task nodes.

```
from sagemaker.workflow.emr_step import EMRStep, EMRStepConfig

emr_step_config = EMRStepConfig(
    jar="jar-location", # required, path to jar file used
    args=["--verbose", "--force"], # optional list of arguments to pass to the jar
    main_class="com.my.Main1", # optional main class, this can be omitted if jar above

emr_step = EMRStep(
    name="emr-step",
    cluster_id=None,
    display_name="emr_step",
    description="MyEMRStepDescription",
    step_config=emr_step_config,
    cluster_config=emr_cluster_config
)
```

For a sample notebook that guides you through a complete example, see Pipelines EMR Step With Cluster Lifecycle Management.

EMR serverless step

To add an EMR serverless step to your pipeline, do the following:

- Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
- In the left navigation pane, select **Pipelines**.
- Choose **Create**.

- Choose **Blank**.
- In the left sidebar, choose **Process data** and drag it to the canvas.
- In the canvas, choose the **Process data** step you added.
- In the right sidebar, under mode, choose **EMR (serverless)**.
- In the right sidebar, complete the forms in the **Setting and Details** tabs.

Notebook job step

Use a `NotebookJobStep` to run your SageMaker Notebook Job non-interactively as a pipeline step. If you build your pipeline in the Pipelines drag-and-drop UI, use the Execute code step to run your notebook. For more information about SageMaker Notebook Jobs, see SageMaker Notebook Jobs.

A `NotebookJobStep` requires at minimum an input notebook, image URI and kernel name. For more information about Notebook Job step requirements and other parameters you can set to customize your step, see sagemaker.workflow.steps.NotebookJobStep.

The following example uses minimum arguments to define a `NotebookJobStep`.

```
from sagemaker.workflow.notebook_job_step import NotebookJobStep

notebook_job_step = NotebookJobStep(
    input_notebook=input_notebook,
    image_uri=image_uri,
    kernel_name=kernel_name
)
```

Your `NotebookJobStep` pipeline step is treated as a SageMaker notebook job. As a result, track the execution status in the Studio Classic UI notebook job dashboard by including specific tags with the `tags` argument. For more details about tags to include, see View your notebook jobs in the Studio UI dashboard.

Also, if you schedule your notebook job using the SageMaker Python SDK, you can only specify certain images to run your notebook job. For more information, see Image constraints for SageMaker AI Python SDK notebook jobs.

Fail step

Use a Fail step to stop an Amazon SageMaker Pipelines execution when a desired condition or state is not achieved. The Fail step also allows you to enter a custom error message, indicating the cause of the pipeline's execution failure.

> **Note**
>
> When a Fail step and other pipeline steps execute at the same time, the pipeline does not terminate until all concurrent steps are completed.

Limitations for using Fail step

- You cannot add a Fail step to the `DependsOn` list of other steps. For more information, see Custom dependency between steps.
- Other steps cannot reference the Fail step. It is *always* the last step in a pipeline's execution.
- You cannot retry a pipeline execution ending with a Fail step.

You can create the Fail step error message in the form of a static text string. Alternatively, you can also use Pipeline Parameters, a Join operation, or other step properties to create a more informative error message if you use the SDK.

Pipeline Designer

To add a Fail step to your pipeline, do the following:

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.
4. Choose **Blank**.
5. In the left sidebar, choose **Fail** and drag it to the canvas.
6. In the canvas, choose the **Fail** step you added.
7. In the right sidebar, complete the forms in the **Setting** and **Details** tabs. For information about the fields in these tabs, see sagemaker.workflow.fail_step.FailStep.

8. If the canvas includes any step that immediately precedes the **Fail** step you added, click and drag the cursor from the step to the **Fail** step to create an edge.
9. If the canvas includes any step that immediately succeeds the **Fail** step you added, click and drag the cursor from the **Fail** step to the step to create an edge.

SageMaker Python SDK

Example

The following example code snippet uses a `FailStep` with an `ErrorMessage` configured with Pipeline Parameters and a `Join` operation.

```
from sagemaker.workflow.fail_step import FailStep
from sagemaker.workflow.functions import Join
from sagemaker.workflow.parameters import ParameterInteger

mse_threshold_param = ParameterInteger(name="MseThreshold", default_value=5)
step_fail = FailStep(
    name="AbaloneMSEFail",
    error_message=Join(
        on=" ", values=["Execution failed due to MSE >", mse_threshold_param]
    ),
)
```

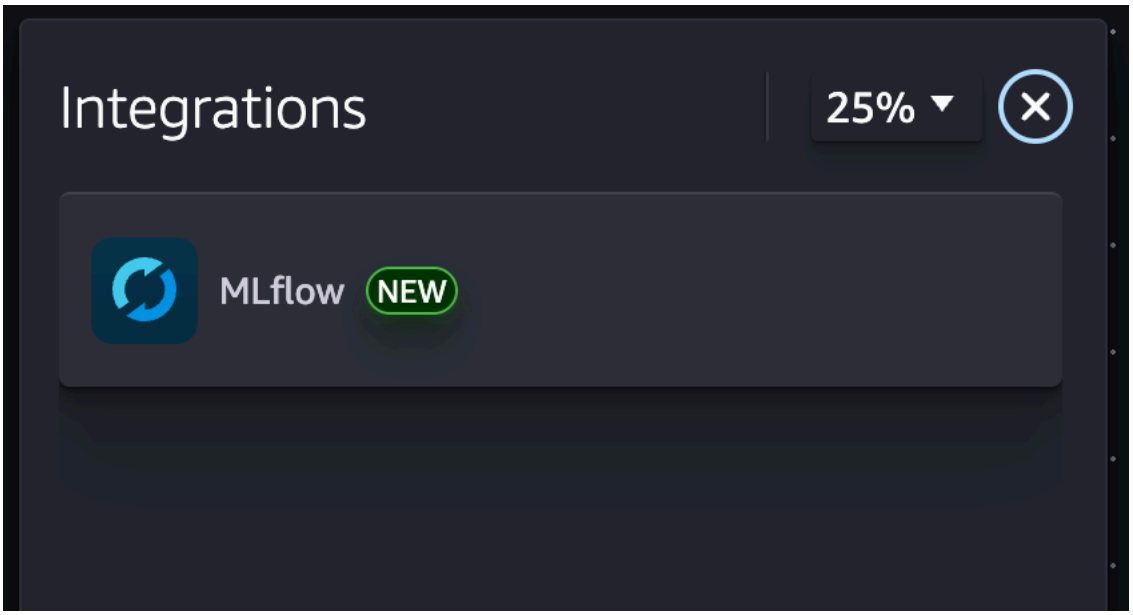
Add integration

MLflow integration allows you to use MLflow with pipelines to select a tracking server or serverless application, choose an experiment, and log metrics.

Key concepts

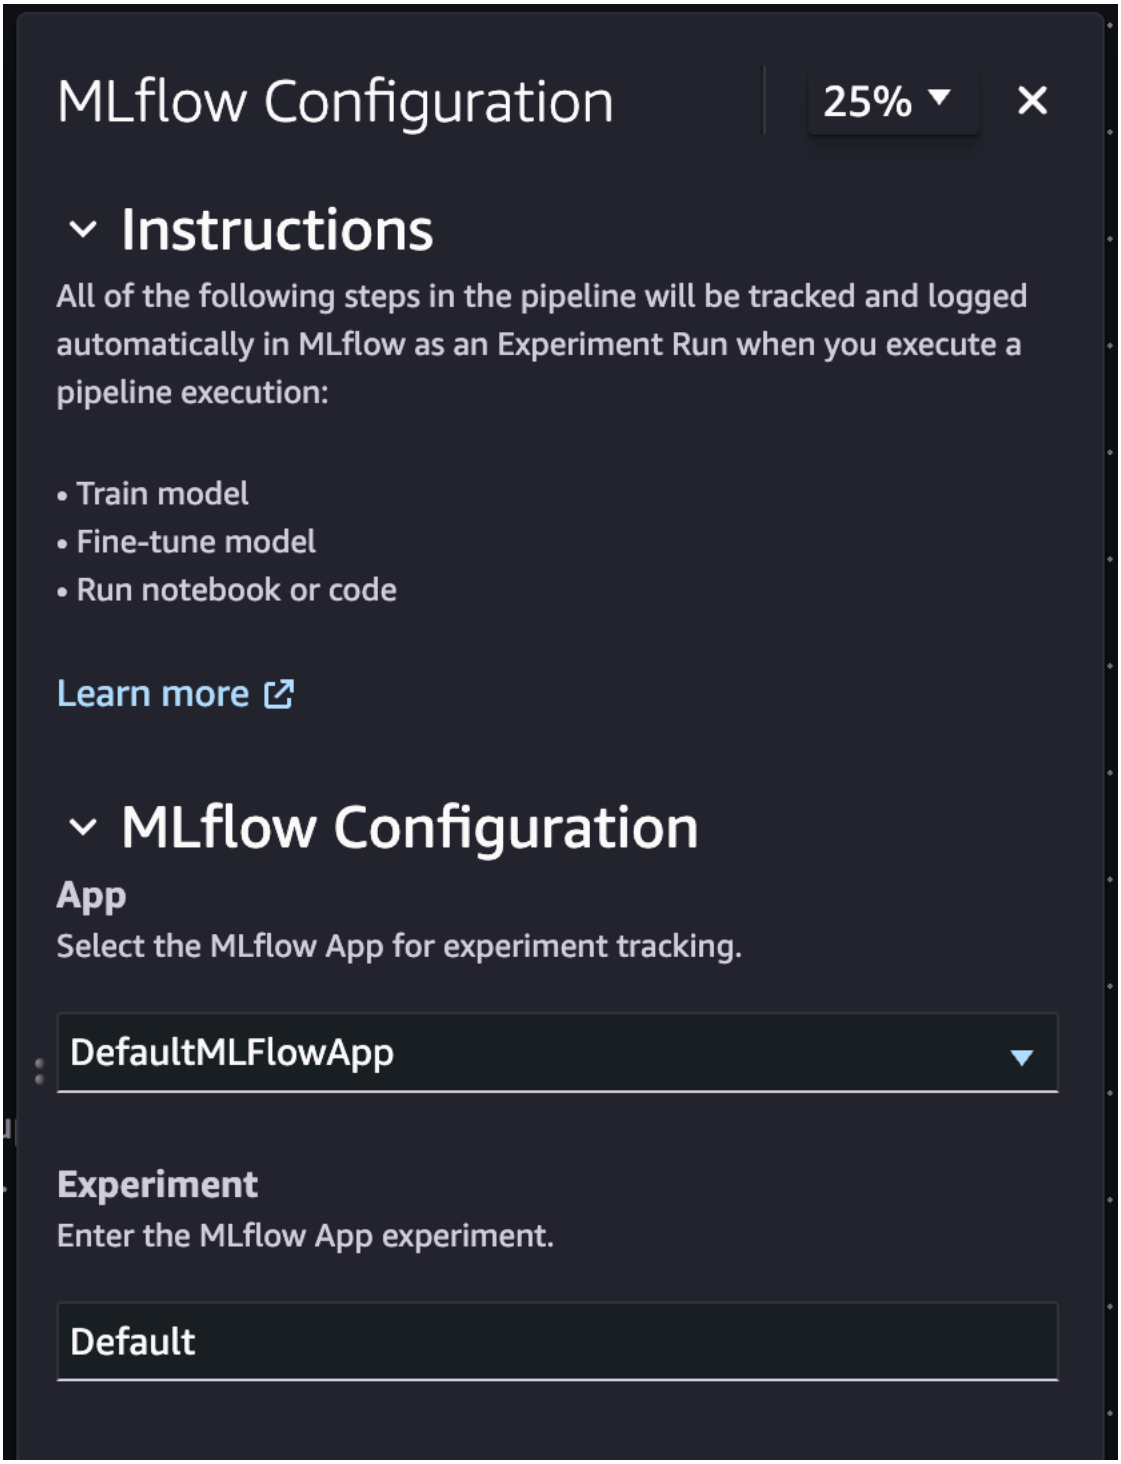
Default app creation - A default MLflow application will be created when you enter the pipeline visual editor.

Integrations panel - A new integrations panel includes MLflow, which you can select and configure.



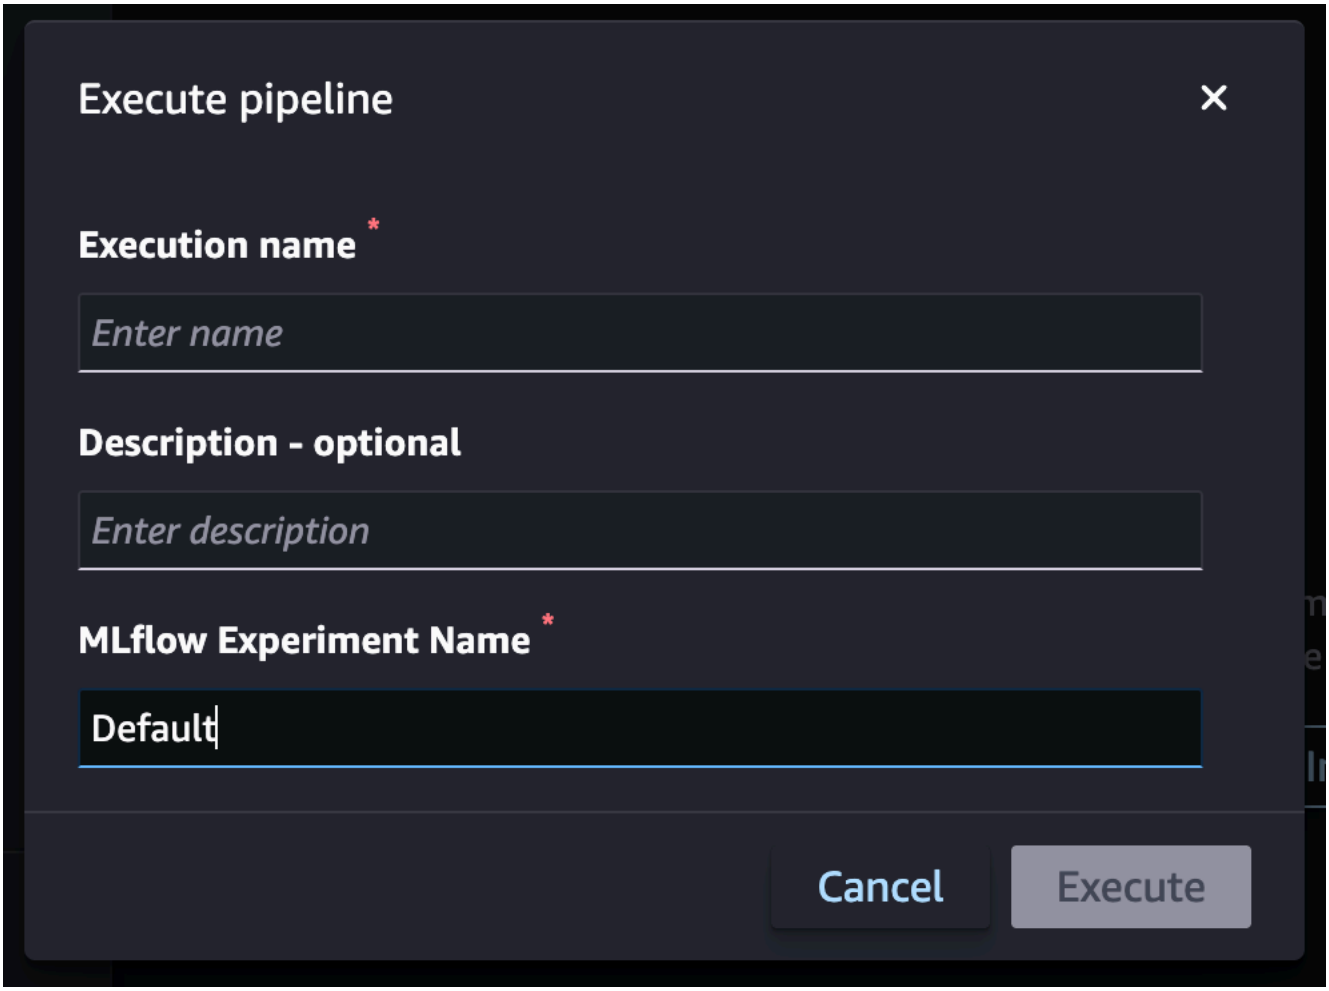
Update app and experiment - The option to override selected application and experiment during the pipeline execution.

How it works



- Go to **Pipeline Visual Editor**
- Choose **Integration** on the toolbar
- Choose **MLflow**
- Configure the MLflow app and experiment

Example screenshots



Integrations side panel

MLflow configuration

How to override experiment during pipeline execution

Step properties

Use the `properties` attribute to add data dependencies between steps in the pipeline. Pipelines use these data dependencies to construct the DAG from the pipeline definition. These properties can be referenced as placeholder values and are resolved at runtime.

The `properties` attribute of a Pipelines step matches the object returned by a `Describe` call for the corresponding SageMaker AI job type. For each job type, the `Describe` call returns the following response object:

- `ProcessingStep` – DescribeProcessingJob
- `TrainingStep` – DescribeTrainingJob
- `TransformStep` – DescribeTransformJob

To check which properties are referrable for each step type during data dependency creation, see *Data Dependency - Property Reference* in the Amazon SageMaker Python SDK.

Step parallelism

When a step does not depend on any other step, it runs immediately upon pipeline execution. However, executing too many pipeline steps in parallel can quickly exhaust available resources. Control the number of concurrent steps for a pipeline execution with `ParallelismConfiguration`.

The following example uses `ParallelismConfiguration` to set the concurrent step limit to five.

```
pipeline.create(
    parallelism_config=ParallelismConfiguration(5),
)
```

Data dependency between steps

You define the structure of your DAG by specifying the data relationships between steps. To create data dependencies between steps, pass the properties of one step as the input to another step in the pipeline. The step receiving the input isn't started until after the step providing the input finishes running.

A data dependency uses JsonPath notation in the following format. This format traverses the JSON property file. This means you can append as many *<property>* instances as needed to reach the desired nested property in the file. For more information on JsonPath notation, see the JsonPath repo.

```
<step_name>.properties.<property>.<property>
```

The following shows how to specify an Amazon S3 bucket using the `ProcessingOutputConfig` property of a processing step.

```
step_process.properties.ProcessingOutputConfig.Outputs["train_data"].S3Output.S3Uri
```

To create the data dependency, pass the bucket to a training step as follows.

```
from sagemaker.workflow.pipeline_context import PipelineSession

sklearn_train = SKLearn(..., sagemaker_session=PipelineSession())
```

```
step_train = TrainingStep(
    name="CensusTrain",
    step_args=sklearn_train.fit(inputs=TrainingInput(
        s3_data=step_process.properties.ProcessingOutputConfig.Outputs[
            "train_data"].S3Output.S3Uri
    ))
)
```

To check which properties are referrable for each step type during data dependency creation, see *Data Dependency - Property Reference* in the Amazon SageMaker Python SDK.

Custom dependency between steps

When you specify a data dependency, Pipelines provides the data connection between the steps. Alternatively, one step can access the data from a previous step without directly using Pipelines. In this case, you can create a custom dependency that tells Pipelines not to start a step until after another step has finished running. You create a custom dependency by specifying a step's `DependsOn` attribute.

As an example, the following defines a step `C` that starts only after both step `A` and step `B` finish running.

```
{
  'Steps': [
    {'Name':'A', ...},
    {'Name':'B', ...},
    {'Name':'C', 'DependsOn': ['A', 'B']}
  ]
}
```

Pipelines throws a validation exception if the dependency would create a cyclic dependency.

The following example creates a training step that starts after a processing step finishes running.

```
processing_step = ProcessingStep(...)
training_step = TrainingStep(...)

training_step.add_depends_on([processing_step])
```

The following example creates a training step that doesn't start until two different processing steps finish running.

```
processing_step_1 = ProcessingStep(...)
processing_step_2 = ProcessingStep(...)

training_step = TrainingStep(...)

training_step.add_depends_on([processing_step_1, processing_step_2])
```

The following provides an alternate way to create the custom dependency.

```
training_step.add_depends_on([processing_step_1])
training_step.add_depends_on([processing_step_2])
```

The following example creates a training step that receives input from one processing step and waits for a different processing step to finish running.

```
processing_step_1 = ProcessingStep(...)
processing_step_2 = ProcessingStep(...)

training_step = TrainingStep(
    ...,
    inputs=TrainingInput(
        s3_data=processing_step_1.properties.ProcessingOutputConfig.Outputs[
            "train_data"
        ].S3Output.S3Uri
    )

training_step.add_depends_on([processing_step_2])
```

The following example shows how to retrieve a string list of the custom dependencies of a step.

```
custom_dependencies = training_step.depends_on
```

Custom images in a step

You can use any of the available SageMaker AI Deep Learning Container images when you create a step in your pipeline.

You can also use your own container with pipeline steps. Because you can't create an image from within Studio Classic, you must create your image using another method before using it with Pipelines.

To use your own container when creating the steps for your pipeline, include the image URI in the estimator definition. For more information on using your own container with SageMaker AI, see Using Docker Containers with SageMaker AI.

Lift-and-shift Python code with the @step decorator

The `@step` decorator is a feature that converts your local machine learning (ML) code into one or more pipeline steps. You can write your ML function as you would for any ML project. Once tested locally or as a training job using the `@remote` decorator, you can convert the function to a SageMaker AI pipeline step by adding a `@step` decorator. You can then pass the output of the `@step`-decorated function call as a step to Pipelines to create and run a pipeline. You can chain a series of functions with the `@step` decorator to create a multi-step directed acyclic graph (DAG) pipeline as well.

The setup to use the `@step` decorator is the same as the setup to use the `@remote` decorator. You can refer to the remote function documentation for details about how to setup the environment and use a configuration file to set defaults. For more information about the `@step` decorator, see sagemaker.workflow.function_step.step.

To view to sample notebooks that demonstrate the use of `@step` decorator, see @step decorator sample notebooks.

The following sections explain how you can annotate your local ML code with a `@step` decorator to create a step, create and run a pipeline using the step, and customize the experience for your use case.

Topics

- Create a pipeline with @step-decorated functions
- Run a pipeline
- Configure your pipeline
- Best Practices
- Limitations

Create a pipeline with `@step`-decorated functions

You can create a pipeline by converting Python functions into pipeline steps using the `@step` decorator, creating dependencies between those functions to create a pipeline graph (or directed

acyclic graph (DAG)), and passing the leaf nodes of that graph as a list of steps to the pipeline. The following sections explain this procedure in detail with examples.

Topics

- Convert a function to a step
- Create dependencies between the steps
- Use ConditionStep with @step-decorated steps
- Define a pipeline using the DelayedReturn output of steps
- Create a pipeline

Convert a function to a step

To create a step using the `@step` decorator, annotate the function with `@step`. The following example shows a `@step`-decorated function that preprocesses the data.

```
from sagemaker.mlops.workflow.function_step import step

@step
def preprocess(raw_data):
    df = pandas.read_csv(raw_data)
    ...
    return procesed_dataframe

step_process_result = preprocess(raw_data)
```

When you invoke a `@step`-decorated function, SageMaker AI returns a `DelayedReturn` instance instead of running the function. A `DelayedReturn` instance is a proxy for the actual return of that function. The `DelayedReturn` instance can be passed to another function as an argument or directly to a pipeline instance as a step. For information about the `DelayedReturn` class, see sagemaker.workflow.function_step.DelayedReturn.

Create dependencies between the steps

When you create a dependency between two steps, you create a connection between the steps in your pipeline graph. The following sections introduce multiple ways you can create a dependency between your pipeline steps.

Data dependencies through input arguments

Passing in the `DelayedReturn` output of one function as an input to another function automatically creates a data dependency in the pipeline DAG. In the following example, passing in the `DelayedReturn` output of the `preprocess` function to the `train` function creates a dependency between `preprocess` and `train`.

```
from sagemaker.mlops.workflow.function_step import step

@step
def preprocess(raw_data):
    df = pandas.read_csv(raw_data)
    ...
    return procesed_dataframe

@step
def train(training_data):
    ...
    return trained_model

step_process_result = preprocess(raw_data)
step_train_result = train(step_process_result)
```

The previous example defines a training function which is decorated with `@step`. When this function is invoked, it receives the `DelayedReturn` output of the preprocessing pipeline step as input. Invoking the training function returns another `DelayedReturn` instance. This instance holds the information about all the previous steps defined in that function (i.e, the `preprocess` step in this example) which form the pipeline DAG.

In the previous example, the `preprocess` function returns a single value. For more complex return types like lists or tuples, refer to Limitations.

Define custom dependencies

In the previous example, the `train` function received the `DelayedReturn` output of `preprocess` and created a dependency. If you want to define the dependency explicitly without passing the previous step output, use the `add_depends_on` function with the step. You can use the `get_step()` function to retrieve the underlying step from its `DelayedReturn` instance, and then call `add_depends_on_on` with the dependency as input. To view the `get_step()` function definition, see sagemaker.workflow.step_outputs.get_step. The following example shows

you how to create a dependency between `preprocess` and `train` using `get_step()` and `add_depends_on()`.

```
from sagemaker.core.workflow.step_outputs import get_step

@step
def preprocess(raw_data):
    df = pandas.read_csv(raw_data)
    ...
    processed_data = ..
    return s3.upload(processed_data)

@step
def train():
    training_data = s3.download(....)
    ...
    return trained_model

step_process_result = preprocess(raw_data)
step_train_result = train()

get_step(step_train_result).add_depends_on([step_process_result])
```

Pass data to and from a `@step`-decorated function to a traditional pipeline step

You can create a pipeline that includes a `@step`-decorated step and a traditional pipeline step and passes data between them. For example, you can use `ProcessingStep` to process the data and pass its result to the `@step`-decorated training function. In the following example, a `@step`-decorated training step references the output of a processing step.

```
# Define processing step

from sagemaker.core.processing import Processor
from sagemaker.core.processing import ProcessingInput, ProcessingOutput
from sagemaker.mlops.workflow.steps import ProcessingStep

sklearn_processor = Processor(
    image_uri='sklearn-processing-image-uri',
    role='arn:aws:iam::123456789012:role/SagemakerExecutionRole',
    instance_type='ml.m5.large',
    instance_count=1,
)
```

```
inputs = [
    ProcessingInput(source=input_data, destination="/opt/ml/processing/input"),
]
outputs = [
    ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
    ProcessingOutput(output_name="validation", source="/opt/ml/processing/validation"),
    ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
]

process_step = ProcessingStep(
    name="MyProcessStep",
    step_args=sklearn_processor.run(inputs=inputs,
 outputs=outputs,code='preprocessing.py'),
)
```

```
# Define a @step-decorated train step which references the
# output of a processing step

@step
def train(train_data_path, test_data_path):
    ...
    return trained_model

step_train_result = train(
   process_step.properties.ProcessingOutputConfig.Outputs["train"].S3Output.S3Uri,
   process_step.properties.ProcessingOutputConfig.Outputs["test"].S3Output.S3Uri,
)
```

Use `ConditionStep` with `@step`-decorated steps

Pipelines supports a `ConditionStep` class which evaluates the results of preceding steps to decide what action to take in the pipeline. You can use `ConditionStep` with a `@step`-decorated step as well. To use the output of any `@step`-decorated step with `ConditionStep`, enter the output of that step as an argument to `ConditionStep`. In the following example, the condition step receives the output of the `@step`-decorated model evaluation step.

```
# Define steps

@step(name="evaluate")
def evaluate_model():
    # code to evaluate the model
```

```
    return {
        "rmse":rmse_value
    }

@step(name="register")
def register_model():
    # code to register the model
    ...
```

```
# Define ConditionStep

from sagemaker.mlops.workflow.condition_step import ConditionStep
from sagemaker.core.workflow.conditions import ConditionGreaterThanOrEqualTo
from sagemaker.mlops.workflow.fail_step import FailStep

conditionally_register = ConditionStep(
    name="conditional_register",
    conditions=[
        ConditionGreaterThanOrEqualTo(
            # Output of the evaluate step must be json serializable
            left=evaluate_model()["rmse"],  #
            right=5,
        )
    ],
    if_steps=[FailStep(name="Fail", error_message="Model performance is not good
 enough")],
    else_steps=[register_model()],
)
```

Define a pipeline using the `DelayedReturn` output of steps

You define a pipeline the same way whether or not you use a `@step` decorator. When you pass a `DelayedReturn` instance to your pipeline, you don't need to pass a full list of steps to build the pipeline. The SDK automatically infers the previous steps based on the dependencies you define. All the previous steps of the `Step` objects you passed to the pipeline or `DelayedReturn` objects are included in the pipeline graph. In the following example, the pipeline receives the `DelayedReturn` object for the `train` function. SageMaker AI adds the `preprocess` step, as a previous step of `train`, to the pipeline graph.

```
from sagemaker.mlops.workflow.pipeline import Pipeline

pipeline = Pipeline(
```

```
    name="<pipeline-name>",
    steps=[step_train_result],
    sagemaker_session=<sagemaker-session>,
)
```

If there are no data or custom dependencies between the steps and you run multiple steps in parallel, the pipeline graph has more than one leaf node. Pass all of these leaf nodes in a list to the `steps` argument in your pipeline definition, as shown in the following example:

```
@step
def process1():
    ...
    return data

@step
def process2():
   ...
   return data

step_process1_result = process1()
step_process2_result = process2()

pipeline = Pipeline(
    name="<pipeline-name>",
    steps=[step_process1_result, step_process2_result],
    sagemaker_session=sagemaker-session,
)
```

When the pipeline runs, both steps run in parallel.

You only pass the leaf nodes of the graph to the pipeline because the leaf nodes contain information about all the previous steps defined through data or custom dependencies. When it compiles the pipeline, SageMaker AI also infers of all of the subsequent steps that form the pipeline graph and adds each of them as a separate step to the pipeline.

Create a pipeline

Create a pipeline by calling `pipeline.create()`, as shown in the following snippet. For details about `create()`, see sagemaker.workflow.pipeline.Pipeline.create.

```
role = "pipeline-role"
pipeline.create(role)
```

When you call `pipeline.create()`, SageMaker AI compiles all of the steps defined as part of the pipeline instance. SageMaker AI uploads the serialized function, arguments, and all the other step-related artifacts to Amazon S3.

Data resides in the S3 bucket according to the following structure:

```
s3_root_uri/
    pipeline_name/
        sm_rf_user_ws/
            workspace.zip  # archive of the current working directory (workdir)
        step_name/
            timestamp/
                arguments/                # serialized function arguments
                function/                 # serialized function
                pre_train_dependencies/   # any dependencies and pre_execution scripts
 provided for the step
        execution_id/
            step_name/
                results     # returned output from the serialized function including
 the model
```

`s3_root_uri` is defined in the SageMaker AI config file and applies to the entire pipeline. If undefined, the default SageMaker AI bucket is used.

> **Note**
>
> Every time SageMaker AI compiles a pipeline, SageMaker AI saves the the steps' serialized functions, arguments and dependencies in a folder timestamped with the current time. This occurs every time you run `pipeline.create()`, `pipeline.update()`, `pipeline.upsert()` or `pipeline.definition()`.

Run a pipeline

The following page describes how to run a pipeline with Amazon SageMaker Pipelines, either with SageMaker AI resources or locally.

Start a new pipeline run with the `pipeline.start()` function as you would for a traditional SageMaker AI pipeline run. For information about the `start()` function, see sagemaker.workflow.pipeline.Pipeline.start.

Note

A step defined using the `@step` decorator runs as a training job. Therefore, be aware of the following limits:

- Instance limits and training job limits in your accounts. Update your limits accordingly to avoid any throttling or resource limit issues.
- The monetary costs associated with every run of a training step in the pipeline. For more details, refer to Amazon SageMaker Pricing.

Retrieve results from a pipeline run locally

To view the result of any step of a pipeline run, use execution.result(), as shown in the following snippet:

```
execution = pipeline.start()
execution.result(step_name="train")
```

Note

Pipelines does not support `execution.result()` in local mode.

You can only retrieve results for one step at a time. If the step name was generated by SageMaker AI, you can retrieve the step name by calling `list_steps` as follows:

```
execution.list_step()
```

Run a pipeline locally

You can run a pipeline with `@step`-decorated steps locally as you would for traditional pipeline steps. For details about local mode pipeline runs, see Run pipelines using local mode. To use local mode, provide a `LocalPipelineSession` instead of a `SageMakerSession` to your pipeline definition, as shown in the following example:

```
from sagemaker.mlops.workflow.function_step import step
from sagemaker.mlops.workflow.pipeline import Pipeline
```

```
from sagemaker.core.workflow.pipeline_context import LocalPipelineSession

@step
def train():
    training_data = s3.download(....)
    ...
    return trained_model

step_train_result = train()

local_pipeline_session = LocalPipelineSession()

local_pipeline = Pipeline(
    name="<pipeline-name>",
    steps=[step_train_result],
    sagemaker_session=local_pipeline_session # needed for local mode
)

local_pipeline.create(role_arn="role_arn")

# pipeline runs locally
execution = local_pipeline.start()
```

Configure your pipeline

You are advised to use the SageMaker AI config file to set the defaults for the pipeline. For information about the SageMaker AI configuration file, see Configuring and using defaults with the SageMaker Python SDK. Any configuration added to the config file applies to all steps in the pipeline. If you want to override options for any of the steps, provide new values in the `@step` decorator arguments. The following topic describes how to set up a config file.

The `@step` decorator's configuration in the config file is identical to the `@remote` decorator's configuration. To set up the pipeline role ARN and pipeline tags in the config file, use the `Pipeline` section shown in the following snippet:

```
SchemaVersion: '1.0'
SageMaker:
  Pipeline:
    RoleArn: 'arn:aws:iam::555555555555:role/IMRole'
    Tags:
    - Key: 'tag_key'
      Value: 'tag_value'
```

For most of the defaults you can set in the configuration file you can also override by passing new values to the `@step` decorator. For example, you can override the instance type set in the config file for your preprocessing step, as shown in the following example:

```
@step(instance_type="ml.m5.large")
def preprocess(raw_data):
    df = pandas.read_csv(raw_data)
    ...
    return procesed_dataframe
```

A few arguments are not part of the `@step` decorator parameters list—these can be configured for the entire pipeline only through the SageMaker AI configuration file. They are listed as follows:

- `sagemaker_session` (`sagemaker.session.Session`): The underlying SageMaker AI session to which SageMaker AI delegates service calls. If unspecified, a session is created using a default configuration as follows:

  ```
  SageMaker:
    PythonSDK:
      Modules:
        Session:
          DefaultS3Bucket: 'default_s3_bucket'
          DefaultS3ObjectKeyPrefix: 'key_prefix'
  ```

- `custom_file_filter` (`CustomFileFilter`): A `CustomFileFilter` object that specifies the local directories and files to include in the pipeline step. If unspecified, this value defaults to None. For `custom_file_filter` to take effect, you must set `IncludeLocalWorkdir` to `True`. The following example shows a configuration that ignores all notebook files, and files and directories named `data`.

  ```
  SchemaVersion: '1.0'
  SageMaker:
    PythonSDK:
      Modules:
        RemoteFunction:
          IncludeLocalWorkDir: true
          CustomFileFilter:
            IgnoreNamePatterns: # files or directories to ignore
            - "*.ipynb" # all notebook files
            - "data" # folder or file named "data"
  ```

For more details about how to use `IncludeLocalWorkdir` with `CustomFileFilter`, see Using modular code with the @remote decorator.

- `s3_root_uri (str)`: The root Amazon S3 folder to which SageMaker AI uploads the code archives and data. If unspecified, the default SageMaker AI bucket is used.
- `s3_kms_key (str)`: The key used to encrypt the input and output data. You can only configure this argument in the SageMaker AI config file and the argument applies to all steps defined in the pipeline. If unspecified, the value defaults to None. See the following snippet for an example S3 KMS key configuration:

```
SchemaVersion: '1.0'
SageMaker:
  PythonSDK:
    Modules:
      RemoteFunction:
        S3KmsKeyId: 's3kmskeyid'
        S3RootUri: 's3://amzn-s3-demo-bucket/my-project
```

Best Practices

The following sections suggest best practices to follow when you use the `@step` decorator for your pipeline steps.

Use warm pools

For faster pipeline step runs, use the warm pooling functionality provided for training jobs. You can turn on the warm pool functionality by providing the `keep_alive_period_in_seconds` argument to the `@step` decorator as demonstrated in the following snippet:

```
@step(
   keep_alive_period_in_seconds=900
)
```

For more information about warm pools, see SageMaker AI Managed Warm Pools.

Structure your directory

You are advised to use code modules while using the `@step` decorator. Put the `pipeline.py` module, in which you invoke the step functions and define the pipeline, at the root of the workspace. The recommended structure is shown as follows:

```
.
### config.yaml # the configuration file that define the infra settings
### requirements.txt # dependencies
### pipeline.py  # invoke @step-decorated functions and define the pipeline here
### steps/
| ### processing.py
| ### train.py
### data/
### test/
```

Secure your serialized data

The `@step` decorator saves function inputs and outputs to Amazon S3. By default, SageMaker AI uses the default bucket. Other projects or users in your account might share this bucket.

To keep your pipeline data safe, set `S3RootUri` in your SageMaker AI configuration file. Use a bucket that only your pipeline uses. The following example shows how to set this value:

```
SchemaVersion: '1.0'
SageMaker:
  PythonSDK:
    Modules:
      RemoteFunction:
        S3RootUri: 's3://amzn-s3-demo-bucket/pipeline-data'
```

> **Important**
>
> Restrict write access to the `S3RootUri` path. This prevents unauthorized users from modifying your pipeline data. Apply a bucket policy so that only the SageMaker AI execution role used by your jobs can write to this path.

For more information about the configuration file, see Configuration file.

Limitations

The following sections outline the limitations that you should be aware of when you use the `@step` decorator for your pipeline steps.

Function argument limitations

When you pass an input argument to the `@step`-decorated function, the following limitations apply:

- You can pass the `DelayedReturn`, `Properties` (of steps of other types), `Parameter`, and `ExecutionVariable` objects to `@step`-decorated functions as arguments. But `@step`-decorated functions do not support `JsonGet` and `Join` objects as arguments.
- You cannot directly access a pipeline variable from a `@step` function. The following example produces an error:

```
param = ParameterInteger(name="<parameter-name>", default_value=10)

@step
def func():
    print(param)

func() # this raises a SerializationError
```

- You cannot nest a pipeline variable in another object and pass it to a `@step` function. The following example produces an error:

```
param = ParameterInteger(name="<parameter-name>", default_value=10)

@step
def func(arg):
    print(arg)

func(arg=(param,)) # this raises a SerializationError because param is nested in a
 tuple
```

- Since inputs and outputs of a function are serialized, there are restrictions on the type of data that can be passed as input or output from a function. See the *Data serialization and deserialization* section of Invoke a remote function for more details. The same restrictions apply to `@step`-decorated functions.
- Any object that has a boto client cannot be serialized, hence you cannot pass such objects as input to or output from a `@step`-decorated function. For example, SageMaker Python SDK client classes such as `Estimator`, `Predictor`, and `Processor` can't be serialized.

Function imports

You should import the libraries required by the step inside rather than outside the function. If you import them at global scope, you risk an import collision while serializing the function. For example, `sklearn.pipeline.Pipeline` could be overridden by `sagemaker.workflow.pipeline.Pipeline`.

Referencing child members of function return value

If you reference child members of a `@step`-decorated function's return value, the following limitations apply:

- You can reference the child members with `[]` if the `DelayedReturn` object represents a tuple, list or dict, as shown in the following example:

```
delayed_return[0]
delayed_return["a_key"]
delayed_return[1]["a_key"]
```

- You cannot unpack a tuple or list output because the exact length of the underlying tuple or list can't be known when you invoke the function. The following example produces an error:

```
a, b, c = func() # this raises ValueError
```

- You cannot iterate over a `DelayedReturn` object. The following example raises an error:

```
for item in func(): # this raises a NotImplementedError
```

- You cannot reference arbitrary child members with '`.`'. The following example produces an error:

```
delayed_return.a_child # raises AttributeError
```

Existing pipeline features that are not supported

You cannot use the `@step` decorator with the following pipeline features:

- Pipeline step caching
- Property files

Pass Data Between Steps

When building pipelines with Amazon SageMaker Pipelines, you might need to pass data from one step to the next. For example, you might want to use the model artifacts generated by a training step as input to a model evaluation or deployment step. You can use this functionality to create interdependent pipeline steps and build your ML workflows.

When you need to retrieve information from the output of a pipeline step, you can use `JsonGet`. `JsonGet` helps you extract information from Amazon S3 or property files. The following sections explain methods you can use to extract step outputs with `JsonGet`.

Pass data between steps with Amazon S3

You can use `JsonGet` in a `ConditionStep` to fetch the JSON output directly from Amazon S3. The Amazon S3 URI can be a `Std:Join` function containing primitive strings, pipeline run variables, or pipeline parameters. The following example shows how you can use `JsonGet` in a `ConditionStep`:

```
# Example json file in s3 bucket generated by a processing_step
{
   "Output": [5, 10]
}

cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step_name="<step-name>",
        s3_uri="<s3-path-to-json>",
        json_path="Output[1]"
    ),
    right=6.0
)
```

If you are using `JsonGet` with an Amazon S3 path in the condition step, you must explicitly add a dependency between the condition step and the step generating the JSON output. In following example, the condition step is created with a dependency on the processing step:

```
cond_step = ConditionStep(
        name="<step-name>",
        conditions=[cond_lte],
        if_steps=[fail_step],
        else_steps=[register_model_step],
        depends_on=[processing_step],
```

```
)
```

Pass data between steps with property files

Use property files to store information from the output of a processing step. This is particularly useful when analyzing the results of a processing step to decide how a conditional step should be executed. The `JsonGet` function processes a property file and enables you to use JsonPath notation to query the property JSON file. For more information on JsonPath notation, see the JsonPath repo.

To store a property file for later use, you must first create a `PropertyFile` instance with the following format. The `path` parameter is the name of the JSON file to which the property file is saved. Any `output_name` must match the `output_name` of the `ProcessingOutput` that you define in your processing step. This enables the property file to capture the `ProcessingOutput` in the step.

```
from sagemaker.workflow.properties import PropertyFile

<property_file_instance> = PropertyFile(
    name="<property_file_name>",
    output_name="<processingoutput_output_name>",
    path="<path_to_json_file>"
)
```

When you create your `ProcessingStep` instance, add the `property_files` parameter to list all of the parameter files that the Amazon SageMaker Pipelines service must index. This saves the property file for later use.

```
property_files=[<property_file_instance>]
```

To use your property file in a condition step, add the `property_file` to the condition that you pass to your condition step as shown in the following example to query the JSON file for your desired property using the `json_path` parameter.

```
cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step_name=step_eval.name,
        property_file=<property_file_instance>,
        json_path="mse"
    ),
```

```
    right=6.0
)
```

For more in-depth examples, see *Property File* in the Amazon SageMaker Python SDK.

Caching pipeline steps

In Amazon SageMaker Pipelines, you can use step caching to save time and resources when rerunning pipelines. Step caching reuses the output of a previous successful run of a step (instead of recomputing it) when the step has the same configuration and inputs. This helps you achieve consistent results across pipeline reruns with identical parameters. The following topic shows you how to configure and turn on step caching for your pipelines.

When you use step signature caching, Pipelines tries to find a previous run of your current pipeline step with the same values for certain attributes. If found, Pipelines propagates the outputs from the previous run rather than recomputing the step. The attributes checked are specific to the step type, and are listed in Default cache key attributes by pipeline step type.

You must opt in to step caching — it is off by default. When you turn on step caching, you must also define a timeout. This timeout defines how old a previous run can be to remain a candidate for reuse.

Step caching only considers successful runs — it never reuses failed runs. When multiple successful runs exist within the timeout period, Pipelines uses the result for the most recent successful run. If no successful runs match in the timeout period, Pipelines reruns the step. If the executor finds a previous run that meets the criteria but is still in progress, both steps continue running and update the cache if they're successful.

Step caching is only scoped for individual pipelines, so you can’t reuse a step from another pipeline even if there is a step signature match.

Step caching is available for the following step types:

- Processing
- Training
- Tuning
- AutoML
- Transform
- `ClarifyCheck`

- QualityCheck
- EMR

Topics

- Turn on step caching
- Turn off step caching
- Default cache key attributes by pipeline step type
- Cached data access control

Turn on step caching

To turn on step caching, you must add a `CacheConfig` property to the step definition. `CacheConfig` properties use the following format in the pipeline definition file:

```
{
    "CacheConfig": {
        "Enabled": false,
        "ExpireAfter": "<time>"
    }
}
```

The `Enabled` field indicates whether caching is turned on for the particular step. You can set the field to `true`, which tells SageMaker AI to try to find a previous run of the step with the same attributes. Or, you can set the field to `false`, which tells SageMaker AI to run the step every time the pipeline runs. `ExpireAfter` is a string in ISO 8601 duration format that defines the timeout period. The `ExpireAfter` duration can be a year, month, week, day, hour, or minute value. Each value consists of a number followed by a letter indicating the unit of duration. For example:

- "30d" = 30 days
- "5y" = 5 years
- "T16m" = 16 minutes
- "30dT5h" = 30 days and 5 hours.

The following discussion describes the procedure to turn on caching for new or pre-existing pipelines using the Amazon SageMaker Python SDK.

Turn on caching for new pipelines

For new pipelines, initialize a `CacheConfig` instance with `enable_caching=True` and provide it as an input to your pipeline step. The following example turns on caching with a 1-hour timeout period for a training step:

```
from sagemaker.core.workflow.pipeline_context import PipelineSession
from sagemaker.mlops.workflow.steps import CacheConfig

cache_config = CacheConfig(enable_caching=True, expire_after="PT1H")
model_trainer = ModelTrainer(..., sagemaker_session=PipelineSession())

step_train = TrainingStep(
    name="TrainAbaloneModel",
    step_args=model_trainer.train(input_data_config=inputs),
    cache_config=cache_config
)
```

Turn on caching for pre-existing pipelines

To turn on caching for pre-existing, already-defined pipelines, turn on the `enable_caching` property for the step, and set `expire_after` to a timeout value. Lastly, update the pipeline with `pipeline.upsert()` or `pipeline.update()`. Once you run it again, the following code example turns on caching with a 1-hour timeout period for a training step:

```
from sagemaker.core.workflow.pipeline_context import PipelineSession
from sagemaker.mlops.workflow.steps import CacheConfig
from sagemaker.mlops.workflow.pipeline import Pipeline

cache_config = CacheConfig(enable_caching=True, expire_after="PT1H")
model_trainer = ModelTrainer(..., sagemaker_session=PipelineSession())

step_train = TrainingStep(
    name="TrainAbaloneModel",
    step_args=model_trainer.train(input_data_config=inputs),
    cache_config=cache_config
)

# define pipeline
pipeline = Pipeline(
    steps=[step_train]
)
```

```
# additional step for existing pipelines
pipeline.update()
# or, call upsert() to update the pipeline
# pipeline.upsert()
```

Alternatively, update the cache config after you have already defined the (pre-existing) pipeline, allowing one continuous code run. The following code sample demonstrates this method:

```
# turn on caching with timeout period of one hour
pipeline.steps[0].cache_config.enable_caching = True
pipeline.steps[0].cache_config.expire_after = "PT1H"

# additional step for existing pipelines
pipeline.update()
# or, call upsert() to update the pipeline
# pipeline.upsert()
```

For more detailed code examples and a discussion about how Python SDK parameters affect caching, see Caching Configuration in the Amazon SageMaker Python SDK documentation.

Turn off step caching

A pipeline step does not rerun if you change any attributes that are not listed in Default cache key attributes by pipeline step type for its step type. However, you may decide that you want the pipeline step to rerun anyway. In this case, you need to turn off step caching.

To turn off step caching, set the `Enabled` attribute in the step definition's `CacheConfig` property in the step definition to `false`, as shown in the following code snippet:

```
{
    "CacheConfig": {
        "Enabled": false,
        "ExpireAfter": "<time>"
    }
}
```

Note that the `ExpireAfter` attribute is ignored when `Enabled` is `false`.

To turn off caching for a pipeline step using the Amazon SageMaker Python SDK, define the pipeline of your pipeline step, turn off the `enable_caching` property, and update the pipeline.

Once you run it again, the following code example turns off caching for a training step:

```
from sagemaker.core.workflow.pipeline_context import PipelineSession
from sagemaker.mlops.workflow.steps import CacheConfig
from sagemaker.mlops.workflow.pipeline import Pipeline

cache_config = CacheConfig(enable_caching=False, expire_after="PT1H")
model_trainer = ModelTrainer(..., sagemaker_session=PipelineSession())

step_train = TrainingStep(
    name="TrainAbaloneModel",
    step_args=model_trainer.train(input_data_config=inputs),
    cache_config=cache_config
)

# define pipeline
pipeline = Pipeline(
    steps=[step_train]
)

# update the pipeline
pipeline.update()
# or, call upsert() to update the pipeline
# pipeline.upsert()
```

Alternatively, turn off the `enable_caching` property after you have already defined the pipeline, allowing one continuous code run. The following code sample demonstrates this solution:

```
# turn off caching for the training step
pipeline.steps[0].cache_config.enable_caching = False

# update the pipeline
pipeline.update()
# or, call upsert() to update the pipeline
# pipeline.upsert()
```

For more detailed code examples and a discussion about how Python SDK parameters affect caching, see Caching Configuration in the Amazon SageMaker Python SDK documentation.

Default cache key attributes by pipeline step type

When deciding whether to reuse a previous pipeline step or rerun the step, Pipelines checks to see if certain attributes have changed. If the set of attributes is different from all previous runs within the timeout period, the step runs again. These attributes include input artifacts, app or algorithm specification, and environment variables. The following list shows each pipeline step type and the attributes that, if changed, initiate a rerun of the step. For more information about which Python SDK parameters are used to create the following attributes, see Caching Configuration in the Amazon SageMaker Python SDK documentation.

Processing step

- AppSpecification
- Environment
- ProcessingInputs. This attribute contains information about the preprocessing script.

Training step

- AlgorithmSpecification
- CheckpointConfig
- DebugHookConfig
- DebugRuleConfigurations
- Environment
- HyperParameters
- InputDataConfig. This attribute contains information about the training script.

Tuning step

- HyperParameterTuningJobConfig
- TrainingJobDefinition. This attribute is composed of multiple child attributes, not all of which cause the step to rerun. The child attributes that could incur a rerun (if changed) are:
  - AlgorithmSpecification
  - HyperParameterRanges
  - InputDataConfig

  - StaticHyperParameters
  - TuningObjective
- TrainingJobDefinitions

AutoML step

- AutoMLJobConfig. This attribute is composed of multiple child attributes, not all of which cause the step to rerun. The child attributes that could incur a rerun (if changed) are:
  - CompletionCriteria
  - CandidateGenerationConfig
  - DataSplitConfig
  - Mode
- AutoMLJobObjective
- InputDataConfig
- ProblemType

Transform step

- DataProcessing
- Environment
- ModelName
- TransformInput

ClarifyCheck step

- ClarifyCheckConfig
- CheckJobConfig
- SkipCheck
- RegisterNewBaseline
- ModelPackageGroupName
- SuppliedBaselineConstraints

QualityCheck step

- QualityCheckConfig
- CheckJobConfig
- SkipCheck
- RegisterNewBaseline
- ModelPackageGroupName
- SuppliedBaselineConstraints
- SuppliedBaselineStatistics

EMR Step

- ClusterId
- StepConfig

Cached data access control

When a SageMaker AI pipeline runs, it caches the parameters and metadata associated with the SageMaker AI jobs launched by the pipeline and saves them for reuse in subsequent runs. This metadata is accessible through a variety of sources in addition to cached pipeline steps, and includes the following types:

- `Describe*Job` requests
- CloudWatch Logs
- CloudWatch Events
- CloudWatch Metrics
- SageMaker AI Search

Note that access to each data source in the list is controlled by its own set of IAM permissions. Removing a particular role's access to one data source does not affect the level of access to the others. For example, an account admin might remove IAM permissions for `Describe*Job` requests

from a caller's role. While the caller can no longer make `Describe*Job` requests, they can still retrieve the metadata from a pipeline run with cached steps as long as they have permission to run the pipeline. If an account admin wants to remove access to the metadata from a particular SageMaker AI job completely, they need to remove permissions for each of the relevant services that provide access to the data.

Retry Policy for Pipeline Steps

Retry policies help you automatically retry your Pipelines steps after an error occurs. Any pipeline step can encounter exceptions, and exceptions happen for various reasons. In some cases, a retry can resolve these issues. With a retry policy for pipeline steps, you can choose whether to retry a particular pipeline step or not.

The retry policy only supports the following pipeline steps:

- Processing step
- Training step
- Tuning step
- AutoML step
- Create model step
- Register model step
- Transform step
- Notebook job step

> **Note**
>
> Jobs running inside both the tuning and AutoML steps conduct retries internally and will not retry the `SageMaker.JOB_INTERNAL_ERROR` exception type, even if a retry policy is configured. You can program your own Retry Strategy using the SageMaker API.

Supported exception types for the retry policy

The retry policy for pipeline steps supports the following exception types:

- `Step.SERVICE_FAULT`: These exceptions occur when an internal server error or transient error happens when calling downstream services. Pipelines retries on this type of error automatically. With a retry policy, you can override the default retry operation for this exception type.
- `Step.THROTTLING`: Throttling exceptions can occur while calling the downstream services. Pipelines retries on this type of error automatically. With a retry policy, you can override the default retry operation for this exception type.
- `SageMaker.JOB_INTERNAL_ERROR`: These exceptions occur when the SageMaker AI job returns `InternalServerError`. In this case, starting a new job may fix a transient issue.
- `SageMaker.CAPACITY_ERROR`: The SageMaker AI job may encounter Amazon EC2 `InsufficientCapacityErrors`, which leads to the SageMaker AI job's failure. You can retry by starting a new SageMaker AI job to avoid the issue.
- `SageMaker.RESOURCE_LIMIT`: You can exceeed the resource limit quota when running a SageMaker AI job. You can wait and retry running the SageMaker AI job after a short period and see if resources are released.

The JSON schema for the retry policy

The retry policy for Pipelines has the following JSON schema:

```
"RetryPolicy": {
   "ExceptionType": [String]
   "IntervalSeconds": Integer
   "BackoffRate": Double
   "MaxAttempts": Integer
   "ExpireAfterMin": Integer
}
```

- `ExceptionType`: This field requires the following exception types in a string array format.
  - `Step.SERVICE_FAULT`
  - `Step.THROTTLING`
  - `SageMaker.JOB_INTERNAL_ERROR`
  - `SageMaker.CAPACITY_ERROR`
  - `SageMaker.RESOURCE_LIMIT`
- `IntervalSeconds` (optional): The number of seconds before the first retry attempt (1 by default). `IntervalSeconds` has a maximum value of 43200 seconds (12 hours).

- `BackoffRate` (optional): The multiplier by which the retry interval increases during each attempt (2.0 by default).
- `MaxAttempts` (optional): A positive integer that represents the maximum number of retry attempts (5 by default). If the error recurs more times than `MaxAttempts` specifies, retries cease and normal error handling resumes. A value of 0 specifies that errors are never retried. `MaxAttempts` has a maximum value of 20.
- `ExpireAfterMin` (optional): A positive integer that represents the maximum timespan of retry. If the error recurs after `ExpireAfterMin` minutes counting from the step gets executed, retries cease and normal error handling resumes. A value of 0 specifies that errors are never retried. `ExpireAfterMin` has a maximum value of 14,400 minutes (10 days).

> **Note**
>
> Only one of `MaxAttempts` or `ExpireAfterMin` can be given, but not both; if both are *not* specified, `MaxAttempts` becomes the default. If both properties are identified within one policy, then the retry policy generates a validation error.

Configuring a retry policy

While SageMaker Pipelines provide a robust and automated way to orchestrate machine learning workflows, you might encounter failures when you run them. To handle such scenarios gracefully and improve the reliability of your pipelines, you can configure retry policies that define how and when to automatically retry specific steps after encountering an exception. The retry policy allows you to specify the types of exceptions to retry, the maximum number of retry attempts, the interval between retries, and the backoff rate for increasing the retry intervals. The following section provides examples of how to configure a retry policy for a training step in your pipeline, both in JSON and using the SageMaker Python SDK.

The following is an example of a training step with a retry policy.

```
{
    "Steps": [
        {
            "Name": "MyTrainingStep",
            "Type": "Training",
            "RetryPolicies": [
                {
```

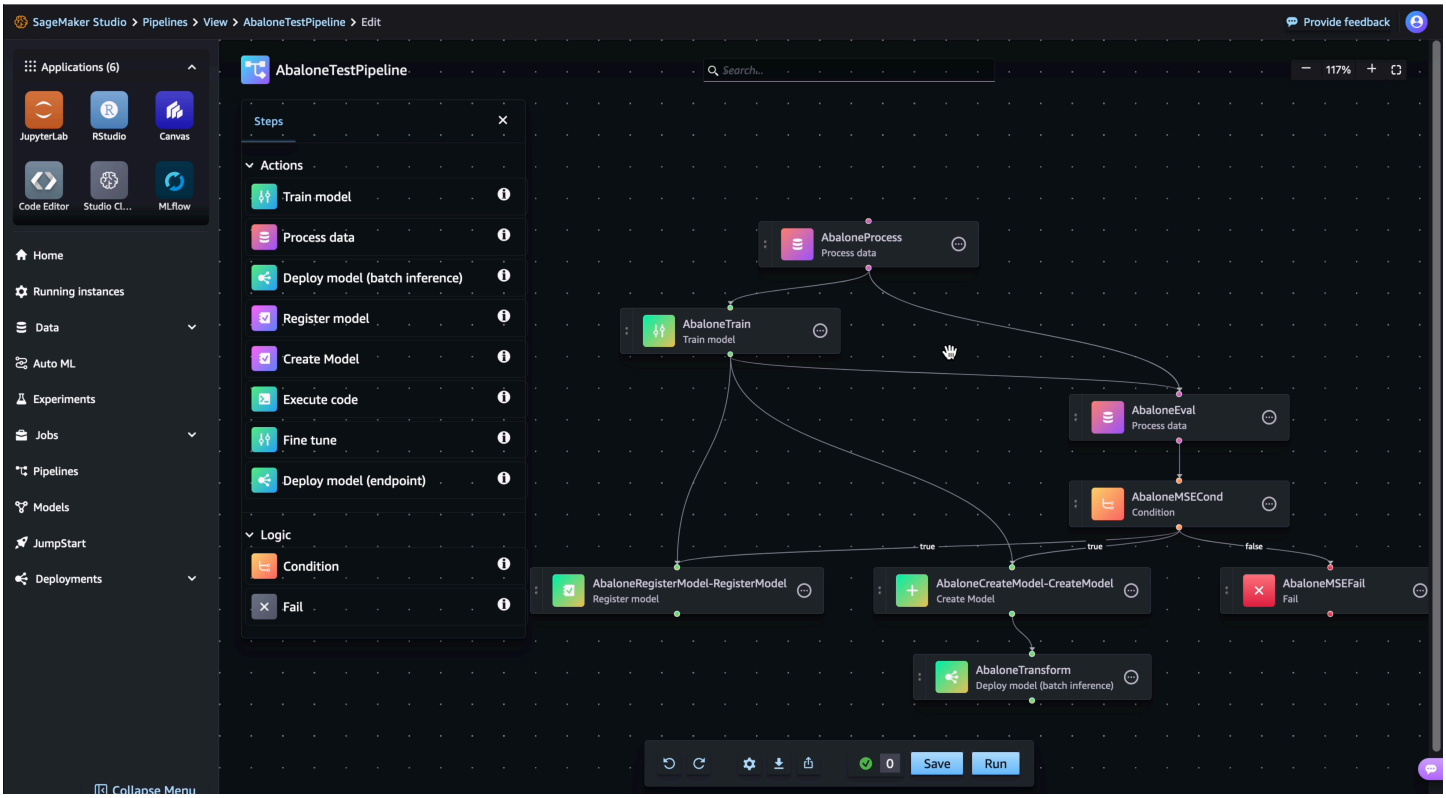
```
                    "ExceptionType": [
                        "SageMaker.JOB_INTERNAL_ERROR",
                        "SageMaker.CAPACITY_ERROR"
                    ],
                    "IntervalSeconds": 1,
                    "BackoffRate": 2,
                    "MaxAttempts": 5
                }
            ]
        }
    ]
}
```

The following is an example of how to build a `TrainingStep` in SDK for Python (Boto3) with a retry policy.

```
from sagemaker.workflow.retry import (
    StepRetryPolicy,
    StepExceptionTypeEnum,
    SageMakerJobExceptionTypeEnum,
    SageMakerJobStepRetryPolicy
)

step_train = TrainingStep(
    name="MyTrainingStep",
    xxx,
    retry_policies=[
        // override the default
        StepRetryPolicy(
            exception_types=[
                StepExceptionTypeEnum.SERVICE_FAULT,
                StepExceptionTypeEnum.THROTTLING
            ],
            expire_after_mins=5,
            interval_seconds=10,
            backoff_rate=2.0
        ),
        // retry when resource limit quota gets exceeded
        SageMakerJobStepRetryPolicy(
            exception_types=[SageMakerJobExceptionTypeEnum.RESOURCE_LIMIT],
            expire_after_mins=120,
            interval_seconds=60,
            backoff_rate=2.0
```

```
        ),
        // retry when job failed due to transient error or EC2 ICE.
        SageMakerJobStepRetryPolicy(
            failure_reason_types=[
                SageMakerJobExceptionTypeEnum.INTERNAL_ERROR,
                SageMakerJobExceptionTypeEnum.CAPACITY_ERROR,
            ],
            max_attempts=10,
            interval_seconds=30,
            backoff_rate=2.0
        )
    ]
)
```



For more information on configuring retry behavior for certain step types, see *Amazon SageMaker Pipelines - Retry Policy* in the Amazon SageMaker Python SDK documentation.

Selective execution of pipeline steps

As you use Pipelines to create workflows and orchestrate your ML training steps, you might need to undertake multiple experimentation phases. Instead of running the full pipeline each time, you might only want to repeat certain steps. With Pipelines, you can execute pipeline steps selectively. This helps optimize your ML training. Selective execution is useful in the following scenarios:

- You want to restart a specific step with updated instance type, hyperparameters, or other variables while keeping the parameters from upstream steps.
- Your pipeline fails an intermediate step. Previous steps in the execution, such as data preparation or feature extraction, are expensive to rerun. You might need to introduce a fix and rerun certain steps manually to complete the pipeline.

Using selective execution, you can choose to run any subset of steps as long as they are connected in the directed acyclic graph (DAG) of your pipeline. The following DAG shows an example pipeline workflow:

You can select steps `AbaloneTrain` and `AbaloneEval` in a selective execution, but you cannot select just `AbaloneTrain` and `AbaloneMSECond` steps because these steps are not connected in the DAG. For non-selected steps in the workflow, the selective execution reuses the outputs from a reference pipeline execution rather than rerunning the steps. Also, non-selected steps that are downstream from the selected steps do not run in a selective execution.

If you choose to run a subset of intermediate steps in your pipeline, your steps may depend on previous steps. SageMaker AI needs a reference pipeline execution from which to resource these dependencies. For example, if you choose to run the steps `AbaloneTrain` and `AbaloneEval`, you need the outputs from the `AbaloneProcess` step. You can either provide a reference execution ARN or direct SageMaker AI to use the latest pipeline execution, which is the default behavior. If you have a reference execution, you can also build the runtime parameters from your reference run and supply them to your selective executive run with overrides. For details, see Reuse runtime parameter values from a reference execution.

In detail, you provide a configuration for your selective execution pipeline run using `SelectiveExecutionConfig`. If you include an ARN for a reference pipeline execution (with the `source_pipeline_execution_arn` argument), SageMaker AI uses the previous step dependencies from the pipeline execution you provided. If you do not include an ARN and a latest pipeline execution exists, SageMaker AI uses it as a reference by default. If you

do not include an ARN and do not want SageMaker AI to use your latest pipeline execution, set `reference_latest_execution` to `False`. The pipeline execution which SageMaker AI ultimately uses as a reference, whether the latest or user-specified, must be in `Success` or `Failed` state.

The following table summarizes how SageMaker AI chooses a reference execution.

The `source_pipeline_execution_arn` argument value	**The `reference_latest_execution` argument value**	**The reference execution used**
A pipeline ARN	`True` or unspecified	The specified pipeline ARN
A pipeline ARN	`False`	The specified pipeline ARN
`null` or unspecified	`True` or unspecified	The latest pipeline execution
`null` or unspecified	`False`	None—in this case, select steps without upstream dependencies

For more information about selective execution configuration requirements, see the [sagemaker.workflow.selective_execution_config.SelectiveExecutionConfig](#) documentation.

The following discussion includes examples for the cases in which you want to specify a pipeline reference execution, use the latest pipeline execution as a reference, or run selective execution without a reference pipeline execution.

Selective execution with a user-specified pipeline reference

The following example demonstrates a selective execution of the steps `AbaloneTrain` and `AbaloneEval` using a reference pipeline execution.

```
from sagemaker.workflow.selective_execution_config import SelectiveExecutionConfig

selective_execution_config = SelectiveExecutionConfig(
    source_pipeline_execution_arn="arn:aws:sagemaker:us-west-2:123123123123:pipeline/
abalone/execution/123ab12cd3ef",
```

```
    selected_steps=["AbaloneTrain", "AbaloneEval"]
)

selective_execution = pipeline.start(
    execution_display_name=f"Sample-Selective-Execution-1",
    parameters={"MaxDepth":6, "NumRound":60},
    selective_execution_config=selective_execution_config,
)
```

Selective execution with the latest pipeline execution as a reference

The following example demonstrates a selective execution of the steps `AbaloneTrain` and `AbaloneEval` using the latest pipeline execution as a reference. Since SageMaker AI uses the latest pipeline execution by default, you can optionally set the `reference_latest_execution` argument to `True`.

```
# Prepare a new selective execution. Select only the first step in the pipeline without
 providing source_pipeline_execution_arn.
selective_execution_config = SelectiveExecutionConfig(
    selected_steps=["AbaloneTrain", "AbaloneEval"],
    # optional
    reference_latest_execution=True
)

# Start pipeline execution without source_pipeline_execution_arn
pipeline.start(
    execution_display_name=f"Sample-Selective-Execution-1",
    parameters={"MaxDepth":6, "NumRound":60},
    selective_execution_config=selective_execution_config,
)
```

Selective execution without a reference pipeline

The following example demonstrates a selective execution of the steps `AbaloneProcess` and `AbaloneTrain` without providing a reference ARN and turning off the option to use the latest pipeline run as a reference. SageMaker AI permits this configuration since this subset of steps doesn't depend on previous steps.

```
# Prepare a new selective execution. Select only the first step in the pipeline without
 providing source_pipeline_execution_arn.
selective_execution_config = SelectiveExecutionConfig(
    selected_steps=["AbaloneProcess", "AbaloneTrain"],
```

```
    reference_latest_execution=False
)

# Start pipeline execution without source_pipeline_execution_arn
pipeline.start(
    execution_display_name=f"Sample-Selective-Execution-1",
    parameters={"MaxDepth":6, "NumRound":60},
    selective_execution_config=selective_execution_config,
)
```

Reuse runtime parameter values from a reference execution

You can build the parameters from your reference pipeline execution using `build_parameters_from_execution`, and supply the result to your selective execution pipeline. You can use the original parameters from the reference execution, or apply any overrides using the `parameter_value_overrides` argument.

The following example shows you how to build parameters from a reference execution and apply an override for the `MseThreshold` parameter.

```
# Prepare a new selective execution.
selective_execution_config = SelectiveExecutionConfig(
    source_pipeline_execution_arn="arn:aws:sagemaker:us-west-2:123123123123:pipeline/
abalone/execution/123ab12cd3ef",
    selected_steps=["AbaloneTrain", "AbaloneEval", "AbaloneMSECond"],
)
# Define a new parameters list to test.
new_parameters_mse={
    "MseThreshold": 5,
}

# Build parameters from reference execution and override with new parameters to test.
new_parameters = pipeline.build_parameters_from_execution(
    pipeline_execution_arn="arn:aws:sagemaker:us-west-2:123123123123:pipeline/abalone/
execution/123ab12cd3ef",
    parameter_value_overrides=new_parameters_mse
)

# Start pipeline execution with new parameters.
execution = pipeline.start(
    selective_execution_config=selective_execution_config,
    parameters=new_parameters
```

```
)
```

Baseline calculation, drift detection and lifecycle with ClarifyCheck and QualityCheck steps in Amazon SageMaker Pipelines

The following topic discusses how baselines and model versions evolve in the Amazon SageMaker Pipelines when using the `ClarifyCheck` and `QualityCheck` steps.

For the `ClarifyCheck` step, a baseline is a single file that resides in the step properties with the suffix `constraints`. For the `QualityCheck` step, a baseline is a combination of two files that resides in the step properties: one with the suffix `statistics` and the other with the suffix `constraints`. In the following topics we discuss these properties with a prefix that describes how they are used, impacting baseline behavior and lifecycle in these two pipeline steps. For example, the `ClarifyCheck` step always calculates and assigns the new baselines in the `CalculatedBaselineConstraints` property and the `QualityCheck` step does the same in the `CalculatedBaselineConstraints` and `CalculatedBaselineStatistics` properties.

Baseline calculation and registration for ClarifyCheck and QualityCheck steps

Both the `ClarifyCheck` and `QualityCheck` steps always calculate new baselines based on step inputs through the underlying processing job run. These newly calculated baselines are accessed through the properties with the prefix `CalculatedBaseline`. You can record these properties as the `ModelMetrics` of your model package in the Model step. This model package can be registered with 5 different baselines. You can register it with one for each check type: data bias, model bias, and model explainability from running the `ClarifyCheck` step and model quality, and data quality from running the `QualityCheck` step. The `register_new_baseline` parameter dictates the value set in the properties with the prefix `BaselineUsedForDriftCheck` after a step runs.

The following table of potential use cases shows different behaviors resulting from the step parameters you can set for the `ClarifyCheck` and `QualityCheck` steps:

Possible use case that you may consider for selecting this configuration	`skip_check` / `register_new_baseline`	Does step do a drift check?	Value of step property `CalculatedBaseline`	Value of step property `BaselineUsedForDriftCheck`
You are doing regular retraining with checks enabled to get a new model version, but you *want to carry over the previous baselines* as the `DriftCheckBaselines` in the model registry for your new model version.	`False`/ `False`	Drift check runs against existing baselines	New baselines calculated by running the step	Baseline from the latest approved model in Model Registry or the baseline supplied as step parameter
You are doing regular retraining with checks enabled to get a new model version, but you *want to refresh the `DriftCheckBaselines` in the model registry with the newly calculated baselines* for	`False`/ `True`	Drift check runs against existing baselines	New baselines calculated by running the step	Newly calculated baseline by running the step (value of property `CalculatedBaseline`)

Possible use case that you may consider for selecting this configuration	`skip_check` / `register_new_baseline`	Does step do a drift check?	Value of step property `CalculatedBaseline`	Value of step property `BaselineUsedForDriftCheck`
your new model version.				
You are initiating the pipeline to retrain a new model version because there is a violation detected by Amazon SageMaker Model Monitor on an endpoint for a particular type of check, and you want to *skip this type of check against the previous baseline, but carry over the previous baseline as `DriftCheckBaselines` in the model registry* for your new model version.	`True`/ `False`	No drift check	New baselines calculated by running	Baseline from the latest approved model in the model registry or the baseline supplied as step parameter

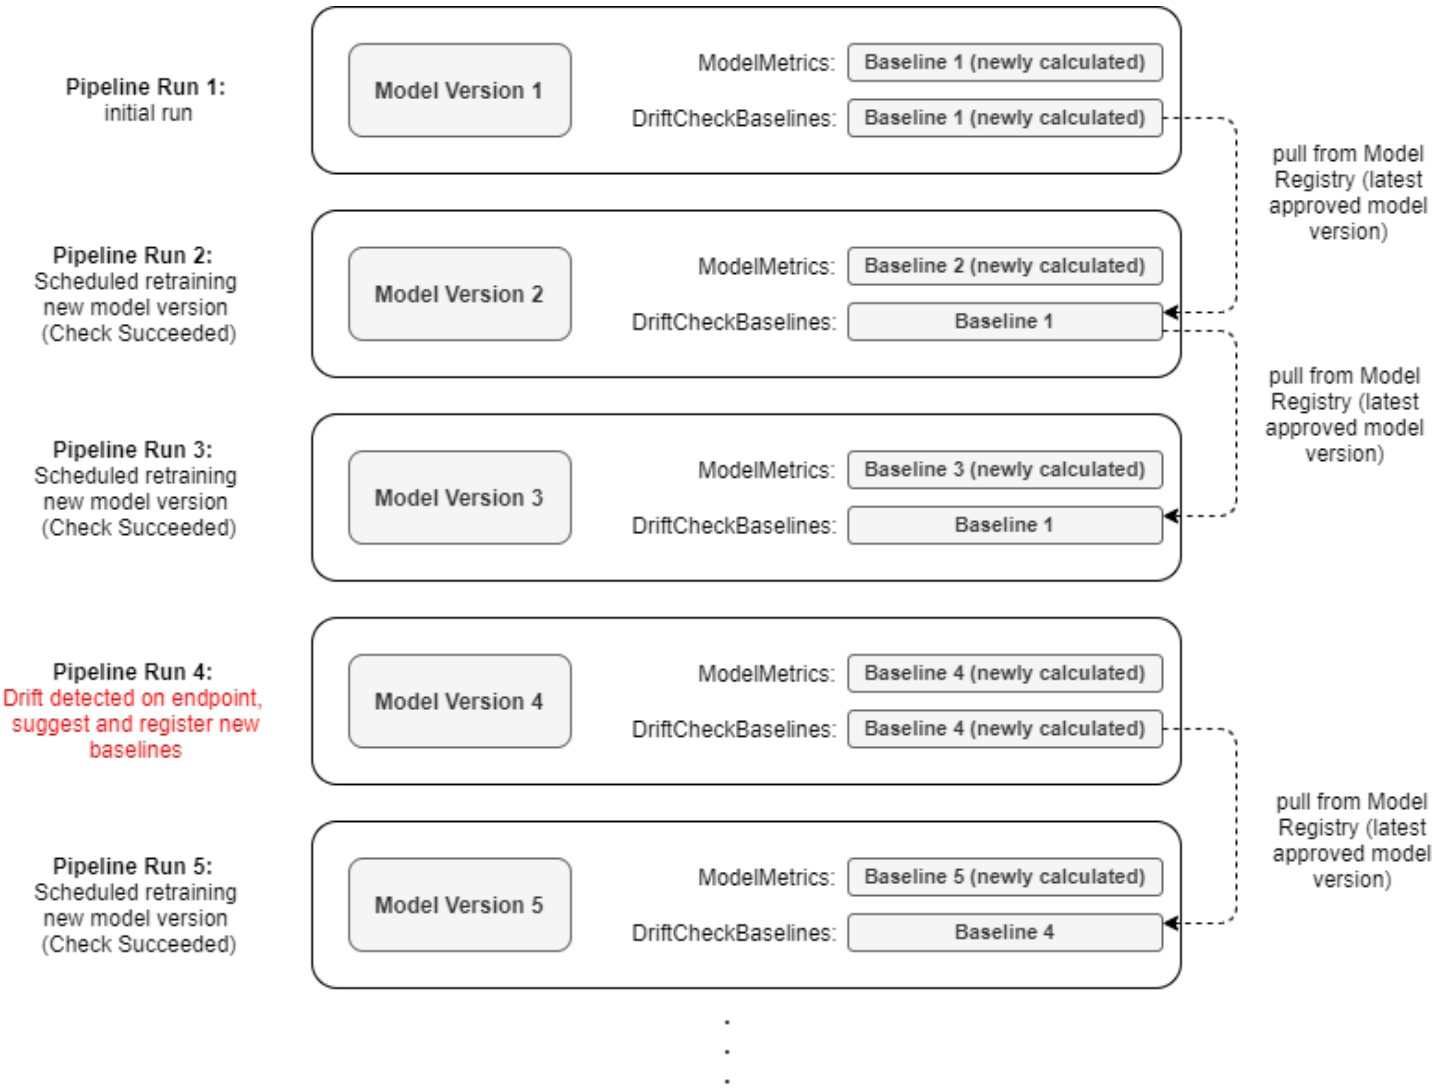
Possible use case that you may consider for selecting this configuration	`skip_check` / `register_new_baseline`	Does step do a drift check?	Value of step property `CalculatedBaseline`	Value of step property `BaselineUsedForDriftCheck`
This happens in the following cases: • You are starting the initial run of the pipeline, building your first model version, and generating the initial baselines. • You are initiating the pipeline to retrain a new model version because there is a violation detected by Model Monitor on the endpoint for a particular type of check. If you want to *skip the*	`True`/ `True`	No drift check	New baselines calculated by running the step	Newly calculated baseline by running the step (value of property `CalculatedBaseline`)

Possible use case that you may consider for selecting this configuration	`skip_check` / `register_new_baseline`	Does step do a drift check?	Value of step property `CalculatedBaseline`	Value of step property `BaselineUsedForDriftCheck`
check against the previous baseline and refresh the `DriftCheckBaselines` with the newly calculated baseline in the model registry directly.				

> **Note**
>
> If you use scientific notation in your constraint, you need to convert to float. For a preprocessing script example of how to do this, see Create a Model Quality Baseline.

When you register a model with Model step, you can register the `BaselineUsedForDriftCheck` property as `DriftCheckBaselines`. These baseline files can then be used by Model Monitor for model and data quality checks. In addition, these baselines can also be used in the ClarifyCheckStep and `QualityCheck` step to compare newly trained models against the existing models that are registered in the model registry for future pipeline runs.

Drift Detection against Previous Baselines in Pipelines



In the case of the `QualityCheck` step, when you initiate the pipeline for regular retraining to get a new model version, you may not want to run the training step if the data quality and the data bias has Schema for Violations (constraint_violations.json file) on the baselines of your previous

approved model version. You also may not want to register the newly trained model version if the model quality, model bias, or model explainability violates the registered baseline of your previous approved model version when running the `ClarifyCheck` step. In these cases, you can enable the checks you want by setting the `skip_check` property of the corresponding check step set to `False`, resulting in the `ClarifyCheck` and `QualityCheck` step failing if violation is detected against previous baselines. The pipeline process then does not proceed so that the model drifted from the baseline isn't registered. `ClarifyCheck` and `QualityCheck` steps are able to get `DriftCheckBaselines` of the latest approved model version of a given model package group against which to compare. Previous baselines can also be supplied directly through `supplied_baseline_constraints` (in addition to `supplied_baseline_statistics` if it is a `QualityCheck` step) and are always prioritized over any baselines pulled from the model package group.

Baseline and model version lifecycle and evolution with Pipelines

By setting `register_new_baseline` of your `ClarifyCheck` and `QualityCheck` step to `False`, your previous baseline is accessible through the step property prefix `BaselineUsedForDriftCheck`. You can then register these baselines as the `DriftCheckBaselines` in the new model version when you register a model with Model step. Once you approve this new model version in the model registry, the `DriftCheckBaseline` in this model version becomes available for the `ClarifyCheck` and `QualityCheck` steps in the next pipeline process. If you want to refresh the baseline of a certain check type for future model versions, you can set `register_new_baseline` to `True` so that the properties with prefix `BaselineUsedForDriftCheck` become the newly calculated baseline. In these ways, you can preserve your preferred baselines for a model trained in the future, or refresh the baselines for drift checks when needed, managing your baseline evolution and lifecycle throughout your model training iterations.

The following diagram illustrates a model-version-centric view of the baseline evolution and lifecycle.

Schedule Pipeline Runs

You can schedule your Amazon SageMaker Pipelines executions using Amazon EventBridge. Amazon SageMaker Pipelines is supported as a target in Amazon EventBridge. This allows you to initiate the execution of your model building pipeline based on any event in your event bus. With EventBridge, you can automate your pipeline executions and respond automatically to events such as training job or endpoint status changes. Events include a new file being uploaded to your Amazon S3 bucket, a change in status of your Amazon SageMaker AI endpoint due to drift, and *Amazon Simple Notification Service* (SNS) topics.

The following Pipelines actions can be automatically initiated:

- `StartPipelineExecution`

For more information on scheduling SageMaker AI jobs, see Automating SageMaker AI with Amazon EventBridge.

Topics

- Schedule a Pipeline with Amazon EventBridge
- Schedule a pipeline with the SageMaker Python SDK

Schedule a Pipeline with Amazon EventBridge

To start a pipeline execution with Amazon CloudWatch Events, you must create an EventBridge rule. When you create a rule for events, you specify a target action to take when EventBridge receives an event that matches the rule. When an event matches the rule, EventBridge sends the event to the specified target and initiates the action defined in the rule.

The following tutorials show how to schedule a pipeline execution with EventBridge using the EventBridge console or the Amazon CLI.

Prerequisites

- A role that EventBridge can assume with the `SageMaker::StartPipelineExecution` permission. This role can be created automatically if you create a rule from the EventBridge console; otherwise, you need to create this role yourself. For information on creating a SageMaker AI role, see SageMaker Roles.
- An Amazon SageMaker AI Pipeline to schedule. To create an Amazon SageMaker AI Pipeline, see Define a Pipeline.

Create an EventBridge rule using the EventBridge console

The following procedure shows how to create an EventBridge rule using the EventBridge console.

1. Navigate to the EventBridge console.
2. Select **Rules** on the left hand side.
3. Select `Create Rule`.
4. Enter a name and description for your rule.
5. Select how you want to initiate this rule. You have the following choices for your rule:

    - **Event pattern**: Your rule is initiated when an event matching the pattern occurs. You can choose a predefined pattern that matches a certain type of event, or you can create a

custom pattern. If you select a predefined pattern, you can edit the pattern to customize it. For more information on Event patterns, see Event Patterns in CloudWatch Events.

- **Schedule**: Your rule is initiated regularly on a specified schedule. You can use a fixed-rate schedule that initiates regularly for a specified number of minutes, hour, or weeks. You can also use a cron expression to create a more fine-grained schedule, such as "the first Monday of each month at 8am." Schedule is not supported on a custom or partner event bus.

6. Select your desired Event bus.
7. Select the target(s) to invoke when an event matches your event pattern or when the schedule is initiated. You can add up to 5 targets per rule. Select `SageMaker Pipeline` in the target dropdown list.
8. Select the pipeline you want to initiate from the pipeline dropdown list.
9. Add parameters to pass to your pipeline execution using a name and value pair. Parameter values can be static or dynamic. For more information on Amazon SageMaker AI Pipeline parameters, see AWS::Events::Rule SagemakerPipelineParameters.

    - Static values are passed to the pipeline execution every time the pipeline is initiated. For example, if `{"Name": "Instance_type", "Value": "ml.4xlarge"}` is specified in the parameter list, then it is passed as a parameter in `StartPipelineExecutionRequest` every time EventBridge initiates the pipeline.
    - Dynamic values are specified using a JSON path. EventBridge parses the value from an event payload, then passes it to the pipeline execution. For example: *`$.detail.param.value`*

10. Select the role to use for this rule. You can either use an existing role or create a new one.
11. (Optional) Add tags.
12. Select `Create` to finalize your rule.

Your rule is now in effect and ready to initiate your pipeline executions.

Create an EventBridge rule using the Amazon CLI

The following procedure shows how to create an EventBridge rule using the Amazon CLI.

1. Create a rule to be initiated. When creating an EventBridge rule using the Amazon CLI, you have two options for how your rule is initiated, event pattern and schedule.

    - **Event pattern**: Your rule is initiated when an event matching the pattern occurs. You can choose a predefined pattern that matches a certain type of event, or you can create a

custom pattern. If you select a predefined pattern, you can edit the pattern to customize it. You can create a rule with event pattern using the following command:

```
aws events put-rule --name <RULE_NAME> ----event-pattern <YOUR_EVENT_PATTERN>
 --description <RULE_DESCRIPTION> --role-arn <ROLE_TO_EXECUTE_PIPELINE> --
tags <TAGS>
```

- **Schedule**: Your rule is initiated regularly on a specified schedule. You can use a fixed-rate schedule that initiates regularly for a specified number of minutes, hour, or weeks. You can also use a cron expression to create a more fine-grained schedule, such as “the first Monday of each month at 8am.” Schedule is not supported on a custom or partner event bus. You can create a rule with schedule using the following command:

```
aws events put-rule --name <RULE_NAME> --schedule-
expression <YOUR_CRON_EXPRESSION> --description <RULE_DESCRIPTION> --role-
arn <ROLE_TO_EXECUTE_PIPELINE> --tags <TAGS>
```

2. Add target(s) to invoke when an event matches your event pattern or when the schedule is initiated. You can add up to 5 targets per rule. For each target, you must specify:

   - ARN: The resource ARN of your pipeline.
   - Role ARN: The ARN of the role EventBridge should assume to execute the pipeline.
   - Parameters: Amazon SageMaker AI pipeline parameters to pass.

3. Run the following command to pass a Amazon SageMaker AI pipeline as a target to your rule using put-targets :

```
aws events put-targets --rule <RULE_NAME> --event-bus-name <EVENT_BUS_NAME>
 --targets "[{\"Id\": <ID>, \"Arn\": <RESOURCE_ARN>, \"RoleArn\": <ROLE_ARN>,
 \"SageMakerPipelineParameter\": { \"SageMakerParameterList\": [{\"Name\": <NAME>,
 \"Value\": <VALUE>}]} }]"]
```

Schedule a pipeline with the SageMaker Python SDK

The following sections show you how to set up permissions to access EventBridge resources and create your pipeline schedule using the SageMaker Python SDK.

Required permissions

You need to have necessary permissions to use the pipeline scheduler. Complete the following steps to set up your permissions:

1. Attach the following minimum privilege policy to the IAM role used to create the pipeline triggers, or use the Amazon managed policy `AmazonEventBridgeSchedulerFullAccess`.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement":
    [
        {
            "Action":
            [
                "scheduler:ListSchedules",
                "scheduler:GetSchedule",
                "scheduler:CreateSchedule",
                "scheduler:UpdateSchedule",
                "scheduler:DeleteSchedule"
            ],
            "Effect": "Allow",
            "Resource":
            [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws-cn:iam::*:role/*",
            "Condition": {
                "StringLike": {
                    "iam:PassedToService": "scheduler.amazonaws.com"
                }
            }
        }
    ]
}
```

2. Establish a trust relationship with EventBridge by adding the service principal `scheduler.amazonaws.com` to this role's trust policy. Make sure you attach the following trust policy to the execution role if you launch the notebook in SageMaker Studio.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "scheduler.amazonaws.com",
                    "sagemaker.amazonaws.com"
                ]
            },
        "Action": "sts:AssumeRole"
        }
    ]
}
```

Create a pipeline schedule

Using the `PipelineSchedule` constructor, you can schedule a pipeline to run once or at a predetermined interval. A pipeline schedule must be of the type `at`, `rate`, or `cron`. This set of scheduling types is an extension of the EventBridge scheduling options. For more information about how to use the `PipelineSchedule` class, see sagemaker.workflow.triggers.PipelineSchedule. The following example demonstrates how to create each scheduling type with `PipelineSchedule`.

```
from sagemaker.workflow.triggers import PipelineSchedule

# schedules a pipeline run for 12/13/2023 at time 10:15:20 UTC
my_datetime_schedule = PipelineSchedule(
    name="<schedule-name>",
    at=datetime(2023, 12, 13, 10, 15, 20)
)
```

```
# schedules a pipeline run every 5 minutes
my_rate_schedule = PipelineSchedule(
    name="<schedule-name>",
    rate=(5, "minutes")
)

# schedules a pipeline run at 10:15am UTC on the last Friday of each month during the
 years 2022 to 2023
my_cron_schedule = PipelineSchedule(
    name="<schedule-name>",
    cron="15 10 ? * 6L 2022-2023"
)
```

> **Note**
>
> If you create a one-time schedule and need to access the current time, use `datetime.utcnow()` instead of `datetime.now()`. The latter does not store the current zone context and results in an incorrect time passed to EventBridge.

Attach the trigger to your pipeline

To attach your `PipelineSchedule` to your pipeline, invoke the `put_triggers` call on your created pipeline object with a list of triggers. If you get a response ARN, you successfully created the schedule in your account and EventBridge begins to invoke the target pipeline at the time or rate specified. You must specify a role with correct permissions to attach triggers to a parent pipeline. If you don't provide one, Pipelines fetches the default role used to create the pipeline from the configuration file.

The following example demonstrates how to attach a schedule to a pipeline.

```
scheduled_pipeline = Pipeline(
    name="<pipeline-name>",
    steps=[...],
    sagemaker_session=<sagemaker-session>,
)
custom_schedule = PipelineSchedule(
    name="<schedule-name>",
    at=datetime(year=2023, month=12, date=25, hour=10, minute=30, second=30)
)
scheduled_pipeline.put_triggers(triggers=[custom_schedule], role_arn=<role>)
```

Describe current triggers

To retrieve information about your created pipeline triggers, you can invoke the `describe_trigger()` API with the trigger name. This command returns details about the created schedule expression such as its start time, enabled state, and other useful information. The following snippet shows a sample invocation:

```
scheduled_pipeline.describe_trigger(name="<schedule-name>")
```

Cleanup trigger resources

Before you delete your pipeline, clean up existing triggers to avoid a resource leak in your account. You should delete the triggers before destroying the parent pipeline. You can delete your triggers by passing a list of trigger names to the `delete_triggers` API. The following snippet demonstrates how to delete triggers.

```
pipeline.delete_triggers(trigger_names=["<schedule-name>"])
```

> **Note**
>
> Be aware of the following limitations when you delete your triggers:
>
> - The option to delete the triggers by specifying trigger names is only available in the SageMaker Python SDK. Deleting the pipeline in the CLI or a `DeletePipeline` API call does not delete your triggers. As a result, the triggers become orphaned and SageMaker AI attempts to start a run for a non-existent pipeline.
> - Also, if you are using another notebook session or already deleted the pipeline target, clean up orphaned schedules through the scheduler CLI or EventBridge console.

Amazon SageMaker Experiments Integration

Amazon SageMaker Pipelines is closely integrated with Amazon SageMaker Experiments. By default, when Pipelines creates and executes a pipeline, the following SageMaker Experiments entities are created if they don't exist:

- An experiment for the pipeline
- A run group for every execution of the pipeline

- A run that's added to the run group for each SageMaker AI job created in a pipeline execution step

You can compare metrics such as model training accuracy across multiple pipeline executions just as you can compare such metrics across multiple run groups of a SageMaker AI model training experiment.

The following sample shows the relevant parameters of the Pipeline class in the Amazon SageMaker Python SDK.

```
Pipeline(
    name="MyPipeline",
    parameters=[...],
    pipeline_experiment_config=PipelineExperimentConfig(
      ExecutionVariables.PIPELINE_NAME,
      ExecutionVariables.PIPELINE_EXECUTION_ID
    ),
    steps=[...]
)
```

If you don't want an experiment and run group created for the pipeline, set `pipeline_experiment_config` to None.

> **Note**
>
> Experiments integration was introduced in the Amazon SageMaker Python SDK v2.41.0.

The following naming rules apply based on what you specify for the `ExperimentName` and `TrialName` parameters of `pipeline_experiment_config`:

- If you don't specify `ExperimentName`, the pipeline `name` is used for the experiment name.

  If you do specify `ExperimentName`, it's used for the experiment name. If an experiment with that name exists, the pipeline-created run groups are added to the existing experiment. If an experiment with that name doesn't exist, a new experiment is created.
- If you don't specify `TrialName`, the pipeline execution ID is used for the run group name.

If you do specify `TrialName`, it's used for the run group name. If a run group with that name exists, the pipeline-created runs are added to the existing run group. If a run group with that name doesn't exist, a new run group is created.

> **Note**
>
> The experiment entities aren't deleted when the pipeline that created the entities is deleted. You can use the SageMaker Experiments API to delete the entities.

For information about how to view the SageMaker AI Experiment entities associated with a pipeline, see Access experiment data from a pipeline. For more information on SageMaker Experiments, see Amazon SageMaker Experiments in Studio Classic.

The following sections show examples of the previous rules and how they are represented in the pipeline definition file. For more information on pipeline definition files, see Pipelines overview.

Topics

- Default Behavior
- Disable Experiments Integration
- Specify a Custom Experiment Name
- Specify a Custom Run Group Name

Default Behavior

Create a pipeline

The default behavior when creating a SageMaker AI Pipeline is to automatically integrate it with SageMaker Experiments. If you don't specify any custom configuration, SageMaker AI creates an experiment with the same name as the pipeline, a run group for each execution of the pipeline using the pipeline execution ID as the name, and individual runs within each run group for every SageMaker AI job launched as part of the pipeline steps. You can seamlessly track and compare metrics across different pipeline executions, similar to how you would analyze a model training experiment. The following section demonstrates this default behavior when defining a pipeline without explicitly configuring the experiment integration.

The `pipeline_experiment_config` is omitted. `ExperimentName` defaults to the pipeline name. `TrialName` defaults to the execution ID.

```
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    steps=[step_train]
)
```

Pipeline definition file

```
{
  "Version": "2020-12-01",
  "Parameters": [
    {
      "Name": "InputDataSource"
    },
    {
      "Name": "InstanceCount",
      "Type": "Integer",
      "DefaultValue": 1
    }
  ],
  "PipelineExperimentConfig": {
    "ExperimentName": {"Get": "Execution.PipelineName"},
    "TrialName": {"Get": "Execution.PipelineExecutionId"}
  },
  "Steps": [...]
}
```

Disable Experiments Integration

Create a pipeline

You can disable your pipeline's integration with SageMaker Experiments by setting the `pipeline_experiment_config` parameter to `None` when you define your pipeline. This way, SageMaker AI will not automatically create an experiment, run groups, or individual runs for tracking metrics and artifacts associated with your pipeline executions. The following example sets the pipeline config parameter to `None`.

```
pipeline_name = f"MyPipeline"
```

```
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    pipeline_experiment_config=None,
    steps=[step_train]
)
```

Pipeline definition file

This is the same as the preceding default example, without the `PipelineExperimentConfig`.

Specify a Custom Experiment Name

While the default behavior is to use the pipeline name as the experiment name in SageMaker Experiments, you can override this and specify a custom experiment name instead. This can be useful if you want to group multiple pipeline executions under the same experiment for easier analysis and comparison. The run group name will still default to the pipeline execution ID unless you explicitly set a custom name for that as well. The following section demonstrates how to create a pipeline with a custom experiment name while leaving the run group name as the default execution ID.

Create a pipeline

```
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    pipeline_experiment_config=PipelineExperimentConfig(
      "CustomExperimentName",
      ExecutionVariables.PIPELINE_EXECUTION_ID
    ),
    steps=[step_train]
)
```

Pipeline definition file

```
{
  ...,
  "PipelineExperimentConfig": {
    "ExperimentName": "CustomExperimentName",
    "TrialName": {"Get": "Execution.PipelineExecutionId"}
  },
```

```
  "Steps": [...]
}
```

Specify a Custom Run Group Name

In addition to setting a custom experiment name, you can also specify a custom name for the run groups created by SageMaker Experiments during pipeline executions. This name is appended with the pipeline execution ID to ensure uniqueness. You can specify a custom run group name to identify and analyze related pipeline runs within the same experiment. The following section shows how to define a pipeline with a custom run group name while using the default pipeline name for the experiment name.

Create a pipeline

```
pipeline_name = f"MyPipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[...],
    pipeline_experiment_config=PipelineExperimentConfig(
      ExecutionVariables.PIPELINE_NAME,
      Join(on="-", values=["CustomTrialName",
 ExecutionVariables.PIPELINE_EXECUTION_ID])
    ),
    steps=[step_train]
)
```

Pipeline definition file

```
{
  ...,
  "PipelineExperimentConfig": {
    "ExperimentName": {"Get": "Execution.PipelineName"},
    "TrialName": {
      "On": "-",
      "Values": [
         "CustomTrialName",
         {"Get": "Execution.PipelineExecutionId"}
       ]
    }
  },
  "Steps": [...]
}
```

Run pipelines using local mode

SageMaker Pipelines local mode is an easy way to test your training, processing and inference scripts, as well as the runtime compatibility of pipeline parameters before you execute your pipeline on the managed SageMaker AI service. By using local mode, you can test your SageMaker AI pipeline locally using a smaller dataset. This allows quick and easy debugging of errors in user scripts and the pipeline definition itself without incurring the costs of using the managed service. The following topic shows you how to define and run pipelines locally.

Pipelines local mode leverages SageMaker AI jobs local mode under the hood. This is a feature in the SageMaker Python SDK that allows you to run SageMaker AI built-in or custom images locally using Docker containers. Pipelines local mode is built on top of SageMaker AI jobs local mode. Therefore, you can expect to see the same results as if you were running those jobs separately. For example, local mode still uses Amazon S3 to upload model artifacts and processing outputs. If you want data generated by local jobs to reside on local disk, you can use the setup mentioned in Local Mode.

Pipeline local mode currently supports the following step types:

- Training step
- Processing step
- Transform step
- Model Step (with Create Model arguments only)
- Condition step
- Fail step

As opposed to the managed Pipelines service which allows multiple steps to execute in parallel using Parallelism Configuration, the local pipeline executor runs the steps sequentially. Therefore, overall execution performance of a local pipeline may be poorer than one that runs on the cloud - this mostly depends on the size of the dataset, algorithm, as well as the power of your local computer. Also note that Pipelines runs in local mode are not recorded in SageMaker Experiments.

> **Note**
>
> Pipelines local mode is not compatible with SageMaker AI algorithms such as XGBoost. If you to want use these algorithms, you must use them in script mode.

In order to execute a pipeline locally, the `sagemaker_session` fields associated with the pipeline steps and the pipeline itself need to be of type `LocalPipelineSession`. The following example shows how you can define a SageMaker AI pipeline to execute locally.

```
from sagemaker.core.workflow.pipeline_context import LocalPipelineSession
from sagemaker.train import ModelTrainer
from sagemaker.train.configs import InputData, SourceCode
from sagemaker.train.configs import Compute
from sagemaker.mlops.workflow.steps import TrainingStep
from sagemaker.mlops.workflow.pipeline import Pipeline
from sagemaker.core.helper.session_helper import get_execution_role
from sagemaker.core import image_uris

local_pipeline_session = LocalPipelineSession()

training_image = image_uris.retrieve(
    framework="pytorch", region=region, version="1.8.0",
    py_version="py36", instance_type="ml.c5.xlarge",
    image_scope="training"
)

pytorch_model_trainer = ModelTrainer(
    role=get_execution_role(),
    compute=Compute(
        instance_type="ml.c5.xlarge",
        instance_count=1,
    ),
    training_image=training_image,
    source_code=SourceCode(entry_script="./entry_point.py"),
)

step = TrainingStep(
    name="MyTrainingStep",
    step_args=pytorch_model_trainer.train(
        input_data_config=[InputData(channel_name="training", data_source="s3://amzn-
s3-demo-bucket/my-data/train")],
    )
)

pipeline = Pipeline(
    name="MyPipeline",
    steps=[step],
```

```
    sagemaker_session=local_pipeline_session
)

pipeline.create(
    role_arn=get_execution_role(),
    description="local pipeline example"
)

# pipeline will execute locally
execution = pipeline.start()

steps = execution.list_steps()

training_job_name = steps['PipelineExecutionSteps'][0]['Metadata']['TrainingJob']
['Arn']

step_outputs =
 local_pipeline_session.sagemaker_client.describe_training_job(TrainingJobName =
 training_job_name)
```

Once you are ready to execute the pipeline on the managed SageMaker Pipelines service, you can do so by replacing `LocalPipelineSession` in the previous code snippet with `PipelineSession` (as shown in the following code sample) and rerunning the code.

```
from sagemaker.workflow.pipeline_context import PipelineSession

pipeline_session = PipelineSession()
```

Troubleshooting Amazon SageMaker Pipelines

When using Amazon SageMaker Pipelines, you might run into issues for various reasons. This topic provides information about common errors and how to resolve them.

Pipeline Definition Issues

Your pipeline definition might not be formatted correctly. This can result in your execution failing or your job being inaccurate. These errors can be caught when the pipeline is created or when an execution occurs. If your definition doesn't validate, Pipelines returns an error message identifying the character where the JSON file is malformed. To fix this problem, review the steps created using the SageMaker AI Python SDK for accuracy.

You can only include steps in a pipeline definition once. Because of this, steps cannot exist as part of a condition step *and* a pipeline in the same pipeline.

Examining Pipeline Logs

You can view the status of your steps using the following command:

```
execution.list_steps()
```

Each step includes the following information:

- The ARN of the entity launched by the pipeline, such as SageMaker AI job ARN, model ARN, or model package ARN.
- The failure reason includes a brief explanation of the step failure.
- If the step is a condition step, it includes whether the condition is evaluated to true or false.
- If the execution reuses a previous job execution, the `CacheHit` lists the source execution.

You can also view the error messages and logs in the Amazon SageMaker Studio interface. For information about how to see the logs in Studio, see View the details of a pipeline run.

Missing Permissions

Correct permissions are required for the role that creates the pipeline execution, and the steps that create each of the jobs in your pipeline execution. Without these permissions, you may not be able to submit your pipeline execution or run your SageMaker AI jobs as expected. To ensure that your permissions are properly set up, see IAM Access Management.

Job Execution Errors

You may run into issues when executing your steps because of issues in the scripts that define the functionality of your SageMaker AI jobs. Each job has a set of CloudWatch logs. To view these logs from Studio, see View the details of a pipeline run. For information about using CloudWatch logs with SageMaker AI, see CloudWatch Logs for Amazon SageMaker AI.

Property File Errors

You may have issues when incorrectly implementing property files with your pipeline. To ensure that your implementation of property files works as expected, see Pass Data Between Steps.

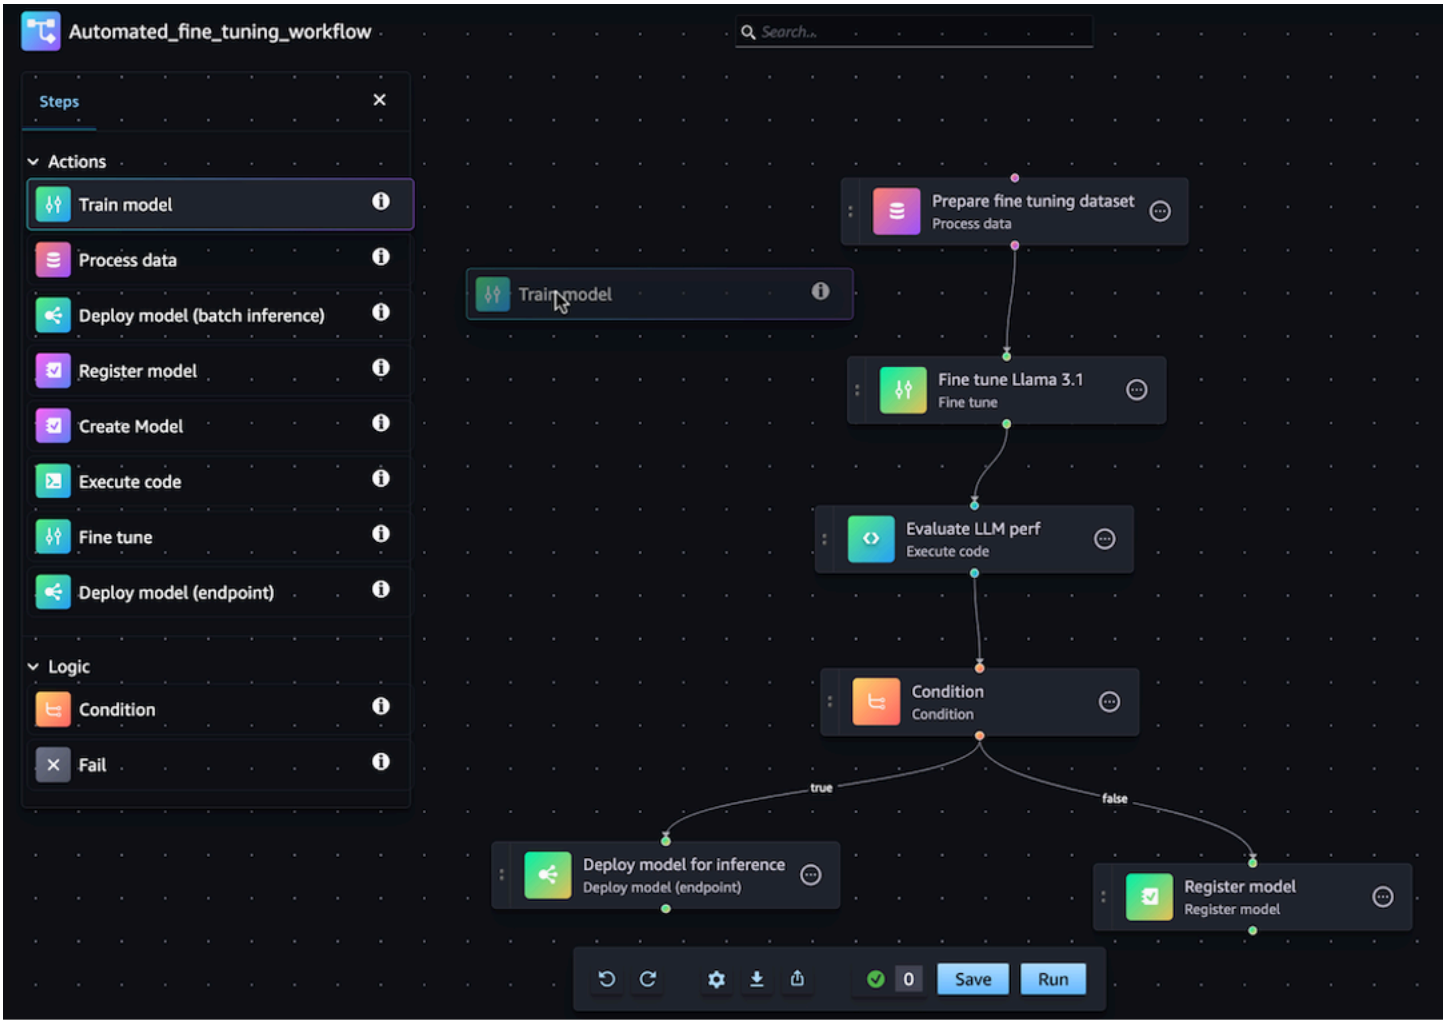
Issues copying the script to the container in the Dockerfile

You can either copy the script to the container or pass it via the `entry_point` argument (of your ModelTrainer entity) or `code` argument (of your processor entity), as demonstrated in the following code sample.

```
step_process = ProcessingStep(
    name="PreprocessAbaloneData",
    processor=sklearn_processor,
    inputs = [
        ProcessingInput(
            input_name='dataset',
            source=...,
            destination="/opt/ml/processing/code",
        )
    ],
    outputs=[
        ProcessingOutput(output_name="train", source="/opt/ml/processing/train",
 destination = processed_data_path),
        ProcessingOutput(output_name="validation", source="/opt/ml/processing/
validation", destination = processed_data_path),
        ProcessingOutput(output_name="test", source="/opt/ml/processing/test",
 destination = processed_data_path),
    ],
    code=os.path.join(BASE_DIR, "process.py"), ## Code is passed through an argument
    cache_config = cache_config,
    job_arguments = ['--input', 'arg1']
)

from sagemaker.core import image_uris

sklearn_image_uri = image_uris.retrieve(
    framework="sklearn",
    region=region,
    version="0.23-1",
    instance_type=training_instance_type
)



sklearn_estimator = ModelTrainer(
    source_code=SourceCode(entry_script=os.path.join(BASE_DIR, "train.py")), ## Code is
 passed through source_code
    training_image=sklearn_image_uri,
    instance_type=training_instance_type,
```

```
    role=role,
    output_path=model_path, # New
    sagemaker_session=sagemaker_session, # New
    instance_count=1, # New
    base_job_name=f"{base_job_prefix}/pilot-train",
    metric_definitions=[
        {'Name': 'train:accuracy', 'Regex': 'accuracy_train=(.*?);'},
        {'Name': 'validation:accuracy', 'Regex': 'accuracy_validation=(.*?);'}
    ],
)
```

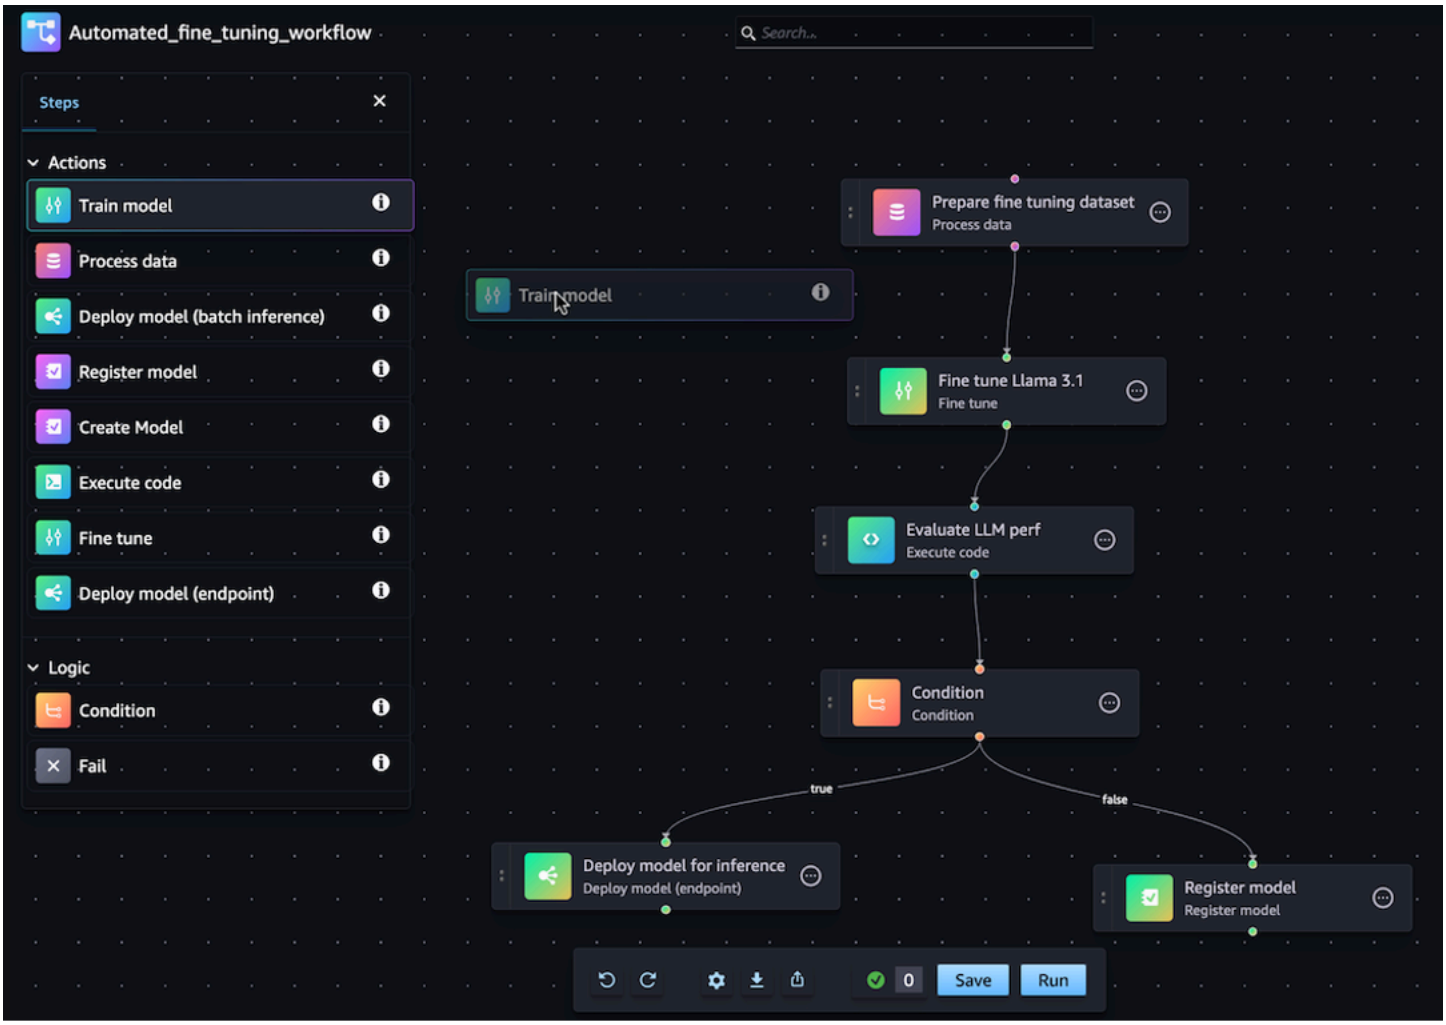
Pipelines actions

You can use either the Amazon SageMaker Pipelines Python SDK or the drag-and-drop visual designer in Amazon SageMaker Studio to author, view, edit, execute, and monitor your ML workflows.

The following screenshot shows the visual designer that you can use to create and manage your Amazon SageMaker Pipelines.

After your pipeline is deployed, you can view the directed acyclic graph (DAG) for your pipeline and manage your executions using Amazon SageMaker Studio. Using SageMaker Studio, you can get information about your current and historical pipelines, compare executions, see the DAG for your executions, get metadata information, and more. To learn about how to view pipelines from Studio, see View the details of a pipeline.

Topics



- Define a pipeline
- Edit a pipeline
- Run a pipeline
- Stop a pipeline
- View the details of a pipeline
- View the details of a pipeline run

- Download a pipeline definition file
- Access experiment data from a pipeline
- Track the lineage of a pipeline

Define a pipeline

To orchestrate your workflows with Amazon SageMaker Pipelines, you must generate a directed acyclic graph (DAG) in the form of a JSON pipeline definition. The DAG specifies the different steps involved in your ML process, such as data preprocessing, model training, model evaluation, and model deployment, as well as the dependencies and flow of data between these steps. The following topic shows you how to generate a pipeline definition.

You can generate your JSON pipeline definition using either the SageMaker Python SDK or the visual drag-and-drop Pipeline Designer feature in Amazon SageMaker Studio. The following image is a representation of the pipeline DAG that you create in this tutorial:

The pipeline that you define in the following sections solves a regression problem to determine the age of an abalone based on its physical measurements. For a runnable Jupyter notebook that includes the content in this tutorial, see Orchestrating Jobs with Amazon SageMaker Model Building Pipelines.

> **Note**
>
> You can reference the model location as a property of the training step, as shown in the end-to-end example CustomerChurn pipeline in Github.

Define a pipeline (Pipeline Designer)

The following walkthrough guides you through the steps to create a barebones pipeline using the drag-and-drop Pipeline Designer. If you need to pause or end your Pipeline editing session in the visual designer at any time, click on the **Export** option. This allows you to download the current definition of your Pipeline to your local environment. Later, when you want to resume the Pipeline editing process, you can import the same JSON definition file into the visual designer.

Create a Processing step

To create a data processing job step, do the following:

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. Choose **Create**.
4. Choose **Blank**.
5. In the left sidebar, choose **Process data** and drag it to the canvas.
6. In the canvas, choose the **Process data** step you added.
7. To add an input dataset, choose **Add** under **Data (input)** in the right sidebar and select a dataset.
8. To add a location to save output datasets, choose **Add** under **Data (output)** in the right sidebar and navigate to the destination.
9. Complete the remaining fields in the right sidebar. For information about the fields in these tabs, see sagemaker.workflow.steps.ProcessingStep.

Create a Training step

To set up a model training step, do the following:

1. In the left sidebar, choose **Train model** and drag it to the canvas.
2. In the canvas, choose the **Train model** step you added.
3. To add an input dataset, choose **Add** under **Data (input)** in the right sidebar and select a dataset.
4. To choose a location to save your model artifacts, enter an Amazon S3 URI in the **Location (S3 URI)** field, or choose **Browse S3** to navigate to the destination location.
5. Complete the remaining fields in the right sidebar. For information about the fields in these tabs, see sagemaker.workflow.steps.TrainingStep.
6. Click and drag the cursor from the **Process data** step you added in the previous section to the **Train model** step to create an edge connecting the two steps.

Create a model package with a Register model step

To create a model package with a model registration step, do the following:

1. In the left sidebar, choose **Register model** and drag it to the canvas.
2. In the canvas, choose the **Register model** step you added.
3. To select a model to register, choose **Add** under **Model (input)**.
4. Choose **Create a model group** to add your model to a new model group.
5. Complete the remaining fields in the right sidebar. For information about the fields in these tabs, see sagemaker.workflow.step_collections.RegisterModel.
6. Click and drag the cursor from the **Train model** step you added in the previous section to the **Register model** step to create an edge connecting the two steps.

Deploy the model to an endpoint with a Deploy model (endpoint) step

To deploy your model using a model deployment step, do the following:

1. In the left sidebar, choose **Deploy model (endpoint)** and drag it to the canvas.
2. In the canvas, choose the **Deploy model (endpoint)** step you added.
3. To choose a model to deploy, choose **Add** under **Model (input)**.

4. Choose the **Create endpoint** radio button to create a new endpoint.
5. Enter a **Name** and **Description** for your endpoint.
6. Click and drag the cursor from the **Register model** step you added in the previous section to the **Deploy model (endpoint)** step to create an edge connecting the two steps.
7. Complete the remaining fields in the right sidebar.

Define the Pipeline parameters

You can configure a set of Pipeline parameters whose values can be updated for every execution. To define the pipeline parameters and set the default values, click on the gear icon at the bottom of the visual designer.

Save Pipeline

After you have entered all the required information to create your pipeline, click on **Save** at the bottom of the visual designer. This validates your pipeline for any potential errors at runtime and notifies you. The **Save** operation won't succeed until you address all errors flagged by the automated validations checks. If you want to resume editing at a later point, you can save your in-progress pipeline as a JSON definition in your local environment. You can export your Pipeline as a JSON definition file by clicking on the **Export** button at the bottom of the visual designer. Later, to resume updating your Pipeline, upload that JSON definition file by clicking on the **Import** button.

Define a pipeline (SageMaker Python SDK)

Prerequisites

To run the following tutorial, complete the following:

- Set up your notebook instance as outlined in Create a notebook instance. This gives your role permissions to read and write to Amazon S3, and create training, batch transform, and processing jobs in SageMaker AI.
- Grant your notebook permissions to get and pass its own role as shown in Modifying a role permissions policy. Add the following JSON snippet to attach this policy to your role. Replace `<your-role-arn>` with the ARN used to create your notebook instance.

  JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:GetRole",
                "iam:PassRole"
            ],
            "Resource": "arn:aws-cn:iam::111122223333:role/role-name"
        }
    ]
}
```

- Trust the SageMaker AI service principal by following the steps in Modifying a role trust policy. Add the following statement fragment to the trust relationship of your role:

```
{
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "sagemaker.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
```

Set up your environment

Create a new SageMaker AI session using the following code block. This returns the role ARN for the session. This role ARN should be the execution role ARN that you set up as a prerequisite.

```
import boto3
import sagemaker
from sagemaker.core.workflow.pipeline_context import PipelineSession
from sagemaker.core.helper.session_helper import Session, get_execution_role

region = boto3.Session().region_name
sagemaker_session = Session()
role = get_execution_role()
default_bucket = sagemaker_session.default_bucket()

pipeline_session = PipelineSession()
```

```
model_package_group_name = f"AbaloneModelPackageGroupName"
```

Create a pipeline

> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.
> Amazon managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

Run the following steps from your SageMaker AI notebook instance to create a pipeline that includes steps for preprocessing, training, evaluation, conditional evaluation, and model registration.

> **Note**
>
> You can use ExecutionVariables and the Join function to specify your output location.

Step 1: Download the dataset

This notebook uses the UCI Machine Learning Abalone Dataset. The dataset contains the following features:

- `length` – The longest shell measurement of the abalone.
- `diameter` – The diameter of the abalone perpendicular to its length.
- `height` – The height of the abalone with meat in the shell.
- `whole_weight` – The weight of the whole abalone.
- `shucked_weight` – The weight of the meat removed from the abalone.
- `viscera_weight` – The weight of the abalone viscera after bleeding.

- `shell_weight` – The weight of the abalone shell after meat removal and drying.
- `sex` – The sex of the abalone. One of 'M', 'F', or 'I', where 'I' is an infant abalone.
- `rings` – The number of rings in the abalone shell.

The number of rings in the abalone shell is a good approximation for its age using the formula `age=rings + 1.5`. However, getting this number is a time-consuming task. You must cut the shell through the cone, stain the section, and count the number of rings through a microscope. However, the other physical measurements are easier to get. This notebook uses the dataset to build a predictive model of the variable rings using the other physical measurements.

To download the dataset

1. Download the dataset into your account's default Amazon S3 bucket.

```
!mkdir -p data
local_path = "data/abalone-dataset.csv"

s3 = boto3.resource("s3")
s3.Bucket(f"sagemaker-servicecatalog-seedcode-{region}").download_file(
    "dataset/abalone-dataset.csv",
    local_path
)

base_uri = f"s3://{default_bucket}/abalone"
input_data_uri = sagemaker.s3.S3Uploader.upload(
    local_path=local_path,
    desired_s3_uri=base_uri,
)
print(input_data_uri)
```

2. Download a second dataset for batch transformation after your model is created.

```
local_path = "data/abalone-dataset-batch.csv"

s3 = boto3.resource("s3")
s3.Bucket(f"sagemaker-servicecatalog-seedcode-{region}").download_file(
    "dataset/abalone-dataset-batch",
    local_path
)

base_uri = f"s3://{default_bucket}/abalone"
```

```
batch_data_uri = sagemaker.s3.S3Uploader.upload(
    local_path=local_path,
    desired_s3_uri=base_uri,
)
print(batch_data_uri)
```

Step 2: Define pipeline parameters

```
from sagemaker.core.workflow.parameters import (
    ParameterInteger,
    ParameterString,
)

processing_instance_count = ParameterInteger(name="ProcessingInstanceCount",
 default_value=1)
model_approval_status = ParameterString(name="ModelApprovalStatus",
 default_value="PendingManualApproval")
input_data = ParameterString(name="InputData", default_value=input_data_uri)
batch_data = ParameterString(name="BatchData", default_value=batch_data_uri)
```

Step 3: Define a processing step for feature engineering

This section shows how to create a processing step to prepare the data from the dataset for training.

To create a processing step

1. Create an instance of a processor to pass in to the processing step.

```
from sagemaker.core.processing import Processor
from sagemaker.core import image_uris

framework_version = "0.23-1"

sklearn_image_uri = image_uris.retrieve(
    framework="sklearn",
    region=region,
    version=framework_version,
    instance_type="ml.m5.xlarge"
)

sklearn_processor = Processor(
```

```
    image_uri=sklearn_image_uri,
    instance_type="ml.m5.xlarge",
    instance_count=processing_instance_count,
    base_job_name="sklearn-abalone-process",
    sagemaker_session=pipeline_session,
    role=role,
)
```

2. Create a processing step.

```
from sagemaker.core.processing import ProcessingInput, ProcessingOutput
from sagemaker.mlops.workflow.steps import ProcessingStep

processor_args = sklearn_processor.run(
    inputs=[
      ProcessingInput(source=input_data, destination="/opt/ml/processing/input"),
    ],
    outputs=[
        ProcessingOutput(output_name="train", source="/opt/ml/processing/train"),
        ProcessingOutput(output_name="validation", source="/opt/ml/processing/
validation"),
        ProcessingOutput(output_name="test", source="/opt/ml/processing/test")
    ],
    code="abalone/preprocessing.py",
)

step_process = ProcessingStep(name="AbaloneProcess", step_args=processor_args)
```

Step 4: Define a training step

This section shows how to use the SageMaker AI XGBoost Algorithm to train a model on the training data output from the processing steps.

To define a training step

1. Specify the model path where you want to save the models from training.

```
model_path = f"s3://{default_bucket}/AbaloneTrain"
```

2. Configure a training estimator for the XGBoost algorithm and the input dataset.

```
from sagemaker.train import ModelTrainer
```

```
from sagemaker.train.configs import Compute, OutputDataConfig
from sagemaker.core import image_uris

image_uri = image_uris.retrieve(
    framework="xgboost",
    region=region,
    version="1.0-1",
    py_version="py3",
    instance_type="ml.m5.xlarge"
)
xgb_train = ModelTrainer(
    training_image=image_uri,
    compute=Compute(instance_type="ml.m5.xlarge", instance_count=1),
    output_data_config=OutputDataConfig(s3_output_path=model_path),
    hyperparameters={
        "objective": "reg:linear",
        "num_round": "50",
        "max_depth": "5",
        "eta": "0.2",
        "gamma": "4",
        "min_child_weight": "6",
        "subsample": "0.7",
        "silent": "0"
    },
    sagemaker_session=pipeline_session,
    role=role,
)
```

3. Create a `TrainingStep` using the training instance and properties of the `ProcessingStep`.

```
from sagemaker.train.configs import InputData
from sagemaker.mlops.workflow.steps import TrainingStep

train_args = xgb_train.train(
    input_data_config=[
        InputData(
            channel_name="train",
            data_source=step_process.properties.ProcessingOutputConfig.Outputs[
                "train"
            ].S3Output.S3Uri,
            content_type="text/csv"
        ),
        InputData(
            channel_name="validation",
```

```
            data_source=step_process.properties.ProcessingOutputConfig.Outputs[
                "validation"
            ].S3Output.S3Uri,
            content_type="text/csv"
        )
    ],
)

step_train = TrainingStep(name="AbaloneTrain", step_args=train_args)
```

Step 5: Define a processing step for model evaluation

This section shows how to create a processing step to evaluate the accuracy of the model.

To define a processing step for model evaluation

1. Create an instance of a `Processor` for evaluation.

```
from sagemaker.core.processing import Processor

script_eval = Processor(
    image_uri=image_uri,
    command=["python3"],
    instance_type="ml.m5.xlarge",
    instance_count=1,
    base_job_name="script-abalone-eval",
    sagemaker_session=pipeline_session,
    role=role,
)
```

2. Create a `ProcessingStep` using the processor instance, the input and output channels, and the `evaluation.py` script.

```
from sagemaker.core.workflow.properties import PropertyFile

evaluation_report = PropertyFile(
    name="EvaluationReport",
    output_name="evaluation",
    path="evaluation.json"
)

eval_args = script_eval.run(
```

```
    inputs=[
        ProcessingInput(
            source=step_train.properties.ModelArtifacts.S3ModelArtifacts,
            destination="/opt/ml/processing/model"
        ),
        ProcessingInput(
            source=step_process.properties.ProcessingOutputConfig.Outputs[
                "test"
            ].S3Output.S3Uri,
            destination="/opt/ml/processing/test"
        )
    ],
    outputs=[
        ProcessingOutput(output_name="evaluation", source="/opt/ml/processing/
evaluation"),
    ],
    code="abalone/evaluation.py",
)

step_eval = ProcessingStep(
    name="AbaloneEval",
    step_args=eval_args,
    property_files=[evaluation_report],
)
```

Step 6: Define a CreateModelStep for batch transformation

This section shows how to create a SageMaker AI model from the output of the training step.

To define a CreateModelStep for batch transformation

- Create a SageMaker AI model and model step.

```
from sagemaker.serve import ModelBuilder
from sagemaker.mlops.workflow.model_step import ModelStep

model_builder = ModelBuilder(
    image_uri=image_uri,
    s3_model_data_url=step_train.properties.ModelArtifacts.S3ModelArtifacts,
    role_arn=role,
    sagemaker_session=pipeline_session,
)
```

```
step_create_model = ModelStep(
    name="AbaloneCreateModel",
    step_args=model_builder.build(),
)
```

Step 7: Define a TransformStep to perform batch transformation

This section shows how to create a `TransformStep` to perform batch transformation on a dataset after the model is trained.

To define a TransformStep to perform batch transformation

- Create a transformer instance and a `TransformStep`.

```
from sagemaker.core.transformer import Transformer
from sagemaker.mlops.workflow.steps import TransformStep

transformer = Transformer(
    model_name=step_create_model.properties.ModelName,
    instance_type="ml.m5.xlarge",
    instance_count=1,
    output_path=f"s3://{default_bucket}/AbaloneTransform",
    sagemaker_session=pipeline_session,
)

transform_args = transformer.transform(data=batch_data)

step_transform = TransformStep(
    name="AbaloneTransform",
    step_args=transform_args,
)
```

Step 8: Define a RegisterModel step to create a model package

This section shows how to register a model. The result is a model package for inference.

To define a model registration step to create a model package

- Construct a model registration step.

```
from sagemaker.core.model_metrics import MetricsSource, ModelMetrics
from sagemaker.mlops.workflow.model_step import ModelStep
from sagemaker.serve import ModelBuilder

model_metrics = ModelMetrics(
    model_statistics=MetricsSource(
        s3_uri="{}/evaluation.json".format(
            step_eval.arguments["ProcessingOutputConfig"]["Outputs"][0]["S3Output"]
["S3Uri"]
        ),
        content_type="application/json"
    )
)

model_builder = ModelBuilder(
    image_uri=image_uri,
    s3_model_data_url=step_train.properties.ModelArtifacts.S3ModelArtifacts,
    role_arn=role,
    sagemaker_session=pipeline_session,
)

register_args = model_builder.register(
    content_types=["text/csv"],
    response_types=["text/csv"],
    inference_instances=["ml.t2.medium", "ml.m5.xlarge"],
    transform_instances=["ml.m5.xlarge"],
    model_package_group_name=model_package_group_name,
    approval_status=model_approval_status,
    model_metrics=model_metrics
)

step_register = ModelStep(
    name="AbaloneRegisterModel",
    step_args=register_args,
)
```

Step 9: Define a condition step to verify model accuracy

A `ConditionStep` allows Pipelines to support conditional running in your pipeline DAG based on the condition of step properties.

To define a condition step to verify model accuracy

- Define a condition and construct a `ConditionStep`.

```
from sagemaker.core.workflow.conditions import ConditionLessThanOrEqualTo
from sagemaker.mlops.workflow.condition_step import ConditionStep
from sagemaker.core.workflow.functions import JsonGet

cond_lte = ConditionLessThanOrEqualTo(
    left=JsonGet(
        step_name=step_eval.name,
        property_file=evaluation_report,
        json_path="regression_metrics.mse.value"
    ),
    right=6.0
)

step_cond = ConditionStep(
    name="AbaloneMSECond",
    conditions=[cond_lte],
    if_steps=[step_register, step_create_model, step_transform],
    else_steps=[],
)
```

Step 10: Create a pipeline

Now that you've created all of the steps, combine them into a pipeline.

To create a pipeline

1. Define the following for your pipeline: `name`, `parameters`, and `steps`.

```
from sagemaker.mlops.workflow.pipeline import Pipeline

pipeline_name = f"AbalonePipeline"
pipeline = Pipeline(
    name=pipeline_name,
    parameters=[
        processing_instance_count,
        model_approval_status,
        input_data,
        batch_data,
```

```
    ],
    steps=[step_process, step_train, step_eval, step_cond],
)
```

2. (Optional) Examine the JSON pipeline definition to ensure that it's well-formed.

```
import json

json.loads(pipeline.definition())
```

This pipeline definition is ready to submit to SageMaker AI. In the next tutorial, you submit this pipeline to SageMaker AI and start a run.

Define a pipeline (JSON)

You can also use boto3 or Amazon CloudFormation to create a pipeline. Creating a pipeline requires a pipeline definition, which is a JSON object that defines each step of the pipeline. The SageMaker SDK offers a simple way to construct the pipeline definition, which you can use with any of the APIs previously mentioned to create the pipeline itself. Without using the SDK, users have to write the raw JSON definition to create the pipeline without any of the error checks provided by the SageMaker Python SDK. To see the schema for the pipeline JSON definition, see SageMaker AI Pipeline Definition JSON Schema. The following code sample shows an example of a SageMaker AI pipeline definition JSON object:

```
{'Version': '2020-12-01',
 'Metadata': {},
 'Parameters': [{'Name': 'ProcessingInstanceType',
   'Type': 'String',
   'DefaultValue': 'ml.m5.xlarge'},
  {'Name': 'ProcessingInstanceCount', 'Type': 'Integer', 'DefaultValue': 1},
  {'Name': 'TrainingInstanceType',
   'Type': 'String',
   'DefaultValue': 'ml.m5.xlarge'},
  {'Name': 'ModelApprovalStatus',
   'Type': 'String',
   'DefaultValue': 'PendingManualApproval'},
  {'Name': 'ProcessedData',
   'Type': 'String',
   'DefaultValue': 'S3_URL',
{'Name': 'InputDataUrl',
   'Type': 'String',
```

```
   'DefaultValue': 'S3_URL',
 'PipelineExperimentConfig': {'ExperimentName': {'Get': 'Execution.PipelineName'},
  'TrialName': {'Get': 'Execution.PipelineExecutionId'}},
 'Steps': [{'Name': 'ReadTrainDataFromFS',
   'Type': 'Processing',
   'Arguments': {'ProcessingResources': {'ClusterConfig': {'InstanceType':
 'ml.m5.4xlarge',
      'InstanceCount': 2,
      'VolumeSizeInGB': 30}},
    'AppSpecification': {'ImageUri': 'IMAGE_URI',
     'ContainerArguments': [....]},
    'RoleArn': 'ROLE',
      'ProcessingInputs': [...],
    'ProcessingOutputConfig': {'Outputs': [.....]},
    'StoppingCondition': {'MaxRuntimeInSeconds': 86400}},
   'CacheConfig': {'Enabled': True, 'ExpireAfter': '30d'}},
   ...
   ...
   ...
  }
```

Next step: Run a pipeline

Edit a pipeline

To make changes to a pipeline before running it, do the following:

1. Open SageMaker Studio by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane of Studio, select **Pipelines**.
3. Select a pipeline name to view details about the pipeline.
4. Choose the **Executions** tab.
5. Select the name of a pipeline execution.
6. Choose **Edit** to open the Pipeline Designer.
7. Update the edges between steps or the step configuration as required and click **Save**.

   Saving a pipeline after editing automatically generates a new version number.
8. Choose **Run**.

Run a pipeline

After defining the steps of your pipeline as a directed acyclic graph (DAG), you can run your pipeline, which executes the steps defined in your DAG. The following walkthroughs show you how to run an Amazon SageMaker AI pipeline using either the drag-and-drop visual editor in Amazon SageMaker Studio or the Amazon SageMaker Python SDK.

Run a pipeline (Pipeline designer)

To start a new execution of your pipeline, do the following:

Studio

1. Open SageMaker Studio by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Pipelines**.
3. (Optional) To filter the list of pipelines by name, enter a full or partial pipeline name in the search field.
4. Choose a pipeline name to open the pipeline details view.
5. Choose **Visual Editor** on the top right.
6. To start an execution from the latest version, choose **Executions**.
7. To start an execution from a specific version, follow these steps:
   - Choose the version icon in the bottom toolbar to open the version panel.
   - Choose the pipeline version you want to execute.
   - Hover over the version item to reveal the three-dot menu, choose **Execute**.
   - (Optional) To view a previous version of the pipeline, choose **Preview** from the three-dot menu in the version panel. You can also edit the version by choosing **Edit** in the notification bar.

> **Note**
>
> If your pipeline fails, the status banner will show a **Failed** status. After troubleshooting the failed step, choose **Retry** on the status banner to resume running the pipeline from that step.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the Studio Classic sidebar, choose the **Home** icon ().
3. Select **Pipelines** from the menu.
4. To narrow the list of pipelines by name, enter a full or partial pipeline name in the search field.
5. Select a pipeline name.
6. From the **Executions** or **Graph** tab in the execution list, choose **Create execution**.
7. Enter or update the following required information:
   - **Name** – Must be unique to your account in the Amazon Region.
   - **ProcessingInstanceCount** – The number of instances to use for processing.
   - **ModelApprovalStatus** – For your convenience.
   - **InputDataUrl** – The Amazon S3 URI of the input data.
8. Choose **Start**.

Once your pipeline is running, you can view the details of the execution by choosing **View details** on the status banner.

To stop the run, choose **Stop** on the status banner. To resume the execution from where it was stopped, choose **Resume** on the status banner.

> **Note**
>
> If your pipeline fails, the status banner will show a **Failed** status. After troubleshooting the failed step, choose **Retry** on the status banner to resume running the pipeline from that step.

Run a pipeline (SageMaker Python SDK)

After you've created a pipeline definition using the SageMaker AI Python SDK, you can submit it to SageMaker AI to start your execution. The following tutorial shows how to submit a pipeline, start an execution, examine the results of that execution, and delete your pipeline.

Topics

- Prerequisites
- Step 1: Start the Pipeline
- Step 2: Examine a Pipeline Execution
- Step 3: Override Default Parameters for a Pipeline Execution
- Step 4: Stop and Delete a Pipeline Execution

Prerequisites

This tutorial requires the following:

- A SageMaker notebook instance.
- A Pipelines pipeline definition. This tutorial assumes you're using the pipeline definition created by completing the Define a pipeline tutorial.

Step 1: Start the Pipeline

First, you need to start the pipeline.

To start the pipeline

1. Examine the JSON pipeline definition to ensure that it's well-formed.

   ```
   import json

   json.loads(pipeline.definition())
   ```

2. Submit the pipeline definition to the Pipelines service to create a pipeline if it doesn't exist, or update the pipeline if it does. The role passed in is used by Pipelines to create all of the jobs defined in the steps.

   ```
   pipeline.upsert(role_arn=role)
   ```

3. Start a pipeline execution.

```
execution = pipeline.start()
```

Step 2: Examine a Pipeline Execution

Next, you need to examine the pipeline execution.

To examine a pipeline execution

1. Describe the pipeline execution status to ensure that it has been created and started successfully.

```
execution.describe()
```

2. Wait for the execution to finish.

```
execution.wait()
```

3. List the execution steps and their status.

```
execution.list_steps()
```

Your output should look like the following:

```
[{'StepName': 'AbaloneTransform',
  'StartTime': datetime.datetime(2020, 11, 21, 2, 41, 27, 870000,
 tzinfo=tzlocal()),
  'EndTime': datetime.datetime(2020, 11, 21, 2, 45, 50, 492000, tzinfo=tzlocal()),
  'StepStatus': 'Succeeded',
  'CacheHitResult': {'SourcePipelineExecutionArn': ''},
  'Metadata': {'TransformJob': {'Arn': 'arn:aws:sagemaker:us-
east-2:111122223333:transform-job/pipelines-cfvy1tjuxdq8-abalonetransform-
ptyjoef3jy'}}},
 {'StepName': 'AbaloneRegisterModel',
  'StartTime': datetime.datetime(2020, 11, 21, 2, 41, 26, 929000,
 tzinfo=tzlocal()),
  'EndTime': datetime.datetime(2020, 11, 21, 2, 41, 28, 15000, tzinfo=tzlocal()),
  'StepStatus': 'Succeeded',
  'CacheHitResult': {'SourcePipelineExecutionArn': ''},
```

```
  'Metadata': {'RegisterModel': {'Arn': 'arn:aws:sagemaker:us-
east-2:111122223333:model-package/abalonemodelpackagegroupname/1'}}},
 {'StepName': 'AbaloneCreateModel',
  'StartTime': datetime.datetime(2020, 11, 21, 2, 41, 26, 895000,
 tzinfo=tzlocal()),
  'EndTime': datetime.datetime(2020, 11, 21, 2, 41, 27, 708000, tzinfo=tzlocal()),
  'StepStatus': 'Succeeded',
  'CacheHitResult': {'SourcePipelineExecutionArn': ''},
  'Metadata': {'Model': {'Arn': 'arn:aws:sagemaker:us-east-2:111122223333:model/
pipelines-cfvy1tjuxdq8-abalonecreatemodel-jl94rai0ra'}}},
 {'StepName': 'AbaloneMSECond',
  'StartTime': datetime.datetime(2020, 11, 21, 2, 41, 25, 558000,
 tzinfo=tzlocal()),
  'EndTime': datetime.datetime(2020, 11, 21, 2, 41, 26, 329000, tzinfo=tzlocal()),
  'StepStatus': 'Succeeded',
  'CacheHitResult': {'SourcePipelineExecutionArn': ''},
  'Metadata': {'Condition': {'Outcome': 'True'}}},
 {'StepName': 'AbaloneEval',
  'StartTime': datetime.datetime(2020, 11, 21, 2, 37, 34, 767000,
 tzinfo=tzlocal()),
  'EndTime': datetime.datetime(2020, 11, 21, 2, 41, 18, 80000, tzinfo=tzlocal()),
  'StepStatus': 'Succeeded',
  'CacheHitResult': {'SourcePipelineExecutionArn': ''},
  'Metadata': {'ProcessingJob': {'Arn': 'arn:aws:sagemaker:us-
east-2:111122223333:processing-job/pipelines-cfvy1tjuxdq8-abaloneeval-
zfraozhmny'}}},
 {'StepName': 'AbaloneTrain',
  'StartTime': datetime.datetime(2020, 11, 21, 2, 34, 55, 867000,
 tzinfo=tzlocal()),
  'EndTime': datetime.datetime(2020, 11, 21, 2, 37, 34, 34000, tzinfo=tzlocal()),
  'StepStatus': 'Succeeded',
  'CacheHitResult': {'SourcePipelineExecutionArn': ''},
  'Metadata': {'TrainingJob': {'Arn': 'arn:aws:sagemaker:us-
east-2:111122223333:training-job/pipelines-cfvy1tjuxdq8-abalonetrain-
tavd6f3wdf'}}},
 {'StepName': 'AbaloneProcess',
  'StartTime': datetime.datetime(2020, 11, 21, 2, 30, 27, 160000,
 tzinfo=tzlocal()),
  'EndTime': datetime.datetime(2020, 11, 21, 2, 34, 48, 390000, tzinfo=tzlocal()),
  'StepStatus': 'Succeeded',
  'CacheHitResult': {'SourcePipelineExecutionArn': ''},
```

```
  'Metadata': {'ProcessingJob': {'Arn': 'arn:aws:sagemaker:us-
east-2:111122223333:processing-job/pipelines-cfvy1tjuxdq8-abaloneprocess-
mgqyfdujcj'}}}]
```

4. After your pipeline execution is complete, download the resulting `evaluation.json` file from Amazon S3 to examine the report.

```
evaluation_json = sagemaker.s3.S3Downloader.read_file("{}/evaluation.json".format(
    step_eval.arguments["ProcessingOutputConfig"]["Outputs"][0]["S3Output"]
["S3Uri"]
))
json.loads(evaluation_json)
```

Step 3: Override Default Parameters for a Pipeline Execution

You can run additional executions of the pipeline by specifying different pipeline parameters to override the defaults.

To override default parameters

1. Create the pipeline execution. This starts another pipeline execution with the model approval status override set to "Approved". This means that the model package version generated by the `RegisterModel` step is automatically ready for deployment through CI/CD pipelines, such as with SageMaker Projects. For more information, see MLOps Automation With SageMaker Projects.

```
execution = pipeline.start(
    parameters=dict(
        ModelApprovalStatus="Approved",
    )
)
```

2. Wait for the execution to finish.

```
execution.wait()
```

3. List the execution steps and their status.

```
execution.list_steps()
```

4. After your pipeline execution is complete, download the resulting `evaluation.json` file from Amazon S3 to examine the report.

```
evaluation_json = sagemaker.s3.S3Downloader.read_file("{}/evaluation.json".format(
    step_eval.arguments["ProcessingOutputConfig"]["Outputs"][0]["S3Output"]
["S3Uri"]
))
json.loads(evaluation_json)
```

Step 4: Stop and Delete a Pipeline Execution

When you're finished with your pipeline, you can stop any ongoing executions and delete the pipeline.

To stop and delete a pipeline execution

1. Stop the pipeline execution.

```
execution.stop()
```

2. Delete the pipeline.

```
pipeline.delete()
```

Stop a pipeline

You can stop a pipeline run in the Amazon SageMaker Studio console.

To stop a pipeline execution in the Amazon SageMaker Studio console, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. In the left navigation pane, select **Pipelines**.
2. (Optional) To filter the list of pipelines by name, enter a full or partial pipeline name in the search field.
3. Select a pipeline name.
4. Choose the **Executions** tab.

5. Select the execution to stop.
6. Choose **Stop**. To resume the execution from where it was stopped, choose **Resume**

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the Studio Classic sidebar, choose the **Home** icon ().
3. Select **Pipelines** from the menu.
4. To narrow the list of pipelines by name, enter a full or partial pipeline name in the search field.
5. To stop a pipeline run, choose **View details** on the status banner of the pipeline, and then choose **Stop**. To resume the execution from where it was stopped, choose **Resume**.

View the details of a pipeline

You can view the details of a SageMaker AI pipeline to understand its parameters, the dependencies of its steps, or monitor its progress and status. This can help you troubleshoot or optimize your workflow. You can access the details of a given pipeline using the Amazon SageMaker Studio console and explore its execution history, definition, parameters, and metadata.

Alternatively, if your pipeline is associated with a SageMaker AI Project, you can access the pipeline details from the project's details page. For more information, see View Project Resources.

To view the details of a SageMaker AI pipeline, complete the following steps based on whether you use Studio or Studio Classic.

> **Note**
>
> Model repacking happens when the pipeline needs to include a custom script in the compressed model file (model.tar.gz) to be uploaded to Amazon S3 and used to deploy a model to a SageMaker AI endpoint. When SageMaker AI pipeline trains a model and registers it to the model registry, it introduces a repack step *if* the trained model output from the training job needs to include a custom inference script. The repack step

uncompresses the model, adds a new script, and recompresses the model. Running the pipeline adds the repack step as a training job.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. (Optional) To filter the list of pipelines by name, enter a full or partial pipeline name in the search field.
4. Select a pipeline name to view details about the pipeline.
5. Choose one of the following tabs to view pipeline details:
   - **Executions** – Details about the executions.
   - **Graph** – The pipeline graph, including all steps.
   - **Parameters** – The run parameters and metrics related to the pipeline.
   - **Information** – The metadata associated with the pipeline, such as tags, the pipeline Amazon Resource Name (ARN), and role ARN. You can also edit the pipeline description from this page.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the Studio Classic sidebar, choose the **Home** icon (
   
).
3. Select **Pipelines** from the menu.
4. To narrow the list of pipelines by name, enter a full or partial pipeline name in the search field.
5. Select a pipeline name to view details about the pipeline. The pipeline details tab opens and displays a list of pipeline executions. You can start an execution or choose one of the other tabs for more information about the pipeline. Use the **Property Inspector** icon

( ) to choose which columns to display.

6. From the pipeline details page, choose one of the following tabs to view details about the pipeline:
   - **Executions** – Details about the executions. You can create an execution from this tab or the **Graph** tab.
   - **Graph** – The DAG for the pipeline.
   - **Parameters** – Includes the model approval status.
   - **Settings** – The metadata associated with the pipeline. You can download the pipeline definition file and edit the pipeline name and description from this tab.

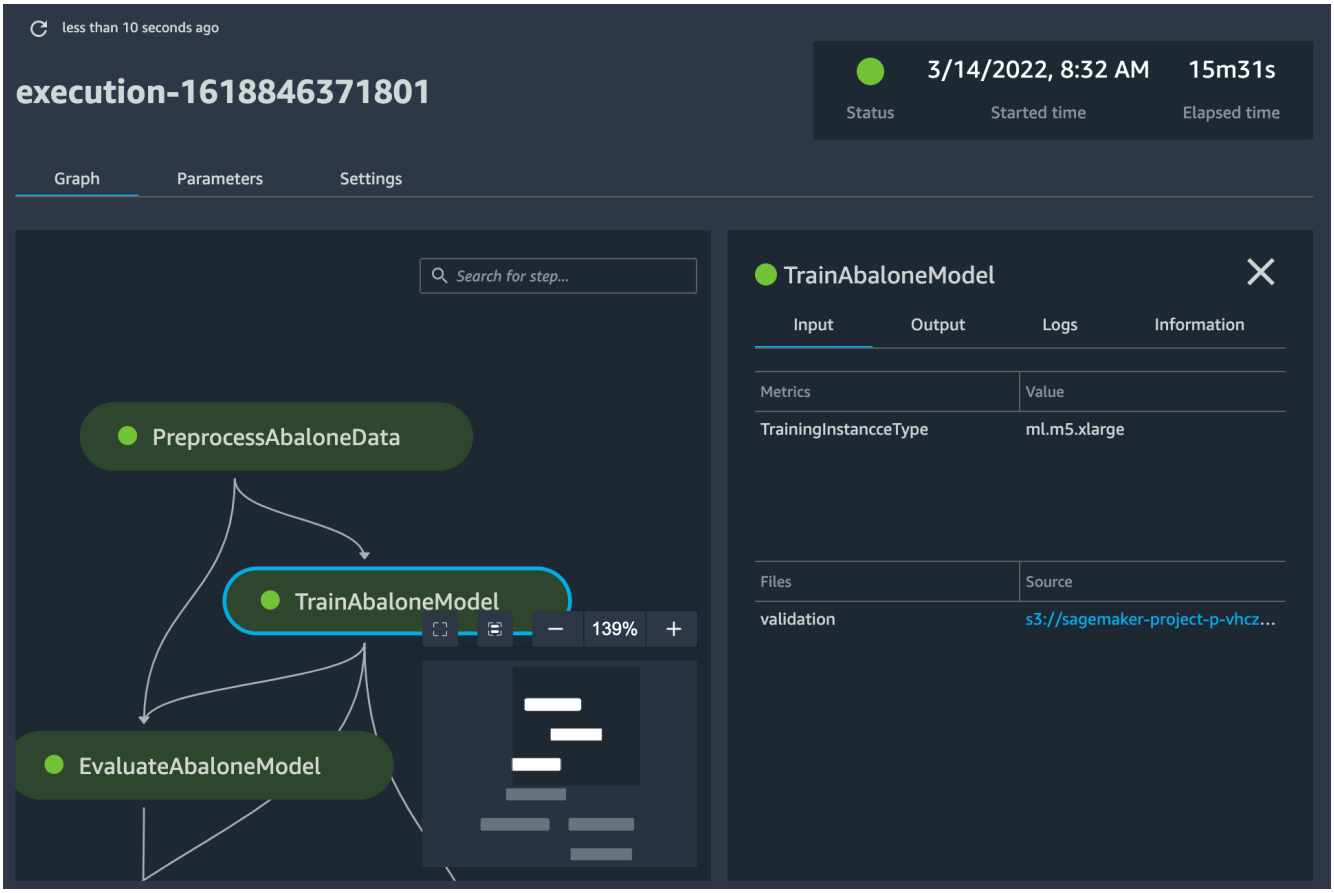
View the details of a pipeline run

You can review the details of a particular SageMaker AI pipeline run. This can help you:

- Identify and resolve problems that may have occurred during the run, such as failed steps or unexpected errors.
- Compare the results of different pipeline executions to understand how changes in input data or parameters impact the overall workflow.
- Identify bottlenecks and opportunities for optimization.

To view the details of a pipeline run, complete the following steps based on whether you use Studio or Studio Classic.

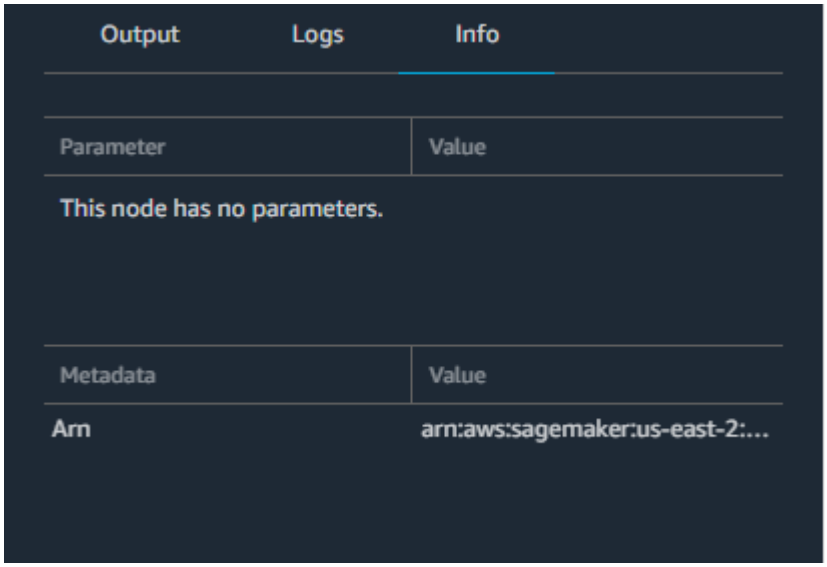
Studio



1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. (Optional) To filter the list of pipelines by name, enter a full or partial pipeline name in the search field.
4. Select a pipeline name to view details about the pipeline.
5. Choose the **Executions** tab.

6. Select the name of a pipeline execution to view. The pipeline graph for that execution appears.
7. Choose any of the pipeline steps in the graph to see step settings in the right sidebar.
8. Choose one of the following tabs to view more pipeline details:

   - **Definition** — The pipeline graph, including all steps.
   - **Parameters** – Includes the model approval status.
   - **Details** – The metadata associated with the pipeline, such as tags, the pipeline Amazon Resource Name (ARN), and role ARN. You can also edit the pipeline description from this page.



Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the Studio Classic sidebar, choose the **Home** icon (
   
).
3. Select **Pipelines** from the menu.
4. To narrow the list of pipelines by name, enter a full or partial pipeline name in the search field.
5. Select a pipeline name. The pipeline's **Executions** page opens.
6. In the **Executions** page, select an execution name to view details about the execution. The execution details tab opens and displays a graph of the steps in the pipeline.
7. To search for a step by name, type characters that match a step name in the search field. Use the resizing icons on the lower-right side of the graph to zoom in and out of the graph, fit the graph to screen, and expand the graph to full screen. To focus on a specific part of the graph, you can select a blank area of the graph and drag the graph to center on that area.

8. Choose one of the pipeline steps in the graph to see details about the step. In the preceding screenshot, a training step is chosen and displays the following tabs:

   - **Input** – The training inputs. If an input source is from Amazon Simple Storage Service (Amazon S3), choose the link to view the file in the Amazon S3 console.
   - **Output** – The training outputs, such as metrics, charts, files, and evaluation outcome. The graphs are produced using the Tracker APIs.
   - **Logs** – The Amazon CloudWatch logs produced by the step.
   - **Info** – The parameters and metadata associated with the step.

Download a pipeline definition file

You can download the definition file for your SageMaker AI pipeline directly from the Amazon SageMaker Studio UI. You can use this pipeline definition file for:

- Backup and restoration: Use the downloaded file to create a backup of your pipeline configuration, which you can restore in case of infrastructure failures or accidental changes.
- Version control: Store the pipeline definition file in a source control system to track changes to the pipeline and revert to previous versions if needed.
- Programmatic interactions: Use the pipeline definition file as input to the SageMaker SDK or Amazon CLI.
- Integration with automation processes: Integrate the pipeline definition into your CI/CD workflows or other automation processes.

To download the definition file of a pipeline, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.

3. (Optional) To filter the list of pipelines by name, enter a full or partial pipeline name in the search field.
4. Select a pipeline name. The **Executions** page opens and displays a list of pipeline executions.
5. Stay on the **Executions** page or choose the **Graph**, **Information**, or **Parameters** page to the left of the pipeline executions table. You can download the pipeline definition from any of these pages.
6. At the top right of the page, choose the vertical ellipsis and choose **Download pipeline definition (JSON)**.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the Studio Classic sidebar, choose the **Home** icon ().
3. Select **Pipelines** from the menu.
4. To narrow the list of pipelines by name, enter a full or partial pipeline name in the search field.
5. Select a pipeline name.
6. Choose the **Settings** tab.
7. Choose **Download pipeline definition file**.

Access experiment data from a pipeline

> **Note**
>
> SageMaker Experiments is a feature provided in Studio Classic only.

When you create a pipeline and specify pipeline_experiment_config, Pipelines creates the following SageMaker Experiments entities by default if they don't exist:

- An experiment for the pipeline

- A run group for every execution of the pipeline
- A run for each SageMaker AI job created in a pipeline step

For information about how experiments are integrated with pipelines, see Amazon SageMaker Experiments Integration. For more information about SageMaker Experiments, see Amazon SageMaker Experiments in Studio Classic.

You can get to the list of runs associated with a pipeline from either the pipeline executions list or the experiments list.

To view the runs list from the pipeline executions list

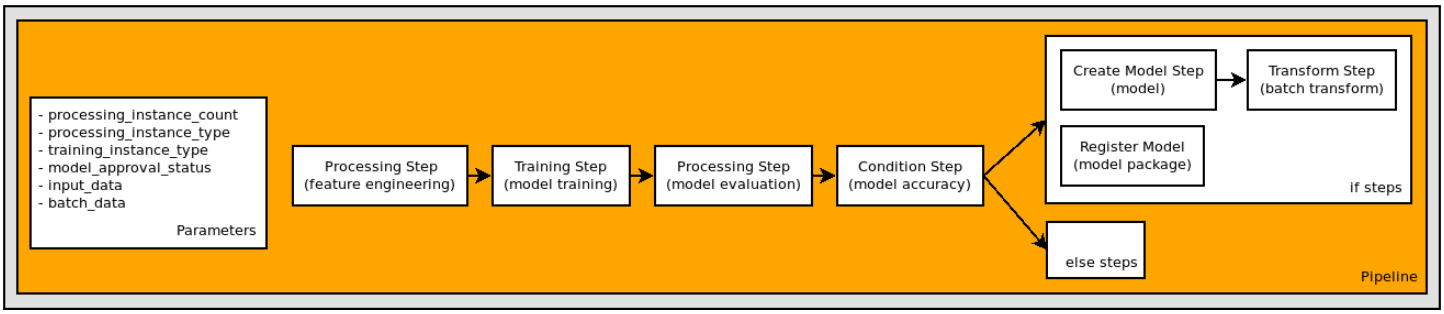
1. To view the pipeline executions list, follow the first five steps in the *Studio Classic* tab of View the details of a pipeline.
2. On the top right of the screen, choose the **Filter** icon ().
3. Choose **Experiment**. If experiment integration wasn't deactivated when the pipeline was created, the experiment name is displayed in the executions list.

   > **Note**
   >
   > Experiments integration was introduced in v2.41.0 of the Amazon SageMaker Python SDK. Pipelines created with an earlier version of the SDK aren't integrated with experiments by default.

4. Select the experiment of your choice to view run groups and runs related to that experiment.

To view the runs list from the experiments list

1. In the left sidebar of Studio Classic, choose the **Home** icon ().
2. Select **Experiments** from the menu.
3. Use search bar or **Filter** icon () to filter the list to experiments created by a pipeline.



4. Open an experiment name and view a list of runs created by the pipeline.

Track the lineage of a pipeline

In this tutorial, you use Amazon SageMaker Studio to track the lineage of an Amazon SageMaker AI ML Pipeline.

The pipeline was created by the Orchestrating Jobs with Amazon SageMaker Model Building Pipelines notebook in the Amazon SageMaker example GitHub repository. For detailed information on how the pipeline was created, see Define a pipeline.

Lineage tracking in Studio is centered around a directed acyclic graph (DAG). The DAG represents the steps in a pipeline. From the DAG you can track the lineage from any step to any other step. The following diagram displays the steps in the pipeline. These steps appear as a DAG in Studio.

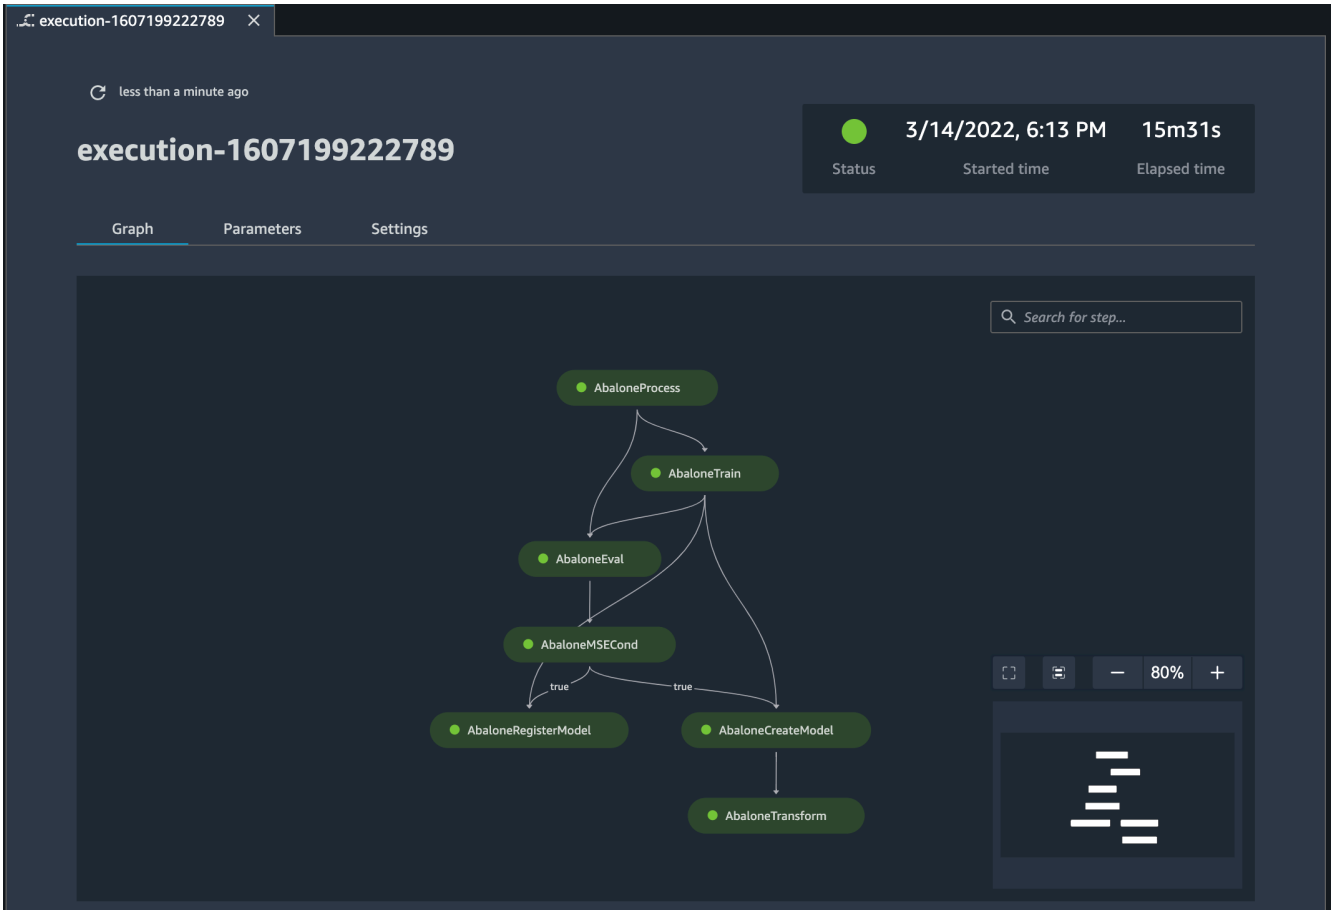
To track the lineage of a pipeline in the Amazon SageMaker Studio console, complete the following steps based on whether you use Studio or Studio Classic.

Studio

To track the lineage of a pipeline

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, select **Pipelines**.
3. (Optional) To filter the list of pipelines by name, enter a full or partial pipeline name in the search field.
4. In the **Name** column, select a pipeline name to view details about the pipeline.
5. Choose the **Executions** tab.
6. In the **Name** column of the **Executions** table, select the name of a pipeline execution to view.

7. At the top right of the **Executions** page, choose the vertical ellipsis and choose **Download pipeline definition (JSON)**. You can view the file to see how the pipeline graph was defined.
8. Choose **Edit** to open the Pipeline Designer.
9. Use the resizing and zoom controls at the top right corner of the canvas to zoom in and out of the graph, fit the graph to screen, or expand the graph to full screen.
10. To view your training, validation, and test datasets, complete the following steps:
    a. Choose the Processing step in your pipeline graph.
    b. In the right sidebar, choose the **Overview** tab.
    c. In the **Files** section, find the Amazon S3 paths to the training, validation, and test datasets.
11. To view your model artifacts, complete the following steps:
    a. Choose the Training step in your pipeline graph.
    b. In the right sidebar, choose the **Overview** tab.
    c. In the **Files** section, find the Amazon S3 paths to the model artifact.
12. To find the model package ARN, complete the following steps:
    a. Choose the Register model step.
    b. In the right sidebar, choose the **Overview** tab.
    c. In the **Files** section, find the ARN of the model package.



Studio Classic

To track the lineage of a pipeline

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left sidebar of Studio, choose the **Home** icon ( ).
3. In the menu, select **Pipelines**.
4. Use the **Search** box to filter the pipelines list.

5. Choose the `AbalonePipeline` pipeline to view the execution list and other details about the pipeline.
6. Choose the **Property Inspector** icon
   ( )
   in the right sidebar to open the **TABLE PROPERTIES** pane, where you can choose which properties to view.
7. Choose the **Settings** tab and then choose **Download pipeline definition file**. You can view the file to see how the pipeline graph was defined.
8. On the **Execution** tab, select the first row in the execution list to view its execution graph and other details about the execution. Note that the graph matches the diagram displayed at the beginning of the tutorial.

   Use the resizing icons on the lower-right side of the graph to zoom in and out of the graph, fit the graph to screen, or expand the graph to full screen. To focus on a specific part of the graph, you can select a blank area of the graph and drag the graph to center on that area. The inset on the lower-right side of the graph displays your location in the graph.

9. On the **Graph** tab, choose the `AbaloneProcess` step to view details about the step.
10. Find the Amazon S3 paths to the training, validation, and test datasets in the **Output** tab, under **Files**.

> **Note**
>
> To get the full paths, right-click the path and then choose **Copy cell contents**.

```
s3://sagemaker-eu-west-1-acct-id/sklearn-abalone-
process-2020-12-05-17-28-28-509/output/train
s3://sagemaker-eu-west-1-acct-id/sklearn-abalone-
process-2020-12-05-17-28-28-509/output/validation
s3://sagemaker-eu-west-1-acct-id/sklearn-abalone-
process-2020-12-05-17-28-28-509/output/test
```

11. Choose the `AbaloneTrain` step.
12. Find the Amazon S3 path to the model artifact in the **Output** tab, under **Files**:

```
s3://sagemaker-eu-west-1-acct-id/AbaloneTrain/pipelines-6locnsqz4bfu-
AbaloneTrain-NtfEpI0Ahu/output/model.tar.gz
```

13. Choose the `AbaloneRegisterModel` step.
14. Find the ARN of the model package in the **Output** tab, under **Files**:

```
arn:aws:sagemaker:eu-west-1:acct-id:model-package/abalonemodelpackagegroupname/2
```

Kubernetes Orchestration

You can orchestrate your SageMaker training and inference jobs with SageMaker AI Operators for Kubernetes and SageMaker AI Components for Kubeflow Pipelines. SageMaker AI Operators for Kubernetes make it easier for developers and data scientists using Kubernetes to train, tune, and deploy machine learning (ML) models in SageMaker AI. SageMaker AI Components for Kubeflow Pipelines allow you to move your data processing and training jobs from the Kubernetes cluster to SageMaker AI's machine learning-optimized managed service.

Contents

SageMaker AI Operators for Kubernetes

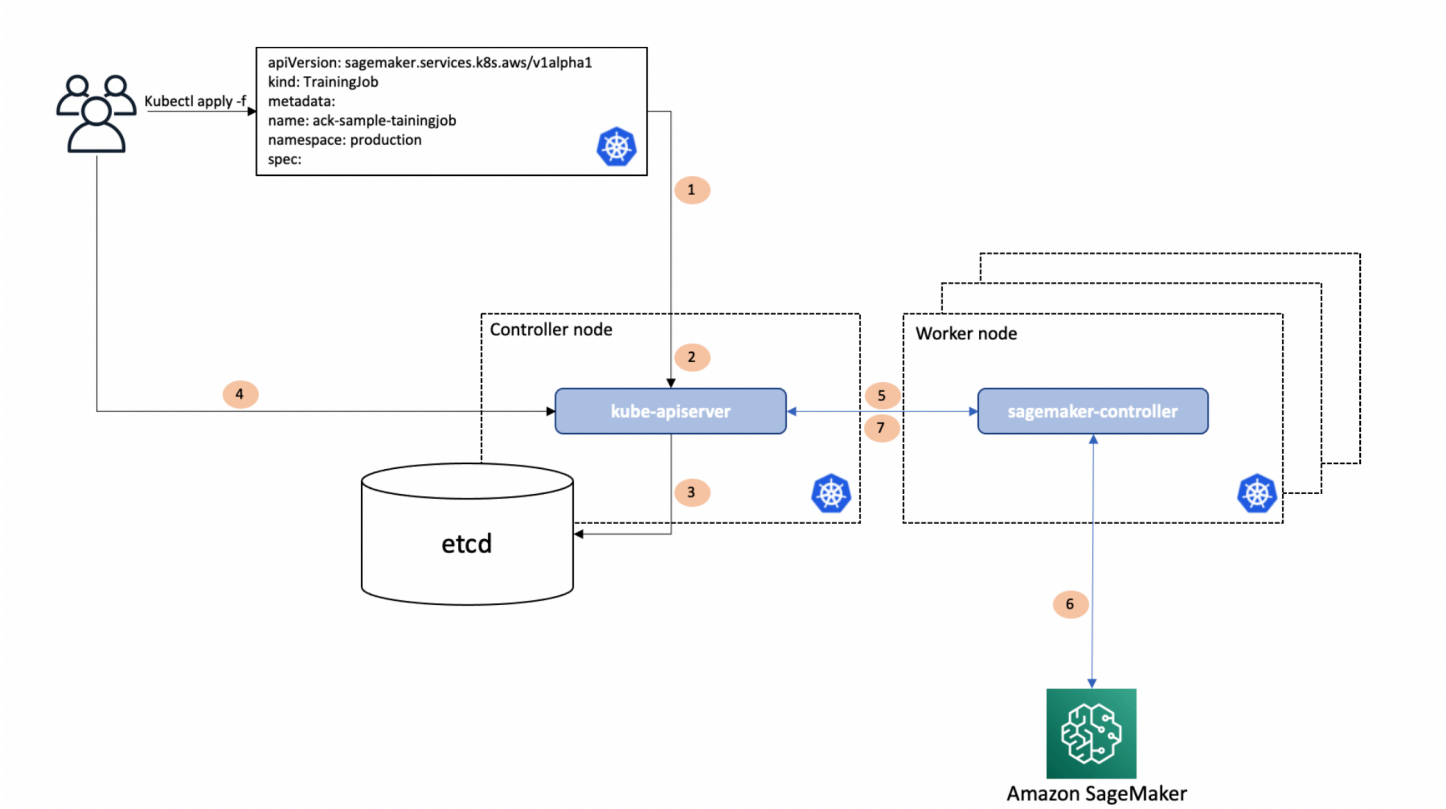
SageMaker AI Operators for Kubernetes make it easier for developers and data scientists using Kubernetes to train, tune, and deploy machine learning (ML) models in SageMaker AI. You can install these SageMaker AI Operators on your Kubernetes cluster in Amazon Elastic Kubernetes Service (Amazon EKS) to create SageMaker AI jobs natively using the Kubernetes API and command-line Kubernetes tools such as `kubectl`. This guide shows how to set up and use the operators to run model training, hyperparameter tuning, or inference (real-time and batch) on SageMaker AI from a Kubernetes cluster. The procedures and guidelines in this chapter assume that you are familiar with Kubernetes and its basic commands.

Important

We are stopping the development and technical support of the original version of SageMaker Operators for Kubernetes.
If you are currently using version `v1.2.2` or below of SageMaker Operators for Kubernetes, we recommend migrating your resources to the ACK service controller for Amazon SageMaker. The ACK service controller is a new generation of SageMaker Operators for Kubernetes based on Amazon Controllers for Kubernetes (ACK).
For information on the migration steps, see Migrate resources to the latest Operators.
For answers to frequently asked questions on the end of support of the original version of SageMaker Operators for Kubernetes, see Announcing the End of Support of the Original Version of SageMaker AI Operators for Kubernetes

Note

There is no additional charge to use these operators. You do incur charges for any SageMaker AI resources that you use through these operators.



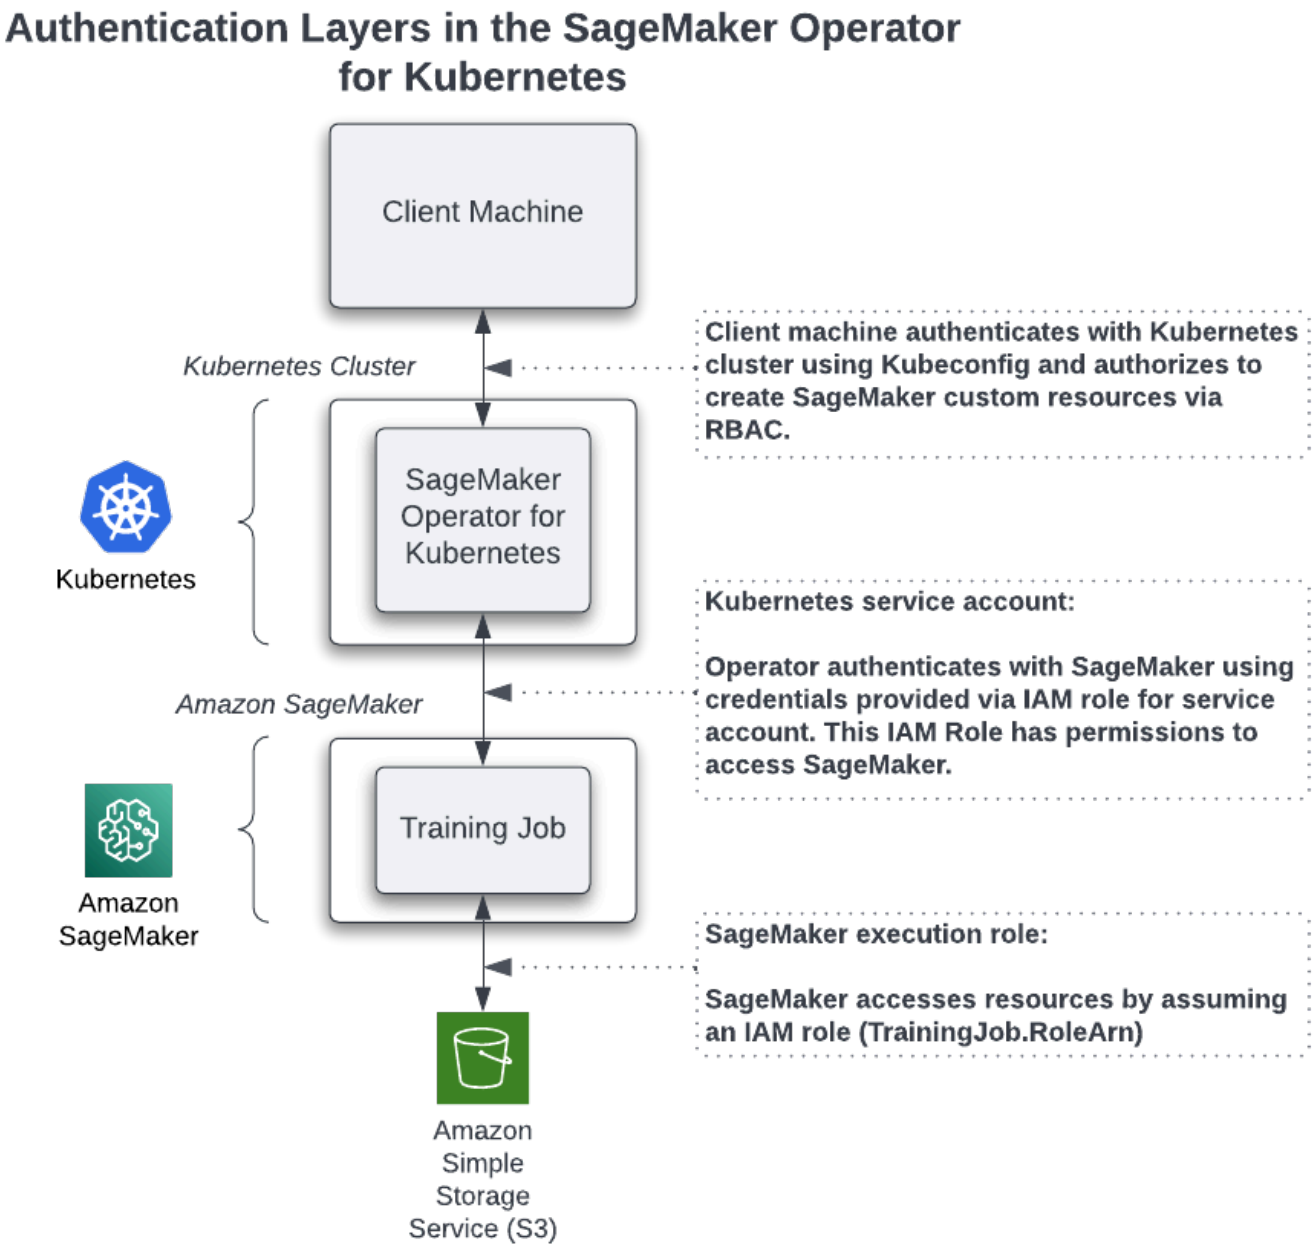
What is an operator?

A Kubernetes operator is an application controller managing applications on behalf of a Kubernetes user. Controllers of the control plane encompass various control loops listening to a central state manager (ETCD) to regulate the state of the application they control. Examples of such applications include the Cloud-controller-manager and `kube-controller-manager`. Operators typically provide a higher-level abstraction than raw Kubernetes API, making it easier for users to deploy and manage applications. To add new capabilities to Kubernetes, developers can extend the Kubernetes API by creating a **custom resource** that contains their application-specific or domain-specific logic and components. Operators in Kubernetes allow users to natively invoke these custom resources and automate associated workflows.

How does Amazon Controllers for Kubernetes (ACK) work?

The SageMaker AI Operators for Kubernetes allow you to manage jobs in SageMaker AI from your Kubernetes cluster. The latest version of SageMaker AI Operators for Kubernetes is based on Amazon Controllers for Kubernetes (ACK). ACK includes a common controller runtime, a code generator, and a set of Amazon service-specific controllers, one of which is the SageMaker AI controller.

The following diagram illustrates how ACK works.



In this diagram, a Kubernetes user wants to run model training on SageMaker AI from within the Kubernetes cluster using the Kubernetes API. The user issues a call to `kubectl apply`, passing in a file that describes a Kubernetes custom resource describing the SageMaker training job. `kubectl apply` passes this file, called a manifest, to the Kubernetes API server running in the Kubernetes controller node (Step *1* in the workflow diagram). The Kubernetes API server receives the manifest with the SageMaker training job specification and determines whether the user has permissions to create a custom resource of kind `sageMaker.services.k8s.aws/TrainingJob`, and whether the custom resource is properly formatted (Step *2*). If the user is authorized and the custom resource is valid, the Kubernetes API server writes (Step *3*) the custom resource to its etcd data store and then responds back (Step *4*) to the user that the custom resource has been created. The SageMaker AI controller, which is running on a Kubernetes worker node within the context of a normal Kubernetes Pod, is notified (Step *5*) that a new custom resource of kind `sageMaker.services.k8s.aws/TrainingJob` has been created. The SageMaker AI controller then communicates (Step *6*) with the SageMaker API, calling the SageMaker AI `CreateTrainingJob` API to create the training job in Amazon. After communicating with the SageMaker API, the SageMaker AI controller calls the Kubernetes API server to update (Step *7*) the custom resource's status with information it received from SageMaker AI. The SageMaker

AI controller therefore provides the same information to the developers that they would have received using the Amazon SDK.

Permissions overview

The operators access SageMaker AI resources on your behalf. The IAM role that the operator assumes to interact with Amazon resources differs from the credentials you use to access the Kubernetes cluster. The role also differs from the role that Amazon assumes when running your machine learning jobs.

The following image explains the various authentication layers.

Latest SageMaker AI Operators for Kubernetes

This section is based on the latest version of SageMaker AI Operators for Kubernetes using Amazon Controllers for Kubernetes (ACK).

Important

If you are currently using version `v1.2.2` or below of SageMaker Operators for Kubernetes, we recommend migrating your resources to the ACK service controller for Amazon SageMaker. The ACK service controller is a new generation of SageMaker Operators for Kubernetes based on Amazon Controllers for Kubernetes (ACK).
For information on the migration steps, see Migrate resources to the latest Operators.
For answers to frequently asked questions on the end of support of the original version of SageMaker Operators for Kubernetes, see Announcing the End of Support of the Original Version of SageMaker AI Operators for Kubernetes

The latest version of SageMaker AI Operators for Kubernetes is based on Amazon Controllers for Kubernetes (ACK), a framework for building Kubernetes custom controllers where each controller communicates with an Amazon service API. These controllers allow Kubernetes users to provision Amazon resources like databases or message queues using the Kubernetes API.

Use the following steps to install and use ACK to train, tune, and deploy machine learning models with Amazon SageMaker AI.

Contents

- Install SageMaker AI Operators for Kubernetes

IAM role-based setup and operator deployment

The following sections describe the steps to set up and deploy the original version of the operator.

> **Warning**
>
> **Reminder:** The following steps do not install the latest version of SageMaker AI Operators for Kubernetes. To install the new ACK-based SageMaker AI Operators for Kubernetes, see Latest SageMaker AI Operators for Kubernetes.

Prerequisites

This guide assumes that you have completed the following prerequisites:

- Install the following tools on the client machine used to access your Kubernetes cluster:
  - `kubectl` Version 1.13 or later. Use a `kubectl` version that is within one minor version of your Amazon EKS cluster control plane. For example, a 1.13 `kubectl` client works with Kubernetes 1.13 and 1.14 clusters. OpenID Connect (OIDC) is not supported in versions earlier than 1.13.
  - `eksctl` Version 0.7.0 or later
  - Amazon CLI Version 1.16.232 or later
  - (optional) Helm Version 3.0 or later
  - aws-iam-authenticator
- Have IAM permissions to create roles and attach policies to roles.
- Created a Kubernetes cluster on which to run the operators. It should either be Kubernetes version 1.13 or 1.14. For automated cluster creation using `eksctl`, see Getting Started with eksctl. It takes 20–30 minutes to provision a cluster.

Cluster-scoped deployment

Before you can deploy your operator using an IAM role, associate an OpenID Connect (OIDC) Identity Provider (IdP) with your role to authenticate with the IAM service.

Create an OIDC provider for your cluster

The following instructions show how to create and associate an OIDC provider with your Amazon EKS cluster.

1. Set the local `CLUSTER_NAME` and `AWS_REGION` environment variables as follows:

```
# Set the Region and cluster
export CLUSTER_NAME="<your cluster name>"
export Amazon_REGION="<your region>"
```

2. Use the following command to associate the OIDC provider with your cluster. For more information, see Enabling IAM Roles for Service Accounts on your Cluster.

```
eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} \
      --region ${AWS_REGION} --approve
```

   Your output should look like the following:

```
[_]  eksctl version 0.10.1
  [_]  using region us-east-1
  [_]  IAM OpenID Connect provider is associated with cluster "my-cluster" in "us-
east-1"
```

Now that the cluster has an OIDC identity provider, you can create a role and give a Kubernetes ServiceAccount permission to assume the role.

Get the OIDC ID

To set up the ServiceAccount, obtain the OIDC issuer URL using the following command:

```
aws eks describe-cluster --name ${CLUSTER_NAME} --region ${AWS_REGION} \
      --query cluster.identity.oidc.issuer --output text
```

The command returns a URL like the following:

```
https://oidc.eks.${AWS_REGION}.amazonaws.com/id/D48675832CA65BD10A532F597OIDCID
```

In this URL, the value `D48675832CA65BD10A532F597OIDCID` is the OIDC ID. The OIDC ID for your cluster is different. You need this OIDC ID value to create a role.

If your output is None, it means that your client version is old. To work around this, run the following command:

```
aws eks describe-cluster --region ${AWS_REGION} --query cluster --name ${CLUSTER_NAME}
 --output text | grep OIDC
```

The OIDC URL is returned as follows:

```
OIDC https://oidc.eks.us-east-1.amazonaws.com/id/D48675832CA65BD10A532F597OIDCID
```

Create an IAM role

1. JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Federated": "arn:aws-cn:iam::111122223333:oidc-provider/
oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
          "StringEquals": {
            "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:aud":
 "sts.amazonaws.com",
            "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:sub":
 "system:serviceaccount:sagemaker-k8s-operator-system:sagemaker-k8s-operator-
default"
          }
        }
      }
    ]
  }
```

Create a file named `trust.json` and insert the following trust relationship code block into it instead. Be sure to replace all <OIDC ID>, <Amazon account number>, and <EKS Cluster region> placeholders with values corresponding to your cluster.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Federated": "arn:aws-cn:iam::111122223333:oidc-provider/
oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
          "StringEquals": {
            "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:aud":
 "sts.amazonaws.com",
            "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:sub":
 "system:serviceaccount:sagemaker-k8s-operator-system:sagemaker-k8s-operator-
default"
          }
        }
      }
    ]
  }
```

2. Run the following command to create a role with the trust relationship defined in `trust.json`. This role allows the Amazon EKS cluster to get and refresh credentials from IAM.

```
aws iam create-role --region ${AWS_REGION} --role-name <role name> --assume-role-
policy-document file://trust.json --output=text
```

Your output should look like the following:

```
ROLE    arn:aws:iam::123456789012:role/my-role 2019-11-22T21:46:10Z    /
 ABCDEFSFODNN7EXAMPLE   my-role
ASSUMEROLEPOLICYDOCUMENT        2012-10-17
STATEMENT       sts:AssumeRoleWithWebIdentity   Allow
STRINGEQUALS    sts.amazonaws.com       system:serviceaccount:sagemaker-k8s-
operator-system:sagemaker-k8s-operator-default
```

```
PRINCIPAL       arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-
east-1.amazonaws.com/id/
```

Take note of `ROLE ARN`; you pass this value to your operator.

Attach the AmazonSageMakerFullAccess policy to the role

To give the role access to SageMaker AI, attach the AmazonSageMakerFullAccess policy. If you want to limit permissions to the operator, you can create your own custom policy and attach it.

Attach the following policy:

```
aws iam attach-role-policy --region ${AWS_REGION} --role-name <role name> --policy-arn
 arn:aws-cn:iam::aws:policy/AmazonSageMakerFullAccess
```

The Kubernetes ServiceAccount `sagemaker-k8s-operator-default` should have `AmazonSageMakerFullAccess` permissions. Confirm this when you install the operator.

Deploy the operator

When deploying your operator, you can use either a YAML file or Helm charts.

Deploy the operator using YAML

This is the simplest way to deploy your operators. The process is as follows:

1. Download the following installer script. Whenever `installer.yaml` is referenced, use `installer_china.yaml` instead.

   ```
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/
   master/release/rolebased/china/installer_china.yaml
   ```

2. Edit the `installer.yaml` file to replace `eks.amazonaws.com/role-arn`. Replace the ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.
3. Use the following command to deploy the cluster:

   ```
   kubectl apply -f installer.yaml
   ```

Deploy the operator using Helm Charts

Use the provided Helm Chart to install the operator.

1. Clone the Helm installer directory using the following command:

```
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/installer` folder. Edit the `rolebased/values.yaml` file, which includes high-level parameters for the chart. Replace the role ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.
3. Install the Helm Chart using the following command:

```
kubectl create namespace sagemaker-k8s-operator-system
  helm install --namespace sagemaker-k8s-operator-system sagemaker-operator
 rolebased/
```

   If you decide to install the operator into a namespace other than the one specified, you need to adjust the namespace defined in the IAM role `trust.json` file to match.
4. After a moment, the chart is installed with a randomly generated name. Verify that the installation succeeded by running the following command:

```
helm ls
```

   Your output should look like the following:

```
NAME                    NAMESPACE                       REVISION        UPDATED
                              STATUS          CHART                           APP
 VERSION
  sagemaker-operator      sagemaker-k8s-operator-system   1
  2019-11-20 23:14:59.6777082 +0000 UTC   deployed        sagemaker-k8s-
operator-0.1.0
```

Verify the operator deployment

1. You should be able to see the SageMaker AI Custom Resource Definitions (CRDs) for each operator deployed to your cluster by running the following command:

```
kubectl get crd | grep sagemaker
```

Your output should look like the following:

```
batchtransformjobs.sagemaker.aws.amazon.com         2019-11-20T17:12:34Z
endpointconfigs.sagemaker.aws.amazon.com            2019-11-20T17:12:34Z
hostingdeployments.sagemaker.aws.amazon.com         2019-11-20T17:12:34Z
hyperparametertuningjobs.sagemaker.aws.amazon.com   2019-11-20T17:12:34Z
models.sagemaker.aws.amazon.com                     2019-11-20T17:12:34Z
trainingjobs.sagemaker.aws.amazon.com               2019-11-20T17:12:34Z
```

2. Ensure that the operator pod is running successfully. Use the following command to list all pods:

```
kubectl -n sagemaker-k8s-operator-system get pods
```

You should see a pod named `sagemaker-k8s-operator-controller-manager-*****` in the namespace `sagemaker-k8s-operator-system` as follows:

```
NAME                                                     READY   STATUS
 RESTARTS   AGE
sagemaker-k8s-operator-controller-manager-12345678-r8abc     2/2     Running   0
       23s
```

Namespace-scoped deployment

You have the option to install your operator within the scope of an individual Kubernetes namespace. In this mode, the controller only monitors and reconciles resources with SageMaker AI if the resources are created within that namespace. This allows for finer-grained control over which controller is managing which resources. This is useful for deploying to multiple Amazon accounts or controlling which users have access to particular jobs.

This guide outlines how to install an operator into a particular, predefined namespace. To deploy a controller into a second namespace, follow the guide from beginning to end and change out the namespace in each step.

Create an OIDC provider for your Amazon EKS cluster

The following instructions show how to create and associate an OIDC provider with your Amazon EKS cluster.

1. Set the local `CLUSTER_NAME` and `AWS_REGION` environment variables as follows:

```
# Set the Region and cluster
export CLUSTER_NAME="<your cluster name>"
export Amazon_REGION="<your region>"
```

2. Use the following command to associate the OIDC provider with your cluster. For more information, see Enabling IAM Roles for Service Accounts on your Cluster.

```
eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} \
      --region ${AWS_REGION} --approve
```

   Your output should look like the following:

```
[_]  eksctl version 0.10.1
  [_]  using region us-east-1
  [_]  IAM OpenID Connect provider is associated with cluster "my-cluster" in "us-
east-1"
```

Now that the cluster has an OIDC identity provider, create a role and give a Kubernetes ServiceAccount permission to assume the role.

Get your OIDC ID

To set up the ServiceAccount, first obtain the OpenID Connect issuer URL using the following command:

```
aws eks describe-cluster --name ${CLUSTER_NAME} --region ${AWS_REGION} \
      --query cluster.identity.oidc.issuer --output text
```

The command returns a URL like the following:

```
https://oidc.eks.${AWS_REGION}.amazonaws.com/id/D48675832CA65BD10A532F597OIDCID
```

In this URL, the value D48675832CA65BD10A532F597OIDCID is the OIDC ID. The OIDC ID for your cluster is different. You need this OIDC ID value to create a role.

If your output is None, it means that your client version is old. To work around this, run the following command:

```
aws eks describe-cluster --region ${AWS_REGION} --query cluster --name ${CLUSTER_NAME}
 --output text | grep OIDC
```

The OIDC URL is returned as follows:

```
OIDC https://oidc.eks.us-east-1.amazonaws.com/id/D48675832CA65BD10A532F597OIDCID
```

Create your IAM role

1. JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
        "Federated": "arn:aws-cn:iam::111122223333:oidc-provider/
oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
          "StringEquals": {
              "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:aud":
 "sts.amazonaws.com",
              "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:sub":
 "system:serviceaccount:<Namespace>:sagemaker-k8s-operator-default"
          }
        }
      }
    ]
  }
```

Create a file named `trust.json` and insert the following trust relationship code block into it instead. Be sure to replace all `<OIDC ID>`, `<Amazon account number>`, and `<EKS Cluster region>` placeholders with values corresponding to your cluster.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Federated": "arn:aws-cn:iam::111122223333:oidc-provider/
oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>"
        },
        "Action": "sts:AssumeRoleWithWebIdentity",
        "Condition": {
          "StringEquals": {
              "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:aud":
 "sts.amazonaws.com",
              "oidc.eks.<EKS Cluster region>.amazonaws.com/id/<OIDC ID>:sub":
 "system:serviceaccount:<Namespace>:sagemaker-k8s-operator-default"
          }
        }
      }
    ]
  }
```

2. Run the following command to create a role with the trust relationship defined in `trust.json`. This role allows the Amazon EKS cluster to get and refresh credentials from IAM.

```
aws iam create-role --region ${AWS_REGION} --role-name <role name> --assume-role-
policy-document file://trust.json --output=text
```

Your output should look like the following:

```
ROLE    arn:aws:iam::123456789012:role/my-role 2019-11-22T21:46:10Z    /
 ABCDEFSFODNN7EXAMPLE   my-role
  ASSUMEROLEPOLICYDOCUMENT        2012-10-17
```

```
  STATEMENT       sts:AssumeRoleWithWebIdentity   Allow
  STRINGEQUALS    sts.amazonaws.com       system:serviceaccount:my-
namespace:sagemaker-k8s-operator-default
  PRINCIPAL       arn:aws:iam::123456789012:oidc-provider/oidc.eks.us-
east-1.amazonaws.com/id/
```

Take note of ROLE ARN. You pass this value to your operator.

Attach the AmazonSageMakerFullAccess policy to your role

To give the role access to SageMaker AI, attach the AmazonSageMakerFullAccess policy. If you want to limit permissions to the operator, you can create your own custom policy and attach it.

Attach the following policy:

```
aws iam attach-role-policy --region ${AWS_REGION} --role-name <role name> --policy-arn
 arn:aws-cn:iam::aws:policy/AmazonSageMakerFullAccess
```

The Kubernetes ServiceAccount sagemaker-k8s-operator-default should have AmazonSageMakerFullAccess permissions. Confirm this when you install the operator.

Deploy the operator to your namespace

When deploying your operator, you can use either a YAML file or Helm charts.

Deploy the operator to your namespace using YAML

There are two parts to deploying an operator within the scope of a namespace. The first is the set of CRDs that are installed at a cluster level. These resource definitions only need to be installed once per Kubernetes cluster. The second part is the operator permissions and deployment itself.

If you have not already installed the CRDs into the cluster, apply the CRD installer YAML using the following command:

```
kubectl apply -f https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-
k8s/master/release/rolebased/namespaced/crd.yaml
```

To install the operator onto the cluster:

1. Download the following operator script. Whenever operator.yaml is referenced, use operator_china.yaml instead.

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/
master/release/rolebased/namespaced/china/operator_china.yaml
```

2. Update the installer YAML to place the resources into your specified namespace using the following command:

```
sed -i -e 's/PLACEHOLDER-NAMESPACE/<YOUR NAMESPACE>/g' operator.yaml
```

3. Edit the `operator.yaml` file to place resources into your `eks.amazonaws.com/role-arn`. Replace the ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.
4. Use the following command to deploy the cluster:

```
kubectl apply -f operator.yaml
```

Deploy the operator to your namespace using Helm Charts

There are two parts needed to deploy an operator within the scope of a namespace. The first is the set of CRDs that are installed at a cluster level. These resource definitions only need to be installed once per Kubernetes cluster. The second part is the operator permissions and deployment itself. When using Helm Charts you have to first create the namespace using `kubectl`.

1. Clone the Helm installer directory using the following command:

```
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/installer/namespaced` folder. Edit the `rolebased/values.yaml` file, which includes high-level parameters for the chart. Replace the role ARN here with the Amazon Resource Name (ARN) for the OIDC-based role you've created.
3. Install the Helm Chart using the following command:

```
helm install crds crd_chart/
```

4. Create the required namespace and install the operator using the following command:

```
kubectl create namespace <namespace>
```

```
helm install --n <namespace> op operator_chart/
```

5. After a moment, the chart is installed with the name `sagemaker-operator`. Verify that the installation succeeded by running the following command:

```
helm ls
```

Your output should look like the following:

```
NAME                    NAMESPACE                       REVISION        UPDATED
                              STATUS          CHART                           APP
 VERSION
sagemaker-operator      my-namespace                    1               2019-11-20
 23:14:59.6777082 +0000 UTC   deployed        sagemaker-k8s-operator-0.1.0
```

Verify the operator deployment to your namespace

1. You should be able to see the SageMaker AI Custom Resource Definitions (CRDs) for each operator deployed to your cluster by running the following command:

```
kubectl get crd | grep sagemaker
```

Your output should look like the following:

```
batchtransformjobs.sagemaker.aws.amazon.com          2019-11-20T17:12:34Z
endpointconfigs.sagemaker.aws.amazon.com             2019-11-20T17:12:34Z
hostingdeployments.sagemaker.aws.amazon.com          2019-11-20T17:12:34Z
hyperparametertuningjobs.sagemaker.aws.amazon.com    2019-11-20T17:12:34Z
models.sagemaker.aws.amazon.com                      2019-11-20T17:12:34Z
trainingjobs.sagemaker.aws.amazon.com                2019-11-20T17:12:34Z
```

2. Ensure that the operator pod is running successfully. Use the following command to list all pods:

```
kubectl -n my-namespace get pods
```

You should see a pod named `sagemaker-k8s-operator-controller-manager-*****` in the namespace `my-namespace` as follows:

```
NAME                                                     READY   STATUS
 RESTARTS   AGE
sagemaker-k8s-operator-controller-manager-12345678-r8abc     2/2     Running   0
       23s
```

Install the SageMaker AI logs `kubectl` plugin

As part of the SageMaker AI Operators for Kubernetes, you can use the `smlogs` plugin for `kubectl`. This allows SageMaker AI CloudWatch logs to be streamed with `kubectl`. `kubectl` must be installed onto your PATH. The following commands place the binary in the `sagemaker-k8s-bin` directory in your home directory, and add that directory to your PATH.

```
export os="linux"

wget https://amazon-sagemaker-operator-for-k8s-us-east-1.s3.amazonaws.com/kubectl-
smlogs-plugin/v1/${os}.amd64.tar.gz
tar xvzf ${os}.amd64.tar.gz

# Move binaries to a directory in your homedir.
mkdir ~/sagemaker-k8s-bin
cp ./kubectl-smlogs.${os}.amd64/kubectl-smlogs ~/sagemaker-k8s-bin/.

# This line adds the binaries to your PATH in your .bashrc.

echo 'export PATH=$PATH:~/sagemaker-k8s-bin' >> ~/.bashrc

# Source your .bashrc to update environment variables:
source ~/.bashrc
```

Use the following command to verify that the `kubectl` plugin is installed correctly:

```
kubectl smlogs
```

If the `kubectl` plugin is installed correctly, your output should look like the following:

```
View SageMaker AI logs via Kubernetes

Usage:
  smlogs [command]
```

```
Aliases:
  smlogs, SMLogs, Smlogs

Available Commands:
  BatchTransformJob       View BatchTransformJob logs via Kubernetes
  TrainingJob             View TrainingJob logs via Kubernetes
  help                    Help about any command

Flags:
   -h, --help   help for smlogs

Use "smlogs [command] --help" for more information about a command.
```

Clean up resources

To uninstall the operator from your cluster, you must first make sure to delete all SageMaker AI resources from the cluster. Failure to do so causes the operator delete operation to hang. Run the following commands to stop all jobs:

```
# Delete all SageMaker AI jobs from Kubernetes
kubectl delete --all --all-namespaces hyperparametertuningjob.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces trainingjobs.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces batchtransformjob.sagemaker.aws.amazon.com
kubectl delete --all --all-namespaces hostingdeployment.sagemaker.aws.amazon.com
```

You should see output similar to the following:

```
$ kubectl delete --all --all-namespaces trainingjobs.sagemaker.aws.amazon.com
trainingjobs.sagemaker.aws.amazon.com "xgboost-mnist-from-for-s3" deleted

$ kubectl delete --all --all-namespaces
 hyperparametertuningjob.sagemaker.aws.amazon.com
hyperparametertuningjob.sagemaker.aws.amazon.com "xgboost-mnist-hpo" deleted

$ kubectl delete --all --all-namespaces batchtransformjob.sagemaker.aws.amazon.com
batchtransformjob.sagemaker.aws.amazon.com "xgboost-mnist" deleted

$ kubectl delete --all --all-namespaces hostingdeployment.sagemaker.aws.amazon.com
hostingdeployment.sagemaker.aws.amazon.com "host-xgboost" deleted
```

After you delete all SageMaker AI jobs, see Delete operators to delete the operator from your cluster.

Delete operators

Delete cluster-based operators

Operators installed using YAML

To uninstall the operator from your cluster, make sure that all SageMaker AI resources have been deleted from the cluster. Failure to do so causes the operator delete operation to hang.

> **Note**
>
> Before deleting your cluster, be sure to delete all SageMaker AI resources from the cluster. See Clean up resources for more information.

After you delete all SageMaker AI jobs, use `kubectl` to delete the operator from the cluster:

```
# Delete the operator and its resources
kubectl delete -f /installer.yaml
```

You should see output similar to the following:

```
$ kubectl delete -f raw-yaml/installer.yaml
namespace "sagemaker-k8s-operator-system" deleted
customresourcedefinition.apiextensions.k8s.io
 "batchtransformjobs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io
 "endpointconfigs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io
 "hostingdeployments.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io
 "hyperparametertuningjobs.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "models.sagemaker.aws.amazon.com" deleted
customresourcedefinition.apiextensions.k8s.io "trainingjobs.sagemaker.aws.amazon.com"
 deleted
role.rbac.authorization.k8s.io "sagemaker-k8s-operator-leader-election-role" deleted
clusterrole.rbac.authorization.k8s.io "sagemaker-k8s-operator-manager-role" deleted
clusterrole.rbac.authorization.k8s.io "sagemaker-k8s-operator-proxy-role" deleted
rolebinding.rbac.authorization.k8s.io "sagemaker-k8s-operator-leader-election-
rolebinding" deleted
clusterrolebinding.rbac.authorization.k8s.io "sagemaker-k8s-operator-manager-
rolebinding" deleted
```

```
clusterrolebinding.rbac.authorization.k8s.io "sagemaker-k8s-operator-proxy-rolebinding"
 deleted
service "sagemaker-k8s-operator-controller-manager-metrics-service" deleted
deployment.apps "sagemaker-k8s-operator-controller-manager" deleted
secrets "sagemaker-k8s-operator-abcde" deleted
```

Operators installed using Helm Charts

To delete the operator CRDs, first delete all the running jobs. Then delete the Helm Chart that was used to deploy the operators using the following commands:

```
# get the helm charts
helm ls

# delete the charts
helm delete <chart_name>
```

Delete namespace-based operators

Operators installed with YAML

To uninstall the operator from your cluster, first make sure that all SageMaker AI resources have been deleted from the cluster. Failure to do so causes the operator delete operation to hang.

> **Note**
>
> Before deleting your cluster, be sure to delete all SageMaker AI resources from the cluster. See Clean up resources for more information.

After you delete all SageMaker AI jobs, use `kubectl` to first delete the operator from the namespace and then the CRDs from the cluster. Run the following commands to delete the operator from the cluster:

```
# Delete the operator using the same yaml file that was used to install the operator
kubectl delete -f operator.yaml

# Now delete the CRDs using the CRD installer yaml
kubectl delete -f https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-
k8s/master/release/rolebased/namespaced/crd.yaml
```

```
# Now you can delete the namespace if you want
kubectl delete namespace <namespace>
```

Operators installed with Helm Charts

To delete the operator CRDs, first delete all the running jobs. Then delete the Helm Chart that was used to deploy the operators using the following commands:

```
# Delete the operator
helm delete <chart_name>

# delete the crds
helm delete crds

# optionally delete the namespace
kubectl delete namespace <namespace>
```

Troubleshooting

Debugging a failed job

Use these steps to debug a failed job.

- Check the job status by running the following:

  ```
  kubectl get <CRD Type> <job name>
  ```

- If the job was created in SageMaker AI, you can use the following command to see the STATUS and the `SageMaker Job Name`:

  ```
  kubectl get <crd type> <job name>
  ```

- You can use `smlogs` to find the cause of the issue using the following command:

  ```
  kubectl smlogs <crd type> <job name>
  ```

- You can also use the `describe` command to get more details about the job using the following command. The output has an `additional` field that has more information about the status of the job.

  ```
  kubectl describe <crd type> <job name>
  ```

- If the job was not created in SageMaker AI, then use the logs of the operator's pod to find the cause of the issue as follows:

```
$ kubectl get pods -A | grep sagemaker
# Output:
sagemaker-k8s-operator-system   sagemaker-k8s-operator-controller-manager-5cd7df4d74-
wh22z   2/2     Running   0          3h33m

$ kubectl logs -p <pod name> -c manager -n sagemaker-k8s-operator-system
```

Deleting an operator CRD

If deleting a job is not working, check if the operator is running. If the operator is not running, then you have to delete the finalizer using the following steps:

1. In a new terminal, open the job in an editor using `kubectl edit` as follows:

   ```
   kubectl edit <crd type> <job name>
   ```

2. Edit the job to delete the finalizer by removing the following two lines from the file. Save the file and the job is be deleted.

   ```
   finalizers:
     - sagemaker-operator-finalizer
   ```

Images and SMlogs in each Region

The following table lists the available operator images and SMLogs in each Region.

Regi	Controller Image	Linux SMLogs
us-east-	957583890962.dkr.ecr.us-east-1.amazonaws.com/amazon-sagemaker-operator-for-k8s:v1	https://s3.us-east-1.amazonaws.com/amazon-sagemaker-operator-for-k8s-us-east-1/kubectl-smlogs-plugin/v1/linux.amd64.tar.gz

Regi	Controller Image	Linux SMLogs
us-east-	922499468684.dkr.ecr.us-east-2.amazonaws.com/amazon-sagemaker-operator-for-k8s:v1	https://s3.us-east-2.amazonaws.com/amazon-sagemaker-operator-for-k8s-us-east-2/kubectl-smlogs-plugin/v1/linux.amd64.tar.gz
us-west	640106867763.dkr.ecr.us-west-2.amazonaws.com/amazon-sagemaker-operator-for-k8s:v1	https://s3.us-west-2.amazonaws.com/amazon-sagemaker-operator-for-k8s-us-west-2/kubectl-smlogs-plugin/v1/linux.amd64.tar.gz
eu-west	613661167059.dkr.ecr.eu-west-1.amazonaws.com/amazon-sagemaker-operator-for-k8s:v1	https://s3.eu-west-1.amazonaws.com/amazon-sagemaker-operator-for-k8s-eu-west-1/kubectl-smlogs-plugin/v1/linux.amd64.tar.gz

Use Amazon SageMaker AI Jobs

This section is based on the original version of SageMaker AI Operators for Kubernetes.

> **Important**
>
> We are stopping the development and technical support of the original version of SageMaker Operators for Kubernetes.
> If you are currently using version `v1.2.2` or below of SageMaker Operators for Kubernetes, we recommend migrating your resources to the ACK service controller for Amazon SageMaker. The ACK service controller is a new generation of SageMaker Operators for Kubernetes based on Amazon Controllers for Kubernetes (ACK).
> For information on the migration steps, see Migrate resources to the latest Operators.
> For answers to frequently asked questions on the end of support of the original version of SageMaker Operators for Kubernetes, see Announcing the End of Support of the Original Version of SageMaker AI Operators for Kubernetes

To run an Amazon SageMaker AI job using the Operators for Kubernetes, you can either apply a YAML file or use the supplied Helm Charts.

All sample operator jobs in the following tutorials use sample data taken from a public MNIST dataset. In order to run these samples, download the dataset into your Amazon S3 bucket. You can find the dataset in Download the MNIST Dataset.

Contents

- The TrainingJob operator
- The HyperParameterTuningJob operator
- The BatchTransformJob operator
- The HostingDeployment operator
- The ProcessingJob operator
- HostingAutoscalingPolicy (HAP) Operator

The TrainingJob operator

Training job operators reconcile your specified training job spec to SageMaker AI by launching it for you in SageMaker AI. You can learn more about SageMaker training jobs in the SageMaker AI CreateTrainingJob API documentation.

Topics

- Create a TrainingJob using a YAML file
- Create a TrainingJob Using a Helm Chart
- List TrainingJobs
- Describe a TrainingJob
- View logs from TrainingJobs
- Delete TrainingJobs

Create a TrainingJob using a YAML file

1. Download the sample YAML file for training using the following command:

   ```
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/
   master/samples/xgboost-mnist-trainingjob.yaml
   ```

2. Edit the `xgboost-mnist-trainingjob.yaml` file to replace the `roleArn` parameter with your `<sagemaker-execution-role>`, and `outputPath` with your Amazon S3 bucket to

which the SageMaker AI execution role has write access. The `roleArn` must have permissions so that SageMaker AI can access Amazon S3, Amazon CloudWatch, and other services on your behalf. For more information on creating an SageMaker AI ExecutionRole, see SageMaker AI Roles. Apply the YAML file using the following command:

```
kubectl apply -f xgboost-mnist-trainingjob.yaml
```

Create a TrainingJob Using a Helm Chart

You can use Helm Charts to run TrainingJobs.

1. Clone the GitHub repository to get the source using the following command:

   ```
   git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
   ```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/training-jobs/` folder and edit the `values.yaml` file to replace values like `rolearn` and `outputpath` with values that correspond to your account. The RoleARN must have permissions so that SageMaker AI can access Amazon S3, Amazon CloudWatch, and other services on your behalf. For more information on creating an SageMaker AI ExecutionRole, see SageMaker AI Roles.

Create the TrainingJob

With the roles and Amazon S3 buckets replaced with appropriate values in `values.yaml`, you can create a training job using the following command:

```
helm install . --generate-name
```

Your output should look like the following:

```
NAME: chart-12345678
LAST DEPLOYED: Wed Nov 20 23:35:49 2019
NAMESPACE: default
STATUS: deployed
REVISION: 1
TEST SUITE: None
NOTES:
Thanks for installing the sagemaker-k8s-trainingjob.
```

Verify your training Helm Chart

To verify that the Helm Chart was created successfully, run:

```
helm ls
```

Your output should look like the following:

```
NAME                    NAMESPACE       REVISION        UPDATED
         STATUS          CHART                           APP VERSION
chart-12345678        default         1               2019-11-20 23:35:49.9136092 +0000
 UTC   deployed        sagemaker-k8s-trainingjob-0.1.0
rolebased-12345678    default         1               2019-11-20 23:14:59.6777082 +0000
 UTC   deployed        sagemaker-k8s-operator-0.1.0
```

`helm install` creates a `TrainingJob` Kubernetes resource. The operator launches the actual training job in SageMaker AI and updates the `TrainingJob` Kubernetes resource to reflect the status of the job in SageMaker AI. You incur charges for SageMaker AI resources used during the duration of your job. You do not incur any charges once your job completes or stops.

Note: SageMaker AI does not allow you to update a running training job. You cannot edit any parameter and re-apply the config file. Either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like TFJob in Kubeflow, `update` is not supported.

List TrainingJobs

Use the following command to list all jobs created using the Kubernetes operator:

```
kubectl get TrainingJob
```

The output listing all jobs should look like the following:

```
kubectl get trainingjobs
NAME                        STATUS       SECONDARY-STATUS   CREATION-TIME
 SAGEMAKER-JOB-NAME
xgboost-mnist-from-for-s3   InProgress   Starting           2019-11-20T23:42:35Z
 xgboost-mnist-from-for-s3-examplef11eab94e0ed4671d5a8f
```

A training job continues to be listed after the job has completed or failed. You can remove a `TrainingJob` job from the list by following the Delete TrainingJobs steps. Jobs that have completed or stopped do not incur any charges for SageMaker AI resources.

TrainingJob status values

The `STATUS` field can be one of the following values:

- `Completed`
- `InProgress`
- `Failed`
- `Stopped`
- `Stopping`

These statuses come directly from the SageMaker AI official API documentation.

In addition to the official SageMaker AI status, it is possible for `STATUS` to be `SynchronizingK8sJobWithSageMaker`. This means that the operator has not yet processed the job.

Secondary status values

The secondary statuses come directly from the SageMaker AI official API documentation. They contain more granular information about the status of the job.

Describe a TrainingJob

You can get more details about the training job by using the `describe kubectl` command. This is typically used for debugging a problem or checking the parameters of a training job. To get information about your training job, use the following command:

```
kubectl describe trainingjob xgboost-mnist-from-for-s3
```

The output for your training job should look like the following:

```
Name:         xgboost-mnist-from-for-s3
Namespace:    default
Labels:       <none>
Annotations:  <none>
API Version:  sagemaker.aws.amazon.com/v1
Kind:         TrainingJob
```

```

View logs from TrainingJobs

Use the following command to see the logs from the `kmeans-mnist` training job:

```
kubectl smlogs trainingjob xgboost-mnist-from-for-s3
```

Your output should look similar to the following. The logs from instances are ordered chronologically.

```
"xgboost-mnist-from-for-s3" has SageMaker TrainingJobName "xgboost-mnist-from-
for-s3-123456789" in region "us-east-2", status "InProgress" and secondary status
 "Starting"

```

Delete TrainingJobs

Use the following command to stop a training job on Amazon SageMaker AI:

```
kubectl delete trainingjob xgboost-mnist-from-for-s3
```

This command removes the SageMaker training job from Kubernetes. This command returns the following output:

```
trainingjob.sagemaker.aws.amazon.com "xgboost-mnist-from-for-s3" deleted
```

If the job is still in progress on SageMaker AI, the job stops. You do not incur any charges for SageMaker AI resources after your job stops or completes.

Note: SageMaker AI does not delete training jobs. Stopped jobs continue to show on the SageMaker AI console. The `delete` command takes about 2 minutes to clean up the resources from SageMaker AI.

The HyperParameterTuningJob operator

Hyperparameter tuning job operators reconcile your specified hyperparameter tuning job spec to SageMaker AI by launching it in SageMaker AI. You can learn more about SageMaker AI hyperparameter tuning jobs in the SageMaker AI CreateHyperParameterTuningJob API documentation.

Topics

- Create a HyperparameterTuningJob using a YAML file
- Create a HyperparameterTuningJob using a Helm Chart
- List HyperparameterTuningJobs

- Describe a HyperparameterTuningJob
- View logs from HyperparameterTuningJobs
- Delete a HyperparameterTuningJob

Create a HyperparameterTuningJob using a YAML file

1. Download the sample YAML file for the hyperparameter tuning job using the following command:

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/
master/samples/xgboost-mnist-hpo.yaml
```

2. Edit the `xgboost-mnist-hpo.yaml` file to replace the `roleArn` parameter with your `sagemaker-execution-role`. For the hyperparameter tuning job to succeed, you must also change the `s3InputPath` and `s3OutputPath` to values that correspond to your account. Apply the updates YAML file using the following command:

```
kubectl apply -f xgboost-mnist-hpo.yaml
```

Create a HyperparameterTuningJob using a Helm Chart

You can use Helm Charts to run hyperparameter tuning jobs.

1. Clone the GitHub repository to get the source using the following command:

```
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
```

2. Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/hyperparameter-tuning-jobs/` folder.
3. Edit the `values.yaml` file to replace the `roleArn` parameter with your `sagemaker-execution-role`. For the hyperparameter tuning job to succeed, you must also change the `s3InputPath` and `s3OutputPath` to values that correspond to your account.

Create the HyperparameterTuningJob

With the roles and Amazon S3 paths replaced with appropriate values in `values.yaml`, you can create a hyperparameter tuning job using the following command:

```
helm install . --generate-name
```

Your output should look similar to the following:

```
NAME: chart-1574292948
LAST DEPLOYED: Wed Nov 20 23:35:49 2019
NAMESPACE: default
STATUS: deployed
REVISION: 1
TEST SUITE: None
NOTES:
Thanks for installing the sagemaker-k8s-hyperparametertuningjob.
```

Verify chart installation

To verify that the Helm Chart was created successfully, run the following command:

```
helm ls
```

Your output should look like the following:

```
NAME                    NAMESPACE       REVISION        UPDATED
chart-1474292948        default         1               2019-11-20 23:35:49.9136092
 +0000 UTC   deployed        sagemaker-k8s-hyperparametertuningjob-0.1.0
                STATUS          CHART                           APP VERSION
chart-1574292948        default         1               2019-11-20 23:35:49.9136092
 +0000 UTC   deployed        sagemaker-k8s-trainingjob-0.1.0
rolebased-1574291698    default         1               2019-11-20 23:14:59.6777082
 +0000 UTC   deployed        sagemaker-k8s-operator-0.1.0
```

`helm install` creates a `HyperParameterTuningJob` Kubernetes resource. The operator launches the actual hyperparameter optimization job in SageMaker AI and updates the `HyperParameterTuningJob` Kubernetes resource to reflect the status of the job in SageMaker AI. You incur charges for SageMaker AI resources used during the duration of your job. You do not incur any charges once your job completes or stops.

Note: SageMaker AI does not allow you to update a running hyperparameter tuning job. You cannot edit any parameter and re-apply the config file. You must either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like `TFJob` in Kubeflow, `update` is not supported.

List HyperparameterTuningJobs

Use the following command to list all jobs created using the Kubernetes operator:

```
kubectl get hyperparametertuningjob
```

Your output should look like the following:

```
NAME         STATUS      CREATION-TIME          COMPLETED   INPROGRESS   ERRORS
 STOPPED   BEST-TRAINING-JOB                                SAGEMAKER-JOB-NAME
xgboost-mnist-hpo   Completed   2019-10-17T01:15:52Z   10          0
        0        0         xgboostha92f5e3cf07b11e9bf6c06d6-009-4c7a123
 xgboostha92f5e3cf07b11e9bf6c123
```

A hyperparameter tuning job continues to be listed after the job has completed or failed. You can remove a `hyperparametertuningjob` from the list by following the steps in Delete a HyperparameterTuningJob. Jobs that have completed or stopped do not incur any charges for SageMaker AI resources.

Hyperparameter tuning job status values

The `STATUS` field can be one of the following values:

- `Completed`
- `InProgress`
- `Failed`
- `Stopped`
- `Stopping`

These statuses come directly from the SageMaker AI official API documentation.

In addition to the official SageMaker AI status, it is possible for `STATUS` to be `SynchronizingK8sJobWithSageMaker`. This means that the operator has not yet processed the job.

Status counters

The output has several counters, like `COMPLETED` and `INPROGRESS`. These represent how many training jobs have completed and are in progress, respectively. For more information about how these are determined, see TrainingJobStatusCounters in the SageMaker API documentation.

Best TrainingJob

This column contains the name of the `TrainingJob` that best optimized the selected metric.

To see a summary of the tuned hyperparameters, run:

```
kubectl describe hyperparametertuningjob xgboost-mnist-hpo
```

To see detailed information about the `TrainingJob`, run:

```
kubectl describe trainingjobs <job name>
```

Spawned TrainingJobs

You can also track all 10 training jobs in Kubernetes launched by `HyperparameterTuningJob` by running the following command:

```
kubectl get trainingjobs
```

Describe a HyperparameterTuningJob

You can obtain debugging details using the `describe kubectl` command.

```
kubectl describe hyperparametertuningjob xgboost-mnist-hpo
```

In addition to information about the tuning job, the SageMaker AI Operator for Kubernetes also exposes the best training job found by the hyperparameter tuning job in the `describe` output as follows:

```
Name:         xgboost-mnist-hpo
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:

View logs from HyperparameterTuningJobs

Hyperparameter tuning jobs do not have logs, but all training jobs launched by them do have logs. These logs can be accessed as if they were a normal training job. For more information, see View logs from TrainingJobs.

Delete a HyperparameterTuningJob

Use the following command to stop a hyperparameter job in SageMaker AI.

```
kubectl delete hyperparametertuningjob xgboost-mnist-hpo
```

This command removes the hyperparameter tuning job and associated training jobs from your Kubernetes cluster and stops them in SageMaker AI. Jobs that have stopped or completed do not incur any charges for SageMaker AI resources. SageMaker AI does not delete hyperparameter tuning jobs. Stopped jobs continue to show on the SageMaker AI console.

Your output should look like the following:

```
hyperparametertuningjob.sagemaker.aws.amazon.com "xgboost-mnist-hpo" deleted
```

Note: The delete command takes about 2 minutes to clean up the resources from SageMaker AI.

The BatchTransformJob operator

Batch transform job operators reconcile your specified batch transform job spec to SageMaker AI by launching it in SageMaker AI. You can learn more about SageMaker AI batch transform job in the SageMaker AI CreateTransformJob API documentation.

Topics

- Create a BatchTransformJob using a YAML File
- Create a BatchTransformJob using a Helm Chart
- List BatchTransformJobs
- Describe a BatchTransformJob
- View logs from BatchTransformJobs
- Delete a BatchTransformJob

Create a BatchTransformJob using a YAML File

1. Download the sample YAML file for the batch transform job using the following command:

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/
master/samples/xgboost-mnist-batchtransform.yaml
```

2. Edit the file `xgboost-mnist-batchtransform.yaml` to change necessary parameters to replace the `inputdataconfig` with your input data and `s3OutputPath` with your Amazon S3 buckets that the SageMaker AI execution role has write access to.
3. Apply the YAML file using the following command:

```
kubectl apply -f xgboost-mnist-batchtransform.yaml
```

Create a BatchTransformJob using a Helm Chart

You can use Helm Charts to run batch transform jobs.

Get the Helm installer directory

Clone the GitHub repository to get the source using the following command:

```
git clone https://github.com/aws/amazon-sagemaker-operator-for-k8s.git
```

Configure the Helm Chart

Navigate to the `amazon-sagemaker-operator-for-k8s/hack/charts/batch-transform-jobs/` folder.

Edit the `values.yaml` file to replace the `inputdataconfig` with your input data and outputPath with your S3 buckets to which the SageMaker AI execution role has write access.

Create a BatchTransformJob

1. Use the following command to create a batch transform job:

```
helm install . --generate-name
```

   Your output should look like the following:

```
NAME: chart-1574292948
LAST DEPLOYED: Wed Nov 20 23:35:49 2019
NAMESPACE: default
STATUS: deployed
REVISION: 1
TEST SUITE: None
NOTES:
Thanks for installing the sagemaker-k8s-batch-transform-job.
```

2. To verify that the Helm Chart was created successfully, run the following command:

```
helm ls
NAME                    NAMESPACE       REVISION        UPDATED
             STATUS          CHART                           APP VERSION
chart-1474292948        default         1               2019-11-20 23:35:49.9136092
 +0000 UTC   deployed        sagemaker-k8s-batchtransformjob-0.1.0
chart-1474292948        default         1               2019-11-20 23:35:49.9136092
 +0000 UTC   deployed        sagemaker-k8s-hyperparametertuningjob-0.1.0
chart-1574292948        default         1               2019-11-20 23:35:49.9136092
 +0000 UTC   deployed        sagemaker-k8s-trainingjob-0.1.0
rolebased-1574291698    default         1               2019-11-20 23:14:59.6777082
 +0000 UTC   deployed        sagemaker-k8s-operator-0.1.0
```

   This command creates a `BatchTransformJob` Kubernetes resource. The operator launches the actual transform job in SageMaker AI and updates the `BatchTransformJob` Kubernetes resource to reflect the status of the job in SageMaker AI. You incur charges for SageMaker AI resources used during the duration of your job. You do not incur any charges once your job completes or stops.

Note: SageMaker AI does not allow you to update a running batch transform job. You cannot edit any parameter and re-apply the config file. You must either change the metadata name or delete the existing job and create a new one. Similar to existing training job operators like `TFJob` in Kubeflow, `update` is not supported.

List BatchTransformJobs

Use the following command to list all jobs created using the Kubernetes operator:

```
kubectl get batchtransformjob
```

Your output should look like the following:

```
NAME                                STATUS      CREATION-TIME          SAGEMAKER-JOB-
NAME
xgboost-mnist-batch-transform       Completed   2019-11-18T03:44:00Z   xgboost-mnist-
a88fb19809b511eaac440aa8axgboost
```

A batch transform job continues to be listed after the job has completed or failed. You can remove a `hyperparametertuningjob` from the list by following the Delete a BatchTransformJob steps. Jobs that have completed or stopped do not incur any charges for SageMaker AI resources.

Batch transform status values

The `STATUS` field can be one of the following values:

- `Completed`
- `InProgress`
- `Failed`
- `Stopped`
- `Stopping`

These statuses come directly from the SageMaker AI official API documentation.

In addition to the official SageMaker AI status, it is possible for `STATUS` to be `SynchronizingK8sJobWithSageMaker`. This means that the operator has not yet processed the job.

Describe a BatchTransformJob

You can obtain debugging details using the `describe` `kubectl` command.

```
kubectl describe batchtransformjob xgboost-mnist-batch-transform
```

Your output should look like the following:

```
Name:         xgboost-mnist-batch-transform
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:
```

```

```

View logs from BatchTransformJobs

Use the following command to see the logs from the `xgboost-mnist` batch transform job:

```
kubectl smlogs batchtransformjob xgboost-mnist-batch-transform
```

Delete a BatchTransformJob

Use the following command to stop a batch transform job in SageMaker AI.

```
kubectl delete batchTransformJob xgboost-mnist-batch-transform
```

Your output should look like the following:

```
batchtransformjob.sagemaker.aws.amazon.com "xgboost-mnist" deleted
```

This command removes the batch transform job from your Kubernetes cluster, as well as stops them in SageMaker AI. Jobs that have stopped or completed do not incur any charges for SageMaker AI resources. Delete takes about 2 minutes to clean up the resources from SageMaker AI.

Note: SageMaker AI does not delete batch transform jobs. Stopped jobs continue to show on the SageMaker AI console.

The HostingDeployment operator

HostingDeployment operators support creating and deleting an endpoint, as well as updating an existing endpoint, for real-time inference. The hosting deployment operator reconciles your specified hosting deployment job spec to SageMaker AI by creating models, endpoint-configs and endpoints in SageMaker AI. You can learn more about SageMaker AI inference in the SageMaker AI CreateEndpoint API documentation.

Topics

- Configure a HostingDeployment resource
- Create a HostingDeployment
- List HostingDeployments
- Describe a HostingDeployment
- Invoking the endpoint
- Update HostingDeployment
- Delete the HostingDeployment

Configure a HostingDeployment resource

Download the sample YAML file for the hosting deployment job using the following command:

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/master/
samples/xgboost-mnist-hostingdeployment.yaml
```

The `xgboost-mnist-hostingdeployment.yaml` file has the following components that can be edited as required:

- *ProductionVariants*. A production variant is a set of instances serving a single model. SageMaker AI load-balances between all production variants according to set weights.
- *Models*. A model is the containers and execution role ARN necessary to serve a model. It requires at least a single container.
- *Containers*. A container specifies the dataset and serving image. If you are using your own custom algorithm instead of an algorithm provided by SageMaker AI, the inference code must meet SageMaker AI requirements. For more information, see Using Your Own Algorithms with SageMaker AI.

Create a HostingDeployment

To create a HostingDeployment, use `kubectl` to apply the file `hosting.yaml` with the following command:

```
kubectl apply -f hosting.yaml
```

SageMaker AI creates an endpoint with the specified configuration. You incur charges for SageMaker AI resources used during the lifetime of your endpoint. You do not incur any charges once your endpoint is deleted.

The creation process takes approximately 10 minutes.

List HostingDeployments

To verify that the HostingDeployment was created, use the following command:

```
kubectl get hostingdeployments
```

Your output should look like the following:

```
NAME           STATUS     SAGEMAKER-ENDPOINT-NAME
host-xgboost   Creating   host-xgboost-def0e83e0d5f11eaaa450aSMLOGS
```

HostingDeployment status values

The status field can be one of several values:

- `SynchronizingK8sJobWithSageMaker`: The operator is preparing to create the endpoint.
- `ReconcilingEndpoint`: The operator is creating, updating, or deleting endpoint resources. If the HostingDeployment remains in this state, use `kubectl describe` to see the reason in the `Additional` field.
- `OutOfService`: The endpoint is not available to take incoming requests.
- `Creating`: CreateEndpoint is running.
- `Updating`: UpdateEndpoint or UpdateEndpointWeightsAndCapacities is running.
- `SystemUpdating`: The endpoint is undergoing maintenance and cannot be updated or deleted or re-scaled until it has completed. This maintenance operation does not change any customer-specified values such as VPC config, Amazon KMS encryption, model, instance type, or instance count.
- `RollingBack`: The endpoint fails to scale up or down or change its variant weight and is in the process of rolling back to its previous configuration. Once the rollback completes, the endpoint returns to an `InService` status. This transitional status only applies to an endpoint that has autoscaling turned on and is undergoing variant weight or capacity changes as part of an UpdateEndpointWeightsAndCapacities call or when the UpdateEndpointWeightsAndCapacities operation is called explicitly.
- `InService`: The endpoint is available to process incoming requests.
- `Deleting`: DeleteEndpoint is running.
- `Failed`: The endpoint could not be created, updated, or re-scaled. Use DescribeEndpoint:FailureReason for information about the failure. DeleteEndpoint is the only operation that can be performed on a failed endpoint.

Describe a HostingDeployment

You can obtain debugging details using the `describe kubectl` command.

```
kubectl describe hostingdeployment
```

Your output should look like the following:

```
Name:         host-xgboost
Namespace:    default
Labels:       <none>
```

```
Annotations:  kubectl.kubernetes.io/last-applied-configuration:

```

The status field provides more information using the following fields:

- `Additional`: Additional information about the status of the hosting deployment. This field is optional and only gets populated in case of error.
- `Creation Time`: When the endpoint was created in SageMaker AI.
- `Endpoint ARN`: The SageMaker AI endpoint ARN.
- `Endpoint Config Name`: The SageMaker AI name of the endpoint configuration.
- `Endpoint Name`: The SageMaker AI name of the endpoint.
- `Endpoint Status`: The status of the endpoint.
- `Endpoint URL`: The HTTPS URL that can be used to access the endpoint. For more information, see Deploy a Model on SageMaker AI Hosting Services.
- `FailureReason`: If a create, update, or delete command fails, the cause is shown here.
- `Last Check Time`: The last time the operator checked the status of the endpoint.
- `Last Modified Time`: The last time the endpoint was modified.
- `Model Names`: A key-value pair of HostingDeployment model names to SageMaker AI model names.

Invoking the endpoint

Once the endpoint status is `InService`, you can invoke the endpoint in two ways: using the Amazon CLI, which does authentication and URL request signing, or using an HTTP client like cURL. If you use your own client, you need to do Amazon v4 URL signing and authentication on your own.

To invoke the endpoint using the Amazon CLI, run the following command. Make sure to replace the Region and endpoint name with your endpoint's Region and SageMaker AI endpoint name. This information can be obtained from the output of `kubectl describe`.

```
# Invoke the endpoint with mock input data.
aws sagemaker-runtime invoke-endpoint \
  --region us-east-2 \
  --endpoint-name <endpoint name> \
  --body $(seq 784 | xargs echo | sed 's/ /,/g') \
  >(cat) \
```

```
  --content-type text/csv > /dev/null
```

For example, if your Region is `us-east-2` and your endpoint config name is `host-xgboost-f56b6b280d7511ea824b129926example`, then the following command would invoke the endpoint:

```
aws sagemaker-runtime invoke-endpoint \
  --region us-east-2 \
  --endpoint-name host-xgboost-f56b6b280d7511ea824b1299example \
  --body $(seq 784 | xargs echo | sed 's/ /,/g') \
  >(cat) \
  --content-type text/csv > /dev/null
4.95847082138
```

Here, `4.95847082138` is the prediction from the model for the mock data.

Update HostingDeployment

1. Once a HostingDeployment has a status of `InService`, it can be updated. It might take about 10 minutes for HostingDeployment to be in service. To verify that the status is `InService`, use the following command:

   ```
   kubectl get hostingdeployments
   ```

2. The HostingDeployment can be updated before the status is `InService`. The operator waits until the SageMaker AI endpoint is `InService` before applying the update.

   To apply an update, modify the `hosting.yaml` file. For example, change the `initialInstanceCount` field from 1 to 2 as follows:

   ```
   apiVersion: sagemaker.aws.amazon.com/v1
   kind: HostingDeployment
   metadata:
     name: host-xgboost
   spec:
       region: us-east-2
       productionVariants:
           - variantName: all-traffic
             modelName: xgboost-model
             initialInstanceCount: 2
             instanceType: ml.c5.large
   ```

```
    models:
        - name: xgboost-model
          executionRoleArn: arn:aws:iam::123456789012:role/service-role/
AmazonSageMaker-ExecutionRole
          primaryContainer: xgboost
          containers:
            - xgboost
    containers:
        - containerHostname: xgboost
          modelDataUrl: s3://amzn-s3-demo-bucket/inference/xgboost-mnist/
model.tar.gz
          image: 123456789012.dkr.ecr.us-east-2.amazonaws.com/xgboost:latest
```

3. Save the file, then use `kubectl` to apply your update as follows. You should see the status change from `InService` to `ReconcilingEndpoint`, then `Updating`.

```
$ kubectl apply -f hosting.yaml
hostingdeployment.sagemaker.aws.amazon.com/host-xgboost configured

$ kubectl get hostingdeployments
NAME           STATUS                SAGEMAKER-ENDPOINT-NAME
host-xgboost   ReconcilingEndpoint   host-xgboost-def0e83e0d5f11eaaa450a350abcdef

$ kubectl get hostingdeployments
NAME           STATUS     SAGEMAKER-ENDPOINT-NAME
host-xgboost   Updating   host-xgboost-def0e83e0d5f11eaaa450a3507abcdef
```

SageMaker AI deploys a new set of instances with your models, switches traffic to use the new instances, and drains the old instances. As soon as this process begins, the status becomes `Updating`. After the update is complete, your endpoint becomes `InService`. This process takes approximately 10 minutes.

Delete the HostingDeployment

1. Use `kubectl` to delete a HostingDeployment with the following command:

```
kubectl delete hostingdeployments host-xgboost
```

   Your output should look like the following:

```
hostingdeployment.sagemaker.aws.amazon.com "host-xgboost" deleted
```

2. To verify that the hosting deployment has been deleted, use the following command:

```
kubectl get hostingdeployments
No resources found.
```

Endpoints that have been deleted do not incur any charges for SageMaker AI resources.

The ProcessingJob operator

ProcessingJob operators are used to launch Amazon SageMaker processing jobs. For more information on SageMaker Processing jobs, see CreateProcessingJob.

Topics

- Create a ProcessingJob using a YAML file
- List ProcessingJobs
- Describe a ProcessingJob
- Delete a ProcessingJob

Create a ProcessingJob using a YAML file

Follow these steps to create an Amazon SageMaker processing job by using a YAML file:

1. Download the `kmeans_preprocessing.py` pre-processing script.

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/
master/samples/kmeans_preprocessing.py
```

2. In one of your Amazon Simple Storage Service (Amazon S3) buckets, create a `mnist_kmeans_example/processing_code` folder and upload the script to the folder.
3. Download the `kmeans-mnist-processingjob.yaml` file.

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/
master/samples/kmeans-mnist-processingjob.yaml
```

4. Edit the YAML file to specify your `sagemaker-execution-role` and replace all instances of `amzn-s3-demo-bucket` with your S3 bucket.

```
...
metadata:
  name: kmeans-mnist-processing
...
  roleArn: arn:aws:iam::<acct-id>:role/service-role/<sagemaker-execution-role>
  ...
  processingOutputConfig:
    outputs:
      ...
          s3Output:
            s3Uri: s3://<amzn-s3-demo-bucket>/mnist_kmeans_example/output/
  ...
  processingInputs:
    ...
        s3Input:
          s3Uri: s3://<amzn-s3-demo-bucket>/mnist_kmeans_example/processing_code/
kmeans_preprocessing.py
```

   The `sagemaker-execution-role` must have permissions so that SageMaker AI can access your S3 bucket, Amazon CloudWatch, and other services on your behalf. For more information on creating an execution role, see SageMaker AI Roles.

5. Apply the YAML file using one of the following commands.

   For cluster-scoped installation:

```
kubectl apply -f kmeans-mnist-processingjob.yaml
```

   For namespace-scoped installation:

```
kubectl apply -f kmeans-mnist-processingjob.yaml -n <NAMESPACE>
```

List ProcessingJobs

Use one of the following commands to list all the jobs created using the ProcessingJob operator. `SAGEMAKER-JOB-NAME` comes from the `metadata` section of the YAML file.

For cluster-scoped installation:

```
kubectl get ProcessingJob kmeans-mnist-processing
```

For namespace-scoped installation:

```
kubectl get ProcessingJob -n <NAMESPACE> kmeans-mnist-processing
```

Your output should look similar to the following:

```
NAME                    STATUS     CREATION-TIME        SAGEMAKER-JOB-NAME
kmeans-mnist-processing InProgress 2020-09-22T21:13:25Z kmeans-mnist-
processing-7410ed52fd1811eab19a165ae9f9e385
```

The output lists all jobs regardless of their status. To remove a job from the list, see Delete a Processing Job.

ProcessingJob Status

- `SynchronizingK8sJobWithSageMaker` – The job is first submitted to the cluster. The operator has received the request and is preparing to create the processing job.
- `Reconciling` – The operator is initializing or recovering from transient errors, along with others. If the processing job remains in this state, use the `kubectl describe` command to see the reason in the `Additional` field.
- `InProgress | Completed | Failed | Stopping | Stopped` – Status of the SageMaker Processing job. For more information, see DescribeProcessingJob.
- `Error` – The operator cannot recover by reconciling.

Jobs that have completed, stopped, or failed do not incur further charges for SageMaker AI resources.

Describe a ProcessingJob

Use one of the following commands to get more details about a processing job. These commands are typically used for debugging a problem or checking the parameters of a processing job.

For cluster-scoped installation:

```
kubectl describe processingjob kmeans-mnist-processing
```

For namespace-scoped installation:

```
kubectl describe processingjob kmeans-mnist-processing -n <NAMESPACE>
```

The output for your processing job should look similar to the following.

```
$ kubectl describe ProcessingJob kmeans-mnist-processing
Name:         kmeans-mnist-processing
Namespace:    default
Labels:       <none>
Annotations:  kubectl.kubernetes.io/last-applied-configuration:

Delete a ProcessingJob

When you delete a processing job, the SageMaker Processing job is removed from Kubernetes but the job isn't deleted from SageMaker AI. If the job status in SageMaker AI is `InProgress` the job is stopped. Processing jobs that are stopped do not incur any charges for SageMaker AI resources. Use one of the following commands to delete a processing job.

For cluster-scoped installation:

```
kubectl delete processingjob kmeans-mnist-processing
```

For namespace-scoped installation:

```
kubectl delete processingjob kmeans-mnist-processing -n <NAMESPACE>
```

The output for your processing job should look similar to the following.

```
processingjob.sagemaker.aws.amazon.com "kmeans-mnist-processing" deleted
```

> **Note**
>
> SageMaker AI does not delete the processing job. Stopped jobs continue to show in the SageMaker AI console. The `delete` command takes a few minutes to clean up the resources from SageMaker AI.

HostingAutoscalingPolicy (HAP) Operator

The HostingAutoscalingPolicy (HAP) operator takes a list of resource IDs as input and applies the same policy to each of them. Each resource ID is a combination of an endpoint name and a variant name. The HAP operator performs two steps: it registers the resource IDs and then applies the scaling policy to each resource ID. `Delete` undoes both actions. You can apply the HAP to an existing SageMaker AI endpoint or you can create a new SageMaker AI endpoint using the HostingDeployment operator. You can read more about SageMaker AI autoscaling in the Application Autoscaling Policy documentation.

> **Note**
>
> In your `kubectl` commands, you can use the short form, `hap`, in place of `hostingautoscalingpolicy`.

Topics

- Create a HostingAutoscalingPolicy using a YAML file
- List HostingAutoscalingPolicies
- Describe a HostingAutoscalingPolicy
- Update a HostingAutoscalingPolicy
- Delete a HostingAutoscalingPolicy
- Update or delete an endpoint with a HostingAutoscalingPolicy

Create a HostingAutoscalingPolicy using a YAML file

Use a YAML file to create a HostingAutoscalingPolicy (HAP) that applies a predefined or custom metric to one or multiple SageMaker AI endpoints.

Amazon SageMaker AI requires specific values in order to apply autoscaling to your variant. If these values are not specified in the YAML spec, the HAP operator applies the following default values.

```
# Do not change
Namespace                   = "sagemaker"
# Do not change
ScalableDimension           = "sagemaker:variant:DesiredInstanceCount"
# Only one supported
PolicyType                  = "TargetTrackingScaling"
# This is the default policy name but can be changed to apply a custom policy
DefaultAutoscalingPolicyName = "SageMakerEndpointInvocationScalingPolicy"
```

Use the following samples to create a HAP that applies a predefined or custom metric to one or multiple endpoints.

Sample 1: Apply a predefined metric to a single endpoint variant

1. Download the sample YAML file for a predefined metric using the following command:

```
wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/
master/samples/hap-predefined-metric.yaml
```

2. Edit the YAML file to specify your `endpointName`, `variantName`, and `Region`.
3. Use one of the following commands to apply a predefined metric to a single resource ID (endpoint name and variant name combination).

   For cluster-scoped installation:

   ```
   kubectl apply -f hap-predefined-metric.yaml
   ```

   For namespace-scoped installation:

   ```
   kubectl apply -f hap-predefined-metric.yaml -n <NAMESPACE>
   ```

Sample 2: Apply a custom metric to a single endpoint variant

1. Download the sample YAML file for a custom metric using the following command:

   ```
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/
   master/samples/hap-custom-metric.yaml
   ```

2. Edit the YAML file to specify your `endpointName`, `variantName`, and `Region`.
3. Use one of the following commands to apply a custom metric to a single resource ID (endpoint name and variant name combination) in place of the recommended `SageMakerVariantInvocationsPerInstance`.

   > **Note**
   >
   > Amazon SageMaker AI does not check the validity of your YAML spec.

   For cluster-scoped installation:

   ```
   kubectl apply -f hap-custom-metric.yaml
   ```

   For namespace-scoped installation:

```
kubectl apply -f hap-custom-metric.yaml -n <NAMESPACE>
```

Sample 3: Apply a scaling policy to multiple endpoints and variants

You can use the HAP operator to apply the same scaling policy to multiple resource IDs. A separate `scaling_policy` request is created for each resource ID (endpoint name and variant name combination).

1. Download the sample YAML file for a predefined metric using the following command:

   ```
   wget https://raw.githubusercontent.com/aws/amazon-sagemaker-operator-for-k8s/
   master/samples/hap-predefined-metric.yaml
   ```

2. Edit the YAML file to specify your `Region` and multiple `endpointName` and `variantName` values.
3. Use one of the following commands to apply a predefined metric to multiple resource IDs (endpoint name and variant name combinations).

   For cluster-scoped installation:

   ```
   kubectl apply -f hap-predefined-metric.yaml
   ```

   For namespace-scoped installation:

   ```
   kubectl apply -f hap-predefined-metric.yaml -n <NAMESPACE>
   ```

Considerations for HostingAutoscalingPolicies for multiple endpoints and variants

The following considerations apply when you use multiple resource IDs:

- If you apply a single policy across multiple resource IDs, one PolicyARN is created per resource ID. Five endpoints have five PolicyARNs. When you run the `describe` command on the policy, the responses show up as one job and include a single job status.
- If you apply a custom metric to multiple resource IDs, the same dimension or value is used for all the resource ID (variant) values. For example, if you apply a customer metric for instances 1-5,

and the endpoint variant dimension is mapped to variant 1, when variant 1 exceeds the metrics, all endpoints are scaled up or down.

- The HAP operator supports updating the list of resource IDs. If you modify, add, or delete resource IDs to the spec, the autoscaling policy is removed from the previous list of variants and applied to the newly specified resource ID combinations. Use the `describe` command to list the resource IDs to which the policy is currently applied.

List HostingAutoscalingPolicies

Use one of the following commands to list all HostingAutoscalingPolicies (HAPs) created using the HAP operator.

For cluster-scoped installation:

```
kubectl get hap
```

For namespace-scoped installation:

```
kubectl get hap -n <NAMESPACE>
```

Your output should look similar to the following:

```
NAME             STATUS   CREATION-TIME
hap-predefined   Created  2021-07-13T21:32:21Z
```

Use the following command to check the status of your HostingAutoscalingPolicy (HAP).

```
kubectl get hap <job-name>
```

One of the following values is returned:

- `Reconciling` – Certain types of errors show the status as `Reconciling` instead of `Error`. Some examples are server-side errors and endpoints in the `Creating` or `Updating` state. Check the `Additional` field in status or operator logs for more details.
- `Created`
- `Error`

To view the autoscaling endpoint to which you applied the policy

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. In the left side panel, expand **Inference**.
3. Choose **Endpoints**.
4. Select the name of the endpoint of interest.
5. Scroll to the **Endpoint runtime settings** section.

Describe a HostingAutoscalingPolicy

Use the following command to get more details about a HostingAutoscalingPolicy (HAP). These commands are typically used for debugging a problem or checking the resource IDs (endpoint name and variant name combinations) of a HAP.

```
kubectl describe hap <job-name>
```

Update a HostingAutoscalingPolicy

The HostingAutoscalingPolicy (HAP) operator supports updates. You can edit your YAML spec to change the values and then reapply the policy. The HAP operator deletes the existing policy and applies the new policy.

Delete a HostingAutoscalingPolicy

Use one of the following commands to delete a HostingAutoscalingPolicy (HAP) policy.

For cluster-scoped installation:

```
kubectl delete hap hap-predefined
```

For namespace-scoped installation:

```
kubectl delete hap hap-predefined -n <NAMESPACE>
```

This command deletes the scaling policy and deregisters the scaling target from Kubernetes. This command returns the following output:

```
hostingautoscalingpolicies.sagemaker.aws.amazon.com "hap-predefined" deleted
```

Update or delete an endpoint with a HostingAutoscalingPolicy

To update an endpoint that has a HostingAutoscalingPolicy (HAP), use the `kubectl delete` command to remove the HAP, update the endpoint, and then reapply the HAP.

To delete an endpoint that has a HAP, use the `kubectl delete` command to remove the HAP before you delete the endpoint.

Migrate resources to the latest Operators

We are stopping the development and technical support of the original version of SageMaker Operators for Kubernetes.

If you are currently using version `v1.2.2` or below of SageMaker Operators for Kubernetes, we recommend migrating your resources to the ACK service controller for Amazon SageMaker. The ACK service controller is a new generation of SageMaker Operators for Kubernetes based on Amazon Controllers for Kubernetes (ACK).

For answers to frequently asked questions on the end of support of the original version of SageMaker Operators for Kubernetes, see Announcing the End of Support of the Original Version of SageMaker AI Operators for Kubernetes

Use the following steps to migrate your resources and use ACK to train, tune, and deploy machine learning models with Amazon SageMaker AI.

> **Note**
>
> The latest SageMaker AI Operators for Kubernetes are not backwards compatible.

Contents

- Prerequisites
- Adopt resources
- Clean up old resources
- Use the new SageMaker AI Operators for Kubernetes

Prerequisites

To successfully migrate resources to the latest SageMaker AI Operators for Kubernetes, you must do the following:

1. Install the latest SageMaker AI Operators for Kubernetes. See Setup in *Machine Learning with the ACK SageMaker AI Controller* for step-by-step instructions.
2. If you are using HostingAutoscalingPolicy resources, install the new Application Auto Scaling Operators. See Setup in *Scale SageMaker AI Workloads with Application Auto Scaling* for step-by-step instructions. This step is optional if you are not using HostingAutoScalingPolicy resources.

If permissions are configured correctly, then the ACK SageMaker AI service controller can determine the specification and status of the Amazon resource and reconcile the resource as if the ACK controller originally created it.

Adopt resources

The new SageMaker AI Operators for Kubernetes provide the ability to adopt resources that were not originally created by the ACK service controller. For more information, see Adopt Existing Amazon Resources in the ACK documentation.

The following steps show how the new SageMaker AI Operators for Kubernetes can adopt an existing SageMaker AI endpoint. Save the following sample to a file named `adopt-endpoint-sample.yaml`.

```
apiVersion: services.k8s.aws/v1alpha1
kind: AdoptedResource
metadata:
  name: adopt-endpoint-sample
spec:
  aws:
    # resource to adopt, not created by ACK
    nameOrID: xgboost-endpoint
  kubernetes:
    group: sagemaker.services.k8s.aws
    kind: Endpoint
    metadata:
      # target K8s CR name
      name: xgboost-endpoint
```

Submit the custom resource (CR) using `kubectl apply`:

```
kubectl apply -f adopt-endpoint-sample.yaml
```

Use `kubectl describe` to check the status conditions of your adopted resource.

```
kubectl describe adoptedresource adopt-endpoint-sample
```

Verify that the ACK.Adopted condition is True. The output should look similar to the following example:

```
---
kind: AdoptedResource
metadata:
  annotations:
    kubectl.kubernetes.io/last-applied-configuration: '{"apiVersion":"services.k8s.aws/
v1alpha1","kind":"AdoptedResource","metadata":{"annotations":{},"name":"xgboost-
endpoint","namespace":"default"},"spec":{"aws":{"nameOrID":"xgboost-
endpoint"},"kubernetes":
{"group":"sagemaker.services.k8s.aws","kind":"Endpoint","metadata":{"name":"xgboost-
endpoint"}}}}'
  creationTimestamp: '2021-04-27T02:49:14Z'
  finalizers:
  - finalizers.services.k8s.aws/AdoptedResource
  generation: 1
  name: adopt-endpoint-sample
  namespace: default
  resourceVersion: '12669876'
  selfLink: "/apis/services.k8s.aws/v1alpha1/namespaces/default/adoptedresources/adopt-
endpoint-sample"
  uid: 35f8fa92-29dd-4040-9d0d-0b07bbd7ca0b
spec:
  aws:
    nameOrID: xgboost-endpoint
  kubernetes:
    group: sagemaker.services.k8s.aws
    kind: Endpoint
    metadata:
      name: xgboost-endpoint
status:
  conditions:
  - status: 'True'
    type: ACK.Adopted
```

Check that your resource exists in your cluster:

```
kubectl describe endpoints.sagemaker xgboost-endpoint
```

HostingAutoscalingPolicy resources

The `HostingAutoscalingPolicy` (HAP) resource consists of multiple Application Auto Scaling resources: `ScalableTarget` and `ScalingPolicy`. When adopting a HAP resource with ACK, first install the Application Auto Scaling controller. To adopt HAP resources, you need to adopt both `ScalableTarget` and `ScalingPolicy` resources. You can find the resource indentifier for these resources in the status of the `HostingAutoscalingPolicy` resource (`status.ResourceIDList`).

HostingDeployment resources

The `HostingDeployment` resource consists of multiple SageMaker AI resources: `Endpoint`, `EndpointConfig`, and each `Model`. If you adopt a SageMaker AI endpoint in ACK, you need to adopt the `Endpoint`, `EndpointConfig`, and each `Model` separately. The `Endpoint`, `EndpointConfig`, and `Model` names can be found in status of the `HostingDeployment` resource (`status.endpointName`, `status.endpointConfigName`, and `status.modelNames`).

For a list of all supported SageMaker AI resources, refer to the ACK API Reference.

Clean up old resources

After the new SageMaker AI Operators for Kubernetes adopt your resources, you can uninstall old operators and clean up old resources.

Step 1: Uninstall the old operator

To uninstall the old operator, see Delete operators.

> **Warning**
>
> Uninstall the old operator before deleting any old resources.

Step 2: Remove finalizers and delete old resources

> **Warning**
>
> Before deleting old resources, be sure that you have uninstalled the old operator.

After uninstalling the old operator, you must explicitly remove the finalizers to delete old operator resources. The following sample script shows how to delete all training jobs managed by the old operator in a given namespace. You can use a similar pattern to delete additional resources once they are adopted by the new operator.

> **Note**
>
> You must use full resource names to get resources. For example, use `kubectl get trainingjobs.sagemaker.aws.amazon.com` instead of `kubectl get trainingjob`.

```
namespace=sagemaker_namespace
training_jobs=$(kubectl get trainingjobs.sagemaker.aws.amazon.com -n $namespace -ojson
 | jq -r '.items | .[] | .metadata.name')

for job in $training_jobs
do
    echo "Deleting $job resource in $namespace namespace"
    kubectl patch trainingjobs.sagemaker.aws.amazon.com $job -n $namespace -p
 '{"metadata":{"finalizers":null}}' --type=merge
    kubectl delete trainingjobs.sagemaker.aws.amazon.com $job -n $namespace
done
```

Use the new SageMaker AI Operators for Kubernetes

For in-depth guides on using the new SageMaker AI Operators for Kubernetes, see Use SageMaker AI Operators for Kubernetes

Announcing the End of Support of the Original Version of SageMaker AI Operators for Kubernetes

This page announces the end of support for the original version of SageMaker AI Operators for Kubernetes and provides answers to frequently asked questions as well as migration information about the ACK service controller for Amazon SageMaker AI, a new generation of fully supported SageMaker AI Operators for Kubernetes. For general information about the new SageMaker AI Operators for Kubernetes, see Latest SageMaker AI Operators for Kubernetes.

End of Support Frequently Asked Questions

Contents

- Why are we ending support for the original version of SageMaker AI Operators for Kubernetes?
- Where can I find more information about the new SageMaker AI Operators for Kubernetes and ACK?
- What does end of support (EOS) mean?
- How can I migrate my workload to the new SageMaker AI Operators for Kubernetes for training and inference?
- Which version of ACK should I migrate to?
- Are the initial SageMaker AI Operators for Kubernetes and the new Operators (ACK service controller for Amazon SageMaker AI) functionally equivalent?

Why are we ending support for the original version of SageMaker AI Operators for Kubernetes?

Users can now take advantage of the ACK service controller for Amazon SageMaker AI. The ACK service controller is a new generation of SageMaker AI Operators for Kubernetes based on Amazon Controllers for Kubernetes (ACK), a community-driven project optimized for production, standardizing the way to expose Amazon services via a Kubernetes operator. We are therefore announcing the end of support (EOS) for the original version (not ACK-based) of SageMaker AI Operators for Kubernetes. The support ends on **Feb 15, 2023** along with Amazon Elastic Kubernetes Service Kubernetes 1.21.

For more information on ACK, see ACK history and tenets.

Where can I find more information about the new SageMaker AI Operators for Kubernetes and ACK?

- For more information about the new SageMaker AI Operators for Kubernetes, see the ACK service controller for Amazon SageMaker AI GitHub repository or read Amazon Controllers for Kubernetes Documentation.
- For a tutorial on how to train a machine learning model with the ACK service controller for Amazon SageMaker AI using Amazon EKS, see this SageMaker AI example.

  For an autoscaling example, see Scale SageMaker AI Workloads with Application Auto Scaling.
- For information on Amazon Controller for Kubernetes (ACK), see the Amazon Controllers for Kubernetes (ACK) documentation.
- For a list of supported SageMaker AI resources, see ACK API Reference.

What does end of support (EOS) mean?

While users can continue to use their current operators, we are no longer developing new features for the operators, nor will we release any patches or security updates for any issues found. `v1.2.2` is the last release of SageMaker AI Operators for Kubernetes. Users should migrate their workloads to use the ACK service controller for Amazon SageMaker AI.

How can I migrate my workload to the new SageMaker AI Operators for Kubernetes for training and inference?

For information about migrating resources from the old to the new SageMaker AI Operators for Kubernetes, follow Migrate resources to the latest Operators.

Which version of ACK should I migrate to?

Users should migrate to the most recent released version of the ACK service controller for Amazon SageMaker AI.

Are the initial SageMaker AI Operators for Kubernetes and the new Operators (ACK service controller for Amazon SageMaker AI) functionally equivalent?

Yes, they are at feature parity.

A few highlights of the main notable differences between the two versions include:

- The Custom Resources Definitions (CRD) used by the ACK-based SageMaker AI Operators for Kubernetes follow the Amazon API definition making it incompatible with the custom resources specifications from the SageMaker AI Operators for Kubernetes in its original version. Refer to the CRDs in the new controller or use the migration guide to adopt the resources and use the new controller.
- The `Hosting Autoscaling` policy is no longer part of the new SageMaker AI Operators for Kubernetes and has been migrated to the Application autoscaling ACK controller. To learn how to use the application autoscaling controller to configure autoscaling on SageMaker AI Endpoints, follow this autoscaling example.
- The `HostingDeployment` resource was used to create Models, Endpoint Configurations, and Endpoints in one CRD. The new SageMaker AI Operators for Kubernetes has a separate CRD for each of these resources.

SageMaker AI Components for Kubeflow Pipelines

With SageMaker AI components for Kubeflow Pipelines, you can create and monitor native SageMaker AI training, tuning, endpoint deployment, and batch transform jobs from your Kubeflow Pipelines. By running Kubeflow Pipeline jobs on SageMaker AI, you move data processing and training jobs from the Kubernetes cluster to SageMaker AI's machine learning-optimized managed service. This document assumes prior knowledge of Kubernetes and Kubeflow.

Contents

- What are Kubeflow Pipelines?
- What are Kubeflow Pipeline components?
- Why use SageMaker AI Components for Kubeflow Pipelines?
- SageMaker AI Components for Kubeflow Pipelines versions
- List of SageMaker AI Components for Kubeflow Pipelines
- IAM permissions
- Converting pipelines to use SageMaker AI
- Install Kubeflow Pipelines
- Use SageMaker AI components

What are Kubeflow Pipelines?

Kubeflow Pipelines (KFP) is a platform for building and deploying portable, scalable machine learning (ML) workflows based on Docker containers. The Kubeflow Pipelines platform consists of the following:

- A user interface (UI) for managing and tracking experiments, jobs, and runs.
- An engine (Argo) for scheduling multi-step ML workflows.
- An SDK for defining and manipulating pipelines and components.
- Notebooks for interacting with the system using the SDK.

A pipeline is a description of an ML workflow expressed as a directed acyclic graph. Every step in the workflow is expressed as a Kubeflow Pipeline component, which is a Amazon SDK for Python (Boto3) module.

For more information on Kubeflow Pipelines, see the Kubeflow Pipelines documentation.

What are Kubeflow Pipeline components?

A Kubeflow Pipeline component is a set of code used to execute one step of a Kubeflow pipeline. Components are represented by a Python module built into a Docker image. When the pipeline runs, the component's container is instantiated on one of the worker nodes on the Kubernetes cluster running Kubeflow, and your logic is executed. Pipeline components can read outputs from the previous components and create outputs that the next component in the pipeline can consume. These components make it fast and easy to write pipelines for experimentation and production environments without having to interact with the underlying Kubernetes infrastructure.

You can use SageMaker AI Components in your Kubeflow pipeline. Rather than encapsulating your logic in a custom container, you simply load the components and describe your pipeline using the Kubeflow Pipelines SDK. When the pipeline runs, your instructions are translated into a SageMaker AI job or deployment. The workload then runs on the fully managed infrastructure of SageMaker AI.

Why use SageMaker AI Components for Kubeflow Pipelines?

SageMaker AI Components for Kubeflow Pipelines offer an alternative to launching your compute-intensive jobs from SageMaker AI. The components integrate SageMaker AI with the portability and orchestration of Kubeflow Pipelines. Using the SageMaker AI Components for Kubeflow Pipelines, you can create and monitor your SageMaker AI resources as part of a Kubeflow Pipelines workflow. Each of the jobs in your pipelines runs on SageMaker AI instead of the local Kubernetes cluster allowing you to take advantage of key SageMaker AI features such as data labeling, large-scale hyperparameter tuning and distributed training jobs, or one-click secure and scalable model deployment. The job parameters, status, logs, and outputs from SageMaker AI are still accessible from the Kubeflow Pipelines UI.

The SageMaker AI components integrate key SageMaker AI features into your ML workflows from preparing data, to building, training, and deploying ML models. You can create a Kubeflow Pipeline built entirely using these components, or integrate individual components into your workflow as needed. The components are available in one or two versions. Each version of a component leverages a different backend. For more information on those versions, see SageMaker AI Components for Kubeflow Pipelines versions.

There is no additional charge for using SageMaker AI Components for Kubeflow Pipelines. You incur charges for any SageMaker AI resources you use through these components.

SageMaker AI Components for Kubeflow Pipelines versions

SageMaker AI Components for Kubeflow Pipelines come in two versions. Each version leverages a different backend to create and manage resources on SageMaker AI.

- The SageMaker AI Components for Kubeflow Pipelines version 1 (v1.x or below) use **Boto3** (Amazon SDK for Python (Boto3)) as backend.
- The version 2 (v2.0.0-alpha2 and above) of SageMaker AI Components for Kubeflow Pipelines use SageMaker AI Operator for Kubernetes (ACK).

  Amazon introduced ACK to facilitate a Kubernetes-native way of managing Amazon Cloud resources. ACK includes a set of Amazon service-specific controllers, one of which is the SageMaker AI controller. The SageMaker AI controller makes it easier for machine learning developers and data scientists using Kubernetes as their control plane to train, tune, and deploy machine learning (ML) models in SageMaker AI. For more information, see SageMaker AI Operators for Kubernetes

Both versions of the SageMaker AI Components for Kubeflow Pipelines are supported. However, the version 2 provides some additional advantages. In particular, it offers:

1. A consistent experience to manage your SageMaker AI resources from any application; whether you are using Kubeflow pipelines, or Kubernetes CLI (`kubectl`) or other Kubeflow applications such as Notebooks.
2. The flexibility to manage and monitor your SageMaker AI resources outside of the Kubeflow pipeline workflow.
3. Zero setup time to use the SageMaker AI components if you deployed the full Kubeflow on Amazon release since the SageMaker AI Operator is part of its deployment.

List of SageMaker AI Components for Kubeflow Pipelines

The following is a list of all SageMaker AI Components for Kubeflow Pipelines and their available versions. Alternatively, you can find all SageMaker AI Components for Kubeflow Pipelines in GitHub.

> **Note**
>
> We encourage users to utilize Version 2 of a SageMaker AI component wherever it is available.

Ground Truth components

- **Ground Truth**

  The Ground Truth component enables you to submit SageMaker AI Ground Truth labeling jobs directly from a Kubeflow Pipelines workflow.

Version 1 of the component	Version 2 of the component
SageMaker AI Ground Truth Kubeflow Pipelines component version 1	X

- **Workteam**

  The Workteam component enables you to create SageMaker AI private workteam jobs directly from a Kubeflow Pipelines workflow.

Version 1 of the component	Version 2 of the component
SageMaker AI create private workteam Kubeflow Pipelines component version 1	X

Data processing components

- **Processing**

  The Processing component enables you to submit processing jobs to SageMaker AI directly from a Kubeflow Pipelines workflow.

Version 1 of the component	Version 2 of the component
SageMaker Processing Kubeflow Pipeline component version 1	X

Training components

- **Training**

  The Training component allows you to submit SageMaker Training jobs directly from a Kubeflow Pipelines workflow.

Version 1 of the component	Version 2 of the component
SageMaker Training Kubeflow Pipelines component version 1	SageMaker Training Kubeflow Pipelines component version 2

- **Hyperparameter Optimization**

  The Hyperparameter Optimization component enables you to submit hyperparameter tuning jobs to SageMaker AI directly from a Kubeflow Pipelines workflow.

Version 1 of the component	Version 2 of the component
SageMaker AI hyperparameter optimization Kubeflow Pipeline component version 1	X

Inference components

- **Hosting Deploy**

  The Hosting components allow you to deploy a model using SageMaker AI hosting services from a Kubeflow Pipelines workflow.

Version 1 of the component	Version 2 of the component
SageMaker AI Hosting Services - Create Endpoint Kubeflow Pipeline component version 1.	Version 2 of the Hosting components consists of the three sub-components needed to create a hosting deployment on SageMaker AI. • A SageMaker AI Model Kubeflow Pipelines component version 2 responsible for the model artifacts and the model image registry path that contains the inference code. • A SageMaker AI Endpoint Configuration Kubeflow Pipelines component version 2 responsible for defining the configuration of the endpoint such as the instance type, models, number of instances, and serverless inference option. • A SageMaker AI Endpoint Kubeflow Pipelines component version 2 responsible for creating or updating the endpoint on SageMaker AI as specified in the endpoint configuration.

- **Batch Transform**

  The Batch Transform component allows you to run inference jobs for an entire dataset in SageMaker AI from a Kubeflow Pipelines workflow.

Version 1 of the component	Version 2 of the component
SageMaker AI Batch Transform Kubeflow Pipeline component version 1	X

- **Model Monitor**

The Model Monitor components allow you to monitor the quality of SageMaker AI machine learning models in production from a Kubeflow Pipelines workflow.

Version 1 of the component	Version 2 of the component
X	The Model Monitor components consist of four sub-components for monitoring drift in a model. • A SageMaker AI Data Quality Job Definition Kubeflow Pipelines component version 2 responsible for monitoring drift in data quality. • A SageMaker AI Model Quality Job Definition Kubeflow Pipelines component version 2 responsible for monitoring drift in model quality metrics. • A SageMaker AI Model Bias Job Definition Kubeflow Pipelines component version 2 responsible for monitoring bias in a model's predictions. • A SageMaker AI Model Explainability Job Definition Kubeflow Pipelines component version 2 responsible for monitoring drift in feature attribution. Additionally, for on-schedule monitoring at a specified frequency, a fifth component, SageMaker AI Monitoring Schedule Kubeflow Pipelines component version 2, is responsible for monitoring the data collected from a real-time endpoint on a schedule. For more information on Amazon SageMaker Model Monitor, see Data and model quality monitoring with Amazon SageMaker Model Monitor.

IAM permissions

Deploying Kubeflow Pipelines with SageMaker AI components requires the following three layers of authentication:

- An IAM role granting your gateway node (which can be your local machine or a remote instance) access to the Amazon Elastic Kubernetes Service (Amazon EKS) cluster.

  The user accessing the gateway node assumes this role to:
  - Create an Amazon EKS cluster and install KFP
  - Create IAM roles
  - Create Amazon S3 buckets for your sample input data

  The role requires the following permissions:
  - CloudWatchLogsFullAccess
  - AWSCloudFormationFullAccess
  - IAMFullAccess
  - AmazonS3FullAccess
  - AmazonEC2FullAccess
  - AmazonEKSAdminPolicy (Create this policy using the schema from Amazon EKS Identity-Based Policy Examples)
- A Kubernetes IAM execution role assumed by Kubernetes pipeline pods (**kfp-example-pod-role**) or the SageMaker AI Operator for Kubernetes controller pod to access SageMaker AI. This role is used to create and monitor SageMaker AI jobs from Kubernetes.

  The role requires the following permission:
  - AmazonSageMakerFullAccess

  You can limit permissions to the KFP and controller pods by creating and attaching your own custom policy.
- A SageMaker AI IAM execution role assumed by SageMaker AI jobs to access Amazon resources such as Amazon S3 or Amazon ECR (**kfp-example-sagemaker-execution-role**).

  SageMaker AI jobs use this role to:
  - Access SageMaker AI resources
  - Input Data from Amazon S3
  - Store your output model to Amazon S3

  The role requires the following permissions:

- AmazonSageMakerFullAccess
- AmazonS3FullAccess

Converting pipelines to use SageMaker AI

You can convert an existing pipeline to use SageMaker AI by porting your generic Python processing containers and training containers. If you are using SageMaker AI for inference, you also need to attach IAM permissions to your cluster and convert an artifact to a model.

Install Kubeflow Pipelines

Kubeflow Pipelines (KFP) is the pipeline orchestration component of Kubeflow.

You can deploy Kubeflow Pipelines (KFP) on an existing Amazon Elastic Kubernetes Service (Amazon EKS) or create a new Amazon EKS cluster. Use a gateway node to interact with your cluster. The gateway node can be your local machine or an Amazon EC2 instance.

The following section guides you through the steps to set up and configure these resources.

Topics

- Choose an installation option
- Configure your pipeline permissions to access SageMaker AI
- Access the KFP UI (Kubeflow Dashboard)

Choose an installation option

Kubeflow Pipelines is available as a core component of the full distribution of Kubeflow on Amazon or as a standalone installation.

Select the option that applies to your use case:

1. Full Kubeflow on Amazon Deployment

   To use other Kubeflow components in addition to Kubeflow Pipelines, choose the full Amazon distribution of Kubeflow deployment.
2. Standalone Kubeflow Pipelines Deployment

   To use the Kubeflow Pipelines without the other components of Kubeflow, install Kubeflow pipelines standalone.

Full Kubeflow on Amazon Deployment

To install the full release of Kubeflow on Amazon, choose the vanilla deployment option from Kubeflow on Amazon deployment guide or any other deployment option supporting integrations with various Amazon services (Amazon S3, Amazon RDS, Amazon Cognito).

Standalone Kubeflow Pipelines Deployment

This section assumes that your user has permissions to create roles and define policies for the role.

Set up a gateway node

You can use your local machine or an Amazon EC2 instance as your gateway node. A gateway node is used to create an Amazon EKS cluster and access the Kubeflow Pipelines UI.

Complete the following steps to set up your node.

1. **Create a gateway node.**

   You can use an existing Amazon EC2 instance or create a new instance with the latest Ubuntu 18.04 DLAMI version using the steps in Launching and Configuring a DLAMI.

2. **Create an IAM role to grant your gateway node access to Amazon resources.**

   Create an IAM role with permissions to the following resources: CloudWatch, Amazon CloudFormation, IAM, Amazon EC2, Amazon S3, Amazon EKS.

   Attach the following policies to the IAM role:

   - CloudWatchLogsFullAccess
   - AWSCloudFormationFullAccess
   - IAMFullAccess
   - AmazonS3FullAccess
   - AmazonEC2FullAccess
   - AmazonEKSAdminPolicy (Create this policy using the schema from Amazon EKS Identity-Based Policy Examples)

   For information on adding IAM permissions to an IAM role, see Adding and removing IAM identity permissions.

3. **Install the following tools and clients**

   Install and configure the following tools and resources on your gateway node to access the Amazon EKS cluster and KFP User Interface (UI).

   - Amazon CLI: The command line tool for working with Amazon services. For Amazon CLI configuration information, see Configuring the Amazon CLI.
   - aws-iam-authenticator version 0.1.31 and above: A tool to use Amazon IAM credentials to authenticate to a Kubernetes cluster.
   - `eksctl` version above 0.15: The command line tool for working with Amazon EKS clusters.
   - `kubectl`: The command line tool for working with Kubernetes clusters. The version needs to match your Kubernetes version within one minor version.
   - `Amazon SDK for Python (Boto3)`.

     ```
     pip install boto3
     ```

Set up an Amazon EKS cluster

1. If you do not have an existing Amazon EKS cluster, run the following steps from the command line of your gateway node, skip this step otherwise.

   a. Run the following command to create an Amazon EKS cluster with version 1.17 or above. Replace `<clustername>` with any name for your cluster.

      ```
      eksctl create cluster --name <clustername> --region us-east-1 --auto-kubeconfig
       --timeout=50m --managed --nodes=1
      ```

   b. When the cluster creation is complete, ensure that you have access to your cluster by listing the cluster's nodes.

      ```
      kubectl get nodes
      ```

2. Ensure that the current `kubectl` context points to your cluster with the following command. The current context is marked with an asterisk (*) in the output.

   ```
   kubectl config get-contexts

   CURRENT NAME     CLUSTER
   ```

```
*   <username>@<clustername>.us-east-1.eksctl.io   <clustername>.us-
east-1.eksctl.io
```

3. If the desired cluster is not configured as your current default, update the default with the following command.

```
aws eks update-kubeconfig --name <clustername> --region us-east-1
```

Install Kubeflow Pipelines

Run the following steps from the terminal of your gateway node to install Kubeflow Pipelines on your cluster.

1. Install all cert-manager components.

```
kubectl apply -f https://github.com/cert-manager/cert-manager/releases/download/
v1.9.1/cert-manager.yaml
```

2. Install the Kubeflow Pipelines.

```
export PIPELINE_VERSION=2.0.0-alpha.5
kubectl apply -k "github.com/kubeflow/pipelines/manifests/kustomize/env/cert-
manager/cluster-scoped-resources?ref=$KFP_VERSION"
kubectl wait --for condition=established --timeout=60s crd/applications.app.k8s.io
kubectl apply -k "github.com/kubeflow/pipelines/manifests/kustomize/env/cert-
manager/dev?ref=$KFP_VERSION"
```

3. Ensure that the Kubeflow Pipelines service and other related resources are running.

```
kubectl -n kubeflow get all | grep pipeline
```

Your output should look like the following.

```
pod/ml-pipeline-6b88c67994-kdtjv                     1/1     Running            0
          2d
pod/ml-pipeline-persistenceagent-64d74dfdbf-66stk    1/1     Running            0
          2d
pod/ml-pipeline-scheduledworkflow-65bdf46db7-5x9qj   1/1     Running            0
          2d
```

```
pod/ml-pipeline-ui-66cc4cffb6-cmsdb                   1/1     Running            0
         2d
pod/ml-pipeline-viewer-crd-6db65ccc4-wqlzj            1/1     Running            0
         2d
pod/ml-pipeline-visualizationserver-9c47576f4-bqmx4   1/1     Running            0
         2d

     2d
replicaset.apps/ml-pipeline-ui-66cc4cffb6                   1         1         1
     2d
replicaset.apps/ml-pipeline-viewer-crd-6db65ccc4            1         1         1
     2d
replicaset.apps/ml-pipeline-visualizationserver-9c47576f4   1         1         1
     2d
```

Configure your pipeline permissions to access SageMaker AI

In this section, you create an IAM execution role granting Kubeflow Pipeline pods access to SageMaker AI services.

Configuration for SageMaker AI components version 2

To run SageMaker AI Components version 2 for Kubeflow Pipelines, you need to install SageMaker AI Operator for Kubernetes and configure Role-Based Access Control (RBAC) allowing the Kubeflow Pipelines pods to create SageMaker AI custom resources in your Kubernetes cluster.

> **Important**
>
> Follow this section if you are using Kubeflow pipelines standalone deployment. If you are using Amazon distribution of Kubeflow version 1.6.0-aws-b1.0.0 or above, SageMaker AI components version 2 are already set up.

1. Install SageMaker AI Operator for Kubernetes to use SageMaker AI components version 2.

   Follow the *Setup* section of Machine Learning with ACK SageMaker AI Controller tutorial.
2. Configure RBAC permissions for the execution role (service account) used by Kubeflow Pipelines pods. In Kubeflow Pipelines standalone deployment, pipeline runs are executed in the namespace `kubeflow` using the `pipeline-runner` service account.

   a. Create a RoleBinding that gives the service account permission to manage SageMaker AI custom resources.

   ```
   cat > manage_sagemaker_cr.yaml <<EOF
   apiVersion: rbac.authorization.k8s.io/v1
   kind: RoleBinding
   metadata:
   name: manage-sagemaker-cr
   namespace: kubeflow
   subjects:
   - kind: ServiceAccount
   name: pipeline-runner
   namespace: kubeflow
   roleRef:
   kind: ClusterRole
   name: ack-sagemaker-controller
   apiGroup: rbac.authorization.k8s.io
   EOF
   ```

   ```
   kubectl apply -f manage_sagemaker_cr.yaml
   ```

b. Ensure that the rolebinding was created by running:

```
kubectl get rolebinding manage-sagemaker-cr -n kubeflow -o yaml
```

Configuration for SageMaker AI components version 1

To run SageMaker AI Components version 1 for Kubeflow Pipelines, the Kubeflow Pipeline pods need access to SageMaker AI.

> **Important**
>
> Follow this section whether you are using the full Kubeflow on Amazon deployment or Kubeflow Pilepines standalone.

To create an IAM execution role granting Kubeflow pipeline pods access to SageMaker AI, follow those steps:

1. Export your cluster name (e.g., *my-cluster-name*) and cluster region (e.g., *us-east-1*).

```
export CLUSTER_NAME=my-cluster-name
export CLUSTER_REGION=us-east-1
```

2. Export the namespace and service account name according to your installation.

   - For the full Kubeflow on Amazon installation, export your profile `namespace` (e.g., *kubeflow-user-example-com*) and *default-editor* as the service account.

```
export NAMESPACE=kubeflow-user-example-com
export KUBEFLOW_PIPELINE_POD_SERVICE_ACCOUNT=default-editor
```

   - For the standalone Pipelines deployment, export *kubeflow* as the `namespace` and *pipeline-runner* as the service account.

```
export NAMESPACE=kubeflow
export KUBEFLOW_PIPELINE_POD_SERVICE_ACCOUNT=pipeline-runner
```

3. Create an IAM OIDC provider for the Amazon EKS cluster with the following command.

```
eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} \
            --region ${CLUSTER_REGION} --approve
```

4. Create an IAM execution role for the KFP pods to access Amazon services (SageMaker AI, CloudWatch).

```
eksctl create iamserviceaccount \
--name ${KUBEFLOW_PIPELINE_POD_SERVICE_ACCOUNT} \
--namespace ${NAMESPACE} --cluster ${CLUSTER_NAME} \
--region ${CLUSTER_REGION} \
--attach-policy-arn arn:aws:iam::aws:policy/AmazonSageMakerFullAccess \
--attach-policy-arn arn:aws:iam::aws:policy/CloudWatchLogsFullAccess \
--override-existing-serviceaccounts \
--approve
```

Once your pipeline permissions are configured to access SageMaker AI Components version 1, follow the SageMaker AI components for Kubeflow pipelines guide on the Kubeflow on Amazon documentation.

Access the KFP UI (Kubeflow Dashboard)

The Kubeflow Pipelines UI is used for managing and tracking experiments, jobs, and runs on your cluster. For instructions on how to access the Kubeflow Pipelines UI from your gateway node, follow the steps that apply to your deployment option in this section.

Full Kubeflow on Amazon Deployment

Follow the instructions on the Kubeflow on Amazon website to connect to the Kubeflow dashboard and navigate to the pipelines tab.

Standalone Kubeflow Pipelines Deployment

Use port forwarding to access the Kubeflow Pipelines UI from your gateway node by following those steps.

Set up port forwarding to the KFP UI service

Run the following command from the command line of your gateway node.

1. Verify that the KFP UI service is running using the following command.

```
kubectl -n kubeflow get service ml-pipeline-ui

NAME             TYPE        CLUSTER-IP     EXTERNAL-IP   PORT(S)   AGE
ml-pipeline-ui   ClusterIP   10.100.38.71   <none>        80/TCP    2d22h
```

2. Run the following command to set up port forwarding to the KFP UI service. This forwards the KFP UI to port 8080 on your gateway node and allows you to access the KFP UI from your browser.

   ```
   kubectl port-forward -n kubeflow service/ml-pipeline-ui 8080:80
   ```

   The port forward from your remote machine drops if there is no activity. Run this command again if your dashboard is unable to get logs or updates. If the commands return an error, ensure that there is no process already running on the port you are trying to use.

Access the KFP UI service

Your method of accessing the KFP UI depends on your gateway node type.

- Local machine as the gateway node:

  1. Access the dashboard in your browser as follows:

     ```
     http://localhost:8080
     ```

  2. Choose **Pipelines** to access the pipelines UI.

- Amazon EC2 instance as the gateway node:

  1. You need to set up an SSH tunnel on your Amazon EC2 instance to access the Kubeflow dashboard from your local machine's browser.

     From a new terminal session in your local machine, run the following. Replace <public-DNS-of-gateway-node> with the IP address of your instance found on the Amazon EC2 console. You can also use the public DNS. Replace <path_to_key> with the path to the pem key used to access the gateway node.

     ```
     public_DNS_address=<public-DNS-of-gateway-node>
     key=<path_to_key>
     ```

```
on Ubuntu:
ssh -i ${key} -L 9000:localhost:8080 ubuntu@${public_DNS_address}

or on Amazon Linux:
ssh -i ${key} -L 9000:localhost:8080 ec2-user@${public_DNS_address}
```

2. Access the dashboard in your browser.

```
http://localhost:9000
```

3. Choose **Pipelines** to access the KFP UI.

(Optional) Grant SageMaker AI notebook instances access to Amazon EKS, and run KFP pipelines from your notebook.

A SageMaker notebook instance is a fully managed Amazon EC2 compute instance that runs the Jupyter Notebook App. You can use a notebook instance to create and manage Jupyter notebooks then define, compile, deploy, and run your KFP pipelines using Amazon SDK for Python (Boto3) or the KFP CLI.

1. Follow the steps in Create a SageMaker Notebook Instance to create your notebook instance, then attach the `S3FullAccess` policy to its IAM execution role.
2. From the command line of your gateway node, run the following command to retrieve the IAM role ARN of the notebook instance you created. Replace `<instance-name>` with the name of your instance.

```
aws sagemaker describe-notebook-instance --notebook-instance-name <instance-name>
 --region <region> --output text --query 'RoleArn'
```

   This command outputs the IAM role ARN in the `arn:aws:iam::<account-id>:role/<role-name>` format. Take note of this ARN.

3. Run this command to attach the following policies (AmazonSageMakerFullAccess, AmazonEKSWorkerNodePolicy, AmazonS3FullAccess) to this IAM role. Replace `<role-name>` with the `<role-name>` in your ARN.

```
aws iam attach-role-policy --role-name <role-name> --policy-arn
 arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
aws iam attach-role-policy --role-name <role-name> --policy-arn
 arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
```

```
aws iam attach-role-policy --role-name <role-name> --policy-arn
 arn:aws:iam::aws:policy/AmazonS3FullAccess
```

4. Amazon EKS clusters use IAM roles to control access to the cluster. The rules are implemented in a config map named `aws-auth`. `eksctl` provides commands to read and edit the `aws-auth` config map. Only the users that have access to the cluster can edit this config map.

   `system:masters` is one of the default user groups with super user permissions to the cluster. Add your user to this group or create a group with more restrictive permissions.

5. Bind the role to your cluster by running the following command. Replace `<IAM-Role-arn>` with the ARN of the IAM role. `<your_username>` can be any unique username.

   ```
   eksctl create iamidentitymapping \
   --cluster <cluster-name> \
   --arn <IAM-Role-arn> \
   --group system:masters \
   --username <your-username> \
   --region <region>
   ```

6. Open a Jupyter notebook on your SageMaker AI instance and run the following command to ensure that it has access to the cluster.

   ```
   aws eks --region <region> update-kubeconfig --name <cluster-name>
   kubectl -n kubeflow get all | grep pipeline
   ```

Use SageMaker AI components

In this tutorial, you run a pipeline using SageMaker AI Components for Kubeflow Pipelines to train a classification model using Kmeans with the MNIST dataset on SageMaker AI. The workflow uses Kubeflow Pipelines as the orchestrator and SageMaker AI to execute each step of the workflow. The example was taken from an existing SageMaker AI example and modified to work with SageMaker AI Components for Kubeflow Pipelines.

You can define your pipeline in Python using Amazon SDK for Python (Boto3) then use the KFP dashboard, KFP CLI, or Boto3 to compile, deploy, and run your workflows. The full code for the MNIST classification pipeline example is available in the Kubeflow Github repository. To use it, clone the Python files to your gateway node.

You can find additional SageMaker AI Kubeflow Pipelines examples on GitHub. For information on the components used, see the KubeFlow Pipelines GitHub repository.

To run the classification pipeline example, create a SageMaker AI IAM execution role granting your training job the permission to access Amazon resources, then continue with the steps that correspond to your deployment option.

Create a SageMaker AI execution role

The `kfp-example-sagemaker-execution-role` IAM role is a runtime role assumed by SageMaker AI jobs to access Amazon resources. In the following command, you create an IAM execution role named `kfp-example-sagemaker-execution-role`, attach two managed policies (AmazonSageMakerFullAccess, AmazonS3FullAccess), and create a trust relationship with SageMaker AI to grant SageMaker AI jobs access to those Amazon resources.

You provide this role as an input parameter when running the pipeline.

Run the following command to create the role. Note the ARN that is returned in your output.

```
SAGEMAKER_EXECUTION_ROLE_NAME=kfp-example-sagemaker-execution-role

TRUST="{ \"Version\": \"2012-10-17       \", \"Statement\": [ { \"Effect\": \"Allow
\", \"Principal\": { \"Service\": \"sagemaker.amazonaws.com\" }, \"Action\":
 \"sts:AssumeRole\" } ] }"
aws iam create-role --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --assume-role-policy-
document "$TRUST"
aws iam attach-role-policy --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --policy-arn
 arn:aws:iam::aws:policy/AmazonSageMakerFullAccess
aws iam attach-role-policy --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --policy-arn
 arn:aws:iam::aws:policy/AmazonS3FullAccess

aws iam get-role --role-name ${SAGEMAKER_EXECUTION_ROLE_NAME} --output text --query
 'Role.Arn'
```

Full Kubeflow on Amazon Deployment

Follow the instructions of the SageMaker Training Pipeline tutorial for MNIST Classification with K-Means.

Standalone Kubeflow Pipelines Deployment

Prepare datasets

To run the pipelines, you need to upload the data extraction pre-processing script to an Amazon S3 bucket. This bucket and all resources for this example must be located in the `us-east-1` region. For information on creating a bucket, see Creating a bucket.

From the `mnist-kmeans-sagemaker` folder of the Kubeflow repository you cloned on your gateway node, run the following command to upload the `kmeans_preprocessing.py` file to your Amazon S3 bucket. Change `<bucket-name>` to the name of your Amazon S3 bucket.

```
aws s3 cp mnist-kmeans-sagemaker/kmeans_preprocessing.py s3://<bucket-name>/
mnist_kmeans_example/processing_code/kmeans_preprocessing.py
```

Compile and deploy your pipeline

After defining the pipeline, you must compile it to an intermediate representation before you submit it to the Kubeflow Pipelines service on your cluster. The intermediate representation is a workflow specification in the form of a YAML file compressed into a tar.gz file. You need the KFP SDK to compile your pipeline.

Install KFP SDK

Run the following from the command line of your gateway node:

1. Install the KFP SDK following the instructions in the Kubeflow pipelines documentation.
2. Verify that the KFP SDK is installed with the following command:

   ```
   pip show kfp
   ```

3. Verify that `dsl-compile` has been installed correctly as follows:

   ```
   which dsl-compile
   ```

Compile your pipeline

You have three options to interact with Kubeflow Pipelines: KFP UI, KFP CLI, or the KFP SDK. The following sections illustrate the workflow using the KFP UI and CLI.

Complete the following steps from your gateway node.

1. Modify your Python file with your Amazon S3 bucket name and IAM role ARN.
2. Use the `dsl-compile` command from the command line to compile your pipeline as follows. Replace `<path-to-python-file>` with the path to your pipeline and `<path-to-output>` with the location where you want your tar.gz file to be.

```
dsl-compile --py <path-to-python-file> --output <path-to-output>
```

Upload and run the pipeline using the KFP CLI

Complete the following steps from the command line of your gateway node. KFP organizes runs of your pipeline as experiments. You have the option to specify an experiment name. If you do not specify one, the run will be listed under **Default** experiment.

1. Upload your pipeline as follows:

```
kfp pipeline upload --pipeline-name <pipeline-name> <path-to-output-tar.gz>
```

Your output should look like the following. Take note of the pipeline `ID`.

```
Pipeline 29c3ff21-49f5-4dfe-94f6-618c0e2420fe has been submitted

Pipeline Details
------------------
ID           29c3ff21-49f5-4dfe-94f6-618c0e2420fe
Name         sm-pipeline
Description
Uploaded at  2020-04-30T20:22:39+00:00
...
...
```

2. Create a run using the following command. The KFP CLI run command currently does not support specifying input parameters while creating the run. You need to update your parameters in the Amazon SDK for Python (Boto3) pipeline file before compiling. Replace `<experiment-name>` and `<job-name>` with any names. Replace `<pipeline-id>` with the ID of your submitted pipeline. Replace `<your-role-arn>` with the ARN of `kfp-example-pod-role`. Replace `<your-bucket-name>` with the name of the Amazon S3 bucket you created.

```
kfp run submit --experiment-name <experiment-name> --run-name <job-name> --
pipeline-id <pipeline-id> role_arn="<your-role-arn>" bucket_name="<your-bucket-
name>"
```

You can also directly submit a run using the compiled pipeline package created as the output of the `dsl-compile` command.

```
kfp run submit --experiment-name <experiment-name> --run-name <job-name> --package-
file <path-to-output> role_arn="<your-role-arn>" bucket_name="<your-bucket-name>"
```

Your output should look like the following:

```
Creating experiment aws.
Run 95084a2c-f18d-4b77-a9da-eba00bf01e63 is submitted
+--------------------------------------+--------+----------
+--------------------------+
| run id                               | name   | status   | created at
    |
+======================================+========+==========
+==========================+
| 95084a2c-f18d-4b77-a9da-eba00bf01e63 | sm-job |          |
 2020-04-30T20:36:41+00:00 |
+--------------------------------------+--------+----------
+--------------------------+
```

3. Navigate to the UI to check the progress of the job.

Upload and run the pipeline using the KFP UI

1. On the left panel, choose the **Pipelines** tab.
2. In the upper-right corner, choose **+UploadPipeline**.
3. Enter the pipeline name and description.
4. Choose **Upload a file** and enter the path to the tar.gz file you created using the CLI or with Amazon SDK for Python (Boto3).
5. On the left panel, choose the **Pipelines** tab.
6. Find the pipeline you created.
7. Choose **+CreateRun**.

8. Enter your input parameters.
9. Choose **Run**.

Run predictions

Once your classification pipeline is deployed, you can run classification predictions against the endpoint that was created by the Deploy component. Use the KFP UI to check the output artifacts for `sagemaker-deploy-model-endpoint_name`. Download the .tgz file to extract the endpoint name or check the SageMaker AI console in the region you used.

Configure permissions to run predictions

If you want to run predictions from your gateway node, skip this section.

To use any other machine to run predictions, assign the `sagemaker:InvokeEndpoint` permission to the IAM role used by the client machine.

1. On your gateway node, run the following to create an IAM policy file:

```
cat <<EoF > ./sagemaker-invoke.json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sagemaker:InvokeEndpoint"
            ],
            "Resource": "*"
        }
    ]
}
EoF
```

2. Attach the policy to the IAM role of the client node.

   Run the following command. Replace <your-instance-IAM-role> with the name of the IAM role. Replace <path-to-sagemaker-invoke-json> with the path to the policy file you created.

```
aws iam put-role-policy --role-name <your-instance-IAM-role> --policy-name
 sagemaker-invoke-for-worker --policy-document file://<path-to-sagemaker-invoke-
json>
```

Run predictions

1. Create a Amazon SDK for Python (Boto3) file from your client machine named `mnist-predictions.py` with the following content. Replace the `ENDPOINT_NAME` variable. The script loads the MNIST dataset, creates a CSV from those digits, then sends the CSV to the endpoint for prediction and prints the results.

```
import boto3
import gzip
import io
import json
import numpy
import pickle

ENDPOINT_NAME='<endpoint-name>'
region = boto3.Session().region_name

# S3 bucket where the original mnist data is downloaded and stored
downloaded_data_bucket = f"jumpstart-cache-prod-{region}"
downloaded_data_prefix = "1p-notebooks-datasets/mnist"

# Download the dataset
s3 = boto3.client("s3")
s3.download_file(downloaded_data_bucket, f"{downloaded_data_prefix}/mnist.pkl.gz",
 "mnist.pkl.gz")

# Load the dataset
with gzip.open('mnist.pkl.gz', 'rb') as f:
    train_set, valid_set, test_set = pickle.load(f, encoding='latin1')

# Simple function to create a csv from our numpy array
def np2csv(arr):
    csv = io.BytesIO()
    numpy.savetxt(csv, arr, delimiter=',', fmt='%g')
    return csv.getvalue().decode().rstrip()
```

```
runtime = boto3.Session(region).client('sagemaker-runtime')

payload = np2csv(train_set[0][30:31])

response = runtime.invoke_endpoint(EndpointName=ENDPOINT_NAME,
                                   ContentType='text/csv',
                                   Body=payload)
result = json.loads(response['Body'].read().decode('utf-8'))
print(result)
```

2. Run the Amazon SDK for Python (Boto3) file as follows:

```
python mnist-predictions.py
```

View results and logs

When the pipeline is running, you can choose any component to check execution details, such as inputs and outputs. This lists the names of created resources.

If the KFP request is successfully processed and an SageMaker AI job is created, the component logs in the KFP UI provide a link to the job created in SageMaker AI. The CloudWatch logs are also provided if the job is successfully created.

If you run too many pipeline jobs on the same cluster, you may see an error message that indicates that you do not have enough pods available. To fix this, log in to your gateway node and delete the pods created by the pipelines you are not using:

```
kubectl get pods -n kubeflow
kubectl delete pods -n kubeflow <name-of-pipeline-pod>
```

Cleanup

When you're finished with your pipeline, you need to clean up your resources.

1. From the KFP dashboard, terminate your pipeline runs if they do not exit properly by choosing **Terminate**.
2. If the **Terminate** option doesn't work, log in to your gateway node and manually terminate all the pods created by your pipeline run as follows:

```
kubectl get pods -n kubeflow
```

```
kubectl delete pods -n kubeflow <name-of-pipeline-pod>
```

3. Using your Amazon account, log in to the SageMaker AI service. Manually stop all training, batch transform, and HPO jobs. Delete models, data buckets, and endpoints to avoid incurring any additional costs. Terminating the pipeline runs does not stop the jobs in SageMaker AI.

SageMaker Notebook Jobs

You can use Amazon SageMaker AI to interactively build, train, and deploy machine learning models from your Jupyter notebook in any JupyterLab environment. However, there are various scenarios in which you might want to run your notebook as a noninteractive, scheduled job. For example, you might want to create regular audit reports that analyze all training jobs run over a certain time frame and analyze the business value of deploying those models into production. Or you might want to scale up a feature engineering job after testing the data transformation logic on a small subset of data. Other common use cases include:

- Scheduling jobs for model drift monitoring
- Exploring the parameter space for better models

In these scenarios, you can use SageMaker Notebook Jobs to create a noninteractive job (which SageMaker AI runs as an underlying training job) to either run on demand or on a schedule. SageMaker Notebook Jobs provides an intuitive user interface so you can schedule your jobs right from JupyterLab by choosing the Notebook Jobs widget () in your notebook. You can also schedule your jobs using the SageMaker AI Python SDK, which offers the flexibility of scheduling multiple notebook jobs in a pipeline workflow. You can run multiple notebooks in parallel, and parameterize cells in your notebooks to customize the input parameters.

This feature leverages the Amazon EventBridge, SageMaker Training and Pipelines services and is available for use in your Jupyter notebook in any of the following environments:

- Studio, Studio Lab, Studio Classic, or Notebook Instances
- Local setup, such as your local machine, where you run JupyterLab

Prerequisites

To schedule a notebook job, make sure you meet the following criteria:

- Ensure your Jupyter notebook and any initialization or startup scripts are self-contained with respect to code and software packages. Otherwise, your noninteractive job may incur errors.
- Review Constraints and considerations to make sure you properly configured your Jupyter notebook, network settings, and container settings.
- Ensure your notebook can access needed external resources, such as Amazon EMR clusters.
- If you are setting up Notebook Jobs in a local Jupyter notebook, complete the installation. For instructions, see Installation guide.
- If you connect to an Amazon EMR cluster in your notebook and want to parameterize your Amazon EMR connection command, you must apply a workaround using environment variables to pass parameters. For details, see Connect to an Amazon EMR cluster from your notebook.
- If you connect to an Amazon EMR cluster using Kerberos, LDAP, or HTTP Basic Auth authentication, you must use the Amazon Secrets Manager to pass your security credentials to your Amazon EMR connection command. For details, see Connect to an Amazon EMR cluster from your notebook.
- (optional) If you want the UI to preload a script to run upon notebook startup, your admin must install it with a Lifecycle Configuration (LCC). For information about how to use a LCC script, see Customize a Notebook Instance Using a Lifecycle Configuration Script.

Installation guide

The following provides information about what you need to install to use Notebook Jobs in your JupyterLab environment.

For Amazon SageMaker Studio and Amazon SageMaker Studio Lab

If your notebook is in Amazon SageMaker Studio or Amazon SageMaker Studio Lab, you don't need to perform additional installation—SageMaker Notebook Jobs is built into the platform. To set up required permissions for Studio, see Set up policies and permissions for Studio.

For local Jupyter notebooks

If you want to use SageMaker Notebook Jobs for your local JupyterLab environment, you need to perform additional installation.

To install SageMaker Notebook Jobs, complete the following steps:

1. Install Python 3. For details, see Installing Python 3 and Python Packages.
2. Install JupyterLab version 4 or higher. For details, see JupyterLab SDK documentation.
3. Install the Amazon CLI. For details, see Installing or updating the latest version of the Amazon CLI.
4. Install two sets of permissions. The IAM user needs permissions to submit jobs to SageMaker AI, and once submitted, the notebook job itself assumes an IAM role that needs permissions to access resources depending on the job tasks.

   a. If you haven't yet created an IAM user, see Creating an IAM user in your Amazon account.

   b. If you haven't yet created your notebook job role, see Creating a role to delegate permissions to an IAM user.

   c. Attach the necessary permissions and trust policy to attach to your user and role. For step-by-step instructions and permission details, see Install policies and permissions for local Jupyter environments.
5. Generate Amazon credentials for your newly-created IAM user and save them in the credentials file (~/.aws/credentials) of your JupyterLab environment. You can do this with the CLI command `aws configure`. For instructions, see section *Set and view configuration settings using commands* in Configuration and credential file settings.
6. (optional) By default, the scheduler extension uses a pre-built SageMaker AI Docker image with Python 2.0. Any non-default kernel used in the notebook should be installed in the container. If you want to run your notebook in a container or Docker image, you need to create an Amazon Elastic Container Registry (Amazon ECR) image. For information about how to push a Docker image to an Amazon ECR, see Pushing a Docker Image.
7. Add the JupyterLab extension for SageMaker Notebook Jobs. You can add it to your JupyterLab environment with the command: `pip install amazon_sagemaker_jupyter_scheduler`. You may need to restart your Jupyter server with the command:`sudo systemctl restart jupyter-server`.
8. Start JupyterLab with the command: `jupyter lab`.
9. Verify that the Notebook Jobs widget () appears in your Jupyter notebook taskbar.

Set up policies and permissions for Studio

You will need to install the proper policies and permissions before you schedule your first notebook run. The following provides instructions on setting up the following permissions:

- Job execution role trust relationships
- Additional IAM permissions attached to the job execution role
- (optional) The Amazon KMS permission policy to use a custom KMS key

> **Important**
>
> If your Amazon account belongs to an organization with service control policies (SCP) in place, your effective permissions are the logical intersection between what is allowed by the SCPs and what is allowed by your IAM role and user policies. For example, if your organization's SCP specifies that you can only access resources in `us-east-1` and `us-west-1`, and your policies only allow you to access resources in `us-west-1` and `us-west-2`, then ultimately you can only access resources in `us-west-1`. If you want to exercise all the permissions allowed in your role and user policies, your organization's SCPs should grant the same set of permissions as your own IAM user and role policies. For details about how to determine your allowed requests, see Determining whether a request is allowed or denied within an account.

Trust relationships

To modify the trust relationships, complete the following steps:

1. Open the IAM console.
2. Select **Roles** in the left panel.
3. Find the job execution role for your notebook job and choose the role name.
4. Choose the **Trust relationships** tab.
5. Choose **Edit trust policy**.
6. Copy and paste the following policy:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "sagemaker.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        },
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "events.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

7. Choose **Update Policy**.

Additional IAM permissions

You might need to include additional IAM permissions in the following situations:

- Your Studio execution and notebook job roles differ
- You need to access Amazon S3 resources through a S3 VPC endpoint
- You want to use a custom KMS key to encrypt your input and output Amazon S3 buckets

The following discussion provides the policies you need for each case.

Permissions needed if your Studio execution and notebook job roles differ

The following JSON snippet is an example policy that you should add to the Studio execution and notebook job roles if you don't use the Studio execution role as the notebook job role. Review and modify this policy if you need to further restrict privileges.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":"iam:PassRole",
         "Resource":"arn:aws-cn:iam::*:role/*",
         "Condition":{
            "StringLike":{
               "iam:PassedToService":[
                  "sagemaker.amazonaws.com",
                  "events.amazonaws.com"
               ]
            }
         }
      },
      {
         "Effect":"Allow",
         "Action":[
            "events:TagResource",
            "events:DeleteRule",
            "events:PutTargets",
            "events:DescribeRule",
            "events:PutRule",
            "events:RemoveTargets",
            "events:DisableRule",
            "events:EnableRule"
         ],
         "Resource":"*",
         "Condition":{
            "StringEquals":{
               "aws:ResourceTag/sagemaker:is-scheduling-notebook-job":"true"
            }
         }
      },
      {
         "Effect":"Allow",
         "Action":[
            "s3:CreateBucket",
            "s3:PutBucketVersioning",
            "s3:PutEncryptionConfiguration"
```

```
            ],
            "Resource":"arn:aws-cn:s3:::sagemaker-automated-execution-*"
        },
        {
            "Sid": "S3DriverAccess",
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:GetObject",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws-cn:s3:::sagemakerheadlessexecution-*"
            ]
        },
        {
            "Effect":"Allow",
            "Action":[
                "sagemaker:ListTags"
            ],
            "Resource":[
                "arn:aws-cn:sagemaker:*:*:user-profile/*",
                "arn:aws-cn:sagemaker:*:*:space/*",
                "arn:aws-cn:sagemaker:*:*:training-job/*",
                "arn:aws-cn:sagemaker:*:*:pipeline/*"
            ]
        },
        {
            "Effect":"Allow",
            "Action":[
                "sagemaker:AddTags"
            ],
            "Resource":[
                "arn:aws-cn:sagemaker:*:*:training-job/*",
                "arn:aws-cn:sagemaker:*:*:pipeline/*"
            ]
        },
        {
            "Effect":"Allow",
            "Action":[
                "ec2:DescribeDhcpOptions",
                "ec2:DescribeNetworkInterfaces",
                "ec2:DescribeRouteTables",
                "ec2:DescribeSecurityGroups",
```

```
            "ec2:DescribeSubnets",
            "ec2:DescribeVpcEndpoints",
            "ec2:DescribeVpcs",
            "ecr:BatchCheckLayerAvailability",
            "ecr:BatchGetImage",
            "ecr:GetDownloadUrlForLayer",
            "ecr:GetAuthorizationToken",
            "s3:ListBucket",
            "s3:GetBucketLocation",
            "s3:GetEncryptionConfiguration",
            "s3:PutObject",
            "s3:DeleteObject",
            "s3:GetObject",
            "sagemaker:DescribeApp",
            "sagemaker:DescribeDomain",
            "sagemaker:DescribeUserProfile",
            "sagemaker:DescribeSpace",
            "sagemaker:DescribeStudioLifecycleConfig",
            "sagemaker:DescribeImageVersion",
            "sagemaker:DescribeAppImageConfig",
            "sagemaker:CreateTrainingJob",
            "sagemaker:DescribeTrainingJob",
            "sagemaker:StopTrainingJob",
            "sagemaker:Search",
            "sagemaker:CreatePipeline",
            "sagemaker:DescribePipeline",
            "sagemaker:DeletePipeline",
            "sagemaker:StartPipelineExecution"
        ],
        "Resource":"*"
    }
  ]
}
```

Permissions needed to access Amazon S3 resources through a S3 VPC endpoint

If you run SageMaker Studio in private VPC mode and access S3 through the S3 VPC endpoint, you can add permissions to the VPC endpoint policy to control which S3 resources are accessible through the VPC endpoint. Add the following permissions to your VPC endpoint policy. You can modify the policy if you need to further restrict permissions—for example, you can provide a more narrow specification for the `Principal` field.

```
{
    "Sid": "S3DriverAccess",
    "Effect": "Allow",
    "Principal": "*",
    "Action": [
        "s3:GetBucketLocation",
        "s3:GetObject",
        "s3:ListBucket"
    ],
    "Resource": "arn:aws:s3:::sagemakerheadlessexecution-*"
}
```

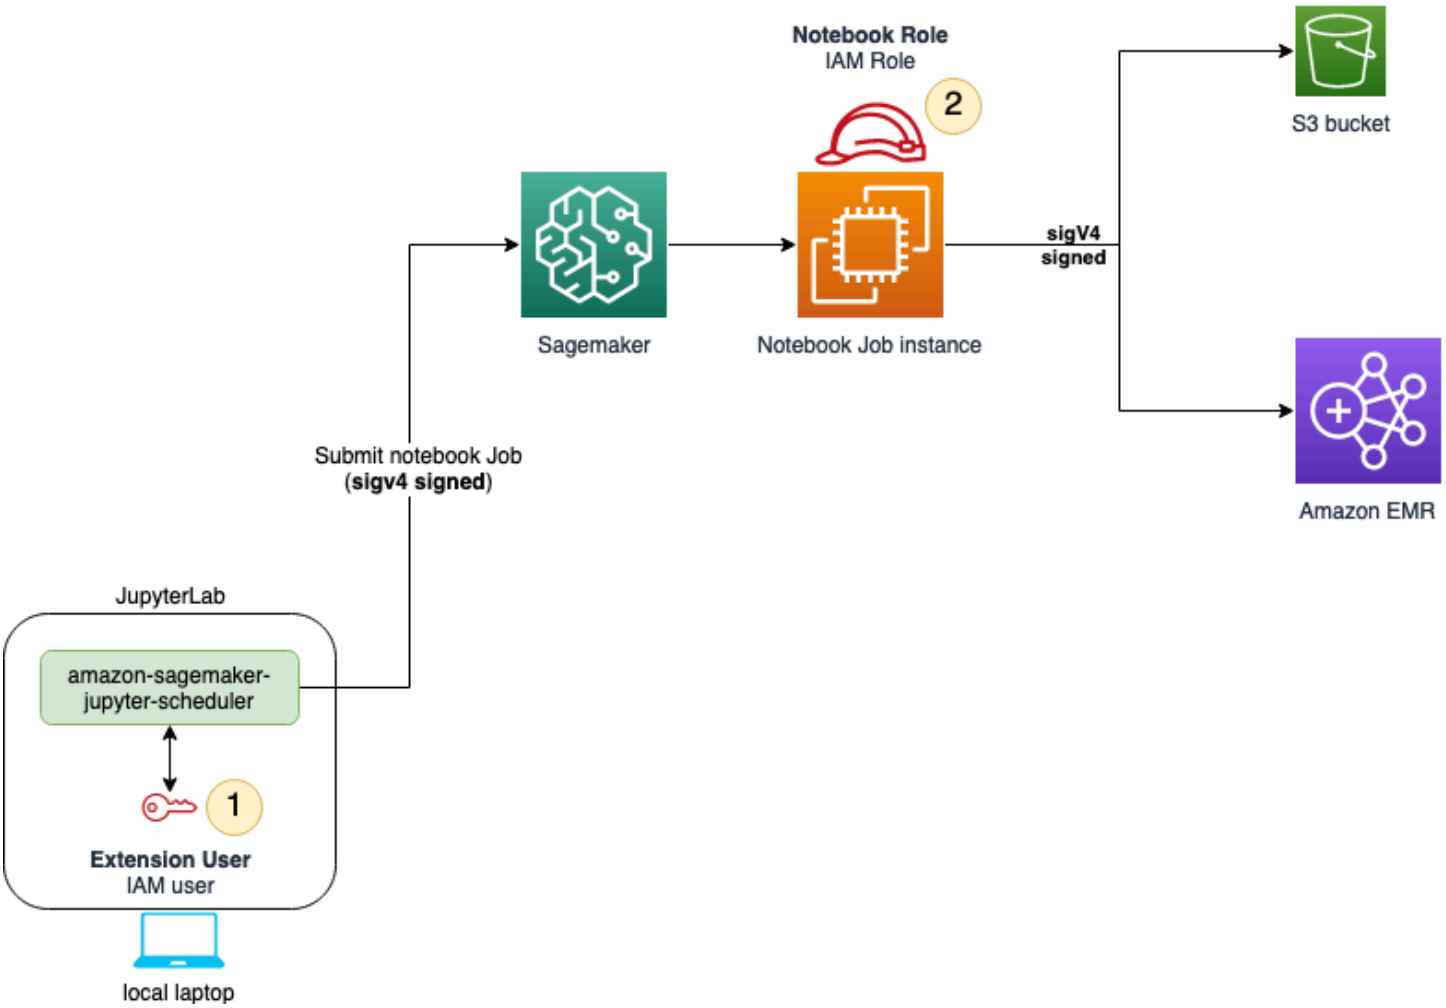
For details about how to set up a S3 VPC endpoint policy, see Edit the VPC endpoint policy.

Permissions needed to use a custom KMS key (optional)

By default, the input and output Amazon S3 buckets are encrypted using server side encryption, but you can specify a custom KMS key to encrypt your data in the output Amazon S3 bucket and the storage volume attached to the notebook job.

If you want to use a custom KMS key, attach the following policy and supply your own KMS key ARN.

JSON



```
{
    "Version":"2012-10-17",
    "Statement": [
      {
         "Effect":"Allow",
         "Action":[
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:ReEncrypt*",
            "kms:GenerateDataKey*",
            "kms:DescribeKey",
            "kms:CreateGrant"
         ],
         "Resource":"arn:aws-cn:kms:us-east-1:111122223333:key/key-id"
      }
   ]
```

```
}
```

Install policies and permissions for local Jupyter environments

You will need to set up the necessary permissions and policies to schedule notebook jobs in a local Jupyter environment. The IAM user needs permissions to submit jobs to SageMaker AI and the IAM role that the notebook job itself assumes needs permissions to access resources, depending on the job tasks. The following will provide instructions on how to set up the necessary permissions and policies.

You will need to install two sets of permissions. The following diagram shows the permission structure for you to schedule notebook jobs in a local Jupyter environment. The IAM user needs to set up IAM permissions in order to submit jobs to SageMaker AI. Once the user submits the notebook job, the job itself assumes an IAM role that has permissions to access resources depending on the job tasks.

The following sections help you install necessary policies and permissions for both the IAM user and the job execution role.

IAM user permissions

Permissions to submit jobs to SageMaker AI

To add permissions to submit jobs, complete the following steps:

1. Open the IAM console.
2. Select **Users** in the left panel.
3. Find the IAM user for your notebook job and choose the user name.
4. Choose **Add Permissions**, and choose **Create inline policy** from the dropdown menu.
5. Choose the **JSON** tab.
6. Copy and paste the following policy:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "EventBridgeSchedule",
            "Effect": "Allow",
            "Action": [
                "events:TagResource",
                "events:DeleteRule",
                "events:PutTargets",
                "events:DescribeRule",
                "events:EnableRule",
                "events:PutRule",
                "events:RemoveTargets",
                "events:DisableRule"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/sagemaker:is-scheduling-notebook-job":
 "true"
                }
            }
```

```
        },
        {
            "Sid": "IAMPassrole",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws-cn:iam::*:role/*",
            "Condition": {
                "StringLike": {
                    "iam:PassedToService": [
                        "sagemaker.amazonaws.com",
                        "events.amazonaws.com"
                    ]
                }
            }
        },
        {
            "Sid": "IAMListRoles",
            "Effect": "Allow",
            "Action": "iam:ListRoles",
            "Resource": "*"
        },
        {
            "Sid": "S3ArtifactsAccess",
            "Effect": "Allow",
            "Action": [
                "s3:PutEncryptionConfiguration",
                "s3:CreateBucket",
                "s3:PutBucketVersioning",
                "s3:ListBucket",
                "s3:PutObject",
                "s3:GetObject",
                "s3:GetEncryptionConfiguration",
                "s3:DeleteObject",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws-cn:s3:::sagemaker-automated-execution-*"
            ]
        },
        {
            "Sid": "S3DriverAccess",
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
```

```
                "s3:GetObject",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws-cn:s3:::sagemakerheadlessexecution-*"
            ]
        },
        {
            "Sid": "SagemakerJobs",
            "Effect": "Allow",
            "Action": [
                "sagemaker:DescribeTrainingJob",
                "sagemaker:StopTrainingJob",
                "sagemaker:DescribePipeline",
                "sagemaker:CreateTrainingJob",
                "sagemaker:DeletePipeline",
                "sagemaker:CreatePipeline"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/sagemaker:is-scheduling-notebook-job":
"true"
                }
            }
        },
        {
            "Sid": "AllowSearch",
            "Effect": "Allow",
            "Action": "sagemaker:Search",
            "Resource": "*"
        },
        {
            "Sid": "SagemakerTags",
            "Effect": "Allow",
            "Action": [
                "sagemaker:ListTags",
                "sagemaker:AddTags"
            ],
            "Resource": [
                "arn:aws-cn:sagemaker:*:*:pipeline/*",
                "arn:aws-cn:sagemaker:*:*:space/*",
                "arn:aws-cn:sagemaker:*:*:training-job/*",
                "arn:aws-cn:sagemaker:*:*:user-profile/*"
```

```
            ]
        },
        {
            "Sid": "ECRImage",
            "Effect": "Allow",
            "Action": [
                "ecr:GetAuthorizationToken",
                "ecr:BatchGetImage"
            ],
            "Resource": "*"
        }
    ]
}
```

Amazon KMS permission policy (optional)

By default, the input and output Amazon S3 buckets are encrypted using server side encryption, but you can specify a custom KMS key to encrypt your data in the output Amazon S3 bucket and the storage volume attached to the notebook job.

If you want to use a custom KMS key, repeat the previous instructions, attaching the following policy, and supply your own KMS key ARN.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
      {
         "Effect":"Allow",
         "Action":[
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:ReEncrypt*",
            "kms:GenerateDataKey*",
            "kms:DescribeKey",
            "kms:CreateGrant"
         ],
         "Resource":"arn:aws-cn:kms:us-east-1:111122223333:key/key-id"
      }
   ]
```

```
}
```

Job execution role permissions

Trust relationships

To modify the job execution role trust relationships, complete the following steps:

1. Open the IAM console.
2. Select **Roles** in the left panel.
3. Find the job execution role for your notebook job and choose the role name.
4. Choose the **Trust relationships** tab.
5. Choose **Edit trust policy**.
6. Copy and paste the following policy:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "sagemaker.amazonaws.com",
                    "events.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Additional permissions

Once submitted, the notebook job needs permissions to access resources. The following instructions show you how to add a minimal set of permissions. If needed, add more permissions

based on your notebook job needs. To add permissions to your job execution role, complete the following steps:

1. Open the IAM console.
2. Select **Roles** in the left panel.
3. Find the job execution role for your notebook job and choose the role name.
4. Choose **Add Permissions**, and choose **Create inline policy** from the dropdown menu.
5. Choose the **JSON** tab.
6. Copy and paste the following policy:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "PassroleForJobCreation",
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws-cn:iam::*:role/*",
            "Condition": {
                "StringLike": {
                    "iam:PassedToService": "sagemaker.amazonaws.com"
                }
            }
        },
        {
            "Sid": "S3ForStoringArtifacts",
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetObject",
                "s3:ListBucket",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws-cn:s3:::sagemaker-automated-execution-*"
        },
        {
            "Sid": "S3DriverAccess",
            "Effect": "Allow",
```

```
            "Action": [
                "s3:ListBucket",
                "s3:GetObject",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws-cn:s3:::sagemakerheadlessexecution-*"
            ]
        },
        {
            "Sid": "SagemakerJobs",
            "Effect": "Allow",
            "Action": [
                "sagemaker:StartPipelineExecution",
                "sagemaker:CreateTrainingJob"
            ],
            "Resource": "*"
        },
        {
            "Sid": "ECRImage",
            "Effect": "Allow",
            "Action": [
                "ecr:GetDownloadUrlForLayer",
                "ecr:BatchGetImage",
                "ecr:GetAuthorizationToken",
                "ecr:BatchCheckLayerAvailability"
            ],
            "Resource": "*"
        }
    ]
}
```

7. Add permissions to other resources your notebook job accesses.
8. Choose **Review policy**.
9. Enter a name for your policy.
10. Choose **Create policy**.

Where you can create a notebook job

If you want to create a notebook job, you have multiple options. The following provides the SageMaker AI options for you to create a notebook job.

You can create a job in your JupyterLab notebook in the Studio UI, or you can programmatically create a job with the SageMaker Python SDK:

- If you create your notebook job in the Studio UI, you supply details about the image and kernel, security configurations, and any custom variables or scripts, and your job is scheduled. For details about how to schedule your job using SageMaker Notebook Jobs, see Create a notebook job in Studio.
- To create a notebook job with the SageMaker Python SDK, you create a pipeline with a Notebook Job step and initiate an on-demand run or optionally use the pipeline scheduling feature to schedule future runs. The SageMaker SDK gives you the flexibility to customize your pipeline—you can expand your pipeline to a workflow with multiple notebook job steps. Since you create both a SageMaker Notebook Job step and a pipeline, you can track your pipeline execution status in the SageMaker Notebook Jobs job dashboard and also view your pipeline graph in Studio. For details about how to schedule your job with the SageMaker Python SDK and links to example notebooks, see Create notebook job with SageMaker AI Python SDK example.

Create notebook job with SageMaker AI Python SDK example

To run a standalone notebook using the SageMaker Python SDK, you need to create a Notebook Job step, attach it into a pipeline, and use the utilities provided by Pipelines to run your job on demand or optionally schedule one or more future jobs. The following sections describe the basic steps to create an on-demand or scheduled notebook job and track the run. In addition, refer to the following discussion if you need to pass parameters to your notebook job or connect to Amazon EMR in your notebook—additional preparation of your Jupyter notebook is required in these cases. You can also apply defaults for a subset of the arguments of `NotebookJobStep` so you don't have to specify them every time you create a Notebook Job step.

To view sample notebooks that demonstrate how to schedule notebook jobs with the SageMaker AI Python SDK, see notebook job sample notebooks.

Topics

- Steps to create a notebook job
- View your notebook jobs in the Studio UI dashboard
- View your pipeline graph in Studio
- Passing parameters to your notebook
- Connecting to an Amazon EMR cluster in your input notebook

- Set up default options

Steps to create a notebook job

You can either create a notebook job that runs immediately or on a schedule. The following instructions describe both methods.

To schedule a notebook job, complete the following basic steps:

1. Create a `NotebookJobStep` instance. For details about `NotebookJobStep` parameters, see sagemaker.workflow.steps.NotebookJobStep. At minimum, you can provide the following arguments as shown in the following code snippet:

   > **Important**
   >
   > If you schedule your notebook job using the SageMaker Python SDK, you can only specify certain images to run your notebook job. For more information, see Image constraints for SageMaker AI Python SDK notebook jobs.

   ```
   notebook_job_step = NotebookJobStep(
       input_notebook=input-notebook,
       image_uri=image-uri,
       kernel_name=kernel-name
   )
   ```

2. Create a pipeline with your `NotebookJobStep` as a single step, as shown in the following snippet:

   ```
   pipeline = Pipeline(
       name=pipeline-name,
       steps=[notebook_job_step],
       sagemaker_session=sagemaker-session,
   )
   ```

3. Run the pipeline on demand or optionally schedule future pipeline runs. To initiate an immediate run, use the following command:

   ```
   execution = pipeline.start(
       parameters={...}
   ```

```
)
```

Optionally, you can schedule a single future pipeline run or multiple runs at a predetermined interval. You specify your schedule in `PipelineSchedule` and then pass the schedule object to your pipeline with `put_triggers`. For more information about pipeline scheduling, see Schedule a pipeline with the SageMaker Python SDK.

The following example schedules your pipeline to run once at December 12, 2023 at 10:31:32 UTC.

```
my_schedule = PipelineSchedule(
    name="my-schedule“,
    at=datetime(year=2023, month=12, date=25, hour=10, minute=31, second=32)
)
pipeline.put_triggers(triggers=[my_schedule])
```

The following example schedules your pipeline to run at 10:15am UTC on the last Friday of each month during the years 2022 to 2023. For details about cron-based scheduling, see Cron-based schedules.

```
my_schedule = PipelineSchedule(
    name="my-schedule“,
    cron="15 10 ? * 6L 2022-2023"
)
pipeline.put_triggers(triggers=[my_schedule])
```

4. (Optional) View your notebook jobs in the SageMaker Notebook Jobs dashboard. The values you supply for the `tags` argument of your Notebook Job step control how the Studio UI captures and displays the job. For more information, see View your notebook jobs in the Studio UI dashboard.

View your notebook jobs in the Studio UI dashboard

The notebook jobs you create as pipeline steps appear in the Studio Notebook Job dashboard if you specify certain tags.

> **Note**
>
> Only notebook jobs created in Studio or local JupyterLab environments create job definitions. Therefore, if you create your notebook job with the SageMaker Python SDK, you don't see job definitions in the Notebook Jobs dashboard. You can, however, view your notebook jobs as described in View notebook jobs.

You can control which team members can view your notebook jobs with the following tags:

- To display the notebook to all user profiles or spaces in a domain, add the domain tag with your domain name. An example is shown as follows:
  - key: `sagemaker:domain-name`, value: `d-abcdefghij5k`
- To display the notebook job to a certain user profile in a domain, add both the user profile and the domain tags. An example of a user profile tag is shown as follows:
  - key: `sagemaker:user-profile-name`, value: `studio-user`
- To display the notebook job to a space, add both the space and the domain tags. An example of a space tag is shown as follows:
  - key: `sagemaker:shared-space-name`, value: `my-space-name`
- If you do not attach any domain or user profile or space tags, then the Studio UI does not show the notebook job created by pipeline step. In this case, you can view the underlying training job in the training job console or you can view the status in the list of pipeline executions.

Once you set up the necessary tags to view your jobs in the dashboard, see View notebook jobs for instructions about how to view your jobs and download outputs.

View your pipeline graph in Studio

Since your notebook job step is part of a pipeline, you can view the pipeline graph (DAG) in Studio. In the pipeline graph, you can view the status of the pipeline run and track lineage. For details, see View the details of a pipeline run.

Passing parameters to your notebook

If you want to pass parameters to your notebook job (using the `parameters` argument of `NotebookJobStep`), you need to prepare your input notebook to receive the parameters.

The Papermill-based notebook job executor searches for a Jupyter cell tagged with the `parameters` tag and applies the new parameters or parameter overrides immediately after this cell. For details, see Parameterize your notebook.

Once you have performed this step, pass your parameters to your `NotebookJobStep`, as shown in the following example:

```
notebook_job_parameters = {
    "company": "Amazon"
}

notebook_job_step = NotebookJobStep(
    image_uri=image-uri,
    kernel_name=kernel-name,
    role=role-name,
    input_notebook=input-notebook,
    parameters=notebook_job_parameters,
    ...
)
```

Connecting to an Amazon EMR cluster in your input notebook

If you connect to an Amazon EMR cluster from your Jupyter notebook in Studio, you might need to further modify your Jupyter notebook. See Connect to an Amazon EMR cluster from your notebook if you need to perform any of the following tasks in your notebook:

- **Pass parameters into your Amazon EMR connection command.** Studio uses Papermill to run notebooks. In SparkMagic kernels, parameters you pass to your Amazon EMR connection command may not work as expected due to how Papermill passes information to SparkMagic.
- **Passing user credentials to Kerberos, LDAP, or HTTP Basic Auth-authenticated Amazon EMR clusters.** You have to pass user credentials through the Amazon Secrets Manager.

Set up default options

The SageMaker SDK gives you the option to set defaults for a subset of parameters so you don't have to specify these parameters every time you create a `NotebookJobStep` instance. These parameters are `role`, `s3_root_uri`, `s3_kms_key`, `volume_kms_key`, `subnets`, and `security_group_ids`. Use the SageMaker AI config file to set the defaults for the step. For information about the SageMaker AI configuration file, see Configuring and using defaults with the SageMaker Python SDK..

To set up the notebook job defaults, apply your new defaults to the notebook job section of the config file as shown in the following snippet:

```
SageMaker:
  PythonSDK:
    Modules:
      NotebookJob:
        RoleArn: 'arn:aws:iam::555555555555:role/IMRole'
        S3RootUri: 's3://amzn-s3-demo-bucket/my-project'
        S3KmsKeyId: 's3kmskeyid'
        VolumeKmsKeyId: 'volumekmskeyid1'
        VpcConfig:
          SecurityGroupIds:
            - 'sg123'
          Subnets:
            - 'subnet-1234'
```

Create a notebook job in Studio

> **Note**
>
> The notebook scheduler is built from the Amazon EventBridge, SageMaker Training, and Pipelines services. If your notebook jobs fail, you might see errors related to these services. The following provides information on how to create a notebook job in the Studio UI.

SageMaker Notebook Jobs gives you the tools to create and manage your noninteractive notebook jobs using the Notebook Jobs widget. You can create jobs, view the jobs you created, and pause, stop, or resume existing jobs. You can also modify notebook schedules.

When you create your scheduled notebook job with the widget, the scheduler tries to infer a selection of default options and automatically populates the form to help you get started quickly. If you are using Studio, at minimum you can submit an on-demand job without setting any options. You can also submit a (scheduled) notebook job definition supplying just the time-specific schedule information. However, you can customize other fields if your scheduled job requires specialized settings. If you are running a local Jupyter notebook, the scheduler extension provides a feature for you to specify your own defaults (for a subset of options) so you don't have to manually insert the same values every time.

When you create a notebook job, you can include additional files such as datasets, images, and local scripts. To do so, choose **Run job with input folder**. The Notebook Job will now have access to all files under the input file's folder. While the notebook job is running the file structure of directory remains unchanged.

To schedule a notebook job, complete the following steps.

1. Open the **Create Job** form.

   In local JupyterLab environments, choose the **Create a notebook job** icon () in the taskbar. If you don't see the icon, follow the instructions in Installation guide to install it.

   In Studio, open the form in one of two ways:

   - Using the **File Browser**

     1. In the **File Browser** in the left panel, right-click on the notebook you want to run as a scheduled job.
     2. Choose **Create Notebook Job**.

   - Within the Studio notebook

     - Inside the Studio notebook you want to run as a scheduled job, choose the **Create a notebook job** icon () in the Studio toolbar.

2. Complete the popup form. The form displays the following fields:

   - **Job name**: A descriptive name you specify for your job.
   - **Input file**: The name of the notebook which you are scheduling to run in noninteractive mode.
   - **Compute type**: The type of Amazon EC2 instance in which you want to run your notebook.
   - **Parameters**: Custom parameters you can optionally specify as inputs to your notebook. To use this feature, you might optionally want to tag a specific cell in your Jupyter notebook with the **`parameters`** tag to control where your parameters are applied. For more details, see Parameterize your notebook.
   - (Optional)**Run job with input folder**: If selected the scheduled job will have access to all the files found in the same folder as the **Input file**.
   - **Additional Options**: You can specify additional customizations for your job. For example, you can specify an image or kernel, input and output folders, job retry and timeout options,

encryption details, and custom initialization scripts. For the complete listing of customizations you can apply, see Available options.

3. Schedule your job. You can run your notebook on demand or on a fixed schedule.

- To run the notebook on demand, complete the following steps:
  - Select **Run Now**.
  - Choose **Create**.
  - The **Notebook Jobs** tab appears. Choose **Reload** to load your job into the dashboard.
- To run the notebook on a fixed schedule, complete the following steps:
  - Choose **Run on a schedule**.
  - Choose the **Interval** dropdown list and select an interval. The intervals range from every minute to monthly. You can also select **Custom schedule**.
  - Based on the interval you choose, additional fields appear to help you further specify your desired run day and time. For example, if you select **Day** for a daily run, an additional field appears for you to specify the desired time. Note that any time you specify is in UTC format. Note also that if you choose a small interval, such as one minute, your jobs overlap if the previous job is not complete when the next job starts.

    If you select a custom schedule, you use cron syntax in the expression box to specify your exact run date and time. The cron syntax is a space-separated list of digits, each of which represent a unit of time from seconds to years. For help with cron syntax, you can choose **Get help with cron syntax** under the expression box.
  - Choose **Create**.
  - The **Notebook Job Definitions** tab appears. Choose **Reload** to load your job definition into the dashboard.

Set up default options for local notebooks

> **Note**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see Amazon SageMaker Studio.
> Studio Classic is still maintained for existing workloads but is no longer available for onboarding. You can only stop or delete existing Studio Classic applications and cannot

create new ones. We recommend that you migrate your workload to the new Studio experience.

You can set up default options when you create a notebook job. This can save you time if you plan to create multiple notebook jobs with different options than the provided defaults. The following provides information on how to set up the default options for local notebooks.

If you have to manually type (or paste in) custom values in the **Create Job** form, you can store new default values and the scheduler extension inserts your new values every time you create a new job definition. This feature is available for the following options:

- **Role ARN**
- **S3 Input Folder**
- **S3 Output Folder**
- **Output encryption KMS key** (if you turn on **Configure Job Encryption**)
- **Job instance volume encryption KMS key** (if you turn on **Configure Job Encryption**)

This feature saves you time if you insert different values than the provided defaults and continue to use those values for future job runs. Your chosen user settings are stored on the machine that runs your JupyterLab server and are retrieved with the help of native API. If you provide new default values for one or more but not all five options, the previous defaults are taken for the ones you don't customize.

The following instructions show you how to preview the existing default values, set new default values, and reset your default values for your notebook jobs.

To preview existing default values for your notebook jobs, complete the following steps:

1. Open the Amazon SageMaker Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. In the **File Browser** in the left panel, right-click on the notebook you want to run as a scheduled job.
3. Choose **Create Notebook Job**.
4. Choose **Additional options** to expand the tab of notebook job settings. You can view the default settings here.

To set new default values for your future notebook jobs, complete the following steps:

1. Open the Amazon SageMaker Studio Classic console by following the instructions in Launch Amazon SageMaker Studio Classic.
2. From the top menu in Studio Classic, choose **Settings**, then choose **Advanced Settings Editor**.
3. Choose **Amazon SageMaker Scheduler** from the list below **Settings**. This may already be open by default.
4. You can update the default settings directly in this UI page or by using the JSON editor.

   - In the UI you can insert new values for **Role ARN**, **S3 Input Folder**, **S3 Output Folder**, **Output encryption KMS key**, or **Job instance volume encryption KMS key**. If you change these values, you will see the new defaults for these fields while you create your next notebook job under **Additional options**.
   - (Optional) To update the user defaults using the **JSON Settings Editor**, complete the following steps:

     1. In the top right corner, choose **JSON Settings Editor**.
     2. In the **Settings** left sidebar, choose **Amazon SageMaker AI Scheduler**. This may already be open by default.

        You can see your current default values in the **User Preferences** panel.

        You can see the system default values in the **System Defaults** panel.
     3. To update your default values, copy and paste the JSON snippet from the **System Defaults** panel to the **User Preferences** panel, and update the fields.
     4. If you updated the default values, choose the **Save User Settings** icon () in the top right corner. Closing the editor does not save the changes.

If you previously changed and now want to reset the user-defined default values, complete following steps:

1. From the top menu in Studio Classic, choose **Settings**, then choose **Advanced Settings Editor**.
2. Choose **Amazon SageMaker Scheduler** from the list below **Settings**. This may already be open by default.
3. You can restore the defaults by directly using this UI page or using the JSON editor.

- In the UI you can choose **Restore to Defaults** in the top right corner. Your defaults are restored to empty strings. You only see this option if you previously changed your default values.
- (Optional) To restart the default settings using the **JSON Settings Editor**, complete the following steps:

  1. In the top right corner, choose **JSON Settings Editor**.
  2. In the **Settings** left sidebar, choose **Amazon SageMaker AI Scheduler**. This may already be open by default.

     You can see your current default values in the **User Preferences** panel.

     You can see the system default values in the **System Defaults** panel.
  3. To restore your current default settings copy the content from the **System Defaults** panel to the **User Preferences** panel.
  4. Choose the **Save User Settings** icon
     ()
     in the top right corner. Closing the editor does not save the changes.

Notebook job workflows

Since a notebook job runs your custom code, you can create a pipeline that includes one or more notebook job steps. ML workflows often contain multiple steps, such as a processing step to preprocess data, a training step to build your model, and a model evaluation step, among others. One possible use of notebook jobs is to handle preprocessing—you might have a notebook that performs data transformation or ingestion, an EMR step that performs data cleaning, and another notebook job that performs featurization of your inputs before initiating a training step. A notebook job may require information from previous steps in the pipeline or from user-specified customization as parameters in the input notebook. For examples that show how to pass environment variables and parameters to your notebook and retrieve information from prior steps, see Pass information to and from your notebook step.

In another use case, one of your notebook jobs might call another notebook to perform some tasks during your notebook run—in this scenario you need to specify these sourced notebooks as dependencies with your notebook job step. For information about how to call another notebook, see Invoke another notebook in your notebook job.

To view sample notebooks that demonstrate how to schedule notebook jobs with the SageMaker AI Python SDK, see notebook job sample notebooks.

Pass information to and from your notebook step

The following sections describe ways to pass information to your notebook as environment variables and parameters.

Pass environment variables

Pass environment variables as a dictionary to the `environment_variable` argument of your `NotebookJobStep`, as shown in the following example:

```
environment_variables = {"RATE": 0.0001, "BATCH_SIZE": 1000}

notebook_job_step = NotebookJobStep(
    ...
    environment_variables=environment_variables,
    ...
)
```

You can use the environment variables in the notebook using `os.getenv()`, as shown in the following example:

```
# inside your notebook
import os
print(f"ParentNotebook: env_key={os.getenv('env_key')}")
```

Pass parameters

When you pass parameters to the first Notebook Job step in your `NotebookJobStep` instance, you might optionally want to tag a cell in your Jupyter notebook to indicate where to apply new parameters or parameter overrides. For instructions about how to tag a cell in your Jupyter notebook, see Parameterize your notebook.

You pass parameters through the Notebook Job step's `parameters` parameter, as shown in the following snippet:

```
notebook_job_parameters = {
    "company": "Amazon",
}
```

```
notebook_job_step = NotebookJobStep(
    ...
    parameters=notebook_job_parameters,
    ...
)
```

Inside your input notebook, your parameters are applied after the cell tagged with `parameters` or at the beginning of the notebook if you don't have a tagged cell.

```
# this cell is in your input notebook and is tagged with 'parameters'
# your parameters and parameter overrides are applied after this cell
company='default'
```

```
# in this cell, your parameters are applied
# prints "company is Amazon"
print(f'company is {company}')
```

Retrieve information from a previous step

The following discussion explains how you can extract data from a previous step to to pass to your Notebook Job step.

Use `properties` attribute

You can use the following properties with the previous step's `properties` attribute:

- `ComputingJobName`—The training job name
- `ComputingJobStatus`—The training job status
- `NotebookJobInputLocation`—The input Amazon S3 location
- `NotebookJobOutputLocationPrefix`—The path to your training job outputs, more specifically {*`NotebookJobOutputLocationPrefix`*}/{*`training-job-name`*}`/output/output.tar.gz`. containing outputs
- `InputNotebookName`—The input notebook file name
- `OutputNotebookName`—The output notebook file name (which may not exist in the training job output folder if the job fails)

The following code snippet shows how to extract parameters from the properties attribute.

```
notebook_job_step2 = NotebookJobStep(
```

```
    ....
    parameters={
        "step1_JobName": notebook_job_step1.properties.ComputingJobName,
        "step1_JobStatus": notebook_job_step1.properties.ComputingJobStatus,
        "step1_NotebookJobInput":
notebook_job_step1.properties.NotebookJobInputLocation,
        "step1_NotebookJobOutput":
notebook_job_step1.properties.NotebookJobOutputLocationPrefix,
    }
```

Use JsonGet

If you want to pass parameters other than the ones previously mentioned and the JSON outputs of your previous step reside in Amazon S3, use `JsonGet`. `JsonGet` is a general mechanism that can directly extract data from JSON files in Amazon S3.

To extract JSON files in Amazon S3 with `JsonGet`, complete the following steps:

1. Upload your JSON file to Amazon S3. If your data is already uploaded to Amazon S3, skip this step. The following example demonstrates uploading a JSON file to Amazon S3.

   ```
   import json
   from sagemaker.s3 import S3Uploader

   output = {
       "key1": "value1",
       "key2": [0,5,10]
   }

   json_output = json.dumps(output)

   with open("notebook_job_params.json", "w") as file:
       file.write(json_output)

   S3Uploader.upload(
       local_path="notebook_job_params.json",
       desired_s3_uri="s3://path/to/bucket"
   )
   ```

2. Provide your S3 URI and the JSON path to the value you want to extract. In the following example, `JsonGet` returns an object representing index 2 of the value associated with key `key2` (`10`).

```
NotebookJobStep(
    ....
    parameters={
        # the key job_key1 returns an object representing the value 10
        "job_key1": JsonGet(
            s3_uri=Join(on="/", values=["s3:/", ..]),
            json_path="key2[2]" # value to reference in that json file
        ),
        "job_key2": "Amazon"
    }
)
```

Invoke another notebook in your notebook job

You can set up a pipeline in which one notebook job calls another notebook. The following sets up an example of a pipeline with a Notebook Job step in which the notebook calls two other notebooks. The input notebook contains the following lines:

```
%run 'subfolder/notebook_to_call_in_subfolder.ipynb'
%run 'notebook_to_call.ipynb'
```

Pass these notebooks into your `NotebookJobStep` instances with `additional_dependencies`, as shown in the following snippet. Note that the paths provided for the notebooks in `additional_dependencies` are provided from the root location. For information about how SageMaker AI uploads your dependent files and folders to Amazon S3 so you can correctly provide paths to your dependencies, see the description for `additional_dependencies` in NotebookJobStep.

```
input_notebook = "inputs/input_notebook.ipynb"
simple_notebook_path = "inputs/notebook_to_call.ipynb"
folder_with_sub_notebook = "inputs/subfolder"

notebook_job_step = NotebookJobStep(
    image_uri=image-uri,
    kernel_name=kernel-name,
    role=role-name,
    input_notebook=input_notebook,
    additional_dependencies=[simple_notebook_path, folder_with_sub_notebook],
    tags=tags,
```

```
)
```

Available options

The following table displays all available options you can use to customize your notebook job, whether you run your Notebook Job in Studio, a local Jupyter environment, or using the SageMaker Python SDK. The table includes the type of custom option, a description, additional guidelines about how to use the option, a field name for the option in Studio (if available) and the parameter name for the notebook job step in the SageMaker Python SDK (if available).

For some options, you can also preset custom default values so you don't have to specify them every time you set up a notebook job. For Studio, these options are **Role**, **Input folder**, **Output folder**, and **KMS Key ID**, and are specified in the following table. If you preset custom defaults for these options, these fields are prepopulated in the **Create Job** form when you create your notebook job. For details about how to create custom defaults in Studio and local Jupyter environments, see Set up default options for local notebooks.

The SageMaker SDK also gives you the option to set intelligent defaults so that you don't have to specify these parameters when you create a `NotebookJobStep`. These parameters are `role`, `s3_root_uri`, `s3_kms_key`, `volume_kms_key`, `subnets`, `security_group_ids`, and are specified in the following table. For information about how to set intelligent defaults, see Set up default options.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Job name	Your job name as it should appear in the Notebook Jobs dashboard.	Field **Job name**.	Same as Studio.	Parameter `notebook_job_name`. Defaults to None.
Image	The container image used to run the notebook	Field **Image**. This field defaults to your notebook's current image.	Field **Image**. This field requires an ECR URI of a Docker image that can run	**Required**. Parameter `image_uri`

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
	noninteractively on the chosen compute type.	Change this field from the default to a custom value if needed. If Studio cannot infer this value, the form displays a validation error requiring you to specify it. This image can be a custom, bring-your-own image or an available Amazon SageMaker image. For a list of available SageMaker images supported by the notebook scheduler, see Amazon SageMaker Images Available for Use With Studio Classic Notebooks.	the provided notebook on the selected compute type. By default, the scheduler extension uses a pre-built SageMaker AI Docker image—base Python 2.0. This is the official Python 3.8 image from DockerHub with boto3, Amazon CLI, and the Python 3 kernel. You can also provide any ECR URI that meets the notebook custom image specification. For details, see Custom SageMaker Image Specifications for Amazon SageMaker Studio Classic. This image should have all the kernels and libraries needed for the notebook run.	. URI location of a Docker image on ECR. You can use specific SageMaker Distribution Images or custom image based on those images, or your own image pre-installed with notebook

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
				job dependencies that meets additional requirements. For details, see Image constraints for SageMaker AI Python SDK notebook jobs.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Instance type	The EC2 instance type to use to run the notebook job. The notebook job uses a SageMaker Training Job as a computing layer, so the specified instance type should be a SageMaker Training supported instance type.	Field **Compute type**. Defaults to `ml.m5.large` .	Same as Studio.	Parameter `instance_type` . Defaults to `ml.m5.large` .

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Kernel	The Jupyter kernel used to run the notebook job.	Field **Kernel**. This field defaults to your notebook's current kernel. Change this field from the default to a custom value if needed. If Studio cannot infer this value, the form displays a validation error requiring you to specify it.	Field **Kernel**. This kernel should be present in the image and follow the Jupyter kernel specs. This field defaults to the Python3 kernel found in the base Python 2.0 SageMaker image. Change this field to a custom value if needed.	**Required.** Parameter `kernel_name` . This kernel should be present in the image and follow the Jupyter kernel specs. To see the kernel identifiers for your image, see (LINK).

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
SageMaker AI session	The underlying SageMaker AI session to which SageMaker AI service calls are delegated.	N/A	N/A	Parameter `sagemaker_session`. If unspecified, one is created using a default configuration chain.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Role ARN	The role's Amazon Resource Name (ARN) used with the notebook job.	Field **Role ARN**. This field defaults to the Studio execution role. Change this field to a custom value if needed. **Note** If Studio cannot infer this value, the **Role ARN** field is blank. In this case, insert the ARN you want to use.	Field **Role ARN**. This field defaults to any role prefixed with `Sagemaker JupyterScheduler` . If you have multiple roles with the prefix, the extension chooses one. Change this field to a custom value if needed. For this field, you can set your own user default that pre-populates whenever you create a new job definition. For details, see Set up default options for local notebooks.	Parameter `role`. Defaults to the SageMaker AI default IAM role if the SDK is running in SageMaker Notebooks or SageMaker Studio Notebooks . Otherwise, it throws a `ValueError` . Allows intellige

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
				nt defaults.
Input notebook	The name of the notebook which you are scheduling to run.	**Required**. Field **Input file**.	Same as Studio.	**Required**.Par `input_notebook .`
Input folder	The folder containing your inputs. The job inputs, including the input notebook and any optional start-up or initialization scripts, are put in this folder.	Field **Input folder**. If you don't provide a folder, the scheduler creates a default Amazon S3 bucket for your inputs.	Same as Studio. For this field, you can set your own user default that pre-populates whenever you create a new job definition. For details, see Set up default options for local notebooks.	N/A. The input folder is placed inside the location specified by parameter `s3_root_uri .`

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Output folder	The folder containing your outputs. The job outputs, including the output notebook and logs, are put in this folder.	Field **Output folder**. If you don't specify a folder, the scheduler creates a default Amazon S3 bucket for your outputs.	Same as Studio. For this field, you can set your own user default that pre-populates whenever you create a new job definition. For details, see Set up default options for local notebooks.	N/A. The output folder is placed inside the location specified by parameter `s3_root_uri`.
Parameters	A dictionary of variables and values to pass to your notebook job.	Field **Parameters**. You need to parameterize your notebook to accept parameters.	Same as Studio.	Parameter `parameters`. You need to parameterize your notebook to accept parameters.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Additional (file or folder) dependencies	The list of file or folder dependencies which the notebook job uploads to s3 staged folder.	Not supported.	Not supported.	Parameter `additional_dependencies` . The notebook job uploads these dependencies to an S3 staged folder so they can be consumed during execution .

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
S3 root URI	The folder containing your inputs. The job inputs, including the input notebook and any optional start-up or initialization scripts, are put in this folder. This S3 bucket must be in the same Amazon Web Services account that you're using to run your notebook job.	N/A. Use **Input Folder** and **Output folder**.	Same as Studio.	Parameter `s3_root_uri` . Defaults to a default S3 bucket. Allows intelligent defaults.
Environment variables	Any existing environment variables that you want to override, or new environment variables that you want to introduce and use in your notebook.	Field **Environment variables**.	Same as Studio.	Parameter `environment_variables` . Defaults to None.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Tags	A list of tags attached to the job.	N/A	N/A	Parameter `tags`. Defaults to None. Your tags control how the Studio UI captures and displays the job created by the pipeline. For details, see View your notebook jobs in the Studio

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
				UI dashboard.
Start-up script	A script preloaded in the notebook startup menu that you can choose to run before you run the notebook.	Field **Start-up script**. Select a Lifecycle Configuration (LCC) script that runs on the image at start-up. **Note** A start-up script runs in a shell outside of the Studio environment. Therefore, this script cannot depend on the Studio local storage, environment variables, or app metadata (in `/opt/ml/metadata`). Also, if you use a start-up script and an initialization script, the start-up script runs first.	Not supported.	Not supported.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Initialization script	A path to a local script you can run when your notebook starts up.	Field **Initialization script**. Enter the EFS file path where a local script or a Lifecycle Configuration (LCC) script is located. If you use a start-up script and an initialization script, the start-up script runs first. **Note** An initialization script is sourced from the same shell as the notebook job. This is not the case for a start-up script described previously. Also, if you use a start-up script and an initialization script, the start-up script runs first.	Field **Initialization script**. Enter the local file path where a local script or a Lifecycle Configuration (LCC) script is located.	Parameter `initialization_script` . Defaults to None.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Max retry attempts	The number of times Studio tries to rerun a failed job run.	Field **Max retry attempts**. Defaults to 1.	Same as Studio.	Parameter `max_retry_attempts`. Defaults to 1.
Max run time (in seconds)	The maximum length of time, in seconds, that a notebook job can run before it is stopped. If you configure both **Max run time** and **Max retry attempts**, the run time applies to each retry. If a job does not complete in this time, its status is set to `Failed`.	Field **Max run time (in seconds)**. Defaults to `172800 seconds (2 days)`.	Same as Studio.	Parameter `max_runtime_in_seconds`. Defaults to `172800 seconds (2 days)`.
Retry policies	A list of retry policies, which govern actions to take in case of failure.	Not supported.	Not supported.	Parameter `retry_policies`. Defaults to None.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Add `Step` or `StepCollection` dependencies	A list of `Step` or `StepCollection` names or instances on which the job depends.	Not supported.	Not supported.	Parameter `depends_on`. Defaults to `None`. Use this to define explicit dependencies between steps in your pipeline graph.
Volume size	The size in GB of the storage volume for storing input and output data during training.	Not supported.	Not supported.	Parameter `volume_size`. Defaults to 30GB.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Encrypt traffic between containers	A flag that specifies whether traffic between training containers is encrypted for the training job.	N/A. Enabled by default.	N/A. Enabled by default.	Parameter `encrypt_inter_container_traffic`. Defaults to `True`.
Configure job encryption	An indicator that you want to encrypt your notebook job outputs, job instance volume, or both.	Field **Configure job encryption**. Check this box to choose encryption. If left unchecked, the job outputs are encrypted with the account's default KMS key and the job instance volume is not encrypted.	Same as Studio.	Not supported.
Output encryption KMS key	A KMS key to use if you want to customize the encryption key used for your notebook job outputs. This field is only applicable if you checked **Configure job encryption**.	Field **Output encryption KMS key**. If you do not specify this field, your notebook job outputs are encrypted with SSE-KMS using the default Amazon S3 KMS key. Also, if you create the Amazon S3 bucket yourself and use encryption, your encryption method is preserved.	Same as Studio. For this field, you can set your own user default that pre-populates whenever you create a new job definition. For details, see Set up default options for local notebooks.	Parameter `s3_kms_key`. Defaults to None. Allows intelligent defaults.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Job instance volume encryption KMS key	A KMS key to use if you want to encrypt your job instance volume. This field is only applicable if you checked **Configure job encryption**.	Field **Job instance volume encryption KMS key**.	Field **Job instance volume encryption KMS key**. For this field, you can set your own user default that pre-populates whenever you create a new job definition. For details, see Set up default options for local notebooks.	Parameter `volume_kms_key` . Defaults to None. Allows intelligent defaults.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Use a Virtual Private Cloud to run this job (for VPC users)	An indicator that you want to run this job in a Virtual Private Cloud (VPC). For better security, it is recommend that you use a private VPC.	Field **Use a Virtual Private Cloud to run this job**. Check this box if you want to use a VPC. At minimum, create the following VPC endpoints to enable your notebook job to privately connect to those Amazon resources: • **SageMaker AI**: For information on how to connect to SageMaker AI through a VPC interface endpoint, see Connect to SageMaker AI Within your VPC. • **Amazon S3**: For information on how to connect to Amazon S3 through a VPC interface endpoint, see Gateway endpoints for Amazon S3. • **Amazon EC2**: For information on how to connect to Amazon EC2 through a VPC interface endpoint, see Access Amazon EC2 using an interface VPC endpoint.	Same as Studio.	N/A

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
		• **Amazon EventBridge**: This endpoint is only needed when setting up a scheduled notebook. It is not needed when launching a job on demand. For information on how to connect to EventBridge through a VPC interface endpoint, see Using Amazon EventBridge with interface VPC Endpoints. If you choose to use a VPC, you need to specify at least one private subnet and at least one security group in the following options. If you don't use any private subnets, you need to consider other configuration options. For details, see **Public VPC subnets not supported** in Constraints and considerations.		

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Subnet(s) (for VPC users)	Your subnets. This field must contain at least one and at most five, and all the subnets you provide should be private. For details, see **Public VPC subnets not supported** in Constraints and considerations.	Field **Subnet(s)**. This field defaults to the subnets associated with the Studio domain, but you can change this field if needed.	Field **Subnet(s)**. The scheduler cannot detect your subnets, so you need to enter any subnets you configured for your VPC.	Parameter `subnets`. Defaults to None. Allows intelligent defaults.
Security group(s) (for VPC users)	Your security groups. This field must contain at least one and at most 15. For details, see **Public VPC subnets not supported** in Constraints and considerations.	Field **Security groups**. This field defaults to the security groups associated with the domain VPC, but you can change this field if needed.	Field **Security groups**. The scheduler cannot detect your security groups, so you need to enter any security groups you configured for your VPC.	Parameter `security_group_ids`. Defaults to None. Allows intelligent defaults.

Custom option	Description	Studio-specific guideline	Local Jupyter environment guideline	SageMaker Python SDK guideline
Name	The name of the notebook job step.	N/A	N/A	Parameter `name`. If unspecified, it is derived from the notebook file name.
Display name	Your job name as it should appear in your list of pipeline executions.	N/A	N/A	Parameter `display_name`. Defaults to None.
Description	A description of your job.	N/A	N/A	Parameter `description`.

Parameterize your notebook

To pass new parameters or parameter overrides to your scheduled notebook job, you might optionally want to modify your Jupyter notebook if you want your new parameters values to be applied after a cell. When you pass a parameter, the notebook job executor uses the methodology enforced by Papermill. The notebook job executor searches for a Jupyter cell tagged with the `parameters` tag and applies the new parameters or parameter overrides immediately after this cell. If you don't have any cells tagged with `parameters`, the parameters are applied at

the beginning of the notebook. If you have more than one cell tagged with `parameters`, the parameters are applied after the first cell tagged with `parameters`.

To tag a cell in your notebook with the `parameters` tag, complete the following steps:

1. Select the cell to parameterize.
2. Choose the **Property Inspector** icon
   ()
   in the right sidebar.
3. Type **`parameters`** in the **Add Tag** box.
4. Choose the **+** sign.
5. The `parameters` tag appears under **Cell Tags** with a check mark, which means the tag is applied to the cell.

Connect to an Amazon EMR cluster from your notebook

If you connect to an Amazon EMR cluster from your Jupyter notebook in Studio, you might need to perform additional setup. In particular, the following discussion addresses two issues:

- **Passing parameters into your Amazon EMR connection command**. In SparkMagic kernels, parameters you pass to your Amazon EMR connection command may not work as expected due to differences in how Papermill passes parameters and how SparkMagic receives parameters. The workaround to address this limitation is to pass parameters as environment variables. For more details about the issue and workaround, see Pass parameters to your EMR connection command.
- **Passing user credentials to Kerberos, LDAP, or HTTP Basic Auth-authenticated Amazon EMR clusters**. In interactive mode, Studio asks for credentials in a popup form where you can enter your sign-in credentials. In your noninteractive scheduled notebook, you have to pass them through the Amazon Secrets Manager. For more details about how to use the Amazon Secrets Manager in your scheduled notebook jobs, see Pass user credentials to your Kerberos, LDAP, or HTTP Basic Auth-authenticated Amazon EMR cluster.

Pass parameters to your EMR connection command

If you are using images with the SparkMagic PySpark and Spark kernels and want to parameterize your EMR connection command, provide your parameters in the **Environment variables** field instead of the Parameters field in the Create Job form (in the **Additional Options** dropdown

menu). Make sure your EMR connection command in the Jupyter notebook passes these parameters as environment variables. For example, suppose you pass `cluster-id` as an environment variable when you create your job. Your EMR connection command should look like the following:

```
%%local
import os
```

```
%sm_analytics emr connect –cluster-id {os.getenv('cluster_id')} --auth-type None
```

You need this workaround to meet requirements by SparkMagic and Papermill. For background context, the SparkMagic kernel expects that the `%%local` magic command accompany any local variables you define. However, Papermill does not pass the `%%local` magic command with your overrides. In order to work around this Papermill limitation, you must supply your parameters as environment variables in the **Environment variables** field.

Pass user credentials to your Kerberos, LDAP, or HTTP Basic Auth-authenticated Amazon EMR cluster

To establish a secure connection to an Amazon EMR cluster that uses Kerberos, LDAP, or HTTP Basic Auth authentication, you use the Amazon Secrets Manager to pass user credentials to your connection command. For information about how to create a Secrets Manager secret, see Create an Amazon Secrets Manager secret. Your secret must contain your username and password. You pass the secret with the `--secrets` argument, as shown in the following example:

```
%sm_analytics emr connect --cluster-id j_abcde12345
    --auth Kerberos
    --secret aws_secret_id_123
```

Your administrator can set up a flexible access policy using an attribute-based-access-control (ABAC) method, which assigns access based on special tags. You can set up flexible access to create a single secret for all users in the account or a secret for each user. The following code samples demonstrate these scenarios:

Create a single secret for all users in the account

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:role/service-role/
AmazonSageMaker-ExecutionRole-20190101T012345"
            },
            "Action": "secretsmanager:GetSecretValue",
            "Resource": [
                "arn:aws-cn:secretsmanager:us-
west-2:111122223333:secret:aes123-1a2b3c",
                "arn:aws-cn:secretsmanager:us-
west-2:111122223333:secret:aes456-4d5e6f",
                "arn:aws-cn:secretsmanager:us-
west-2:111122223333:secret:aes789-7g8h9i"
            ]
        }
    ]
}
```

Create a different secret for each user

You can create a different secret for each user using the `PrincipleTag` tag, as shown in the following example:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:role/service-role/
AmazonSageMaker-ExecutionRole-20190101T012345"
            },
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/user-identity": "${aws:PrincipalTag/user-
identity}"
                }
```

```
            },
            "Action": "secretsmanager:GetSecretValue",
            "Resource": [
                "arn:aws-cn:secretsmanager:us-
west-2:111122223333:secret:aes123-1a2b3c",
                "arn:aws-cn:secretsmanager:us-
west-2:111122223333:secret:aes456-4d5e6f",
                "arn:aws-cn:secretsmanager:us-
west-2:111122223333:secret:aes789-7g8h9i"
            ]
        }
    ]
}
```

Notebook jobs details in Amazon SageMaker Studio

SageMaker Notebook Jobs dashboards help organize the job definitions that you schedule, and also keep track of the actual jobs that run from your job definitions. There are two important concepts to understand when scheduling notebook jobs: *job definitions* and *job runs*. Job definitions are schedules you set to run specific notebooks. For example, you can create a job definition that runs notebook XYZ.ipynb every Wednesday. This job definition launches the actual job runs which occur this coming Wednesday, next Wednesday, the Wednesday after that, and so on.

> **Note**
>
> The SageMaker Python SDK notebook job step does not create job definitions. However, you can view your jobs in the Notebook Jobs dashboard. Both jobs and job definitions are available if you schedule your job in a JupyterLab environment.

The interface provides two main tabs that help you track your existing job definitions and job runs:

- **Notebook Jobs** tab: This tab displays a list of all your job runs from your on-demand jobs and job definitions. From this tab, you can directly access the details for a single job run. For example, you can view a single job run that occurred two Wednesdays ago.
- **Notebook Job Definitions** tab: This tab displays a list of all your job definitions. From this tab, you can directly access the details for a single job definition. For example, you can view the schedule you created to run XYZ.ipynb every Wednesday.

For details about the **Notebook Jobs** tab, see View notebook jobs.

For details about the **Notebook Job Definitions** tab, see View notebook job definitions.

View notebook jobs

> **Note**
>
> You can automatically view your notebook jobs if you scheduled your notebook job from the Studio UI. If you used the SageMaker Python SDK to schedule your notebook job, you need to supply additional tags when you create the notebook job step. For details, see View your notebook jobs in the Studio UI dashboard.

The following topic gives information about the **Notebook Jobs** tab and how to view the details of a single notebook job. The **Notebook Jobs** tab (which you access by choosing the **Create a notebook job** icon ( ) in the Studio toolbar) shows a history of your on-demand jobs and all the jobs that run from the job definitions you created. This tab opens after you create an on-demand job, or you can just view this tab yourself to see a history of past and current jobs. If you select the **Job name** for any job, you can view details for a single job in its **Job Detail** page. For more information about the **Job Detail** page, see the following section View a single job.

The **Notebook Jobs** tab includes the following information for each job:

- **Output files**: Displays the availability of output files. This column can contain one of the following:
  - A download icon ( ): The output notebook and log are available for download; choose this button to download them. Note that a failed job can still generate output files if the failure occurred after the files were created. In this case, it is helpful to view the output notebook to identify the failure point.
  - Links to the **Notebook** and **Output log**: The notebook and output log are downloaded. Choose the links to view their contents.
  - (blank): The job was stopped by the user, or a failure occurred in the job run before it could generate output files. For example, network failures could prevent the job from starting.

The output notebook is the result of running all cells in the notebook, and also incorporates any new or overriding parameters or environment variables you included. The output log captures the details of the job run to help you troubleshoot failed jobs.

- **Created at**: The time the on-demand job or scheduled job was created.
- **Status**: The current status of the job, which is one of the following values:
  - **In progress**: The job is running
  - **Failed**: The job failed from configuration or notebook logic errors
  - **Stopped**: The job was stopped by the user
  - **Completed**: The job completed
- **Actions**: This column provides shortcuts to help you stop or remove any job directly in the interface.

View a single job

From the **Notebook Jobs** tab, you can select a job name to view the **Job Detail** page for a specific job. The **Job Detail** page includes all the details you provided in the **Create Job** form. Use this page to confirm the settings you specified when you created the job definition.

In addition, you can access shortcuts to help you perform the following actions in the page itself:

- **Delete Job**: Remove the job from the **Notebook Jobs** tab.
- **Stop Job**: Stop your running job.

View notebook job definitions

> **Note**
>
> If you scheduled your notebook job with the SageMaker Python SDK, skip this section. Only notebook jobs created in Studio or local JupyterLab environments create job definitions. Therefore, if you created your notebook job with the SageMaker Python SDK, you won't see job definitions in the Notebook Jobs dashboard. You can, however, view your notebook jobs as described in View notebook jobs.

When you create a job definition, you create a schedule for a job. The **Notebook Job Definitions** tab lists these schedules, as well as information about specific notebook job definitions. For example, you might create a job definition that runs a specific notebook every minute. Once this job definition is active, you see a new job every minute in the **Notebook Jobs** tab. The following page gives information about the **Notebook Job Definitions** tab, as well as how to view a notebook job definition.

The **Notebook Job Definitions** tab displays a dashboard with all your job definitions and includes the input notebook, the creation time, the schedule, and the status for each job definition. The value in the **Status** column is one of the following values:

- **Paused**: You paused the job definition. Studio does not initiate any jobs until you resume the definition.
- **Active**: The schedule is on and Studio can run the notebook according to the schedule you specified.

In addition, the **Actions** column provides shortcuts to help you perform the following tasks directly in the interface:

- Pause: Pauses the job definition. Studio won't create any jobs until you resume the definition.
- Delete: Removes the job definition from the **Notebook Job Definitions** tab.
- Resume: Continues a paused job definition so that it can start jobs.

If you created a job definition but it doesn't initiate jobs, see Job definition doesn't create jobs in the Troubleshooting guide.

View a single job definition

If you select a job definition name in the **Notebook Job Definitions** tab, you see the **Job Definition** page where you can view specific details for a job definition. Use this page to confirm the settings you specified when you created the job definition. If you don't see any jobs created from your job definition, see Job definition doesn't create jobs in the Troubleshooting guide.

This page also contains a section listing the jobs that run from this job definition. Viewing your jobs in the **Job Definition** page may be a more productive way to help you organize your jobs instead of viewing jobs in the **Notebook Jobs** tab, which combines all jobs from all your job definitions.

In addition, this page provides shortcuts for the following actions:

- **Pause/Resume**: Pause your job definition, or resume a paused definition. Note that if a job is currently running for this definition, Studio does not stop it.
- **Run**: Run a single on-demand job from this job definition. This option also lets you specify different input parameters to your notebook before starting the job.
- **Edit Job Definition**: Change the schedule of your job definition. You can select a different time interval, or you can opt for a custom schedule using cron syntax.
- **Delete Job Definition**: Remove the job definition from the **Notebook Job Definitions** tab. Note that if a job is currently running for this definition, Studio does not stop it.

Troubleshooting guide

Refer to this troubleshooting guide to help you debug failures you might experience when your scheduled notebook job runs.

Job definition doesn't create jobs

If your job definition does not initiate any jobs, the notebook or training job may not be displayed in the **Jobs** section on the left navigation bar in Amazon SageMaker Studio. If this is the case, you can find error messages in the **Pipelines** section on the left navigation bar in Studio. Each notebook or training job definition belongs to an execution pipeline. The following are common causes for failing to initiate notebook jobs.

Missing permissions

- The role assigned to the job definition does not have a trust relationship with Amazon EventBridge. That is, EventBridge cannot assume the role.
- The role assigned to the job definition does not have permission to call `SageMaker AI:StartPipelineExecution`.
- The role assigned to the job definition does not have permission to call `SageMaker AI:CreateTrainingJob`.

EventBridge quota exceeded

If you see a `Put*` error such as the following example, you exceeded an EventBridge quota. To resolve this, you can clean up unused EventBridge runs, or ask Amazon Web Services Support to increase your quota.

```
LimitExceededException) when calling the PutRule operation:
```

```
The requested resource exceeds the maximum number allowed
```

For more information about EventBridge quotas, see Amazon EventBridge quotas.

Pipeline quota limit exceeded

If you see an error such as the following example, you exceeded the number of pipelines that you can run. To resolve this, you can clean up unused pipelines in your account, or ask Amazon Web Services Support to increase your quota.

```
ResourceLimitExceeded: The account-level service limit
'Maximum number of pipelines allowed per account' is XXX Pipelines,
with current utilization of XXX Pipelines and a request delta of 1 Pipelines.
```

For more information about pipeline quotas, see Amazon SageMaker AI endpoints and quotas.

Training job limit exceeded

If you see an error such as the following example, you exceeded the number of training jobs that you can run. To resolve this, reduce the number of training jobs in your account, or ask Amazon Web Services Support to increase your quota.

```
ResourceLimitExceeded: The account-level service limit
'ml.m5.2xlarge for training job usage' is 0 Instances, with current
utilization of 0 Instances and a request delta of 1 Instances.
Please contact Amazon support to request an increase for this limit.
```

For more information about training job quotas, see Amazon SageMaker AI endpoints and quotas.

Auto visualizations disabled in SparkMagic notebooks

If your notebook uses the SparkMagic PySpark kernel and you run the notebook as a Notebook Job, you may see that your auto visualizations are disabled in the output. Turning on auto visualization causes the kernel to hang, so the notebook job executor currently disables auto visualizations as a workaround.

Constraints and considerations

Review the following constraints to ensure your notebook jobs complete successfully. Studio uses Papermill to run notebooks. You might need to update Jupyter notebooks to align to Papermill's requirements. There are also restrictions on the content of LCC scripts and important details to understand regarding VPC configuration.

JupyterLab version

JupyterLab version 4.0 is supported.

Installation of packages that require kernel restart

Papermill does not support calling `pip install` to install packages that require a kernel restart. In this situation, use `pip install` in an initialization script. For a package installation that does not require kernel restart, you can still include `pip install` in the notebook.

Kernel and language names registered with Jupyter

Papermill registers a translator for specific kernels and languages. If you bring your own instance (BYOI), use a standard kernel name as shown in the following snippet:

```
papermill_translators.register("python", PythonTranslator)
papermill_translators.register("R", RTranslator)
papermill_translators.register("scala", ScalaTranslator)
papermill_translators.register("julia", JuliaTranslator)
papermill_translators.register("matlab", MatlabTranslator)
papermill_translators.register(".net-csharp", CSharpTranslator)
papermill_translators.register(".net-fsharp", FSharpTranslator)
papermill_translators.register(".net-powershell", PowershellTranslator)
papermill_translators.register("pysparkkernel", PythonTranslator)
papermill_translators.register("sparkkernel", ScalaTranslator)
papermill_translators.register("sparkrkernel", RTranslator)
papermill_translators.register("bash", BashTranslator)
```

Parameters and environment variable limits

Parameters and environment variable limits. When you create your notebook job, it receives the parameters and environment variables you specify. You can pass up to 100 parameters. Each parameter name can be up to 256 characters long, and the associated value can be up to 2500 characters long. If you pass environment variables, you can pass up to 28 variables. The variable name and associated value can be up to 512 characters long. If you need more than 28 environment variables, use additional environment variables in an initialization script which has no limit on the number of environment variables you can use.

Viewing jobs and job definitions

Viewing jobs and job definitions. If you schedule your notebook job in the Studio UI in the JupyterLab notebook, you can view your notebook jobs and your notebook job definitions in the

Studio UI. If you scheduled your notebook job with the SageMaker Python SDK, you can view your jobs only—the SageMaker Python SDK notebook job step does not create job definitions. To view your jobs, you also need to supply additional tags to your notebook job step instance. For details, see View your notebook jobs in the Studio UI dashboard.

Image

You need to manage image constraints depending on whether you run notebook jobs in Studio or the SageMaker Python SDK notebook job step in a pipeline.

Image constraints for SageMaker AI Notebook Jobs (Studio)

Image and kernel support. The driver that launches your notebook job assumes the following:

- A base Python runtime environment is installed in the Studio or bring-your-own (BYO) images and is the default in the shell.
- The base Python runtime environment includes the Jupyter client with kernelspecs properly configured.
- The base Python runtime environment includes the `pip` function so the notebook job can install system dependencies.
- For images with multiple environments, your initialization script should switch to the proper kernel-specific environment before installing notebook-specific packages. You should switch back to the default Python runtime environment, if different from the kernel runtime environment, after configuring the kernel Python runtime environment.

The driver that launches your notebook job is a bash script, and Bash v4 must be available at /bin/bash.

Root privileges on bring-your-own-images (BYOI). You must have root privileges on your own Studio images, either as the root user or through `sudo` access. If you are not a root user but accessing root privileges through `sudo`, use **`1000/100`** as the `UID/GID`.

Image constraints for SageMaker AI Python SDK notebook jobs

The notebook job step supports the following images:

- SageMaker Distribution Images listed in Amazon SageMaker Images Available for Use With Studio Classic Notebooks.

- A custom image based on the SageMaker Distribution images in the previous list. Use a SageMaker Distribution image as a base.
- A custom image (BYOI) pre-installed with notebook job dependencies (i.e., sagemaker-headless-execution-driver. Your image must meet the following requirements:
  - The image is pre-installed with notebook job dependencies.
  - A base Python runtime environment is installed and is default in the shell environment.
  - The base Python runtime environment includes the Jupyter client with kernelspecs properly configured.
  - You have root privileges, either as the root user or through `sudo` access. If you are not a root user but accessing root privileges through `sudo`, use **`1000/100`** as the `UID/GID`.

VPC subnets used during job creation

If you use a VPC, Studio uses your private subnets to create your job. Specify one to five private subnets (and 1–15 security groups).

If you use a VPC with private subnets, you must choose one of the following options to ensure the notebook job can connect to dependent services or resources:

- If the job needs access to an Amazon service that supports interface VPC endpoints, create an endpoint to connect to the service. For a list of services that support interface endpoints, see Amazon services that integrate with Amazon PrivateLink. For information about creating an interface VPC endpoint, see Access an Amazon service using an interface VPC endpoint. At minimum, an Amazon S3 VPC endpoint gateway must be provided.
- If a notebook job needs access to an Amazon service that doesn't support interface VPC endpoints or to a resource outside of Amazon, create a NAT gateway and configure your security groups to allow outbound connections. For information about setting up a NAT gateway for your VPC, see *VPC with public and private Subnets (NAT)* in the Amazon Virtual Private Cloud User Guide.

Service limits

Since the notebook job scheduler is built from Pipelines, SageMaker Training, and Amazon EventBridge services, your notebook jobs are subject to their service-specific quotas. If you exceed these quotas, you may see error messages related to these services. For example, there are limits for how many pipelines you can run at one time, and how many rules you can set up for a single

event bus. For more information about SageMaker AI quotas, see Amazon SageMaker AI Endpoints and Quotas. For more information about EventBridge quotas, see Amazon EventBridge Quotas.

Pricing for SageMaker Notebook Jobs

When you schedule notebook jobs, your Jupyter notebooks run on SageMaker training instances. After you select an **Image** and **Kernel** in your **Create Job** form, the form provides a list of available compute types. You are charged for the compute type you choose, based on the combined duration of use for all notebook jobs that run from the job definition. If you don't specify a compute type, SageMaker AI assigns you a default Amazon EC2 instance type of `ml.m5.large`. For a breakdown of SageMaker AI pricing by compute type, see Amazon SageMaker AI Pricing.

Schedule your ML workflows

With Amazon SageMaker AI you can manage your entire ML workflow as you create datasets, perform data transforms, build models from data, and deploy your models to endpoints for inference. If you perform any subset of steps of your workflow periodically, you can also choose to run these steps on a schedule. For example, you might want to schedule a job in SageMaker Canvas to run a transform on new data every hour. In another scenario, you might want to schedule a weekly job to monitor model drift of your deployed model. You can specify a recurring schedule of any time interval—you can iterate every second, minute, daily, weekly, monthly, or the 3rd Friday of every month at 3pm.

The following scenarios summarize the options available to you depending on your use case.

- Use case 1: **Build and schedule your ML workflow in a no-code environment**. For beginners or those new to SageMaker AI, you can use Amazon SageMaker Canvas to both build your ML workflow and create scheduled runs using the Canvas UI-based scheduler.
- Use case 2: **Build your workflow in a single Jupyter notebook and use a no-code scheduler**. Experienced ML practitioners can use code to build their ML workflow in a Jupyter notebook and use the no-code scheduling option available with the Notebook Jobs widget. If your ML workflow consists of multiple Jupyter notebooks, you can use the scheduling feature in the Pipelines Python SDK described in use case 3.
- Use case 3: **Build and schedule your ML workflow using Pipelines**. Advanced users can use the Amazon SageMaker Python SDK, the Amazon SageMaker Pipelines visual editor, or Amazon EventBridge scheduling options available with Pipelines. You can build an ML workflow comprised of steps that include operations with various SageMaker AI features and Amazon services, such as Amazon EMR.

Descript r	Use case 1	Use case 2	Use case 3
SageMak AI feature	Amazon SageMaker Canvas data processin g and ML workflow scheduling	Notebook Jobs schedule widget (UI)	Pipelines Python SDK scheduling options
Descripti on	With Amazon SageMaker Canvas, you can schedule automatic runs of data processing steps and, in a separate procedure , automatic dataset updates. You can also indirectly schedule your entire ML workflow by setting up a configuration that runs a batch predictio n whenever a specific dataset is updated. For both automated data processing and dataset updates, SageMaker Canvas provides a basic form where you select a start time and date and a time interval between runs (or a cron expressio n if you schedule a data processing step). For more information about how to schedule data processin g steps, see Create a schedule to automatic ally process new data. For	If you built your data processing and pipeline workflow in a single Jupyter notebook, you can use the Notebook Jobs widget to run your notebook on demand or on a schedule. The Notebook Jobs widget displays a basic form where you specify the compute type, run schedule, and optional custom settings. You define your run schedule by selecting a time-base d interval or by inserting a cron expression. The widget is automatically installed in Studio, or you can perform additiona l installation to use this feature in your local JupyterLab environme nt. For more informati on about Notebook Jobs, see SageMaker Notebook Jobs.	You can use the schedulin g features in the SageMaker SDK if you implemented your ML workflow with Pipelines. Your pipeline can include steps such as fine-tuni ng, data processing, and deployment. Pipelines supports two ways to schedule your pipeline. You can create an Amazon EventBridge rule or use the SageMaker SDK PipelineSchedule constructor or the Amazon SageMaker Pipelines visual editor to define a schedule. For more information about the scheduling options available in Pipelines, see Schedule Pipeline Runs.

Descript r	Use case 1	Use case 2	Use case 3
	more information about how to schedule dataset and batch prediction updates, see How to manage automations.		
Optimize for	Provides a scheduling option for a SageMaker Canvas ML workflow	Provides a UI-based scheduling option for Jupyter notebook-based ML workflows	Provides a SageMaker SDK or EventBridge scheduling option for ML workflows
Consider tions	You can schedule your workflow with the Canvas no-code framework, but dataset updates and batch transform updates can handle up to 5GB of data.	You can schedule one notebook using the UI-based scheduling form, but not multiple notebooks, in the same job. To schedule multiple notebooks, use the Pipelines SDK code-based solution described in use case 3.	You can use the more advanced (SDK based) scheduling capabilities provided by Pipelines, but you need to reference API documentation to specify the correct options rather than selecting from a UI-based menu of options.
Recomm ed environn nt	Amazon SageMaker Canvas	Studio, local JupyterLab environment	Studio, local JupyterLa b environment, any code editor

Additional resources

SageMaker AI offers the following additional options for scheduling your workflows.

- What is Amazon EventBridge Scheduler?. The scheduling options discussed in this section include pre-built options available in SageMaker Canvas, Studio, and the SageMaker AI Python SDK. All options extend the features of Amazon EventBridge, and you can also create your own custom scheduling solution with EventBridge.

- Scheduled and event based executions for Feature Processor pipelines. With Amazon SageMaker Feature Store Feature Processing, you can configure your Feature Processing pipelines to run on a schedule or as a result of another Amazon service event.

Amazon Batch support for SageMaker AI training jobs

An Amazon Batch job queue stores and prioritizes submitted jobs before they run on compute resources. You can submit SageMaker AI training jobs to a job queue in order to take advantage of the serverless job scheduling and prioritization tools provided by Amazon Batch.

How it works

The following steps describe the workflow of how to use an Amazon Batch job queue with SageMaker AI training jobs. For more detailed tutorials and example notebooks, see the Get started section.

- Set up Amazon Batch and any necessary permissions. For more information, see Setting up Amazon Batch in the *Amazon Batch User Guide*.
- Create the following Amazon Batch resources in the console or using the Amazon CLI:
  - Service environment – Contains configuration parameters for integrating with SageMaker AI.
  - SageMaker AI training job queue – Integrates with SageMaker AI to submit training jobs.
- Configure your details and request for a SageMaker AI training job, such as your training container image. To submit a training job to an Amazon Batch queue, you can use the Amazon CLI, the Amazon SDK for Python (Boto3), or the SageMaker AI Python SDK.
- Submit your training jobs to the job queue. You can use the following options to submit jobs:
  - Use the Amazon Batch SubmitServiceJob API.
  - Use the `aws_batch` module from the SageMaker AI Python SDK. After creating a TrainingQueue object and a model training object (such as a ModelTrainer), you can submit training jobs to the TrainingQueue using the `queue.submit()` method.
- After submitting jobs, view your job queue and job status with the Amazon Batch console, the Amazon Batch DescribeServiceJob API, or the SageMaker AI DescribeTrainingJob API.

Cost and availability

For detailed pricing information about training jobs, see Amazon SageMaker AI pricing. With Amazon Batch, you only pay for any Amazon resources used, such as Amazon EC2 instances. For more information, see Amazon Batch pricing.

You can use Amazon Batch for SageMaker AI training jobs in any Amazon Web Services Region where training jobs are available. For more information, see Amazon SageMaker AI endpoints and quotas.

To ensure you have the required capacity when you need it, you can use SageMaker AI Flexible Training Plans (FTP). These plans allow you to reserve capacity for your training jobs. When combined with Amazon Batch's queuing capabilities, you can maximize utilization during your plan's duration. For more information, see Reserve training plans for you training jobs or HyperPod clusters.

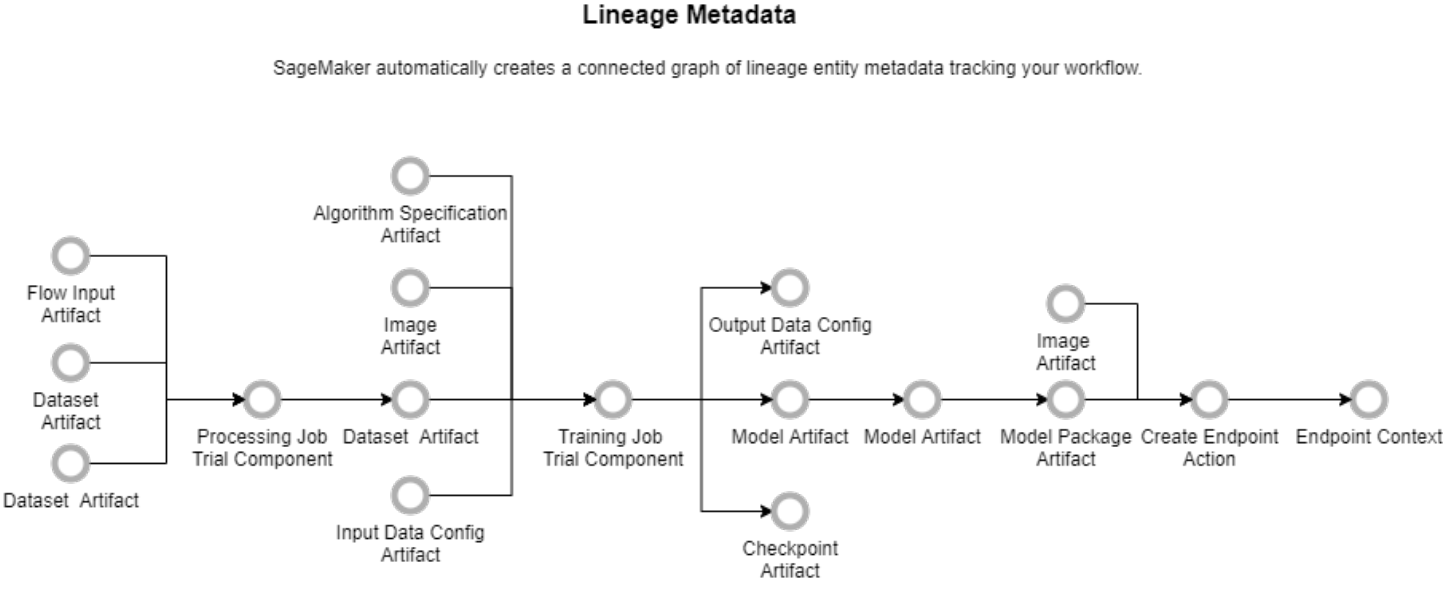
Get started

For a tutorial on how to set up an Amazon Batch job queue and submit SageMaker AI training jobs, see Getting started with Amazon Batch on SageMaker AI in the *Amazon Batch User Guide*.

For Jupyter notebooks that show how to use the `aws_batch` module in the SageMaker AI Python SDK, see the Amazon Batch for SageMaker AI Training jobs notebook examples in the amazon-sagemaker-examples GitHub repository.

Amazon SageMaker ML Lineage Tracking

> **Note**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see Amazon SageMaker Studio.
> Studio Classic is still maintained for existing workloads but is no longer available for onboarding. You can only stop or delete existing Studio Classic applications and cannot create new ones. We recommend that you migrate your workload to the new Studio experience.



Amazon SageMaker ML Lineage Tracking creates and stores information about the steps of a machine learning (ML) workflow from data preparation to model deployment. With the tracking information, you can reproduce the workflow steps, track model and dataset lineage, and establish model governance and audit standards.

SageMaker AI's Lineage Tracking feature works in the backend to track all the metadata associated with your model training and deployment workflows. This includes your training jobs, datasets used, pipelines, endpoints, and the actual models. You can query the lineage service at any point to find the exact artifacts used to train a model. Using those artifacts, you can recreate the same ML workflow to reproduce the model as long as you have access to the exact dataset that was used. A trial component tracks the training job. This trial component has all the parameters used as part of the training job. If you don't need to rerun the entire workflow, you can reproduce the training job to derive the same model.

With SageMaker AI Lineage Tracking data scientists and model builders can do the following:

- Keep a running history of model discovery experiments.
- Establish model governance by tracking model lineage artifacts for auditing and compliance verification.

The following diagram shows an example lineage graph that Amazon SageMaker AI automatically creates in an end-to-end model training and deployment ML workflow.

Topics

- Lineage Tracking Entities
- Amazon SageMaker AI–Created Tracking Entities
- Manually Create Tracking Entities
- Querying Lineage Entities
- Tracking Cross-Account Lineage

Lineage Tracking Entities

Tracking entities maintain a representation of all the elements of your end-to-end machine learning workflow. You can use this representation to establish model governance, reproduce your workflow, and maintain a record of your work history.

Amazon SageMaker AI automatically creates tracking entities for trial components and their associated trials and experiments when you create SageMaker AI jobs such as processing jobs, training jobs, and batch transform jobs. In additional to auto tracking, you can also Manually Create Tracking Entities to model custom steps in your workflow. For more information, see Amazon SageMaker Experiments in Studio Classic.

SageMaker AI also automatically creates tracking entities for the other steps in a workflow so you can track the workflow from end to end. For more information, see Amazon SageMaker AI–Created Tracking Entities.

You can create additional entities to supplement those created by SageMaker AI. For more information, see Manually Create Tracking Entities.

SageMaker AI reuses any existing entities rather than creating new ones. For example, there can be only one artifact with a unique `SourceUri`.

Key concepts for querying lineage

- **Lineage** – Metadata that tracks the relationships between various entities in your ML workflows.
- **QueryLineage** – The action to inspect your lineage and discover relationships between entities.
- **Lineage entities** – The metadata elements of which your lineage is composed.
- **Cross-account lineage** – Your ML workflow may span more than one account. With cross-account lineage, you can configure multiple accounts to automatically create lineage associations between shared entity resources. QueryLineage then can return entities even from these shared accounts.

The following tracking entities are defined:

Experiment entities

- Trial component – A stage of a machine learning trial. Includes processing jobs, training jobs, and batch transform jobs.
- Trial – A combination of trial components that generally produces a model.
- Experiment – A grouping of trials generally focused on solving a specific use case.

Lineage entities

- Trial Component – Represents processing, training, and transform jobs in the lineage. Also part of experiment management.
- Context – Provides a logical grouping of other tracking or experiment entities. Conceptually, experiments and trials are contexts. Some examples are an endpoint and a model package.
- Action – Represents an action or activity. Generally, an action involves at least one input artifact or output artifact. Some examples are a workflow step and a model deployment.
- Artifact – Represents a URI addressable object or data. An artifact is generally either an input or an output to a trial component or action. Some examples include a dataset (S3 bucket URI), or an image (Amazon ECR registry path).
- Association – Links other tracking or experiment entities, such as an association between the location of training data and a training job.

  An association has an optional `AssociationType` property. The following values are available along with the suggested use for each type. SageMaker AI places no restrictions on their use:

  - `ContributedTo` – The source contributed to the destination or had a part in enabling the destination. For example, the training data contributed to the training job.
  - `AssociatedWith` – The source is connected to the destination. For example, an approval workflow is associated with a model deployment.
  - `DerivedFrom` - The destination is a modification of the source. For example, a digest output of a channel input for a processing job is derived from the original inputs.
  - `Produced` – The source generated the destination. For example, a training job produced a model artifact.
  - `SameAs` – When the same lineage entity used in different accounts.

Common properties

- **Type property**

  The action, artifact, and context entities have a *type* property, `ActionType`, `ArtifactType`, and `ContextType`, respectively. This property is a custom string which can associate meaningful information with the entity and be used as a filter in the List APIs.

- **Source property**

  The action, artifact, and context entities have a `Source` property. This property provides the underlying URI that the entity represents. Some examples are:

  - An `UpdateEndpoint` action where the source is the `EndpointArn`.
  - An image artifact for a processing job where the source is the `ImageUri`.
  - An `Endpoint` context where the source is the `EndpointArn`.

- **Metadata property**

  The action and artifact entities have an optional `Metadata` property which can provide the following information:

  - `ProjectId` – For example, the ID of the SageMaker AI MLOps project to which a model belongs.
  - `GeneratedBy` – For example, the SageMaker AI pipeline execution that registered a model package version.
  - `Repository` – For example, the repository that contains an algorithm.
  - `CommitId` – For example, the commit ID of an algorithm version.

Amazon SageMaker AI–Created Tracking Entities

Amazon SageMaker AI automatically creates tracking entities for SageMaker AI jobs, models, model packages, and endpoints if the data is available. There is no limit to the number of lineage entities created by SageMaker AI.

For information on how you can manually create tracking entities, see Manually Create Tracking Entities.

Topics

- Tracking Entities for SageMaker AI Jobs

- Tracking Entities for Model Packages
- Tracking Entities for Endpoints

Tracking Entities for SageMaker AI Jobs

SageMaker AI creates a trial component for and associated with each SageMaker AI job. SageMaker AI creates artifacts to track the job metadata and associations between each artifact and the job.

Artifacts are created for the following job properties and associated with the Amazon Resource Name (ARN) of the SageMaker AI job. The artifact `SourceUri` is listed in parentheses.

Training Job

- The image that contains the training algorithm (`TrainingImage`).
- The data source of each input channel (`S3Uri`).
- The location for the model (`S3OutputPath`).
- The location for the managed spot checkpoint data (`S3Uri`).

Processing Job

- The container to be run by the processing job (`ImageUri`).
- The data location for each processing input and processing output (`S3Uri`).

Transform Job

- The input data source to be transformed (`S3Uri`).
- The results of the transform (`S3OutputPath`).

> **Note**
>
> Amazon Simple Storage Service (Amazon S3) artifacts are tracked based on the Amazon S3 URI values provided to the Create API, for example CreateTrainingJob, and not on the Amazon S3 key and hash or etag values from each file.

Tracking Entities for Model Packages

The following entities are created:

Model Packages

- A context for each model package group.
- An artifact for each model package.
- An association between each model package artifact and the context for each model package group to which the package belongs to.
- An action for the creation of a model package version.
- An association between the model package artifact and the creation action.
- An association between the model package artifact and each model package group context to which the package belongs to.
- Inference containers
  - An artifact for the image used in each container defined in the model package.
  - An artifact for the model used in each container.
  - An association between each artifact and the model package artifact.
- Algorithms
  - An artifact for each algorithm defined in the model package.
  - An artifact for the model created by each algorithm.
  - An association between each artifact and the model package artifact.

Tracking Entities for Endpoints

The following entities are created by Amazon SageMaker AI:

Endpoints

- A context for each endpoint
- An action for the model deployment that created each endpoint
- An artifact for each model deployed to the endpoint
- An artifact for the image used in the model
- An artifact for the model package for the model

- An artifact for each image deployed to the endpoint
- An association between each artifact and the model deployment action

Manually Create Tracking Entities

You can manually create tracking entities for any property to establish model governance, reproduce your workflow, and maintain a record of your work history. For information on the tracking entities that Amazon SageMaker AI automatically creates, see Amazon SageMaker AI–Created Tracking Entities. The following tutorial demonstrates the steps needed to manually create and associate artifacts between a SageMaker training job and endpoint, then track the workflow.

You can add tags to all entities except associations. Tags are arbitrary key-value pairs that provide custom information. You can filter or sort a list or search query by tags. For more information, see Tagging Amazon resources in the *Amazon Web Services General Reference*.

For a sample notebook that demonstrates how to create lineage entities, see the Amazon SageMaker AI Lineage notebook in the Amazon SageMaker example GitHub repository.

Topics

- Manually Create Entities
- Manually Track a Workflow
- Limits

Manually Create Entities

The following procedure shows you how to create and associate artifacts between a SageMaker AI training job and endpoint. You perform the following steps:

Import tracking entities and associations

1. Import the lineage tracking entities.

```
import sys
!{sys.executable} -m pip install -q sagemaker

from sagemaker.core.helper.session_helper import get_execution_role
from sagemaker.core.helper.session_helper import Session
from sagemaker.lineage import context, artifact, association, action
```

```
import boto3
boto_session = boto3.Session(region_name=region)
sagemaker_client = boto_session.client("sagemaker")
```

2. Create the input and output artifacts.

```
code_location_arn = artifact.Artifact.create(
    artifact_name='source-code-location',
    source_uri='s3://...',
    artifact_type='code-location'
).artifact_arn

# Similar constructs for train_data_location_arn and test_data_location_arn

model_location_arn = artifact.Artifact.create(
    artifact_name='model-location',
    source_uri='s3://...',
    artifact_type='model-location'
).artifact_arn
```

3. Train the model and get the `trial_component_arn` that represents the training job.
4. Associate the input artifacts and output artifacts with the training job (trial component).

```
input_artifacts = [code_location_arn, train_data_location_arn,
 test_data_location_arn]
for artifact_arn in input_artifacts:
    try:
        association.Association.create(
            source_arn=artifact_arn,
            destination_arn=trial_component_arn,
            association_type='ContributedTo'
        )
    except:
        logging.info('association between {} and {} already exists', artifact_arn,
 trial_component_arn)

output_artifacts = [model_location_arn]
for artifact_arn in output_artifacts:
    try:
         association.Association.create(
            source_arn=trial_component_arn,
            destination_arn=artifact_arn,
```

```
            association_type='Produced'
        )
    except:
        logging.info('association between {} and {} already exists', artifact_arn,
 trial_component_arn)
```

5. Create the inference endpoint.

```
from sagemaker.serve import ModelBuilder

# model_trainer is the trained model from the training step above
model_builder = ModelBuilder(
    model=model_trainer,
    role_arn=role,
    instance_type='ml.m4.xlarge'
)
model = model_builder.build()
endpoint = model_builder.deploy(
    initial_instance_count=1,
    endpoint_name="my-endpoint"
)
```

6. Create the endpoint context.

```
from sagemaker.lineage import context

endpoint_details =
 sagemaker_client.describe_endpoint(EndpointName=endpoint.endpoint_name)
endpoint_arn = endpoint_details['EndpointArn']

endpoint_context_arn = context.Context.create(
    context_name=endpoint.endpoint_name,
    context_type='Endpoint',
    source_uri=endpoint_arn
).context_arn
```

7. Associate the training job (trial component) and endpoint context.

```
association.Association.create(
    source_arn=trial_component_arn,
    destination_arn=endpoint_context_arn
)
```

Manually Track a Workflow

You can manually track the workflow created in the previous section.

Given the endpoint Amazon Resource Name (ARN) from the previous example, the following procedure shows you how to track the workflow back to the datasets used to train the model that was deployed to the endpoint. You perform the following steps:

To track a workflow from endpoint to training data source

1. Import the tracking entities.

```
import sys
!{sys.executable} -m pip install -q sagemaker

from sagemaker.core.helper.session_helper import get_execution_role
from sagemaker.core.helper.session_helper import Session
from sagemaker.lineage import context, artifact, association, action

import boto3
boto_session = boto3.Session(region_name=region)
sagemaker_client = boto_session.client("sagemaker")
```

2. Get the endpoint context from the endpoint ARN.

```
endpoint_context_arn = sagemaker_client.list_contexts(
    SourceUri=endpoint_arn)['ContextSummaries'][0]['ContextArn']
```

3. Get the trial component from the association between the trial component and the endpoint context.

```
trial_component_arn = sagemaker_client.list_associations(
    DestinationArn=endpoint_context_arn)['AssociationSummaries'][0]['SourceArn']
```

4. Get the training data location artifact from the association between the trial component and the endpoint context.

```
train_data_location_artifact_arn = sagemaker_client.list_associations(
    DestinationArn=trial_component_arn, SourceType='Model')['AssociationSummaries']
[0]['SourceArn']
```

5. Get the training data location from the training data location artifact.

```
train_data_location = sagemaker_client.describe_artifact(
    ArtifactArn=train_data_location_artifact_arn)['Source']['SourceUri']
    print(train_data_location)
```

Response:

```
s3://sagemaker-sample-data-us-east-2/mxnet/mnist/train
```

Limits

You can create an an association between any entities, experiment and lineage, except the following:

- You cannot create an association between two experiment entities. Experiment entities consist of experiments, trials, and trial components.
- You can create an association with another association.

An error occurs if you try to create an entity that already exists.

Maximum number of manually created lineage entities

- Actions: 3000
- Artifacts: 6000
- Associations: 6000
- Contexts: 500

There is no limit to the number of lineage entities automatically created by Amazon SageMaker AI.

Querying Lineage Entities

Amazon SageMaker AI automatically generates graphs of lineage entities as you use them. You can query this data to answer a variety of questions. The following provides instructions on how to query this data in SDK for Python (Boto).

For information on how to view a registered model lineage in Amazon SageMaker Studio, see View model lineage details in Studio.

You can query your lineage entities to:

- Retrieve all data sets that went into the creation of a model.
- Retrieve all jobs that went into the creation of an endpoint.
- Retrieve all models that use a data set.
- Retrieve all endpoints that use a model.
- Retrieve which endpoints are derived from a certain data set.
- Retrieve the pipeline execution that created a training job.
- Retrieve the relationships between entities for investigation, governance, and reproducibility.
- Retrieve all downstream trials that use the artifact.
- Retrieve all upstream trials that use the artifact.
- Retrieve a list of artifacts that use the provided S3 uri.
- Retrieve upstream artifacts that use the dataset artifact.
- Retrieve downstream artifacts that use the dataset artifact.
- Retrieve datasets that use the image artifact.
- Retrieve actions that use the context.
- Retrieve processing jobs that use the endpoint.
- Retrieve transform jobs that use the endpoint.
- Retrieve trial components that use the endpoint.
- Retrieve the ARN for the pipeline execution associated with the model package group.
- Retrieve all artifacts that use the action.
- Retrieve all upstream datasets that use the model package approval action.
- Retrieve model package from model package approval action.
- Retrieve downstream endpoint contexts that use the endpoint.
- Retrieve the ARN for the pipeline execution associated with the trial component.
- Retrieve datasets that use the trial component.
- Retrieve models that use the trial component.
- Explore your lineage for visualization.

Limitations

- Lineage querying is not available in the following Regions:

- Africa (Cape Town) – af-south
- Asia Pacific (Jakarta) – ap-southeast-3
- Asia Pacific (Osaka) – ap-northeast-3
- Europe (Milan) – eu-south-1
- Europe (Spain) – eu-south-2
- Israel (Tel Aviv) – il-central-1

- The maximum depth of relationships to discover is currently limited to 10.
- Filtering is limited to the following properties: last modified date, created date, type, and lineage entity type.

Topics

- Getting Started with Querying Lineage Entities

Getting Started with Querying Lineage Entities

The easiest way to get started is either via the:

- Amazon SageMaker Python SDK which has defined many common use cases.
- For a notebook that demonstrates how to use SageMaker AI Lineage APIs to query relationships across the lineage graph, see sagemaker-lineage-multihop-queries.ipynb.

The following examples show how to use the `LineageQuery` and `LineageFilter` APIs to construct queries to answer questions about the Lineage Graph and extract entity relationships for a few use cases.

Example Using the `LineageQuery` API to find entity associations

```
from sagemaker.lineage.context import Context, EndpointContext
from sagemaker.lineage.action import Action
from sagemaker.lineage.association import Association
from sagemaker.lineage.artifact import Artifact, ModelArtifact, DatasetArtifact

from sagemaker.lineage.query import (
    LineageQuery,
    LineageFilter,
    LineageSourceEnum,
```

```
    LineageEntityEnum,
    LineageQueryDirectionEnum,
)
# Find the endpoint context and model artifact that should be used for the lineage
 queries.

contexts = Context.list(source_uri=endpoint_arn)
context_name = list(contexts)[0].context_name
endpoint_context = EndpointContext.load(context_name=context_name)
```

Example Find all the datasets associated with an endpoint

```
# Define the LineageFilter to look for entities of type `ARTIFACT` and the source of
 type `DATASET`.

query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT], sources=[LineageSourceEnum.DATASET]
)

# Providing this `LineageFilter` to the `LineageQuery` constructs a query that
 traverses through the given context `endpoint_context`
# and find all datasets.

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[endpoint_context.context_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

# Parse through the query results to get the lineage objects corresponding to the
 datasets
dataset_artifacts = []
for vertex in query_result.vertices:
    dataset_artifacts.append(vertex.to_lineage_object().source.source_uri)

pp.pprint(dataset_artifacts)
```

Example Find the models associated with an endpoint

```
# Define the LineageFilter to look for entities of type `ARTIFACT` and the source of
 type `MODEL`.
```

```
query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT], sources=[LineageSourceEnum.MODEL]
)

# Providing this `LineageFilter` to the `LineageQuery` constructs a query that
 traverses through the given context `endpoint_context`
# and find all datasets.

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[endpoint_context.context_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

# Parse through the query results to get the lineage objects corresponding to the model
model_artifacts = []
for vertex in query_result.vertices:
    model_artifacts.append(vertex.to_lineage_object().source.source_uri)

# The results of the `LineageQuery` API call return the ARN of the model deployed to
 the endpoint along with
# the S3 URI to the model.tar.gz file associated with the model
pp.pprint(model_artifacts)
```

Example Find the trial components associated with the endpoint

```
# Define the LineageFilter to look for entities of type `TRIAL_COMPONENT` and the
 source of type `TRAINING_JOB`.

query_filter = LineageFilter(
    entities=[LineageEntityEnum.TRIAL_COMPONENT],
    sources=[LineageSourceEnum.TRAINING_JOB],
)

# Providing this `LineageFilter` to the `LineageQuery` constructs a query that
 traverses through the given context `endpoint_context`
# and find all datasets.

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[endpoint_context.context_arn],
    query_filter=query_filter,
```

```
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

# Parse through the query results to get the ARNs of the training jobs associated with
 this Endpoint
trial_components = []
for vertex in query_result.vertices:
    trial_components.append(vertex.arn)

pp.pprint(trial_components)
```

Example Changing the focal point of lineage

The `LineageQuery` can be modified to have different `start_arns` which changes the focal point of lineage. In addition, the `LineageFilter` can take multiple sources and entities to expand the scope of the query.

In the following we use the model as the lineage focal point and find the endpoints and datasets associated with it.

```
# Get the ModelArtifact

model_artifact_summary = list(Artifact.list(source_uri=model_package_arn))[0]
model_artifact = ModelArtifact.load(artifact_arn=model_artifact_summary.artifact_arn)
query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[LineageSourceEnum.ENDPOINT, LineageSourceEnum.DATASET],
)

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],  # Model is the starting artifact
    query_filter=query_filter,
    # Find all the entities that descend from the model, i.e. the endpoint
    direction=LineageQueryDirectionEnum.DESCENDANTS,
    include_edges=False,
)

associations = []
for vertex in query_result.vertices:
    associations.append(vertex.to_lineage_object().source.source_uri)

query_result = LineageQuery(sagemaker_session).query(
```

```
    start_arns=[model_artifact.artifact_arn],  # Model is the starting artifact
    query_filter=query_filter,
    # Find all the entities that ascend from the model, i.e. the datasets
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

for vertex in query_result.vertices:
    associations.append(vertex.to_lineage_object().source.source_uri)

pp.pprint(associations)
```

Example Using `LineageQueryDirectionEnum.BOTH` to find ascendent and descendent relationships

When the direction is set to BOTH, the query traverses the graph to find ascendant and descendant relationships. This traversal takes place not only from the starting node, but from each node that is visited. For example; if a training job is run twice and both models generated by the training job are deployed to endpoints, the result of the query with direction set to BOTH shows both endpoints. This is because the same image is used for training and deploying the model. Since the image is common to the model, the `start_arn` and both the endpoints, appear in the query result.

```
query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[LineageSourceEnum.ENDPOINT, LineageSourceEnum.DATASET],
)

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],  # Model is the starting artifact
    query_filter=query_filter,
    # This specifies that the query should look for associations both ascending and
 descending for the start
    direction=LineageQueryDirectionEnum.BOTH,
    include_edges=False,
)

associations = []
for vertex in query_result.vertices:
    associations.append(vertex.to_lineage_object().source.source_uri)

pp.pprint(associations)
```

Example Directions in `LineageQuery` - `ASCENDANTS` vs. `DESCENDANTS`

To understand the direction in the Lineage Graph, take the following entity relationship graph - Dataset -> Training Job -> Model -> Endpoint

The endpoint is a descendant of the model, and the model is a descendant of the dataset. Similarly, the model is an ascendant of the endpoint. The `direction` parameter can be used to specify whether the query should return entities that are descendants or ascendants of the entity in `start_arns`. If the `start_arns` contains a model and the direction is `DESCENDANTS`, the query returns the endpoint. If the direction is `ASCENDANTS`, the query returns the dataset.

```
# In this example, we'll look at the impact of specifying the direction as ASCENDANT or
 DESCENDANT in a `LineageQuery`.

query_filter = LineageFilter(
    entities=[LineageEntityEnum.ARTIFACT],
    sources=[
        LineageSourceEnum.ENDPOINT,
        LineageSourceEnum.MODEL,
        LineageSourceEnum.DATASET,
        LineageSourceEnum.TRAINING_JOB,
    ],
)

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.ASCENDANTS,
    include_edges=False,
)

ascendant_artifacts = []

# The lineage entity returned for the Training Job is a TrialComponent which can't be
 converted to a
# lineage object using the method `to_lineage_object()` so we extract the
 TrialComponent ARN.
for vertex in query_result.vertices:
    try:
        ascendant_artifacts.append(vertex.to_lineage_object().source.source_uri)
    except:
        ascendant_artifacts.append(vertex.arn)
```

```
print("Ascendant artifacts : ")
pp.pprint(ascendant_artifacts)

query_result = LineageQuery(sagemaker_session).query(
    start_arns=[model_artifact.artifact_arn],
    query_filter=query_filter,
    direction=LineageQueryDirectionEnum.DESCENDANTS,
    include_edges=False,
)

descendant_artifacts = []
for vertex in query_result.vertices:
    try:
        descendant_artifacts.append(vertex.to_lineage_object().source.source_uri)
    except:
        # Handling TrialComponents.
        descendant_artifacts.append(vertex.arn)

print("Descendant artifacts : ")
pp.pprint(descendant_artifacts)
```

Example SDK helper functions to make lineage queries easier

The classes `EndpointContext`, `ModelArtifact`, and `DatasetArtifact` have helper functions that are wrappers over the `LineageQuery` API to make certain lineage queries easier to leverage. The following example shows how to use these helper function.

```
# Find all the datasets associated with this endpoint

datasets = []
dataset_artifacts = endpoint_context.dataset_artifacts()
for dataset in dataset_artifacts:
    datasets.append(dataset.source.source_uri)
print("Datasets : ", datasets)

# Find the training jobs associated with the endpoint
training_job_artifacts = endpoint_context.training_job_arns()
training_jobs = []
for training_job in training_job_artifacts:
    training_jobs.append(training_job)
print("Training Jobs : ", training_jobs)

# Get the ARN for the pipeline execution associated with this endpoint (if any)
```

```
pipeline_executions = endpoint_context.pipeline_execution_arn()
if pipeline_executions:
    for pipeline in pipelines_executions:
        print(pipeline)

# Here we use the `ModelArtifact` class to find all the datasets and endpoints
 associated with the model

dataset_artifacts = model_artifact.dataset_artifacts()
endpoint_contexts = model_artifact.endpoint_contexts()

datasets = [dataset.source.source_uri for dataset in dataset_artifacts]
endpoints = [endpoint.source.source_uri for endpoint in endpoint_contexts]

print("Datasets associated with this model : ")
pp.pprint(datasets)

print("Endpoints associated with this model : ")
pp.pprint(endpoints)

# Here we use the `DatasetArtifact` class to find all the endpoints hosting models that
 were trained with a particular dataset
# Find the artifact associated with the dataset

dataset_artifact_arn = list(Artifact.list(source_uri=training_data))[0].artifact_arn
dataset_artifact = DatasetArtifact.load(artifact_arn=dataset_artifact_arn)

# Find the endpoints that used this training dataset
endpoint_contexts = dataset_artifact.endpoint_contexts()
endpoints = [endpoint.source.source_uri for endpoint in endpoint_contexts]

print("Endpoints associated with the training dataset {}".format(training_data))
pp.pprint(endpoints)
```

Example Getting a Lineage graph visualization

A helper class `Visualizer` is provided in the sameple notebook visualizer.py to help plot the lineage graph. When the query response is rendered, a graph with the lineage relationships from the `StartArns` is displayed. From the `StartArns` the visualization shows the relationships with the other lineage entities returned in the `query_lineage` API action.

```
# Graph APIs
# Here we use the boto3 `query_lineage` API to generate the query response to plot.
```

```
from visualizer import Visualizer

query_response = sm_client.query_lineage(
    StartArns=[endpoint_context.context_arn], Direction="Ascendants", IncludeEdges=True
)

viz = Visualizer()
viz.render(query_response, "Endpoint")

        query_response = sm_client.query_lineage(
    StartArns=[model_artifact.artifact_arn], Direction="Ascendants", IncludeEdges=True
)
viz.render(query_response, "Model")
```

Tracking Cross-Account Lineage

Amazon SageMaker AI supports tracking lineage entities from a different Amazon account. Other Amazon accounts can share their lineage entities with you and you can access these lineage entities through direct API calls or SageMaker AI lineage queries.

SageMaker AI uses Amazon Resource Access Manager to help you securely share your lineage resources. You can share your resources through the Amazon RAM console.

Set Up Cross-Account Lineage Tracking

You can group and share your Lineage Tracking Entities through a lineage group in Amazon SageMaker AI. SageMaker AI supports only one default lineage group per account. SageMaker AI creates the default lineage group whenever a lineage entity is created in your account. Every lineage entity owned by your account is assigned to this default lineage group. To share lineage entities with another account, you share this default lineage group with that account.

> **Note**
>
> You can share all lineage tracking entities in a lineage group or none.

Create a resource share for your lineage entities using Amazon Resource Access Manager console. For more information, see Sharing your Amazon resources in the *Amazon Resource Access Manager User Guide*.

> **Note**
>
> After the resource share is created, it can take a few minutes for the resource and principal associations to complete. Once the association is set, the shared account receives an invitation to join the resource share. The shared account must accept the invite to gain access to shared resources. For more information on accepting a resource share invite in Amazon RAM, see Using shared Amazon resources in the *Amazon Resource Access Manager User Guide*.

Your cross-account lineage tracking resource policy

Amazon SageMaker AI supports only one type of resource policy. The SageMaker AI resource policy must allow all of the following operations:

```
"sagemaker:DescribeAction"
"sagemaker:DescribeArtifact"
"sagemaker:DescribeContext"
"sagemaker:DescribeTrialComponent"
"sagemaker:AddAssociation"
"sagemaker:DeleteAssociation"
"sagemaker:QueryLineage"
```

Example The following is a SageMaker AI resource policy created using Amazon Resource Access Manager for creating a resource share for an accounts lineage group.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "FullLineageAccess",
      "Effect": "Allow",
      "Principal": {
        "AWS": "111122223333"
      },
      "Action": [
        "sagemaker:DescribeAction",
```

```
        "sagemaker:DescribeArtifact",
        "sagemaker:DescribeContext",
        "sagemaker:DescribeTrialComponent",
        "sagemaker:AddAssociation",
        "sagemaker:DeleteAssociation",
        "sagemaker:QueryLineage"
      ],
      "Resource": "arn:aws-cn:sagemaker:us-west-2:111111111111:lineage-group/
sagemaker-default-lineage-group"
    }
  ]
}
```

Tracking Cross-Account Lineage Entities

With cross-account lineage tracking you can associate lineage entities in different accounts using the same `AddAssociation` API action. When you associate two lineage entities, SageMaker AI validates if you have permissions to perform the `AddAssociation` API action on both lineage entities. SageMaker AI then establishes the association. If you don't have the permissions, SageMaker AI *does not* create the association. Once the cross-account association is established, you can access either lineage entity from the other through the `QueryLineage` API action. For more information, see Querying Lineage Entities.

In addition to SageMaker AI automatically creating lineage entities, if you have cross-account access, SageMaker AI connects artifacts that reference the same object or data. If the data from one account is used in lineage tracking by different accounts, SageMaker AI creates an artifact in each account to track that data. With cross-account lineage, whenever SageMaker AI creates new artifacts, SageMaker AI checks if there are other artifacts created for the same data that are also shared with you. SageMaker AI then establishes associations between the newly created artifact and each of the artifacts shared with you with the `AssociationType` set to `SameAs`. You can then use the `QueryLineage` API action to traverse the lineage entities in your own account to lineage entities shared with you but owned by a different Amazon account. For more information, see Querying Lineage Entities

Topics

- Accessing lineage resources from a different accounts
- Authorization for querying cross-account lineage entities

Accessing lineage resources from a different accounts

Once the cross-account access for sharing lineage has been set up, you can call the following SageMaker API actions directly with the ARN to describe the shared lineage entities from another account:

- `DescribeAction`
- `DescribeArtifact`
- `DescribeContext`
- `DescribeTrialComponent`

You can also manage Associations for lineage entities owned by different accounts that are shared with you, using the following SageMaker API actions:

- `AddAssociation`
- `DeleteAssociation`

For a notebook that demonstrates how to use SageMaker AI Lineage APIs to query lineage across accounts., see sagemaker-lineage-cross-account-with-ram.ipynb.

Authorization for querying cross-account lineage entities

Amazon SageMaker AI must validate that you have permissions to perform the `QueryLineage` API action on the `StartArns`. This is enforced through the resource policy attached to the `LineageGroup`. The result from this action includes all the lineage entities to which you have access, whether they are owned by your account or shared by another account. For more information, see Querying Lineage Entities.

Model Registration Deployment with Model Registry

With the Amazon SageMaker Model Registry you can do the following:

- Catalog models for production.
- Manage model versions.
- Associate metadata, such as training metrics, with a model.
- View information from Amazon SageMaker Model Cards in your registered models.

- View model lineage for traceability and reproducibility.
- Define a staging construct that models can progress through for your model lifecycle.
- Manage the approval status of a model.
- Deploy models to production.
- Automate model deployment with CI/CD.
- Share models with other users.

Catalog models by creating SageMaker Model Registry Model (Package) Groups that contain different versions of a model. You can create a Model Group that tracks all of the models that you train to solve a particular problem. You can then register each model you train and the Model Registry adds it to the Model Group as a new model version. Lastly, you can create categories of Model Groups by further organizing them into SageMaker Model Registry Collections. A typical workflow might look like the following:

- Create a Model Group.
- Create an ML pipeline that trains a model. For information about SageMaker pipelines, see Pipelines actions.
- For each run of the ML pipeline, create a model version that you register in the Model Group you created in the first step.
- Add your Model Group into one or more Model Registry Collections.

For details about how to create and work with models, model versions, and Model Groups, see Model Registry Models, Model Versions, and Model Groups. Optionally, if you want to further group your Model Groups into Collections, see Model Registry Collections.

Model Registry Models, Model Versions, and Model Groups

The SageMaker Model Registry is structured as several Model (Package) Groups with model packages in each group. These Model Groups can optionally be added to one or more Collections. Each model package in a Model Group corresponds to a trained model. The version of each model package is a numerical value that starts at 1 and is incremented with each new model package added to a Model Group. For example, if 5 model packages are added to a Model Group, the model package versions will be 1, 2, 3, 4, and 5.

A model package is the actual model that is registered into the Model Registry as a versioned entity. There are two types of model packages in SageMaker AI. One type is used in the Amazon

Marketplace, and the other is used in the Model Registry. Model packages used in the Amazon Marketplace are not versionable entities and are not associated with Model Groups in the Model Registry. The Model Registry receives every new model that you retrain, gives it a version, and assigns it to a Model Group inside the Model Registry. The following image shows an example of a Model Group with 25 consecutively-versioned models. For more information about model packages used in the Amazon Marketplace, see Algorithms and packages in the Amazon Web Services Marketplace.

The model packages used in the Model Registry are versioned, and **must** be associated with a Model Group. The ARN of this model package type has the structure: `'arn:aws:sagemaker:region:account:model-package-group/version'`

The following topics show you how to create and work with models, model versions, and Model Groups in the Model Registry.

Topics

- Create a Model Group

- View the Deployment History of a Model
- View model lineage details in Studio

Create a Model Group

A Model Group contains different versions of a model. You can create a Model Group that tracks all of the models that you train to solve a particular problem. Create a Model Group by using either the Amazon SDK for Python (Boto3) or the Amazon SageMaker Studio console.

Create a Model Group (Boto3)

> **Important**
>
> Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.
> Amazon managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

To create a Model Group by using Boto3, call the `create_model_package_group` API operation and specify a name and description as parameters. The following example shows how to create a Model Group. The response from the `create_model_package_group` call is the Amazon Resource Name (ARN) of the new Model Group.

First, import the required packages and set up the SageMaker AI Boto3 client.

```
import time
import os
from sagemaker.core.helper.session_helper import get_execution_role, session
import boto3

region = boto3.Session().region_name

role = get_execution_role()

sm_client = boto3.client('sagemaker', region_name=region)
```

Now create the Model Group.

```
import time
model_package_group_name = "scikit-iris-detector-" + str(round(time.time()))
model_package_group_input_dict = {
 "ModelPackageGroupName" : model_package_group_name,
 "ModelPackageGroupDescription" : "Sample model package group"
}

create_model_package_group_response =
 sm_client.create_model_package_group(**model_package_group_input_dict)
print('ModelPackageGroup Arn :
 {}'.format(create_model_package_group_response['ModelPackageGroupArn']))
```

Create a Model Group (Studio or Studio Classic)

To create a Model Group in the Amazon SageMaker Studio console, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models**.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. Choose **Register**, then choose **Model group**.
6. In the **Register model group** dialog box, enter the following information:
   - The name of the new Model Group in the **Model group name** field.
   - (Optional) A description for the Model Group in the **Description** field.
   - (Optional) Any key-value pairs you want to associate with the Model Group in the **Tags** field. For information about using tags, see Tagging Amazon resources in the *Amazon Web Services General Reference*.
7. Choose **Register model group**.
8. (Optional) In the **Models** page, choose the **Registered models** tab, then choose **Model Groups**. Confirm your newly-created Model Group appears in the list of Model Groups.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon (

).
3. Choose **Models**, and then **Model registry**.
4. Choose **Actions**, then choose **Create model group**.
5. In the **Create model group** dialog box, enter the following information:
   - Enter the name of the new Model Group in the **Model group name** field.
   - (Optional) Enter a description for the Model Group in the **Description** field.
   - (Optional) Enter any key-value pairs you want to associate with the Model Group in the **Tags** field. For information about using tags, see Tagging Amazon resources in the *Amazon Web Services General Reference*.
   - (Optional) Choose a project with which to associate the Model Group in the **Project** field. For information about projects, see MLOps Automation With SageMaker Projects.
6. Choose **Create model group**.

Delete a Model Group

This procedure demonstrates how to delete a Model Group in the Amazon SageMaker Studio console. When you delete a Model Group, you lose access to the model versions in the Model Group.

Delete a Model Group (Studio or Studio Classic)

> **Important**
>
> You can only delete an empty model group. Before you delete your model group, remove its model versions, if any.

To delete a Model Group in the Amazon SageMaker Studio console, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models**.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. From the model groups list, select the check box next to the name of the Model Group you want to delete.
6. Choose the vertical ellipsis above the top right corner of the model groups list, and choose **Delete**.
7. In the **Delete model group** dialog box, choose **Yes, delete the model group**.
8. Choose **Delete**.
9. Confirm that your deleted model groups no longer appear in your list of model groups.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**. A list of your Model Groups appears.
4. From the model groups list, select the name of the Model Group you want to delete.
5. In the top right corner, choose **Remove**.
6. In the confirmation dialog box, enter `REMOVE`.
7. Choose **Remove**.

Register a Model Version

You can register an Amazon SageMaker AI model by creating a model version that specifies the model group to which it belongs. A model version must include a model artifacts (the trained weights of a model) and optionally the inference code for the model.

An *inference pipeline* is a SageMaker AI model composed of a linear sequence of two to fifteen containers that process inference requests. You register an inference pipeline by specifying the containers and the associated environment variables. For more information on inference pipelines, see Inference pipelines in Amazon SageMaker AI.

You can register a model with an inference pipeline, by specifying the containers and the associated environment variables. To create a model version with an inference pipeline by using either the Amazon SDK for Python (Boto3), the Amazon SageMaker Studio console, or by creating a step in a SageMaker AI model building pipeline, use the following steps.

Topics

- Register a Model Version (SageMaker AI Pipelines)
- Register a Model Version (Boto3)
- Register a Model Version (Studio or Studio Classic)
- Register a Model Version from a Different Account

Register a Model Version (SageMaker AI Pipelines)

To register a model version by using a SageMaker AI model building pipeline, create a `RegisterModel` step in your pipeline. For information about creating a `RegisterModel` step as part of a pipeline, see Step 8: Define a RegisterModel step to create a model package.

Register a Model Version (Boto3)

To register a model version by using Boto3, call the `create_model_package` API operation.

First, you set up the parameter dictionary to pass to the `create_model_package` API operation.

```
# Specify the model source
model_url = "s3://your-bucket-name/model.tar.gz"

modelpackage_inference_specification =  {
    "InferenceSpecification": {
      "Containers": [
         {
            "Image": image_uri,
     "ModelDataUrl": model_url
         }
      ],
```

```
      "SupportedContentTypes": [ "text/csv" ],
      "SupportedResponseMIMETypes": [ "text/csv" ],
   }
 }

# Alternatively, you can specify the model source like this:
# modelpackage_inference_specification["InferenceSpecification"]["Containers"][0]
["ModelDataUrl"]=model_url

create_model_package_input_dict = {
    "ModelPackageGroupName" : model_package_group_name,
    "ModelPackageDescription" : "Model to detect 3 different types of irises (Setosa,
 Versicolour, and Virginica)",
    "ModelApprovalStatus" : "PendingManualApproval"
}
create_model_package_input_dict.update(modelpackage_inference_specification)
```

Then you call the `create_model_package` API operation, passing in the parameter dictionary that you just set up.

```
create_model_package_response =
 sm_client.create_model_package(**create_model_package_input_dict)
model_package_arn = create_model_package_response["ModelPackageArn"]
print('ModelPackage Version ARN : {}'.format(model_package_arn))
```

Register a Model Version (Studio or Studio Classic)

To register a model version in the Amazon SageMaker Studio console, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models** from the menu.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups** and **My models**, if not selected already.
5. Choose **Register**. This will open the **Register model** page.
6. Follow the instructions provided in the **Register model** page.

7. Once you have reviewed your choices, choose **Register**. Once completed, you will be taken to the model version **Overview** page.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. Open the **Register Version** form. You can do this in one of two ways:
   - Choose **Actions**, and then choose **Create model version**.
   - Select the name of the model group for which you want to create a model version, then choose **Create model version**.
5. In the **Register model version** form, enter the following information:
   - In the **Model package group name** dropdown, select the model group name.
   - (Optional) Enter a description for your model version.
   - In the **Model Approval Status** dropdown, select the version approval status.
   - (Optional) In the **Custom metadata** field, add custom tags as key-value pairs.
6. Choose **Next**.
7. In the **Inference Specification** form, enter the following information:
   - Enter your inference image location.
   - Enter your model data artifacts location.
   - (Optional) Enter information about images to use for transform and real-time inference jobs, and supported input and output MIME types.
8. Choose **Next**.
9. (Optional) Provide details to aid endpoint recommendations.
10. Choose **Next**.
11. (Optional) Choose model metrics you want to include.
12. Choose **Next**.

13. Ensure the displayed settings are correct, and choose **Register model version**. If you subsequently see a modal window with an error message, choose **View** (next to the message) to view the source of the error.
14. Confirm your new model version appears in the parent model group page.

Register a Model Version from a Different Account

To register model versions with a Model Group created by a different Amazon account, you must add a cross-account Amazon Identity and Access Management resource policy to enable that account. For example, one Amazon account in your organization is responsible for training models, and a different account is responsible for managing, deploying, and updating models. You create IAM resource policies and apply the policies to the specific account resource to which you want to grant access for this case. For more information about cross-account resource policies in Amazon, see Cross-account policy evaluation logic in the *Amazon Identity and Access Management User Guide*.

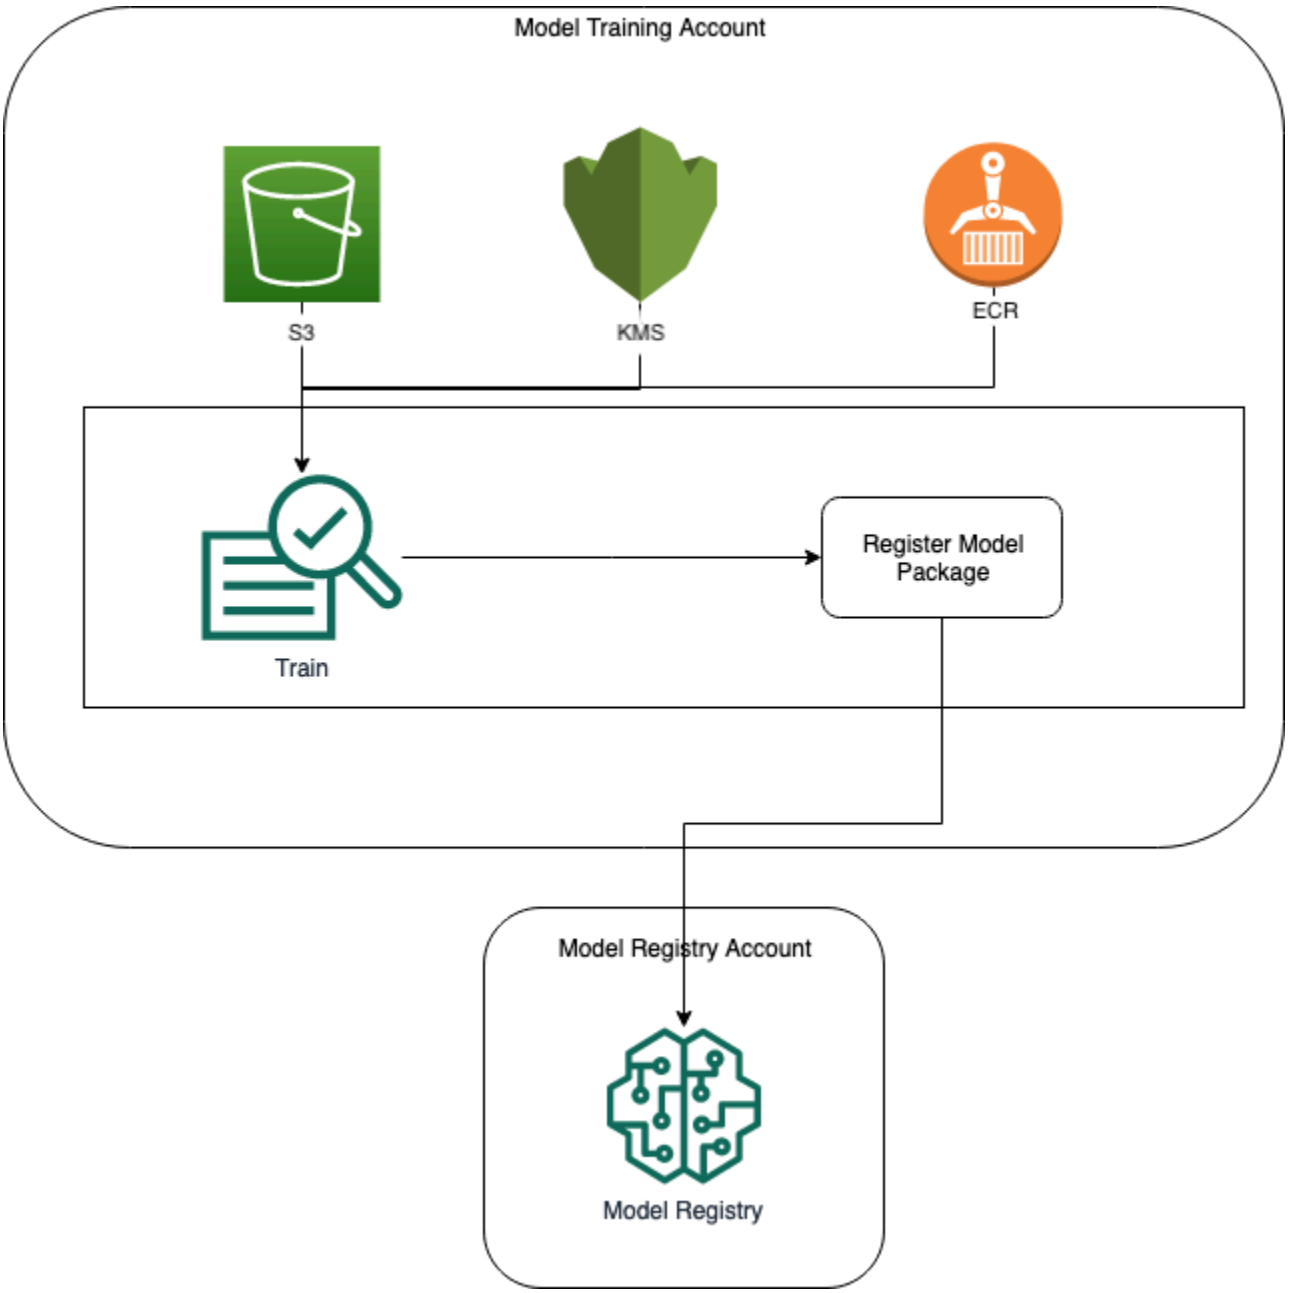
To enable cross-account discoverability, which allows other accounts to view model package groups from the resource owner account, see Cross-account discoverability.

> **Note**
>
> You must also use a KMS key to encrypt the output data config action during training for cross-account model deployment.

To enable cross-account model registry in SageMaker AI, you have to provide a cross-account resource policy for the Model Group that contains the model versions. The following is an example that creates cross-account policies for the Model Group and applies these policies to that specific resource.

The following configuration must be set in the source account which registers models cross-account in a Model Group. In this example, the source account is the model training account which will train and then register the model cross-account into the Model Registry of the Model Registry account.

The example assumes that you previously defined the following variables:



- `sm_client` – A SageMaker AI Boto3 client.

- `model_package_group_name` – The Model Group to which you want to grant access.
- `model_package_group_arn` – The Model Group ARN to which you want to grant cross-account access.
- `bucket` – The Amazon S3 bucket where the model training artifacts are stored.

To be able to deploy a model created in a different account, the user must have a role that has access to SageMaker AI actions, such as a role with the `AmazonSageMakerFullAccess` managed policy. For information about SageMaker AI managed policies, see Amazon managed policies for Amazon SageMaker AI.

Required IAM resource policies

The following diagram captures the policies required to allow cross-account model registration. As shown, these policies need to be active during model training to properly register the model into the Model Registry account.

Amazon ECR, Amazon S3, and Amazon KMS policies are demonstrated in the following code samples.

Sample Amazon ECR policy

JSON

```
{
    "Version":"2012-10-17",
```

```
    "Statement": [
        {
            "Sid": "AddPerm",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:root"
            },
            "Action": [
                "ecr:BatchGetImage",
                "ecr:Describe*"
            ]
        }
    ]
}
```

Sample Amazon S3 policy

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AddPerm",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:root"
            },
            "Action": [
                "s3:GetObject",
                "s3:GetBucketAcl",
                "s3:GetObjectAcl"
            ],
            "Resource": "arn:aws-cn:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Sample Amazon KMS policy

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "AddPerm",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:root"
            },
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey*"
            ],
            "Resource": "*"
        }
    ]
}
```

Apply resource policies to accounts

The following policy configuration applies the policies discussed in the previous section and must be put in the model training account.

```
import json

# The Model Registry account id of the Model Group
model_registry_account = "111111111111"

# The model training account id where training happens
model_training_account = "222222222222"

# 1. Create a policy for access to the ECR repository
# in the model training account for the Model Registry account Model Group
ecr_repository_policy = {"Version": "2012-10-17",
    "Statement": [{"Sid": "AddPerm",
        "Effect": "Allow",
        "Principal": {
          "AWS": f"arn:aws:iam::{model_registry_account}:root"
        },
```

```
        "Action": [
          "ecr:BatchGetImage",
          "ecr:Describe*"
        ]
    }]
}

# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
    registryId = model_training_account,
    repositoryName = "decision-trees-sample",
    policyText = ecr_repository_policy
)

# 2. Create a policy in the model training account for access to the S3 bucket
# where the model is present in the Model Registry account Model Group
bucket_policy = {"Version": "2012-10-17",
    "Statement": [{"Sid": "AddPerm",
        "Effect": "Allow",
        "Principal": {"AWS": f"arn:aws:iam::{model_registry_account}:root"
        },
        "Action": [
          "s3:GetObject",
          "s3:GetBucketAcl",
          "s3:GetObjectAcl"
        ],
        "Resource": [
          "arn:aws:s3:::{bucket}/*",
   "Resource: arn:aws:s3:::{bucket}"
        ]
    }]
}

# Convert the S3 policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new bucket policy
s3 = boto3.client("s3")
response = s3.put_bucket_policy(
    Bucket = bucket,
```

```
    Policy = bucket_policy)

# 3. Create the KMS grant for the key used during training for encryption
# in the model training account to the Model Registry account Model Group
client = boto3.client("kms")

response = client.create_grant(
    GranteePrincipal=model_registry_account,
    KeyId=kms_key_id
    Operations=[
        "Decrypt",
        "GenerateDataKey",
    ],
)
```

The following configuration needs to be put in the Model Registry account where the Model Group exists.

```
# The Model Registry account id of the Model Group
model_registry_account = "111111111111"

# 1. Create policy to allow the model training account to access the ModelPackageGroup
model_package_group_policy = {"Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AddPermModelPackageVersion",
            "Effect": "Allow",
            "Principal": {"AWS": f"arn:aws:iam::{model_training_account}:root"},
            "Action": ["sagemaker:CreateModelPackage"],
            "Resource": f"arn:aws:sagemaker:{region}:{model_registry_account}:model-
package/{model_package_group_name}/*"
        }
    ]
}

# Convert the policy from JSON dict to string
model_package_group_policy = json.dumps(model_package_group_policy)

# Set the new policy
response = sm_client.put_model_package_group_policy(
    ModelPackageGroupName = model_package_group_name,
    ResourcePolicy = model_package_group_policy)
```

Finally, use the `create_model_package` action from the model training account to register the model package in the cross-account.

```
# Specify the model source
model_url = "s3://{bucket}/model.tar.gz"

#Set up the parameter dictionary to pass to the create_model_package API operation
modelpackage_inference_specification =  {
    "InferenceSpecification": {
        "Containers": [
            {
                "Image": f"{model_training_account}.dkr.ecr.us-east-2.amazonaws.com/
decision-trees-sample:latest",
                "ModelDataUrl": model_url
            }
        ],
        "SupportedContentTypes": [ "text/csv" ],
        "SupportedResponseMIMETypes": [ "text/csv" ],
    }
}

# Alternatively, you can specify the model source like this:
# modelpackage_inference_specification["InferenceSpecification"]["Containers"][0]
["ModelDataUrl"]=model_url

create_model_package_input_dict = {
    "ModelPackageGroupName" : model_package_group_arn,
    "ModelPackageDescription" : "Model to detect 3 different types of irises (Setosa,
 Versicolour, and Virginica)",
    "ModelApprovalStatus" : "PendingManualApproval"
}
create_model_package_input_dict.update(modelpackage_inference_specification)

# Create the model package in the Model Registry account
create_model_package_response =
 sm_client.create_model_package(**create_model_package_input_dict)
model_package_arn = create_model_package_response["ModelPackageArn"]
print('ModelPackage Version ARN : {}'.format(model_package_arn))
```

Restrict artifact access to model package deployments

When you share a model package across accounts, the consuming account's execution role needs `s3:GetObject` on the model artifacts in the producing account. By default, that permission applies whenever the role is used. As a result, any principal that uses the role can read the artifacts from a notebook, from a training job, or through a direct API call—not only from an endpoint deployed from a model package.

You can narrow that access so that only endpoints deployed from a model package can read the artifacts. When you deploy an endpoint from a model package, SageMaker AI applies the session tag `sagemaker:ModelPackageArn` to the execution-role sessions it assumes for that endpoint. The tag value is the ARN of the model package version. The tag applies for the life of the endpoint, both to the sessions SageMaker AI uses to download the model artifacts and to the credentials that the inference container receives at runtime. A bucket policy that requires this tag therefore grants access only to sessions that belong to an endpoint deployed from a matching model package. Notebooks, training jobs, and endpoints deployed from a plain container image do not carry the tag.

If code in your inference container assumes another role, the resulting credentials do not carry the `sagemaker:ModelPackageArn` tag.

> **Note**
>
> This applies to real-time endpoint deployments. Serverless endpoints and inference components do not carry the `sagemaker:ModelPackageArn` session tag, so a bucket policy that requires the tag denies them at read time. If you need to deploy the same artifacts that way, keep them in a bucket that does not require the tag.

This requires three pieces working together. All three are yours to configure; SageMaker AI supplies only the session tag:

- An execution role tagged `ManagedBy=SageMaker` whose trust policy allows only the SageMaker AI service principal to assume it.
- A service control policy that prevents anyone other than SageMaker AI from assuming that role or from setting the `sagemaker:ModelPackageArn` tag key. Without this, a principal with permission to call Amazon STS might supply the tag themselves.

- An Amazon S3 bucket policy that grants `s3:GetObject` only when the session carries the tag, the caller is in your organization, and the role is tagged `ManagedBy=SageMaker`.

> **Important**
>
> The SCP is what makes the session tag trustworthy. If you apply the bucket policy without the SCP, a principal that can assume the execution role directly can attach the `sagemaker:ModelPackageArn` tag to its own session and satisfy the bucket policy.

Step 1: Tag and scope the execution role

In the consuming account, tag the execution role `ManagedBy=SageMaker` and restrict its trust policy to the SageMaker AI service principal. The trust policy must allow both `sts:AssumeRole` and `sts:TagSession`. Without `sts:TagSession`, SageMaker AI cannot apply the `sagemaker:ModelPackageArn` session tag, and Amazon S3 denies every read that the bucket policy in Step 3 requires.

```
{
  "RoleName": "GovernedModelExecutionRole",
  "Tags": [ { "Key": "ManagedBy", "Value": "SageMaker" } ],
  "AssumeRolePolicyDocument": {
    "Version": "2012-10-17",
    "Statement": [{
      "Effect": "Allow",
      "Principal": { "Service": "sagemaker.amazonaws.com" },
      "Action": [ "sts:AssumeRole", "sts:TagSession" ]
    }]
  }
}
```

Step 2: Add a service control policy

Attach the following SCP in your organization. The first statement allows only the SageMaker AI service principal to assume a role tagged `ManagedBy=SageMaker`. The second allows only SageMaker AI to set the `sagemaker:ModelPackageArn` tag key, which is the only tag key that the bucket policy evaluates. For more information, see Creating, updating, and deleting service control policies.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DenyNonSageMakerAssumeOnManagedRoles",
      "Effect": "Deny",
      "Action": "sts:AssumeRole",
      "Resource": "*",
      "Condition": {
        "StringEquals": { "aws:ResourceTag/ManagedBy": "SageMaker" },
        "StringNotEquals": { "aws:PrincipalServiceName": "sagemaker.amazonaws.com" }
      }
    },
    {
      "Sid": "DenyTaggingProtectedKeysUnlessSageMaker",
      "Effect": "Deny",
      "Action": [ "iam:TagRole", "iam:UntagRole", "sts:TagSession" ],
      "Resource": "*",
      "Condition": {
        "StringLike": { "aws:RequestTag/sagemaker:ModelPackageArn": "*" },
        "StringNotEquals": { "aws:PrincipalServiceName": "sagemaker.amazonaws.com" }
      }
    }
  ]
}
```

Note

Both statements use `StringNotEquals` on `aws:PrincipalServiceName`, which evaluates to true when the key is absent. The SCP therefore denies these actions to every IAM user and role in your member accounts, including sessions that carry no service principal at all. SCPs do not apply to calls that Amazon services make with their own service principals; the role's trust policy, which grants access only to the SageMaker AI service principal, is what excludes other Amazon services.

Step 3: Add the Amazon S3 bucket policy

In the producing account, apply the following policy to the bucket holding the model artifacts. The first statement governs reads by endpoints deployed from a model package. All three of its

conditions must hold, and Amazon S3 denies any session that is missing one. The second statement allows model package registration, which happens before any deployment tag exists.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowOnlyModelPackageDeployments",
      "Effect": "Allow",
      "Principal": "*",
      "Action": "s3:GetObject",
      "Resource": "arn:aws:s3:::model-artifacts-bucket/model-package-prefix/*",
      "Condition": {
        "StringLike": {
          "aws:PrincipalTag/sagemaker:ModelPackageArn":
            "arn:aws:sagemaker:*:producer-account-id:model-package/model-package-group/
*"
        },
        "StringEquals": {
          "aws:PrincipalOrgID": "o-organization-id",
          "aws:PrincipalTag/ManagedBy": "SageMaker"
        }
      }
    },
    {
      "Sid": "AllowModelPackageRegistrationReads",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::registering-account-id:role/model-registration-role"
      },
      "Action": [ "s3:GetObject", "s3:ListBucket" ],
      "Resource": [
        "arn:aws:s3:::model-artifacts-bucket",
        "arn:aws:s3:::model-artifacts-bucket/model-package-prefix/*"
      ],
      "Condition": {
        "StringEquals": {
          "aws:PrincipalOrgID": "o-organization-id"
        }
      }
    }
  ]
}
```

`AllowModelPackageRegistrationReads` is required. `CreateModelPackage` reads the artifact to validate it, and at that point the model package does not exist yet, so no `sagemaker:ModelPackageArn` session tag can be present. Without this statement, the first statement denies registration, and you cannot create the model package at all. Set *`model-registration-role`* to the role that calls `CreateModelPackage`, and keep it scoped to that role rather than to the whole account.

Using `Principal` with a value of `*` together with these conditions means any role in your organization can read the artifacts, provided it is tagged `ManagedBy=SageMaker` and carries the session tag. You do not have to edit the policy for each consuming role. The wildcard on the model package ARN covers every version in the group.

To allow more than one model package group, add one statement per group. Pair that group's ARN pattern with that group's artifact prefix. The condition also accepts a list of ARN patterns in a single statement. Use that form only when the groups are meant to share the same artifacts, because a single statement grants every pattern it lists access to everything its `Resource` covers.

Artifacts from more than one producer account need the same treatment: one pattern per account, because the tag value carries the account that owns the model package.

Important

Do not put a wildcard immediately after a version number. A pattern ending `model-package/`*`model-package-group`*`/1*` also matches versions 10, 11, and 19. To restrict access to a single version, end the pattern at the version and omit the wildcard. An over-broad pattern is not visible from the endpoint or the model package, because deployments succeed either way.

Important

Scope `Resource` to the artifacts of a single model package group. A prefix spanning several groups would let a deployment of one model package read another group's artifacts. The session tag is checked against the group wildcard rather than the object path.

If the artifacts are encrypted with a customer managed Amazon KMS key, the execution role also needs `kms:Decrypt` on that key. Because the key and the role are in different accounts,

grant it in both places: the key policy in the producing account must allow the execution role, and the execution role's IAM policy must allow `kms:Decrypt` on the key. Either grant alone is not sufficient.

Monitor artifact access

Your account records both the tagging of the session and the resulting access decision.

- In CloudTrail, the `AssumeRole` event for the execution role lists the session tags under `requestParameters`. Confirm that at least one event carries `sagemaker:ModelPackageArn` and that its value matches the model package you deployed. A single deployment also produces *untagged* `AssumeRole` events, because SageMaker AI validates the artifact before the tagged session is created. Untagged events alongside a tagged one are expected and do not mean the tag was not applied.
- In Amazon S3 data events or server access logs, `GetObject` requests against the artifact prefix show whether each read was allowed or denied, so you can confirm that access from outside a model package endpoint is being refused. A successful deployment also produces a denied `GetObject` from SageMaker AI, because SageMaker AI validates the artifact with an untagged session before the tagged session is created. This denial is expected and does not stop the deployment.

Before applying the policies to a production bucket, you can evaluate them with the IAM policy simulator to confirm that a deployment session is allowed and that a session without the tag is denied. The simulator evaluates your policy against context keys that you supply, so it confirms the policy logic but not that a deployment actually produces the tag. Confirm that separately in CloudTrail, as described earlier in this section. For more information, see Testing IAM policies with the IAM policy simulator.

View Model Groups and Versions

Model Groups and versions help you organize your models. You can view a list of the model versions in a Model Group by using either the Amazon SDK for Python (Boto3) (Boto3) or the Amazon SageMaker Studio console.

View a List of Model Versions in a Group

You can view all of the model versions that are associated with a Model Group. If a Model Group represents all models that you train to address a specific ML problem, you can view all of those related models.

View a List of Model Versions in a Group (Boto3)

To view model versions associated with a Model Group by using Boto3, call the `list_model_packages` API operation, and pass the name of the Model Group as the value of the `ModelPackageGroupName` parameter. The following code lists the model versions associated with the Model Group you created in Create a Model Group (Boto3).

```
sm_client.list_model_packages(ModelPackageGroupName=model_package_group_name)
```

View a List of Model Versions in a Group (Studio or Studio Classic)

To view a list of the model versions in a Model Group in the Amazon SageMaker Studio console, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models** from the menu.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. From the model groups list, choose the angle bracket to the left of the model group you want to view.
6. A list of the model versions in the model group appears.
7. (Optional) Choose **View all**, if shown, to view additional model versions.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. From the model groups list, select the name of the Model Group you want to view.
5. A new tab appears with a list of the model versions in the Model Group.

Update the Details of a Model Version

You can view and update details of a specific model version by using either the Amazon SDK for Python (Boto3) or the Amazon SageMaker Studio console.

> **Important**
>
> Amazon SageMaker AI integrates Model Cards into Model Registry. A model package registered in the Model Registry includes a simplified Model Card as a component of the model package. For more information, see Model package model card schema (Studio).

View and Update the Details of a Model Version (Boto3)

To view the details of a model version by using Boto3, complete the following steps.

1. Call the `list_model_packages` API operation to view the model versions in a Model Group.

```
sm_client.list_model_packages(ModelPackageGroupName="ModelGroup1")
```

The response is a list of model package summaries. You can get the Amazon Resource Name (ARN) of the model versions from this list.

```
{'ModelPackageSummaryList': [{'ModelPackageGroupName':
 'AbaloneMPG-16039329888329896',
   'ModelPackageVersion': 1,
   'ModelPackageArn': 'arn:aws:sagemaker:us-east-2:123456789012:model-package/
ModelGroup1/1',
   'ModelPackageDescription': 'TestMe',
   'CreationTime': datetime.datetime(2020, 10, 29, 1, 27, 46, 46000,
 tzinfo=tzlocal()),
   'ModelPackageStatus': 'Completed',
   'ModelApprovalStatus': 'Approved'}],
 'ResponseMetadata': {'RequestId': '12345678-abcd-1234-abcd-aabbccddeeff',
  'HTTPStatusCode': 200,
  'HTTPHeaders': {'x-amzn-requestid': '12345678-abcd-1234-abcd-aabbccddeeff',
   'content-type': 'application/x-amz-json-1.1',
   'content-length': '349',
   'date': 'Mon, 23 Nov 2020 04:56:50 GMT'},
  'RetryAttempts': 0}}
```

2. Call `describe_model_package` to see the details of the model version. You pass in the ARN of a model version that you got in the output of the call to `list_model_packages`.

```
sm_client.describe_model_package(ModelPackageName="arn:aws:sagemaker:us-
east-2:123456789012:model-package/ModelGroup1/1")
```

The output of this call is a JSON object with the model version details.

```
{'ModelPackageGroupName': 'ModelGroup1',
 'ModelPackageVersion': 1,
 'ModelPackageArn': 'arn:aws:sagemaker:us-east-2:123456789012:model-package/
ModelGroup/1',
 'ModelPackageDescription': 'Test Model',
 'CreationTime': datetime.datetime(2020, 10, 29, 1, 27, 46, 46000,
 tzinfo=tzlocal()),
 'InferenceSpecification': {'Containers': [{'Image': '257758044811.dkr.ecr.us-
east-2.amazonaws.com/sagemaker-xgboost:1.0-1-cpu-py3',
    'ImageDigest':
 'sha256:99fa602cff19aee33297a5926f8497ca7bcd2a391b7d600300204eef803bca66',
    'ModelDataUrl': 's3://sagemaker-us-east-2-123456789012/ModelGroup1/
pipelines-0gdonccek7o9-AbaloneTrain-stmiylhtIR/output/model.tar.gz'}],
  'SupportedTransformInstanceTypes': ['ml.m5.xlarge'],
  'SupportedRealtimeInferenceInstanceTypes': ['ml.t2.medium', 'ml.m5.xlarge'],
  'SupportedContentTypes': ['text/csv'],
  'SupportedResponseMIMETypes': ['text/csv']},
 'ModelPackageStatus': 'Completed',
 'ModelPackageStatusDetails': {'ValidationStatuses': [],
  'ImageScanStatuses': []},
 'CertifyForMarketplace': False,
 'ModelApprovalStatus': 'PendingManualApproval',
 'LastModifiedTime': datetime.datetime(2020, 10, 29, 1, 28, 0, 438000,
 tzinfo=tzlocal()),
 'ResponseMetadata': {'RequestId': '12345678-abcd-1234-abcd-aabbccddeeff',

   'content-type': 'application/x-amz-json-1.1',
   'content-length': '1038',
   'date': 'Mon, 23 Nov 2020 04:59:38 GMT'},
  'RetryAttempts': 0}}
```

Model package model card schema (Studio)

All details related to the model version are encapsulated in the model package's model card. The model card of a model package is a special usage of the Amazon SageMaker Model Card and its schema is simplified. The model package model card schema is shown in the following expandable dropdown.

Model package model card schema

```
{
  "title": "SageMakerModelCardSchema",
  "description": "Schema of a model package's model card.",
  "version": "0.1.0",
  "type": "object",
  "additionalProperties": false,
  "properties": {
    "model_overview": {
      "description": "Overview about the model.",
      "type": "object",
      "additionalProperties": false,

```

View and Update the Details of a Model Version (Studio or Studio Classic)

To view and update the details of a model version, complete the following steps based on whether you use Studio or Studio Classic. In Studio Classic, you can update the approval status for a model version. For details, see Update the Approval Status of a Model. In Studio, on the other hand, SageMaker AI creates a model card for a model package, and the model version UI provides options to update details in the model card.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models** from the menu.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. Select the name of the model group containing the model version to view.
6. In the list of model versions, select the model version to view.
7. Choose one of the following tabs.

   - **Training**: To view or edit details related to your training job, including performance metrics, artifacts, IAM role and encryption, and containers. For more information, see Add a training job (Studio).
   - **Evaluate**: To view or edit details related to your training job, such as performance metrics, evaluation datasets, and security. For more information, see Add an evaluation job (Studio).
   - **Audit**: To view or edit high-level details related to the model's business purpose, usage, risk, and technical details such as algorithm and performance limitations. For more information, see Update audit (governance) information (Studio).
   - **Deploy**: To view or edit the location of your inference image container and instances which compose the endpoint. For more information, see Update deployment information (Studio).

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. From the model groups list, select the name of the Model Group you want to view.
5. A new tab appears with a list of the model versions in the Model Group.
6. In the list of model versions, select the name of the model version for which you want to view details.
7. On the model version tab that opens, choose one of the following to see details about the model version:

   - **Activity**: Shows events for the model version, such as approval status updates.
   - **Model quality**: Reports metrics related to your Model Monitor model quality checks, which compare model predictions to Ground Truth. For more information about Model Monitor model quality checks, see Model quality.
   - **Explainability**: Reports metrics related to your Model Monitor feature attribution checks, which compare the relative rankings of your features in training data versus live data. For more information about Model Monitor explainability checks, see Feature attribution drift for models in production.
   - **Bias**: Reports metrics related to your Model Monitor bias drift checks, which compare the distribution of live data to training data. For more information about Model Monitor bias drift checks, see Bias drift for models in production.
   - **Inference recommender**: Provides initial instance recommendations for optimal performance based on your model and sample payloads.
   - **Load test**: Runs load tests across your choice of instance types when you provide your specific production requirements, such as latency and throughput constraints.
   - **Inference specification**: Displays instance types for your real-time inference and transform jobs, and information about your Amazon ECR containers.
   - **Information**: Shows information such as the project with which the model version is associated, the pipeline that generated the model, the Model Group, and the model's location in Amazon S3.

Add a training job (Studio)

> **Important**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see Amazon SageMaker Studio Classic.

You can add one training job, created externally or with SageMaker AI, to your model. If you add a SageMaker training job, SageMaker AI prepopulates the fields for all of the subpages in the **Train** tab. If you add an externally created training job, you need to add details related to your training job manually.

To add a training job to your model package, complete the following steps.

1. Choose the **Train** tab.
2. Choose **Add**. If you do not see this option, you may already have a training job attached. If you want to remove this training job, complete the following instructions to remove a training job.
3. You can add a training job you created in SageMaker AI or a training job you created externally.
    a. To add a training job you created in SageMaker AI, complete the following steps.
        i. Choose **SageMaker AI**.
        ii. Select the radio box next to the training job you want to add.
        iii. Choose **Add**.
    b. To add a training job you created externally, complete the following steps.
        i. Choose **Custom**.
        ii. In the **Name** field, insert the name of your custom training job.
        iii. Choose **Add**.

Remove a training job (Studio)

You can remove a training job, created externally or with SageMaker AI, from your model by completing the following steps.

To remove a training job from your model package, complete the following steps.

1. Choose **Train**.
2. Choose the **Gear** (
   
)
   icon under the **Train** tab.
3. Choose **Remove** next to your training job.
4. Choose **Yes, I want to remove <name of your training job>**.
5. Choose **Done**.

Update training job details (Studio)

Complete the following steps to update the details of a training job, created externally or with SageMaker AI, associated with your model.

To update (and view) details related to the training job:

1. On the **Train** tab, view the status of the training job. The status is `Complete` if you added a training job to your model package and `Undefined` if not.
2. To view details related to your training job such as performance, hyperparameters, and identifying details, choose the **Train** tab.
3. To update and view details related to model performance, complete the following steps.
   a. Choose **Performance** in the left sidebar of the **Train** tab.
   b. View **Metrics** related to your training job. The **Performance** page lists metrics by name, value, and any notes you added related to the metric.
   c. (Optional) To add notes to existing metrics, complete the following steps.
      i. Choose the vertical ellipsis in the top right corner of the model version page, and choose **Edit**.
      ii. Add notes to any of the listed metrics.
      iii. At the top of the model version page, choose **Save** in the **Editing Model Version...** banner.
   d. View **Custom Metrics** related to your training job. Custom metrics are formatted similarly to metrics.
   e. (Optional) To add custom metrics, complete the following steps.

i. Choose **Add**.

ii. Insert a name, value, and any optional notes for your new metric.

f. (Optional) To remove custom metrics, choose the **Trash** icon next to the metric you want to remove.

g. In the **Observations** text box, view any notes you added related to the performance of your training job.

h. (Optional) To add or update observations, complete the following steps.

i. Choose the vertical ellipsis in the top right corner of the model version page, and choose **Edit**.

ii. Add or update your notes in the **Observations** text box.

iii. At the top of the model version page, choose **Save** in the **Editing Model Version...** banner.

4. To update and view details related to model artifacts, complete the following steps.

a. Choose **Artifacts** in the left sidebar of the **Train** tab.

b. In the **Location (S3 URI)** field, view the Amazon S3 location of your training datasets.

c. In the **Models** field, view the name and Amazon S3 locations of model artifacts from other models that you included in the training job.

d. To update any of the fields in the **Artifacts** page, complete the following steps.

i. Choose the vertical ellipsis in the top right of the model version page, and choose **Edit**.

ii. Enter new values in any of the fields.

iii. At the top of the model version page, choose **Save** in the **Editing Model Version...** banner.

5. To update and view details related to hyperparameters, complete the following steps.

a. Choose **Hyperparameters** in the left sidebar of the **Train** tab.

b. View the SageMaker AI provided and custom hyperparameters defined. Each hyperparameter is listed with its name and value.

c. View the custom hyperparameters you added.

d. (Optional) To add an additional custom hyperparameter, complete the following steps.

i. Above the top right corner of the **Custom Hyperparameters** table, choose **Add**. A pair of new blank fields appears.

ii. Enter the name and value of the new custom hyperparameter. These values are automatically saved.

e. (Optional) To remove a custom hyperparameter, choose the **Trash** icon to the right of the hyperparameter.

6. To update and view details related to the training job environment, complete the following steps.

a. Choose **Environment** in the left sidebar of the **Train** tab.

b. View the Amazon ECR URI locations for any training job containers added by SageMaker AI (for a SageMaker training job) or by you (for a custom training job).

c. (Optional) To add an additional training job container, choose **Add**, and then enter the URI of the new training container.

7. To update and view the training job name and the Amazon Resource Names (ARN) for the training job, complete the following steps.

a. Choose **Details** in the left sidebar of the **Train** tab.

b. View the training job name and ARN of the training job.

Add an evaluation job (Studio)

> **Important**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see Amazon SageMaker Studio Classic.

After you register your model, you can test your model with one or more datasets to assess its performance. You can add one or more evaluation jobs from Amazon S3 or define your own evaluation job by manually entering all details. If you add a job from Amazon S3, SageMaker AI prepopulates the fields for all of the subpages in the **Evaluate** tab. If you define your own evaluation job, you need to add details related to your evaluation job manually.

To add your first evaluation job to your model package, complete the following steps.

1. Choose the **Evaluate** tab.
2. Choose **Add**.
3. You can add an evaluation job from Amazon S3 or a custom evaluation job.
    a. To add an evaluation job with collaterals from Amazon S3, complete the following steps.
        i. Choose **S3**.
        ii. Enter a name for the evaluation job.
        iii. Enter the Amazon S3 location to the output collaterals of your evaluation job.
        iv. Choose **Add**.
    b. To add a custom evaluation job, complete the following step:
        i. Choose **Custom**.
        ii. Enter a name for the evaluation job.
        iii. Choose **Add**.

To add an additional evaluation job to your model package, complete the following steps.

1. Choose the **Evaluate** tab.
2. Choose the **Gear** (

)
icon under the **Train** tab.
3. In the dialog box, choose **Add**.
4. You can add an evaluation job from Amazon S3 or a custom evaluation job.
    a. To add an evaluation job with collaterals from Amazon S3, complete the following steps.
        i. Choose **S3**.
        ii. Enter a name for the evaluation job.
        iii. Enter the Amazon S3 location to the output collaterals of your evaluation job.
        iv. Choose **Add**.
    b. To add a custom evaluation job, complete the following step:
        i. Choose **Custom**.

ii. Enter a name for the evaluation job.

iii. Choose **Add**.

Remove an evaluation job (Studio)

You can remove an evaluation job, created externally or with SageMaker AI, from your model by completing the following steps.

To remove an evaluation job from your model package, complete the following steps.

1. Choose the **Evaluate** tab.
2. Choose the **Gear** (
   
)
   icon under the **Train** tab.
3. (Optional) To find your evaluation job from the list, enter a search term in the search box to narrow the list of choices.
4. Choose the radio button next to your evaluation job.
5. Choose **Remove**.
6. Choose **Yes, I want to remove <name of your evaluation job>**.
7. Choose **Done**.

Update an evaluation job (Studio)

Complete the following steps to update the details of an evaluation job, created externally or with SageMaker AI, associated with your model.

To update (and view) details related to the evaluation job:

1. On the **Evaluate** tab, view the status of the evaluation job. The status is `Complete` if you added an evaluation job to your model package and `Undefined` if not.
2. To view details related to your evaluation job, such as performance and artifacts location, choose the **Evaluate** tab.
3. To update and view details related to model performance during evaluation, complete the following steps.

   a. Choose **Performance** in the **Evaluate** tab sidebar.

b. View metrics related to your evaluation job in the **Metrics** list. The **Metrics** list displays the individual metrics by name, value, and any notes you added related to the metric.

c. In the **Observations** text box, view any notes you added related to the performance of your evaluation job.

d. To update any of the **Notes** fields for any metric or the **Observations** field, complete the following steps.

i. Choose the vertical ellipsis in the top right of the model version page, and choose **Edit**.

ii. Enter notes for any metric or in the **Observations** text box.

iii. At the top of the model version page, choose **Save** in the **Editing Model Version...** banner.

4. To update and view details related to your evaluation job datasets, complete the following steps.

a. Choose **Artifacts** in the left sidebar of the **Evaluate** page.

b. View datasets used in your evaluation job.

c. (Optional) To add a dataset, choose **Add** and enter an Amazon S3 URI to the dataset.

d. (Optional) To remove a dataset, choose the **Trash** icon next to the dataset you want to remove.

5. To view the job name and evaluation job ARN, choose **Details**.

Update audit (governance) information (Studio)

> **Important**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see Amazon SageMaker Studio Classic.

Document important model details to help your organization establish a robust framework of model governance. You and your team members can reference these details so they use the model for the appropriate use cases, know the business domain and owners of the model, and understand

model risks. You can also save details about how the model is expected to perform and reasons for performance limitations.

To view or update details related to the model governance, complete the following steps.

1. On the **Audit** tab, view the approval status of the model card. The status can be one the following:
   - **Draft**: The model card is still a draft.
   - **Pending approval**: The model card is waiting to be approved.
   - **Approved**: The model card is approved.
2. To update the approval status of the model card, choose the pulldown menu next to the approval status and choose the updated approval status.
3. To update and view details related to your model package risk, complete the following steps.
   a. Choose **Risk** in the left sidebar of the **Audit** tab.
   b. View the current risk rating and explanation for the risk rating.
   c. To update the rating or explanation, complete the following steps.
      i. Choose the vertical ellipsis at the top right corner of the **Audit** page, and choose **Edit**.
      ii. (Optional) Choose an updated risk rating.
      iii. (Optional) Update the risk rating explanation.
      iv. At the top of the model version page, choose **Save** in the **Editing Model Version...** banner.
4. To update and view details related to the usage of your model package, complete the following steps.
   a. Choose **Usage** in the left sidebar of the **Audit** tab.
   b. View text you added in the following fields:
      - **Problem type**: The category of machine learning algorithm used to build your model.
      - **Algorithm type**: The specific algorithm used to create your model.
      - **Intended uses**: The current application of the model in your business problem.
      - **Factors affecting model efficacy**: Notes about your model's performance limitations.

- **Recommended use**: The types of applications you can create with the model, the scenarios in which you can expect a reasonable performance, or the type of data to use with the model.
- **Ethical considerations**: A description of how your model might discriminate based on factors such as age or gender.

c. To update any of the previously listed fields, complete the following steps.

i. Choose the vertical ellipsis at the top right corner of the model version page, and choose **Edit**.

ii. (Optional) Use the dropdown menus for **Problem type** and **Algorithm type** to select new values, if needed.

iii. (Optional) Update the text descriptions in the remaining fields.

iv. At the top of the model version page, choose **Save** in the **Editing Model Version...** banner.

5. To update and view details related to the stakeholders of your model package, complete the following steps.

a. Choose **Stakeholders** in the left sidebar of the **Audit** tab.

b. View the current model owner and creator, if any.

c. To update the model owner or creator, complete the following steps:

i. Choose the vertical ellipsis at the top right corner of the model version page, and choose **Edit**.

ii. Update the model owner or model creator fields.

iii. At the top of the model version page, choose **Save** in the **Editing Model Version...** banner.

6. To update and view details related to the business problem that your model package addresses, complete the following steps.

a. Choose **Business** in the left sidebar of the **Audit** tab.

b. View the current descriptions, if any, for the business problem that the model addresses, the business problem stakeholders, and the line of business.

c. To update any of the fields in the **Business** tab, complete the following steps.

i. Choose the vertical ellipsis at the top right corner of the model version page, and choose **Edit**.

ii. Update the descriptions in any of the fields.

iii. At the top of the model version page, choose **Save** in the **Editing Model Version...** banner.

7. To update and view existing documentation (represented as key-value pairs) for your model, complete the following steps.

   a. Choose **Documentation** in the left sidebar of the **Audit** page.

   b. View existing key-value pairs.

   c. To add any key-value pairs, complete the following steps.

      i. Choose the vertical ellipsis at the top right corner of the model version page, and choose **Edit**.

      ii. Choose **Add**.

      iii. Enter a new key and associated value.

      iv. At the top of the model version page, choose **Save** in the **Editing Model Version...** banner.

   d. To remove any key-value pairs, complete the following steps.

      i. Choose the vertical ellipsis at the top right corner of the model version page, and choose **Edit**.

      ii. Choose the **Trash** icon next to the key-value pair to remove.

      iii. At the top of the model version page, choose **Save** in the **Editing Model Version...** banner.

Update deployment information (Studio)

> **Important**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the updated Studio experience. For information about using the Studio Classic application, see Amazon SageMaker Studio Classic.

After you evaluate your model performance and determine that it is ready to use for production workloads, you can change the approval status of the model to initiate CI/CD deployment. For more about approval status definitions, see Update the Approval Status of a Model.

To view or update details related to the model package deployment, complete the following steps.

1. On the **Deploy** tab, view the model package approval status. Possible values can be the following:

   - **Pending Approval**: The model is registered but not yet approved or rejected for deployment.
   - **Approved**: The model is approved for CI/CD deployment. If there is an EventBridge rule in place that initiates model deployment upon a model approval event, as is the case for a model built from a SageMaker AI project template, SageMaker AI also deploys the model.
   - **Rejected**: The model is rejected for deployment.

   If you need to change the approval status, choose the dropdown menu next to the status and choose the updated status.
2. To update the model package approval status, choose the dropdown next to the approval status and choose the updated approval status.
3. In the **Containers** list, view the inference image containers.
4. In the **Instances** list, view the instances which compose your deployment endpoint.

Compare Model Versions

As you generate model versions, you might want to compare models versions by viewing relevant model quality metrics side-by-side. For example, you might want to track accuracy by comparing mean squared error (MSE) values, or you might decide to remove models that perform poorly on selected measures. The following procedure shows you how to set up model version comparison in Model Registry using the Amazon SageMaker Studio Classic console.

Compare Model Versions (Amazon SageMaker Studio Classic)

> **Note**
>
> You can only compare model versions the Amazon SageMaker Studio Classic console.

To compare model versions within a model group, complete the following steps:

1. Sign in to Studio Classic. For more information, see Amazon SageMaker AI domain overview.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. From the model groups list, select the name of the Model Group you want to view. A new tab opens with a list of the model versions in the Model Group.
5. In the list of model versions, check the boxes next to the model versions you want to compare.
6. Choose the **Actions** dropdown menu, then choose **Compare**. A listing of model quality metrics appears for your selected models.

View and Manage Model Group and Model Version Tags

Model Registry helps you view and manage tags related to your model groups. You can use tags to categorize model groups by purpose, owner, environment, or other criteria. The following instructions show you how to view, add, delete, and edit your tags in the Amazon SageMaker Studio console.

> **Note**
>
> Model packages in the SageMaker Model Registry do not support tags—these are versioned model packages. Instead, you can add key value pairs using `CustomerMetadataProperties`. Model package groups in the model registry support tagging.

View and manage model group tags

Studio

To view a model group tag, complete the following steps:

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models** to display a list of your model groups.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. From the Model Groups list, select the name of the Model Group you want to view.
6. In the model group page, choose the **Tags** tab. View the tags associated with your model group.

To add a model group tag, complete the following steps:

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models** to display a list of your model groups.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. From the Model Groups list, select the name of the Model Group you want to edit.
6. In the model group page, choose the **Tags** tab.
7. Choose **Add/Edit tags**.
8. Above **+ Add new tag**, enter your new key in the blank **Key** field.
9. (Optional) Enter your new value in the blank **Value** field.
10. Choose **Confirm changes**.
11. Confirm your new tag appears in the **Tags** section of the **Information** page.

To delete a model group tag, complete the following steps:

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models** to display a list of your model groups.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. From the Model Groups list, select the name of the Model Group you want to edit.
6. In the model group page, choose the **Tags** tab.
7. Choose **Add/Edit tags**.
8. Choose the **Trash** icon next to the key-value pair you want to remove.
9. Choose **Confirm changes**.

To edit a model group tag, complete the following steps:

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models** to display a list of your model groups.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. From the Model Groups list, select the name of the Model Group you want to edit.
6. In the model group page, choose the **Tags** tab.
7. Choose **Add/Edit tags**.
8. Enter a new value in the **Value** field of the key-pair you want to edit.
9. Choose **Confirm changes**.

Studio Classic

To view a model group tag, complete the following steps:

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.

2. In the left navigation pane, choose the **Home** icon (

).
3. Choose **Models**, and then **Model registry**.
4. From the Model Groups list, select the name of the Model Group you want to edit.
5. Choose **Information**.
6. View your tags in the **Tags** section of the **Information** page.

To add a model group tag, complete the following steps:

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Amazon SageMaker AI domain overview.
2. In the left navigation pane, choose the **Home** icon (

).
3. Choose **Models**, and then **Model registry**.
4. From the Model Groups list, select the name of the Model Group you want to edit.
5. Choose **Information**.
6. If you don't have any tags, choose **Add tags**.
7. If you have pre-existing tags, choose **Manage tags** in the **Tags** section. A list of the model group's tags appears as key-value pairs.
8. Above **Add new tag**, enter your new key in the blank **Key** field.
9. (Optional) Enter your new value in the blank **Value** field.
10. Choose **Confirm changes**.
11. Confirm your new tag appears in the **Tags** section of the **Information** page.

To delete a model group tag, complete the following steps:

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Amazon SageMaker AI domain overview.
2. In the left navigation pane, choose the **Home** icon (

).
3. Choose **Models**, and then **Model registry**.
4. From the Model Groups list, select the name of the Model Group you want to edit.

5. Choose **Information**.
6. In the **Tags** section, choose **Manage tags**. A list of the model group's tags appears as key-value pairs.
7. Choose the **Trash** icon to the right of the tag you want to remove.
8. Choose **Confirm changes**.
9. Confirm your removed tag does not appear in the **Tags** section of the **Information** page.

To edit a model group tag, complete the following steps:

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Amazon SageMaker AI domain overview.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. From the Model Groups list, select the name of the Model Group you want to edit.
5. Choose **Information**.
6. In the **Tags** section, choose **Manage tags**. A list of the model group's tags appears as key-value pairs.
7. Edit any key or value.
8. Choose **Confirm changes**.
9. Confirm your tag contains your edits in the **Tags** section of the **Information** page.

To assign or tag model groups to a project, complete the following steps:

1. Get tags with key `sagemaker:project-name` and `sagemaker:project-id` for the SageMaker AI project using the ListTags API.
2. To apply the tags to your model package group, choose one of the following methods:
   - If you create a new model package group and want to add tags, pass your tags from Step 1 to the CreateModelPackageGroup API.
   - If you want to add tags to an existing model package group, use the AddTags APIs.

- If you create your model package group through Pipelines, use the `pipeline.create()` or `pipeline.upsert()` methods, or pass your tags to the RegisterModel step.

Delete a Model Version

This procedure demonstrates how to delete a model version in the Amazon SageMaker Studio console.

Delete a Model Version (Studio or Studio Classic)

To delete a model version in the Amazon SageMaker Studio console, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models** to display a list of your model groups.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. From the model groups list, choose the angle bracket to the left of the model group that you want to view.
6. A list of the model versions in the model group appears. If you don't see the model version that you want to delete, choose **View all**.
7. Select the check boxes next to the model versions that you want to delete.
8. Choose the vertical ellipsis above the top right corner of the table, and choose **Delete** (or **Delete model version** if you are in the model group details page).
9. In the **Delete model version** dialog box, choose **Yes, delete the model version**.
10. Choose **Delete**.
11. Confirm that your deleted model versions no longer appear in the model group.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon (

).
3. Choose **Models**, and then **Model registry**. A list of your Model Groups appears.
4. From the model groups list, select the name of the Model Group of the model version that you want to delete.
5. From the list of model versions, select the name of the model version that you want to delete.
6. Choose the **Actions** dropdown menu, and choose **Remove**.
7. In the confirmation dialog box, enter `REMOVE`.
8. Choose **Remove**.
9. Confirm the model version you removed does not appear in the list of the model group's model versions.

Staging Construct for your Model Lifecycle

You can define a series of stages that models can progress through for your model workflows and lifecycle with the Model Registry staging construct. This simplifies tracking and managing models as they transition through development, testing, and production stages. The following will provide information on staging constructs and how to use them in your model governance.

The stage construct allows you to define a series of stages and statuses that models progress through. At each stage, specific personas with the relevant permissions can update the stage status. As a model advances through the stages, its metadata is carried forward, providing a comprehensive view of the model's lifecycle. This metadata can be accessed and reviewed by authorized personas at each stage, enabling informed decision making. This includes the following benefits.

- Model Life Cycle Permissions - Set permissions for designated personas to update a model stage state and enforce approval gates at critical transition points. Administrators can assign permission by using IAM policies and condition keys with the API. For example, you can restrict you data scientist from updating the Model Lifecycle stage transition from "Development" to "Production". For examples, see Set up Staging Construct Examples.

- Model Life Cycle Events via Amazon EventBridge - You can consume the lifecycle stage events using EventBridge. This sets you up to receive event notifications when models change approval or staging state, enabling integration with third-party governance tools. See Get event notifications for ModelLifeCycle for an example.
- Search based on Model Life Cycle Fields - You can search and filter stage and stage status using the `Search` API.
- Audit Trails for Model Life Cycle Events - You can view the history of model approval and staging events for the model lifecycle transitions.

The following topics will walk you through how to set up a stage construct on the administrator side and how to update a stage status from the user side.

Topics

- Set up Staging Construct Examples
- Update a model package stage and status in Studio
- Update a model package stage and status example (boto3)
- Invoke ModelLifeCycle using the Amazon CLI examples
- Get event notifications for ModelLifeCycle

Set up Staging Construct Examples

To set up stage constructs for your Amazon SageMaker Model Registry, the administrator will need to grant the relevant permissions to the intended roles. The following provides examples on how to set up stage constructs for various roles.

> **Note**
>
> Users within a Amazon SageMaker AI domain will be able to view all stages defined within the domain, but can only use the ones they have permissions for.

Stages are defined by the `ModelLifeCycle` parameter and have the following structure. The administrator sets up the permissions for which `stage` and `stageStatus` can be accessed by which roles. The users assuming a role can use the relevant `stage` and `stageStatus` and include their own `stageDescription`.

```
ModelLifeCycle {
    stage: String # Required (e.g., Development/QA/Production)
    stageStatus: String # Required (e.g., PendingApproval/Approved/Rejected)
    stageDescription: String # Optional
}
```

The following table contains Model Registry pre-defined stage construct templates. You can define your own stage constructs based on your use cases. The relevant permissions will need to be set up before users can use them.

Stage	Stage status
Proposal	PendingApproval
Development	InProgress
QA	OnHold
PreProduction	Approved
Production	Rejected
Archived	Retired

The `ModelLifeCycle` parameter can be invoked by the following APIs:

- `CreateModelPackage`
- `UpdateModelPackage`
- `DescribeModelPackage`

Policy for a data scientist role

The following is an example IAM policy using model lifecycle condition keys. You can modify them based on your own requirements. In this example, the role's permissions are limited to set or define the model lifecycle stage to:

- Create or update a model with the stage `"Development"` and status `"Approved"`.

- Update a model package with the stage quality assurance, `"QA"`, and status `"PendingApproval"`.

```
{
    "Action" : [
        "sagemaker:UpdateModelPackage",
        "sagemaker:CreateModelPackage"
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "StringEquals": {
            "sagemaker:ModelLifeCycle:stage" : "Development"
            "sagemaker:ModelLifeCycle:stageStatus" : "Approved"
        }
    }
},
{
    "Action" : [
        "sagemaker:UpdateModelPackage"
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "StringEquals": {
            "sagemaker:ModelLifeCycle:stage" : "Staging"
            "sagemaker:ModelLifeCycle:stageStatus" : "PendingApproval"
        }
    }
}
```

Policy for a quality assurance specialist

The following is an example IAM policy using model lifecycle condition keys. You can modify them based on your own requirements. In this example, the role's permissions are limited to set or define the model lifecycle stage to:

- Update a model package with:
  - The stage `"QA"` and status `"Approved"` or `"Rejected"`.

- The stage `"Production"` and status `"PendingApproval"`.

```
{
    "Action": [
        "sagemaker:UpdateModelPackage"
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "StringEquals": {
            "sagemaker:ModelLifeCycle:stage": "Staging",
            "sagemaker:ModelLifeCycle:stageStatus": "Approved"
        }
    }
}, {
    "Action": [
        "sagemaker:UpdateModelPackage"
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "StringEquals": {
            "sagemaker:ModelLifeCycle:stage": "Staging",
            "sagemaker:ModelLifeCycle:stageStatus": "Rejected"
        }
    }
}, {
    "Action": [
        "sagemaker:UpdateModelPackage"
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "StringEquals": {
            "sagemaker:ModelLifeCycle:stage": "Production",
            "sagemaker:ModelLifeCycle:stageStatus": "PendingApproval"
        }
    }
}
```

Policy for lead engineer role

The following is an example IAM policy using model lifecycle condition keys. You can modify them based on your own requirements. In this example, the role's permissions are limited to set or define the model lifecycle stage to:

- Update a model package with:
  - The stage `"Production"` and status `"Approved"` or `"Rejected"`.
  - The stage `"Development"` and status `"PendingApproval"`.

```
{
    "Action" : [
        "sagemaker:UpdateModelPackage"
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "ForAnyvalue:StringEquals" : {
            "sagemaker:ModelLifeCycle:stage" : "Production",
            "sagemaker:ModelLifeCycle:stageStatus" : "Approved"
        }
    }
},
{
    "Action" : [
        "sagemaker:UpdateModelPackage"
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "StringEquals:" {
            "sagemaker:ModelLifeCycle:stage" : "Production"
            "sagemaker:ModelLifeCycle:stageStatus" : "Rejected"
        }
    }
},
{
    "Action" : [
        "sagemaker:UpdateModelPackage"
```

```
    ],
    "Resource": [
        "*"
    ],
    "Condition": {
        "StringEquals": {
            "sagemaker:ModelLifeCycle:stage" : "Development"
            "sagemaker:ModelLifeCycle:stageStatus" : "PendingApproval"
        }
    }
}
```

To get Amazon EventBridge notifications on any model status update, see the example in Get event notifications for ModelLifeCycle. For an example EventBridge payload you may receive, see SageMaker model package state change.

Update a model package stage and status in Studio

To use a model package stage construct, you will need to assume an execution role with the relevant permissions. The following page provides information on how to update the stage status using Amazon SageMaker Studio.

All stage constructs defined in the domain will be viewable by all users. To update a stage, you will need have the administrator set up the relevant permissions for you to access it. For information on how, see Set up Staging Construct Examples.

The following procedure will take you to the Studio UI where you can update your model package stage.

1. Sign in to Amazon SageMaker Studio. For more information, see Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose the **Models**.
3. Find your model.
   - You can use the tabs to find your models. For example, choose the **Registered models** or **Deployable models** tabs.
   - You can use the **My models** and **Shared with me** options to find models you created or ones that are shared by you.
4. Select the checkbox next to the model you wish to update.

5. Choose the **More options** icon.
6. Choose **Update model lifecycle**. This will take you to the **Update model lifecycle** section.
7. Complete the tasks to update the stage.

   If you cannot update the stage, you will receive an error. Your administrator will need to set up the permissions for you to do so. For information on how to set up the permissions, see Set up Staging Construct Examples.

Update a model package stage and status example (boto3)

To update a model package stage and status, you will need to assume an execution role with the relevant permissions. The following provides an example on how you can update the stage status using the `UpdateModelPackage` API using Amazon SDK for Python (Boto3).

In this example, the `ModelLifeCycle` stage `"Development"` and stage status `"Approved"` condition keys for the `UpdateModelPackage` API action has been granted to the your execution role. You can include a description in *`stage-description`*. See Set up Staging Construct Examples for more information.

```
from sagemaker.core.helper.session_helper import get_execution_role, session
import boto3

region = boto3.Session().region_name role = get_execution_role()
sm_client = boto3.client('sagemaker', region_name=region)

model_package_update_input_dict = {
    "ModelLifeCycle" : {
        "stage" : "Development",
        "stageStatus" : "Approved",
        "stageDescription" : "stage-description"
    }
}
model_package_update_response =
 sm_client.update_model_package(**model_package_update_input_dict)
```

Invoke ModelLifeCycle using the Amazon CLI examples

You can use the Amazon CLI tool to manage your Amazon resources. A few Amazon CLI commands include search and list-actions. The following page will provide examples on how to use

`ModelPackage` while using these commands. For information and examples on setting up your stage construct, see Set up Staging Construct Examples.

The examples on this page uses the following variables.

- *`region`* is the region that your model package exists in.
- *`stage-name`* is the name of your defined stage.
- *`stage-status`* is the name of your defined stage status.

The following are example Amazon CLI commands using ModelLifeCycle.

Search for your model packages with a *`stage-name`* you have already defined.

```
aws sagemaker search --region 'region' --resource ModelPackage --search-expression
 '{"Filters": [{"Name": "ModelLifeCycle.Stage","Value": "stage-name"}]}'
```

List the actions associated with `ModelLifeCycle`.

```
aws sagemaker list-actions --region 'region' --action-type ModelLifeCycle
```

Create a model package with ModelLifeCycle.

```
aws sagemaker create-model-package --model-package-group-name 'model-package-group-
name' --source-uri 'source-uri' --region 'region' --model-life-cycle '{"Stage":"stage-
name", "StageStatus":"stage-status", "StageDescription":"Your Staging Comment"}'
```

Update a model package with ModelLifeCycle.

```
aws sagemaker update-model-package --model-package 'model-package-arn' --region
 'region' --model-life-cycle '{"Stage":"stage-name", "StageStatus":"stage-status"}'
```

Search via the ModelLifeCycle field.

```
aws sagemaker search --region 'region' --resource ModelPackage --search-expression
 '{"Filters": [{"Name": "ModelLifeCycle.Stage","Value": "stage-name"}]}'
```

Fetch audit records for ModelLifeField updates via Amazon SageMaker ML Lineage Tracking APIs.

```
aws sagemaker list-actions --region 'region' --action-type ModelLifeCycle
```

```
aws sagemaker describe-action --region 'region' --action-name 'action-arn or action-name'
```

Get event notifications for ModelLifeCycle

You can get the ModelLifeCycle update notifications and events with EventBridge in your account. The following is an example of an EventBridge rule, to be configured in your account, in order to get the ModelLifeCycle event notifications.

```
{
  "source": ["aws.sagemaker"],
  "detail-type": ["SageMaker Model Package State Change"]
}
```

For an example EventBridge payload you may receive, see SageMaker model package state change.

Update the Approval Status of a Model

After you create a model version, you typically want to evaluate its performance before you deploy it to a production endpoint. If it performs to your requirements, you can update the approval status of the model version to `Approved`. Setting the status to `Approved` can initiate CI/CD deployment for the model. If the model version does not perform to your requirements, you can update the approval status to `Rejected`.

You can manually update the approval status of a model version after you register it, or you can create a condition step to evaluate the model when you create a SageMaker AI pipeline. For information about creating a condition step in a SageMaker AI pipeline, see Pipelines steps.

When you use one of the SageMaker AI provided project templates and the approval status of a model version changes, the following action occurs. Only valid transitions are shown.

- `PendingManualApproval` to `Approved` – initiates CI/CD deployment for the approved model version
- `PendingManualApproval` to `Rejected` – No action
- `Rejected` to `Approved` – initiates CI/CD deployment for the approved model version

- `Approved` to `Rejected` – initiates CI/CD to deploy the latest model version with an `Approved` status

You can update the approval status of a model version by using the Amazon SDK for Python (Boto3) or by using the Amazon SageMaker Studio console. You can also update the approval status of a model version as part of a condition step in a SageMaker AI pipeline. For information about using a model approval step in a SageMaker AI pipeline, see Pipelines overview.

Update the Approval Status of a Model (Boto3)

When you created the model version in Register a Model Version, you set the `ModelApprovalStatus` to `PendingManualApproval`. You update the approval status for the model by calling `update_model_package`. Note that you can automate this process by writing code that, for example, sets the approval status of a model depending on the result of an evaluation of some measure of the model's performance. You can also create a step in a pipeline that automatically deploys a new model version when it is approved. The following code snippet shows how to manually change the approval status to `Approved`.

```
model_package_update_input_dict = {
    "ModelPackageArn" : model_package_arn,
    "ModelApprovalStatus" : "Approved"
}
model_package_update_response =
 sm_client.update_model_package(**model_package_update_input_dict)
```

Update the Approval Status of a Model (Studio or Studio Classic)

To manually change the approval status in the Amazon SageMaker Studio console, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose the **Models** to display a list of your model groups.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.

5. From the model groups list, choose the angle bracket to the left of the model group that you want to view.
6. A list of the model versions in the model group appears. If you don't see the model version that you want to delete, choose **View all** to display the complete list of model versions in the model group details page.
7. Select the name of the model version that you want to update.
8. The **Deploy** tab displays the current approval status. Choose the dropdown menu next to the current approval status and select the updated approval status.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. From the model groups list, select the name of the Model Group that you want to view. A new tab opens with a list of the model versions in the Model Group.
5. In the list of model versions, select the name of the model version that you want to update.
6. Under the **Actions** dropdown menu, you can choose one of two possible menu options to update the model version status.

   - Using the **Update Status** option

     1. Under the **Actions** dropdown menu, choose the **Update Status** dropdown menu, and choose the new model version status.
     2. (Optional) In the **Comment** field, add additional details.
     3. Choose **Save and Update**.

   - Using the **Edit** option

     1. Under the **Actions** dropdown menu, choose **Edit**.
     2. (Optional) In the **Comment** field, add additional details.
     3. Choose **Save changes**.

7. Confirm the model version status is updated to the correct value in the model version page.

For `us-east-1`, `us-west-2`, `ap-northeast-1`, and `eu-west-1` regions, you can use the following instructions to access the lineage details for logged and registered model versions:

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Models** from the left navigation pane.
3. Choose the Logged **models** tab, if not selected already, then select **Registered Models**.
4. Select a model and choose **View Latest Version**.
5. Choose the **Governance** tab.
6. The **Deploy** section under **Governance overview** displays the current approval status. Select the updated approval status from the dropdown menu.

Deploy a Model from the Registry with Python

After you register a model version and approve it for deployment, deploy it to a SageMaker AI endpoint for real-time inference. You can deploy your model by using the SageMaker AI SDK or the Amazon SDK for Python (Boto3).

When you create a machine learning operations (MLOps) project and choose an MLOps project template that includes model deployment, approved model versions in the Model Registry are automatically deployed to production. For information about using SageMaker AI MLOps projects, see MLOps Automation With SageMaker Projects.

You can also enable an Amazon account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models.

- Deploy a Model from the Registry (SageMaker SDK)
- Deploy a Model from the Registry (Boto3)
- Deploy a Model Version from a Different Account

Deploy a Model from the Registry (SageMaker SDK)

To deploy a model version using the Amazon SageMaker Python SDK use the following code snippet:

```
from sagemaker.serve import ModelBuilder

model_package_arn = 'arn:aws:sagemaker:us-east-2:12345678901:model-package/modeltest/1'

# In V3, deploy a model package through ModelBuilder
model_builder = ModelBuilder(
    model=model_package_arn,
    role_arn=role,
    sagemaker_session=sagemaker_session,
    instance_type='ml.m5.xlarge'
)
model_builder.build()
endpoint = model_builder.deploy(
    initial_instance_count=1,
    instance_type='ml.m5.xlarge'
)
```

Deploy a Model from the Registry (Boto3)

To deploy a model version using the Amazon SDK for Python (Boto3), complete the following steps:

1. The following code snippet assumes you already created the SageMaker AI Boto3 client `sm_client` and a model version whose ARN is stored in the variable `model_version_arn`.

   Create a model object from the model version by calling the create_model API operation. Pass the Amazon Resource Name (ARN) of the model version as part of the `Containers` for the model object:

   ```
   model_name = 'DEMO-modelregistry-model-' + strftime("%Y-%m-%d-%H-%M-%S", gmtime())
   print("Model name : {}".format(model_name))
   container_list = [{'ModelPackageName': model_version_arn}]

   create_model_response = sm_client.create_model(
       ModelName = model_name,
       ExecutionRoleArn = role,
       Containers = container_list
   )
   print("Model arn : {}".format(create_model_response["ModelArn"]))
   ```

2. Create an endpoint configuration by calling `create_endpoint_config`. The endpoint configuration specifies the number and type of Amazon EC2 instances to use for the endpoint.

```
endpoint_config_name = 'DEMO-modelregistry-EndpointConfig-' + strftime("%Y-%m-%d-
%H-%M-%S", gmtime())
print(endpoint_config_name)
create_endpoint_config_response = sm_client.create_endpoint_config(
    EndpointConfigName = endpoint_config_name,
    ProductionVariants=[{
        'InstanceType':'ml.m4.xlarge',
        'InitialVariantWeight':1,
        'InitialInstanceCount':1,
        'ModelName':model_name,
        'VariantName':'AllTraffic'}])
```

3. Create the endpoint by calling `create_endpoint`.

```
endpoint_name = 'DEMO-modelregistry-endpoint-' + strftime("%Y-%m-%d-%H-%M-%S",
 gmtime())
print("EndpointName={}".format(endpoint_name))

create_endpoint_response = sm_client.create_endpoint(
    EndpointName=endpoint_name,
    EndpointConfigName=endpoint_config_name)
print(create_endpoint_response['EndpointArn'])
```

Deploy a Model Version from a Different Account

You can permit an Amazon account to deploy model versions that were created in a different account by adding a cross-account resource policy. For example, one team in your organization might be responsible for training models, and a different team is responsible for deploying and updating models. When you create these resource policies, you apply the policy to the specific resource to which you want to grant access. For more information about cross-account resource policies in Amazon, see Cross-account policy evaluation logic in the *Amazon Identity and Access Management User Guide*.

> **Note**
>
> You must use a KMS key to encrypt the output data config action during training for cross-account model deployment.

To enable cross-account model deployment in SageMaker AI, you have to provide a cross-account resource policy for the Model Group that contains the model versions you want to deploy, the Amazon ECR repository where the inference image for the Model Group resides, and the Amazon S3 bucket where the model versions are stored.

To be able to deploy a model that was created in a different account, you must have a role that has access to SageMaker AI actions, such as a role with the `AmazonSageMakerFullAccess` managed policy. For information about SageMaker AI managed policies, see Amazon managed policies for Amazon SageMaker AI.

The following example creates cross-account policies for all three of these resources, and applies the policies to the resources. The example also assumes that you previously defined the following variables:

- `bucket` – The Amazon S3 bucket where the model versions are stored.
- `kms_key_id` – The KMS key used to encrypt the training output.
- `sm_client` – A SageMaker AI Boto3 client.
- `model_package_group_name` – The Model Group to which you want to grant cross-account access.
- `model_package_group_arn` – The Model Group ARN to which you want to grant cross-account access.

```
import json

# The cross-account id to grant access to
cross_account_id = "123456789012"

# Create the policy for access to the ECR repository
ecr_repository_policy = {
    'Version': '2012-10-17       ',
    'Statement': [{
        'Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['ecr:*']
    }]
}
```

```
# Convert the ECR policy from JSON dict to string
ecr_repository_policy = json.dumps(ecr_repository_policy)

# Set the new ECR policy
ecr = boto3.client('ecr')
response = ecr.set_repository_policy(
    registryId = account,
    repositoryName = 'decision-trees-sample',
    policyText = ecr_repository_policy
)

# Create a policy for accessing the S3 bucket
bucket_policy = {
    'Version': '2012-10-17       ',
    'Statement': [{
        'Sid': 'AddPerm',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': 's3:*',
        'Resource': f'arn:aws:s3:::{bucket}/*'
    }]
}

# Convert the policy from JSON dict to string
bucket_policy = json.dumps(bucket_policy)

# Set the new policy
s3 = boto3.client('s3')
response = s3.put_bucket_policy(
    Bucket = bucket,
    Policy = bucket_policy)

# Create the KMS grant for encryption in the source account to the
# Model Registry account Model Group
client = boto3.client('kms')

response = client.create_grant(
    GranteePrincipal=cross_account_id,
    KeyId=kms_key_id
    Operations=[
        'Decrypt',
```

```
        'GenerateDataKey',
    ],
)

# 3. Create a policy for access to the Model Group.
model_package_group_policy = {
    'Version': '2012-10-17       ',
    'Statement': [{
        'Sid': 'AddPermModelPackageGroup',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ['sagemaker:DescribeModelPackageGroup'],
        'Resource': f'arn:aws:sagemaker:{region}:{account}:model-package-group/
{model_package_group_name}'
    },{
        'Sid': 'AddPermModelPackageVersion',
        'Effect': 'Allow',
        'Principal': {
            'AWS': f'arn:aws:iam::{cross_account_id}:root'
        },
        'Action': ["sagemaker:DescribeModelPackage",
                   "sagemaker:ListModelPackages",
                   "sagemaker:UpdateModelPackage",
                   "sagemaker:CreateModel"],
        'Resource': f'arn:aws:sagemaker:{region}:{account}:model-package/
{model_package_group_name}/*'
    }]
}

# Convert the policy from JSON dict to string
model_package_group_policy = json.dumps(model_package_group_policy)

# Set the policy to the Model Group
response = sm_client.put_model_package_group_policy(
    ModelPackageGroupName = model_package_group_name,
    ResourcePolicy = model_package_group_policy)

print('ModelPackageGroupArn :
 {}'.format(create_model_package_group_response['ModelPackageGroupArn']))
print("First Versioned ModelPackageArn: " + model_package_arn)
print("Second Versioned ModelPackageArn: " + model_package_arn2)
```

```
print("Success! You are all set to proceed for cross-account deployment.")
```

Deploy a Model in Studio

After you register a model version and approve it for deployment, deploy it to a Amazon SageMaker AI endpoint for real-time inference. You can Deploy a Model from the Registry with Python or deploy your model in Amazon SageMaker Studio. The following provides instructions on how to deploy your model in Studio.

This feature is not available in Amazon SageMaker Studio Classic.

- If Studio is your default experience, the UI is similar to the images found in Amazon SageMaker Studio UI overview.
- If Studio Classic is your default experience, the UI is similar to the images found in Amazon SageMaker Studio Classic UI Overview.

Before you can deploy a model package, the following requirements must be met for the model package:

- A valid inference specification available. See InferenceSpecification for more information.
- Model with approved status. See Update the Approval Status of a Model for more information.

The following provides instructions on how to deploy a model in Studio.

To deploy a model in Studio

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Models** from the left navigation pane.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. (Optional) If you have models that are shared with you, you can choose between **My models** or **Shared with me**.
6. Select the checkboxes for the registered models. If the above requirements are met, the **Deploy** button becomes available to choose.
7. Choose **Deploy** to open the **Deploy model to endpoint** page.

8. Configure the deployment resources in the **Endpoint settings**.
9. Once you have verified the settings, choose **Deploy**. The model will then be deployed to the endpoint with the **In service** status.

For `us-east-1`, `us-west-2`, `ap-northeast-1`, and `eu-west-1` regions, you can use the following instructions to deploy models:

To deploy a model in Studio

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Models** from the left navigation pane.
3. Choose the **My models** tab.
4. Choose the Logged **models** tab, if not selected already.
5. Select a model and choose **View Latest Version**.
6. Choose **Deploy** and select between SageMaker AI or Amazon Bedrock.
7. Once you have verified the settings, choose **Deploy**. The model will then be deployed to the endpoint with the **In service** status.

Cross-account discoverability

By exploring and accessing model package groups registered in other accounts, data scientists and data engineers can promote data consistency, streamline collaboration, and reduce duplication of effort. With Amazon SageMaker Model Registry, you can share model package groups across accounts. There are two categories of permissions associated with the sharing of resources:

- **Discoverability**: *Discoverability* is the ability of the resource consumer account to see the model package groups shared by one or more resource owner accounts. Discoverability is only possible if the resource owner attaches the necessary resource policies to the shared model package groups. The resource consumer can view all shared model package groups in the Amazon RAM UI and Amazon CLI.
- **Accessibility**: *Accessibility* is the ability of the resource consumer account to use the shared model package groups. For example, the resource consumer can register or deploy a model package from a different account if they have the necessary permissions.

Topics

- Share model group in Studio
- View shared model groups in Studio
- Accessibility
- Set up discoverability
- View shared model package groups
- Dissociate principals from a resource share and remove a resource share
- Promote the permission and resource share

Share model group in Studio

You can share your model groups with other Amazon principals (Amazon Web Services accounts or Amazon Organizations) using the Studio UI. This streamlined sharing process enables cross-team collaboration, promotes best practices, and facilitates model reuse across your teams. The following will provide instructions on how to share model groups in Studio.

This feature is not available in Amazon SageMaker Studio Classic.

- If Studio is your default experience, the UI is similar to the images found in Amazon SageMaker Studio UI overview.
- If Studio Classic is your default experience, the UI is similar to the images found in Amazon SageMaker Studio Classic UI Overview.

To share model groups you will first need to make sure that you have the following permission added to the execution role you a sharing the resources from.

1. Get your execution role.
2. Update role permissions with the following:

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
```

```
                "ram:ListPermissions",
                "ram:GetPermission",
                "ram:GetResourceShareAssociations",
                "ram:ListResourceSharePermissions",
                "ram:DeleteResourceShare",
                "ram:GetResourceShareInvitations",
                "ram:AcceptResourceShareInvitation"
            ],
            "Resource": "*"
        }
    ]
}
```

The following provides instructions on how to share a model group with other Amazon principals.

To share a model group with other Amazon principals

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Models** from the left navigation pane.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. Select a registered model.
6. At the top right corner, choose **Share**. This will open the **Share model group** section.

   If you see an error message at the bottom of the screen, you will need add the appropriate permissions to your execution role. See the above permissions for more information.
7. Under **Resource shares**, choose a resource share to update or create a new resource share.
8. Under **Managed permission**, choose a managed permission to control the level of access for your model.

   The viewable options include permissions that have already been created for you or your custom made permissions in Amazon RAM. See Creating and using customer managed permissions in the *Amazon Resource Access Manager* User Guide.
9. Under **Amazon principals**, input the Amazon Organizations ARN or Amazon Web Services account IDs you wish to share to and then choose **Add**. You can add multiple Amazon principals this way.

10. When the minimum requirements are satisfied, the **Share** button becomes accessible. Once you have verified your settings, choose **Share**.

    A successful share will result in a green banner message at the bottom of the screen.

View shared model groups in Studio

You can view model groups that are shared with you or an account belonging to the same Amazon Organizations. If a model group is shared with an account belonging to the same Amazon Organizations, the shared model group will be automatically approved and available for you to view in Studio. Otherwise, you will need to approve the pending invitation before you can view the shared model group in Studio. The following will provide instructions on how to view shared model groups and accept model group share invitations in Studio.

This feature is not available in Amazon SageMaker Studio Classic.

- If Studio is your default experience, the UI is similar to the images found in Amazon SageMaker Studio UI overview.
- If Studio Classic is your default experience, the UI is similar to the images found in Amazon SageMaker Studio Classic UI Overview.

The following provides instructions on how to view and accept model groups shared with you.

View and accept model groups shared with you

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Models** from the left navigation pane.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. Choose **Shared with me** to view the model groups that are shared with you.
6. To accept pending model group invitations:

    a. Choose **View pending approvals** to open the **Pending invitations** list.

    b. If you would like to accept the invitation, choose **Accept**.

Accessibility

If the resource consumer has access permissions to use a shared model package group, they can register or deploy a version of the model package group. For details about how the resource consumer can register a shared model package group, see Register a Model Version from a Different Account. For details about how the resource consumer can deploy a shared model package group, see Deploy a Model Version from a Different Account.

Set up discoverability

The resource owner can set up model package group discoverability by creating resource shares and attaching resource policies to the entities. For detailed steps about how to create a general resource share in Amazon RAM, see Create a resource share in the Amazon RAM documentation.

Complete the following instructions to set up model package group discoverability using the Amazon RAM console or Model Registry Resource Policy APIs.

Amazon CLI

1. Create a resource share in the model owner account.

    a. The model owner attaches a resource policy to the model package group using the SageMaker AI Resource Policy API put-model-package-group-policy, as demonstrated in the following command.

```
aws sagemaker put-model-package-group-policy
--model-package-group-name <model-package-group-name>
--resource-policy "{\"Version\":\"2012-10-17\",       \"Statement\":[{\"Sid
\":
\"ExampleResourcePolicy\",\"Effect\":\"Allow\",\"Principal\":<principal>,
\"Action\":[\"sagemaker:DescribeModelPackage\",
\"sagemaker:ListModelPackages\",\"sagemaker:DescribeModelPackageGroup\"],
\"Resource\":[\"<model-package-group-arn>,\"
\"arn:aws:sagemaker:<region>:<owner-account-id>:model-package/
<model-package-group-name>/*\"]}]}"
```

> **Note**
>
> Different combinations of actions can be attached to the resource policy. For custom policies, the permission created should be promoted by the model package group owner, and only entities with promoted permissions attached

are discoverable. Unpromotable resource shares cannot be made discoverable or managed through Amazon RAM.

b. To check that Amazon RAM created the resource share ARN, use the following command:

```
aws ram get-resource-share-associations --association-type resource --
resource-arn <model-package-group-arn>
```

The response contains the *resource-share-arn* for the entity.

c. To check if the attached policy permission is a managed or custom policy, use the following command:

```
aws ram list-resource-share-permissions --resource-share-arn <resource-
share-arn>
```

The `featureSet` field can take values `CREATED_FROM_POLICY` or `STANDARD`, which are defined as follows:

- `STANDARD`: The permission already exists.
- `CREATED_FROM_POLICY`: The permission needs to be promoted in order for the entity to be discoverable. For more information, see Promote the permission and resource share.

2. Accept the resource share invitation in the model consumer account.

a. The model package group consumer accepts the invitation for resource share. To see all resource invitations, run the following command:

```
aws ram get-resource-share-invitations
```

Identify the requests that have status `PENDING` and include the account ID of the owner account.

b. Accept the resource share invitation from the model owner using the following command:

```
aws ram accept-resource-share-invitation --resource-share-invitation-
arn <resource-share-invitation-arn>
```

Amazon RAM console

1. Log into the Amazon RAM console.
2. Complete the following steps to create a resource share from the model package group owner account.

   a. Complete the following steps to specify resource share details.

      i. In the **Name** field, add a unique name for your resource.

      ii. In the **Resources** card, choose the dropdown menu and select **SageMaker AI Model Package Groups**.

      iii. Select the check box of the ARN of the model package group resource share.

      iv. In the **Select resources** card, select the check box of your model package group resource share.

      v. In the **Tags** card, add key-value pairs for tags to add to your resource share.

      vi. Choose **Next**.

   b. Complete the following steps to associate managed permissions to the resource share.

      i. If you use a managed permission, choose a managed permission in the **Managed permissions** dropdown menu.

      ii. If you use a custom permission, choose **Customer Managed Permission**. In this case, the model package group is not immediately discoverable. You have to promote the permission and the resource policy after you create the resource share. For information about how to promote permissions and resource shares, see Promote the permission and resource share. For more information about how to attach custom permissions, see Creating and using customer managed permissions in Amazon RAM.

      iii. Choose **Next**.

   c. Complete the following steps to grant access to principals.

      i. Choose **Allow sharing with anyone** to allow sharing with accounts outside of your organization, or choose **Allow sharing only within your organization**.

      ii. In the **Select principal type** dropdown menu, add the principal types and ID for the principals you want to add.

      iii. Add and select the chosen principals for the share.

      iv. Choose **Next**.

d. Review the displayed share configuration and then choose **Create resource share**.

3. Accept the resource share invitation from the consumer account. Once the model owner creates the resource share and principal associations, the specified resource consumer accounts receive an invitation to join the resource share. The resource consumer accounts can view and accept the invitations in the Shared with me: Resource shares page in the Amazon RAM console. For more information about accepting and viewing resources in Amazon RAM, see Access Amazon resources shared with you.

View shared model package groups

After the resource owner completes the previous steps to create a resource share and the consumer accepts the invitation for the share, the consumer can view the shared model package groups using the Amazon CLI or in the Amazon RAM console.

Amazon CLI

To view the model package groups shared, use the following command in the model consumer account:

```
aws sagemaker list-model-package-groups --cross-account-filter-option CrossAccount
```

Amazon RAM console

In the Amazon RAM console, the resource owner and consumer can view shared model package groups. The resource owner can view the model package groups shared with the consumer by following the steps in Viewing resource shares you created in Amazon RAM. The resource consumer can view the model package groups shared by the owner by following the steps in Viewing resource shares shared with you.

Dissociate principals from a resource share and remove a resource share

The resource owner can dissociate principals from the resource share for a set of permissions or delete the entire resource share using the Amazon CLI or the Amazon RAM console. For details about how to dissociate principals from a resource share, see Update a Resource Share in the Amazon RAM documentation. For details about how to delete a resource share, see Deleting a resource share in the Amazon RAM documentation.

Amazon CLI

To dissociate principals from a resource share, use the command dissociate-resource-share as follows:

```
aws ram disassociate-resource-share --resource-share-arn <resource-share-arn> --
principals <principal>
```

To delete a resource share, use the command delete-resource-share as follows:

```
aws ram delete-resource-share --resource-share-arn <resource-share-arn>
```

Amazon RAM console

For more details about how to dissociate principals from a resource share, see Update a Resource Share in the Amazon RAM documentation. For more details about how to delete a resource share, see Deleting a resource share in the Amazon RAM documentation.

Promote the permission and resource share

If you use customized (customer managed) permissions, you need to promote the permission and the associated resource share in order for the model package group to be discoverable. Complete the following steps to promote the permission and resource share.

1. To promote your customized permission to be accessible by Amazon RAM, use the following command:

   ```
   aws ram promote-permission-created-from-policy –permission-arn <permission-arn>
   ```

2. Promote the resource share using the following command:

   ```
   aws ram promote-resource-share-created-from-policy --resource-share-arn <resource-
   share-arn>
   ```

If you see the `OperationNotPermittedException` error while performing the previous steps, the entity is not discoverable but is accessible. For example, if the resource owner attaches a resource policy with an assume role principal such as `“Principal”: {“AWS”: “arn:aws:iam::3333333333:role/Role-1”}`, or if the resource policy allows `“Action”: “*”` , the associated model package group is not promotable nor discoverable.

View the Deployment History of a Model

To view the deployments for a model version in the Amazon SageMaker Studio console, complete the following steps based on whether you use Studio or Studio Classic.

Studio

View the deployment history for a model version

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models** to display a list of your model groups.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. From the model groups list, choose the angle bracket to the left of the model group that you want to view.
6. A list of the model versions in the model group appears. If you don't see the model version that you want to delete, choose **View all**.
7. Select the name of the model version that you want to view.
8. Choose the **Activity** tab. Deployments for the model version appear as events in the activity list with an **Event type** of **ModelDeployment**.

Studio Classic

View the deployment history for a model version

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. From the model groups list, select the name of the Model Group that you want to view.
5. A new tab appears with a list of the model versions in the Model Group.

6. In the list of model versions, select the name of the model version for which you want to view details.
7. On the model version tab that opens, choose **Activity**. Deployments for the model version appear as events in the activity list with an **Event type** of **ModelDeployment**.

View model lineage details in Studio

You can view the lineage details of a registered model in Amazon SageMaker Studio. The following will provide instructions on how to access the lineage view in Studio. See Amazon SageMaker ML Lineage Tracking for more information about lineage tracking in Amazon SageMaker Studio.

This feature is not available in Amazon SageMaker Studio Classic.

- If Studio is your default experience, the UI is similar to the images found in Amazon SageMaker Studio UI overview.
- If Studio Classic is your default experience, the UI is similar to the images found in Amazon SageMaker Studio Classic UI Overview.

The lineage view is an interactive visualization of the resources associated with your registered models. These resources include datasets, training jobs, approvals, models, and endpoints. In the lineage you can also view the associated resource details, including the source URI, creation timestamp, and other metadata.

The following capabilities are available in `us-east-1`, `us-west-2`, `ap-northeast-1`, and `eu-west-1` regions:

You can track the lineage of logged and registered models. Furthermore, lineage for models resources include datasets, evaluators, training jobs, approvals, models, inference components, and endpoints. In the lineage you can also view the associated resource details, including the source URI, creation timestamp, and other metadata.

The following provides instructions on how to access the lineage details for a registered model version.

To access the lineage details for a registered model version

1. Open the Studioconsole by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Models** from the left navigation pane.

3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. (Optional) If you have models that are shared with you, you can choose between **My models** or **Shared with me**.
6. Select a registered model.
7. Choose the **Versions** tab, if not selected already.
8. Choose a specific model version from the **Versions** list.
9. Choose the **Lineage** tab.

In the **Lineage** tab you can navigate through the resources associated with the model version. You can also choose a resource to view the resource details.

Note that the Lineage view is for visualization purposes only. Rearranging or moving the components in this view does not affect the actual registered model resources.

For `us-east-1`, `us-west-2`, `ap-northeast-1`, and `eu-west-1` regions, you can use the following instructions to access the lineage details for logged and registered model versions:

1. Open the Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. Choose **Models** from the left navigation pane.
3. Choose the **My models** tab.
4. (Optional) If you have models that are shared with you, you can choose between **Created by me** or **Shared with me**.
5. Select a model and choose **View Latest Version**.
6. Choose the **Lineage** tab.

Model Registry Collections

You can use Collections to group registered models that are related to each other and organize them in hierarchies to improve model discoverability at scale. With Collections, you can organize registered models that are associated with one another. For example, you could categorize your models based on the domain of the problem they solve as Collections titled *NLP-models*, *CV-models*, or *Speech-recognition-models*. To organize your registered models in a tree structure, you

can nest Collections within each other. Any operations you perform on a Collection, such as create, read, update, or delete, will not alter your registered models. You can use the Amazon SageMaker Studio UI or the Python SDK to manage your Collections.

The **Collections** tab in the Model Registry displays a list of all the Collections in your account. The following sections describe how you can use options in the **Collections** tab to do the following:

- Create Collections
- Add Model Groups to a Collection
- Move Model Groups between Collections
- Remove Model Groups or Collections from other Collections

Any operation you perform on your Collections does not affect the integrity of the individual Model Groups they contain—the underlying Model Group artifacts in Amazon S3 and Amazon ECR are not modified.

While Collections provide greater flexibility in organizing your models, the internal representation imposes some constraints on the size of your hierarchy. For a summary of these constraints, see Constraints.

The following topics show you how to create and work with Collections in the Model Registry.

Topics

- Set up prerequisite permissions
- Create a Collection
- Add Model Groups to a Collection
- Remove Model Groups or Collections from a Collection
- Move a Model Group Between Collections
- View a Model Group's Parent Collection
- Constraints

Set up prerequisite permissions

Create a custom policy which includes the following required Resource Groups actions:

- `resource-groups:CreateGroup`

- `resource-groups:DeleteGroup`
- `resource-groups:GetGroupQuery`
- `resource-groups:ListGroupResources`
- `resource-groups:Tag`
- `tag:GetResources`

For instructions on how to add an inline policy, see Adding IAM identity permissions (console). When you choose the policy format, choose the JSON format and add the following policy:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "resource-groups:ListGroupResources"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "resource-groups:GetGroupQuery"
            ],
            "Resource": "arn:aws-cn:resource-groups:*:*:group/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "resource-groups:CreateGroup",
                "resource-groups:Tag"
            ],
            "Resource": "arn:aws-cn:resource-groups:*:*:group/*",
            "Condition": {
                "ForAnyValue:StringEquals": {
                    "aws:TagKeys": "sagemaker:collection"
                }
            }
```

```
        },
        {
            "Effect": "Allow",
            "Action": "resource-groups:DeleteGroup",
            "Resource": "arn:aws-cn:resource-groups:*:*:group/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceTag/sagemaker:collection": "true"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "tag:GetResources",
            "Resource": "*"
        }
    ]
}
```

Create a Collection

Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.
Amazon managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

You can create a Collection in the Amazon SageMaker Studio console. To create a Collection, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models**.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Collections**.
5. (Optional) To create a Collection inside another Collection, navigate to the hierarchy where you want to add your Collection. Otherwise, your Collection is created at the root level.
6. In the **Actions** dropdown menu in the top right, choose **Create new collection**.
7. Enter a name for your Collection in the **Name** field of the dialog box.

   > **Note**
   >
   > If you plan to create multiple hierarchies in this Collection, keep your Collection names short. The absolute path, which is a string representing the location of your Collections from the root level, must be 256 characters or less. For additional details, see Collection and Model Group tagging.

8. (Optional) To add Model Groups to your Collection, complete the following steps:
   a. Choose **Select model groups**.
   b. Select the Model Groups that you want to add. You can select up to 10.
9. Choose **Create**.
10. Check to make sure your Collection was created in the current hierarchy. If you do not immediately see your new Collection, choose **Refresh**.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. Choose the **Collections** tab.

5. (Optional) To create a Collection inside another Collection, navigate to the hierarchy where you want to add your Collection. Otherwise, your Collection is created at the root level.
6. In the **Actions** dropdown menu in the top right, choose **Create new collection**.
7. Enter a name for your Collection in the **Name** field of the dialog box.

   > **Note**
   >
   > If you plan to create multiple hierarchies in this Collection, keep your Collection names short. The absolute path, which is a string representing the location of your Collections from the root level, must be 256 characters or less. For additional details, see Collection and Model Group tagging.

8. (Optional) To add Model Groups to your Collection, complete the following steps:
   a. Choose **Select model groups**.
   b. Select the Model Groups that you want to add. You can select up to 10.
9. Choose **Create**.
10. Check to make sure your Collection was created in the current hierarchy. If you do not immediately see your new Collection, choose **Refresh**.

Add Model Groups to a Collection

You can add model groups to a Collection in the Amazon SageMaker Studio console. To add Model Groups to a Collection, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models**.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Models**, if not selected already.

5. Select the check box next to the model groups that you want to add. You can select up to 10 Model Groups. If you select more than 10, the UI option to add your Model Groups to a Collection is inactive.
6. Choose the vertical ellipsis next to **Create**, and choose **Add to collection**.
7. Select the radio button for the collection to which you want to add your selected Model Groups.
8. Choose **Add to collection**.
9. Check to make sure your Model Groups were added in to the collection. In the **Collections** column of the Model Groups you selected, you should see the name of collection to which you added the Model Groups.

Studio Classic

You can add Model Groups to a Collection from either the **Model Groups** or **Collections** tab.

To add one or more Model Groups to a Collection from the **Collections** tab, complete the following steps:

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. Choose the **Collections** tab.
5. Select the Collection to which you want to add Model Groups. If the desired Collection is not at root level, navigate to the hierarchy where you want to add your Model Groups.
6. In the **Actions** dropdown menu in the top right, choose **Add model groups**.
7. Select the Model Groups that you want to add. You can select up to 10 Model Groups. If you select more than 10, the UI option to add your Model Groups to a Collection is inactive.
8. Choose **Add to collection**.
9. Check to make sure your Model Groups were added in the current hierarchy. If you do not immediately see your new Model Groups, choose **Refresh**.

To add one or more Model Groups to a Collection from the **Model Groups** tab, complete the following steps:

1. Sign in to Studio Classic. For more information, see Amazon SageMaker AI domain overview.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. Choose the **Model Groups** tab.
5. Select the Model Groups that you want to add. You can select up to 10. If you select more than 10, the UI option to add your Model Groups to a Collection is inactive.
6. In the **Actions** dropdown menu in the top right, choose **Add to collection**.
7. In the pop-up dialog, choose the root path location `Collections`. This link to the root location appears above the table.
8. Navigate to the hierarchy which contains your destination Collection, or where you want to create a new Collection to which you add your models.
9. (Optional) To add your Model Groups to an existing Collection, complete the following steps:
    a. Select the destination Collection.
    b. Choose **Add to collection**.
10. (Optional) To add your Model Groups to a new Collection, complete the following steps:
    a. Choose **New collection**.
    b. Enter a name for your new Collection.
    c. Choose **Create**.

Remove Model Groups or Collections from a Collection

When you remove Model Groups or Collections from a Collection, you are removing them from a particular grouping and not from the Model Registry. You can remove Model Groups from a Collection in the Amazon SageMaker Studio console.

To remove one or more Model Groups or Collections from a Collection, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models**.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Collections**.
5. Navigate to the Collection which contains the Model Groups or Collections you want to remove.
6. Select the Model Groups or Collections that you want to remove. You can select up to 10. If you select more than 10 Model Groups or Collections, the UI option to remove them is inactive.

> **Important**
>
> You cannot simultaneously select Model Groups and Collections for removal. To remove both Model Groups and Collections, first remove Model Groups, and then remove Collections.

> **Important**
>
> You cannot remove non-empty Collections. To remove a non-empty Collection, first remove its contents.

7. In the **Actions** dropdown menu in the top right, choose **Remove X items from collection** (where X is the number of Model Groups that you selected).
8. Confirm that you want to remove the selected Model Groups.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon (

).

3. Choose **Models**, and then **Model registry**.
4. Choose the **Collections** tab.
5. Navigate to the Collection which contains the Model Groups or Collections you want to remove.
6. Select the Model Groups or Collections that you want to remove. You can select up to 10. If you select more than 10 Model Groups or Collections, the UI option to remove them is inactive.

> **Important**
>
> You cannot simultaneously select Model Groups and Collections for removal. To remove both Model Groups and Collections, first remove Model Groups, and then remove Collections.

> **Important**
>
> You cannot remove non-empty Collections. To remove a non-empty Collection, first remove its contents.

7. In the **Actions** dropdown menu in the top right, choose **Remove X items from collection** (where X is the number of Model Groups you selected).
8. Confirm that you want to remove the selected Model Groups.

Move a Model Group Between Collections

You can move one or more Model Groups from one Collection to another in the Amazon SageMaker Studio console.

To move Model Groups, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models**.

3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Collections**.
5. Navigate to the Collection which contains the Model Groups that you want to move.
6. Select the Model Groups that you want to move. You can select up to 10. If you select more than 10, the UI option to move your Model Groups is inactive.
7. In the **Actions** dropdown menu in the top right, choose **Move to**.
8. In the dialog box, choose the root path location `Collections`. This link to the root location appears above the table.
9. Navigate to the hierarchy which contains your destination Collection.
10. Select your destination Collection in the table.
11. Choose **Move here**.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. Choose the **Collections** tab.
5. Navigate to the Collection which contains the Model Groups that you want to move.
6. Select the Model Groups that you want to move. You can select up to 10. If you select more than 10, the UI option to move your Model Groups is inactive.
7. In the **Actions** dropdown menu in the top right, choose **Move to**.
8. In the dialog box, choose the root path location `Collections`. This link to the root location appears above the table.
9. Navigate to the hierarchy which contains your destination Collection.
10. Select your destination Collection in the table.
11. Choose **Move here**.

View a Model Group's Parent Collection

You can view the Collections which contain a particular Model Group in the Amazon SageMaker Studio console.

To view the Collections which contain a particular Model Group, complete the following steps based on whether you use Studio or Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Models**.
3. Choose the **Registered models** tab, if not selected already.
4. Immediately below the **Registered models** tab label, choose **Model Groups**, if not selected already.
5. View the **Collection** column for your Model Group, which displays the name of the Collection which contains this Model Group. If multiple Collections contain this Model Group, choose the **Collection** column entry to display a pop-up listing the Collections which contain this Model Group.

Studio Classic

1. Sign in to Amazon SageMaker Studio Classic. For more information, see Launch Amazon SageMaker Studio Classic.
2. In the left navigation pane, choose the **Home** icon ().
3. Choose **Models**, and then **Model registry**.
4. Choose the **Model Groups** tab.
5. Find your Model Group in the table.
6. View the **Collection** column for your Model Group, which displays the name of the Collection which contains this Model Group. If multiple Collections contain this Model Group, choose the **Collection** column entry to display a pop-up listing the Collections which contain this Model Group.

Constraints

While using Collections, you may face issues related to tag length constraints or rate limits for Collection operations. Review the following list of caveats so you can avoid issues related to these limitations when you work with your Collections.

VPC constraints

- Collections are not supported in VPC mode.

Collection operation constraints

- You can add a maximum of 10 Model Groups to a Collection at a time.
- You can remove a maximum of 10 Model Groups from a Collection at a time.
- You can move a maximum of 10 Model Groups from one Collection to another at a time.
- You cannot delete a Collection unless it is empty.
- A Model Group can belong to multiple Collections, but a Collection can only belong to one Collection.

Tag-related constraints

- A Model Group can belong to a maximum of 48 Collections. For more details, see the following section Collection and Model Group tagging.
- A Collection's absolute path can be a maximum of 256 characters long. Since Collection names are user-specified, you can control the path length. For more details, see the following section Collection and Model Group tagging.

Collection and Model Group tagging

The SageMaker Model Registry uses tag rules and tags to internally represent your Collection groupings and hierarchy. You can access these tag elements in the Amazon Resource Access Manager, the SageMaker SDK, and the Amazon CLI, but it is important that you do not alter or delete them.

> **Important**
>
> Do not delete or alter any tag rules or tags which belong to your Collections or Model Groups. Doing so prevents you from performing Collection operations!

A tag rule is a key-value pair that SageMaker AI uses to identify a Collection's location in the hierarchy. In short, the key is the key of the parent Collection, and the value is the path of the Collection within the hierarchy. SageMaker AI allows tag values to be 256 characters or less, so if you have multiple nested hierarchies you are advised to keep your Collection names short.

> **Important**
>
> Keep your Collection names short. The absolute path to any Collection must be 256 characters long or less.

Model Groups, on the other hand, do not have tag rules but use tags. A Model Group's tags include the tag rules for all the Collections which contain the Model Group. For example, if four Collections contain *model-group-1*, *model-group-1* has four tags. SageMaker AI allows a single Amazon resource to have a maximum of 50 tags. Since two are pre-allocated for general purposes, a Model Group can have a maximum of 48 tags. In conclusion, a Model Group can belong to a maximum of 48 Collections.

Model Deployment in SageMaker AI

Once you train and approve a model for production, use SageMaker AI to deploy your model to an endpoint for real-time inference. SageMaker AI provides multiple inference options so that you can pick the option that best suits your workload. You also configure your endpoint by choosing the instance type and number of instances you need for optimal performance. For details about model deployment, see Deploy models for inference.

After you deploy your models to production, you might want to explore ways to further optimize model performance while maintaining availability of your current models. For example, you can set up a shadow test to try out a different model or model serving infrastructure before committing to the change. SageMaker AI deploys the new model, container, or instance in shadow mode and routes to it a copy of the inference requests in real time within the same endpoint. You can log the

responses of the shadow variant for comparison. For details about shadow testing, see Shadow tests. If you decide to go ahead and change your model, deployment guardrails help you control the switch from the current model to a new one. You can select such methods as blue/green or canary testing of the traffic shifting process to maintain granular control during the update. For information about deployment guardrails, see Deployment guardrails for updating models in production.

SageMaker Model Monitor

Once a model is in production, you can monitor its performance in real time with Amazon SageMaker Model Monitor. Model Monitor helps you maintain model quality by detecting violations of user-defined thresholds for data quality, model quality, bias drift and feature attribution drift. In addition, you can configure alerts so you can troubleshoot violations as they arise and promptly initiate retraining. Model Monitor is integrated with SageMaker Clarify to improve visibility into potential bias.

To learn about SageMaker Model Monitor, see Data and model quality monitoring with Amazon SageMaker Model Monitor.

MLOps Automation With SageMaker Projects

Create end-to-end ML solutions with CI/CD by using SageMaker Projects.

Use SageMaker Projects to create a MLOps solution to orchestrate and manage:

- Building custom images for processing, training, and inference
- Data preparation and feature engineering
- Training models
- Evaluating models
- Deploying models
- Monitoring and updating models

Topics

- What is a SageMaker AI Project?
- Granting SageMaker Studio Permissions Required to Use Projects

- Create a MLOps Project using Amazon SageMaker Studio or Studio Classic
- MLOps Project Templates
- View Project Resources
- Update a MLOps Project in Amazon SageMaker Studio or Studio Classic
- Delete a MLOps Project using Amazon SageMaker Studio or Studio Classic
- Walk Through a SageMaker AI MLOps Project Using Third-party Git Repos

What is a SageMaker AI Project?

SageMaker Projects help organizations set up and standardize developer environments for data scientists and CI/CD systems for MLOps engineers. Projects also help organizations set up dependency management, code repository management, build reproducibility, and artifact sharing.

You can provision SageMaker Projects using custom templates that are stored in Amazon S3 buckets, or by using templates from the Amazon Service Catalog or SageMaker AI. For information about the Amazon Service Catalog, see What Is Amazon Service Catalog. With SageMaker Projects, MLOps engineers and organization admins can define their own templates or use SageMaker AI-provided templates. The SageMaker AI-provided templates bootstrap the ML workflow with source version control, automated ML pipelines, and a set of code to quickly start iterating over ML use cases.

When Should You Use a SageMaker AI Project?

> **Important**
>
> Effective September 9, 2024, project templates that use the Amazon CodeCommit repository are no longer supported. For new projects, select from the available project templates that use third-party Git repositories.

While notebooks are helpful for model building and experimentation, a team of data scientists and ML engineers sharing code needs a more scalable way to maintain code consistency and strict version control.

Every organization has its own set of standards and practices that provide security and governance for its Amazon environment. SageMaker AI provides a set of first-party templates for organizations that want to quickly get started with ML workflows and CI/CD. The templates include projects

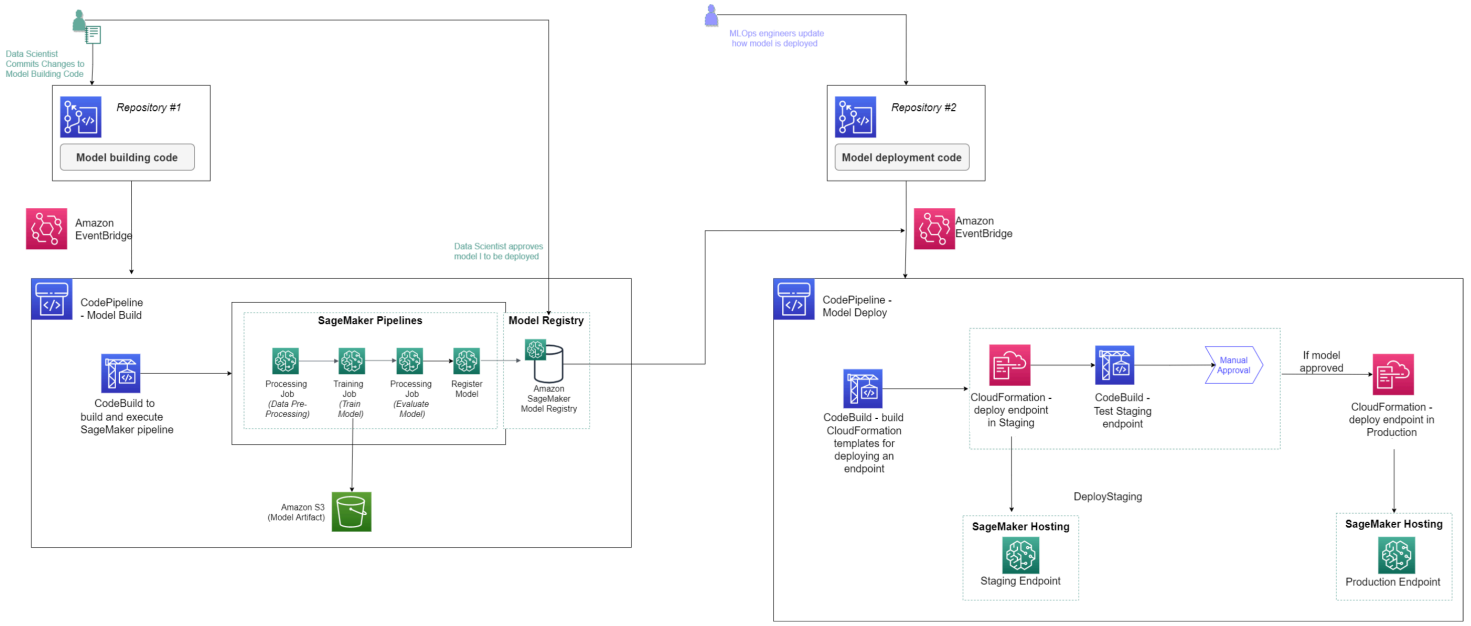
that use Amazon-native services for CI/CD, such as Amazon CodeBuild, Amazon CodePipeline, and Amazon CodeCommit. The templates also offer the option to create projects that use third-party tools, such as Jenkins and GitHub. For a list of the project templates that SageMaker AI provides, see Use SageMaker AI-Provided Project Templates.

Organizations often need tight control over the MLOps resources that they provision and manage. Such responsibility assumes certain tasks, including configuring IAM roles and policies, enforcing resource tags, enforcing encryption, and decoupling resources across multiple accounts. SageMaker Projects can support all these tasks through custom template offerings where organizations use Amazon CloudFormation templates to define the resources needed for an ML workflow. Data Scientists can choose a template to bootstrap and pre-configure their ML workflow.

To get started, we recommend that you create and store custom templates inside an Amazon S3 bucket. Doing so lets you create a bucket in any supported Region for your organization. S3 supports version control, so you can maintain multiple versions of your templates and roll back if necessary. For information about how to create a project from template store in an Amazon S3 bucket, see Using a template from an Amazon S3 bucket.

Alternatively, you can also create custom templates as Service Catalog products and you can provision them in the Studio or Studio Classic UI under **Organization Templates**. The Service Catalog is a service that helps organizations create and manage catalogs of products that are approved for use on Amazon. For more information about creating custom templates, see Build Custom SageMaker AI Project Templates – Best Practices.

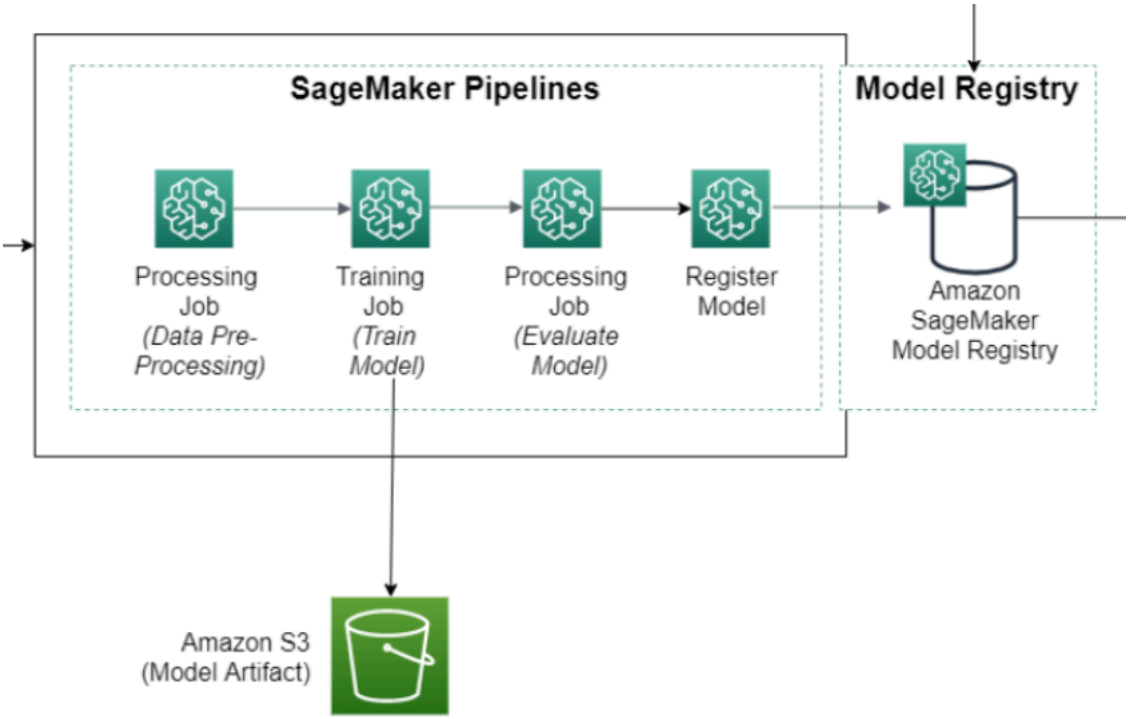
While you can use either option, we recommend that you use S3 buckets over the Service Catalog, so you can create a bucket in supported Regions where SageMaker AI is available without needing to manage the complexities of the Service Catalog.



SageMaker Projects can help you manage your Git repositories so that you can collaborate more efficiently across teams, ensure code consistency, and support CI/CD. SageMaker Projects can help you with the following tasks:

- Organize all entities of the ML lifecycle under one project.
- Establish a single-click approach to set up standard ML infrastructure for model training and deployment that incorporates best practices.
- Create and share templates for ML infrastructure to serve multiple use cases.
- Leverage SageMaker AI-provided pre-built templates to quickly start focusing on model building, or create custom templates with organization-specific resources and guidelines.

- Integrate with tools of your choice by extending the project templates. For an example, see Create a SageMaker AI Project to integrate with GitLab and GitLab Pipelines.
- Organize all entities of the ML lifecycle under one project.



What is in a SageMaker AI Project?

Customers have the flexibility to set up their projects with the resources that best serve their use case. The example below showcases the MLOps setup for an ML workflow, including model training and deployment.

A typical project with a SageMaker AI-provided template might include the following:

- One or more repositories with sample code to build and deploy ML solutions. These are working examples that you can modify for your needs. You own this code and can take advantage of the version-controlled repositories for your tasks.
- A SageMaker AI pipeline that defines steps for data preparation, training, model evaluation, and model deployment, as shown in the following diagram.

- A CodePipeline or Jenkins pipeline that runs your SageMaker AI pipeline every time you check in a new version of the code. For information about CodePipeline, see What is Amazon CodePipeline. For information about Jenkins, see Jenkins User Documentation.
- A model group that contains model versions. Every time you approve the resulting model version from a SageMaker AI pipeline run, you can deploy it to a SageMaker AI endpoint.

Each SageMaker AI project has a unique name and ID that are applied as tags to all of the SageMaker AI and Amazon resources created in the project. With the name and ID, you can view all of the entities associated with your project. These include:

- Pipelines
- Registered models
- Deployed models (endpoints)
- Datasets
- Service Catalog products
- CodePipeline and Jenkins pipelines
- CodeCommit and third-party Git repositories

Do I Need to Create a Project to Use SageMaker AI Pipelines?

No. SageMaker pipelines are standalone entities just like training jobs, processing jobs, and other SageMaker AI jobs. You can create, update, and run pipelines directly within a notebook by using the SageMaker Python SDK without using a SageMaker AI project.

Projects provide an additional layer to help you organize your code and adopt operational best practices that you need for a production-quality system.

Granting SageMaker Studio Permissions Required to Use Projects

The Amazon SageMaker Studio (or Studio Classic) administrator and Studio (or Studio Classic) users that you add to your domain can view project templates provided by SageMaker AI and create projects with those templates. By default, the administrator can view the SageMaker AI templates in the Service Catalog console. The administrator can see what another user creates if the user has permission to use SageMaker Projects. The administrator can also view the Amazon CloudFormation template that the SageMaker AI project templates define in the Service Catalog console. For information about using the Service Catalog console, see What Is Service Catalog in the *Service Catalog User Guide*.

Studio (and Studio Classic) users of the domain who are configured to use the same execution role as the domain by default have permission to create projects using SageMaker AI project templates.

> **Important**
>
> Do not manually create your roles. Always create roles through **Studio Settings** using the steps described in the following procedure.

For users who use any role other than the domain's execution role to view and use SageMaker AI-provided project templates, you need to grant **Projects** permissions to the individual user profiles by turning on **Enable Amazon SageMaker AI project templates and Amazon SageMaker JumpStart** for Studio users when you add them to your domain. For more information about this step, see Add user profiles.

Since SageMaker Projects is backed by Service Catalog, you must add each role that requires access to SageMaker Projects to the **Amazon SageMaker AI Solutions and ML Ops products** Portfolio in the service catalog. You can do this in the **Groups, roles, and users** tab, as shown in the following

image. If each user profile in Studio Classic has a different role, you should add each of those roles to the service catalog. You can also do this while creating a user profile in Studio Classic.

Grant new domain roles access to projects

When you change your domain's execution role or add user profiles with different roles, you must grant these new roles access to the Service Catalog portfolio to use SageMaker Projects. Follow these steps to ensure all roles have the necessary permissions:

To grant new domain roles access to projects

1. Open the Service Catalog console.
2. In the left navigation menu, choose **Portfolios**.
3. Select the **Imported** section.
4. Select **Amazon SageMaker Solutions and ML Ops products**.
5. Choose the **Access** tab.
6. Choose **Grant access**.
7. In the **Grant access** dialog, select **Roles**.
8. Grant access for all roles that are used by the domain's user profiles, including:
   - The domain's execution role
   - Any custom execution roles assigned to individual user profiles
9. Choose **Grant access** to confirm.

> **Important**
>
> You must complete this process whenever you change your domain's execution role or add user profiles with new execution roles. Without this access, users will not be able to create or use SageMaker Projects.

The following procedures show how to grant **Projects** permissions after you onboard to Studio or Studio Classic. For more information about onboarding to Studio or Studio Classic, see Amazon SageMaker AI domain overview.

To confirm that your SageMaker AI Domain has active project template permissions:

1. Open the SageMaker AI console.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. Select your domain.
5. Choose the **Domain Settings** tab.
6. Under **SageMaker Projects and JumpStart**, make sure the following options are turned on:
   - **Enable Amazon SageMaker AI project templates and Amazon SageMaker JumpStart for this account**
   - **Enable Amazon SageMaker AI project templates and Amazon SageMaker JumpStart for Studio users**

To view a list of your roles:

1. Open the SageMaker AI console.
2. On the left navigation pane, choose **Admin configurations**.
3. Under **Admin configurations**, choose **domains**.
4. Select your domain.
5. Choose the **Domain Settings** tab.
6. A list of your roles appears in the Apps card under the **Studio** tab.

> **Important**
>
> As of July 25, we require additional roles to use project templates. Here is the complete list of roles you should see under `Projects`:
> `AmazonSageMakerServiceCatalogProductsLaunchRole`
> `AmazonSageMakerServiceCatalogProductsUseRole`
> `AmazonSageMakerServiceCatalogProductsApiGatewayRole`
> `AmazonSageMakerServiceCatalogProductsCloudformationRole`
> `AmazonSageMakerServiceCatalogProductsCodeBuildRole`
> `AmazonSageMakerServiceCatalogProductsCodePipelineRole`
> `AmazonSageMakerServiceCatalogProductsEventsRole`
> `AmazonSageMakerServiceCatalogProductsFirehoseRole`

```
AmazonSageMakerServiceCatalogProductsGlueRole
AmazonSageMakerServiceCatalogProductsLambdaRole
AmazonSageMakerServiceCatalogProductsExecutionRole
```

For descriptions of these roles, see Amazon Managed Policies for SageMaker Projects and JumpStart.

Create a MLOps Project using Amazon SageMaker Studio or Studio Classic

Important

Custom IAM policies that allow Amazon SageMaker Studio or Amazon SageMaker Studio Classic to create Amazon SageMaker resources must also grant permissions to add tags to those resources. The permission to add tags to resources is required because Studio and Studio Classic automatically tag any resources they create. If an IAM policy allows Studio and Studio Classic to create resources but does not allow tagging, "AccessDenied" errors can occur when trying to create resources. For more information, see Provide permissions for tagging SageMaker AI resources.

Amazon managed policies for Amazon SageMaker AI that give permissions to create SageMaker resources already include permissions to add tags while creating those resources.

This procedure demonstrates how to create an MLOps project using Amazon SageMaker Studio Classic.

Prerequisites

- An IAM account or IAM Identity Center to sign in to Studio or Studio Classic. For more information, see Amazon SageMaker AI domain overview.
- Permission to use SageMaker AI-provided project templates. For more information, see Granting SageMaker Studio Permissions Required to Use Projects.
- Basic familiarity with the Studio Classic user interface. For nore information, see Amazon SageMaker Studio Classic UI Overview.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Deployments**, and then choose **Projects**.
3. In the upper-right corner above the projects list, choose **Create project**.
4. In the **Templates** page, choose a template to use for your project. For more information about project templates, see MLOps Project Templates.
5. Choose **Next**.
6. In the **Project details** page, enter the following information:
   - **Name**: A name for your project.
   - **Description**: An optional description for your project.
   - The values for the Service Catalog provisioning parameters related to your chosen template.
7. Choose **Create project** and wait for the project to appear in the **Projects** list.
8. (Optional) In the Studio sidebar, choose **Pipelines** to view the pipeline created from your project. For more information about Pipelines, see Pipelines.

Studio Classic

1. Sign in to Studio Classic. For more information, see Amazon SageMaker AI domain overview.
2. In the Studio Classic sidebar, choose the **Home** icon ().
3. Select **Deployments** from the menu, and then select **Projects**.
4. Choose **Create project**.

   The **Create project** tab opens displaying a list of available templates.
5. If not selected already, choose **SageMaker AI templates**. For more information about project templates, see MLOps Project Templates.
6. Choose the template **Model building, training, and deployment**.
7. Choose **Select project template**.

The **Create project** tab changes to display **Project details**.

8. Enter the following information:

   - For **Project details**, enter a name and description for your project.
   - Optionally, add tags, which are key-value pairs that you can use to track your projects.

9. Choose **Create project** and wait for the project to appear in the **Projects** list.

MLOps Project Templates

An Amazon SageMaker AI project template automates the setup and implementation of MLOps for your projects. A SageMaker AI project template is an Service Catalog product that SageMaker AI makes available to Amazon SageMaker Studio (or Studio Classic) users. These Service Catalog products are visible in your Service Catalog console after you enable permissions when you onboard or update Amazon SageMaker Studio (or Studio Classic). For information about enabling permissions to use SageMaker AI project templates, see Granting SageMaker Studio Permissions Required to Use Projects. Use SageMaker AI project templates to create a project that is an end-to-end MLOps solution.

You can use a SageMaker Projects template to implement image-building CI/CD. With this template, you can automate the CI/CD of images that are built and pushed to Amazon ECR. Changes in the container files in your project's source control repositories initiate the ML pipeline and deploy the latest version for your container. For more information, see the blog Create Amazon SageMaker Projects with image building CI/CD pipelines.

If you are an administrator, you can create custom project templates from scratch or modify one of the project templates provided by SageMaker AI. Studio (or Studio Classic) users in your organization can use these custom project templates to create their projects.

Topics

- Use SageMaker AI-Provided Project Templates
- Create Custom Project Templates

Use SageMaker AI-Provided Project Templates

Important

As of October 28, 2024, the Amazon CodeCommit templates have been removed. For new projects, select from the available project templates that use third-party Git repositories.

Amazon SageMaker AI provides project templates that create the infrastructure you need to create an MLOps solution for continuous integration and continuous deployment (CI/CD) of ML models. Use these templates to process data, extract features, train and test models, register the models in the SageMaker Model Registry, and deploy the models for inference. You can customize the seed code and the configuration files to suit your requirements.

Note

Additional roles are required to use project templates. For a complete list of required roles and instructions on how to create them, see Granting SageMaker Studio Permissions Required to Use Projects. If you do not have the new roles, you will get the error message **CodePipeline is not authorized to perform AssumeRole on role arn:aws:iam::xxx:role/service-role/AmazonSageMakerServiceCatalogProductsCodePipelineRole** when you try to create a new project and cannot proceed.

SageMaker AI project templates offer you the following choice of code repositories, workflow automation tools, and pipeline stages:

- **Code repository**: Third-party Git repositories such as GitHub and Bitbucket
- **CI/CD workflow automation**: Amazon CodePipeline or Jenkins
- **Pipeline stages**: Model building and training, model deployment, or both

The following discussion provides an overview of each template you can choose when you create your SageMaker AI project. You can also view the available templates in Studio (or Studio Classic) by following Create the Project of the Project walkthrough.

For step-by-step instructions on how to create a real project, you can follow one of the project walkthroughs:

- If you want to use the template MLOps templates for model building, training, and deployment with third-party Git using CodePipeline, see Walk Through a SageMaker AI MLOps Project Using Third-party Git Repos.
- If you want to use the template MLOps templates for model building, training, and deployment with third-party Git repositories using Jenkins, see Create Amazon SageMaker Projects using third-party source control and Jenkins.

MLOps templates for model building, training, and deployment with third-party Git using CodePipeline

- **Code repository**: Third-party Git.

> **Note**
>
> Establish the AWS CodeStar connection from your Amazon account to your GitHub user or organization. Add a tag with the key `sagemaker` and value `true` to this AWS CodeStar connection.

- **CI/CD workflow automation**: Amazon CodePipeline

Model building and training

This template provides the following resources:

- Associations with one customer-specified Git repositories. Repository contains sample code that creates an Amazon SageMaker AI pipeline in Python code and shows how to create and update the SageMaker AI pipeline. This repository also has a sample Python notebook that you can open and run in Studio (or Studio Classic).
- An Amazon CodePipeline pipeline that has source and build steps. The source step points to the third-party Git repository. The build step gets the code from that repository, creates and updates the SageMaker AI pipeline, starts a pipeline execution, and waits for the pipeline execution to complete.
- An Amazon CodeBuild project to populate the Git repositories with the seed code information. This requires an AWS CodeStar connection from your Amazon Web Services account to your account on the Git repository host.
- An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker AI pipeline runs.

Model deployment

This template provides the following resources:

- Associations with one customer-specified Git repositories. Repository contains sample code that deploys models to endpoints in staging and production environments.
- An Amazon CodePipeline pipeline that has source, build, deploy-to-staging, and deploy-to-production steps. The source step points to the third-party Git repository and the build step gets the code from that repository and generates Amazon CloudFormation stacks to deploy. The deploy-to-staging and deploy-to-production steps deploy the Amazon CloudFormation stacks to their respective environments. There is a manual approval step between the staging and production build steps, so that a MLOps engineer must approve the model before it is deployed to production.
- An Amazon CodeBuild project to populate the Git repositories with the seed code information. This requires an AWS CodeStar connection from your Amazon Web Services account to your account on the Git repository host.
- An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker AI pipeline runs.

Model building, training, and deployment

This template provides the following resources:

- Associations with one or more customer-specified Git repositories.
- An Amazon CodePipeline pipeline that has source, build, deploy-to-staging, and deploy-to-production steps. The source step points to the third-party Git repository and the build step gets the code from that repository and generates CloudFormation stacks to deploy. The deploy-to-staging and deploy-to-production steps deploy the CloudFormation stacks to their respective environments. There is a manual approval step between the staging and production build steps, so that a MLOps engineer must approve the model before it is deployed to production.
- An Amazon CodeBuild project to populate the Git repositories with the seed code information. This requires an AWS CodeStar connection from your Amazon account to your account on the Git repository host.
- An Amazon S3 bucket to store artifacts, including CodePipeline and CodeBuild artifacts, and any artifacts generated from the SageMaker AI pipeline runs.

As previously mentioned, see Project Walkthrough Using Third-party Git Repos for a demonstration that uses this template to create a real project.

MLOps template for model building, training, deployment, and Amazon SageMaker Model Monitor using CodePipeline

- **Code repository**: Third-party Git.

> **Note**
>
> Establish the AWS CodeStar connection from your Amazon account to your GitHub user or organization. Add a tag with the key `sagemaker` and value `true` to this AWS CodeStar connection.

- **CI/CD workflow automation**: Amazon CodePipeline

The following templates include an additional Amazon SageMaker Model Monitor template that provides the following types of monitoring:

- Data Quality – Monitor drift in data quality.
- Model Quality – Monitor drift in model quality metrics, such as accuracy.
- Bias Drift for Models in Production – Monitor bias in a model's predictions.

Model building, training, deployment, and Amazon SageMaker Model Monitor

This template is an extension of the MLOps template for model building, training, and deployment with Git repositories using CodePipeline. It includes both the model building, training, and deployment components of the template, and an additional Amazon SageMaker Model Monitor template that provides the following types of monitoring:

Monitor a deployed model

You can use this template for an MLOps solution to deploy one or more of the Amazon SageMaker AI data quality, model quality, model bias, and model explainability monitors to monitor a deployed model on a SageMaker AI inference endpoint. This template provides the following resources:

- Associations with one or more customer-specified Git repositories. Repository contains sample Python code that gets the baselines used by the monitors from the Amazon SageMaker Model

Registry, and updates the template's parameters for the staging and production environments. It also contains a Amazon CloudFormation template to create the Amazon SageMaker Model Monitors.

- An Amazon CodePipeline pipeline that has source, build, and deploy steps. The source step points to the CodePipeline repository. The build step gets the code from that repository, gets the baseline from the Model Registry, and updates template parameters for the staging and production environments. The deploy steps deploy the configured monitors into the staging and production environments. The manual approval step, within the `DeployStaging` stage, requires you to verify that the production SageMaker AI endpoint is `InService` before approving and moving to the `DeployProd` stage.
- An Amazon CodeBuild project to populate the Git repositories with the seed code information. This requires an AWS CodeStar connection from your Amazon Web Services account to your account on the Git repository host.
- The template uses the same Amazon S3 bucket created by the MLOps template for model building, training, and deployment to store the monitors' outputs.
- Two Amazon EventBridge events rules initiate the Amazon SageMaker Model Monitor Amazon CodePipeline every time the staging SageMaker AI endpoint is updated.

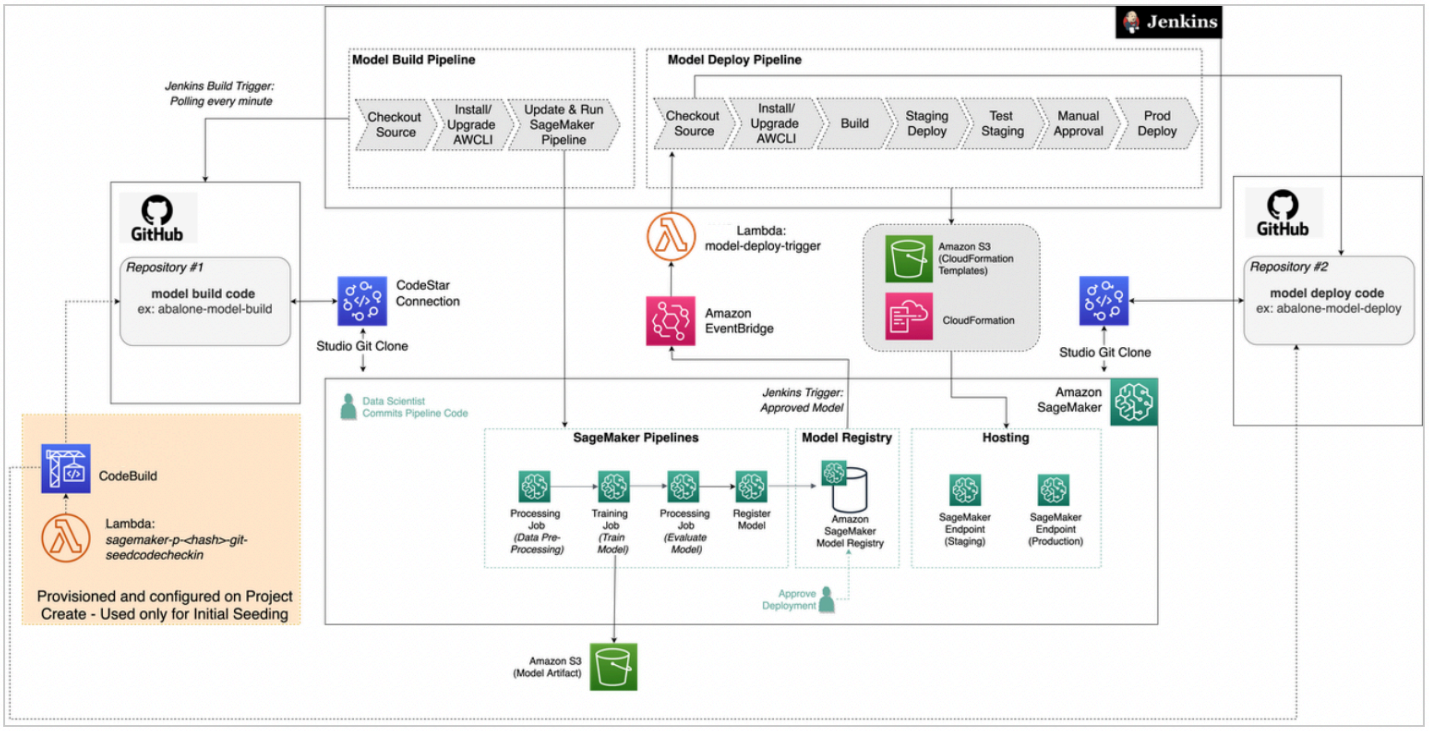
MLOps templates for model building, training, and deployment with third-party Git repositories using Jenkins

- **Code repository**: Third-party Git.

> **Note**
>
> Establish the AWS CodeStar connection from your Amazon account to your GitHub user or organization. Add a tag with the key `sagemaker` and value `true` to this AWS CodeStar connection.

- **CI/CD workflow automation**: Jenkins

Model building, training, and deployment



This template provides the following resources:

- Associations with one or more customer-specified Git repositories.

- Seed code to generate Jenkins pipelines that have source, build, deploy-to-staging, and deploy-to-production steps. The source step points to the customer-specified Git repository. The build step gets the code from that repository and generates two CloudFormation stacks. The deploy steps deploy the CloudFormation stacks to their respective environments. There is an approval step between the staging step and the production step.
- An Amazon CodeBuild project to populate the Git repositories with the seed code information. This requires an AWS CodeStar connection from your Amazon account to your account on the Git repository host.
- An Amazon S3 bucket to store artifacts of the SageMaker AI project and SageMaker AI pipeline.

The template creates the association between your project and the source control repositories, but you need to perform additional manual steps to establish communication between your Amazon account and Jenkins. For the detailed steps, see Create Amazon SageMaker Projects using third-party source control and Jenkins.

The instructions help you build the architecture shown in the following diagram, with GitHub as the source control repository in this example. As shown, you are attaching your Git repository to the project to check in and manage code versions. Jenkins initiates the model build pipeline when it detects changes to the model build code in the Git repository. You are also connecting the project to Jenkins to orchestrate your model deployment steps, which start when you approve the model registered in the model registry, or when Jenkins detects changes to the model deployment code.

In summary, the steps guide you through the following tasks:

1. Establish the connection between your Amazon and GitHub accounts.
2. Create the Jenkins account and import needed plugins.
3. Create the Jenkins IAM user and permissions policy.
4. Set the Amazon credentials for the Jenkins IAM user on your Jenkins server.
5. Create an API token for communication with your Jenkins server.
6. Use a CloudFormation template to set up an EventBridge rule to monitor the model registry for newly-approved models.
7. Create the SageMaker AI project, which seeds your GitHub repositories with model build and deploy code.
8. Create your Jenkins model build pipeline with the model build seed code.
9. Create your Jenkins model deploy pipeline with the model deploy seed code.

MLOps template for image building, model building, and model deployment

This template is an extension of the MLOps templates for model building, training, and deployment with third-party Git using CodePipeline. It includes both the model building, training, and deployment components of that template and the following options:

- Include processing image–building pipeline
- Include training image–building pipeline
- Include inference image–building pipeline

For each of the components selected during project creation, the following are created by using the template:

- An Amazon ECR repository
- A SageMaker Image
- A CodeCommit repository containing a Dockerfile that you can customize
- A CodePipeline that is initiated by changes to the CodePipeline repository
- A CodeBuild project that builds a Docker image and registers it in the Amazon ECR repository
- An EventBridge rule that initiates the CodePipeline on a schedule

When the CodePipeline is initiated, it builds a new Docker container and registers it with an Amazon ECR repository. When a new container is registered with the Amazon ECR repository, a new `ImageVersion` is added to the SageMaker image. This initiates the model building pipeline, which in turn initiates the deployment pipeline.

The newly created image is used in the model building, training, and deployment portions of the workflow where applicable.

Update SageMaker Projects to Use Third-Party Git Repositories

The managed policy attached to the `AmazonSageMakerServiceCatalogProductsUseRole` role was updated on July 27, 2021 for use with the third-party Git templates. Users who onboard to Amazon SageMaker Studio (or Studio Classic) after this date and enable project templates use the new policy. Users who onboarded prior to this date must update the policy to use these templates. Use one of the following options to update the policy:

- Delete role and toggle Studio (or Studio Classic) settings

  1. In the IAM console, delete `AmazonSageMakerServiceCatalogProductsUseRole`.
  2. In the Studio (or Studio Classic) control panel, choose **Edit Settings**.
  3. Toggle both settings and then choose **Submit**.

- In the IAM console, add the following permissions to `AmazonSageMakerServiceCatalogProductsUseRole`:

```
{
      "Effect": "Allow",
      "Action": [
          "codestar-connections:UseConnection"
      ],
      "Resource": "arn:aws:codestar-connections:*:*:connection/*",
      "Condition": {
          "StringEqualsIgnoreCase": {
              "aws:ResourceTag/sagemaker": "true"
          }
      }
  },
  {
      "Effect": "Allow",
      "Action": [
          "s3:PutObjectAcl"
      ],
      "Resource": [
          "arn:aws:s3:::sagemaker-*"
      ]
  }
```

Create Custom Project Templates

> **Important**
>
> As of October 28, 2024, the Amazon CodeCommit templates have been removed. For new projects, select from the available project templates that use third-party Git repositories. For more information, see MLOps Project Templates.

If the SageMaker AI-provided templates do not meet your needs (for example, you want to have more complex orchestration in the CodePipeline with multiple stages or custom approval steps), create your own templates.

We recommend starting by using SageMaker AI-provided templates to understand how to organize your code and resources and build on top of it. To do this, after you enable administrator access to

the SageMaker AI templates, log in to the https://console.amazonaws.cn/servicecatalog/, choose **Portfolios**, then choose **Imported**. For information about Service Catalog, see Overview of Service Catalog in the *Service Catalog User Guide*.

Create your own project templates to customize your MLOps project. SageMaker AI project templates are Service Catalog–provisioned products to provision the resources for your MLOps project.

To create a custom project template, complete the following steps.

1. Create a portfolio. For information, see Step 3: Create an Service Catalog Portfolio.
2. Create a product. A product is a CloudFormation template. You can create multiple versions of the product. For information, see Step 4: Create an Service Catalog Product.

   For the product to work with SageMaker Projects, add the following parameters to your product template.

```
SageMakerProjectName:
Type: String
Description: Name of the project

SageMakerProjectId:
Type: String
Description: Service generated Id of the project.
```

> **Important**
>
> We recommend that you wrap the CodeCommit repository into the SageMaker AI code repository for the project's repositories to be visible in VPC mode. The sample template and required addition are shown in the following code samples.
> Original (sample) template:

```
ModelBuildCodeCommitRepository:
    Type: AWS::CodeCommit::Repository
    Properties:
      # Max allowed length: 100 chars
      RepositoryName: !Sub sagemaker-${SageMakerProjectName}-
${SageMakerProjectId}-modelbuild # max: 10+33+15+10=68
      RepositoryDescription: !Sub SageMaker Model building workflow
 infrastructure as code for the Project ${SageMakerProjectName}
```

```
      Code:
        S3:
          Bucket: SEEDCODE_BUCKETNAME
          Key: toolchain/model-building-workflow-v1.0.zip
        BranchName: main
```

Additional content to add in VPC mode:

```
SageMakerRepository:
    Type: AWS::SageMaker::CodeRepository
    Properties:
        GitConfig:
            RepositoryUrl: !GetAtt
 ModelBuildCodeCommitRepository.CloneUrlHttp
            Branch: main
```

3. Add a launch constraint. A launch constraint designates an IAM role that Service Catalog assumes when a user launches a product. For information, see Step 6: Add a Launch Constraint to Assign an IAM Role.
4. Provision the product on https://console.amazonaws.cn/servicecatalog/ to test the template. If you are satisfied with your template, continue to the next step to make the template available in Studio (or Studio Classic).
5. Grant access to the Service Catalog portfolio that you created in step 1 to your Studio (or Studio Classic) execution role. Use either the domain execution role or a user role that has Studio (or Studio Classic) access. For information about adding a role to the portfolio, see Step 7: Grant End Users Access to the Portfolio.
6. To make your project template available in your **Organization templates** list in Studio (or Studio Classic), create a tag with the following key and value to the Service Catalog product you created in step 2.
   - **key**: `sagemaker:studio-visibility`
   - **value**: `true`

After you complete these steps, Studio (or Studio Classic) users in your organization can create a project with the template you created by following the steps in Create a MLOps Project using Amazon SageMaker Studio or Studio Classic and choosing **Organization templates** when you choose a template.

Using a template from an Amazon S3 bucket

You can also create SageMaker projects using templates stored in Amazon S3.

> **Note**
>
> While you can use the templates in the Amazon Service Catalog, we recommend that you store templates in an S3 bucket and create projects using those templates.

Admin setup

Before you can create projects using templates in an S3 bucket, perform the following steps.

1. Create an S3 bucket, and upload your templates to the bucket.
2. Set up a CORS policy on your S3 bucket to configure access permissions.
3. Add the following key-value tag to the template so they become visible to SageMaker AI.

   ```
   sagemaker:studio-visibility : true
   ```

4. Create a domain.
5. After SageMaker AI finishes creating your domain, add the following key-value tag to the domain:

   ```
   sagemaker:projectS3TemplatesLocation : s3://<amzn-s3-demo-bucket>
   ```

Then use the Amazon console, Python, or the CreateProject and UpdateProject API operations to create or update a SageMaker project from templates inside the S3 bucket.

Studio

Create a project

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
3. In the left navigation pane, choose **Deployments**, **Projects**, **Create project**.

4. Choose **Organization templates** and then **S3 Templates** to see the templates that are available to you. If you don't see a template that you're expecting, notify your administrator.
5. Choose the template that you want to use, and then choose **Next**.
6. Enter a name for your project, an optional description, and the other required fields. When you're done, choose **Create**.

Update a project

1. Open the Amazon SageMaker AI console at https://console.amazonaws.cn/sagemaker/.
2. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
3. Choose the project that you want to update. Choose **Actions**, then choose **Update Project**.
4. When updating a project, you can update the template parameters or the template URL. When you're done, choose **Next**.
5. Review the project updates in the summary table, and choose **Update**.

Python Boto3

After you create the S3 bucket and uploaded your templates, you can use the following example to create a SageMaker project.

```
sagemaker_client = boto3.client('sagemaker', region_name='us-west-2')

response = sagemaker_client.create_project(
    ProjectName='my-custom-project',
    ProjectDescription='SageMaker project with custom CFN template stored in S3',
    TemplateProviders=[{
        'CfnTemplateProvider': {
            'TemplateName': 'CustomProjectTemplate',
            'TemplateURL': f'https://<bucket_name>.s3.us-
west-2.amazonaws.com/custom-project-template.yml',
            'Parameters': [
                {'Key': 'ParameterKey', 'Value': 'ParameterValue'}
            ]
        }
    }]
)
```

```
print(f"Project ARN: {response['ProjectArn']}")
```

To update a SageMaker project, see the following example.

```
sagemaker_client = boto3.client('sagemaker', region_name='us-west-2')

response = sagemaker_client.update_project(
    ProjectName='my-custom-project',
    ProjectDescription='SageMaker project with custom CFN template stored in S3',
    TemplateProvidersToUpdate=[{
        'CfnTemplateProvider': {
            'TemplateName': 'CustomProjectTemplate',
            'TemplateURL': f'https://<bucket_name>.s3.us-
west-2.amazonaws.com/custom-project-template.yml',
            'Parameters': [
                {'Key': 'ParameterKey', 'Value': 'ParameterValue'}
            ]
        }
    }]
)
print(f"Project ARN: {response['ProjectArn']}")
```

View Project Resources

After you create a project, view the resources associated with the project in Amazon SageMaker Studio Classic.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Deployments**, and then choose **Projects**.
3. Select the name of the project for which you want to view details. A page with the project details appears.

On the project details page, you can view the following entities can open any of the following tabs corresponding to the entity associated with the project.

- Repositories: Code repositories (repos) associated with this project. If you use a SageMaker AI-provided template when you create your project, it creates a Amazon CodeCommit repo or a third-party Git repo. For more information about CodeCommit, see What is Amazon CodeCommit.
- Pipelines: SageMaker AI ML pipelines that define steps to prepare data, train, and deploy models. For information about SageMaker AI ML pipelines, see Pipelines actions.
- Experiments: One or more Amazon SageMaker Autopilot experiments associated with the project. For information about Autopilot, see SageMaker Autopilot.
- Model groups: Groups of model versions that were created by pipeline executions in the project. For information about model groups, see Create a Model Group.
- Endpoints: SageMaker AI endpoints that host deployed models for real-time inference. When a model version is approved, it is deployed to an endpoint.
- Tags: All the tags associated with the project. For more information about tags, see Tagging Amazon resources in the *Amazon Web Services General Reference*.
- Metadata: Metadata associated with the project. This includes the template and version used, and the template launch path.

Studio Classic

1. Sign in to Studio Classic. For more information, see Amazon SageMaker AI domain overview.
2. In the Studio Classic sidebar, choose the **Home** icon (
   
).
3. Select **Deployments** from the menu, and then select **Projects**.
4. Select the name of the project for which you want to view details.

   A tab with the project details appears.

On the project details tab, you can view the following entities associated with the project.

- Repositories: Code repositories (repos) associated with this project. If you use a SageMaker AI-provided template when you create your project, it creates a Amazon CodeCommit repo or a third-party Git repo. For more information about CodeCommit, see What is Amazon CodeCommit.

- Pipelines: SageMaker AI ML pipelines that define steps to prepare data, train, and deploy models. For information about SageMaker AI ML pipelines, see Pipelines actions.
- Experiments: One or more Amazon SageMaker Autopilot experiments associated with the project. For information about Autopilot, see SageMaker Autopilot.
- Model groups: Groups of model versions that were created by pipeline executions in the project. For information about model groups, see Create a Model Group.
- Endpoints: SageMaker AI endpoints that host deployed models for real-time inference. When a model version is approved, it is deployed to an endpoint.
- Settings: Settings for the project. This includes the name and description of the project, information about the project template and `SourceModelPackageGroupName`, and metadata about the project.

Update a MLOps Project in Amazon SageMaker Studio or Studio Classic

This procedure demonstrates how to update a MLOps project in Amazon SageMaker Studio or Studio Classic. Updating the project gives you the option to modify your end-to-end ML solution. You can update the **Description**, template version, and template parameters.

Prerequisites

- An IAM account or IAM Identity Center to sign in to Studio or Studio Classic. For information, see Amazon SageMaker AI domain overview.
- Basic familiarity with the Studio or Studio Classic user interface. For information about the Studio UI, see Amazon SageMaker Studio. For information about Studio Classic, see Amazon SageMaker Studio Classic UI Overview.
- Add the following custom inline policies to the specified roles:

  User-created role having `AmazonSageMakerFullAccess`

  JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "servicecatalog:CreateProvisionedProductPlan",
```

```
                "servicecatalog:DescribeProvisionedProductPlan",
                "servicecatalog:DeleteProvisionedProductPlan"
            ],
            "Resource": "*"
        }
    ]
}
```

`AmazonSageMakerServiceCatalogProductsLaunchRole`

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudformation:CreateChangeSet",
                "cloudformation:DeleteChangeSet",
                "cloudformation:DescribeChangeSet"
            ],
            "Resource": "arn:aws-cn:cloudformation:*:*:stack/SC-*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "codecommit:PutRepositoryTriggers"
            ],
            "Resource": "arn:aws-cn:codecommit:*:*:sagemaker-*"
        }
    ]
}
```

To update your project in Studio or Studio Classic, complete the following steps.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Deployments**, and then choose **Projects**.

3. Choose the radio button next to the project you want to update.
4. Choose the vertical ellipsis above the upper-right corner of the projects list, and choose **Update**.
5. Choose **Next**.
6. Review the project updates in the summary table, and choose **Update**. It may take a few minutes for the project to update.

Studio Classic

To update a project in Studio Classic

1. Sign in to Studio Classic. For more information, see Amazon SageMaker AI domain overview.
2. In the Studio Classic sidebar, choose the **Home** icon ().
3. Select **Deployments** from the menu, and then select **Projects**. A list of your projects appears.
4. Select the name of the project you want to update in the projects list.
5. Choose **Update** from the **Actions** menu in the upper-right corner of the project tab.
6. In the **Update project** dialog box, you can edit the **Description** and listed template parameters.
7. Choose **View difference**.

   A dialog box displays your original and updated project settings. Any change in your project settings can modify or delete resources in the current project. The dialog box displays these changes as well.
8. You may need to wait a few minutes for the **Update** button to become active. Choose **Update**.
9. The project update may take a few minutes to complete. Select **Settings** in the project tab and ensure the parameters have been updated correctly.

Delete a MLOps Project using Amazon SageMaker Studio or Studio Classic

This procedure demonstrates how to delete a MLOps project using Amazon SageMaker Studio or Studio Classic.

Prerequisites

> **Note**
>
> You can only delete projects in Studio or Studio Classic that you have created. This condition is part of the service catalog permission `servicecatalog:TerminateProvisionedProduct` in the `AmazonSageMakerFullAccess` policy. If needed, you can update this policy to remove this condition.

- An IAM account or IAM Identity Center to sign in to Studio or Studio Classic. For information, see Amazon SageMaker AI domain overview.
- Basic familiarity with the Studio or Studio Classic user interface. For information about the Studio UI, see Amazon SageMaker Studio. For information about Studio Classic, see Amazon SageMaker Studio Classic UI Overview.

Studio

1. Open the SageMaker Studio console by following the instructions in Launch Amazon SageMaker Studio.
2. In the left navigation pane, choose **Deployments**, and then choose **Projects**.
3. Choose the radio button next to the project you want to delete.
4. Choose the vertical ellipsis above the upper-right corner of the projects list, and choose **Delete**.
5. Review the information in the **Delete project** dialog box, and choose **Yes, delete the project** if you still want to delete the project.
6. Choose **Delete**.
7. Your projects list appears. Confirm that your project no longer appears in the list.

Studio Classic

1. Sign in to Studio Classic. For more information, see Amazon SageMaker AI domain overview.
2. In the Studio Classic sidebar, choose the **Home** icon ().
3. Select **Deployments** from the menu, and then select **Projects**.
4. Select the target project from the dropdown list. If you don't see your project, type the project name and apply the filter to find your project.
5. Once you've found your project, select the project name to view details.
6. Choose **Delete** from the **Actions** menu.
7. Confirm your choice by choosing **Delete** from the **Delete Project** window.

Walk Through a SageMaker AI MLOps Project Using Third-party Git Repos

> **Note**
>
> As of November 30, 2023, the previous Amazon SageMaker Studio experience is now named Amazon SageMaker Studio Classic. The following section is specific to using the Studio Classic application. For information about using the updated Studio experience, see Amazon SageMaker Studio.
> Studio Classic is still maintained for existing workloads but is no longer available for onboarding. You can only stop or delete existing Studio Classic applications and cannot create new ones. We recommend that you migrate your workload to the new Studio experience.

This walkthrough uses the template MLOps templates for model building, training, and deployment with third-party Git using CodePipeline to demonstrate how to use MLOps projects to create a CI/CD system to build, train, and deploy models.

Prerequisites

To complete this walkthrough, you need:

- An IAM or IAM Identity Center account to sign in to Studio Classic. For information, see Amazon SageMaker AI domain overview.
- Permission to use SageMaker AI-provided project templates. For information, see Granting SageMaker Studio Permissions Required to Use Projects.
- Basic familiarity with the Studio Classic user interface. For information, see Amazon SageMaker Studio Classic UI Overview.
- Two empty GitHub repositories. You input these repositories into the project template, which will seed these repos with model build and deploy code.

Topics

- Step 1: Set up the GitHub connection
- Step 2: Create the Project
- Step 3: Make a Change in the Code
- Step 4: Approve the Model
- (Optional) Step 5: Deploy the Model Version to Production
- Step 6: Clean Up Resources

Step 1: Set up the GitHub connection

In this step, you connect to your GitHub repositories using an Amazon CodeConnections connection. The SageMaker AI project uses this connection to access your source code repositories.

To set up the GitHub connection:

1. Log in to the CodePipeline console at https://console.amazonaws.cn/codepipeline/
2. Under **Settings** in the navigation pane, choose **Connections**.
3. Choose **Create connection**.
4. For **Select a provider**, select **GitHub**.
5. For **Connection name**, enter a name.
6. Choose **Connect to GitHub**.
7. If the Amazon Connector GitHub app isn't previously installed, choose **Install new app**.

   This displays a list of all the GitHub personal accounts and organizations to which you have access.

8. Choose the account where you want to establish connectivity for use with SageMaker Projects and GitHub repositories.
9. Choose **Configure**.
10. You can optionally select your specific repositories or choose **All repositories**.
11. Choose **Save**. When the app is installed, you're redirected to the **Connect to GitHub** page and the installation ID is automatically populated.
12. Choose **Connect**.
13. Add a tag with the key `sagemaker` and value `true` to this Amazon CodeConnections connection.
14. Copy the connection ARN to save for later. You use the ARN as a parameter in the project creation step.

Step 2: Create the Project

In this step, you create a SageMaker AI MLOps project by using a SageMaker AI-provided project template to build, train, and deploy models.

To create the SageMaker AI MLOps project

1. Sign in to Studio. For more information, see Amazon SageMaker AI domain overview.
2. In the Studio sidebar, choose the **Home** icon ().
3. Select **Deployments** from the menu, and then select **Projects**.
4. Choose **Create project**.

   The **Create project** tab appears.
5. For **SageMaker AI project templates**, choose **Model building, training, and deployment with third-party Git repositories using CodePipeline**.
6. Choose **Next**.
7. Under **ModelBuild CodeRepository Info**, provide the following parameters:

   - For **Branch**, enter the branch to use from your Git repository for pipeline activities.
   - For **Full Repository Name**, enter the Git repository name in the format of *`username/repository name`* or *`organization/repository name`*.

- For **Code Connection ARN**, enter the ARN of the Amazon CodeConnections connection you created in Step 1.

8. Under **ModelDeploy CodeRepository Info**, provide the following parameters:

   - For **Branch**, enter the branch to use from your Git repository for pipeline activities.
   - For **Full Repository Name**, enter the Git repository name in the format of *`username/repository name`* or *`organization/repository name`*.
   - For **Code Connection ARN**, enter the ARN of the Amazon CodeConnections connection you created in Step 1.

9. Choose **Create Project**.

The project appears in the **Projects** list with a **Status** of **Created**.

Step 3: Make a Change in the Code

Now make a change to the pipeline code that builds the model and commit the change to initiate a new pipeline run. The pipeline run registers a new model version.

To make a code change

1. In your model build GitHub repo, navigate to the `pipelines/abalone` folder. Double-click `pipeline.py` to open the code file.
2. In the `pipeline.py` file, find the line that sets the training instance type.

   ```
   training_instance_type = ParameterString(
           name="TrainingInstanceType", default_value="ml.m5.xlarge"
   ```

   Open the file for editing, change `ml.m5.xlarge` to `ml.m5.large`, then commit.

After you commit your code change, the MLOps system initiates a run of the pipeline that creates a new model version. In the next step, you approve the new model version to deploy it to production.

Step 4: Approve the Model

Now you approve the new model version that was created in the previous step to initiate a deployment of the model version to a SageMaker AI endpoint.

To approve the model version

1. In the Studio Classic sidebar, choose the **Home** icon (

).
2. Select **Deployments** from the menu, and then select **Projects**.
3. Find the name of the project you created in the first step and double-click on it to open the project tab for your project.
4. In the project tab, choose **Model groups**, then double-click the name of the model group that appears.

   The model group tab appears.
5. In the model group tab, double-click **Version 1**. The **Version 1** tab opens. Choose **Update status**.
6. In the model **Update model version status** dialog box, in the **Status** dropdown list, select **Approve** and then choose **Update status**.

   Approving the model version causes the MLOps system to deploy the model to staging. To view the endpoint, choose the **Endpoints** tab on the project tab.

(Optional) Step 5: Deploy the Model Version to Production

Now you can deploy the model version to the production environment.

> **Note**
>
> To complete this step, you need to be an administrator in your Studio Classic domain. If you are not an administrator, skip this step.

To deploy the model version to the production environment

1. Log in to the CodePipeline console at https://console.amazonaws.cn/codepipeline/
2. Choose **Pipelines**, then choose the pipeline with the name **sagemaker-*projectname*-*projectid*-modeldeploy**, where *projectname* is the name of your project, and *projectid* is the ID of your project.
3. In the **DeployStaging** stage, choose **Review**.

4. In the **Review** dialog box, choose **Approve**.

   Approving the **DeployStaging** stage causes the MLOps system to deploy the model to production. To view the endpoint, choose the **Endpoints** tab on the project tab in Studio Classic.

Step 6: Clean Up Resources

To stop incurring charges, clean up the resources that were created in this walkthrough.

> **Note**
>
> To delete the Amazon CloudFormation stack and the Amazon S3 bucket, you need to be an administrator in Studio Classic. If you are not an administrator, ask your administrator to complete those steps.

1. In the Studio Classic sidebar, choose the **Home** icon (
   
).
2. Select **Deployments** from the menu, and then select **Projects**.
3. Select the target project from the dropdown list. If you don't see your project, type the project name and apply the filter to find your project.
4. Select your project to view its details in the main panel.
5. Choose **Delete** from the **Actions** menu.
6. Confirm your choice by choosing **Delete** from the **Delete Project** window.

   This deletes the Service Catalog provisioned product that the project created. This includes the CodeCommit, CodePipeline, and CodeBuild resources created for the project.
7. Delete the Amazon CloudFormation stacks that the project created. There are two stacks, one for staging and one for production. The names of the stacks are **sagemaker-*`projectname`*-*`project-id`*-deploy-staging** and **sagemaker-*`projectname`*-*`project-id`*-deploy-prod**, where *`projectname`* is the name of your project, and *`project-id`* is the ID of your project.

   For information about how to delete a Amazon CloudFormation stack, see Deleting a stack on the Amazon CloudFormation console in the *Amazon CloudFormation User Guide*.

8. Delete the Amazon S3 bucket that the project created. The name of the bucket is **sagemaker-project-*project-id***, where *project-id* is the ID of your project.

Amazon SageMaker AI MLOps troubleshooting

Use the following to troubleshoot issues with MLOps in SageMaker AI. This topic provides information about common errors and how to resolve them.

If I try to delete a SageMaker AI project created from a SageMaker AI template and receive an error due to non-empty Amazon S3 buckets or Amazon ECR repositories, how can I delete the project?

If you try to delete your SageMaker AI project and get one of the following error messages:

```
The bucket you tried to delete is not empty
```

```
The repository with name 'repository-name' in registry
        with id 'id' cannot be deleted because it still contains images
```

then you have non-empty Amazon S3 buckets or Amazon ECR repositories which you need to manually delete before you delete the SageMaker AI project. Amazon CloudFormation does not automatically delete non-empty Amazon S3 buckets or Amazon ECR repositories for you.

Data and model quality monitoring with Amazon SageMaker Model Monitor

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

Amazon SageMaker Model Monitor monitors the quality of Amazon SageMaker AI machine learning models in production. With Model Monitor, you can set up:

- Continuous monitoring with a real-time endpoint.
- Continuous monitoring with a batch transform job that runs regularly.
- On-schedule monitoring for asynchronous batch transform jobs.

With Model Monitor, you can set alerts that notify you when there are deviations in the model quality. Early and proactive detection of these deviations lets you to take corrective actions. You can take actions like retraining models, auditing upstream systems, or fixing quality issues without having to monitor models manually or build additional tooling. You can use Model Monitor prebuilt monitoring capabilities that do not require coding. You also have the flexibility to monitor models by coding to provide custom analysis.

Model Monitor provides the following types of monitoring:

- Data quality - Monitor drift in data quality.
- Model quality - Monitor drift in model quality metrics, such as accuracy.
- Bias drift for models in production - Monitor bias in your model's predictions.
- Feature attribution drift for models in production - Monitor drift in feature attribution.

Open-source SageMaker AI monitoring solutions + Amazon QuickSight + Amazon CloudWatch

The combination of the open-source Amazon SageMaker AI monitoring solutions, Amazon QuickSight governance dashboards, and Amazon CloudWatch serves as a replacement for Amazon SageMaker Model Monitor.

The **open-source Amazon SageMaker AI monitoring solutions** (published in the `aws-samples` GitHub organization) provide a highly scalable and customizable foundation for comprehensive data and model quality monitoring. They are built on Amazon managed services (Amazon SageMaker AI, Amazon Athena, Amazon Lambda, Amazon EventBridge, Amazon SQS, Amazon

SNS, Amazon QuickSight) combined with open-source ML tooling (SageMaker AI MLflow Apps and Evidently AI). The solutions run entirely within your Amazon Web Services account and scale from low-volume batch workloads to high-throughput real-time endpoints. They cover batch inference, real-time endpoints, LLM evaluation, and GPU resource observability, and you adapt them to your own datasets, models, and drift thresholds.

Inference monitoring with Amazon QuickSight adds a governance layer above your production inference pipelines for real-time and predictive monitoring. It continuously tracks prediction and data quality metrics, handles delayed ground truth, and visualizes drift and model-performance trends in executive dashboards. This solution combines SageMaker AI MLflow Apps and Evidently AI for statistical drift analysis with an Athena Iceberg data lake, EventBridge-triggered Lambda for scheduled analysis, SNS alerting, and QuickSight dashboards.

Amazon CloudWatch provides system-level and inference-level monitoring with enhanced metrics for SageMaker endpoints, including invocation latency, model errors, CPU/GPU utilization, and custom metrics with anomaly detection alarms.

Replacing Amazon SageMaker Model Monitor with open-source solutions, QuickSight, and CloudWatch

This section guides you through replacing your existing Amazon SageMaker Model Monitor deployment using the open-source Amazon SageMaker AI monitoring solutions (SageMaker AI MLflow Apps + Evidently AI), Amazon QuickSight governance dashboards, and Amazon CloudWatch. This solution supports equivalent and expanded functionality for data quality monitoring, model quality monitoring, bias drift detection, feature attribution drift detection, and system performance monitoring for models deployed on Amazon SageMaker AI.

Removing Model Monitor

Discontinue Model Monitor for new monitoring schedules

If your workflow includes creating monitoring schedules using the `DefaultModelMonitor`, `ModelQualityMonitor`, `ModelBiasMonitor`, or `ModelExplainabilityMonitor` classes from the SageMaker Python SDK, or the `CreateMonitoringSchedule` API, transition to the alternatives described in the Configuring Replacements section below.

Delete existing monitoring schedules

Monitoring schedules spin up Processing Job instances (example: `ml.m5.xlarge`) on a recurring schedule. Deleting them helps eliminate ongoing compute costs.

Using the SageMaker Python SDK:

```
import sagemaker
from sagemaker.model_monitor import DefaultModelMonitor

session = sagemaker.Session()
# List all monitoring schedules
schedules = session.sagemaker_client.list_monitoring_schedules()
# Delete each schedule
for schedule in schedules['MonitoringScheduleSummaries']:
    schedule_name = schedule['MonitoringScheduleName']
    print(f"Deleting monitoring schedule: {schedule_name}")
    session.sagemaker_client.delete_monitoring_schedule(
        MonitoringScheduleName=schedule_name
    )
```

Using the Amazon CLI:

```
# List all monitoring schedules
aws sagemaker list-monitoring-schedules
# Delete a specific monitoring schedule
aws sagemaker delete-monitoring-schedule \
    --monitoring-schedule-name "my-data-quality-monitor"
```

> **Note**
>
> Deleting a monitoring schedule also stops the schedule if it has not already been stopped. This does not delete the job execution history of the monitoring schedule.

Configuring replacements

Choosing a monitoring solution

The open-source Amazon SageMaker AI monitoring solutions repository provides seven production-ready monitoring solutions built on SageMaker AI MLflow Apps and Evidently AI. Select the one that matches your inference pattern and operational needs. All of them are open-source, run inside your Amazon Web Services account, and are designed to be customized for your datasets, models, and drift thresholds.

Solution	Inference type	Deployment	Monitoring focus	Best for
Predictive ML Batch Monitoring Pipeline	Batch Transform	2 notebooks (experiment + SageMaker Pipeline)	Data + model quality drift	Periodic batch predictions
Predictive ML Endpoint Monitoring	Real-time endpoint (Data Capture)	Notebook + CDK Lambda	Data + model quality drift	Real-time endpoints scaled with CDK
Real-Time Inference Monitoring with Evidently AI + SNS	Real-time endpoint (Data Capture)	Workshop notebook (referral)	Data + model quality drift	Lightweight email alerting on an existing endpoint
Real-Time Inference Monitoring with QuickSight Dashboards	Real-time endpoint	Notebooks + scripts (Athena Iceberg lake)	Drift + performance + delayed ground truth	Production governance dashboards (see meta-monitoring below)
LLM Inference Monitoring	Real-time endpoint (Data Capture)	CDK (Step Functions + Lambda)	Generative AI evaluations (safety, relevance, fluency, etc.)	LLM safety and quality monitoring
SageMaker Resource Observability with Grafana	Real-time endpoint	Single notebook (Amazon Managed Grafana)	GPU/CPU/memory + cost	Multi-model cost and capacity optimization
LLM Quality Observability with Grafana	Real-time endpoint	Notebook (Managed	Safety, relevance, tone,	LLM output quality regression detection

Solution	Inference type	Deployment	Monitoring focus	Best for
		Grafana + CloudWatch)	composite quality	

Getting started with the monitoring solutions

The recommended starting points for replacing Model Monitor's data and model quality monitoring are the **Predictive ML Batch Monitoring Pipeline** (for batch/Batch Transform workloads) and the **Predictive ML Endpoint Monitoring** solution (for real-time endpoints). Both use the UCI Bank Marketing dataset out of the box, so you can run them end to end before adapting them to your own model.

Predictive ML Batch Monitoring Pipeline (two notebooks, run in sequence):

1. **Experimentation** (`predictive_ml_experimentation_data_model_monitoring_evidently.ipynb`): trains an XGBoost model with MLflow tracking, runs Batch Transform inference, then runs Evidently `DataDriftPreset`, `ClassificationPreset`, and `DataSummaryPreset`, logging all metrics and HTML/JSON reports to your MLflow App.
2. **Pipeline automation** (`batch_monitoring_pipeline.ipynb`): operationalizes the workflow into a SageMaker Pipeline with a `TransformStep` and Evidently `ProcessingSteps`, an SNS topic for alerts, and an EventBridge schedule. In Section 2, set `baseline_s3_uri`, `production_s3_uri`, `mlflow_app_name`, `mlflow_experiment_name` (match Notebook 1), `notification_email`, and `schedule_expression` (for example, `rate(1 day)`). Confirm the SNS email subscription before the first run. Drift thresholds live in `scripts/monitoring_processor.py` (default: alert when more than 30% of features drift).

Predictive ML Endpoint Monitoring (notebook, then optional CDK for scale): Open `ml_experimentation_with_data_model_monitoring_evidently_realtime.ipynb`, set `mlflow_app_name` in Section 2, and run Sections 1-8. This trains the model, deploys a real-time endpoint with Data Capture, and runs Evidently `DataDriftPreset` against the baseline and `ClassificationPreset` against ground truth.

To scale, deploy the two Docker-based Lambda functions (data drift and model quality) with CDK. From `cdk/`, run `npm install`, export the variables printed in Section 9

(ENDPOINT_NAME, BUCKET, PREFIX, BASELINE_KEY, CAPTURE_PREFIX, GROUND_TRUTH_KEY, MLFLOW_TRACKING_URI, MLFLOW_EXPERIMENT, FEATURE_COLUMNS, optional SNS_TOPIC_ARN), then run bash scripts/deploy.sh (runs cdk bootstrap automatically).

Enable S3 EventBridge notifications on the bucket and add S3 triggers: data drift on s3:ObjectCreated:* under ${PREFIX}/data-capture/, model quality under ${PREFIX}/data/ground_truth/.

```
aws s3api put-bucket-notification-configuration \
  --bucket <your-sagemaker-bucket> \
  --notification-configuration '{"EventBridgeConfiguration": {}}'
```

The model quality Lambda alerts via SNS when a metric falls below its threshold (defaults: F1 0.70, Accuracy 0.80, Receiver Operating Characteristic AUC 0.75; override with THRESHOLD_F1, THRESHOLD_ACCURACY, THRESHOLD_ROC_AUC).

The model quality Lambda alerts via SNS when a metric falls below its threshold (defaults: F1 0.70, Accuracy 0.80, Receiver Operating Characteristic AUC 0.75; override with THRESHOLD_F1, THRESHOLD_ACCURACY, THRESHOLD_ROC_AUC).

For a lightweight alternative on an existing endpoint, the **Real-Time Inference Monitoring with Evidently AI + SNS** solution adds a single FrameworkProcessor Processing step (EvidentlyMonitoring) plus an EventBridge Scheduler and SNS topic, with no data lake or dashboard. It is a referral to Section 8 of Notebook 06 in the amazon-sagemaker-from-idea-to-production workshop. Alerts fire when drifted_columns_share exceeds DriftThreshold (default 0.05) or when configured CriticalFeatures drift.

Replacing data quality monitoring

Model Monitor's data quality monitoring detects statistical drift in input features by comparing live inference data against a training data baseline. It computes statistics (mean, standard deviation, min, max, unique count) and checks constraints (data type, completeness, value ranges) using a Deequ-based engine running on scheduled Processing Jobs.

Option 1: Open-source solutions with Evidently AI

The monitoring solutions use Evidently AI's DataDriftPreset to detect feature drift, computing PSI (Population Stability Index) and KS statistics for every feature. The training baseline is read as the reference dataset and recent inference data as the current dataset. The batch and endpoint

solutions additionally run `DataSummaryPreset` to surface data quality issues (missing values, outliers, integrity checks), closely matching Model Monitor's constraint checks. Drift scores are compared against configurable thresholds, logged to a SageMaker AI MLflow App alongside training metrics, and surfaced as interactive HTML reports.

This replacement is highly scalable and fully customizable:

- **Scalable**: Compute scales to zero when idle. EventBridge-triggered Lambda runs drift analysis on a schedule, and Athena Iceberg table partitioning keeps scan costs low as data volume grows. High-volume deployments scale linearly with no reserved capacity.
- **Customizable**: You control the drift presets, per-feature thresholds, lookback windows, and schedule via a central `config.yaml`. You can add domain-specific drift tests beyond PSI (for example, business KPIs such as approval-rate shifts).
- **Unified lineage**: Drift metrics are co-located with training metrics in the same SageMaker AI MLflow App, giving complete model lineage and drift trend analysis.

Refer to the open-source Amazon SageMaker AI monitoring solutions for detailed setup steps. The QuickSight-based real-time solution is described in the Inference Meta-Monitoring section below.

Option 2: Amazon CloudWatch custom metrics + anomaly detection

For lightweight data quality monitoring without the full monitoring pipeline, publish custom metrics to CloudWatch and use anomaly detection alarms. Refer to Using CloudWatch anomaly detection for detailed steps.

Replacing model quality monitoring

Model Monitor's model quality monitoring tracks prediction accuracy by merging ground truth labels from S3 with endpoint predictions and computing metrics (accuracy, precision, recall, F1, AUC, RMSE, MAE) on a schedule.

Option 1: Open-source solutions with Evidently AI

The monitoring solutions use Evidently AI's `ClassificationPreset` to compute Receiver Operating Characteristic-AUC, precision, recall, F1, and the confusion matrix whenever ground truth is available. The solutions include a pattern for reconciling delayed ground truth with predictions by inference ID, which addresses the real-world label latency that makes model quality monitoring difficult.

Option 2: CloudWatch custom metrics

Publish model quality metrics to CloudWatch when ground truth becomes available.

Replacing bias drift monitoring

Model Monitor's bias drift monitoring detects changes in fairness metrics over time by comparing live predictions against a bias baseline across protected attributes.

Segment-sliced metrics with Evidently AI, logged to MLflow and QuickSight

Track bias by computing performance and outcome metrics per protected-attribute segment (for example, by `gender`, `age_band`, or `region`) and comparing them to the training baseline. The same Evidently `ClassificationPreset` used for model quality is run per segment, and the resulting per-segment metrics (selection rate, true/false positive rates, precision/recall) are logged to the SageMaker AI MLflow App and surfaced in the QuickSight governance dashboard.

Define your own fairness thresholds (for example, maximum acceptable gap in selection rate or true positive rate between segments) and alert via Amazon SNS when a gap crosses the threshold, using the same EventBridge + Lambda pattern as the data and model quality monitors. Because everything is open-source and runs in your account, you control which attributes are monitored and which fairness definitions apply.

Inference meta-monitoring with Amazon QuickSight (real-time and predictive monitoring)

Predictive models can silently degrade in production. Fraud handlers start seeing false-positive spikes, loan officers see applications that should have been flagged, and planners end up with excess inventory from overestimated demand. Meta-monitoring gives teams continuous feedback on production model performance and alerts them as soon as model quality or data drift appears, so they can upgrade models proactively.

This solution combines Amazon managed services (Amazon SageMaker AI, Amazon Athena, Amazon Lambda, Amazon SQS, Amazon SNS, Amazon EventBridge, Amazon QuickSight) with open-source ML tooling (SageMaker AI MLflow Apps, Evidently AI) to create a production-ready monitoring system. In the monitoring solutions repository it is the **Real-Time Inference Monitoring with QuickSight Dashboards** solution; the complete reference implementation lives at sample-mlops-bestpractices and uses a credit card fraud detection model (XGBoost) as the worked example. It implements an 11-step architecture spanning a training pipeline, inference monitoring, and a governance dashboard, with three guided notebooks driving the workflow.

Prerequisites:

- A SageMaker AI domain with an MLflow tracking server.
- A SageMaker execution role with permissions for S3, Athena, Lambda, SQS, SNS, and EventBridge (the repo includes the exact inline IAM policies and `create_or_update_sagemaker_role` / `create_lambda_role` helpers).
- An S3 bucket for data storage.
- Python 3.12+ and the `uv` package manager (for the script/CLI path); a QuickSight Enterprise subscription for the governance dashboard.

Choose a setup path:

Option A (recommended for new users): If you do not have a SageMaker domain, deploy the CloudFormation template in `cloudformation/`. It provisions the SageMaker domain, user profile, JupyterLab space, MLflow tracking server, S3 bucket, and supporting VPC, auto-clones the repo, and writes a populated `.env` on first launch.

Option B (existing domains): If you already have a SageMaker domain with an MLflow tracking server, clone the repo in JupyterLab and populate `.env` manually.

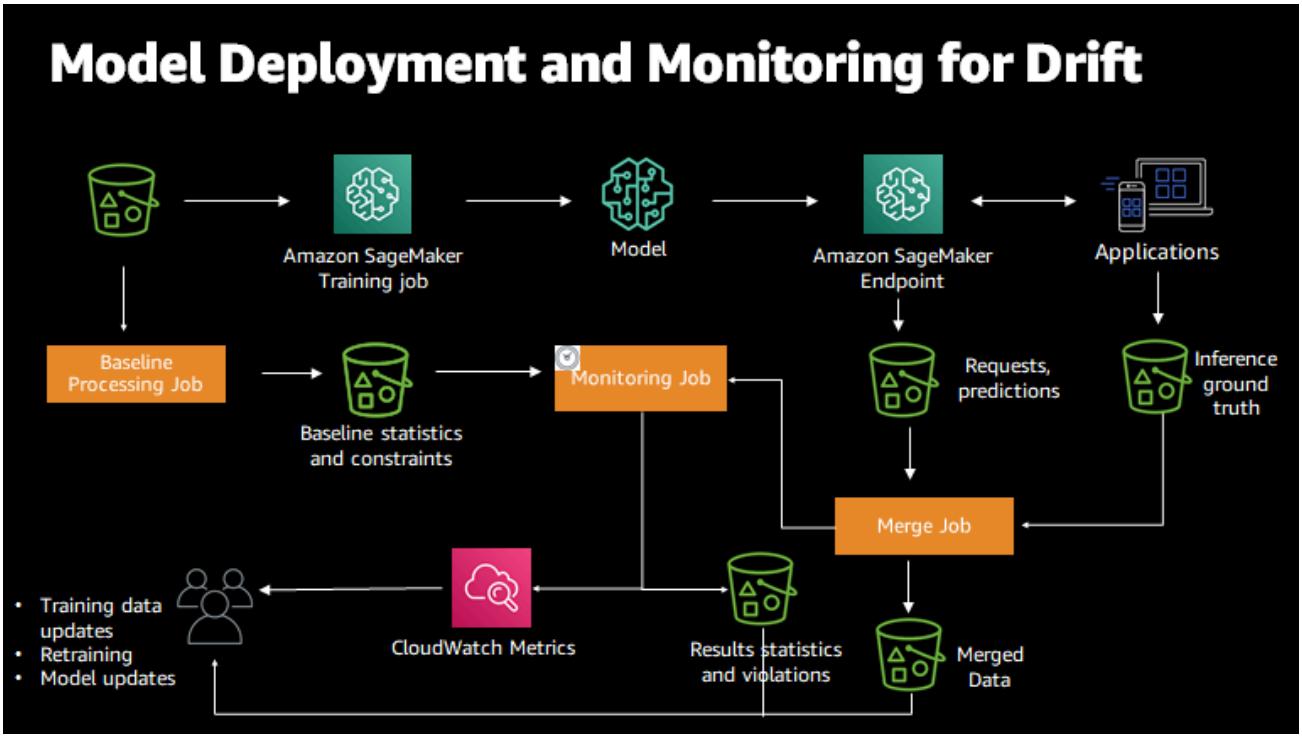
Setup

Set up training to prepare for monitoring. You can drive everything from the three notebooks in SageMaker Studio, or use the equivalent CLI commands (each notebook cell maps to a `python main.py ...` command for CI/CD). If you run the sample end to end, you do not need to edit `config.yaml`; populating `.env` and using the defaults works. If you already have a model deployed, adapt the training pipeline to your own steps and ensure the inference endpoint pushes prediction records to Amazon SQS.

Monitoring a Model in Production

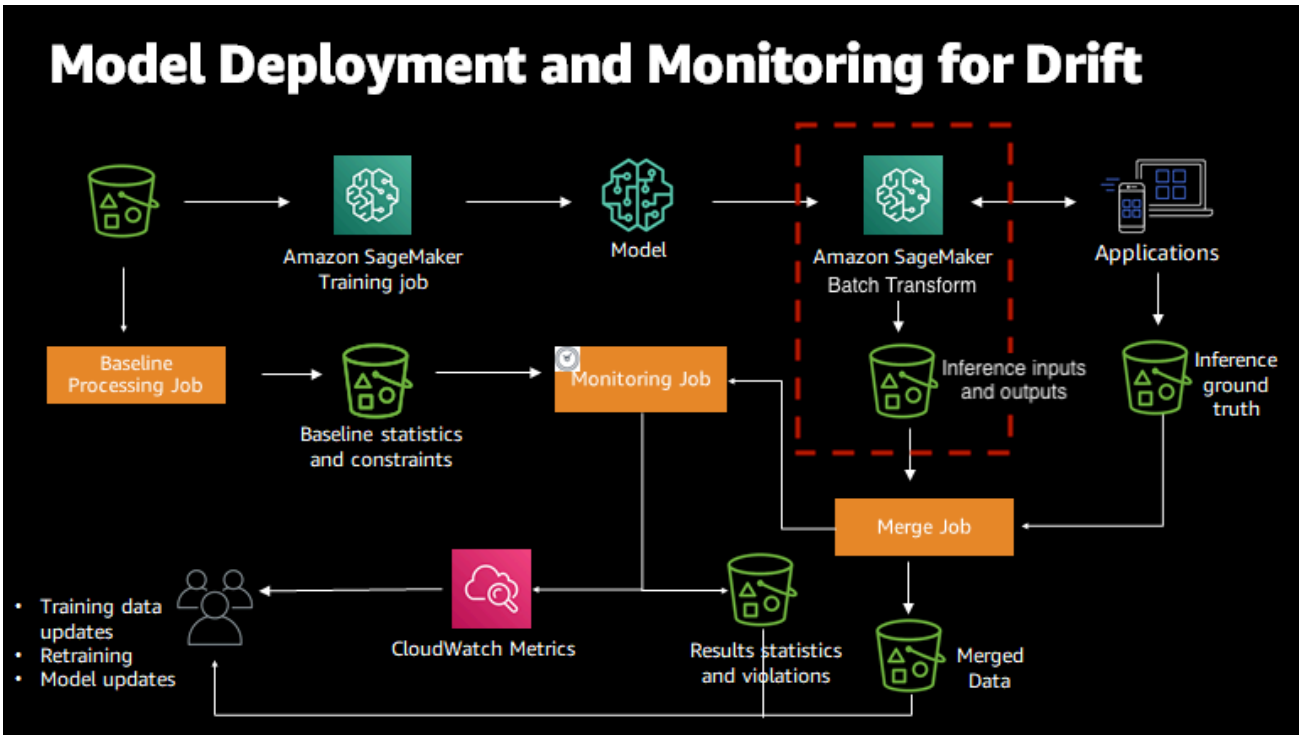
> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

After you deploy a model into your production environment, use Amazon SageMaker Model Monitor to continuously monitor the quality of your machine learning models in real time. Amazon SageMaker Model Monitor enables you to set up an automated alert triggering system when there are deviations in the model quality, such as data drift and anomalies. Amazon CloudWatch Logs collects log files of monitoring the model status and notifies when the quality of your model hits certain thresholds that you preset. CloudWatch stores the log files to an Amazon S3 bucket you specify. Early and pro-active detection of model deviations through Amazon model monitor products enables you to take prompt actions to maintain and improve the quality of your deployed model.



For more information about SageMaker Model Monitoring products, see Data and model quality monitoring with Amazon SageMaker Model Monitor.

To start your machine learning journey with SageMaker AI, sign up for an Amazon account at Set Up SageMaker AI.



How Amazon SageMaker Model Monitor works

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

Amazon SageMaker Model Monitor automatically monitors machine learning (ML) models in production and notifies you when quality issues happen. Model Monitor uses rules to detect drift in your models and alerts you when it happens. The following figure shows how this process works in the case that your model is deployed to a real-time endpoint.

You can also use Model Monitor to monitor a batch transform job instead of a real-time endpoint. In this case, instead of receiving requests to an endpoint and tracking the predictions, Model Monitor monitors inference inputs and outputs. The following figure diagrams the process of monitoring a batch transform job.

To enable model monitoring, take the following steps. These steps follow the path of the data through the various data collection, monitoring, and analysis processes.

- For a real-time endpoint, enable the endpoint to capture data from incoming requests to a trained ML model and the resulting model predictions.
- For a batch transform job, enable data capture of the batch transform inputs and outputs.
- Create a baseline from the dataset that was used to train the model. The baseline computes metrics and suggests constraints for the metrics. Real-time or batch predictions from your model are compared to the constraints. They are reported as violations if they are outside the constrained values.
- Create a monitoring schedule specifying what data to collect, how often to collect it, how to analyze it, and which reports to produce.
- Inspect the reports, which compare the latest data with the baseline. Watch for any violations reported, metrics, and notifications from Amazon CloudWatch.

Notes

- Model Monitor computes model metrics and statistics on tabular data only. For example, an image classification model that takes images as input and outputs a label based on that image can still be monitored. Model Monitor would be able to calculate metrics and statistics for the output, not the input.
- Model Monitor currently supports only endpoints that host a single model and does not support monitoring multi-model endpoints. For information on using multi-model endpoints, see Multi-model endpoints.
- Model Monitor supports monitoring inference pipelines. However, capturing and analyzing data is done for the entire pipeline, not for individual containers in the pipeline.
- To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. We recommended that you keep your disk utilization below 75% to ensure data capture continues capturing requests.
- If you launch SageMaker Studio in a custom Amazon VPC, you must create VPC endpoints to let Model Monitor communicate with Amazon S3 and CloudWatch. For information about VPC endpoints, see VPC endpoints in the *Amazon Virtual Private Cloud*

User Guide. For information about launching SageMaker Studio in a custom VPC, see Connect Studio notebooks in a VPC to external resources.

Model Monitor sample notebooks

For a sample notebook that takes you through the end-to-end workflow using Model Monitor with your real-time endpoint, see Introduction to Amazon SageMaker Model Monitor.

For a sample notebook that visualizes the statistics.json file for a selected execution in a monitoring schedule, see the Model Monitor Visualization.

For instructions about how to create and access Jupyter notebook instances that you can use to run the example in SageMaker AI, see Amazon SageMaker notebook instances. After you have created a notebook instance and opened it, choose the **SageMaker AI Examples** tab to see a list of all the SageMaker AI samples. To open a notebook, choose the notebook's **Use** tab and choose **Create copy**.

Data capture

Note

Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

To log the inputs to your endpoint and the inference outputs from your deployed model to Amazon S3, you can enable a feature called *Data Capture*. *Data Capture* is commonly used to record information that can be used for training, debugging, and monitoring. Amazon SageMaker Model Monitor automatically parses this captured data and compares metrics from this data with a baseline that you create for the model. For more information about Model Monitor see Data and model quality monitoring with Amazon SageMaker Model Monitor.

You can implement *Data Capture* for both real-time and batch model-monitor modes using the Amazon SDK for Python (Boto) or the SageMaker Python SDK. For a real-time endpoint, you will

specify your *Data Capture* configuration when you create your endpoint. Due to the persistent nature of your real-time endpoint, you can configure additional options to turn data capturing on or off at certain times, or change the sampling frequency. You can also choose to encrypt your inference data.

For a batch transform job, you can enable *Data Capture* if you want to run on-schedule model monitoring or continuous model-monitoring for regular, periodic batch transform jobs. You will specify your *Data Capture* configuration when you create your batch transform job. Within this configuration, you have the option to turn on encryption or generate the inference ID with your output, which helps you match your captured data to Ground Truth data.

Capture data from real-time endpoint

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

> **Note**
>
> To prevent impact to inference requests, Data Capture stops capturing requests at high levels of disk usage. It is recommended you keep your disk utilization below 75% in order to ensure data capture continues capturing requests.

To capture data for your real-time endpoint, you must deploy a model using SageMaker AI hosting services. This requires that you create a SageMaker AI model, define an endpoint configuration, and create an HTTPS endpoint.

The steps required to turn on data capture are similar whether you use the Amazon SDK for Python (Boto) or the SageMaker Python SDK. If you use the Amazon SDK, define the DataCaptureConfig dictionary, along with required fields, within the CreateEndpointConfig method to turn on data capture. If you use the SageMaker Python SDK, import the DataCaptureConfig Class and initialize an instance from this class. Then, pass this object to the `DataCaptureConfig` parameter in the `sagemaker.model.Model.deploy()` method.

To use the proceeding code snippets, replace the *italicized placeholder text* in the example code with your own information.

How to enable data capture

Specify a data capture configuration. You can capture the request payload, the response payload, or both with this configuration. The proceeding code snippet demonstrates how to enable data capture using the Amazon SDK for Python (Boto) and the SageMaker AI Python SDK.

> **Note**
>
> You do not need to use Model Monitor to capture request or response payloads.

Amazon SDK for Python (Boto)

Configure the data you want to capture with the DataCaptureConfig dictionary when you create an endpoint using the `CreateEndpointConfig` method. Set `EnableCapture` to the boolean value True. In addition, provide the following mandatory parameters:

- `EndpointConfigName`: the name of your endpoint configuration. You will use this name when you make a `CreateEndpoint` request.
- `ProductionVariants`: a list of models you want to host at this endpoint. Define a dictionary data type for each model.
- `DataCaptureConfig`: dictionary data type where you specify an integer value that corresponds to the initial percentage of data to sample (`InitialSamplingPercentage`), the Amazon S3 URI where you want captured data to be stored, and a capture options (`CaptureOptions`) list. Specify either `Input` or `Output` for `CaptureMode` within the `CaptureOptions` list.

You can optionally specify how SageMaker AI should encode captured data by passing key-value pair arguments to the `CaptureContentTypeHeader` dictionary.

```
# Create an endpoint config name.
endpoint_config_name = '<endpoint-config-name>'

# The name of the production variant.
variant_name = '<name-of-production-variant>'
```

```
# The name of the model that you want to host.
# This is the name that you specified when creating the model.
model_name = '<The_name_of_your_model>'

instance_type = '<instance-type>'
#instance_type='ml.m5.xlarge' # Example

# Number of instances to launch initially.
initial_instance_count = <integer>

# Sampling percentage. Choose an integer value between 0 and 100
initial_sampling_percentage = <integer>

# The S3 URI containing the captured data
s3_capture_upload_path = 's3://<bucket-name>/<data_capture_s3_key>'

# Specify either Input, Output, or both
capture_modes = [ "Input",  "Output" ]
#capture_mode = [ "Input"] # Example - If you want to capture input only

endpoint_config_response = sagemaker_client.create_endpoint_config(
    EndpointConfigName=endpoint_config_name,
    # List of ProductionVariant objects, one for each model that you want to host at
 this endpoint.
    ProductionVariants=[
        {
            "VariantName": variant_name,
            "ModelName": model_name,
            "InstanceType": instance_type, # Specify the compute instance type.
            "InitialInstanceCount": initial_instance_count # Number of instances to
 launch initially.
        }
    ],
    DataCaptureConfig= {
        'EnableCapture': True, # Whether data should be captured or not.
        'InitialSamplingPercentage' : initial_sampling_percentage,
        'DestinationS3Uri': s3_capture_upload_path,
        'CaptureOptions': [{"CaptureMode" : capture_mode} for capture_mode in
 capture_modes] # Example - Use list comprehension to capture both Input and Output
    }
)
```

For more information about other endpoint configuration options, see the CreateEndpointConfig API in the Amazon SageMaker AI Service API Reference Guide.

SageMaker Python SDK

Import the `DataCaptureConfig` Class from sagemaker.model_monitor module. Enable data capture by setting `EnableCapture` to the boolean value `True`.

Optionally provide arguments for the following parameters:

- `SamplingPercentage`: an integer value that corresponds to percentage of data to sample. If you do not provide a sampling percentage, SageMaker AI will sample a default of 20 (20%) of your data.
- `DestinationS3Uri`: the Amazon S3 URI SageMaker AI will use to store captured data. If you do not provide one, SageMaker AI will store captured data in "`s3://<default-session-bucket>/ model-monitor/data-capture`".

```
from sagemaker.model_monitor import DataCaptureConfig

# Set to True to enable data capture
enable_capture = True

# Optional - Sampling percentage. Choose an integer value between 0 and 100
sampling_percentage = <int>
# sampling_percentage = 30 # Example 30%

# Optional - The S3 URI of stored captured-data location
s3_capture_upload_path = 's3://<bucket-name>/<data_capture_s3_key>'

# Specify either Input, Output or both.
capture_modes = ['REQUEST','RESPONSE'] # In this example, we specify both
# capture_mode = ['REQUEST'] # Example - If you want to only capture input.

# Configuration object passed in when deploying Models to SM endpoints
data_capture_config = DataCaptureConfig(
    enable_capture = enable_capture,
    sampling_percentage = sampling_percentage, # Optional
    destination_s3_uri = s3_capture_upload_path, # Optional
    capture_options = ["REQUEST", "RESPONSE"],
```

```
)
```

Deploy your model

Deploy your model and create an HTTPS endpoint with `DataCapture` enabled.

Amazon SDK for Python (Boto3)

Provide the endpoint configuration to SageMaker AI. The service launches the ML compute instances and deploys the model or models as specified in the configuration.

Once you have your model and endpoint configuration, use the `CreateEndpoint` API to create your endpoint. The endpoint name must be unique within an Amazon Region in your Amazon account.

The following creates an endpoint using the endpoint configuration specified in the request. Amazon SageMaker AI uses the endpoint to provision resources and deploy models.

```
# The name of the endpoint. The name must be unique within an AWS Region in your AWS
 account.
endpoint_name = '<endpoint-name>'

# The name of the endpoint configuration associated with this endpoint.
endpoint_config_name='<endpoint-config-name>'

create_endpoint_response = sagemaker_client.create_endpoint(
                                            EndpointName=endpoint_name,

 EndpointConfigName=endpoint_config_name)
```

For more information, see the `CreateEndpoint` API.

SageMaker Python SDK

Define a name for your endpoint. This step is optional. If you do not provide one, SageMaker AI will create a unique name for you:

```
from datetime import datetime

endpoint_name = f"DEMO-{datetime.utcnow():%Y-%m-%d-%H%M}"
```

```
print("EndpointName =", endpoint_name)
```

Deploy your model to a real-time, HTTPS endpoint with the Model object's built-in `deploy()` method. Provide the name of the Amazon EC2 instance type to deploy this model to in the `instance_type` field along with the initial number of instances to run the endpoint on for the `initial_instance_count` field:

```
initial_instance_count=<integer>
# initial_instance_count=1 # Example

instance_type='<instance-type>'
# instance_type='ml.m4.xlarge' # Example

# Uncomment if you did not define this variable in the previous step
#data_capture_config = <name-of-data-capture-configuration>

model.deploy(
    initial_instance_count=initial_instance_count,
    instance_type=instance_type,
    endpoint_name=endpoint_name,
    data_capture_config=data_capture_config
)
```

View Captured Data

Create an `Endpoint` object from the SageMaker Python SDK. You will use the `Endpoint` object to invoke your endpoint in a future step. Provide the name of your endpoint (defined earlier as `endpoint_name`).

```
from sagemaker.core.resources import Endpoint

endpoint = Endpoint(endpoint_name=endpoint_name)

# Example
#from sagemaker.core.resources import Endpoint
#endpoint = Endpoint(endpoint_name=endpoint_name)
```

In the proceeding code example scenario we invoke the endpoint with sample validation data that we have stored locally in a CSV file named `validation_with_predictions`. Our sample validation set contains labels for each input.

The first few lines of the with statement first opens the validation set CSV file, then splits each row within the file by the comma character ",", and then stores the two returned objects into a label and input_cols variables. For each row, the input (`input_cols`) is passed to the endpoint variable's (`endpoint`) built-in method `invoke()`.

Suppose the model returns a probability. Probabilities range between integer values of 0 and 1.0. If the probability returned by the model is greater than 80% (0.8) we assign the prediction an integer value label of 1. Otherwise, we assign the prediction an integer value label of 0.

```
from time import sleep

validate_dataset = "validation_with_predictions.csv"

# Cut off threshold of 80%
cutoff = 0.8

limit = 200  # Need at least 200 samples to compute standard deviations
i = 0
with open(f"test_data/{validate_dataset}", "w") as validation_file:
    validation_file.write("probability,prediction,label\n")  # CSV header
    with open("test_data/validation.csv", "r") as f:
        for row in f:
            (label, input_cols) = row.split(",", 1)
            probability = float(endpoint.invoke(input_cols))
            prediction = "1" if probability > cutoff else "0"
            baseline_file.write(f"{probability},{prediction},{label}\n")
            i += 1
            if i > limit:
                break
            print(".", end="", flush=True)
            sleep(0.5)
print()
print("Done!")
```

Because you enabled the data capture in the previous steps, the request and response payload, along with some additional meta data, is saved in the Amazon S3 location that you specified in `DataCaptureConfig`. The delivery of capture data to Amazon S3 can require a couple of minutes.

View captured data by listing the data capture files stored in Amazon S3. The format of the Amazon S3 path is: `s3:///`*`{endpoint-name}/{variant-name}/yyyy/mm/dd/hh/filename`*`.jsonl`.

Expect to see different files from different time periods, organized based on the hour when the invocation occurred. Run the following to print out the contents of a single capture file:

```
print("\n".join(capture_file[-3:-1]))
```

This will return a SageMaker AI specific JSON-line formatted file. The following is a response sample taken from a real-time endpoint that we invoked using `csv/text` data:

```
{"captureData":{"endpointInput":{"observedContentType":"text/csv","mode":"INPUT",
"data":"69,0,153.7,109,194.0,105,256.1,114,14.1,6,1,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0
"encoding":"CSV"},"endpointOutput":{"observedContentType":"text/csv;
 charset=utf-8","mode":"OUTPUT","data":"0.0254181120544672","encoding":"CSV"}},
"eventMetadata":{"eventId":"aaaaaaaa-bbbb-cccc-dddd-
eeeeeeeeeeee","inferenceTime":"2022-02-14T17:25:49Z"},"eventVersion":"0"}
{"captureData":{"endpointInput":{"observedContentType":"text/csv","mode":"INPUT",
"data":"94,23,197.1,125,214.5,136,282.2,103,9.5,5,4,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0
"encoding":"CSV"},"endpointOutput":{"observedContentType":"text/csv;
 charset=utf-8","mode":"OUTPUT","data":"0.07675473392009735","encoding":"CSV"}},
"eventMetadata":{"eventId":"aaaaaaaa-bbbb-cccc-dddd-
eeeeeeeeeeee","inferenceTime":"2022-02-14T17:25:49Z"},"eventVersion":"0"}
```

In the proceeding example, the `capture_file` object is a list type. Index the first element of the list to view a single inference request.

```
# The capture_file object is a list. Index the first element to view a single inference
 request
print(json.dumps(json.loads(capture_file[0]), indent=2))
```

This will return a response similar to the following. The values returned will differ based on your endpoint configuration, SageMaker AI model, and captured data:

```
{
  "captureData": {
    "endpointInput": {
      "observedContentType": "text/csv", # data MIME type
      "mode": "INPUT",
      "data":
 "50,0,188.9,94,203.9,104,151.8,124,11.6,8,3,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,
      "encoding": "CSV"
    },
    "endpointOutput": {
```

```
      "observedContentType": "text/csv; charset=character-encoding",
      "mode": "OUTPUT",
      "data": "0.023190177977085114",
      "encoding": "CSV"
    }
  },
  "eventMetadata": {
    "eventId": "aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee",
    "inferenceTime": "2022-02-14T17:25:06Z"
  },
  "eventVersion": "0"
}
```

Capture data from batch transform job

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

The steps required to turn on data capture for your batch transform job are similar whether you use the Amazon SDK for Python (Boto) or the SageMaker Python SDK. If you use the Amazon SDK, define the DataCaptureConfig dictionary, along with required fields, within the `CreateTransformJob` method to turn on data capture. If you use the SageMaker AI Python SDK, import the `BatchDataCaptureConfig` class and initialize an instance from this class. Then, pass this object to the `batch_data_capture_config` parameter of your transform job instance.

To use the following code snippets, replace the *`italicized placeholder text`* in the example code with your own information.

How to enable data capture

Specify a data capture configuration when you launch a transform job. Whether you use the Amazon SDK for Python (Boto3) or the SageMaker Python SDK, you must provide the `DestinationS3Uri` argument, which is the directory where you want the transform job to log the captured data. Optionally, you can also set the following parameters:

- `KmsKeyId`: The Amazon KMS key used to encrypt the captured data.
- `GenerateInferenceId`: A Boolean flag that, when capturing the data, indicates if you want the transform job to append the inference ID and time to your output. This is useful for model quality monitoring, where you need to ingest the Ground Truth data. The inference ID and time help to match the captured data with your Ground Truth data.

Amazon SDK for Python (Boto3)

Configure the data you want to capture with the DataCaptureConfig dictionary when you create a transform job using the `CreateTransformJob` method.

```
input_data_s3_uri = "s3://input_S3_uri"
output_data_s3_uri = "s3://output_S3_uri"
data_capture_destination = "s3://captured_data_S3_uri"

model_name = "model_name"

sm_client.create_transform_job(
    TransformJobName="transform_job_name",
    MaxConcurrentTransforms=2,
    ModelName=model_name,
    TransformInput={
        "DataSource": {
            "S3DataSource": {
                "S3DataType": "S3Prefix",
                "S3Uri": input_data_s3_uri,
            }
        },
        "ContentType": "text/csv",
        "CompressionType": "None",
        "SplitType": "Line",
    },
    TransformOutput={
        "S3OutputPath": output_data_s3_uri,
        "Accept": "text/csv",
        "AssembleWith": "Line",
    },
    TransformResources={
        "InstanceType": "ml.m4.xlarge",
        "InstanceCount": 1,
    },
    DataCaptureConfig={
```

```
        "DestinationS3Uri": data_capture_destination,
        "KmsKeyId": "kms_key",
        "GenerateInferenceId": True,
    }
    )
```

SageMaker Python SDK

Import the `BatchDataCaptureConfig` class from the sagemaker.model_monitor.

```
from sagemaker.core.transformer import Transformer
from sagemaker.core.inputs import BatchDataCaptureConfig

# Optional - The S3 URI of where to store captured data in S3
data_capture_destination = "s3://captured_data_S3_uri"

model_name = "model_name"

transformer = Transformer(model_name=model_name, ...)
transform_arg = transformer.transform(
    batch_data_capture_config=BatchDataCaptureConfig(
        destination_s3_uri=data_capture_destination,
        kms_key_id="kms_key",
        generate_inference_id=True,
    ),
    ...
)
```

How to view data captured

Once the transform job completes, the captured data gets logged under the `DestinationS3Uri` you provided with the data capture configuration. There are two subdirectories under `DestinationS3Uri`, `/input` and `/output`. If `DestinationS3Uri` is `s3://my-data-capture`, then the transform job creates the the following directories:

- `s3://my-data-capture/input`: The captured input data for the transform job.
- `s3://my-data-capture/output`: The captured output data for the transform job.

To avoid data duplication, the captured data under the preceding two directories are manifests. Each manifest is a JSONL file that contains the Amazon S3 locations of the source objects. A manifest file may look like the following example:

```
# under "/input" directory
[
    {"prefix":"s3://input_S3_uri/"},
    "dummy_0.csv",
    "dummy_1.csv",
    "dummy_2.csv",
    ...
]

# under "/output" directory
[
    {"prefix":"s3://output_S3_uri/"},
    "dummy_0.csv.out",
    "dummy_1.csv.out",
    "dummy_2.csv.out",
    ...
]
```

The transform job organizes and labels these manifests with a *yyyy/mm/dd/hh* S3 prefix to indicate when they were captured. This helps the model monitor determine the appropriate portion of data to analyze. For example, if you start your transform job at 2022-8-26 13PM UTC, then the captured data is labeled with a `2022/08/26/13/` prefix string.

InferenceId Generation

When you configure `DataCaptureConfig` for a transform job, you can turn on the Boolean flag `GenerateInferenceId`. This is particularly useful when you need to run model quality and model bias monitoring jobs, for which you need user-ingested Ground Truth data. Model monitor relies on an inference ID to match the captured data and the Ground Truth data. For addition details about Ground Truth ingestion, see Ingest Ground Truth labels and merge them with predictions. When `GenerateInferenceId` is on, the transform output appends an inference ID (a random UUID) as well as the transform job start time in UTC for each record. You need these two values to run model quality and model bias monitoring. When you construct the Ground Truth data, you need to provide the same inference ID to match the output data. Currently, this feature supports transform outputs in CSV, JSON, and JSONL formats.

If your transform output is in CSV format, the output file looks like the following example:

```
0, 1f1d57b1-2e6f-488c-8c30-db4e6d757861,2022-08-30T00:49:15Z
1, 22445434-0c67-45e9-bb4d-bd1bf26561e6,2022-08-30T00:49:15Z
...
```

The last two columns are inference ID and the transform job start time. Do not modify them. The remaining columns are your transform job outputs.

If your transform output is in JSON or JSONL format, the output file looks like the following example:

```
{"output": 0, "SageMakerInferenceId": "1f1d57b1-2e6f-488c-8c30-db4e6d757861",
 "SageMakerInferenceTime": "2022-08-30T00:49:15Z"}
{"output": 1, "SageMakerInferenceId": "22445434-0c67-45e9-bb4d-bd1bf26561e6",
 "SageMakerInferenceTime": "2022-08-30T00:49:15Z"}
...
```

There are two appended fields that are reserved, `SageMakerInferenceId` and `SageMakerInferenceTime`. Do not modify these fields if you need to run model quality or model bias monitoring — you need them for merge jobs.

Data quality

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

Data quality monitoring automatically monitors machine learning (ML) models in production and notifies you when data quality issues arise. ML models in production have to make predictions on real-life data that is not carefully curated like most training datasets. If the statistical nature of the data that your model receives while in production drifts away from the nature of the baseline data it was trained on, the model begins to lose accuracy in its predictions. Amazon SageMaker Model Monitor uses rules to detect data drift and alerts you when it happens. To monitor data quality, follow these steps:

- Enable data capture. This captures inference input and output from a real-time inference endpoint or batch transform job and stores the data in Amazon S3. For more information, see Data capture.
- Create a baseline. In this step, you run a baseline job that analyzes an input dataset that you provide. The baseline computes baseline schema constraints and statistics for each feature using Deequ, an open source library built on Apache Spark, which is used to measure data quality in large datasets. For more information, see Create a Baseline.
- Define and schedule data quality monitoring jobs. For specific information and code samples of data quality monitoring jobs, see Schedule data quality monitoring jobs. For general information about monitoring jobs, see Schedule monitoring jobs.
  - Optionally use preprocessing and postprocessing scripts to transform the data coming out of your data quality analysis. For more information, see Preprocessing and Postprocessing.
- View data quality metrics. For more information, see Schema for Statistics (statistics.json file).
- Integrate data quality monitoring with Amazon CloudWatch. For more information, see CloudWatch Metrics.
- Interpret the results of a monitoring job. For more information, see Interpret results.
- Use SageMaker Studio to enable data quality monitoring and visualize results if you are using a real-time endpoint. For more information, see Visualize results for real-time endpoints in Amazon SageMaker Studio.

> **Note**
>
> Model Monitor computes model metrics and statistics on tabular data only. For example, an image classification model that takes images as input and outputs a label based on that image can still be monitored. Model Monitor would be able to calculate metrics and statistics for the output, not the input.

Topics

- Create a Baseline
- Schedule data quality monitoring jobs
- Schema for Statistics (statistics.json file)
- CloudWatch Metrics
- Schema for Violations (constraint_violations.json file)

Create a Baseline

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

The baseline calculations of statistics and constraints are needed as a standard against which data drift and other data quality issues can be detected. Model Monitor provides a built-in container that provides the ability to suggest the constraints automatically for CSV and flat JSON input. This *sagemaker-model-monitor-analyzer* container also provides you with a range of model monitoring capabilities, including constraint validation against a baseline, and emitting Amazon CloudWatch metrics. This container is based on Spark version 3.3.0 and is built with Deequ version 2.0.2. All column names in your baseline dataset must be compliant with Spark. For column names, use only lowercase characters, and _ as the only special character.

The training dataset that you used to train the model is usually a good baseline dataset. The training dataset data schema and the inference dataset schema should exactly match (the number and order of the features). Note that the prediction/output columns are assumed to be the first columns in the training dataset. From the training dataset, you can ask SageMaker AI to suggest a set of baseline constraints and generate descriptive statistics to explore the data. For this example, upload the training dataset that was used to train the pretrained model included in this example. If you already stored the training dataset in Amazon S3, you can point to it directly.

To Create a baseline from a training dataset

When you have your training data ready and stored in Amazon S3, start a baseline processing job with `DefaultModelMonitor.suggest_baseline(..)` using the Amazon SageMaker Python SDK. This uses an Amazon SageMaker Model Monitor prebuilt container that generates baseline statistics and suggests baseline constraints for the dataset and writes them to the `output_s3_uri` location that you specify.

```
from sagemaker.model_monitor import DefaultModelMonitor
from sagemaker.model_monitor.dataset_format import DatasetFormat

my_default_monitor = DefaultModelMonitor(
```

```
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge',
    volume_size_in_gb=20,
    max_runtime_in_seconds=3600,
)

my_default_monitor.suggest_baseline(
    baseline_dataset=baseline_data_uri+'/training-dataset-with-header.csv',
    dataset_format=DatasetFormat.csv(header=True),
    output_s3_uri=baseline_results_uri,
    wait=True
)
```

Note

If you provide the feature/column names in the training dataset as the first row and set the `header=True` option as shown in the previous code sample, SageMaker AI uses the feature name in the constraints and statistics file.

The baseline statistics for the dataset are contained in the statistics.json file and the suggested baseline constraints are contained in the constraints.json file in the location you specify with `output_s3_uri`.

Output Files for Tabular Dataset Statistics and Constraints

File Name	Description
`statistics.json`	This file is expected to have columnar statistic s for each feature in the dataset that is analyzed. For more information about the schema for this file, see Schema for Statistics (statistics.json file).
`constraints.json`	This file is expected to have the constraints on the features observed. For more information about the schema for this file, see Schema for Constraints (constraints.json file).

The Amazon SageMaker Python SDK provides convenience functions described to generate the baseline statistics and constraints. But if you want to call processing job directly for this purpose instead, you need to set the `Environment` map as shown in the following example:

```
"Environment": {
    "dataset_format": "{\"csv\": { \"header\": true}",
    "dataset_source": "/opt/ml/processing/sm_input",
    "output_path": "/opt/ml/processing/sm_output",
    "publish_cloudwatch_metrics": "Disabled",
}
```

Schedule data quality monitoring jobs

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

After you create your baseline, you can call the `create_monitoring_schedule()` method of your `DefaultModelMonitor` class instance to schedule an hourly data quality monitor. The following sections show you how to create a data quality monitor for a model deployed to a real-time endpoint as well as for a batch transform job.

> **Important**
>
> You can specify either a batch transform input or an endpoint input, but not both, when you create your monitoring schedule.

Data quality monitoring for models deployed to real-time endpoints

To schedule a data quality monitor for a real-time endpoint, pass your `EndpointInput` instance to the `endpoint_input` argument of your `DefaultModelMonitor` instance, as shown in the following code sample:

```
from sagemaker.model_monitor import CronExpressionGenerator
```

```
data_quality_model_monitor = DefaultModelMonitor(
   role=get_execution_role(),
   ...
)

schedule = data_quality_model_monitor.create_monitoring_schedule(
   monitor_schedule_name=schedule_name,
   post_analytics_processor_script=s3_code_postprocessor_uri,
   output_s3_uri=s3_report_path,
   schedule_cron_expression=CronExpressionGenerator.hourly(),
   statistics=data_quality_model_monitor.baseline_statistics(),
   constraints=data_quality_model_monitor.suggested_constraints(),
   schedule_cron_expression=CronExpressionGenerator.hourly(),
   enable_cloudwatch_metrics=True,
   endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
   )
)
```

Data quality monitoring for batch transform jobs

To schedule a data quality monitor for a batch transform job, pass your `BatchTransformInput` instance to the `batch_transform_input` argument of your `DefaultModelMonitor` instance, as shown in the following code sample:

```
from sagemaker.model_monitor import CronExpressionGenerator

data_quality_model_monitor = DefaultModelMonitor(
   role=get_execution_role(),
   ...
)

schedule = data_quality_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=mon_schedule_name,
    batch_transform_input=BatchTransformInput(
        data_captured_destination_s3_uri=s3_capture_upload_path,
        destination="/opt/ml/processing/input",
        dataset_format=MonitoringDatasetFormat.csv(header=False),
    ),
    output_s3_uri=s3_report_path,
    statistics= statistics_path,
```

```
    constraints = constraints_path,
    schedule_cron_expression=CronExpressionGenerator.hourly(),
    enable_cloudwatch_metrics=True,
)
```

Schema for Statistics (statistics.json file)

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

Amazon SageMaker Model Monitor prebuilt container computes per column/feature statistics. The statistics are calculated for the baseline dataset and also for the current dataset that is being analyzed.

```
{
    "version": 0,
    # dataset level stats
    "dataset": {
        "item_count": number
    },

                                [
                                    num,
                                    num,
                                    num,
                                    num
                                ],
                                [
                                    num,
                                    num
                                ][
                                    num,
                                    num
                                ]
                            ]
                        }#sketch
                    }#KLL
                }#distribution
            }#num_stats
        },
        {
            "name": "feature-name",
            "inferred_type": "String",
            "string_statistics": {
                "common": {
                    "num_present": number,
                    "num_missing": number
                },
                "distinct_count": number,
                "distribution": {
                    "categorical": {
```

```
                        "buckets": [
                               {
                                   "value": "string",
                                   "count": number
                               }
                            ]
                        }
                    }
                },
                #provision for custom stats
            }
        ]
}
```

Note the following:

- The prebuilt containers compute KLL sketch, which is a compact quantiles sketch.
- By default, we materialize the distribution in 10 buckets. This is not currently configurable.

CloudWatch Metrics

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

You can use the built-in Amazon SageMaker Model Monitor container for CloudWatch metrics. When the `emit_metrics` option is `Enabled` in the baseline constraints file, SageMaker AI emits these metrics for each feature/column observed in the dataset in the following namespace:

- `For real-time endpoints: /aws/sagemaker/Endpoints/data-metric` namespace with `EndpointName` and `ScheduleName` dimensions.
- `For batch transform jobs: /aws/sagemaker/ModelMonitoring/data-metric` namespace with `MonitoringSchedule` dimension.

For numerical fields, the built-in container emits the following CloudWatch metrics:

- Metric: Max → query for `MetricName: feature_data_{feature_name}, Stat: Max`
- Metric: Min → query for `MetricName: feature_data_{feature_name}, Stat: Min`
- Metric: Sum → query for `MetricName: feature_data_{feature_name}, Stat: Sum`
- Metric: SampleCount → query for `MetricName: feature_data_{feature_name}, Stat: SampleCount`
- Metric: Average → query for `MetricName: feature_data_{feature_name}, Stat: Average`

For both numerical and string fields, the built-in container emits the following CloudWatch metrics:

- Metric: Completeness → query for `MetricName: feature_non_null_{feature_name}, Stat: Sum`
- Metric: Baseline Drift → query for `MetricName: feature_baseline_drift_{feature_name}, Stat: Sum`

Schema for Violations (constraint_violations.json file)

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

The violations file is generated as the output of a `MonitoringExecution`, which lists the results of evaluating the constraints (specified in the constraints.json file) against the current dataset that was analyzed. The Amazon SageMaker Model Monitor prebuilt container provides the following violation checks.

```
{
    "violations": [{
      "feature_name" : "string",
      "constraint_check_type" :
```

```
              "data_type_check",
            | "completeness_check",
            | "baseline_drift_check",
            | "missing_column_check",
            | "extra_column_check",
            | "categorical_values_check"
      "description" : "string"
    }]
}
```

Types of Violations Monitored

Violation Check Type	Description
`data_type_check`	If the data types in the current execution are not the same as in the baseline dataset, this violation is flagged. During the baseline step, the generated constraints suggest the inferred data type for each column. The `monitoring_config.datatype_check_threshold` parameter can be tuned to adjust the threshold on when it is flagged as a violation.
`completeness_check`	If the completeness (% of non-null items) observed in the current execution exceeds the threshold specified in completeness threshold specified per feature, this violation is flagged. During the baseline step, the generated constraints suggest a completeness value.
`baseline_drift_check`	If the calculated distribution distance between the current and the baseline datasets is more than the threshold specified in `monitoring_config.comparison_threshold`, this violation is flagged.

Violation Check Type	Description
`missing_column_check`	If the number of columns in the current dataset is less than the number in the baseline dataset, this violation is flagged.
`extra_column_check`	If the number of columns in the current dataset is more than the number in the baseline, this violation is flagged.
`categorical_values_check`	If there are more unknown values in the current dataset than in the baseline dataset, this violation is flagged. This value is dictated by the threshold in `monitoring_config.domain_content_threshold` .

Model quality

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

Model quality monitoring jobs monitor the performance of a model by comparing the predictions that the model makes with the actual Ground Truth labels that the model attempts to predict. To do this, model quality monitoring merges data that is captured from real-time or batch inference with actual labels that you store in an Amazon S3 bucket, and then compares the predictions with the actual labels.

To measure model quality, model monitor uses metrics that depend on the ML problem type. For example, if your model is for a regression problem, one of the metrics evaluated is mean square error (mse). For information about all of the metrics used for the different ML problem types, see Model quality metrics and Amazon CloudWatch monitoring.

Model quality monitoring follows the same steps as data quality monitoring, but adds the additional step of merging the actual labels from Amazon S3 with the predictions captured from the real-time inference endpoint or batch transform job. To monitor model quality, follow these steps:

- Enable data capture. This captures inference input and output from a real-time inference endpoint or batch transform job and stores the data in Amazon S3. For more information, see Data capture.
- Create a baseline. In this step, you run a baseline job that compares predictions from the model with Ground Truth labels in a baseline dataset. The baseline job automatically creates baseline statistical rules and constraints that define thresholds against which the model performance is evaluated. For more information, see Create a model quality baseline.
- Define and schedule model quality monitoring jobs. For specific information and code samples of model quality monitoring jobs, see Schedule model quality monitoring jobs. For general information about monitoring jobs, see Schedule monitoring jobs.
- Ingest Ground Truth labels that model monitor merges with captured prediction data from a real-time inference endpoint or batch transform job. For more information, see Ingest Ground Truth labels and merge them with predictions.
- Integrate model quality monitoring with Amazon CloudWatch. For more information, see Monitoring model quality metrics with CloudWatch.
- Interpret the results of a monitoring job. For more information, see Interpret results.
- Use SageMaker Studio to enable model quality monitoring and visualize results. For more information, see Visualize results for real-time endpoints in Amazon SageMaker Studio.

Topics

Create a model quality baseline

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

Create a baseline job that compares your model predictions with ground truth labels in a baseline dataset that you have stored in Amazon S3. Typically, you use a training dataset as the baseline dataset. The baseline job calculates metrics for the model and suggests constraints to use to monitor model quality drift.

To create a baseline job, you need to have a dataset that contains predictions from your model along with labels that represent the Ground Truth for your data.

To create a baseline job use the `ModelQualityMonitor` class provided by the SageMaker Python SDK, and complete the following steps.

To create a model quality baseline job

1. First, create an instance of the `ModelQualityMonitor` class. The following code snippet shows how to do this.

```
from sagemaker.core.helper.session_helper import get_execution_role, session,
 Session
from sagemaker.model_monitor import ModelQualityMonitor

role = get_execution_role()
session = Session()

model_quality_monitor = ModelQualityMonitor(
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge',
    volume_size_in_gb=20,
    max_runtime_in_seconds=1800,
    sagemaker_session=session
```

```
)
```

2. Now call the `suggest_baseline` method of the `ModelQualityMonitor` object to run a baseline job. The following code snippet assumes that you have a baseline dataset that contains both predictions and labels stored in Amazon S3.

```
baseline_job_name = "MyBaseLineJob"
job = model_quality_monitor.suggest_baseline(
    job_name=baseline_job_name,
    baseline_dataset=baseline_dataset_uri, # The S3 location of the validation
 dataset.
    dataset_format=DatasetFormat.csv(header=True),
    output_s3_uri = baseline_results_uri, # The S3 location to store the results.
    problem_type='BinaryClassification',
    inference_attribute= "prediction", # The column in the dataset that contains
 predictions.
    probability_attribute= "probability", # The column in the dataset that contains
 probabilities.
    ground_truth_attribute= "label" # The column in the dataset that contains
 ground truth labels.
)
job.wait(logs=False)
```

3. After the baseline job finishes, you can see the constraints that the job generated. First, get the results of the baseline job by calling the `latest_baselining_job` method of the `ModelQualityMonitor` object.

```
baseline_job = model_quality_monitor.latest_baselining_job
```

4. The baseline job suggests constraints, which are thresholds for metrics that model monitor measures. If a metric goes beyond the suggested threshold, Model Monitor reports a violation. To view the constraints that the baseline job generated, call the `suggested_constraints` method of the baseline job. The following code snippet loads the constraints for a binary classification model into a Pandas dataframe.

```
import pandas as pd
pd.DataFrame(baseline_job.suggested_constraints().body_dict["binary_classification_constrai
```

We recommend that you view the generated constraints and modify them as necessary before using them for monitoring. For example, if a constraint is too aggressive, you might get more alerts for violations than you want.

If your constraint contains numbers expressed in scientific notation, you will need to convert them to float. The following python preprocessing script example shows how to convert numbers in scientific notation to float.

```
import csv

def fix_scientific_notation(col):
    try:
        return format(float(col), "f")
    except:
        return col

def preprocess_handler(csv_line):
    reader = csv.reader([csv_line])
    csv_record = next(reader)
    #skip baseline header, change HEADER_NAME to the first column's name
    if csv_record[0] == “HEADER_NAME”:
       return []
    return { str(i).zfill(20) : fix_scientific_notation(d) for i, d in
 enumerate(csv_record)}
```

You can add your pre-processing script to a baseline or monitoring schedule as a `record_preprocessor_script`, as defined in the Model Monitor documentation.

5. When you are satisfied with the constraints, pass them as the `constraints` parameter when you create a monitoring schedule. For more information, see Schedule model quality monitoring jobs.

The suggested baseline constraints are contained in the constraints.json file in the location you specify with `output_s3_uri`. For information about the schema for this file in the Schema for Constraints (constraints.json file).

Schedule model quality monitoring jobs

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and

availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

After you create your baseline, you can call the `create_monitoring_schedule()` method of your `ModelQualityMonitor` class instance to schedule an hourly model quality monitor. The following sections show you how to create a model quality monitor for a model deployed to a real-time endpoint as well as for a batch transform job.

Important

You can specify either a batch transform input or an endpoint input, but not both, when you create your monitoring schedule.

Unlike data quality monitoring, you need to supply Ground Truth labels if you want to monitor model quality. However, Ground Truth labels could be delayed. To address this, specify offsets when you create your monitoring schedule.

Model monitor offsets

Model quality jobs include `StartTimeOffset` and `EndTimeOffset`, which are fields of the `ModelQualityJobInput` parameter of the `create_model_quality_job_definition` method that work as follows:

- `StartTimeOffset` - If specified, jobs subtract this time from the start time.
- `EndTimeOffset` - If specified, jobs subtract this time from the end time.

The format of the offsets are, for example, -PT7H, where 7H is 7 hours. You can use -PT#H or -P#D, where H=hours, D=days, and M=minutes, and # is the number. In addition, the offset should be in ISO 8601 duration format.

For example, if your Ground Truth starts coming in after 1 day, but is not complete for a week, set `StartTimeOffset` to `-P8D` and `EndTimeOffset` to `-P1D`. Then, if you schedule a job to run at `2020-01-09T13:00`, it analyzes data from between `2020-01-01T13:00` and `2020-01-08T13:00`.

> **Important**
>
> The schedule cadence should be such that one execution finishes before the next execution starts, which allows the Ground Truth merge job and monitoring job from the execution to complete. The maximum runtime of an execution is divided between the two jobs, so for an hourly model quality monitoring job, the value of `MaxRuntimeInSeconds` specified as part of `StoppingCondition` should be no more than 1800.

Model quality monitoring for models deployed to real-time endpoints

To schedule a model quality monitor for a real-time endpoint, pass your `EndpointInput` instance to the `endpoint_input` argument of your `ModelQualityMonitor` instance, as shown in the following code sample:

```
from sagemaker.model_monitor import CronExpressionGenerator
from sagemaker.core.helper.session_helper import get_execution_role

model_quality_model_monitor = ModelQualityMonitor(
   role=get_execution_role(),
   ...
)

schedule = model_quality_model_monitor.create_monitoring_schedule(
   monitor_schedule_name=schedule_name,
   post_analytics_processor_script=s3_code_postprocessor_uri,
   output_s3_uri=s3_report_path,
   schedule_cron_expression=CronExpressionGenerator.hourly(),
   statistics=model_quality_model_monitor.baseline_statistics(),
   constraints=model_quality_model_monitor.suggested_constraints(),
   schedule_cron_expression=CronExpressionGenerator.hourly(),
   enable_cloudwatch_metrics=True,
   endpoint_input=EndpointInput(
        endpoint_name=endpoint_name,
        destination="/opt/ml/processing/input/endpoint",
        start_time_offset="-PT2D",
        end_time_offset="-PT1D",
    )
)
```

Model quality monitoring for batch transform jobs

To schedule a model quality monitor for a batch transform job, pass your `BatchTransformInput` instance to the `batch_transform_input` argument of your `ModelQualityMonitor` instance, as shown in the following code sample:

```
from sagemaker.model_monitor import CronExpressionGenerator
from sagemaker.core.helper.session_helper import get_execution_role

model_quality_model_monitor = ModelQualityMonitor(
   role=get_execution_role(),
   ...
)

schedule = model_quality_model_monitor.create_monitoring_schedule(
    monitor_schedule_name=mon_schedule_name,
    batch_transform_input=BatchTransformInput(
        data_captured_destination_s3_uri=s3_capture_upload_path,
        destination="/opt/ml/processing/input",
        dataset_format=MonitoringDatasetFormat.csv(header=False),
        # the column index of the output representing the inference probablity
        probability_attribute="0",

Ingest Ground Truth labels and merge them with predictions

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

Model quality monitoring compares the predictions your model makes with ground truth labels to measure the quality of the model. For this to work, you periodically label data captured by your endpoint or batch transform job and upload it to Amazon S3.

To match Ground Truth labels with captured prediction data, there must be a unique identifier for each record in the dataset. The structure of each record for ground truth data is as follows:

```
{
  "groundTruthData": {
    "data": "1",
    "encoding": "CSV"
  },
  "eventMetadata": {
    "eventId": "aaaa-bbbb-cccc"
  },
  "eventVersion": "0"
}
```

In the `groundTruthData` structure, `eventId` can be one of the following:

- `eventId` – This ID is automatically generated when a user invokes the endpoint.
- `inferenceId` – The caller supplies this ID when they invoke the endpoint.

If `inferenceId` is present in captured data records, Model Monitor uses it to merge captured data with Ground Truth records. You are responsible for making sure that the `inferenceId` in the Ground Truth records match the `inferenceId` in the captured records. If `inferenceId` is not present in captured data, model monitor uses `eventId` from the captured data records to match them with a Ground Truth record.

You must upload Ground Truth data to an Amazon S3 bucket that has the same path format as captured data.

> **Data format requirements**
>
> When you save your data to Amazon S3 it must use the jsonlines format (.jsonl), and be saved using the following naming structure. To learn more about jsonline requirements, see Use input and output data.

```
s3://amzn-s3-demo-bucket1/prefix/yyyy/mm/dd/hh
```

The date in this path is the date when the Ground Truth label is collected, and does not have to match the date when the inference was generated.

After you create and upload the Ground Truth labels, include the location of the labels as a parameter when you create the monitoring job. If you are using Amazon SDK for Python (Boto3), do this by specifying the location of Ground Truth labels as the `S3Uri` field of the `GroundTruthS3Input` parameter in a call to the `create_model_quality_job_definition` method. If you are using the SageMaker Python SDK, specify the location of the Ground Truth labels as the `ground_truth_input` parameter in the call to the `create_monitoring_schedule` of the `ModelQualityMonitor` object.

Model quality metrics and Amazon CloudWatch monitoring

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

Model quality monitoring jobs compute different metrics to evaluate the quality and performance of your machine learning models. The specific metrics calculated depend on the type of ML problem: regression, binary classification, or multiclass classification. Monitoring these metrics is crucial for detecting model drift over time. The following sections cover the key model quality

metrics for each problem type, as well as how to set up automated monitoring and alerting using CloudWatch to continuously track your model's performance.

> **Note**
>
> Standard deviation for metrics are provided only when at least 200 samples are available. Model Monitor computes standard deviation by randomly sampling 80% of the data five times, computing the metric, and taking the standard deviation for those results.

Regression metrics

The following shows an example of the metrics that model quality monitor computes for a regression problem.

```
"regression_metrics" : {
    "mae" : {
      "value" : 0.3711832061068702,
      "standard_deviation" : 0.0037566388129940394
    },
    "mse" : {
      "value" : 0.3711832061068702,
      "standard_deviation" : 0.0037566388129940524
    },
    "rmse" : {
      "value" : 0.609248066149471,
      "standard_deviation" : 0.003079253267651125
    },
    "r2" : {
      "value" : -1.3766111872212665,
      "standard_deviation" : 0.022653980022771227
    }
  }
```

Binary classification metrics

The following shows an example of the metrics that model quality monitor computes for a binary classification problem.

```
"binary_classification_metrics" : {
    "confusion_matrix" : {
```

```
      "0" : {
        "0" : 1,
        "1" : 2
      },
      "1" : {
        "0" : 0,
        "1" : 1
      }
    },
    "recall" : {
      "value" : 1.0,
      "standard_deviation" : "NaN"
    },
    "precision" : {
      "value" : 0.3333333333333333,
      "standard_deviation" : "NaN"
    },
    "accuracy" : {
      "value" : 0.5,
      "standard_deviation" : "NaN"
    },
    "recall_best_constant_classifier" : {
      "value" : 1.0,
      "standard_deviation" : "NaN"
    },

    }
  }
```

Monitoring model quality metrics with CloudWatch

If you set the value of the `enable_cloudwatch_metrics` to `True` when you create the monitoring schedule, model quality monitoring jobs send all metrics to CloudWatch.

Model quality metrics appear in the following namespace:

- For real-time endpoints: `aws/sagemaker/Endpoints/model-metrics`
- For batch transform jobs: `aws/sagemaker/ModelMonitoring/model-metrics`

For a list of the metrics that are emitted, see the previous sections on this page.

You can use CloudWatch metrics to create an alarm when a specific metric doesn't meet the threshold you specify. For instructions about how to create CloudWatch alarms, see Create a CloudWatch alarm based on a static threshold in the *CloudWatch User Guide*.

Bias drift for models in production

> **Note**
>
> Amazon SageMaker Model Monitor is no longer open to new customers. Existing customers can continue to use the service as normal. Amazon continues to invest in security and availability improvements for Model Monitor, but we do not plan to introduce new features. For more information, see Amazon SageMaker Model Monitor availability change.

Amazon SageMaker Clarify bias monitoring helps data scientists and ML engineers monitor predictions for bias on a regular basis. As the model is monitored, customers can view exportable reports and graphs detailing bias in SageMaker Studio and configure alerts in Amazon CloudWatch to receive notifications if bias beyond a certain threshold is detected. Bias can be introduced or exacerbated in deployed ML models when the training data differs from the data that the model sees during deployment (that is, the live data). These kinds of changes in the live data distribution might be temporary (for example, due to some short-lived, real-world events) or permanent. In either case, it might be important to detect these changes. For example, the outputs of a model for predicting home prices can become biased if the mortgage rates used to train the model differ from current, real-world mortgage rates. With bias detection capabilities in Model Monitor, when SageMaker AI detects bias beyond a certain threshold, it automatically generates metrics that you can view in SageMaker Studio and through Amazon CloudWatch alerts.

In general, measuring bias only during the train-and-deploy phase might not be sufficient. It is possible that after the model has been deployed, the distribution of the data that the deployed model sees (that is, the live data) is different from data distribution in the training dataset. This change might introduce bias in a model over time. The change in the live data distribution might be temporary (for example, due to some short-lived behavior like the holiday season) or permanent. In either case, it might be important to detect these changes and take steps to reduce the bias when appropriate.

To detect these changes, SageMaker Clarify provides functionality to monitor the bias metrics of a deployed model continuously and raise automated alerts if the metrics exceed a threshold. For example, consider the DPPL bias metric. Specify an allowed range of values $A=(a_{min},a_{max})$, for instance an interval of (-0.1, 0.1), that DPPL should belong to during deployment. Any deviation from this range should raise a *bias detected* alert. With SageMaker Clarify, you can perform these checks at regular intervals.
