           --automation-execution-id 4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
   ```

PowerShell

```
Get-SSMAutomationExecution `
        -AutomationExecutionId a4a3c0e9-7efd-462a-8594-01234EXAMPLE
```

> **Note**
>
> You can also monitor the status of the automation in the console. In the **Automation executions** list, choose the automation you just ran and then choose the **Execution steps** tab. This tab shows the status of the automation actions.

More info

Centralized multi-account and multi-Region patching with Amazon Systems Manager Automation

Run automations based on EventBridge events

You can start an automation by specifying a runbook as the target of an Amazon EventBridge event. You can start automations according to a schedule, or when a specific Amazon system event occurs. For example, let's say you create a runbook named *BootStrapInstances* that installs software on an instance when an instance starts. To specify the *BootStrapInstances* runbook (and corresponding automation) as a target of an EventBridge event, you first create a new EventBridge rule. (Here's an example rule: **Service name**: EC2, **Event Type**: EC2 Instance State-change Notification, **Specific state(s)**: running, **Any instance**.) Then you use the following procedures to specify the *BootStrapInstances* runbook as the target of the event using the EventBridge console and Amazon Command Line Interface (Amazon CLI). When a new instance starts, the system runs the automation and installs software.

For information about creating runbooks, see Creating your own runbooks.

Creating an EventBridge event that uses a runbook (console)

Use the following procedure to configure a runbook as the target of a EventBridge event.

To configure a runbook as a target of a EventBridge event rule

1. Open the Amazon EventBridge console at https://console.amazonaws.cn/events/.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule.

   A rule can't have the same name as another rule in the same Region and on the same event bus.
5. For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to respond to matching events that come from your own Amazon Web Services account, select **default**. When an Amazon Web Services service in your account emits an event, it always goes to your account's default event bus.
6. Choose how the rule is triggered.

To create a rule based on...	Do this...
Event	a. For **Rule type**, choose **Rule with an event pattern**. b. Choose **Next**. c. For **Event source**, choose **Amazon events or EventBridge partner events**. d. In the **Event pattern** section, do one of the following: • To use a template to create your event pattern, choose **Event pattern form** and choose **Event source**, **Amazon service**, and **Event type**. If you

To create a rule based on...	Do this...	
	choose **All Events** as the event type, all events emitted by the Amazon Web Services service will match the rule. To customize the template, choose **Custom pattern (JSON editor)** and make your changes. • To use a custom event pattern, choose **Custom pattern (JSON editor)** and create your event pattern.	

To create a rule based on...	Do this...
Schedule	a. For **Rule type**, choose **Schedule**. b. Choose **Next**. c. For **Schedule pattern**, do one of the following: • To use a cron expression to define the schedule, choose **A fine-grained schedule that runs at a specific time, such as 8:00 a.m. PST on the first Monday of every month** and enter the cron expression. • To use a rate expression to define the schedule, choose **A schedule that runs at a regular rate, such as every 10 minutes** and enter the rate expression.

7. Choose **Next**.
8. For **Target types**, choose **Amazon service**.
9. For **Select a target**, choose **Systems Manager Automation**.
10. For **Document**, choose a runbook to use when your target is invoked.
11. In the **Configure automation parameter(s)** section, either keep the default parameter values (if available) or enter your own values.

> **Note**
>
> To create a target, you must specify a value for each required parameter. If you don't, the system creates the rule, but the rule won't run.

12. For many target types, EventBridge needs permissions to send events to the target. In these cases, EventBridge can create the IAM role needed for your rule to run. Do one of the following:

    - To create an IAM role automatically, choose **Create a new role for this specific resource**.
    - To use an IAM role that you created earlier, choose **Use existing role** and select the existing role from the dropdown. Note that you might need to update the trust policy for your IAM role to include EventBridge. The following is an example:

    JSON

    ```
    {
        "Version":"2012-10-17",
        "Statement": [
            {
                "Sid": "",
                "Effect": "Allow",
                "Principal": {
                    "Service": [
                        "events.amazonaws.com.cn",
                        "ssm.amazonaws.com.cn"
                    ]
                },
                "Action": "sts:AssumeRole"
            }
        ]
    }
    ```

13. Choose **Next**.
14. (Optional) Enter one or more tags for the rule. For more information, see Tagging Your Amazon EventBridge Resources in the *Amazon EventBridge User Guide*.
15. Choose **Next**.

16. Review the details of the rule and choose **Create rule**.

Create an EventBridge event that uses a runbook (command line)

The following procedure describes how to use the Amazon CLI (on Linux or Windows) or Amazon Tools for PowerShell to create an EventBridge event rule and configure a runbook as the target.

To configure a runbook as a target of an EventBridge event rule

1. Install and configure the Amazon CLI or the Amazon Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI and Installing the Amazon Tools for PowerShell.

2. Create a command to specify a new EventBridge event rule. Replace each *example resource placeholder* with your own information.

   Triggers based on a schedule

   Linux & macOS

   ```
   aws events put-rule \
   --name "rule name" \
   --schedule-expression "cron or rate expression"
   ```

   Windows

   ```
   aws events put-rule ^
   --name "rule name" ^
   --schedule-expression "cron or rate expression"
   ```

   PowerShell

   ```
   Write-CWERule `
   -Name "rule name" `
   -ScheduleExpression "cron or rate expression"
   ```

   The following example creates an EventBridge event rule that starts every day at 9:00 AM (UTC).

Linux & macOS

```
aws events put-rule \
--name "DailyAutomationRule" \
--schedule-expression "cron(0 9 * * ? *)"
```

Windows

```
aws events put-rule ^
--name "DailyAutomationRule" ^
--schedule-expression "cron(0 9 * * ? *)"
```

PowerShell

```
Write-CWERule `
-Name "DailyAutomationRule" `
-ScheduleExpression "cron(0 9 * * ? *)"
```

Triggers based on an event

Linux & macOS

```
aws events put-rule \
--name "rule name" \
--event-pattern "{\"source\":[\"aws.service\"],\"detail-type\":[\"service event
 detail type\"]}"
```

Windows

```
aws events put-rule ^
--name "rule name" ^
--event-pattern "{\"source\":[\"aws.service\"],\"detail-type\":[\"service event
 detail type\"]}"
```

PowerShell

```
Write-CWERule `
-Name "rule name" `
```

```
-EventPattern '{"source":["aws.service"],"detail-type":["service event detail
 type"]}'
```

The following example creates an EventBridge event rule that starts when any EC2 instance in the Region changes state.

Linux & macOS

```
aws events put-rule \
--name "EC2InstanceStateChanges" \
--event-pattern "{\"source\":[\"aws.ec2\"],\"detail-type\":[\"EC2 Instance
 State-change Notification\"]}"
```

Windows

```
aws events put-rule ^
--name "EC2InstanceStateChanges" ^
--event-pattern "{\"source\":[\"aws.ec2\"],\"detail-type\":[\"EC2 Instance
 State-change Notification\"]}"
```

PowerShell

```
Write-CWERule `
-Name "EC2InstanceStateChanges" `
-EventPattern '{"source":["aws.ec2"],"detail-type":["EC2 Instance State-change
 Notification"]}'
```

The command returns details for the new EventBridge rule similar to the following.

Linux & macOS

```
{
"RuleArn": "arn:aws-cn:events:us-east-1:123456789012:rule/automationrule"
}
```

Windows

```
{
"RuleArn": "arn:aws-cn:events:us-east-1:123456789012:rule/automationrule"
```

```
}
```

PowerShell

```
arn:aws-cn:events:us-east-1:123456789012:rule/EC2InstanceStateChanges
```

3. Create a command to specify a runbook as a target of the EventBridge event rule you created in step 2. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws events put-targets \
   --rule rule name \
   --targets '{"Arn": " arn:aws-cn:ssm:region:account ID:automation-
   definition/runbook name","Input":"{\"Message\":[\"{\\\"Key\\\":\\\"key name\\
   \",\\\"Values\\\":[\\\"value\\\"]}\"]}","Id": "target ID","RoleArn": "arn:aws-
   cn:iam::123456789012:role/service-role/EventBridge service role"}'
   ```

   Windows

   ```
   aws events put-targets ^
   --rule rule name ^
   --targets '{"Arn": "arn:aws-cn:ssm:region:account ID:automation-
   definition/runbook name","Input":"{\"Message\":[\"{\\\"Key\\\":\\\"key name\\
   \",\\\"Values\\\":[\\\"value\\\"]}\"]}","Id": "target ID","RoleArn": "arn:aws-
   cn:iam::123456789012:role/service-role/EventBridge service role"}'
   ```

   PowerShell

   ```
   $Target = New-Object Amazon.CloudWatchEvents.Model.Target
   $Target.Id = "target ID"
   $Target.Arn = "arn:aws-cn:ssm:region:account ID:automation-definition/runbook
    name"
   $Target.RoleArn = "arn:aws-cn:iam::123456789012:role/service-role/EventBridge
    service role"
   $Target.Input = '{"input parameter":["value"],"AutomationAssumeRole":["arn:aws-
   cn:iam::123456789012:role/AutomationServiceRole"]}'

   Write-CWETarget `
   -Rule "rule name" `
   -Target $Target
   ```

The following example creates an EventBridge event target that starts the specified instance ID using the runbook `AWS-StartEC2Instance`.

Linux & macOS

```
aws events put-targets \
--rule DailyAutomationRule \
--targets '{"Arn": "arn:aws-cn:ssm:region:*:automation-
definition/AWS-StartEC2Instance","Input":"{\"InstanceId\":
[\"i-02573cafcfEXAMPLE\"],\"AutomationAssumeRole\":[\"arn:aws-
cn:iam::123456789012:role/AutomationServiceRole\"]}","Id":
 "Target1","RoleArn": "arn:aws-cn:iam::123456789012:role/service-role/
AWS_Events_Invoke_Start_Automation_Execution_1213609520"}'
```

Windows

```
aws events put-targets ^
--rule DailyAutomationRule ^
--targets '{"Arn": "arn:aws-cn:ssm:region:*:automation-
definition/AWS-StartEC2Instance","Input":"{\"InstanceId\":
[\"i-02573cafcfEXAMPLE\"],\"AutomationAssumeRole\":[\"arn:aws-
cn:iam::123456789012:role/AutomationServiceRole\"]}","Id":
 "Target1","RoleArn": "arn:aws-cn:iam::123456789012:role/service-role/
AWS_Events_Invoke_Start_Automation_Execution_1213609520"}'
```

PowerShell

```
$Target = New-Object Amazon.CloudWatchEvents.Model.Target
$Target.Id = "Target1"
$Target.Arn = "arn:aws-cn:ssm:region:*:automation-definition/AWS-
StartEC2Instance"
$Target.RoleArn = "arn:aws-cn:iam::123456789012:role/service-role/
AWS_Events_Invoke_Start_Automation_Execution_1213609520"
$Target.Input = '{"InstanceId":["i-02573cafcfEXAMPLE"],"AutomationAssumeRole":
["arn:aws-cn:iam::123456789012:role/AutomationServiceRole"]}'

Write-CWETarget `
-Rule "DailyAutomationRule" `
-Target $Target
```

The system returns information like the following.

Linux & macOS

```
{
"FailedEntries": [],
"FailedEntryCount": 0
}
```

Windows

```
{
"FailedEntries": [],
"FailedEntryCount": 0
}
```

PowerShell

There is no output if the command succeeds for PowerShell.

Run an automation step by step

The following procedures describe how to use the Amazon Systems Manager console and Amazon Command Line Interface (Amazon CLI) to run an automation using the manual execution mode. By using the manual execution mode, the automation starts in a *Waiting* status and pauses in the *Waiting* status between each step. This lets you control when the automation proceeds, which is useful if you need to review the result of a step before continuing.

The automation runs in the context of the current user. This means that you don't need to configure additional IAM permissions as long as you have permission to use the runbook, and any actions called by the runbook. If you have administrator permissions in IAM, then you already have permission to run this automation.

Running an automation step by step (console)

The following procedure shows how to use the Systems Manager console to manually run an automation step by step.

To run an automation step by step

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

   > **Note**
   >
   > You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:

   - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
   - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
   - **1 (Default)** – Choose this option to run the first version of the document, which is the default.

5. Choose **Next**.
6. In the **Execution Mode** section, choose **Manual execution**.
7. In the **Input parameters** section, specify the required inputs. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list.
8. Choose **Execute**.
9. Choose **Execute this step** when you're ready to start the first step of the automation. The automation proceeds with step one and pauses before running any subsequent steps specified in the runbook you chose in step 3 of this procedure. If the runbook has multiple steps, you must select **Execute this step** for each step for the automation to proceed. Each time you choose **Execute this step** the action runs.

> **Note**
>
> The console displays the status of the automation. If the automation fails to run a step, see Troubleshooting Systems Manager Automation.

10. After you complete all steps specified in the runbook, choose **Complete and view results** to finish the automation and view the results.

After an automation execution completes, you can rerun the execution with the same or modified parameters. For more information, see Rerunning automation executions.

Running an automation step by step (command line)

The following procedure describes how to use the Amazon CLI (on Linux, macOS, or Windows) or Amazon Tools for PowerShell to manually run an automation step by step.

To run an automation step by step

1. Install and configure the Amazon CLI or the Amazon Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI and Installing the Amazon Tools for PowerShell.

2. Run the following command to start a manual automation. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm start-automation-execution \
       --document-name runbook name \
       --mode Interactive \
       --parameters runbook parameters
   ```

   Windows

   ```
   aws ssm start-automation-execution ^
       --document-name runbook name ^
       --mode Interactive ^
   ```

```
    --parameters runbook parameters
```

PowerShell

```
Start-SSMAutomationExecution `
    -DocumentName runbook name `
    -Mode Interactive `
    -Parameter runbook parameters
```

Here is an example using the runbook `AWS-RestartEC2Instance` to restart the specified EC2 instance.

Linux & macOS

```
aws ssm start-automation-execution \
    --document-name "AWS-RestartEC2Instance" \
    --mode Interactive \
    --parameters "InstanceId=i-02573cafcfEXAMPLE"
```

Windows

```
aws ssm start-automation-execution ^
    --document-name "AWS-RestartEC2Instance" ^
    --mode Interactive ^
    --parameters "InstanceId=i-02573cafcfEXAMPLE"
```

PowerShell

```
Start-SSMAutomationExecution `
    -DocumentName AWS-RestartEC2Instance `
    -Mode Interactive
    -Parameter @{"InstanceId"="i-02573cafcfEXAMPLE"}
```

The system returns information like the following.

Linux & macOS

```
{
    "AutomationExecutionId": "ba9cd881-1b36-4d31-a698-0123456789ab"
```

```
}
```

Windows

```
{
    "AutomationExecutionId": "ba9cd881-1b36-4d31-a698-0123456789ab"
}
```

PowerShell

```
ba9cd881-1b36-4d31-a698-0123456789ab
```

3. Run the following command when you're ready to start the first step of the automation. Replace each *example resource placeholder* with your own information. The automation proceeds with step one and pauses before running any subsequent steps specified in the runbook you chose in step 1 of this procedure. If the runbook has multiple steps, you must run the following command for each step for the automation to proceed.

   Linux & macOS

   ```
   aws ssm send-automation-signal \
       --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab \
       --signal-type StartStep \
       --payload StepName="stopInstances"
   ```

   Windows

   ```
   aws ssm send-automation-signal ^
       --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab ^
       --signal-type StartStep ^
       --payload StepName="stopInstances"
   ```

   PowerShell

   ```
   Send-SSMAutomationSignal `
       -AutomationExecutionId ba9cd881-1b36-4d31-a698-0123456789ab `
       -SignalType StartStep
       -Payload @{"StepName"="stopInstances"}
   ```

There is no output if the command succeeds.

4. Run the following command to retrieve the status of each step execution in the automation.

Linux & macOS

```
aws ssm describe-automation-step-executions \
    --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab
```

Windows

```
aws ssm describe-automation-step-executions ^
    --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab
```

PowerShell

```
Get-SSMAutomationStepExecution `
    -AutomationExecutionId ba9cd881-1b36-4d31-a698-0123456789ab
```

The system returns information like the following.

Linux & macOS

```
{
    "StepExecutions": [
        {
            "StepName": "stopInstances",
            "Action": "aws:changeInstanceState",
            "ExecutionStartTime": 1557167178.42,
            "ExecutionEndTime": 1557167220.617,
            "StepStatus": "Success",
            "Inputs": {
                "DesiredState": "\"stopped\"",
                "InstanceIds": "[\"i-02573cafcfEXAMPLE\"]"
            },
            "Outputs": {
                "InstanceStates": [
                    "stopped"
                ]
            },
```

```
            "StepExecutionId": "654243ba-71e3-4771-b04f-0123456789ab",
            "OverriddenParameters": {},
            "ValidNextSteps": [
                "startInstances"
            ]
        },
        {
            "StepName": "startInstances",
            "Action": "aws:changeInstanceState",
            "ExecutionStartTime": 1557167273.754,
            "ExecutionEndTime": 1557167480.73,
            "StepStatus": "Success",
            "Inputs": {
                "DesiredState": "\"running\"",
                "InstanceIds": "[\"i-02573cafcfEXAMPLE\"]"
            },
            "Outputs": {
                "InstanceStates": [
                    "running"
                ]
            },
            "StepExecutionId": "8a4a1e0d-dc3e-4039-a599-0123456789ab",
            "OverriddenParameters": {}
        }
    ]
}
```

Windows

```
{
    "StepExecutions": [
        {
            "StepName": "stopInstances",
            "Action": "aws:changeInstanceState",
            "ExecutionStartTime": 1557167178.42,
            "ExecutionEndTime": 1557167220.617,
            "StepStatus": "Success",
            "Inputs": {
                "DesiredState": "\"stopped\"",
                "InstanceIds": "[\"i-02573cafcfEXAMPLE\"]"
            },
            "Outputs": {
                "InstanceStates": [
```

```
                    "stopped"
                ]
            },
            "StepExecutionId": "654243ba-71e3-4771-b04f-0123456789ab",
            "OverriddenParameters": {},
            "ValidNextSteps": [
                "startInstances"
            ]
        },
        {
            "StepName": "startInstances",
            "Action": "aws:changeInstanceState",

OnFailure            :
Outputs              : {[InstanceStates,
 Amazon.Runtime.Internal.Util.AlwaysSendList`1[System.String]]}
OverriddenParameters : {}
Response             :
ResponseCode         :
StepExecutionId      : 8fcc9641-24b7-40b3-a9be-0123456789ab
StepName             : stopInstances
StepStatus           : Success
TimeoutSeconds       : 0
ValidNextSteps       : {startInstances}
```

5. Run the following command to complete the automation after all steps specified within the chosen runbook have finished. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm stop-automation-execution \
       --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab \
       --type Complete
   ```

   Windows

   ```
   aws ssm stop-automation-execution ^
       --automation-execution-id ba9cd881-1b36-4d31-a698-0123456789ab ^
       --type Complete
   ```

   PowerShell

   ```
   Stop-SSMAutomationExecution `
       -AutomationExecutionId ba9cd881-1b36-4d31-a698-0123456789ab `
       -Type Complete
   ```

   There is no output if the command succeeds.

Scheduling automations with State Manager associations

You can start an automation by creating a State Manager association with a runbook. State Manager is a tool in Amazon Systems Manager. By creating a State Manager association with

a runbook, you can target different types of Amazon resources. For example, you can create associations that enforce a desired state on an Amazon resource, including the following:

- Attach a Systems Manager role to Amazon Elastic Compute Cloud (Amazon EC2) instances to make them *managed instances*.
- Enforce desired ingress and egress rules for a security group.
- Create or delete Amazon DynamoDB backups.
- Create or delete Amazon Elastic Block Store (Amazon EBS) snapshots.
- Turn off read and write permissions on Amazon Simple Storage Service (Amazon S3) buckets.
- Start, restart, or stop managed instances and Amazon Relational Database Service (Amazon RDS) instances.
- Apply patches to Linux, macOS, and Window AMIs.

Use the following procedures to create a State Manager association that runs an automation using the Amazon Systems Manager console and Amazon Command Line Interface (Amazon CLI). For general information about associations and information about creating an association that uses an SSM `Command` document or `Policy` document, see Creating associations.

Before you begin

Be aware of the following important details before you run an automation by using State Manager:

- Before you can create an association that uses a runbook, verify that you configured permissions for Automation. For more information, see Setting up Automation.
- State Manager associations that use runbooks contribute to the maximum number of concurrently running automations in your Amazon Web Services account. You can have a maximum of 100 concurrent automations running. For information, see Systems Manager service quotas in the *Amazon Web Services General Reference*.
- When running an automation, State Manager does not log the API operations initiated by the automation in Amazon CloudTrail.
- Systems Manager automatically creates a service-linked role so that State Manager has permission to call Systems Manager Automation API operations. If you want, you can create the service-linked role yourself by running the following command from the Amazon CLI or Amazon Tools for PowerShell.

Linux & macOS

```
aws iam create-service-linked-role \
--aws-service-name ssm.amazonaws.com.cn
```

Windows

```
aws iam create-service-linked-role ^
--aws-service-name ssm.amazonaws.com.cn
```

PowerShell

```
New-IAMServiceLinkedRole `
-AWSServiceName ssm.amazonaws.com.cn
```

For more information about service-linked roles, see Using service-linked roles for Systems Manager.

Creating an association that runs an automation (console)

The following procedure describes how to use the Systems Manager console to create a State Manager association that runs an automation.

To create a State Manager association that runs an automation

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **State Manager**, and then choose **Create association**.
3. In the **Name** field, specify a name. This is optional, but recommended.
4. In the **Document** list, choose a runbook. Use the Search bar to filter on **Document type : Equal : Automation** runbooks. To view more runbooks, use the numbers to the right of the Search bar.

> **Note**
>
> You can view information about a runbook by choosing the runbook name.

5. Choose **Simple execution** to run the automation on one or more targets by specifying the resource ID for those targets. Choose **Rate control** to run the automation across a fleet of Amazon resources by specifying a targeting option such as tags or Amazon Resource Groups. You can also control the operation of the automation across your resources by specifying concurrency and error thresholds.

   If you chose **Rate control**, the **Targets** section is displayed.

6. In the **Targets** section, choose a method for targeting resources.

   a. (Required) In the **Parameter** list, choose a parameter. The items in the **Parameter** list are determined by the parameters in the runbook that you selected at the start of this procedure. By choosing a parameter, you define the type of resource on which the automation runs.

   b. (Required) In the **Targets** list, choose a method for targeting the resources.

      - **Resource Group**: Choose the name of the group from the **Resource Group** list. For more information about targeting Amazon Resource Groups in runbooks, see Targeting Amazon Resource Groups.
      - **Tags**: Enter the tag key and (optionally) the tag value in the fields provided. Choose **Add**. For more information about targeting tags in runbooks, see Targeting a tag.
      - **Parameter Values**: Enter values in the **Input parameters** section. If you specify multiple values, Systems Manager runs a child automation on each value specified.

        For example, say that your runbook includes an **InstanceID** parameter. If you target the values of the **InstanceID** parameter when you run the automation, then Systems Manager runs a child automation for each instance ID value specified. The parent automation is complete when the automation finishes running each specified instance, or if the automation fails. You can target a maximum of 50 parameter values. For more information about targeting parameter values in runbooks, see Targeting parameter values.

7. In the **Input parameters** section, specify the required input parameters.

   If you chose to target resources by using tags or a resource group, then you might not need to choose some of the options in the **Input parameters** section. For example, if you chose the `AWS-RestartEC2Instance` runbook, and you chose to target instances by using tags, then you don't need to specify or choose instance IDs in the **Input parameters** section. The automation locates the instances to restart by using the tags you specified.

> **Important**
>
> You must specify a role ARN in the **AutomationAssumeRole** field. State Manager uses the assume role to call Amazon Web Services services specified in the runbook and run Automation associations on your behalf.

8. In the **Specify schedule** section, choose **On Schedule** if you want to run the association at regular intervals. If you choose this option, then use the options provided to create the schedule using Cron or Rate expressions. For more information about Cron and Rate expressions for State Manager, see Cron and rate expressions for associations.

   > **Note**
   >
   > Rate expressions are the preferred scheduling mechanism for State Manager associations that use runbooks. Rate expressions allow more flexibility for running associations if you reach the maximum number of concurrently running automations. With a rate schedule, Systems Manager can retry the automation shortly after receiving notification that concurrent automations have reached their maximum and have been throttled.

   Choose **No schedule** if you want to run the association one time.

9. (Optional) In the **Rate Control** section, choose **Concurrency** and **Error threshold** options to control the automation deployment across your Amazon resources.

   a. In the **Concurrency** section, choose an option:

      - Choose **targets** to enter an absolute number of targets that can run the automation simultaneously.
      - Choose **percentage** to enter a percentage of the target set that can run the automation simultaneously.

   b. In the **Error threshold** section, choose an option:

      - Choose **errors** to enter an absolute number of errors allowed before Automation stops sending the automation to other resources.

- Choose **percentage** to enter a percentage of errors allowed before Automation stops sending the automation to other resources.

For more information about using targets and rate controls with Automation, see Run automated operations at scale.

10. Choose **Create Association**.

> **Important**
>
> When you create an association, the association immediately runs against the specified targets. The association then runs based on the cron or rate expression you chose. If you chose **No schedule**, the association doesn't run again.

Creating an association that runs an automation (command line)

The following procedure describes how to use the Amazon CLI (on Linux or Windows Server) or Amazon Tools for PowerShell to create a State Manager association that runs an automation.

Before you begin

Before you complete the following procedure, make sure you have created an IAM service role that contains the permissions necessary to run the runbook, and configured a trust relationship for Automation. For more information, see Task 1: Create a service role for Automation.

To create an association that runs an automation

1. Install and configure the Amazon CLI or the Amazon Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI and Installing the Amazon Tools for PowerShell.

2. Run the following command to view a list of documents.

   Linux & macOS

   ```
   aws ssm list-documents
   ```

Windows

```
aws ssm list-documents
```

PowerShell

```
Get-SSMDocumentList
```

Note the name of the runbook that you want to use for the association.

3. Run the following command to view details about the runbook. In the following command, replace *runbook name* with your own information.

Linux & macOS

```
aws ssm describe-document \
--name runbook name
```

Note a parameter name (for example, `InstanceId`) that you want to use for the `--automation-target-parameter-name` option. This parameter determines the type of resource on which the automation runs.

Windows

```
aws ssm describe-document ^
--name runbook name
```

Note a parameter name (for example, `InstanceId`) that you want to use for the `--automation-target-parameter-name` option. This parameter determines the type of resource on which the automation runs.

PowerShell

```
Get-SSMDocumentDescription `
-Name runbook name
```

Note a parameter name (for example, `InstanceId`) that you want to use for the `AutomationTargetParameterName` option. This parameter determines the type of resource on which the automation runs.

4. Create a command that runs an automation using a State Manager association. Replace each *example resource placeholder* with your own information.

   Targeting using tags

   Linux & macOS

   ```
   aws ssm create-association \
   --association-name association name \
   --targets Key=tag:key name,Values=value \
   --name runbook name \
   --parameters AutomationAssumeRole=arn:aws-cn:iam::123456789012:role/
   RunbookAssumeRole \
   --automation-target-parameter-name target parameter \
   --schedule "cron or rate expression"
   ```

   > **Note**
   >
   > If you create an association by using the Amazon CLI, use the `--targets` parameter to target instances for the association. Don't use the `--instance-id` parameter. The `--instance-id` parameter is a legacy parameter.

   Windows

   ```
   aws ssm create-association ^
   --association-name association name ^
   --targets Key=tag:key name,Values=value ^
   --name runbook name ^
   --parameters AutomationAssumeRole=arn:aws-cn:iam::123456789012:role/
   RunbookAssumeRole ^
   --automation-target-parameter-name target parameter ^
   --schedule "cron or rate expression"
   ```

   > **Note**
   >
   > If you create an association by using the Amazon CLI, use the `--targets` parameter to target instances for the association. Don't use the `--instance-id` parameter. The `--instance-id` parameter is a legacy parameter.

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "tag:key name"
$Targets.Values = "value"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws-cn:iam::123456789012:role/RunbookAssumeRole" } `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression"
```

> **Note**
>
> If you create an association by using the Amazon Tools for PowerShell, use the `Target` parameter to target instances for the association. Don't use the `InstanceId` parameter. The `InstanceId` parameter is a legacy parameter.

Targeting using parameter values

Linux & macOS

```
aws ssm create-association \
--association-name association name \
--targets Key=ParameterValues,Values=value,value 2,value 3 \
--name runbook name \
--parameters AutomationAssumeRole=arn:aws-cn:iam::123456789012:role/
RunbookAssumeRole \
--automation-target-parameter-name target parameter \
--schedule "cron or rate expression"
```

Windows

```
aws ssm create-association ^
--association-name association name ^
```

```
--targets Key=ParameterValues,Values=value,value 2,value 3 ^
--name runbook name ^
--parameters AutomationAssumeRole=arn:aws-cn:iam::123456789012:role/
RunbookAssumeRole ^
--automation-target-parameter-name target parameter ^
--schedule "cron or rate expression"
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ParameterValues"
$Targets.Values = "value","value 2","value 3"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws-cn:iam::123456789012:role/RunbookAssumeRole"} `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression"
```

Targeting using Amazon Resource Groups

Linux & macOS

```
aws ssm create-association \
--association-name association name \
--targets Key=ResourceGroup,Values=resource group name \
--name runbook name \
--parameters AutomationAssumeRole=arn:aws-cn:iam::123456789012:role/
RunbookAssumeRole \
--automation-target-parameter-name target parameter \
--schedule "cron or rate expression"
```

Windows

```
aws ssm create-association ^
--association-name association name ^
--targets Key=ResourceGroup,Values=resource group name ^
--name runbook name ^
```

```
--parameters AutomationAssumeRole=arn:aws-cn:iam::123456789012:role/
RunbookAssumeRole ^
--automation-target-parameter-name target parameter ^
--schedule "cron or rate expression"
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ResourceGroup"
$Targets.Values = "resource group name"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws-cn:iam::123456789012:role/RunbookAssumeRole"} `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression"
```

Targeting multiple accounts and Regions

Linux & macOS

```
aws ssm create-association \
--association-name association name \
--targets Key=ResourceGroup,Values=resource group name \
--name runbook name \
--parameters AutomationAssumeRole=arn:aws-cn:iam::123456789012:role/
RunbookAssumeRole \
--automation-target-parameter-name target parameter \
--schedule "cron or rate expression" \
--target-locations
 Accounts=111122223333,444455556666,444455556666,Regions=region,region
```

Windows

```
aws ssm create-association ^
--association-name association name ^
--targets Key=ResourceGroup,Values=resource group name ^
--name runbook name ^
```

```
--parameters AutomationAssumeRole=arn:aws-cn:iam::123456789012:role/
RunbookAssumeRole ^
--automation-target-parameter-name target parameter ^
--schedule "cron or rate expression" ^
--target-locations
 Accounts=111122223333,444455556666,444455556666,Regions=region,region
```

PowerShell

```
$Targets = New-Object Amazon.SimpleSystemsManagement.Model.Target
$Targets.Key = "ResourceGroup"
$Targets.Values = "resource group name"

New-SSMAssociation `
-AssociationName "association name" `
-Target $Targets `
-Name "runbook name" `
-Parameters @{
"AutomationAssumeRole"="arn:aws-cn:iam::123456789012:role/RunbookAssumeRole"} `
-AutomationTargetParameterName "target parameter" `
-ScheduleExpression "cron or rate expression" `
-TargetLocations @{
    "Accounts"=["111122223333,444455556666,444455556666"],
    "Regions"=["region,region"]
```

The command returns details for the new association similar to the following.

Linux & macOS

```
{
"AssociationDescription": {
    "ScheduleExpression": "cron(0 7 ? * MON *)",
    "Name": "AWS-StartEC2Instance",
    "Parameters": {
        "AutomationAssumeRole": [
            "arn:aws-cn:iam::123456789012:role/RunbookAssumeRole"
        ]
    },
    "Overview": {
        "Status": "Pending",
        "DetailedStatus": "Creating"
    },
```

```
    "AssociationId": "1450b4b7-bea2-4e4b-b340-01234EXAMPLE",
    "DocumentVersion": "$DEFAULT",
    "AutomationTargetParameterName": "InstanceId",
    "LastUpdateAssociationDate": 1564686638.498,
    "Date": 1564686638.498,
    "AssociationVersion": "1",
    "AssociationName": "CLI",
    "Targets": [
        {
            "Values": [
                "DEV"
            ],
            "Key": "tag:ENV"
        }
    ]
}
}
```

Windows

```
{
"AssociationDescription": {
    "ScheduleExpression": "cron(0 7 ? * MON *)",
    "Name": "AWS-StartEC2Instance",
    "Parameters": {
        "AutomationAssumeRole": [
            "arn:aws-cn:iam::123456789012:role/RunbookAssumeRole"
        ]
    },
    "Overview": {
        "Status": "Pending",
        "DetailedStatus": "Creating"
    },
    "AssociationId": "1450b4b7-bea2-4e4b-b340-01234EXAMPLE",
    "DocumentVersion": "$DEFAULT",
    "AutomationTargetParameterName": "InstanceId",
    "LastUpdateAssociationDate": 1564686638.498,
    "Date": 1564686638.498,
    "AssociationVersion": "1",
    "AssociationName": "CLI",
    "Targets": [
        {
            "Values": [
```

```
                "DEV"
            ],
            "Key": "tag:ENV"
        }
    ]
}
}
```

PowerShell

```
Name                 : AWS-StartEC2Instance
InstanceId           :
Date                 : 8/1/2019 7:31:38 PM
Status.Name          :
Status.Date          :
Status.Message       :
Status.AdditionalInfo :
```

Note

If you use tags to create an association on one or more target instances, and then you remove the tags from an instance, that instance no longer runs the association. The instance is disassociated from the State Manager document.

Troubleshooting automations run by State Manager associations

Systems Manager Automation enforces a limit of 100 concurrent automations, and 1,000 queued automations per account, per Region. If a State Manager association that uses a runbook shows a status of **Failed** and a detailed status of **AutomationExecutionLimitExceeded**, then your automation might have reached the limit. As a result, Systems Manager throttles the automations. To resolve this issue, do the following:

- Use a different rate or cron expression for your association. For example, if the association is scheduled to run every 30 minutes, then change the expression so that it runs every hour or two.
- Delete existing automations that have a status of **Pending**. By deleting these automations, you clear the current queue.

Schedule automations with maintenance windows

You can start an automation by configuring a runbook as a registered task for a maintenance window. By registering the runbook as a registered task, the maintenance window runs the automation during the scheduled maintenance period.

For example, let's say you create a runbook named `CreateAMI` that creates an Amazon Machine Image (AMI) of instances registered as targets to the maintenance window. To specify the `CreateAMI` runbook (and corresponding automation) as a registered task of a maintenance window, you first create a maintenance window and register targets. Then you use the following procedure to specify the `CreateAMI` document as a registered task within the maintenance window. When the maintenance window starts during the scheduled period, the system runs the automation and creates an AMI of the registered targets.

For information about creating Automation runbooks, see Creating your own runbooks. Automation is a tool in Amazon Systems Manager.

Use the following procedures to configure an automation as a registered task for a maintenance window using the Amazon Systems Manager console, Amazon Command Line Interface (Amazon CLI), or Amazon Tools for Windows PowerShell.

Registering an automation task to a maintenance window (console)

The following procedure describes how to use the Systems Manager console to configure an automation as a registered task for a maintenance window.

Before you begin

Before you complete the following procedure, you must create a maintenance window and register at least one target. For more information, see the following procedures:

- Create a maintenance window using the console.
- Assign targets to a maintenance window using the console

To configure an automation as a registered task for a maintenance window

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the left navigation pane, choose **Maintenance Windows**, and then choose the maintenance window you want to register an Automation task with.

3. Choose **Actions**. Then choose **Register Automation task** to run your choice of an automation on targets by using a runbook.
4. For **Name**, enter a name for the task.
5. For **Description**, enter a description.
6. For **Document**, choose the runbook that defines the tasks to run.
7. For **Document version**, choose the runbook version to use.
8. For **Task priority**, specify a priority for this task. 1 is the highest priority. Tasks in a maintenance window are scheduled in priority order; tasks that have the same priority are scheduled in parallel.
9. In the **Targets** section, if the runbook you chose is one that runs tasks on resources, identify the targets on which you want to run this automation by specifying tags or by selecting instances manually.

   > **Note**
   >
   > If you want to pass the resources through input parameters instead of targets, you don't need to specify a maintenance window target.
   > In many cases, you don't need to explicitly specify a target for an automation task. For example, say that you're creating an Automation-type task to update an Amazon Machine Image (AMI) for Linux using the `AWS-UpdateLinuxAmi` runbook. When the task runs, the AMI is updated with the latest available Linux distribution packages and Amazon software. New instances created from the AMI already have these updates installed. Because the ID of the AMI to be updated is specified in the input parameters for the runbook, there is no need to specify a target again in the maintenance window task.

   For information about maintenance window tasks that don't require targets, see the section called “Registering maintenance window tasks without targets”.
10. (Optional) For **Rate control**:

    > **Note**
    >
    > If the task you're running doesn't specify targets, you don;t need to specify rate controls.

- For **Concurrency**, specify either a number or a percentage of targets on which to run the automation at the same time.

  If you selected targets by choosing tag key-value pairs, and you aren't certain how many targets use the selected tags, then limit the number of automations that can run at the same time by specifying a percentage.

  When the maintenance window runs, a new automation is initiated per target. There is a limit of 100 concurrent automations per Amazon Web Services account. If you specify a concurrency rate greater than 100, concurrent automations greater than 100 are automatically added to the automation queue. For information, see Systems Manager service quotas in the *Amazon Web Services General Reference*.

- For **Error threshold**, specify when to stop running the automation on other targets after it fails on either a number or a percentage of targets. For example, if you specify three errors, then Systems Manager stops running automations when the fourth error is received. Targets still processing the automation might also send errors.

11. In the **Input Parameters** section, specify parameters for the runbook. For runbooks, the system auto-populates some of the values. You can keep or replace these values.

> **Important**
>
> For runbooks, you can optionally specify an Automation Assume Role. If you don't specify a role for this parameter, then the automation assumes the maintenance window service role you choose in step 11. As such, you must make sure that the maintenance window service role you choose has the appropriate Amazon Identity and Access Management (IAM) permissions to perform the actions defined within the runbook.
> For example, the service-linked role for Systems Manager doesn't have the IAM permission `ec2:CreateSnapshot`, which is required to use the runbook `AWS-CopySnapshot`. In this scenario, you must either use a custom maintenance window service role or specify an Automation assume role that has `ec2:CreateSnapshot` permissions. For information, see Setting up Automation.

12. In the **IAM service role** area, choose a role to provide permissions for Systems Manager to start the automation.

To create a service role for maintenance window tasks, see Setting up Maintenance Windows.

13. Choose **Register Automation task**.

Registering an Automation task to a maintenance window (command line)

The following procedure describes how to use the Amazon CLI (on Linux or Windows Server) or Amazon Tools for PowerShell to configure an automation as a registered task for a maintenance window.

Before you begin

Before you complete the following procedure, you must create a maintenance window and register at least one target. For more information, see the following procedures:

- Step 1: Create the maintenance window using the Amazon CLI.
- Step 2: Register a target node with the maintenance window using the Amazon CLI

To configure an automation as a registered task for a maintenance window

1. Install and configure the Amazon CLI or the Amazon Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI and Installing the Amazon Tools for PowerShell.

2. Create a command to configure an automation as a registered task for a maintenance window. Replace each *example resource placeholder* with your own information.

   Linux & macOS

```
aws ssm register-task-with-maintenance-window \
--window-id window ID \
--name task name \
--task-arn runbook name \
--targets Key=targets,Values=value \
--service-role-arn IAM role arn \
--task-type AUTOMATION \
--task-invocation-parameters task parameters \
--priority task priority \
--max-concurrency 10% \
```

```
--max-errors 5
```

> **Note**
>
> If you configure an automation as a registered task by using the Amazon CLI, use the `--Task-Invocation-Parameters` parameter to specify parameters to pass to a task when it runs. Don't use the `--Task-Parameters` parameter. The `--Task-Parameters` parameter is a legacy parameter.
> For maintenance window tasks without a target specified, you can't supply values for `--max-errors` and `--max-concurrency`. Instead, the system inserts a placeholder value of 1, which might be reported in the response to commands such as describe-maintenance-window-tasks and get-maintenance-window-task. These values don't affect the running of your task and can be ignored.
> For information about maintenance window tasks that don't require targets, see Registering maintenance window tasks without targets.

Windows

```
aws ssm register-task-with-maintenance-window ^
--window-id window ID ^
--name task name ^
--task-arn runbook name ^
--targets Key=targets,Values=value ^
--service-role-arn IAM role arn ^
--task-type AUTOMATION ^
--task-invocation-parameters task parameters ^
--priority task priority ^
--max-concurrency 10% ^
--max-errors 5
```

> **Note**
>
> If you configure an automation as a registered task by using the Amazon CLI, use the `--task-invocation-parameters` parameter to specify parameters to pass to a task when it runs. Don't use the `--task-parameters` parameter. The `--task-parameters` parameter is a legacy parameter.

For maintenance window tasks without a target specified, you can't supply values for `--max-errors` and `--max-concurrency`. Instead, the system inserts a placeholder value of 1, which might be reported in the response to commands such as describe-maintenance-window-tasks and get-maintenance-window-task. These values don't affect the running of your task and can be ignored.
For information about maintenance window tasks that don't require targets, see Registering maintenance window tasks without targets.

PowerShell

```
Register-SSMTaskWithMaintenanceWindow `
-WindowId window ID `
-Name "task name" `
-TaskArn "runbook name" `
-Target @{ Key="targets";Values="value" } `
-ServiceRoleArn "IAM role arn" `
-TaskType "AUTOMATION" `
-Automation_Parameter @{ "task parameter"="task parameter value"} `
-Priority task priority `
-MaxConcurrency 10% `
-MaxError 5
```

Note

If you configure an automation as a registered task by using the Amazon Tools for PowerShell, use the `-Automation_Parameter` parameter to specify parameters to pass to a task when the task runs. Don't use the `-TaskParameters` parameter. The `-TaskParameters` parameter is a legacy parameter.
For maintenance window tasks without a target specified, you can't supply values for `-MaxError` and `-MaxConcurrency`. Instead, the system inserts a placeholder value of 1, which might be reported in the response to commands such as `Get-SSMMaintenanceWindowTaskList` and `Get-SSMMaintenanceWindowTask`. These values don't affect the running of your task and can be ignored.
For information about maintenance window tasks that don't require targets, see Registering maintenance window tasks without targets.

The following example configures an automation as a registered task to a maintenance window with priority 1. It also demonstrates omitting the `--targets`, `--max-errors`, and `--max-concurrency` options for a targetless maintenance window task. The automation uses the `AWS-StartEC2Instance` runbook and the specified Automation assume role to start EC2 instances registered as targets to the maintenance window. The maintenance window runs the automation simultaneously on 5 instances maximum at any given time. Also, the registered task stops running on more instances for a particular interval if the error count exceeds 1.

Linux & macOS

```
aws ssm register-task-with-maintenance-window \
--window-id mw-0c50858d01EXAMPLE \
--name StartEC2Instances \
--task-arn AWS-StartEC2Instance \
--service-role-arn arn:aws-cn:iam::123456789012:role/MaintenanceWindowRole \
--task-type AUTOMATION \
--task-invocation-parameters "{\"Automation\":{\"Parameters\":
{\"InstanceId\":[\"{{TARGET_ID}}\"],\"AutomationAssumeRole\":[\"arn:aws-
cn:iam::123456789012:role/AutomationAssumeRole\"]}}}" \
--priority 1
```

Windows

```
aws ssm register-task-with-maintenance-window ^
--window-id mw-0c50858d01EXAMPLE ^
--name StartEC2Instances ^
--task-arn AWS-StartEC2Instance ^
--service-role-arn arn:aws-cn:iam::123456789012:role/MaintenanceWindowRole ^
--task-type AUTOMATION ^
--task-invocation-parameters "{\"Automation\":{\"Parameters\":
{\"InstanceId\":[\"{{TARGET_ID}}\"],\"AutomationAssumeRole\":[\"arn:aws-
cn:iam::123456789012:role/AutomationAssumeRole\"]}}}" ^
--priority 1
```

PowerShell

```
Register-SSMTaskWithMaintenanceWindow `
-WindowId mw-0c50858d01EXAMPLE `
-Name "StartEC2" `
```

```
-TaskArn "AWS-StartEC2Instance" `
-ServiceRoleArn "arn:aws-cn:iam::123456789012:role/MaintenanceWindowRole" `
-TaskType "AUTOMATION" `
-Automation_Parameter
 @{ "InstanceId"="{{TARGET_ID}}";"AutomationAssumeRole"="arn:aws-
cn:iam::123456789012:role/AutomationAssumeRole" } `
-Priority 1
```

The command returns details for the new registered task similar to the following.

Linux & macOS

```
{
"WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```

Windows

```
{
"WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```

PowerShell

```
4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

3. To view the registered task, run the following command. Replace *maintenance windows ID* with your own information.

Linux & macOS

```
aws ssm describe-maintenance-window-tasks \
--window-id maintenance window ID
```

Windows

```
aws ssm describe-maintenance-window-tasks ^
--window-id maintenance window ID
```

PowerShell

```
Get-SSMMaintenanceWindowTaskList `
-WindowId maintenance window ID
```

The system returns information like the following.

Linux & macOS

```
{
"Tasks": [
    {
        "ServiceRoleArn": "arn:aws-cn:iam::123456789012:role/
MaintenanceWindowRole",
        "MaxErrors": "1",
        "TaskArn": "AWS-StartEC2Instance",
        "MaxConcurrency": "1",
        "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
        "TaskParameters": {},
        "Priority": 1,
        "WindowId": "mw-0c50858d01EXAMPLE",
        "Type": "AUTOMATION",
        "Targets": [
        ],
        "Name": "StartEC2"
    }
]
}
```

Windows

```
{
"Tasks": [
    {
        "ServiceRoleArn": "arn:aws-cn:iam::123456789012:role/
MaintenanceWindowRole",
        "MaxErrors": "1",
        "TaskArn": "AWS-StartEC2Instance",
        "MaxConcurrency": "1",
        "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
        "TaskParameters": {},
```

```
        "Priority": 1,
        "WindowId": "mw-0c50858d01EXAMPLE",
        "Type": "AUTOMATION",
        "Targets": [
        ],
        "Name": "StartEC2"
    }
]
}
```

PowerShell

```
Description    :

```

Configuring Automations to monitor CloudWatch Alarms

You can configure your Automation runbook executions to monitor CloudWatch alarms. If a specified alarm enters `ALARM` state, Automation stops the execution. For executions using rate control mode or running across multiple accounts, Automation cancels all pending executions. If you define on`Cancel` steps in your runbook, those steps run before the execution ends. This prevents runbooks from continuing when monitored resources are unhealthy.

Before you begin

Complete these prerequisites before configuring CloudWatch alarm monitoring:

- **Create a CloudWatch alarm** – Create an alarm that monitors resources affected by your Automation execution. For more information, see Using Amazon CloudWatch alarms.

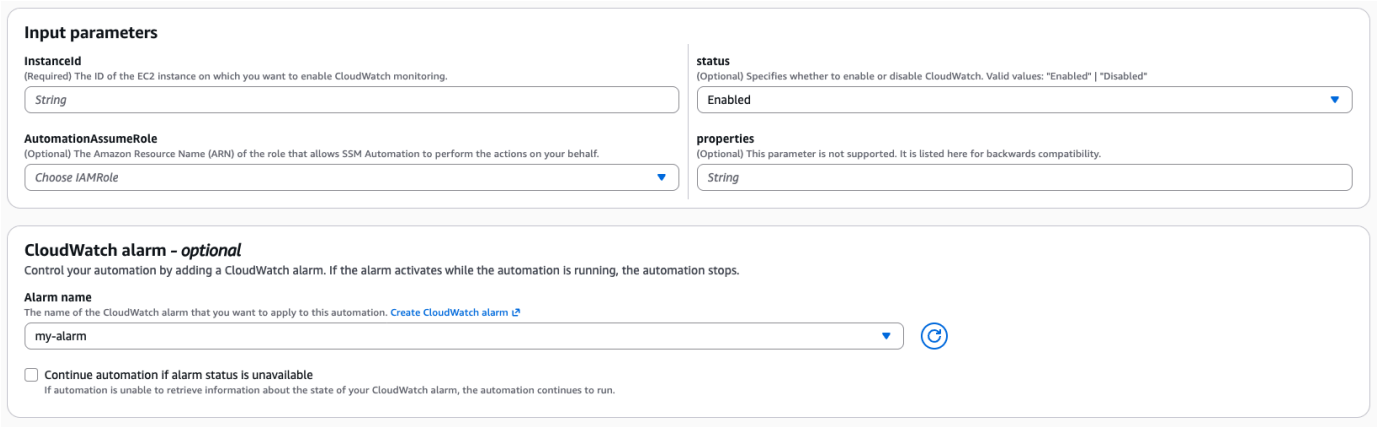
- **Configure execution identity permissions** – The execution identity used by Automation must have the following permissions for CloudWatch alarm monitoring to work correctly:
  - `cloudwatch:DescribeAlarms` – Required to monitor alarm states.
  - `ssm:StopAutomationExecution` – Required to stop the execution when an alarm activates.

  The execution identity is determined by the IAM role ARN specified in the `assumeRole` field of your Automation runbook. If no `assumeRole` value is specified, the runbook executes using the identity of the IAM principal that called `StartAutomationExecution`.

The following example shows a minimal IAM policy that grants the required permissions for CloudWatch alarm monitoring:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:DescribeAlarms",
                "ssm:StopAutomationExecution"
            ],
            "Resource": "*"
        }
    ]
}
```

Configuring alarm monitoring (console)



Use the following procedure to configure CloudWatch alarm monitoring when starting an automation from the Systems Manager console.

To configure alarm monitoring

Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.

1. In the navigation pane, choose **Automation**.
2. Choose **Execute automation**.
3. Select a runbook and configure the input parameters for your execution.

4. In the **CloudWatch alarm** section, choose an alarm to monitor during the execution.

5. (Optional) Toggle **Continue automation if alarm state is unavailable** to control behavior when Automation cannot retrieve the alarm state. When enabled, the execution continues even if the alarm state cannot be determined. When disabled (default), the execution stops if the alarm state cannot be retrieved.
6. Choose **Execute**.

Configuring alarm monitoring (Amazon CLI)

Use the `--alarm-configuration` parameter with the `aws ssm start-automation-execution` command to specify CloudWatch alarms to monitor.

The `--alarm-configuration` parameter accepts a JSON structure with the following fields:

- `Alarms` (required) – An alarm object with a `Name` field that identifies the CloudWatch alarm to monitor.
- `IgnorePollAlarmFailure` (optional, boolean) – Controls behavior when Automation cannot retrieve the alarm state. Set to `false` (default) to stop the execution if alarm state cannot be determined, or `true` to continue the execution regardless.

The following example starts an automation that monitors a CloudWatch alarm named `my-alarm`. Because `IgnorePollAlarmFailure` is set to `false`, the automation stops if it cannot retrieve the alarm state:

```
aws ssm start-automation-execution \
    --document-name "AWS-RestartEC2Instance" \
    --parameters '{"InstanceId":["i-02573cafcfEXAMPLE"]}' \
```

```
    --alarm-configuration '{"IgnorePollAlarmFailure":false,"Alarms":[{"Name":"my-
alarm"}]}'
```

Cross-account and cross-region alarm monitoring

For automations running across multiple Accounts and Regions, you can configure alarm monitoring per target location using the `TargetLocationAlarmConfiguration` field within `TargetLocations`. The execution role in each target account (for example, `AWS-SystemsManager-AutomationExecutionRole`) must have `cloudwatch:DescribeAlarms` and `ssm:StopAutomationExecution` permissions.

For more information about setting up cross-account roles, see Setting up management account permissions for multi-Region and multi-account automation.

Systems Manager Automation actions reference

This reference describes the Automation actions that you can specify in an Automation runbook. Automation is a tool in Amazon Systems Manager. These actions can't be used in other types of Systems Manager (SSM) documents. For information about plugins for other types of SSM documents, see Command document plugin reference.

Systems Manager Automation runs steps defined in Automation runbooks. Each step is associated with a particular action. The action determines the inputs, behavior, and outputs of the step. Steps are defined in the `mainSteps` section of your runbook.

You don't need to specify the outputs of an action or step. The outputs are predetermined by the action associated with the step. When you specify step inputs in your runbooks, you can reference one or more outputs from an earlier step. For example, you can make the output of `aws:runInstances` available for a subsequent `aws:runCommand` action. You can also reference outputs from earlier steps in the `Output` section of the runbook.

Important

If you run an automation workflow that invokes other services by using an Amazon Identity and Access Management (IAM) service role, be aware that the service role must be configured with permission to invoke those services. This requirement applies to all Amazon Automation runbooks (`AWS-*` runbooks) such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks, to name a few. This requirement also applies to any

custom Automation runbooks you create that invoke other Amazon Web Services services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:createStack`, or `aws:copyImage` actions, configure the service role with permission to invoke those services. You can give permissions to other Amazon Web Services services by adding an IAM inline policy to the role. For more information, see (Optional) Add an Automation inline policy or customer managed policy to invoke other Amazon Web Services services.

Topics

- Properties shared by all actions
- aws:approve – Pause an automation for manual approval
- aws:assertAwsResourceProperty – Assert an Amazon resource state or event state
- aws:branch – Run conditional automation steps
- aws:changeInstanceState – Change or assert instance state
- aws:copyImage – Copy or encrypt an Amazon Machine Image
- aws:createImage – Create an Amazon Machine Image
- aws:createStack – Create an Amazon CloudFormation stack
- aws:createTags – Create tags for Amazon resources
- aws:deleteImage – Delete an Amazon Machine Image
- aws:deleteStack – Delete an Amazon CloudFormation stack
- aws:executeAutomation – Run another automation
- aws:executeAwsApi – Call and run Amazon API operations
- aws:executeScript – Run a script
- aws:executeStateMachine – Run an Amazon Step Functions state machine
- aws:invokeWebhook – Invoke an Automation webhook integration
- aws:invokeLambdaFunction – Invoke an Amazon Lambda function
- aws:loop – Iterate over steps in an automation
- aws:pause – Pause an automation
- aws:runCommand – Run a command on a managed instance
- aws:runInstances – Launch an Amazon EC2 instance
- aws:sleep – Delay an automation

- aws:updateVariable – Updates a value for a runbook variable
- aws:waitForAwsResourceProperty – Wait on an Amazon resource property
- Automation system variables

Properties shared by all actions

Common properties are parameters or options that are found in all actions. Some options define behavior for a step, such as how long to wait for a step to complete and what to do if the step fails. The following properties are common to all actions.

description

Information you provide to describe the purpose of a runbook or a step.

Type: String

Required: No

name

An identifier that must be unique across all step names in the runbook.

Type: String

Allowed pattern: [a-zA-Z0-9_]+$

Required: Yes

action

The name of the action the step is to run. `aws:runCommand` – Run a command on a managed instance is an example of an action you can specify here. This document provides detailed information about all available actions.

Type: String

Required: Yes

maxAttempts

The number of times the step should be retried in case of failure. If the value is greater than 1, the step isn't considered to have failed until all retry attempts have failed. The default value is 1.

Type: Integer

Required: No

timeoutSeconds

The timeout value for the step. If the timeout is reached and the value of `maxAttempts` is greater than 1, then the step isn't considered to have timed out until all retries have been attempted.

Type: Integer

Required: No

onFailure

Indicates whether the automation should stop, continue, or go to a different step on failure. The default value for this option is abort.

Type: String

Valid values: Abort | Continue | step:*step_name*

Required: No

onCancel

Indicates which step the automation should go to if a user cancels the automation. Automation runs the cancellation workflow for a maximum of two minutes.

Type: String

Valid values: Abort | step:*step_name*

Required: No

The `onCancel` property doesn't support moving to the following actions:

- `aws:approve`
- `aws:copyImage`
- `aws:createImage`
- `aws:createStack`
- `aws:createTags`
- `aws:loop`

- `aws:pause`
- `aws:runInstances`
- `aws:sleep`

isEnd

This option stops an automation at the end of a specific step. The automation stops if the step failed or succeeded. The default value is false.

Type: Boolean

Valid values: true | false

Required: No

nextStep

Specifies which step in an automation to process next after successfully completing a step.

Type: String

Required: No

isCritical

Designates a step as critical for the successful completion of the Automation. If a step with this designation fails, then Automation reports the final status of the Automation as Failed. This property is only evaluated if you explicitly define it in your step. If the `onFailure` property is set to `Continue` in a step, the value defaults to false. Otherwise, the default value for this option is true.

Type: Boolean

Valid values: true | false

Required: No

inputs

The properties specific to the action.

Type: Map

Required: Yes

```

`aws:approve` – Pause an automation for manual approval

Temporarily pauses an automation until designated principals either approve or reject the action. After the required number of approvals is reached, the automation resumes. You can insert the approval step any place in the `mainSteps` section of your runbook.

> **Note**
>
> This action doesn't support multi-account and Region automations. The default timeout for this action is 7 days (604800 seconds) and the maximum value is 30 days (2592000 seconds). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:approve` step.

In the following example, the `aws:approve` action temporarily pauses the automation until one approver either accepts or rejects the automation. Upon approval, the automation runs a simple PowerShell command.

   ]
}
```

You can approve or deny Automations that are waiting for approval in the console.

To approve or deny waiting Automations

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Automation**.
3. Choose the option next to an Automation with a status of **Waiting**.

4. Choose **Approve/Deny**.
5. Review the details of the Automation.
6. Choose either **Approve** or **Deny**, type an optional comment, and then choose **Submit**.

Input example

YAML

```
NotificationArn: arn:aws:sns:us-west-1:12345678901:Automation-ApprovalRequest
Message: Please approve this step of the Automation.
MinRequiredApprovals: 3
Approvers:
- IamUser1
- IamUser2
- arn:aws:iam::12345678901:user/IamUser3
- arn:aws:iam::12345678901:role/IamRole
```

JSON

```
{
   "NotificationArn":"arn:aws:sns:us-west-1:12345678901:Automation-ApprovalRequest",
   "Message":"Please approve this step of the Automation.",
   "MinRequiredApprovals":3,
   "Approvers":[
      "IamUser1",
      "IamUser2",
```

```
      "arn:aws:iam::12345678901:user/IamUser3",
      "arn:aws:iam::12345678901:role/IamRole"
   ]
}
```

NotificationArn

The Amazon Resource Name (ARN of an Amazon Simple Notification Service (Amazon SNS) topic for Automation approvals. When you specify an `aws:approve` step in a runbook, Automation sends a message to this topic letting principals know that they must either approve or reject an Automation step. The title of the Amazon SNS topic must be prefixed with "Automation".

Type: String

Required: No

Message

The information you want to include in the Amazon SNS topic when the approval request is sent. The maximum message length is 4096 characters.

Type: String

Required: No

MinRequiredApprovals

The minimum number of approvals required to resume the automation. If you don't specify a value, the system defaults to one. The value for this parameter must be a positive number. The value for this parameter can't exceed the number of approvers defined by the `Approvers` parameter.

Type: Integer

Required: No

Approvers

A list of Amazon authenticated principals who can either approve or reject the action. The maximum number of approvers is 10. You can specify principals by using any of the following formats:

- A user name

- A user ARN
- An IAM role ARN
- An IAM assume role ARN

Type: StringList

Required: Yes

EnhancedApprovals

This input is only used for Change Manager templates. A list of Amazon authenticated principals who can either approve or reject the action, the type of IAM principal, and the minimum number of approvers. The following is an example:

```
schemaVersion: "0.3"
emergencyChange: false
autoApprovable: false
mainSteps:
    - name: ApproveAction1
    action: aws:approve
    timeoutSeconds: 604800
    inputs:
        Message: Please approve this change request
        MinRequiredApprovals: 3
        EnhancedApprovals:
        Approvers:
            - approver: John Stiles
            type: IamUser
            minRequiredApprovals: 0
            - approver: Ana Carolina Silva
            type: IamUser
            minRequiredApprovals: 0
            - approver: GroupOfThree
            type: IamGroup
            minRequiredApprovals: 0
            - approver: RoleOfTen
            type: IamRole
            minRequiredApprovals: 0
```

Type: StringList

Required: Yes

Output

ApprovalStatus

The approval status of the step. The status can be one of the following: Approved, Rejected, or Waiting. Waiting means that Automation is waiting for input from approvers.

Type: String

ApproverDecisions

A JSON map that includes the approval decision of each approver.

Type: MapList

`aws:assertAwsResourceProperty` – Assert an Amazon resource state or event state

The `aws:assertAwsResourceProperty` action lets you assert a specific resource state or event state for a specific Automation step.

> **Note**
>
> The `aws:assertAwsResourceProperty` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

For more examples of how to use this action, see Additional runbook examples.

Input

Inputs are defined by the API operation that you choose.

YAML

```
action: aws:assertAwsResourceProperty
inputs:
  Service: The official namespace of the service
  Api: The API operation or method name
  API operation inputs or parameters: A value
  PropertySelector: Response object
  DesiredValues:
  - Desired property values
```

JSON

```
{
  "action": "aws:assertAwsResourceProperty",
  "inputs": {
    "Service":"The official namespace of the service",
    "Api":"The API operation or method name",
    "API operation inputs or parameters":"A value",
    "PropertySelector": "Response object",
    "DesiredValues": [
      "Desired property values"
    ]
  }
}
```

Service

The Amazon Web Services service namespace that contains the API operation that you want to run. For example, the namespace for Systems Manager is `ssm`. The namespace for Amazon EC2 is `ec2`. You can view a list of supported Amazon Web Services service namespaces in the Available Services section of the *Amazon CLI Command Reference*.

Type: String

Required: Yes

Api

The name of the API operation that you want to run. You can view the API operations (also called methods) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: Amazon RDS methods.

Type: String

Required: Yes

API operation inputs

One or more API operation inputs. You can view the available inputs (also called parameters) by choosing a service in the left navigation on the following Services Reference page. Choose

a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to see the available parameters, such as **DBInstanceIdentifier**, **Name**, and **Values**. Use the following format to specify more than one input.

YAML

```
inputs:
  Service: The official namespace of the service
  Api: The API operation name
  API input 1: A value
  API Input 2: A value
  API Input 3: A value
```

JSON

```
"inputs":{
      "Service":"The official namespace of the service",
      "Api":"The API operation name",
      "API input 1":"A value",
      "API Input 2":"A value",
      "API Input 3":"A value"
}
```

Type: Determined by chosen API operation

Required: Yes

PropertySelector

The JSONPath to a specific attribute in the response object. You can view the response objects by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to the **Response Structure** section. **DBInstances** is listed as a response object.

Type: String

Required: Yes

DesiredValues

The expected status or state on which to continue the automation. If you specify a Boolean value, you must use a capital letter such as True or False.

Type: StringList

Required: Yes

aws:branch – Run conditional automation steps

The aws:branch action lets you create a dynamic automation that evaluates different choices in a single step and then jumps to a different step in the runbook based on the results of that evaluation.

When you specify the aws:branch action for a step, you specify Choices that the automation must evaluate. The Choices can be based on a value from the Parameters section of the runbook, or a dynamic value generated as output from the previous step. The automation evaluates each choice by using a Boolean expression. If the first choice is true, then the automation jumps to the step designated for that choice. If the first choice is false, the automation evaluates the next choice. The automation continues evaluating each choice until it process a true choice. The automation then jumps to the designated step for the true choice.

If none of the choices are true, the automation checks to see if the step contains a default value. A default value defines a step that the automation should jump to if none of the choices are true. If no default value is specified for the step, then the automation processes the next step in the runbook.

The aws:branch action supports complex choice evaluations by using a combination of And, Not, and Or operators. For more information about how to use aws:branch, including example runbooks and examples that use different operators, see Using conditional statements in runbooks.

Input

Specify one or more Choices in a step. The Choices can be based on either a value that you specified in the Parameters section of the runbook, or a dynamic value generated as the output from the previous step. Here is a YAML sample that evaluates a parameter.

```
mainSteps:
```

```
- name: chooseOS
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runWindowsCommand
      Variable: "{{Name of a parameter defined in the Parameters section. For example:
 OS_name}}"
      StringEquals: windows
    - NextStep: runLinuxCommand
      Variable: "{{Name of a parameter defined in the Parameters section. For example:
 OS_name}}"
      StringEquals: linux
    Default:
      sleep3
```

Here is a YAML sample that evaluates output from a previous step.

```
mainSteps:
- name: chooseOS
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runPowerShellCommand
      Variable: "{{Name of a response object. For example: GetInstance.platform}}"
      StringEquals: Windows
    - NextStep: runShellCommand
      Variable: "{{Name of a response object. For example: GetInstance.platform}}"
      StringEquals: Linux
    Default:
      sleep3
```

Choices

One or more expressions that the Automation should evaluate when determining the next step to process. Choices are evaluated by using a Boolean expression. Each choice must define the following options:

- **NextStep**: The next step in the runbook to process if the designated choice is true.
- **Variable**: Specify either the name of a parameter that is defined in the `Parameters` section of the runbook. Or specify an output object from a previous step in the runbook. For more information about creating variables for `aws:branch`, see About creating the output variable.

- **Operation**: The criteria used to evaluate the choice. The `aws:branch` action supports the following operations:

  String operations

  - StringEquals
  - EqualsIgnoreCase
  - StartsWith
  - EndsWith
  - Contains

  Numeric operations

  - NumericEquals
  - NumericGreater
  - NumericLesser
  - NumericGreaterOrEquals
  - NumericLesser
  - NumericLesserOrEquals

  Boolean operation

  - BooleanEquals

  > **Important**
  >
  > When you create a runbook, the system validates each operation in the runbook. If an operation isn't supported, the system returns an error when you try to create the runbook.

Default

The name of a step the automation should jump to if none of the `Choices` are true.

Type: String

Required: No

> **Note**
>
> The `aws:branch` action supports `And`, `Or`, and `Not` operators. For examples of `aws:branch` that use operators, see Using conditional statements in runbooks.

`aws:changeInstanceState` – Change or assert instance state

Changes or asserts the state of the instance.

This action can be used in assert mode (doesn't run the API to change the state but verifies the instance is in the desired state.) To use assert mode, set the `CheckStateOnly` parameter to true. This mode is useful when running the Sysprep command on Windows Server, which is an asynchronous command that can run in the background for a long time. You can make sure that the instance is stopped before you create an Amazon Machine Image (AMI).

> **Note**
>
> The default timeout value for this action is 3600 seconds (one hour). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:changeInstanceState` step.

> **Note**
>
> The `aws:changeInstanceState` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

YAML

```
name: startMyInstance
action: aws:changeInstanceState
maxAttempts: 3
timeoutSeconds: 3600
onFailure: Abort
inputs:
  InstanceIds:
```

```
  - i-1234567890abcdef0
  CheckStateOnly: true
  DesiredState: running
  FailOnUnexpectedStopped: true
```

JSON

```
{
    "name":"startMyInstance",
    "action": "aws:changeInstanceState",
    "maxAttempts": 3,
    "timeoutSeconds": 3600,
    "onFailure": "Abort",
    "inputs": {
        "InstanceIds": ["i-1234567890abcdef0"],
        "CheckStateOnly": true,
        "DesiredState": "running",
        "FailOnUnexpectedStopped": true
    }
}
```

InstanceIds

The IDs of the instances.

Type: StringList

Required: Yes

CheckStateOnly

If false, sets the instance state to the desired state. If true, asserts the desired state using polling.

Default: `false`

Type: Boolean

Required: No

DesiredState

The desired state. When set to `running`, this action waits for the Amazon EC2 state to be Running, the Instance Status to be OK, and the System Status to be OK before completing.

Type: String

Valid values: `running` | `stopped` | `terminated`

Required: Yes

Force

If set, forces the instances to stop. The instances don't have an opportunity to flush file system caches or file system metadata. If you use this option, you must perform file system check and repair procedures. This option isn't recommended for EC2 instances for Windows Server.

Type: Boolean

Required: No

FailOnUnexpectedStopped

If set to true, the automation step fails when an instance transitions to the stopped state during a start operation. This is useful for detecting cases where an instance fails to start successfully, such as when an instance has an encrypted EBS volume but lacks the required KMS key permissions.

Type: Boolean

Required: No

AdditionalInfo

Reserved.

Type: String

Required: No

Output

None

`aws:copyImage` – Copy or encrypt an Amazon Machine Image

Copies an Amazon Machine Image (AMI) from any Amazon Web Services Region into the current Region. This action can also encrypt the new AMI.

> **Note**
>
> The `aws:copyImage` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports most `CopyImage` parameters. For more information, see CopyImage.

The following example creates a copy of an AMI in the Seoul region (`SourceImageID`: ami-0fe10819. `SourceRegion`: ap-northeast-2). The new AMI is copied to the region where you initiated the Automation action. The copied AMI will be encrypted because the optional `Encrypted` flag is set to `true`.

YAML

```
name: createEncryptedCopy
action: aws:copyImage
maxAttempts: 3
onFailure: Abort
inputs:
  SourceImageId: ami-0fe10819
  SourceRegion: ap-northeast-2
  ImageName: Encrypted Copy of LAMP base AMI in ap-northeast-2
  Encrypted: true
```

JSON

```
{
    "name": "createEncryptedCopy",
    "action": "aws:copyImage",
    "maxAttempts": 3,
    "onFailure": "Abort",
    "inputs": {
        "SourceImageId": "ami-0fe10819",
        "SourceRegion": "ap-northeast-2",
        "ImageName": "Encrypted Copy of LAMP base AMI in ap-northeast-2",
        "Encrypted": true
    }
}
```

SourceRegion

The region where the source AMI exists.

Type: String

Required: Yes

SourceImageId

The AMI ID to copy from the source Region.

Type: String

Required: Yes

ImageName

The name for the new image.

Type: String

Required: Yes

ImageDescription

A description for the target image.

Type: String

Required: No

Encrypted

Encrypt the target AMI.

Type: Boolean

Required: No

KmsKeyId

The full Amazon Resource Name (ARN) of the Amazon KMS key to use when encrypting the snapshots of an image during a copy operation. For more information, see CopyImage.

Type: String

Required: No

ClientToken

A unique, case-sensitive identifier that you provide to ensure request idempotency. For more information, see CopyImage.

Type: String

Required: No

Output

ImageId

The ID of the copied image.

ImageState

The state of the copied image.

Valid values: `available` | `pending` | `failed`

`aws:createImage` – Create an Amazon Machine Image

Creates an Amazon Machine Image (AMI) from an instance that is either running, stopping, or stopped, and polls for the `ImageState` to be `available`.

> **Note**
>
> The `aws:createImage` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports the following `CreateImage` parameters. For more information, see CreateImage.

YAML

```
name: createMyImage
```

```
action: aws:createImage
maxAttempts: 3
onFailure: Abort
inputs:
  InstanceId: i-1234567890abcdef0
  ImageName: AMI Created on{{global:DATE_TIME}}
  NoReboot: true
  ImageDescription: My newly created AMI
```

JSON

```
{
    "name": "createMyImage",
    "action": "aws:createImage",
    "maxAttempts": 3,
    "onFailure": "Abort",
    "inputs": {
        "InstanceId": "i-1234567890abcdef0",
        "ImageName": "AMI Created on{{global:DATE_TIME}}",
        "NoReboot": true,
        "ImageDescription": "My newly created AMI"
    }
}
```

InstanceId

The ID of the instance.

Type: String

Required: Yes

ImageName

The name for the image.

Type: String

Required: Yes

ImageDescription

A description of the image.

Type: String

Required: No

NoReboot

A Boolean literal.

By default, Amazon Elastic Compute Cloud (Amazon EC2) attempts to shut down and reboot the instance before creating the image. If the **No Reboot** option is set to `true`, Amazon EC2 doesn't shut down the instance before creating the image. When this option is used, file system integrity on the created image can't be guaranteed.

If you don't want the instance to run after you create an AMI from it, first use the `aws:changeInstanceState` – Change or assert instance state action to stop the instance, and then use this `aws:createImage` action with the **NoReboot** option set to `true`.

Type: Boolean

Required: No

BlockDeviceMappings

The block devices for the instance.

Type: Map

Required: No

Output

ImageId

The ID of the newly created image.

Type: String

ImageState

The current state of the image. If the state is available, the image is successfully registered and can be used to launch an instance.

Type: String

`aws:createStack` – Create an Amazon CloudFormation stack

Creates an Amazon CloudFormation stack from a template.

> **Note**
>
> The `aws:createStack` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

For supplemental information about creating CloudFormation stacks, see CreateStack in the *Amazon CloudFormation API Reference*.

Input

YAML

```
name: makeStack
action: aws:createStack
maxAttempts: 1
onFailure: Abort
inputs:
  Capabilities:
  - CAPABILITY_IAM
  StackName: myStack
  TemplateURL: http://s3.amazonaws.com.cn/amzn-s3-demo-bucket/myStackTemplate
  TimeoutInMinutes: 5
  Parameters:
    - ParameterKey: LambdaRoleArn
      ParameterValue: "{{LambdaAssumeRole}}"
    - ParameterKey: createdResource
      ParameterValue: createdResource-{{automation:EXECUTION_ID}}
```

JSON

```
{
    "name": "makeStack",
    "action": "aws:createStack",
    "maxAttempts": 1,
    "onFailure": "Abort",
    "inputs": {
```

```
        "Capabilities": [
            "CAPABILITY_IAM"
        ],
        "StackName": "myStack",
        "TemplateURL": "http://s3.amazonaws.com.cn/amzn-s3-demo-bucket/
myStackTemplate",
        "TimeoutInMinutes": 5,
        "Parameters": [
          {
            "ParameterKey": "LambdaRoleArn",
            "ParameterValue": "{{LambdaAssumeRole}}"
          },
          {
            "ParameterKey": "createdResource",
            "ParameterValue": "createdResource-{{automation:EXECUTION_ID}}"
          }
    }
}
```

Capabilities

A list of values that you specify before CloudFormation can create certain stacks. Some stack templates include resources that can affect permissions in your Amazon Web Services account. For those stacks, you must explicitly acknowledge their capabilities by specifying this parameter.

Valid values include `CAPABILITY_IAM`, `CAPABILITY_NAMED_IAM`, and `CAPABILITY_AUTO_EXPAND`.

CAPABILITY_IAM and CAPABILITY_NAMED_IAM

If you have IAM resources, you can specify either capability. If you have IAM resources with custom names, you must specify `CAPABILITY_NAMED_IAM`. If you don't specify this parameter, this action returns an `InsufficientCapabilities` error. The following resources require you to specify either `CAPABILITY_IAM` or `CAPABILITY_NAMED_IAM`.

- `AWS::IAM::AccessKey`
- `AWS::IAM::Group`
- `AWS::IAM::InstanceProfile`
- `AWS::IAM::Policy`

- AWS::IAM::Role
- AWS::IAM::User
- AWS::IAM::UserToGroupAddition

If your stack template contains these resources, we recommend that you review all permissions associated with them and edit their permissions, if necessary.

For more information, see Acknowledging IAM Resources in Amazon CloudFormation Templates.

CAPABILITY_AUTO_EXPAND

Some template contain macros. Macros perform custom processing on templates; this can include simple actions like find-and-replace operations, all the way to extensive transformations of entire templates. Because of this, users typically create a change set from the processed template, so that they can review the changes resulting from the macros before actually creating the stack. If your stack template contains one or more macros, and you choose to create a stack directly from the processed template, without first reviewing the resulting changes in a change set, you must acknowledge this capability.

For more information, see Using Amazon CloudFormation Macros to Perform Custom Processing on Templates in the *Amazon CloudFormation User Guide*.

Type: array of Strings

Valid Values: `CAPABILITY_IAM | CAPABILITY_NAMED_IAM | CAPABILITY_AUTO_EXPAND`

Required: No

ClientRequestToken

A unique identifier for this CreateStack request. Specify this token if you set maxAttempts in this step to a value greater than 1. By specifying this token, CloudFormation knows that you aren't attempting to create a new stack with the same name.

Type: String

Required: No

Length Constraints: Minimum length of 1. Maximum length of 128.

Pattern: [a-zA-Z0-9][-a-zA-Z0-9]*

DisableRollback

Set to `true` to turn off rollback of the stack if stack creation failed.

Conditional: You can specify either the `DisableRollback` parameter or the `OnFailure` parameter, but not both.

Default: `false`

Type: Boolean

Required: No

NotificationARNs

The Amazon Simple Notification Service (Amazon SNS) topic ARNs for publishing stack-related events. You can find SNS topic ARNs using the Amazon SNS console, https://console.amazonaws.cn/sns/v3/home.

Type: array of Strings

Array Members: Maximum number of 5 items.

Required: No

OnFailure

Determines the action to take if stack creation failed. You must specify `DO_NOTHING`, `ROLLBACK`, or `DELETE`.

Conditional: You can specify either the `OnFailure` parameter or the `DisableRollback` parameter, but not both.

Default: `ROLLBACK`

Type: String

Valid Values: `DO_NOTHING | ROLLBACK | DELETE`

Required: No

Parameters

A list of `Parameter` structures that specify input parameters for the stack. For more information, see the Parameter data type.

Type: array of Parameter objects

Required: No

ResourceTypes

The template resource types that you have permissions to work with for this create stack action. For example: `AWS::EC2::Instance`, `AWS::EC2::*`, or `Custom::MyCustomInstance`. Use the following syntax to describe template resource types.

- For all Amazon resources:

```
AWS::*
```

- For all custom resources:

```
Custom::*
```

- For a specific custom resource:

```
Custom::logical_ID
```

- For all resources of a particular Amazon Web Services service:

```
AWS::service_name::*
```

- For a specific Amazon resource:

```
AWS::service_name::resource_logical_ID
```

If the list of resource types doesn't include a resource that you're creating, the stack creation fails. By default, CloudFormation grants permissions to all resource types. IAM uses this parameter for CloudFormation-specific condition keys in IAM policies. For more information, see Controlling Access with Amazon Identity and Access Management.

Type: array of Strings

Length Constraints: Minimum length of 1. Maximum length of 256.

Required: No

RoleARN

The Amazon Resource Name (ARN) of an IAM role that CloudFormation assumes to create the stack. CloudFormation uses the role's credentials to make calls on your behalf. CloudFormation always uses this role for all future operations on the stack. As long as users have permission to operate on the stack, CloudFormation uses this role even if the users don't have permission to pass it. Make sure that the role grants the least amount of privileges.

If you don't specify a value, CloudFormation uses the role that was previously associated with the stack. If no role is available, CloudFormation uses a temporary session that is generated from your user credentials.

Type: String

Length Constraints: Minimum length of 20. Maximum length of 2048.

Required: No

StackName

The name that is associated with the stack. The name must be unique in the Region in which you're creating the stack.

> **Note**
>
> A stack name can contain only alphanumeric characters (case sensitive) and hyphens. It must start with an alphabetic character and can't be longer than 128 characters.

Type: String

Required: Yes

StackPolicyBody

Structure containing the stack policy body. For more information, see Prevent Updates to Stack Resources.

Conditional: You can specify either the `StackPolicyBody` parameter or the `StackPolicyURL` parameter, but not both.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 16384.

Required: No

StackPolicyURL

Location of a file containing the stack policy. The URL must point to a policy located in an S3 bucket in the same region as the stack. The maximum file size allowed for the stack policy is 16 KB.

Conditional: You can specify either the `StackPolicyBody` parameter or the `StackPolicyURL` parameter, but not both.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 1350.

Required: No

Tags

Key-value pairs to associate with this stack. CloudFormation also propagates these tags to the resources created in the stack. You can specify a maximum number of 10 tags.

Type: array of Tag objects

Required: No

TemplateBody

Structure containing the template body with a minimum length of 1 byte and a maximum length of 51,200 bytes. For more information, see Template Anatomy.

Conditional: You can specify either the `TemplateBody` parameter or the `TemplateURL` parameter, but not both.

Type: String

Length Constraints: Minimum length of 1.

Required: No

TemplateURL

Location of a file containing the template body. The URL must point to a template that is located in an S3 bucket. The maximum size allowed for the template is 460,800 bytes. For more information, see Template Anatomy.

Conditional: You can specify either the `TemplateBody` parameter or the `TemplateURL` parameter, but not both.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 1024.

Required: No

TimeoutInMinutes

The amount of time that can pass before the stack status becomes `CREATE_FAILED`. If `DisableRollback` isn't set or is set to `false`, the stack will be rolled back.

Type: Integer

Valid Range: Minimum value of 1.

Required: No

Outputs

StackId

Unique identifier of the stack.

Type: String

StackStatus

Current status of the stack.

Type: String

Valid Values: `CREATE_IN_PROGRESS | CREATE_FAILED | CREATE_COMPLETE | ROLLBACK_IN_PROGRESS | ROLLBACK_FAILED | ROLLBACK_COMPLETE`

| DELETE_IN_PROGRESS | DELETE_FAILED | DELETE_COMPLETE | UPDATE_IN_PROGRESS | UPDATE_COMPLETE_CLEANUP_IN_PROGRESS | UPDATE_COMPLETE | UPDATE_ROLLBACK_IN_PROGRESS | UPDATE_ROLLBACK_FAILED | UPDATE_ROLLBACK_COMPLETE_CLEANUP_IN_PROGRESS | UPDATE_ROLLBACK_COMPLETE | REVIEW_IN_PROGRESS

Required: Yes

StackStatusReason

Success or failure message associated with the stack status.

Type: String

Required: No

For more information, see CreateStack.

Security considerations

Before you can use the `aws:createStack` action, you must assign the following policy to the IAM Automation assume role. For more information about the assume role, see Task 1: Create a service role for Automation.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "sqs:*",
            "cloudformation:CreateStack",
            "cloudformation:DescribeStacks"
         ],
         "Resource":"*"
      }
   ]
}
```

`aws:createTags` – Create tags for Amazon resources

Creates new tags for Amazon Elastic Compute Cloud (Amazon EC2) instances or Amazon Systems Manager managed instances.

> **Note**
>
> The `aws:createTags` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports most Amazon EC2 `CreateTags` and Systems Manager `AddTagsToResource` parameters. For more information, see CreateTags and AddTagsToResource.

The following example shows how to tag an Amazon Machine Image (AMI) and an instance as production resources for a particular department.

YAML

```
name: createTags
action: aws:createTags
maxAttempts: 3
onFailure: Abort
inputs:
  ResourceType: EC2
  ResourceIds:
  - ami-9a3768fa
  - i-02951acd5111a8169
  Tags:
  - Key: production
    Value: ''
  - Key: department
    Value: devops
```

JSON

```
{
    "name": "createTags",
    "action": "aws:createTags",
```

```
    "maxAttempts": 3,
    "onFailure": "Abort",
    "inputs": {
        "ResourceType": "EC2",
        "ResourceIds": [
            "ami-9a3768fa",
            "i-02951acd5111a8169"
        ],
        "Tags": [
            {
                "Key": "production",
                "Value": ""
            },
            {
                "Key": "department",
                "Value": "devops"
            }
        ]
    }
}
```

ResourceIds

The IDs of the resource(s) to be tagged. If resource type isn't "EC2", this field can contain only a single item.

Type: String List

Required: Yes

Tags

The tags to associate with the resource(s).

Type: List of Maps

Required: Yes

ResourceType

The type of resource(s) to be tagged. If not supplied, the default value of "EC2" is used.

Type: String

Required: No

Valid Values: EC2 | ManagedInstance | MaintenanceWindow | Parameter

Output

None

aws:deleteImage – Delete an Amazon Machine Image

Deletes the specified Amazon Machine Image (AMI) and all related snapshots.

> **Note**
>
> The aws:deleteImage action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports only one parameter. For more information, see the documentation for DeregisterImage and DeleteSnapshot.

YAML

```
name: deleteMyImage
action: aws:deleteImage
maxAttempts: 3
timeoutSeconds: 180
onFailure: Abort
inputs:
  ImageId: ami-12345678
```

JSON

```
{
    "name": "deleteMyImage",
    "action": "aws:deleteImage",
    "maxAttempts": 3,
    "timeoutSeconds": 180,
    "onFailure": "Abort",
```

```
    "inputs": {
        "ImageId": "ami-12345678"
    }
}
```

ImageId

The ID of the image to be deleted.

Type: String

Required: Yes

Output

None

`aws:deleteStack` – Delete an Amazon CloudFormation stack

Deletes an Amazon CloudFormation stack.

> **Note**
>
> The `aws:deleteStack` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

YAML

```
name: deleteStack
action: aws:deleteStack
maxAttempts: 1
onFailure: Abort
inputs:
  StackName: "{{stackName}}"
```

JSON

```
{
```

```
   "name":"deleteStack",
   "action":"aws:deleteStack",
   "maxAttempts":1,
   "onFailure":"Abort",
   "inputs":{
      "StackName":"{{stackName}}"
   }
}
```

ClientRequestToken

A unique identifier for this `DeleteStack` request. Specify this token if you plan to retry requests so that CloudFormation knows that you aren't attempting to delete a stack with the same name. You can retry `DeleteStack` requests to verify that CloudFormation received them.

Type: String

Length Constraints: Minimum length of 1. Maximum length of 128.

Pattern: [a-zA-Z][-a-zA-Z0-9]*

Required: No

RetainResources.member.N

This input applies only to stacks that are in a `DELETE_FAILED` state. A list of logical resource IDs for the resources you want to retain. During deletion, CloudFormation deletes the stack, but doesn't delete the retained resources.

Retaining resources is useful when you can't delete a resource, such as a non-empty S3 bucket, but you want to delete the stack.

Type: array of strings

Required: No

RoleARN

The Amazon Resource Name (ARN) of an Amazon Identity and Access Management (IAM) role that CloudFormation assumes to create the stack. CloudFormation uses the role's credentials to make calls on your behalf. CloudFormation always uses this role for all future operations on the stack. As long as users have permission to operate on the stack, CloudFormation uses this

role even if the users don't have permission to pass it. Make sure that the role grants the least amount of privileges.

If you don't specify a value, CloudFormation uses the role that was previously associated with the stack. If no role is available, CloudFormation uses a temporary session that is generated from your user credentials.

Type: String

Length Constraints: Minimum length of 20. Maximum length of 2048.

Required: No

StackName

The name or the unique stack ID that is associated with the stack.

Type: String

Required: Yes

Security considerations

Before you can use the `aws:deleteStack` action, you must assign the following policy to the IAM Automation assume role. For more information about the assume role, see Task 1: Create a service role for Automation.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "sqs:*",
            "cloudformation:DeleteStack",
            "cloudformation:DescribeStacks"
         ],
         "Resource":"*"
      }
   ]
```

```
}
```

`aws:executeAutomation` – Run another automation

Runs a secondary automation by calling a secondary runbook. With this action, you can create runbooks for your most common operations, and reference those runbooks during an automation. This action can simplify your runbooks by removing the need to duplicate steps across similar runbooks.

The secondary automation runs in the context of the user who initiated the primary automation. This means that the secondary automation uses the same Amazon Identity and Access Management (IAM) role or user as the user who started the first automation.

> **Important**
>
> If you specify parameters in a secondary automation that use an assume role (a role that uses the iam:passRole policy), then the user or role that initiated the primary automation must have permission to pass the assume role specified in the secondary automation. For more information about setting up an assume role for Automation, see Create the service roles for Automation using the console.

Input

YAML

```
name: Secondary_Automation
action: aws:executeAutomation
maxAttempts: 3
timeoutSeconds: 3600
onFailure: Abort
inputs:
  DocumentName: secondaryAutomation
  RuntimeParameters:
    instanceIds:
    - i-1234567890abcdef0
```

JSON

```
{
```

```
   "name":"Secondary_Automation",
   "action":"aws:executeAutomation",
   "maxAttempts":3,
   "timeoutSeconds":3600,
   "onFailure":"Abort",
   "inputs":{
      "DocumentName":"secondaryAutomation",
      "RuntimeParameters":{
         "instanceIds":[
            "i-1234567890abcdef0"
         ]
      }
   }
}
```

DocumentName

The name of the secondary runbook to run during the step. For runbooks in the same Amazon Web Services account, specify the runbook name. For runbooks shared from a different Amazon Web Services account, specify the Amazon Resource Name (ARN) of the runbook. For information about using shared runbooks, see Using shared SSM documents.

Type: String

Required: Yes

DocumentVersion

The version of the secondary runbook to run. If not specified, Automation runs the default runbook version.

Type: String

Required: No

MaxConcurrency

The maximum number of targets allowed to run this task in parallel. You can specify a number, such as 10, or a percentage, such as 10%.

Type: String

Required: No

MaxErrors

The number of errors that are allowed before the system stops running the automation on additional targets. You can specify either an absolute number of errors, for example 10, or a percentage of the target set, for example 10%. If you specify 3, for example, the system stops running the automation when the fourth error is received. If you specify 0, then the system stops running the automation on additional targets after the first error result is returned. If you run an automation on 50 resources and set `MaxErrors` to 10%, then the system stops running the automation on additional targets when the sixth error is received.

Automations that are already running when the `MaxErrors` threshold is reached are allowed to complete, but some of these automations may fail as well. If you need to make sure that there won't be more failed automations than the specified `MaxErrors`, set `MaxConcurrency` to 1 so the automations proceed one at a time.

Type: String

Required: No

RuntimeParameters

Required parameters for the secondary runbook. The mapping uses the following format: {"parameter1" : "value1", "parameter2" : "value2" }

Type: Map

Required: No

Tags

Optional metadata that you assign to a resource. You can specify a maximum of five tags for an automation.

Type: MapList

Required: No

TargetLocations

A location is a combination of Amazon Web Services Regions and/or Amazon Web Services accounts where you want to run the automation. A minimum number of 1 item must be specified and a maximum number of 100 items can be specified. When specifying a value for this parameter, outputs aren't returned to the parent automation. If needed, you must make subsequent calls to API operations to retrieve the output from child automations.

Type: MapList

Required: No

TargetMaps

A list of key-value mappings of document parameters to target resources. Both `Targets` and `TargetMaps` can't be specified together.

Type: MapList

Required: No

TargetParameterName

The name of the parameter used as the target resource for the rate-controlled automation. Required if you specify `Targets`.

Type: String

Required: No

Targets

A list of key-value mappings to target resources. Required if you specify `TargetParameterName`.

Type: MapList

Required: No

Output

Output

The output generated by the secondary automation. You can reference the output by using the following format: *`Secondary_Automation_Step_Name`*.Output

Type: StringList

Here is an example:

```
- name: launchNewWindowsInstance
  action: 'aws:executeAutomation'
```

```
  onFailure: Abort
  inputs:
    DocumentName: launchWindowsInstance
  nextStep: getNewInstanceRootVolume
- name: getNewInstanceRootVolume
  action: 'aws:executeAwsApi'
  onFailure: Abort
  inputs:
    Service: ec2
    Api: DescribeVolumes
    Filters:
    - Name: attachment.device
      Values:
      - /dev/sda1
    - Name: attachment.instance-id
      Values:
      - '{{launchNewWindowsInstance.Output}}'
  outputs:
  - Name: rootVolumeId
    Selector: '$.Volumes[0].VolumeId'
    Type: String
  nextStep: snapshotRootVolume
- name: snapshotRootVolume
  action: 'aws:executeAutomation'
  onFailure: Abort
  inputs:
    DocumentName: AWS-CreateSnapshot
    RuntimeParameters:
    VolumeId:
    - '{{getNewInstanceRootVolume.rootVolumeId}}'
    Description:
    - 'Initial root snapshot for {{launchNewWindowsInstance.Output}}'
```

ExecutionId

The ID of the secondary automation.

Type: String

Status

The status of the secondary automation.

Type: String

`aws:executeAwsApi` – Call and run Amazon API operations

Calls and runs Amazon API operations. Most API operations are supported, although not all API operations have been tested. Streaming API operations, such as the GetObject operation, aren't supported. If you're not sure if an API operation you want to use is a streaming operation, review the Boto3 documentation for the service to determine if an API requires streaming inputs or outputs. We regularly update the Boto3 version used by this action. However, following the release of a new Boto3 version it can take up to a few weeks for changes to be reflected in this action. Each `aws:executeAwsApi` action can run up to a maximum duration of 25 seconds. For more examples of how to use this action, see Additional runbook examples.

> **Note**
>
> The `aws:executeAwsApi` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Inputs

Inputs are defined by the API operation that you choose.

YAML

```
action: aws:executeAwsApi
inputs:
  Service: The official namespace of the service
  Api: The API operation or method name
  API operation inputs or parameters: A value
outputs: # These are user-specified outputs
- Name: The name for a user-specified output key
  Selector: A response object specified by using jsonpath format
  Type: The data type
```

JSON

```
{
   "action":"aws:executeAwsApi",
   "inputs":{
      "Service":"The official namespace of the service",
      "Api":"The API operation or method name",
      "API operation inputs or parameters":"A value"
```

```
    },
    "outputs":[ These are user-specified outputs
       {
          "Name":"The name for a user-specified output key",
          "Selector":"A response object specified by using JSONPath format",
          "Type":"The data type"
       }
    ]
}
```

Service

The Amazon Web Services service namespace that contains the API operation that you want to run. You can view a list of supported Amazon Web Services service namespaces in Available services of the Amazon SDK for Python (Boto3). The namespace can be found in the **Client** section. For example, the namespace for Systems Manager is `ssm`. The namespace for Amazon Elastic Compute Cloud (Amazon EC2) is `ec2`.

Type: String

Required: Yes

Api

The name of the API operation that you want to run. You can view the API operations (also called methods) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: Amazon RDS methods.

Type: String

Required: Yes

API operation inputs

One or more API operation inputs. You can view the available inputs (also called parameters) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to see the available parameters, such as **DBInstanceIdentifier**, **Name**, and **Values**.

YAML

```
inputs:
  Service: The official namespace of the service
  Api: The API operation name
  API input 1: A value
  API Input 2: A value
  API Input 3: A value
```

JSON

```
"inputs":{
      "Service":"The official namespace of the service",
      "Api":"The API operation name",
      "API input 1":"A value",
      "API Input 2":"A value",
      "API Input 3":"A value"
}
```

Type: Determined by chosen API operation

Required: Yes

Outputs

Outputs are specified by the user based on the response from the chosen API operation.

Name

A name for the output.

Type: String

Required: Yes

Selector

The JSONPath to a specific attribute in the response object. You can view the response objects by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the

describe_db_instances method and scroll down to the **Response Structure** section. **DBInstances** is listed as a response object.

Type: Integer, Boolean, String, StringList, StringMap, or MapList

Required: Yes

Type

The data type for the response element.

Type: Varies

Required: Yes

`aws:executeScript` – Run a script

Runs the Python or PowerShell script provided using the specified runtime and handler. Each `aws:executeScript` action can run up to a maximum duration of 600 seconds (10 minutes). You can limit the timeout by specifying the `timeoutSeconds` parameter for an `aws:executeScript` step.

Use return statements in your function to add outputs to your output payload. For examples of defining outputs for your `aws:executeScript` action, see Example 2: Scripted runbook. You can also send the output from `aws:executeScript` actions in your runbooks to the Amazon CloudWatch Logs log group you specify. For more information, see Logging Automation action output with CloudWatch Logs.

If you want to send output from `aws:executeScript` actions to CloudWatch Logs, or if the scripts you specify for `aws:executeScript` actions call Amazon API operations, an Amazon Identity and Access Management (IAM) service role (or assume role) is always required to run the runbook.

> **Note**
>
> The `aws:executeScript` action does not support automatic throttling retry. If your script makes Amazon API calls that might be throttled, you must implement your own retry logic in your script code.

The `aws:executeScript` action contains the following preinstalled PowerShell Core modules:

- Microsoft.PowerShell.Host
- Microsoft.PowerShell.Management
- Microsoft.PowerShell.Security
- Microsoft.PowerShell.Utility
- PackageManagement
- PowerShellGet

To use PowerShell Core modules that aren't preinstalled, your script must install the module with the `-Force` flag, as shown in the following command. The `AWSPowerShell.NetCore` module isn't supported. Replace *`ModuleName`* with the module you want to install.

```
Install-Module ModuleName -Force
```

To use PowerShell Core cmdlets in your script, we recommend using the `AWS.Tools` modules, as shown in the following commands. Replace each *`example resource placeholder`* with your own information.

- Amazon S3 cmdlets.

  ```
  Install-Module AWS.Tools.S3 -Force
  Get-S3Bucket -BucketName amzn-s3-demo-bucket
  ```

- Amazon EC2 cmdlets.

  ```
  Install-Module AWS.Tools.EC2 -Force
  Get-EC2InstanceStatus -InstanceId instance-id
  ```

- Common, or service independent Amazon Tools for Windows PowerShell cmdlets.

  ```
  Install-Module AWS.Tools.Common -Force
  Get-AWSRegion
  ```

If your script initializes new objects in addition to using PowerShell Core cmdlets, you must also import the module as shown in the following command.

```
Install-Module AWS.Tools.EC2 -Force
Import-Module AWS.Tools.EC2
```

```
$tag = New-Object Amazon.EC2.Model.Tag
$tag.Key = "Tag"
$tag.Value = "TagValue"

New-EC2Tag -Resource i-02573cafcfEXAMPLE -Tag $tag
```

For examples of installing and importing `AWS.Tools` modules, and using PowerShell Core cmdlets in runbooks, see Visual design experience for Automation runbooks.

Input

Provide the information required to run your script. Replace each *example resource placeholder* with your own information.

> **Note**
>
> The attachment for a Python script can be a .py file or a .zip file that contains the script. PowerShell scripts must be stored in .zip files.

YAML

```
action: "aws:executeScript"
inputs:
 Runtime: runtime
 Handler: "functionName"
 InputPayload:
  scriptInput: '{{parameterValue}}'
 Script: |-
   def functionName(events, context):
   ...
 Attachment: "scriptAttachment.zip"
```

JSON

```
{
    "action": "aws:executeScript",
    "inputs": {
        "Runtime": "runtime",
        "Handler": "functionName",
        "InputPayload": {
```

```
            "scriptInput": "{{parameterValue}}"
        },
        "Attachment": "scriptAttachment.zip"
    }
}
```

Runtime

The runtime language to be used for running the provided script. `aws:executeScript` supports the runtimes in the following table.

Runtime name	Runtime value for *runtime* input
Python 3.12	**python3.12**
Python 3.11	**python3.11**
Python 3.10	**python3.10**
PowerShell 7.4 (`dotnet8`)	**PowerShell 7.4**

Type: String

Required: Yes

> **Note**
>
> For python runtimes, the environment provides 512MB of memory and 512MB of disk space. For PowerShell runtimes, the environment provides 1024MB of memory and 512MB of disk space.

Handler

The name of your function. You must make sure the function defined in the handler has two parameters, `events` and `context`. The PowerShell runtime does not support this parameter.

Type: String

Required: Yes (Python) | Not supported (PowerShell)

InputPayload

A JSON or YAML object that will be passed to the first parameter of the handler. This can be used to pass input data to the script.

Type: String

Required: No

Python

```
description: Tag an instance
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
    AutomationAssumeRole:
        type: String
        description: '(Required) The Amazon Resource Name (ARN) of the IAM role
 that allows Automation to perform the actions on your behalf. If no role is
 specified, Systems Manager Automation uses your IAM permissions to operate this
 runbook.'
    InstanceId:
        type: String
        description: (Required) The ID of the EC2 instance you want to tag.
mainSteps:
  - name: tagInstance
    action: 'aws:executeScript'
    inputs:
        Runtime: "python3.11"
        Handler: tagInstance
        InputPayload:
            instanceId: '{{InstanceId}}'
        Script: |-
          def tagInstance(events,context):
            import boto3

            #Initialize client
            ec2 = boto3.client('ec2')
            instanceId = events['instanceId']
            tag = {
                "Key": "Env",
                "Value": "ExamplePython"
            }
            print(f"Adding tag {tag} to instance id {instanceId}")
```

```
            ec2.create_tags(
                Resources=[instanceId],
                Tags=[tag]
            )
            return tag
    outputs:
      - Type: String
        Name: TagKey
        Selector: $.Payload.Key
outputs:
  - tagInstance.TagKey
```

PowerShell

```
description: Tag an instance
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: (Required) The Amazon Resource Name (ARN) of the IAM role
 that allows Automation to perform the actions on your behalf. If no role is
 specified, Systems Manager Automation uses your IAM permissions to operate this
 runbook.
  InstanceId:
    type: String
    description: (Required) The ID of the EC2 instance you want to tag.
mainSteps:
  - name: tagInstance
    action: aws:executeScript
    isEnd: true
    inputs:
      Runtime: PowerShell 7.4
      InputPayload:
        instanceId: '{{InstanceId}}'
      Script: |-
        Install-Module AWS.Tools.EC2 -Force
        Import-Module AWS.Tools.EC2

        $input = $env:InputPayload | ConvertFrom-Json

        $tag = New-Object Amazon.EC2.Model.Tag
        $tag.Key = "Env"
```

```
        $tag.Value = "ExamplePowerShell"

        Write-Information "Adding tag key: $($tag.Key) and value: $($tag.Value)
 to instance id $($input.instanceId)"
        New-EC2Tag -Resource $input.instanceId -Tag $tag

        return $tag
    outputs:
      - Type: String
        Name: TagKey
        Selector: $.Payload.Key
outputs:
  - tagInstance.TagKey
```

Script

An embedded script that you want to run during the automation.

Type: String

Required: No (Python) | Yes (PowerShell)

Attachment

The name of a standalone script file or .zip file that can be invoked by the action. Specify the same value as the `Name` of the document attachment file you specify in the `Attachments` request parameter. For more information, see Attachments in the *Amazon Systems Manager API Reference*. If you're providing a script using an attachment, you must also define a `files` section in the top-level elements of your runbook. For more information, see Schema version 0.3.

To invoke a file for Python, use the `filename.method_name` format in `Handler`.

> **Note**
>
> The attachment for a Python script can be a .py file or a .zip file that contains the script. PowerShell scripts must be stored in .zip files.

When including Python libraries in your attachment, we recommend adding an empty `__init__.py` file in each module directory. This lets you import the modules from the library in your attachment within your script content. For example: `from library import module`

Type: String

Required: No

Output

Payload

The JSON representation of the object returned by your function. Up to 100KB is returned. If you output a list, a maximum of 100 items is returned.

Using attachments with aws:executeScript

Attachments provide a powerful way to package and reuse complex scripts, multiple modules, and external dependencies with your `aws:executeScript` actions. Use attachments when you need to:

- Package multiple Python modules or PowerShell scripts together.
- Reuse the same script logic across multiple runbooks.
- Include external libraries or dependencies with your scripts.
- Keep your runbook definition clean by separating complex script logic.
- Share script packages across teams or automation workflows.

Attachment structure and packaging

You can attach either single files or zip packages containing multiple files. The structure depends on your use case:

Single file attachments

For simple scripts, you can attach a single `.py` file (Python) or a `.zip` file containing a single PowerShell script.

Multi-module packages

For complex automation that requires multiple modules, create a zip package with the following recommended structure:

```
my-automation-package.zip
### main.py                    # Entry point script
### utils/
#   ### __init__.py           # Required for Python module imports
#   ### helper_functions.py   # Utility functions
#   ### aws_operations.py     # AWS-specific operations
### config/
#   ### __init__.py
#   ### settings.py           # Configuration settings
### requirements.txt          # Optional: document dependencies
```

> **Important**
>
> For Python packages, you must include an empty `__init__.py` file in each directory that contains Python modules. This lets you import modules using standard Python import syntax like `from utils import helper_functions`.

PowerShell package structure

PowerShell attachments must be packaged in zip files with the following structure:

```
my-powershell-package.zip
### Main.ps1                   # Entry point script
### Modules/
#   ### HelperFunctions.ps1    # Utility functions
#   ### AWSOperations.ps1      # AWS-specific operations
### Config/
    ### Settings.ps1           # Configuration settings
```

Creating runbooks with attachments

Follow these steps to create runbooks that use attachments:

1. **Upload your attachment to Amazon S3**

   Upload your script file or zip package to an S3 bucket that your automation role can access. Note the S3 URI for use in the next step.

   ```
   aws s3 cp my-automation-package.zip s3://my-automation-bucket/scripts/
   ```

2. **Calculate the attachment checksum**

   Calculate the SHA-256 checksum of your attachment file for security verification:

```
# Linux/macOS
shasum -a 256 my-automation-package.zip

# Windows PowerShell
Get-FileHash -Algorithm SHA256 my-automation-package.zip
```

3. **Define the files section in your runbook**

   Add a `files` section at the top level of your runbook to reference your attachment:

```
files:
  my-automation-package.zip:
    checksums:
      sha256: "your-calculated-checksum-here"
```

4. **Reference the attachment in your executeScript step**

   Use the `Attachment` parameter to reference your uploaded file:

```
- name: runMyScript
  action: aws:executeScript
  inputs:
    Runtime: python3.11
    Handler: main.process_data
    Attachment: my-automation-package.zip
    InputPayload:
      inputData: "{{InputParameter}}"
```

aws:executeScript attachment examples

The following examples demonstrate different ways to use attachments with the `aws:executeScript` action.

Example 1: Single file attachment

This example shows how to use a single Python file as an attachment to process EC2 instance data.

Attachment file: process_instance.py

Create a Python file with the following content:

```
import boto3
import json

def process_instance_data(events, context):
    """Process EC2 instance data and return formatted results."""
    try:
        instance_id = events.get('instanceId')
        if not instance_id:
            raise ValueError("instanceId is required")

        ec2 = boto3.client('ec2')

        # Get instance details
        response = ec2.describe_instances(InstanceIds=[instance_id])
        instance = response['Reservations'][0]['Instances'][0]

        # Format the response
        result = {
            'instanceId': instance_id,
            'instanceType': instance['InstanceType'],
            'state': instance['State']['Name'],
            'availabilityZone': instance['Placement']['AvailabilityZone'],
            'tags': {tag['Key']: tag['Value'] for tag in instance.get('Tags', [])}
        }

        print(f"Successfully processed instance {instance_id}")
        return result

    except Exception as e:
        print(f"Error processing instance: {str(e)}")
        raise
```

Complete runbook

Here's the complete runbook that uses the single file attachment:

```
description: Process EC2 instance data using single file attachment
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
```

```
    type: String
    description: (Required) IAM role for automation execution
  InstanceId:
    type: String
    description: (Required) EC2 instance ID to process

files:
  process_instance.py:
    checksums:
      sha256: "abc123def456..."

mainSteps:
  - name: processInstance
    action: aws:executeScript
    inputs:
      Runtime: python3.11
      Handler: process_instance.process_instance_data
      Attachment: process_instance.py
      InputPayload:
        instanceId: '{{InstanceId}}'
    outputs:
      - Type: StringMap
        Name: InstanceData
        Selector: $.Payload

outputs:
  - processInstance.InstanceData
```

Example 2: Multi-module package

This example demonstrates using a zip package containing multiple Python modules for complex S3 bucket operations.

Package structure

Create a zip package with the following structure:

```
s3-operations.zip
### main.py
### utils/
#   ### __init__.py
#   ### s3_helper.py
#   ### validation.py
```

```
### config/
    ### __init__.py
    ### settings.py
```

main.py (entry point)

The main script that orchestrates the operations:

```
from utils.s3_helper import S3Operations
from utils.validation import validate_bucket_name
from config.settings import get_default_settings

def cleanup_s3_bucket(events, context):
    """Clean up S3 bucket based on specified criteria."""
    try:
        bucket_name = events.get('bucketName')
        max_age_days = events.get('maxAgeDays', 30)

        # Validate inputs
        if not validate_bucket_name(bucket_name):
            raise ValueError(f"Invalid bucket name: {bucket_name}")

        # Initialize S3 operations
        s3_ops = S3Operations()
        settings = get_default_settings()

        # Perform cleanup
        deleted_objects = s3_ops.delete_old_objects(
            bucket_name,
            max_age_days,
            settings['dry_run']
        )

        result = {
            'bucketName': bucket_name,
            'deletedCount': len(deleted_objects),
            'deletedObjects': deleted_objects[:10],  # Return first 10 for brevity
            'dryRun': settings['dry_run']
        }

        print(f"Cleanup completed for bucket {bucket_name}")
        return result

    except Exception as e:
```

```
        print(f"Error during S3 cleanup: {str(e)}")
        raise
```

Troubleshooting aws:executeScript attachments

Use the following guidance to resolve common issues with `aws:executeScript` attachments:

Module import errors

If you receive import errors when using multi-module packages:

- Make sure you have included an empty `__init__.py` file in each directory containing Python modules.
- Verify that your import statements match the actual file and directory structure in your zip package.
- Use relative imports (e.g., `from .utils import helper`) or absolute imports (e.g., `from utils import helper`) consistently.

Attachment not found errors

If your automation fails to find the attachment:

- Verify that the `Attachment` parameter value exactly matches the key in your `files` section.
- Check that your S3 bucket path and file name are correct in the `files` section.
- Make sure your automation role has `s3:GetObject` permission for the attachment S3 location.
- Verify that the checksum in your runbook matches the actual file checksum.

Handler function errors

If you receive handler-related errors:

- For Python: Use the format `filename.function_name` in the `Handler` parameter (e.g., `main.process_data`).
- Make sure your handler function accepts exactly two parameters: `events` and `context`.
- For PowerShell: Do not specify a `Handler` parameter; the script runs directly.

Script execution failures

If your script fails during execution:

- Check the automation execution history for detailed error messages and stack traces.
- Use `print()` statements (Python) or `Write-Information` (PowerShell) to add debugging output.
- Verify that all required Amazon permissions are granted to your automation role.
- Test your script logic locally before packaging it as an attachment.

Exit codes and error handling

To properly handle errors and return exit codes:

- In Python: Use `raise Exception("error message")` to indicate script failure.
- In PowerShell: Use `throw "error message"` or `Write-Error` to indicate failure.
- Return structured data from your functions to provide detailed success/failure information.
- Use try-catch blocks to handle exceptions gracefully and provide meaningful error messages.

`aws:executeStateMachine` – Run an Amazon Step Functions state machine

Runs an Amazon Step Functions state machine.

> **Note**
>
> The `aws:executeStateMachine` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports most parameters for the Step Functions StartExecution API operation.

Required Amazon Identity and Access Management (IAM) permissions

- `states:DescribeExecution`
- `states:StartExecution`
- `states:StopExecution`

YAML

```
name: executeTheStateMachine
action: aws:executeStateMachine
inputs:
  stateMachineArn: StateMachine_ARN
  input: '{"parameters":"values"}'
  name: name
```

JSON

```
{
    "name": "executeTheStateMachine",
    "action": "aws:executeStateMachine",
    "inputs": {
        "stateMachineArn": "StateMachine_ARN",
        "input": "{\"parameters\":\"values\"}",
        "name": "name"
    }
}
```

stateMachineArn

The Amazon Resource Name (ARN) of the Step Functions state machine.

Type: String

Required: Yes

name

The name of the execution.

Type: String

Required: No

input

A string that contains the JSON input data for the execution.

Type: String

Required: No

Outputs

The following outputs are predefined for this action.

executionArn

The ARN of the execution.

Type: String

input

The string that contains the JSON input data of the execution. Length constraints apply to the payload size, and are expressed as bytes in UTF-8 encoding..

Type: String

name

The name of the execution.

Type: String

output

The JSON output data of the execution. Length constraints apply to the payload size, and are expressed as bytes in UTF-8 encoding.

Type: String

startDate

The date the execution is started.

Type: String

stateMachineArn

The ARN of the executed stated machine.

Type: String

status

The current status of the execution.

Type: String

stopDate

If the execution has already ended, the date the execution stopped.

Type: String

`aws:invokeWebhook` – Invoke an Automation webhook integration

Invokes the specified Automation webhook integration. For information about creating Automation integrations, see Creating webhook integrations for Automation.

> **Note**
>
> The `aws:invokeWebhook` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

> **Note**
>
> To use the `aws:invokeWebhook` action, your user or service role must allow the following actions:
>
> - ssm:GetParameter
> - kms:Decrypt
>
> Permission for the Amazon Key Management Service (Amazon KMS) `Decrypt` operation is only required if you use a customer managed key to encrypt the parameter for your integration.

Input

Provide the information for the Automation integration you want to invoke.

YAML

```
action: "aws:invokeWebhook"
inputs:
 IntegrationName: "exampleIntegration"
 Body: "Request body"
```

JSON

```
{
    "action": "aws:invokeWebhook",
    "inputs": {
        "IntegrationName": "exampleIntegration",
        "Body": "Request body"
    }
}
```

IntegrationName

The name of the Automation integration. For example, `exampleIntegration`. The integration you specify must already exist.

Type: String

Required: Yes

Body

The payload you want to send when your webhook integration is invoked.

Type: String

Required: No

Output

Response

The text received from the webhook provider response.

ResponseCode

The HTTP status code received from the webhook provider response.

`aws:invokeLambdaFunction` – Invoke an Amazon Lambda function

Invokes the specified Amazon Lambda function.

> **Note**
>
> Each `aws:invokeLambdaFunction` action can run up to a maximum duration of 300 seconds (5 minutes). You can limit the timeout by specifying the `timeoutSeconds` parameter for an `aws:invokeLambdaFunction` step.

> **Note**
>
> The `aws:invokeLambdaFunction` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

This action supports most invoked parameters for the Lambda service. For more information, see Invoke.

YAML

```
name: invokeMyLambdaFunction
action: aws:invokeLambdaFunction
maxAttempts: 3
timeoutSeconds: 120
onFailure: Abort
inputs:
  FunctionName: MyLambdaFunction
```

JSON

```
{
    "name": "invokeMyLambdaFunction",
    "action": "aws:invokeLambdaFunction",
    "maxAttempts": 3,
    "timeoutSeconds": 120,
    "onFailure": "Abort",
    "inputs": {
```

```
        "FunctionName": "MyLambdaFunction"
    }
}
```

FunctionName

The name of the Lambda function. This function must exist.

Type: String

Required: Yes

Qualifier

The function version or alias name.

Type: String

Required: No

InvocationType

The invocation type. The default value is `RequestResponse`.

Type: String

Valid values: `Event` | `RequestResponse` | `DryRun`

Required: No

LogType

If the default value is `Tail`, the invocation type must be `RequestResponse`. Lambda returns the last 4 KB of log data produced by your Lambda function, base64-encoded.

Type: String

Valid values: `None` | `Tail`

Required: No

ClientContext

The client-specific information.

Required: No

InputPayload

A YAML or JSON object that is passed to the first parameter of the handler. You can use this input to pass data to the function. This input provides more flexibility and support than the legacy `Payload` input. If you define both `InputPayload` and `Payload` for the action, `InputPayload` takes precedence and the `Payload` value is not used.

Type: StringMap

Required: No

Payload

A JSON string that's passed to the first parameter of the handler. This can be used to pass input data to the function. We recommend using `InputPayload` input for added functionality.

Type: String

Required: No

Output

StatusCode

The HTTP status code.

FunctionError

If present, it indicates that an error occurred while executing the function. Error details are included in the response payload.

LogResult

The base64-encoded logs for the Lambda function invocation. Logs are present only if the invocation type is `RequestResponse`, and the logs were requested.

Payload

The JSON representation of the object returned by the Lambda function. Payload is present only if the invocation type is `RequestResponse`.

The following is a portion from the `AWS-PatchInstanceWithRollback` runbook demonstrating how to reference outputs from the `aws:invokeLambdaFunction` action.

YAML

```
- name: IdentifyRootVolume
  action: aws:invokeLambdaFunction
  inputs:
    FunctionName: "IdentifyRootVolumeLambda-{{automation:EXECUTION_ID}}"
    Payload: '{"InstanceId": "{{InstanceId}}"}'
- name: PrePatchSnapshot
  action: aws:executeAutomation
  inputs:
    DocumentName: "AWS-CreateSnapshot"
    RuntimeParameters:
      VolumeId: "{{IdentifyRootVolume.Payload}}"
      Description: "ApplyPatchBaseline restoration case contingency"
```

JSON

```
{
    "name": "IdentifyRootVolume",
    "action": "aws:invokeLambdaFunction",
    "inputs": {
      "FunctionName": "IdentifyRootVolumeLambda-{{automation:EXECUTION_ID}}",
      "Payload": "{\"InstanceId\": \"{{InstanceId}}\"}"
    }
  },
  {
    "name": "PrePatchSnapshot",
    "action": "aws:executeAutomation",
    "inputs": {
      "DocumentName": "AWS-CreateSnapshot",
      "RuntimeParameters": {
        "VolumeId": "{{IdentifyRootVolume.Payload}}",
        "Description": "ApplyPatchBaseline restoration case contingency"
      }
    }
  }
```

aws:loop – Iterate over steps in an automation

This action iterates over a subset of steps in an automation runbook. You can choose a `do while` or `for each` style loop. To construct a `do while` loop, use the `LoopCondition` input parameter. To construct a `for each` loop, use the `Iterators` and `IteratorDataType` input parameters.

When using an `aws:loop` action, only specify either the `Iterators` or `LoopCondition` input parameter. The maximum number of iterations is 100.

The on`Cancel` property can only be used for steps defined within a loop. The on`Cancel` property isn't supported for the `aws:loop` action. The on`Failure` property can be used for an `aws:loop` action, however it will only be used if an unexpected error occurs causing the step to fail. If you define on`Failure` properties for the steps within a loop, the `aws:loop` action inherits those properties and reacts accordingly when a failure occurs.

Examples

The following are examples of how to construct the different types of loop actions.

do while

```
name: RepeatMyLambdaFunctionUntilOutputIsReturned
action: aws:loop
inputs:
    Steps:
    - name: invokeMyLambda
        action: aws:invokeLambdaFunction
        inputs:
        FunctionName: LambdaFunctionName
        outputs:
        - Name: ShouldRetry
            Selector: $.Retry
            Type: Boolean
    LoopCondition:
        Variable: "{{ invokeMyLambda.ShouldRetry }}"
        BooleanEquals: true
    MaxIterations: 3
```

for each

```
name: stopAllInstancesWithWaitTime
action: aws:loop
inputs:
    Iterators: "{{ DescribeInstancesStep.InstanceIds }}"
    IteratorDataType: "String"
    Steps:
    - name: stopOneInstance
        action: aws:changeInstanceState
        inputs:
```

```
        InstanceIds:
            - "{{stopAllInstancesWithWaitTime.CurrentIteratorValue}}"
        CheckStateOnly: false
        DesiredState: stopped
    - name: wait10Seconds
        action: aws:sleep
        inputs:
        Duration: PT10S
```

Input

The input is as follows.

Iterators

The list of items for the steps to iterate over. The maximum number of iterators is 100.

Type: StringList

Required: No

IteratorDataType

An optional parameter to specify the data type of the `Iterators`. A value for this parameter can be provided along with the `Iterators` input parameter. If you don't specify a value for this parameter and `Iterators`, then you must specify a value for the `LoopCondition` parameter.

Type: String

Valid values: Boolean | Integer | String | StringMap

Default: String

Required: No

LoopCondition

Consists of a `Variable` and an operator condition to evaluate. If you don't specify a value for this parameter, then you must specify values for the `Iterators` and `IteratorDataType` parameters. You can use complex operator evaluations by using a combination of `And`, `Not`, and `Or` operators. The condition is evaluated after the steps in the loop complete. If the condition is `true` and the `MaxIterations` value has not been reached, the steps in the loop run again. The operator conditions are as follows:

String operations

- StringEquals
- EqualsIgnoreCase
- StartsWith
- EndsWith
- Contains

Numeric operations

- NumericEquals
- NumericGreater
- NumericLesser
- NumericGreaterOrEquals
- NumericLesser
- NumericLesserOrEquals

Boolean operation

- BooleanEquals

Type: StringMap

Required: No

MaxIterations

The maximum number of times the steps in the loop run. Once the value specified for this input is reached, the loop stops running even if the `LoopCondition` is still `true` or if there are objects remaining in the `Iterators` parameter.

Type: Integer

Valid values: 1 - 100

Required: No

Steps

The list of steps to run in the loop. These function like a nested runbook. Within these steps you can access the current iterator value for a `for each` loop using the syntax `{{loopStepName.CurrentIteratorValue}}`. You can also access

an integer value of the current iteration for both loop types using the syntax `{{loopStepName.CurrentIteration}}`.

Type: List of steps

Required: Yes

Output

CurrentIteration

The current loop iteration as an integer. Iteration values start at 1.

Type: Integer

CurrentIteratorValue

The value of the current iterator as a string. This output is only present in `for each` loops.

Type: String

aws:pause – Pause an automation

This action pauses the automation. Once paused, the automation status is *Waiting*. To continue the automation, use the SendAutomationSignal API operation with the `Resume` signal type. We recommend using the `aws:sleep` or `aws:approve` action for more granular control of your workflows.

> **Note**
>
> The default timeout for this action is 7 days (604800 seconds) and the maximum value is 30 days (2592000 seconds). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:pause` step.

Input

The input is as follows.

YAML

```
name: pauseThis
```

```
action: aws:pause
timeoutSeconds: 1209600
inputs: {}
```

JSON

```
{
    "name": "pauseThis",
    "action": "aws:pause",
    "timeoutSeconds": "1209600",
    "inputs": {}
}
```

Output

None

`aws:runCommand` – Run a command on a managed instance

Runs the specified commands.

> **Note**
>
> Automation only supports *output* of one Amazon Systems Manager Run Command action. A runbook can include multiple Run Command actions, but output is supported for only one action at a time.

Input

This action supports most send command parameters. For more information, see SendCommand.

YAML

```
- name: checkMembership
  action: 'aws:runCommand'
  inputs:
    DocumentName: AWS-RunPowerShellScript
    InstanceIds:
```

```
      - '{{InstanceIds}}'
    Parameters:
      commands:
        - (Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain
```

JSON

```
{
    "name": "checkMembership",
    "action": "aws:runCommand",
    "inputs": {
        "DocumentName": "AWS-RunPowerShellScript",
        "InstanceIds": [
            "{{InstanceIds}}"
        ],
        "Parameters": {
            "commands": [
                "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
            ]
        }
    }
}
```

DocumentName

If the Command type document is owned by you or Amazon, specify the name of the document. If you're using a document shared with you by a different Amazon Web Services account, specify the Amazon Resource Name (ARN) of the document. For more information about using shared documents, see Using shared SSM documents.

Type: String

Required: Yes

InstanceIds

The instance IDs where you want the command to run. You can specify a maximum of 50 IDs.

You can also use the pseudo parameter `{{RESOURCE_ID}}` in place of instance IDs to run the command on all instances in the target group. For more information about pseudo parameters, see Using pseudo parameters when registering maintenance window tasks.

Another alternative is to send commands to a fleet of instances by using the `Targets` parameter. The `Targets` parameter accepts Amazon Elastic Compute Cloud (Amazon EC2) tags. For more information about how to use the `Targets` parameter, see Run commands at scale.

Type: StringList

Required: No (If you don't specify InstanceIds or use the `{{RESOURCE_ID}}` pseudo parameter, then you must specify the `Targets` parameter.)

Targets

An array of search criteria that targets instances by using a Key,Value combination that you specify. `Targets` is required if you don't provide one or more instance IDs in the call. For more information about how to use the `Targets` parameter, see Run commands at scale.

Type: MapList (The schema of the map in the list must match the object.) For information, see Target in the *Amazon Systems Manager API Reference*.

Required: No (If you don't specify `Targets`, then you must specify InstanceIds or use the `{{RESOURCE_ID}}` pseudo parameter.)

Following is an example.

YAML

```
- name: checkMembership
  action: aws:runCommand
  inputs:
    DocumentName: AWS-RunPowerShellScript
    Targets:
      - Key: tag:Stage
        Values:
          - Gamma
          - Beta
      - Key: tag-key
        Values:
          - Suite
    Parameters:
      commands:
        - (Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain
```

JSON

```
{
```

```
    "name": "checkMembership",
    "action": "aws:runCommand",
    "inputs": {
        "DocumentName": "AWS-RunPowerShellScript",
        "Targets": [
            {
                "Key": "tag:Stage",
                "Values": [
                    "Gamma", "Beta"
                ]
            },
            {
                "Key": "tag:Application",
                "Values": [
                    "Suite"
                ]
            }
        ],
        "Parameters": {
            "commands": [
                "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
            ]
        }
    }
}
```

Parameters

The required and optional parameters specified in the document.

Type: Map

Required: No

CloudWatchOutputConfig

Configuration options for sending command output to Amazon CloudWatch Logs. For more information about sending command output to CloudWatch Logs, see Configuring Amazon CloudWatch Logs for Run Command.

Type: StringMap (The schema of the map must match the object. For more information, see CloudWatchOutputConfig in the *Amazon Systems Manager API Reference*).

Required: No

Following is an example.

YAML

```
- name: checkMembership
  action: aws:runCommand
  inputs:
    DocumentName: AWS-RunPowerShellScript
    InstanceIds:
      - "{{InstanceIds}}"
    Parameters:
      commands:
        - "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
    CloudWatchOutputConfig:
      CloudWatchLogGroupName: CloudWatchGroupForSSMAutomationService
      CloudWatchOutputEnabled: true
```

JSON

```
{
    "name": "checkMembership",
    "action": "aws:runCommand",
    "inputs": {
        "DocumentName": "AWS-RunPowerShellScript",
        "InstanceIds": [
            "{{InstanceIds}}"
        ],
        "Parameters": {
            "commands": [
                "(Get-WmiObject -Class Win32_ComputerSystem).PartOfDomain"
            ]
        },
        "CloudWatchOutputConfig" : {
                "CloudWatchLogGroupName":
 "CloudWatchGroupForSSMAutomationService",
                "CloudWatchOutputEnabled": true
        }
    }
}
```

Comment

User-defined information about the command.

Type: String

Required: No

DocumentHash

The hash for the document.

Type: String

Required: No

DocumentHashType

The type of the hash.

Type: String

Valid values: Sha256 | Sha1

Required: No

NotificationConfig

The configurations for sending notifications.

Required: No

OutputS3BucketName

The name of the S3 bucket for command output responses. Your managed node must have permissions for the S3 bucket to successfully log output.

Type: String

Required: No

OutputS3KeyPrefix

The prefix.

Type: String

Required: No

ServiceRoleArn

The ARN of the Amazon Identity and Access Management (IAM) role.

Type: String

Required: No

TimeoutSeconds

The amount of time in seconds to wait for a command to deliver to the Amazon Systems Manager SSM Agent on an instance. If the command isn't received by the SSM Agent on the instance before the value specified is reached, then the status of the command changes to `Delivery Timed Out`.

Type: Integer

Required: No

Valid values: 30-2592000

Output

CommandId

The ID of the command.

Status

The status of the command.

ResponseCode

The response code of the command. If the document you run has more than 1 step, a value isn't returned for this output.

Output

The output of the command. If you target a tag or multiple instances with your command, no output value is returned. You can use the `GetCommandInvocation` and `ListCommandInvocations` API operations to retrieve output for individual instances.

`aws:runInstances` – Launch an Amazon EC2 instance

Launches a new Amazon Elastic Compute Cloud (Amazon EC2) instance.

> **Note**
>
> The `aws:runInstances` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

The action supports most API parameters. For more information, see the RunInstances API documentation.

YAML

```
name: launchInstance
action: aws:runInstances
maxAttempts: 3
timeoutSeconds: 1200
onFailure: Abort
inputs:
  ImageId: ami-12345678
  InstanceType: t2.micro
  MinInstanceCount: 1
  MaxInstanceCount: 1
  IamInstanceProfileName: myRunCmdRole
  TagSpecifications:
  - ResourceType: instance
    Tags:
    - Key: LaunchedBy
      Value: SSMAutomation
    - Key: Category
      Value: HighAvailabilityFleetHost
```

JSON

```
{
   "name":"launchInstance",
   "action":"aws:runInstances",
   "maxAttempts":3,
   "timeoutSeconds":1200,
   "onFailure":"Abort",
   "inputs":{
      "ImageId":"ami-12345678",
```

```
      "InstanceType":"t2.micro",
      "MinInstanceCount":1,
      "MaxInstanceCount":1,
      "IamInstanceProfileName":"myRunCmdRole",
      "TagSpecifications":[
         {
            "ResourceType":"instance",
            "Tags":[
               {
                  "Key":"LaunchedBy",
                  "Value":"SSMAutomation"
               },
               {
                  "Key":"Category",
                  "Value":"HighAvailabilityFleetHost"
               }
            ]
         }
      ]
   }
}
```

AdditionalInfo

Reserved.

Type: String

Required: No

BlockDeviceMappings

The block devices for the instance.

Type: MapList

Required: No

ClientToken

The identifier to ensure idempotency of the request.

Type: String

Required: No

DisableApiTermination

Turns on or turns off instance API termination.

Type: Boolean

Required: No

EbsOptimized

Turns on or turns off Amazon Elastic Block Store (Amazon EBS) optimization.

Type: Boolean

Required: No

IamInstanceProfileArn

The Amazon Resource Name (ARN) of the Amazon Identity and Access Management (IAM) instance profile for the instance.

Type: String

Required: No

IamInstanceProfileName

The name of the IAM instance profile for the instance.

Type: String

Required: No

ImageId

The ID of the Amazon Machine Image (AMI).

Type: String

Required: Yes

InstanceInitiatedShutdownBehavior

Indicates whether the instance stops or terminates on system shutdown.

Type: String

Required: No

InstanceType

The instance type.

> **Note**
>
> If an instance type value isn't provided, the m1.small instance type is used.

Type: String

Required: No

KernelId

The ID of the kernel.

Type: String

Required: No

KeyName

The name of the key pair.

Type: String

Required: No

MaxInstanceCount

The maximum number of instances to be launched.

Type: String

Required: No

MetadataOptions

The metadata options for the instance. For more information, see InstanceMetadataOptionsRequest.

Type: StringMap

Required: No

MinInstanceCount

The minimum number of instances to be launched.

Type: String

Required: No

Monitoring

Turns on or turns off detailed monitoring.

Type: Boolean

Required: No

NetworkInterfaces

The network interfaces.

Type: MapList

Required: No

Placement

The placement for the instance.

Type: StringMap

Required: No

PrivateIpAddress

The primary IPv4 address.

Type: String

Required: No

RamdiskId

The ID of the RAM disk.

Type: String

Required: No

SecurityGroupIds

The IDs of the security groups for the instance.

Type: StringList

Required: No

SecurityGroups

The names of the security groups for the instance.

Type: StringList

Required: No

SubnetId

The subnet ID.

Type: String

Required: No

TagSpecifications

The tags to apply to the resources during launch. You can only tag instances and volumes at launch. The specified tags are applied to all instances or volumes that are created during launch. To tag an instance after it has been launched, use the `aws:createTags` – Create tags for Amazon resources action.

Type: MapList (For more information, see TagSpecification.)

Required: No

UserData

A script provided as a string literal value. If a literal value is entered, then it must be Base64-encoded.

Type: String

Required: No

Output

InstanceIds

The IDs of the instances.

InstanceStates

The current state of the instance.

`aws:sleep` – Delay an automation

Delays an automation for a specified amount of time. This action uses the International Organization for Standardization (ISO) 8601 date and time format. For more information about this date and time format, see ISO 8601.

Input

You can delay an automation for a specified duration.

YAML

```
name: sleep
action: aws:sleep
inputs:
  Duration: PT10M
```

JSON

```
{
   "name":"sleep",
   "action":"aws:sleep",
   "inputs":{
      "Duration":"PT10M"
   }
}
```

You can also delay an automation until a specified date and time. If the specified date and time has passed, the action proceeds immediately.

YAML

```
name: sleep
action: aws:sleep
inputs:
  Timestamp: '2020-01-01T01:00:00Z'
```

JSON

```
{
    "name": "sleep",
    "action": "aws:sleep",
    "inputs": {
        "Timestamp": "2020-01-01T01:00:00Z"
    }
}
```

Note

Automation supports a maximum delay of 604799 seconds (7 days).

Duration

An ISO 8601 duration. You can't specify a negative duration.

Type: String

Required: No

Timestamp

An ISO 8601 timestamp. If you don't specify a value for this parameter, then you must specify a value for the `Duration` parameter.

Type: String

Required: No

Output

None

`aws:updateVariable` – Updates a value for a runbook variable

This action updates a value for a runbook variable. The data type of the value must match the data type of the variable you want to update. Data type conversions aren't supported. The `onCancel` property isn't supported for the `aws:updateVariable` action.

Input

The input is as follows.

YAML

```
name: updateStringList
action: aws:updateVariable
inputs:
    Name: variable:variable name
    Value:
    - "1"
    - "2"
```

JSON

```
{
    "name": "updateStringList",
    "action": "aws:updateVariable",
    "inputs": {
        "Name": "variable:variable name",
        "Value": ["1","2"]
    }
}
```

Name

The name of the variable whose value you want to update. You must use the format `variable:variable name`

Type: String

Required: Yes

Value

The new value to assign to the variable. The value must match the data type of the variable. Data type conversions aren't supported.

Type: Boolean | Integer | MapList | String | StringList | StringMap

Required: Yes

Constraints:

- MapList can contain a maximum number of 200 items.
- Key lengths can be a minimum length of 1 and a maximum length of 50.
- StringList can be a minimum number of 0 items and a maximum number of 50 items.
- String lengths can be a minimum length of 1 and a maximum length of 512.

Output

None

`aws:waitForAwsResourceProperty` – Wait on an Amazon resource property

The `aws:waitForAwsResourceProperty` action allows your automation to wait for a specific resource state or event state before continuing the automation. For more examples of how to use this action, see Additional runbook examples.

> **Note**
>
> The default timeout value for this action is 3600 seconds (one hour). You can limit or extend the timeout by specifying the `timeoutSeconds` parameter for an `aws:waitForAwsResourceProperty` step. For more information and examples of how to use this action, see Handling timeouts in runbooks.

> **Note**
>
> The `aws:waitForAwsResourceProperty` action supports automatic throttling retry. For more information, see Configuring automatic retry for throttled operations.

Input

Inputs are defined by the API operation that you choose.

YAML

```
action: aws:waitForAwsResourceProperty
inputs:
  Service: The official namespace of the service
  Api: The API operation or method name
  API operation inputs or parameters: A value
  PropertySelector: Response object
  DesiredValues:
  - Desired property value
```

JSON

```
{
  "action": "aws:waitForAwsResourceProperty",
  "inputs": {
    "Service":"The official namespace of the service",
    "Api":"The API operation or method name",
    "API operation inputs or parameters":"A value",
    "PropertySelector": "Response object",
    "DesiredValues": [
      "Desired property value"
    ]
  }
}
```

Service

The Amazon Web Services service namespace that contains the API operation that you want to run. For example, the namespace for Amazon Systems Manager is `ssm`. The namespace for Amazon Elastic Compute Cloud (Amazon EC2) is `ec2`. You can view a list of supported Amazon

Web Services service namespaces in the Available Services section of the *Amazon CLI Command Reference*.

Type: String

Required: Yes

Api

The name of the API operation that you want to run. You can view the API operations (also called methods) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: Amazon RDS methods.

Type: String

Required: Yes

API operation inputs

One or more API operation inputs. You can view the available inputs (also called parameters) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to see the available parameters, such as **DBInstanceIdentifier**, **Name**, and **Values**.

YAML

```
inputs:
  Service: The official namespace of the service
  Api: The API operation name
  API input 1: A value
  API Input 2: A value
  API Input 3: A value
```

JSON

```
"inputs":{
      "Service":"The official namespace of the service",
      "Api":"The API operation name",
      "API input 1":"A value",
```

```
        "API Input 2":"A value",
        "API Input 3":"A value"
}
```

Type: Determined by chosen API operation

Required: Yes

PropertySelector

The JSONPath to a specific attribute in the response object. You can view the response objects by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all methods for Amazon RDS are listed on the following page: Amazon RDS methods. Choose the describe_db_instances method and scroll down to the **Response Structure** section. **DBInstances** is listed as a response object.

Type: String

Required: Yes

DesiredValues

The expected status or state on which to continue the automation.

Type: MapList, StringList

Required: Yes

Automation system variables

Amazon Systems Manager Automation runbooks use the following variables. For an example of how these variables are used, view the JSON source of the `AWS-UpdateWindowsAmi` runbook.

To view the JSON source of the `AWS-UpdateWindowsAmi` runbook

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. In the document list, use either the Search bar or the numbers to the right of the Search bar to choose the runbook **`AWS-UpdateWindowsAmi`**.
4. Choose the **Content** tab.

System variables

Automation runbooks support the following system variables.

Variable	Details
`global:ACCOUNT_ID`	The Amazon Web Services account ID of the user or role in which Automation runs.
`global:DATE`	The date (at run time) in the format yyyy-MM-dd.
`global:DATE_TIME`	The date and time (at run time) in the format yyyy-MM-dd_HH.mm.ss.
`global:AWS_PARTITION`	The partition that the resource is in. For standard Amazon Web Services Regions, the partition is `aws`. For resources in other partitions, the partition is `aws-`*`partition name`* . For example, the partition for resources in the Amazon GovCloud (US-West) Region is `aws-us-gov` .
`global:REGION`	The Region that the runbook is run in. For example, us-east-2.

Automation variables

Automation runbooks support the following automation variables.

Variable	Details
`automation:EXECUTION_ID`	The unique identifier assigned to the current automation. For example, `1a2b3c-1a2b3c-1a2b3c-1a2b3c1a2b3c1a2b3c` .

Topics

- Terminology
- Supported scenarios
- Unsupported scenarios

Terminology

The following terms describe how variables and parameters are resolved.

Term	Definition	Example
Constant ARN	A valid Amazon Resource Name (ARN) without variables.	`arn:aws:iam::123456789012:role/roleName`
Runbook parameter	A parameter defined at the runbook level (for example, `instanceId`). The parameter is used in a basic string replace. Its value is supplied at Start Execution time.	`{ "description": "Create Image Demo", "version": "0.3", "assumeRole": "Your_Automation_Assume_Role_ARN", "parameters":{ "instanceId": { "type": "String", "description": "Instance to create image from" } }}`
System variable	A general variable substituted into the runbook when any part of the runbook is evaluated.	`"activities": [ { "id": "copyImage", "activityType": "AWS-CopyImage", "maxAttempts": 1, "onFailure": "Continue",`

Term	Definition	Example
		"inputs": { "ImageName": "{{imageName}}", "SourceImageId": "{{sourceImageId}}", "SourceRegion": "{{sourceRegion}}", "Encrypted": true, "ImageDescription": "Test CopyImage Description created on **{{global:DATE}}** " } }]

Term	Definition	Example

Automation variable	A variable relating to the automation substituted into the runbook when any part of the runbook is evaluated.	{
		"name": "runFixedCmds",
		"action": "aws:runCommand",
		"maxAttempts": 1,
		"onFailure": "Continue",
		"inputs": {
		"DocumentName": "AWS-RunPowerShellScript",
		"InstanceIds": [
		"{{LaunchInstance.InstanceIds}}"
		],
		"Parameters": {
		"commands": [
		"dir",
		"date",
		""{{outputFormat}}" -f "left","right","{{global:DATE}}"," **{{automation:EXECUTION_ID}}** "
		]
		}
		}
		}

Term	Definition	Example
Systems Manager Parameter	A variable defined within Amazon Systems Manager Parameter Store. It can't be directly referenced in step input. Permissions might be required to access the parameter.	description: Launch new Windows test instance schemaVersion: '0.3' assumeRole: '{{AutomationAssumeRole}}' parameters: AutomationAssumeRole: type: String default: '' description: >- (Required) The ARN of the role that allows Automation to perform the actions on your behalf. If no role is specified, Systems Manager Automation uses your IAM permissions to run this runbook. LatestAmi: type: String default: >- {{ssm:/aws/service/ami-windows-latest/Windows_Server-2016-English-Full-Base}} description: The latest Windows Server 2016 AMI queried from the public parameter. mainSteps: - name: launchInstance action: 'aws:runInstances' maxAttempts: 3

Term	Definition	Example
		timeoutSeconds: 1200 onFailure: Abort inputs: ImageId: '{{LatestAmi}}' ...

Supported scenarios

Scenario	Comments	Example
Constant ARN `assumeRole` at creation.	An authorization check is performed to verify that the calling user is permitted to pass the given `assumeRole` .	{ "description": "Test all Automation resolvable parameters", "schemaVersion": "0.3", "assumeRole": ***"arn:aws:iam::123456789012:role/roleName"*** , "parameters": { ...
Runbook parameter supplied for `AssumeRole` when the automation is started.	Must be defined in the parameter list of the runbook.	{ "description": "Test all Automation resolvable parameters", "schemaVersion": "0.3", "assumeRole": **"{{dynamicARN}}"** , "parameters": { ...

Scenario	Comments	Example

Value supplied for runbook parameter at start.	Customer supplies the value to use for a parameter. Any inputs supplied at start time need to be defined in the parameter list of the runbook.	<pre>...
		"parameters": {
		    "amiId": {
		      "type": "String",
		      "default":
		 "*ami-12345678* ",
		      "description":
		 "list of commands to
		 run as part of first
		 step"
		    },
		...</pre>
		Inputs to Start Automatio n Execution include : {"amiId" : ["*ami-12345 678* "] }

Scenario	Comments	Example

Systems Manager Parameter referenced within runbook content.	The variable exists within the customer's account, or is a publicly accessibly parameter , and the `AssumeRole` for the runbook has access to the variable. A check is performed at create time to confirm the `AssumeRole` has access. The parameter can't be directly referenced in step input.	```
		...
		parameters:
		    LatestAmi:
		    type: String
		    default: >-
		      {{ssm:/aws/
		service/ami-wind
		ows-latest/Windows
		_Server-2016-English-
		Full-Base}}
		    description: The
		 latest Windows Server
		 2016 AMI queried from
		 the public parameter.
		mainSteps:
		  - name: launchIns
		tance
		    action: 'aws:runI
		nstances'
		    maxAttempts: 3
		    timeoutSeconds:
		 1200
		    onFailure: Abort
		    inputs:
		      ImageId: '{{Latest
		Ami}}'
		...
		``

Scenario	Comments	Example

System variable referenced within step definition	A system variable is substituted into the runbook when the automation is started. The value injected into the runbook is relative to when the substitution occurs. That is, the value of a time variable injected at step 1 is different from the value injected at step 3 because of the time it takes to run the steps between. System variables don't need to be set in the parameter list of the runbook.	```
		...
		  "mainSteps": [
		    {
		      "name": "RunSomeCommands",
		      "action": "aws:runCommand",
		      "maxAttempts": 1,
		      "onFailure": "Continue",
		      "inputs": {
		        "DocumentName": "AWS:RunPowerShell",
		        "InstanceIds": ["{{LaunchInstance.InstanceIds}}"],
		        "Parameters": {
		            "commands" : [
		                "echo {The time is now {{global:DATE_TIME}}}"
		            ]
		        }
		    }
		}, ...
		``

Scenario	Comments	Example
Automation variable referenced within step definition.	Automation variables don't need to be set in the parameter list of the runbook. The only supported Automation variable is **automation:EXECUTION_ID**.	... "mainSteps": [{ "name": "invokeLambdaFunction", "action": "aws:invokeLambdaFunction", "maxAttempts": 1, "onFailure": "Continue", "inputs": { "FunctionName": "Hello-World-LambdaFunction", "Payload" : "{ "executionId" : "{{automation:EXECUTION_ID}}" }" } } ...

Scenario	Comments	Example

Refer to output from previous step within next step definitio n.	This is parameter redirection. The output of a previous step is referenced using the syntax `{{stepName.OutputN ame}}` . This syntax can't be used by the customer for runbook parameters. This is resolved when the referring step runs. The parameter isn't listed in the parameters of the runbook.	```
		...
		"mainSteps": [
		    {
		      "name": "LaunchIn
		stance",
		      "action":
		 "aws:runInstances",
		      "maxAttempts": 1,
		      "onFailure":
		 "Continue",
		      "inputs": {
		        "ImageId":
		 "{{amiId}}",
		        "MinInsta
		nceCount": 1,
		        "MaxInsta
		nceCount": 2
		      }
		    },
		    {
		      "name":"c
		hangeState",
		      "action":
		 "aws:changeInstanc
		eState",

		      "onFailure":
		 "Continue",
		      "inputs": {
		        "InstanceIds":
		 ["{{LaunchInstance
		.InstanceIds}}"],
		        "DesiredState":
		 "terminated"
		      }
		    }
		
		...
		``

Unsupported scenarios

Scenario	Comment	Example

Systems Manager Parameter supplied for `assumeRole` at create	Not supported.	`...`
		
		`{`
		`  "description":`
		` "Test all Automation`
		` resolvable parameter`
		`s",`
		`  "schemaVersion":`
		` "0.3",`
		`  "assumeRole":`
		` "{{ssm:administrato`
		`rRoleARN}}  ",`
		`  "parameters": {`
		
		`...`

Systems Manager Parameter directly referenced in step input.	Returns `InvalidDocumentContent` exception at create time.	`...`
		`mainSteps:`
		`  - name: launchIns`
		`tance`
		`    action: 'aws:runI`
		`nstances'`
		`    maxAttempts: 3`
		`    timeoutSeconds:`
		` 1200`
		`    onFailure: Abort`
		`    inputs:`
		`      ImageId: '{{ssm:/`
		`aws/service/ami-win`
		`dows-latest/Window`
		`s_Server-2016-Engl`
		`ish-Full-Base}}'`
		`...`

Scenario	Comment	Example
Variable step definition	The definition of a step in the runbook is constructed by variables.	... "mainSteps": [{ "name": "LaunchInstance", "action": "aws:runInstances", "**{{attemptModel}}** ": 1, "onFailure": "Continue", "inputs": { "ImageId": "*ami-12345678* ", "MinInstanceCount": 1, "MaxInstanceCount": 2 } ... User supplies input : { "attemptModel" : "**minAttempts** " }

Scenario	Comment	Example
Cross referencing runbook parameters	The user supplies an input parameter at start time, which is a reference to another parameter in the runbook.	... "parameters": { "amiId": { "type": "String", "default": "ami-7f2e6015 ", "description": "list of commands to run as part of first step" }, "alternateAmiId": { "type": "String", "description": "The alternate AMI to try if this first fails". "default" : "{{amiId} }" }, ...

Scenario	Comment	Example
Multi-level expansion	The runbook defines a variable that evaluates to the name of a variable. This sits within the variable delimiters (that is *{{ }}*) and is expanded to the value of that variable/parameter.	... "parameters": { "*firstParameter* ": { "type": "String", "default": "param2", "description": "The parameter to reference" }, "*secondParameter* ": { "type": "String", "default" : "echo {Hello world}", "description": "What to run" } }, "mainSteps": [{ "name": "runFixedCmds", "action": "aws:runCommand", "maxAttempts": 1, "onFailure": "Continue", "inputs": { "DocumentName": "AWS-RunPowerShellScript", "InstanceIds" : "{{LaunchInstance.InstanceIds}}", "Parameters": { "commands": ["{{ ***{{firstParameter}}*** }}"] }

Scenario	Comment	Example
		... Note: The customer intention here would be to run a command of "echo {Hello world}"

Scenario	Comment	Example
Referencing output from a runbook step that is a different variable type	The user references the output from a preceding runbook step within a subsequent step. The output is a variable type that doesn't meet the requirements of the action in the subsequent step.	... mainSteps: - name: getImageId action: aws:execu teAwsApi inputs: Service: ec2 Api: DescribeImages Filters: - Name: "name" Values: - "{{ImageName}}" outputs: - Name: ImageIdList Selector: "$.Images " Type: "StringList" - name: copyMyImages action: aws:copyImage maxAttempts: 3 onFailure: Abort inputs: SourceImageId: {{getImageId.Image IdList}} SourceRegion: ap- northeast-2 ImageName: Encrypted Copies of LAMP base AMI in ap- northeast-2 Encrypted: true ... Note: You must provide the type required by the Automation action. In this case, aws:copyI mage requires a "String" type variable but the preceding step

Scenario	Comment	Example
		`outputs a "StringList" type variable.`

Creating your own runbooks

An Automation runbook defines the *actions* that Systems Manager performs on your managed instances and other Amazon resources when an automation runs. Automation is a tool in Amazon Systems Manager. A runbook contains one or more steps that run in sequential order. Each step is built around a single action. Output from one step can be used as input in a later step.

The process of running these actions and their steps is called the *automation*.

Action types supported for runbooks let you automate a wide variety of operations in your Amazon environment. For example, using the `executeScript` action type, you can embed a python or PowerShell script directly in your runbook. (When you create a custom runbook, you can add your script inline, or attach it from an S3 bucket or from your local machine.) You can automate management of your Amazon CloudFormation resources by using the `createStack` and `deleteStack` action types. In addition, using the `executeAwsApi` action type, a step can run *any* API operation in any Amazon Web Services service, including creating or deleting Amazon resources, starting other processes, initiating notifications, and many more.

For a list of all 20 supported action types for Automation, see Systems Manager Automation actions reference.

Amazon Systems Manager Automation provides several runbooks with pre-defined steps that you can use to perform common tasks like restarting one or more Amazon Elastic Compute Cloud (Amazon EC2) instances or creating an Amazon Machine Image (AMI). You can also create your own runbooks and share them with other Amazon Web Services accounts, or make them public for all Automation users.

Runbooks are written using YAML or JSON. Using the **Document Builder** in the Systems Manager Automation console, however, you can create a runbook without having to author in native JSON or YAML.

Important

If you run an automation workflow that invokes other services by using an Amazon Identity and Access Management (IAM) service role, be aware that the service role must be configured with permission to invoke those services. This requirement applies to all Amazon Automation runbooks (`AWS-*` runbooks) such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks, to name a few. This requirement also applies to any custom Automation runbooks you create that invoke other Amazon Web Services services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:createStack`, or `aws:copyImage` actions, configure the service role with permission to invoke those services. You can give permissions to other Amazon Web Services services by adding an IAM inline policy to the role. For more information, see (Optional) Add an Automation inline policy or customer managed policy to invoke other Amazon Web Services services.

For information about the actions that you can specify in a runbook, see Systems Manager Automation actions reference.

For information about using the Amazon Toolkit for Visual Studio Code to create runbooks, see Working with Systems Manager Automation documents in the *Amazon Toolkit for Visual Studio Code User Guide*.

For information about using the visual designer to create a custom runbook, see Visual design experience for Automation runbooks.

Visual design experience for Automation runbooks

Amazon Systems Manager Automation provides a low-code visual design experience that helps you create automation runbooks. It offers a drag-and-drop interface with the option to add your own code. With the visual design experience, you can do the following:

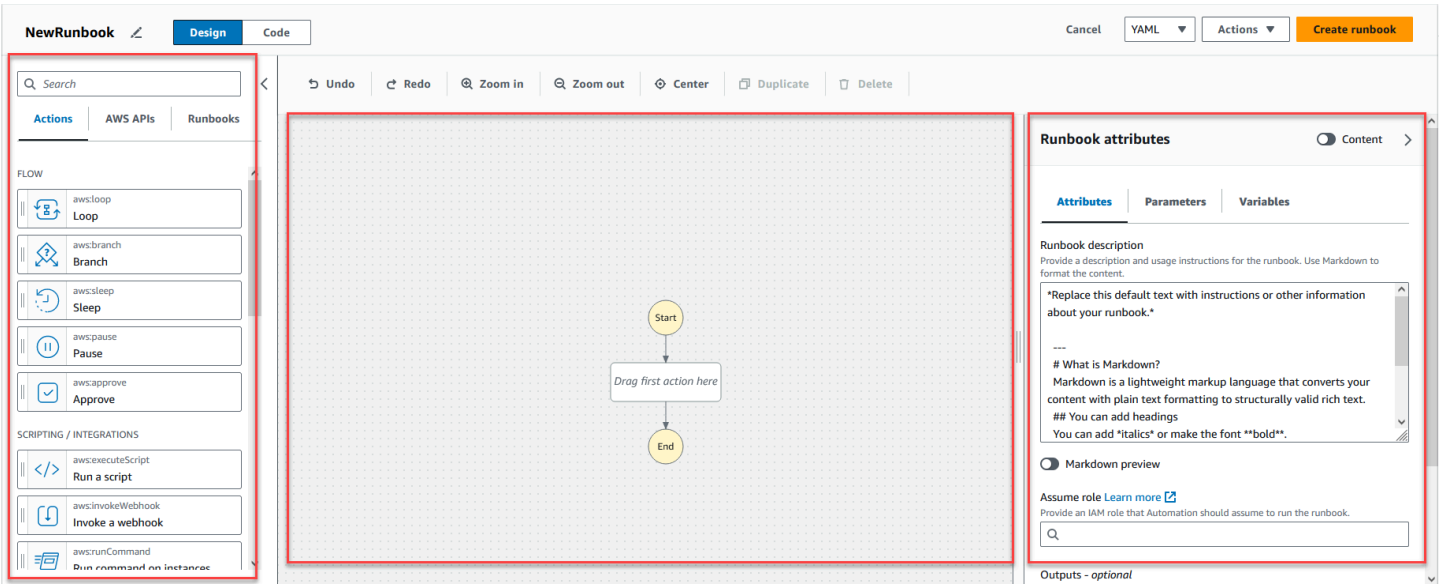
This section includes the following topics.

- Error handling with the visual design experience
- Configuring inputs and outputs for your actions
- Tutorial: Create a runbook using the visual design experience

- Overview of the visual design experience interface
- Using the visual design experience

- Control conditional statements.
- Control how input and output is filtered or transformed for each action.
- Configure error handling.
- Prototype new runbooks.
- Use your prototype runbooks as the starting point for local development with the Amazon Toolkit for Visual Studio Code.

When you create or edit a runbook, you can access the visual design experience from the Automation console. As you create a runbook, the visual design experience validates your work and auto-generates code. You can review the generated code, or export it for local development. When you're finished, you can save your runbook, run it, and examine the results in the Systems Manager Automation console.



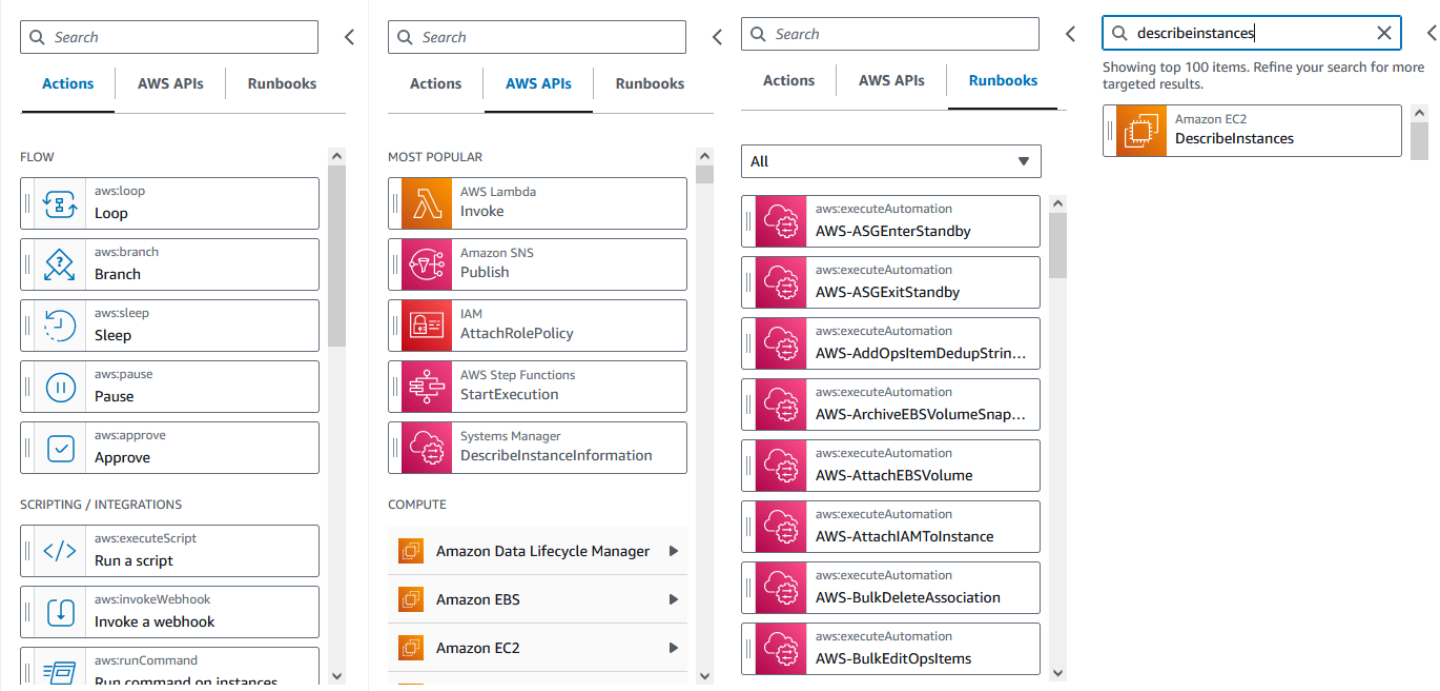
Topics

- Overview of the visual design experience interface
- Using the visual design experience
- Configuring inputs and outputs for your actions
- Error handling with the visual design experience
- Tutorial: Create a runbook using the visual design experience

Overview of the visual design experience interface

The visual design experience for Systems Manager Automation is a low-code visual workflow designer that helps you create automation runbooks.

Get to know the visual design experience with an overview of the interface components:

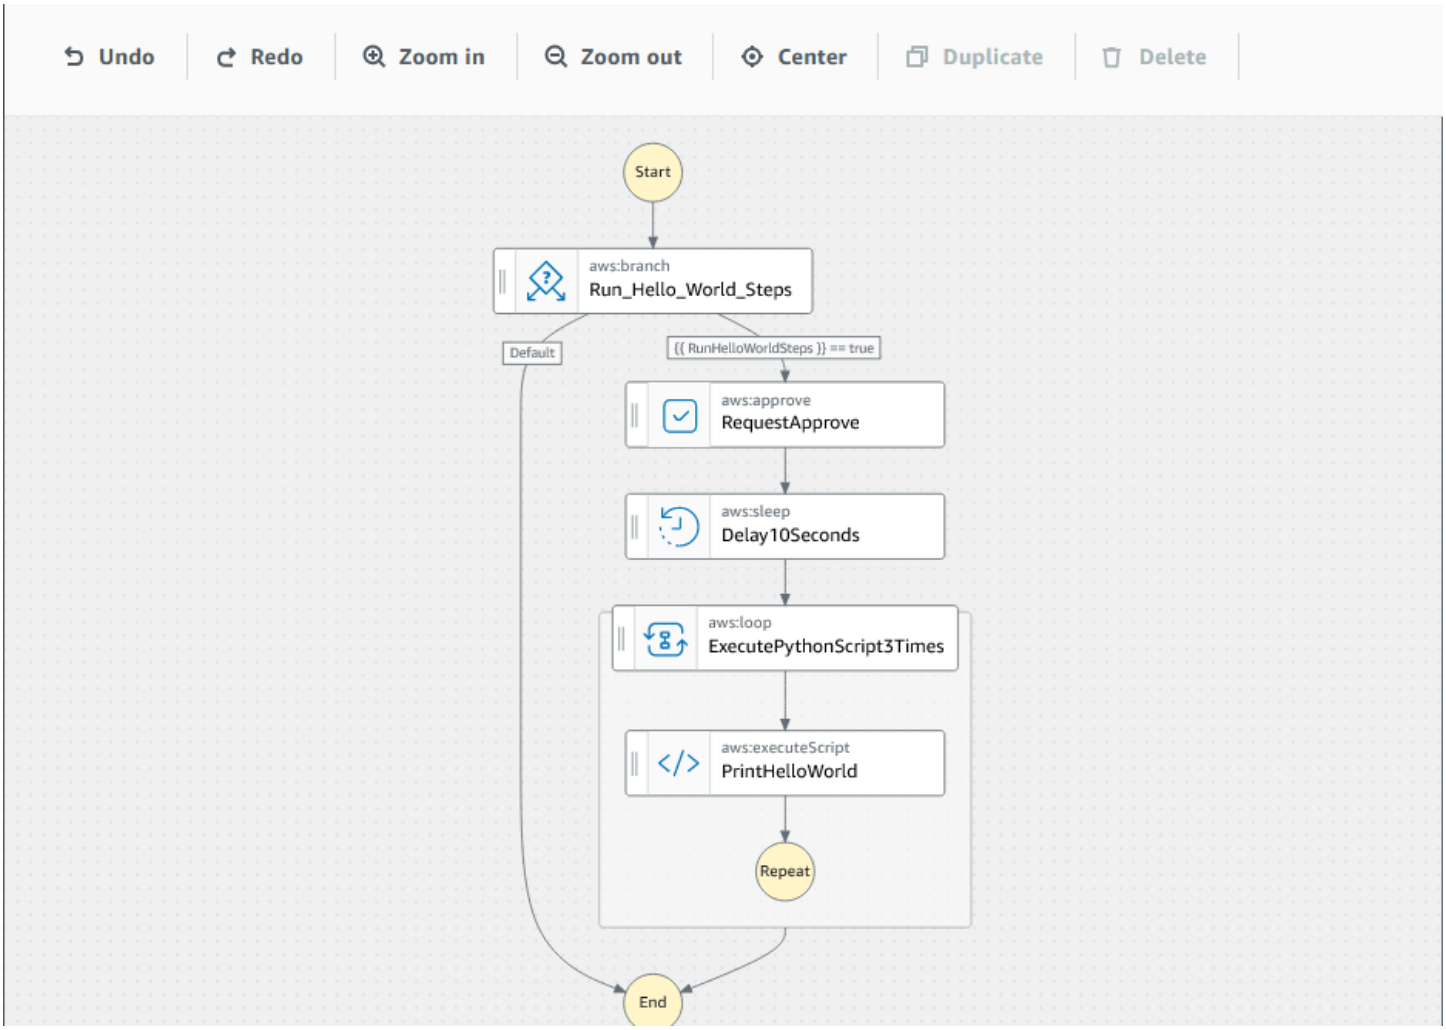


- The **Actions** browser contains the **Actions**, **Amazon APIs**, and **Runbooks** tabs.
- The *canvas* is where you move actions into your workflow graph. You can also change the order of actions and select them to configure.
- The **Form** panel is where you can view and edit the properties of any action that you selected on the canvas. Select the **Content** toggle to view the YAML or JSON for your runbook, with the currently selected action highlighted.

Info links open a panel with contextual information when you need help. These panels also include links to related topics in the Systems Manager Automation documentation.

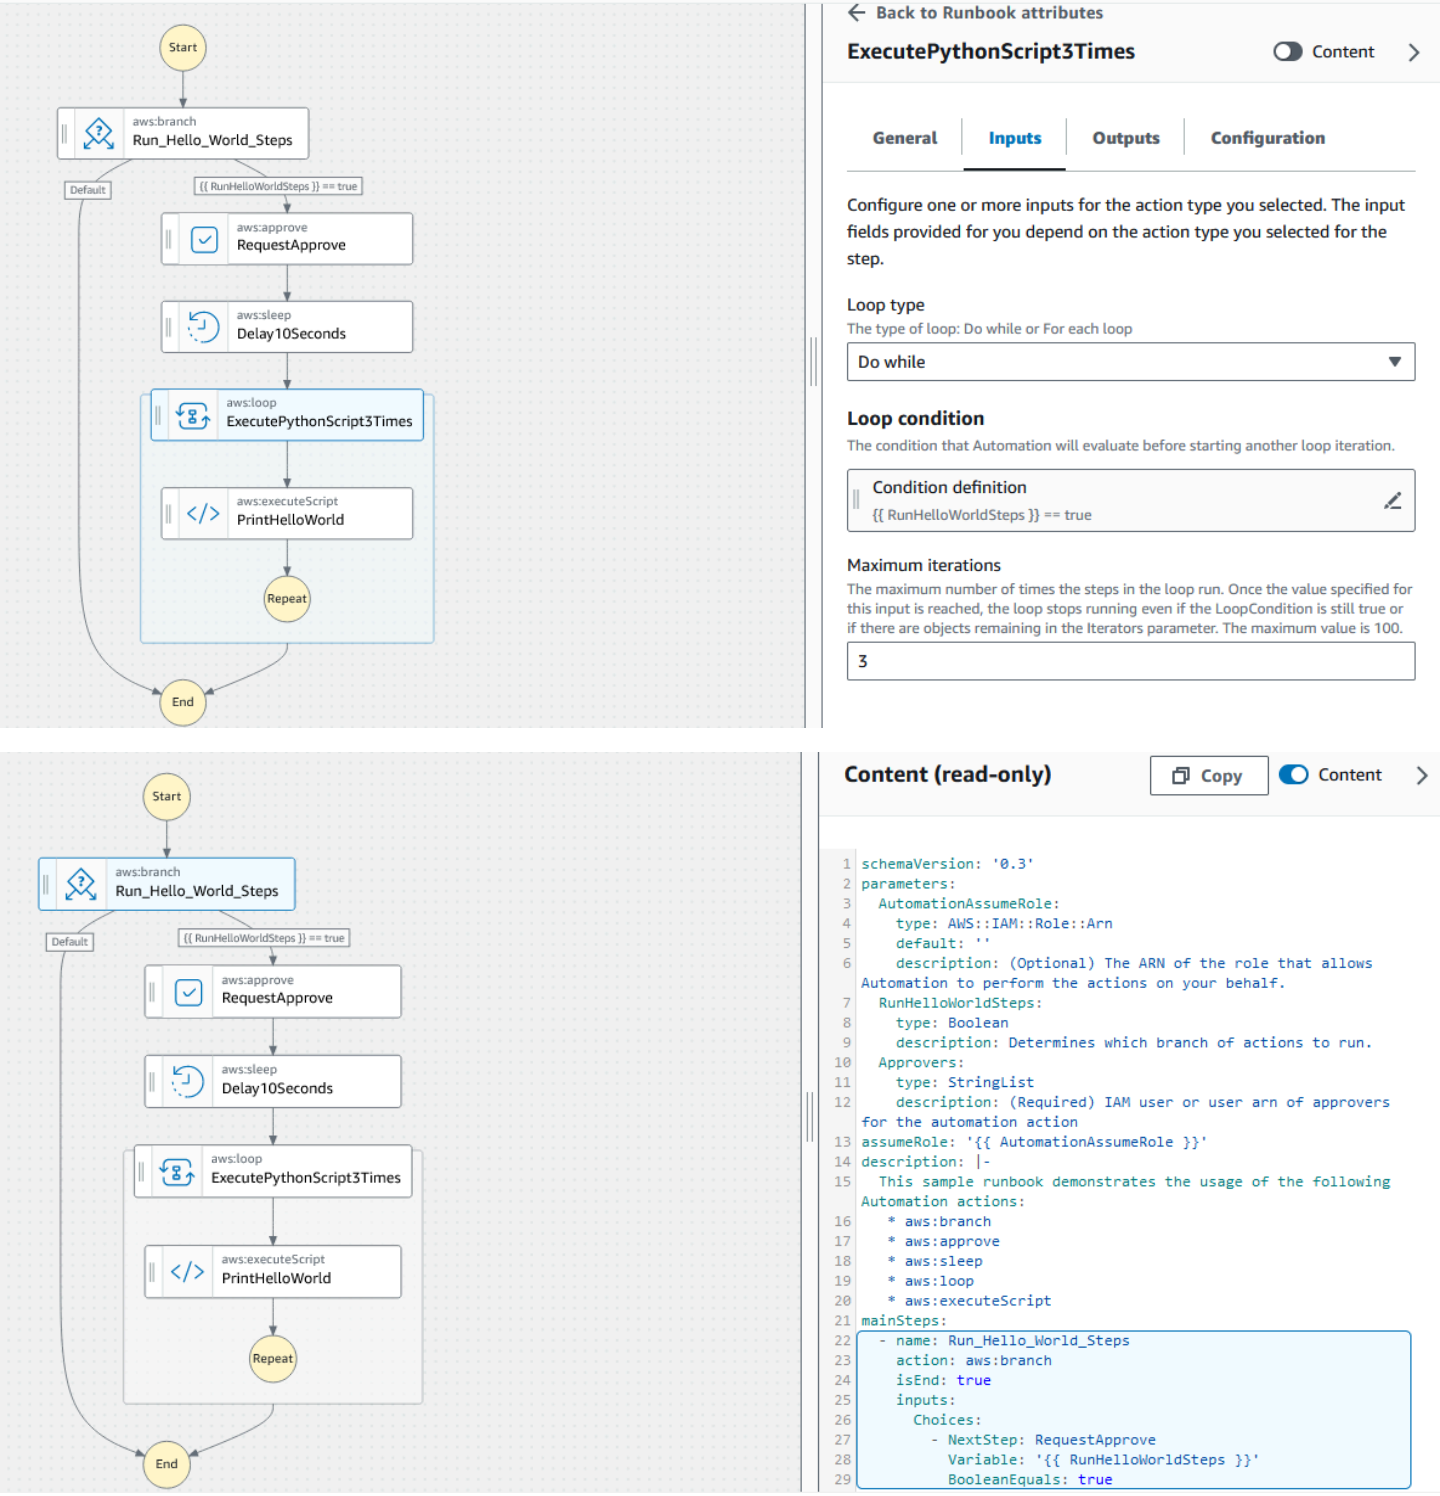
Actions browser

From the **Actions** browser, you can select actions to move into your workflow graph. You can search all actions using the search field at the top of the **Actions** browser. The **Actions** browser contains the following tabs:



- The **Actions** tab provides a list of automation actions that you can move into your runbook's workflow graph in the canvas.
- The **Amazon APIs** tab lists Amazon APIs that you can move into your runbook's workflow graph.
- The **Runbooks** tab provides ready-to-use runbooks as building blocks. For example, you can use them to perform common remediation tasks on Amazon EC2 instances without re-creating the same actions.

Canvas



After you choose an action, drag it to the canvas and drop it into your workflow graph. You can also move actions to reorder them. If your workflow is complex, you might not see all of it at once. Use the controls at the top to zoom in or out. To view other parts, move the workflow graph in the canvas.

Move an action from the **Actions** browser into your runbook's workflow graph. A line shows where it will be placed in your workflow. To change the order of an action, you can move it to a different place in your workflow. The new action has been added to your workflow, and its code is auto-generated.

Form

After you add an action to your runbook workflow, you can configure it to meet your use case. Choose the action that you want to configure, and you see its parameters and options in the **Form** panel. You can also see the YAML or JSON code by choosing the **Content** toggle. The code associated with the action you have selected is highlighted.

Keyboard shortcuts

The visual design experience supports the keyboard shortcuts shown in the following table.

Keyboard shortcut	
Ctrl+Z	Undo the last operation.
Ctrl+Shift+Z	Redo the last operation.
Ctrl+C	Center the workflow in the canvas.
Backspace	Remove all selected states.
Delete	Remove all selected states.
Ctrl+D	Duplicate the selected state.

Using the visual design experience

Learn to create, edit, and run runbook workflows using the visual design experience. When your workflow is ready, save or export it. You can also use it for rapid prototyping.

Create a runbook workflow

1. Sign in to the Systems Manager Automation console.
2. Choose **Create runbook**.
3. In the **Name** box, enter a name for your runbook, for example, *MyNewRunbook*.
4. Next to the **Design** and **Code** toggle, select the pencil icon and enter a name for your runbook.

You can now design a workflow for your new runbook.

Design a runbook

To design a runbook workflow, move an automation action from the **Actions** browser into the canvas. Place it where you want it in your workflow. You can re-order actions by moving them to a different location. As you move an action onto the canvas, a line shows where you can drop it. After you drop an action, its code is auto-generated and added to your runbook's content.

Use the search box at the top of the **Actions** browser to find an action by name.

After you drop an action onto the canvas, configure it using the **Form** panel on the right. This panel has **General**, **Inputs**, **Outputs**, and **Configuration** tabs for each action on the canvas. The **General** tab has the following sections:

- The **Step name** identifies the step. Specify a unique value for the step name.
- The **Description** helps you describe what the action is doing in your runbook's workflow.

The **Inputs** tab contains fields that vary based on the action. For example, the `aws:executeScript` automation action consists of the following sections:

- The **Runtime** is the language to use for running the provided script.
- The **Handler** is the name of your function. You must make sure that the function defined in the handler has two parameters: `events` and `context`. The PowerShell runtime doesn't support this parameter.
- The **Script** is an embedded script that you want to run during the workflow.

- (Optional) The **Attachment** is for standalone scripts or .zip files that can be invoked by the action. This parameter is required for JSON runbooks.

The **Outputs** tab helps you specify the values that you want to output from an action. You can reference output values in later actions of your workflow, or generate output from actions for logging purposes. Not all actions will have an **Outputs** tab because not all actions support outputs. For example, the `aws:pause` action doesn't support outputs. For actions that do support outputs, the **Outputs** tab consists of the following sections:

- The **Name** is the name to be used for the output value. You can reference outputs in later actions of your workflow.
- The **Selector** is a JSONPath expression string beginning with `"$."` that is used to select one or more components within a JSON element.
- The **Type** is the data type for the output value. For example, a `String` or `Integer` data type.

The **Configuration** tab contains properties and options that all automation actions can use. The action consists of the following sections:

- The **Max attempts** property is the number of times an action retries if it fails.
- The **Timeout seconds** property specifies the timeout value for an action.
- The **Is critical** property determines if the action failure stops the entire automation.
- The **Next step** property determines which action the automation goes to next in the runbook.
- The **On failure** property determines which action the automation goes to next in the runbook if the action fails.
- The **On cancel** property determines which action the automation goes to next in the runbook if the action is canceled by a user.

To delete an action, you can use backspace, the toolbar above the canvas, or open the context menu and choose **Delete action**.

As your workflow grows, it might not fit in the canvas. To help make the workflow fit in the canvas, try one of the following options:

- Use the controls on the side panels to resize or close the panels.
- Use the toolbar at the top of the canvas to zoom the workflow graph in or out.

Update your runbook

You can update an existing runbook workflow by creating a new version of your runbook. Updates to your runbooks can be made by using the visual design experience, or by editing the code directly. To update an existing runbook, use the following procedure:

1. Sign in to the Systems Manager Automation console.
2. Choose the runbook that you want to update.
3. Choose **Create new version**.
4. The visual design experience has two panes: A code pane and a visual workflow pane. Choose **Design** in the visual workflow pane to edit your workflow with the visual design experience. When you're done, choose **Create new version** to save your changes and exit.
5. (Optional) Use the code pane to edit the runbook content in YAML or JSON.

Export your runbook

To export your runbook's workflow YAML or JSON code, and also a graph of your workflow, use the following procedure:

1. Choose your runbook in the **Documents** console.
2. Choose **Create new version**.
3. In the **Actions** dropdown, choose whether you want to export the graph or runbook, and which format you prefer.

Configuring inputs and outputs for your actions

Each automation action responds based on input that it receives. Usually, you then pass output to the subsequent actions. In the visual design experience, you can configure an action's input and output data in the **Inputs** and **Outputs** tabs of the **Form** panel.

For detailed information about how to define and use output for automation actions, see Using action outputs as inputs.

Provide input data for an action

Each automation action has one or more inputs that you must provide a value for. The value you provide for an action's input is determined by the data type and format that's accepted by the

action. For example, the `aws:sleep` actions requires an ISO 8601 formatted string value for the `Duration` input.

Generally, you use actions in your runbook's workflow that return output that you want to use in subsequent actions. It's important to make sure your input values are correct to avoid errors in your runbook's workflow. Input values are also important because they determine whether the action returns the expected output. For example, when using the `aws:executeAwsApi` action, you want to make sure you're providing the right value for the API operation.

Define output data for an action

Some automation actions return output after performing their defined operations. Actions that return output either have predefined outputs, or allow you to define the outputs yourself. For example, the `aws:createImage` action has predefined outputs that return an `ImageId` and `ImageState`. Comparatively, with the `aws:executeAwsApi` action, you can define the outputs you that want from the specified API operation. As a result, you can return one or more values from a single API operation to use in subsequent actions.

Defining your own outputs for an automation action requires that you specify a name of the output, the data type, and the output value. To continue using the `aws:executeAwsApi` action as an example, let's say you're calling the `DescribeInstances` API operation from Amazon EC2. In this example, you want to return, or output, the `State` of an Amazon EC2 instance and branch your runbook's workflow based on the output. You choose to name the output **`InstanceState`**, and use the **`String`** data type.

How you define the output value depends on the action. For example, with `aws:executeScript`, use `return` statements in your functions to provide data to outputs. With actions like `aws:executeAwsApi`, `aws:waitForAwsResourceProperty`, and `aws:assertAwsResourceProperty`, a `Selector` is required. The `Selector` (also called `PropertySelector`) is a JSONPath string that processes the JSON response from an API operation. You need to understand how the JSON response is structured so you can select the correct value. Using the `DescribeInstances` API operation, see the following example response:

```

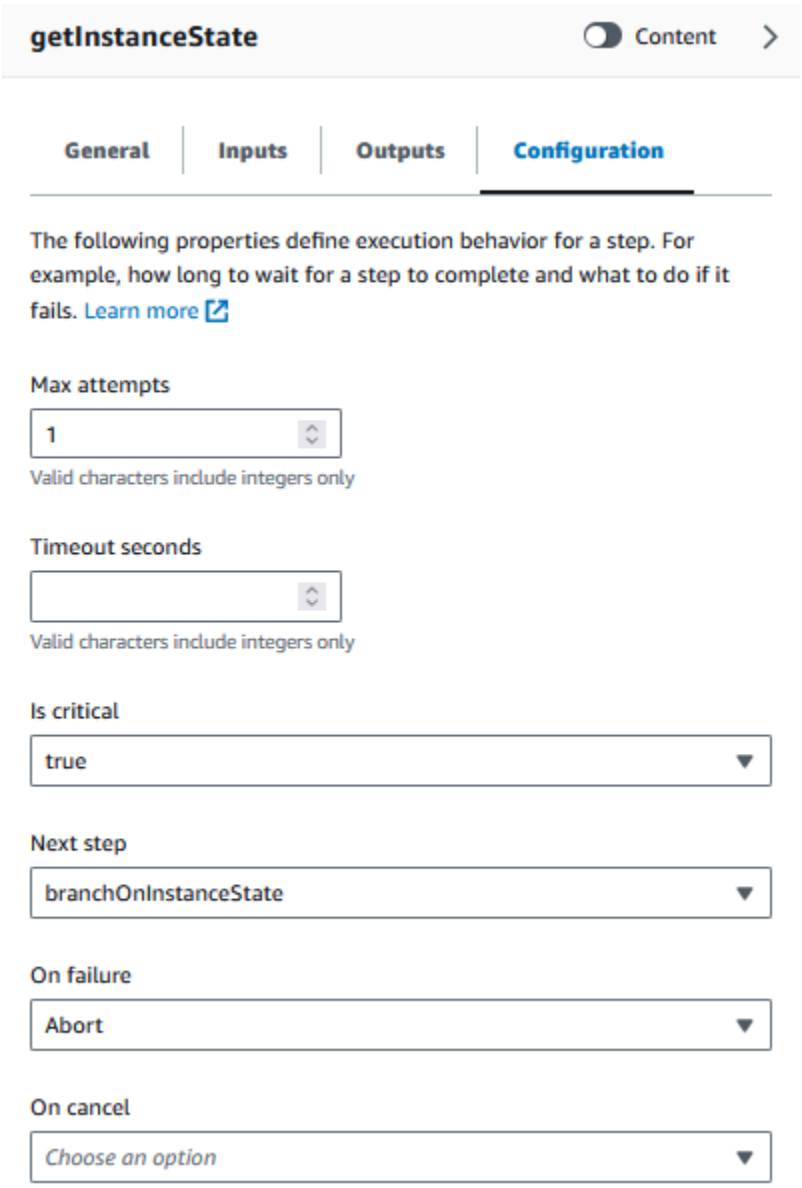
          "cpuOptions": {
            "coreCount": 1,
            "threadsPerCore": 1
          }
        }
      }
    }
  }
}
```



In the JSON response object, the instance `State` is nested in an `Instances` object, which is nested in the `Reservations` object. To return the value of the instance `State`, use the following string for the `Selector` so the value can be used in our output: **`$.Reservations[0].Instances[0].State.Name`**.

To reference an output value in subsequent actions of your runbook's workflow, the following format is used: {{ *`StepName.NameOfOutput`* }}. For example, **`{{ GetInstanceState.InstanceState }}`**. In the visual design experience, you can choose

output values to use in subsequent actions using the dropdown for the input. When using outputs in subsequent actions, the data type of the output must match the data type for the input. In this example, the `InstanceState` output is a `String`. Therefore, to use the value in a subsequent action's input, the input must accept a `String`.

Error handling with the visual design experience

By default, when an action reports an error, Automation stops the runbook's workflow entirely. This is because the default value for the on`Failure` property on all actions is `Abort`. You can configure how Automation handles errors in your runbook's workflow. Even if you have configured error handling, some errors might still cause an automation to fail. For more information, see Troubleshooting Systems Manager Automation. In the visual design experience, you configure error handling in the **Configuration** panel.

Retry action on error

To retry an action in case of an error, specify a value for the **Max attempts** property. The default value is 1. If you specify a value greater than 1, the action isn't considered to have failed until all of the retry attempts have failed.

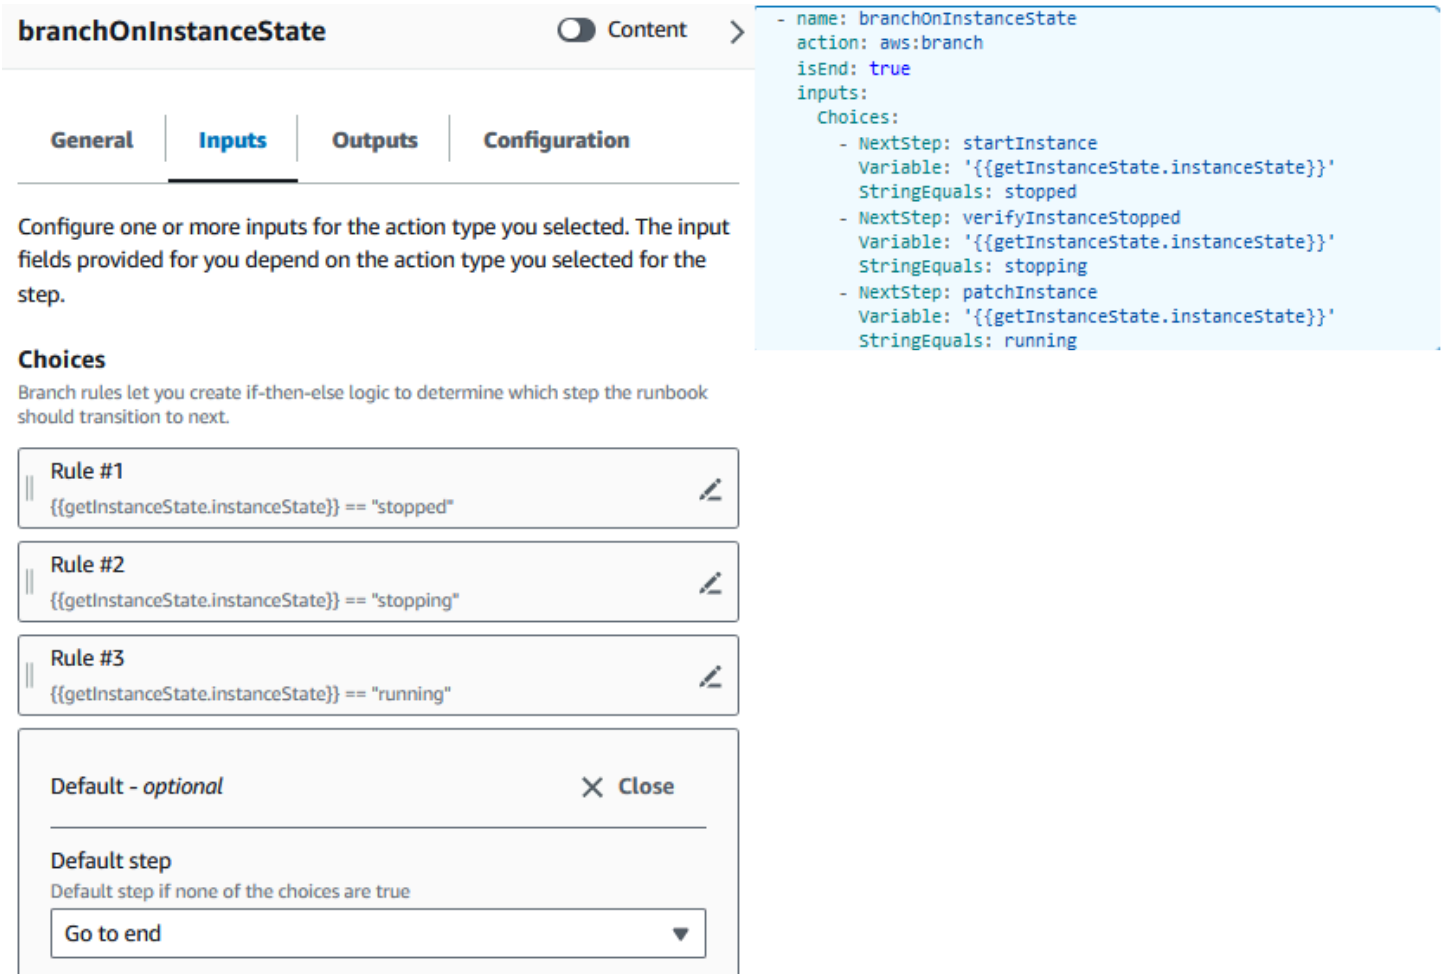
Timeouts

You can configure a timeout for actions to set the maximum number of seconds your action can run before it fails. Enter the value in the **Timeout seconds** property. If the timeout is reached and `Max attempts` is greater than 1, the step isn't considered timed out until all retries complete.

Failed actions

By default, when an action fails, Automation stops the runbook's workflow entirely. You can modify this behavior by specifying an alternative value for the **On failure** property of the actions in your runbook. If you want the workflow to continue to the next step in the runbook, choose **Continue**. If you want the workflow to jump to a different subsequent step in the runbook, choose **Step** and then enter the name of the step.

Canceled actions



By default, when an action is canceled by a user, Automation stops the runbook's workflow entirely. You can modify this behavior by specifying an alternative value for the **On cancel** property of the actions in your runbook. If you want the workflow to jump to a different subsequent step in the runbook, choose **Step** and then enter the name of the step.

Critical actions

You can designate an action as *critical*, meaning it determines the overall reporting status of your automation. If a step with this designation fails, Automation reports the final status as `Failed` regardless of the success of other actions. To configure an action as critical, leave the default value as **True** for the **Is critical** property.

Ending actions

The **Is end** property stops an automation at the end of the specified action. The default value for this property is `false`. If you configure this property for an action, the automation stops whether the action succeeds or fails. This property is most often used with `aws:branch` actions to handle unexpected or undefined input values. The following example shows a runbook that is expecting an instance state of either `running`, `stopping`, or `stopped`. If an instance is in a different state, the automation ends.

Tutorial: Create a runbook using the visual design experience

In this tutorial, you learn the basics of working with the visual design experience provided by Systems Manager Automation. In the visual design experience, you can create a runbook that uses multiple actions. You use the move feature to arrange actions on the canvas. You also search for, select, and configure these actions. Then, you can view the auto-generated YAML code for your runbook's workflow, exit the visual design experience, run the runbook, and review the execution details.

This tutorial also shows you how to update the runbook and view the new version. At the end of the tutorial, you perform a clean-up step and delete your runbook.

After you complete this tutorial, you'll know how to use the visual design experience to create a runbook. You'll also know how to update, run, and delete your runbook.

> **Note**
>
> Before you start this tutorial, make sure to complete Setting up Automation.

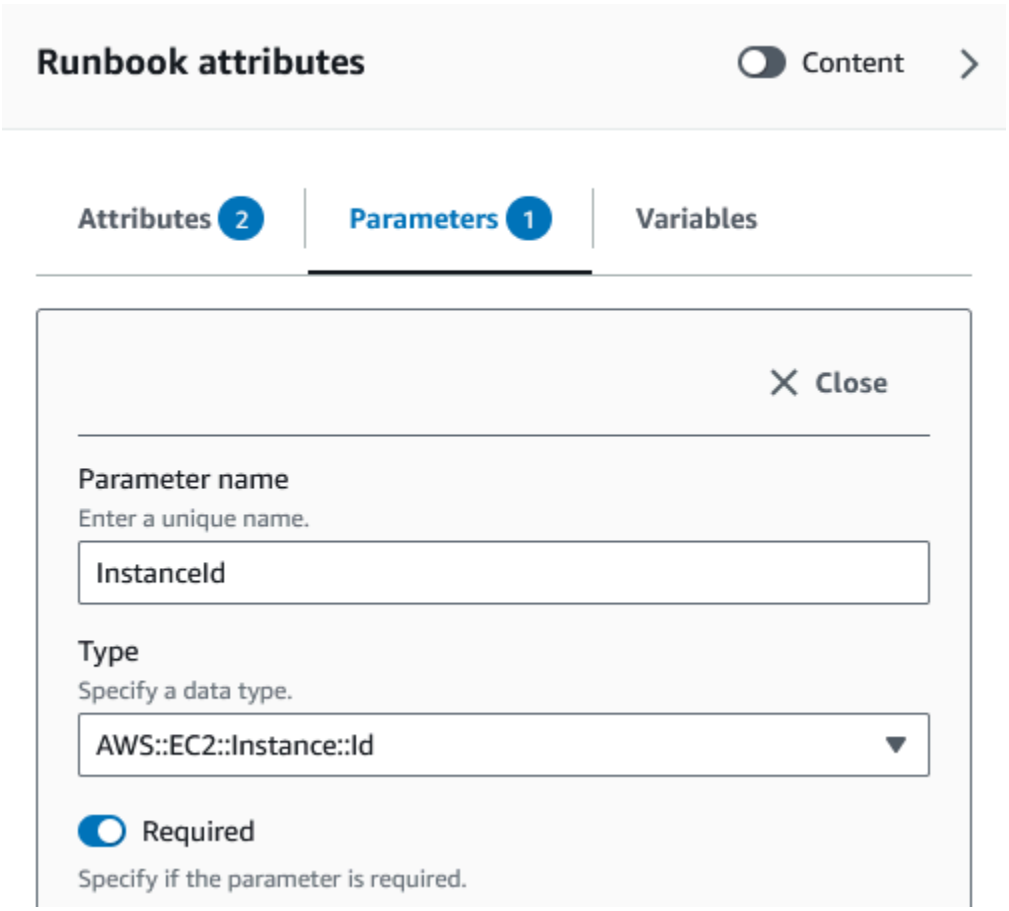
Topics

- Step 1: Navigate to the visual design experience
- Step 2: Create a workflow
- Step 3: Review the auto-generated code
- Step 4: Run your new runbook
- Step 5: Clean up

Step 1: Navigate to the visual design experience

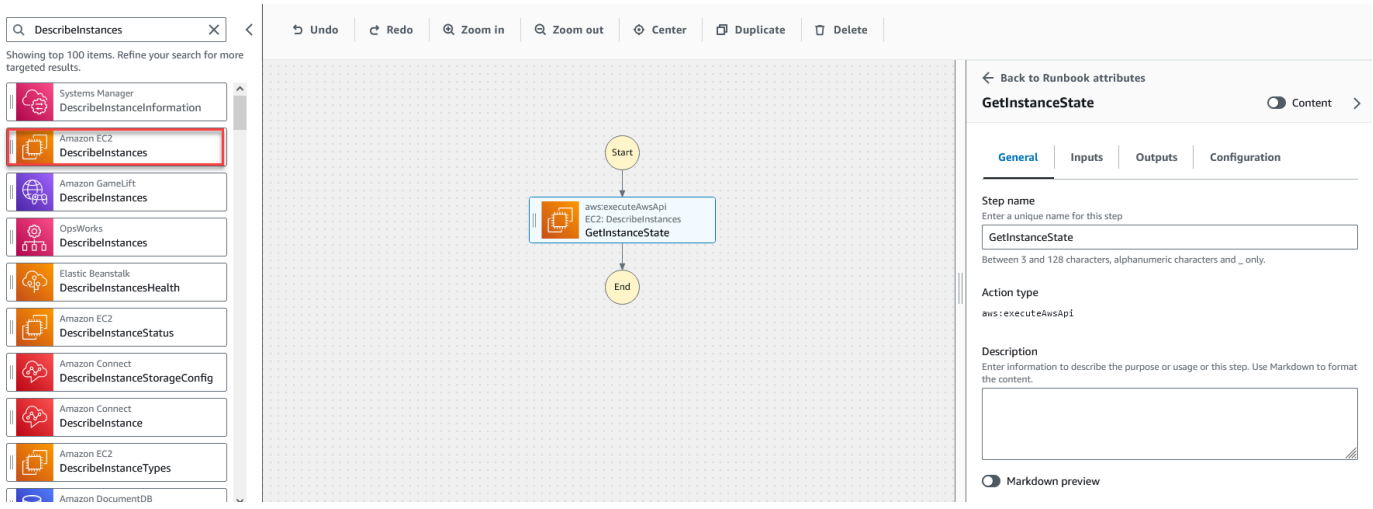
1. Sign in to the Systems Manager Automation console.
2. Choose **Create automation runbook**.

Step 2: Create a workflow



In the visual design experience, a workflow is a graphical representation of your runbook on the canvas. You can use the visual design experience to define, configure, and examine the individual actions of your runbook.

To create a workflow



1. Next to the **Design** and **Code** toggle, select the pencil icon and enter a name for your runbook. For this tutorial, enter **`VisualDesignExperienceTutorial`**.

2. In the **Document attributes** section of the **Form** panel, expand the **Input parameters** dropdown, and select **Add a parameter**.
   a. In the **Parameter name** field, enter **`InstanceId`**.
   b. In the **Type** dropdown, choose **AWS::EC2::Instance**.
   c. Select the **Required** toggle.

3. In the **Amazon APIs** browser, enter **`DescribeInstances`** in the search bar.
4. Move an **Amazon EC2 – DescribeInstances** action to the empty canvas.
5. For **Step name**, enter a value. For this tutorial, you can use the name **`GetInstanceState`**.

a. Expand the **Additional inputs** dropdown, and in the **Input name** field, enter **`InstanceIds`**.

b. Choose the **Inputs** tab.

c. In the **Input value** field, choose the **`InstanceId`** document input. This references the value of the input parameter that you created at the beginning of the procedure. Since the **InstanceIds** input for the `DescribeInstances` action accepts `StringList` values, you must wrap the **InstanceId** input in square brackets. The YAML for the **Input value** should match the following: **`['{{ InstanceId }}']`**.

d. In the **Outputs** tab, select **Add an output** and enter **`InstanceState`** in the **Name** field.

e. In the **Selector** field, enter **`$.Reservations[0].Instances[0].State.Name`**.

f. In the **Type** dropdown, choose **String**.

6. Move a **Branch** action from the **Actions** browser, into the position below the **`GetInstanceState`** step.

7. For **Step name**, enter a value. For this tutorial, use the name **`BranchOnInstanceState`**.

   To define the branching logic, do the following:

   a. Choose the **`Branch`** state on the canvas. Then, under **Inputs** and **Choices**, select the pencil icon to edit **Rule #1**.

   b. Choose **Add conditions**.

   c. In the **Conditions for rule #1** dialog box, choose the **`GetInstanceState.InstanceState`** step output from the **Variable** dropdown.

   d. For **Operator**, choose **is equal to**.

   e. For **Value**, choose **String** from the dropdown list. Enter **`stopped`**.

   f. Select **Save conditions**.

   g. Choose **Add new choice rule**.

   h. Choose **Add conditions** for **Rule #2**.

i. In the **Conditions for rule #2** dialog box, choose the **`GetInstanceState.InstanceState`** step output from the **Variable** dropdown.

j. For **Operator**, choose **is equal to**.

k. For **Value**, choose **String** from the dropdown list. Enter **`stopping`**.

l. Select **Save conditions**.

m. Choose **Add new choice rule**.

n. For **Rule #3**, choose **Add conditions**.

o. In the **Conditions for rule #3** dialog box, choose the **`GetInstanceState.InstanceState`** step output from the **Variable** dropdown.

p. For **Operator**, choose **is equal to**.

q. For **Value**, choose **String** from the dropdown list. Enter **`running`**.

r. Select **Save conditions**.

s. In the **Default rule**, choose **Go to end** for the **Default step**.

8. Move a **Change an instance state** action to the empty **Drag action here** box under the **{{ GetInstanceState.InstanceState }} == "stopped"** condition.

   a. For the **Step name**, enter **`StartInstance`**.

   b. In the **Inputs** tab, under **Instance IDs**, choose the **InstanceId** document input value from the dropdown.

   c. For the **Desired state**, specify **`running`**.

9. Move a **Wait on Amazon resource** action to the empty **Drag action here** box under the **{{ GetInstanceState.InstanceState }} == "stopping"** condition.

10. For **Step name**, enter a value. For this tutorial, use the name **`WaitForInstanceStop`**.

    a. For the **Service** field, choose **Amazon EC2**.

    b. For the **API** field, choose **DescribeInstances**.

    c. For the **Property selector** field, enter **`$.Reservations[0].Instances[0].State.Name`**.

    d. For the **Desired values** parameter, enter **`["stopped"]`**.

    e. In the **Configuration** tab of the **WaitForInstanceStop** action, choose **StartInstance** from the **Next step** dropdown.

11. Move a **Run command on instances** action to the empty **Drag action here** box under the **{{ GetInstanceState.InstanceState }} == "running"** condition.

12. For the **Step name**, enter **`SayHello`**.

    a. In the **Inputs** tab, enter **`AWS-RunShellScript`** for the **Document name** parameter.

    b. For **InstanceIds**, choose the **InstanceId** document input value from the dropdown.

    c. Expand the **Additional inputs** dropdown, and in the **Input name** dropdown, choose **Parameters**.

    d. In the **Input value** field, enter **`{"commands": "echo 'Hello World'"}`**.

13. Review the completed runbook in the canvas and select **Create runbook** to save the tutorial runbook.

Step 3: Review the auto-generated code

As you move actions from the **Actions** browser onto the canvas, the visual design experience automatically composes the YAML or JSON content of your runbook in real-time. You can view and edit this code. To view the auto-generated code, select **Code** for the **Design** and **Code** toggle.

Step 4: Run your new runbook

After creating your runbook, you can run the automation.

To run your new automation runbook

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Automation**, and then choose **Execute automation**.

3. In the **Automation document** list, choose a runbook. Choose one or more options in the **Document categories** pane to filter SSM documents according to their purpose. To view a runbook that you own, choose the **Owned by me** tab. To view a runbook that is shared with your account, choose the **Shared with me** tab. To view all runbooks, choose the **All documents** tab.

   > **Note**
   >
   > You can view information about a runbook by choosing the runbook name.

4. In the **Document details** section, verify that **Document version** is set to the version that you want to run. The system includes the following version options:

   - **Default version at runtime** – Choose this option if the Automation runbook is updated periodically and a new default version is assigned.
   - **Latest version at runtime** – Choose this option if the Automation runbook is updated periodically, and you want to run the version that was most recently updated.
   - **1 (Default)** – Choose this option to run the first version of the document, which is the default.

5. Choose **Next**.
6. In the **Execute automation runbook** section, choose **Simple execution**.
7. In the **Input parameters** section, specify the required inputs. Optionally, you can choose an IAM service role from the **AutomationAssumeRole** list.
8. (Optional) Choose a CloudWatch alarm to apply to your automation for monitoring. If your alarm enters `ALARM` state, the automation is canceled and any defined on`Cancel` steps run. If you use Amazon CloudTrail, you see the `StopAutomationExecution` API call in your trail. For more information, see Configuring Automations to monitor CloudWatch Alarms.
9. Choose **Execute**.

Step 5: Clean up

To delete your runbook

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.

3. Select the **Owned by me** tab.
4. Locate the **VisualDesignExperienceTutorial** runbook.
5. Select the button on the document card page, and then choose **Delete document** from the **Actions** dropdown.

Authoring Automation runbooks

Each runbook in Automation defines an automation. Automation runbooks define the actions that are performed during an automation. In the runbook content, you define the input parameters, outputs, and actions that Systems Manager performs on your managed instances and Amazon resources.

This section includes the following topics.

- Creating input parameters that populate Amazon resources
- Deploy VPC architecture and Microsoft Active Directory domain controllers
- Restore a root volume from the latest snapshot
- Create an AMI and cross-Region copy

Automation includes several pre-defined runbooks that you can use to perform common tasks like restarting one or more Amazon Elastic Compute Cloud (Amazon EC2) instances or creating an Amazon Machine Image (AMI). However, your use cases might extend beyond the capabilities of the pre-defined runbooks. If this is the case, you can create your own runbooks and modify them to your needs.

A runbook consists of automation actions, parameters for those actions, and input parameters that you specify. A runbook's content is written in either YAML or JSON. If you're not familiar with either YAML or JSON, we recommend using the visual designer, or learning more about either markup language before attempting to author your own runbook. For more information about the visual designer, see Visual design experience for Automation runbooks.

The following sections will help you author your first runbook.

Identify your use case

The first step in authoring a runbook is identifying your use case. For example, you scheduled the `AWS-CreateImage` runbook to run daily on all of your production Amazon EC2 instances. At the end of the month, you decide you have more images than are necessary for recovery points. Going

forward, you want to automatically delete the oldest AMI of an Amazon EC2 instance when a new AMI is created. To accomplish this, you create a new runbook that does the following:

1. Runs the `aws:createImage` action and specifies the instance ID in the image description.
2. Runs the `aws:waitForAwsResourceProperty` action to poll the state of the image until it's `available`.
3. After the image state is `available`, the `aws:executeScript` action runs a custom Python script that gathers the IDs of all images associated with your Amazon EC2 instance. The script does this by filtering, using the instance ID in the image description you specified at creation. Then, the script sorts the list of image IDs based on the `creationDate` of the image and outputs the ID of the oldest AMI.
4. Lastly, the `aws:deleteImage` action runs to delete the oldest AMI using the ID from the output of the previous step.

In this scenario, you were already using the `AWS-CreateImage` runbook but found that your use case required greater flexibility. This is a common situation because there can be overlap between runbooks and automation actions. As a result, you might have to adjust which runbooks or actions you use to address your use case.

For example, the `aws:executeScript` and `aws:invokeLambdaFunction` actions both allow you to run custom scripts as part of your automation. To choose between them, you might prefer `aws:invokeLambdaFunction` because of the additional supported runtime languages. However, you might prefer `aws:executeScript` because it lets you author your script content directly in YAML runbooks and provide script content as attachments for JSON runbooks. You might also consider `aws:executeScript` to be simpler in terms of Amazon Identity and Access Management (IAM) setup. Because it uses the permissions provided in the `AutomationAssumeRole`, `aws:executeScript` doesn't require an additional Amazon Lambda function execution role.

In any given scenario, one action might provide more flexibility, or added functionality, over another. Therefore, we recommend that you review the available input parameters for the runbook or action you want to use to determine which best fits your use case and preferences.

Set up your development environment

After you've identified your use case and the pre-defined runbooks or automation actions you want to use in your runbook, it's time to set up your development environment for the content of your

runbook. To develop your runbook content, we recommend using the Amazon Toolkit for Visual Studio Code instead of the Systems Manager Documents console.

The Toolkit for VS Code is an open-source extension for Visual Studio Code (VS Code) that offers more features than the Systems Manager Documents console. Helpful features include schema validation for both YAML and JSON, snippets for automation action types, and auto-complete support for various options in both YAML and JSON.

For more information about installing the Toolkit for VS Code, see Installing the Amazon Toolkit for Visual Studio Code. For more information about using the Toolkit for VS Code to develop runbooks, see Working with Systems Manager Automation documents in the *Amazon Toolkit for Visual Studio Code User Guide*.

Develop runbook content

With your use case identified and environment set up, you're ready to develop the content for your runbook. Your use case and preferences will largely dictate the automation actions or runbooks you use in your runbook content. Some actions support only a subset of input parameters when compared to another action that lets you accomplish a similar task. Other actions have specific outputs, such as `aws:createImage`, where some actions allow you to define your own outputs, such as `aws:executeAwsApi`.

If you're unsure how to use a particular action in your runbook, we recommend reviewing the corresponding entry for the action in the Systems Manager Automation actions reference. We also recommend reviewing the content of pre-defined runbooks to see real-world examples of how these actions are used. For more examples of real-world applications of runbooks, see Additional runbook examples.

To demonstrate the differences in simplicity and flexibility that runbook content provides, the following tutorials provide an example of how to patch groups of Amazon EC2 instances in stages:

- Example 1: Creating parent-child runbooks – In this example, two runbooks are used in a parent-child relationship. The parent runbook initiates a rate control automation of the child runbook.
- Example 2: Scripted runbook – This example demonstrates how you can accomplish the same tasks of Example 1 by condensing the content into a single runbook and using scripts in your runbook.

Example 1: Creating parent-child runbooks

The following example demonstrates how to create two runbooks that patch tagged groups of Amazon Elastic Compute Cloud (Amazon EC2) instances in stages. These runbooks are used in a parent-child relationship with the parent runbook used to initiate a rate control automation of the child runbook. For more information about rate control automations, see Run automated operations at scale. For more information about the automation actions used in this example, see the Systems Manager Automation actions reference.

Create the child runbook

This example runbook addresses the following scenario. Emily is a Systems Engineer at AnyCompany Consultants, LLC. She needs to configure patching for groups of Amazon Elastic Compute Cloud (Amazon EC2) instances that host primary and secondary databases. Applications access these databases 24 hours a day, so one of the database instances must always be available.

She decides that patching the instances in stages is the best approach. The primary group of database instances will be patched first, followed by the secondary group of database instances. Also, to avoid incurring additional costs by leaving instances running that were previously stopped, Emily wants the patched instances to be returned to their original state before the patching occurred.

Emily identifies the primary and secondary groups of database instances by the tags associated with the instances. She decides to create a parent runbook that starts a rate control automation of a child runbook. By doing that, she can target the tags associated with the primary and secondary groups of database instances and manage the concurrency of the child automations. After reviewing the available Systems Manager (SSM) documents for patching, she chooses the `AWS-RunPatchBaseline` document. By using this SSM document, her colleagues can review the associated patch compliance information after the patching operation completes.

To start creating her runbook content, Emily reviews the available automation actions and begins authoring the content for the child runbook as follows:

1. First, she provides values for the schema and description of the runbook, and defines the input parameters for the child runbook.

   By using the `AutomationAssumeRole` parameter, Emily and her colleagues can use an existing IAM role that allows Automation to perform the actions in the runbook on their behalf. Emily uses the `InstanceId` parameter to determine the instance that should be patched. Optionally, the `Operation`, `RebootOption`, and `SnapshotId` parameters can be used to provide values

to document parameters for `AWS-RunPatchBaseline`. To prevent invalid values from being provided to those document parameters, she defines the `allowedValues` as needed.

YAML

```
schemaVersion: '0.3'
description: 'An example of an Automation runbook that patches groups of Amazon
 EC2 instances in stages.'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: >-
      '(Optional) The Amazon Resource Name (ARN) of the IAM role that allows
 Automation to perform the
      actions on your behalf. If no role is specified, Systems Manager
      Automation uses your IAM permissions to operate this runbook.'
    default: ''
  InstanceId:
    type: String
    description: >-
      '(Required) The instance you want to patch.'
  SnapshotId:
    type: String
    description: '(Optional) The snapshot ID to use to retrieve a patch baseline
 snapshot.'
    default: ''
  RebootOption:
    type: String
    description: '(Optional) Reboot behavior after a patch Install operation. If
 you choose NoReboot and patches are installed, the instance is marked as non-
compliant until a subsequent reboot and scan.'
    allowedValues:
      - NoReboot
      - RebootIfNeeded
    default: RebootIfNeeded
  Operation:
    type: String
    description: '(Optional) The update or configuration to perform on the
 instance. The system checks if patches specified in the patch baseline are
 installed on the instance. The install operation installs patches missing from
 the baseline.'
    allowedValues:
      - Install
```

```
      - Scan
    default: Install
```

JSON

```
{
   "schemaVersion":"0.3",
   "description":"An example of an Automation runbook that patches groups of
 Amazon EC2 instances in stages.",
   "assumeRole":"{{AutomationAssumeRole}}",
   "parameters":{
      "AutomationAssumeRole":{
         "type":"String",
         "description":"(Optional) The Amazon Resource Name (ARN) of the IAM role
 that allows Automation to perform the actions on your behalf. If no role is
 specified, Systems Manager Automation uses your IAM permissions to operate this
 runbook.",
         "default":""
      },
      "InstanceId":{
         "type":"String",
         "description":"(Required) The instance you want to patch."
      },
      "SnapshotId":{
         "type":"String",
         "description":"(Optional) The snapshot ID to use to retrieve a patch
 baseline snapshot.",
         "default":""
      },
      "RebootOption":{
         "type":"String",
         "description":"(Optional) Reboot behavior after a patch Install
 operation. If you choose NoReboot and patches are installed, the instance is
 marked as non-compliant until a subsequent reboot and scan.",
         "allowedValues":[
            "NoReboot",
            "RebootIfNeeded"
         ],
         "default":"RebootIfNeeded"
      },
      "Operation":{
         "type":"String",
```

```
        "description":"(Optional) The update or configuration to perform on
 the instance. The system checks if patches specified in the patch baseline are
 installed on the instance. The install operation installs patches missing from
 the baseline.",
        "allowedValues":[
           "Install",
           "Scan"
        ],
        "default":"Install"
     }
   }
},
```

2. With the top-level elements defined, Emily proceeds with authoring the actions that make up the `mainSteps` of the runbook. The first step outputs the current state of the target instance specified in the `InstanceId` input parameter using the `aws:executeAwsApi` action. The output of this action is used in later actions.

   YAML

```
mainSteps:
  - name: getInstanceState
    action: 'aws:executeAwsApi'
    onFailure: Abort
    inputs:
      inputs:
      Service: ec2
      Api: DescribeInstances
      InstanceIds:
        - '{{InstanceId}}'
    outputs:
      - Name: instanceState
        Selector: '$.Reservations[0].Instances[0].State.Name'
        Type: String
    nextStep: branchOnInstanceState
```

   JSON

```
"mainSteps":[
      {
         "name":"getInstanceState",
         "action":"aws:executeAwsApi",
         "onFailure":"Abort",
```

```
         "inputs":{
            "inputs":null,
            "Service":"ec2",
            "Api":"DescribeInstances",
            "InstanceIds":[
               "{{InstanceId}}"
            ]
         },
         "outputs":[
            {
               "Name":"instanceState",
               "Selector":"$.Reservations[0].Instances[0].State.Name",
               "Type":"String"
            }
         ],
         "nextStep":"branchOnInstanceState"
      },
```

3. Rather than manually starting and keeping track of the original state of every instance that needs to be patched, Emily uses the output from the previous action to branch the automation based on the state of the target instance. This allows the automation to run different steps depending on the conditions defined in the `aws:branch` action and improves the overall efficiency of the automation without manual intervention.

   If the instance state is already `running`, the automation proceeds with patching the instance with the `AWS-RunPatchBaseline` document using the `aws:runCommand` action.

   If the instance state is `stopping`, the automation polls for the instance to reach the `stopped` state using the `aws:waitForAwsResourceProperty` action, starts the instance using the `executeAwsApi` action, and polls for the instance to reach a `running` state before patching the instance.

   If the instance state is `stopped`, the automation starts the instance and polls for the instance to reach a `running` state before patching the instance using the same actions.

   YAML

```
- name: branchOnInstanceState
    action: 'aws:branch'
    onFailure: Abort
    inputs:
      Choices:
```

```
        - NextStep: startInstance
          Variable: '{{getInstanceState.instanceState}}'
          StringEquals: stopped
        - NextStep: verifyInstanceStopped
          Variable: '{{getInstanceState.instanceState}}'
          StringEquals: stopping
        - NextStep: patchInstance
          Variable: '{{getInstanceState.instanceState}}'
          StringEquals: running
    isEnd: true
  - name: startInstance
    action: 'aws:executeAwsApi'
    onFailure: Abort
    inputs:
      Service: ec2
      Api: StartInstances
      InstanceIds:
        - '{{InstanceId}}'
    nextStep: verifyInstanceRunning
  - name: verifyInstanceRunning
    action: 'aws:waitForAwsResourceProperty'
    timeoutSeconds: 120
    inputs:
      Service: ec2
      Api: DescribeInstances
      InstanceIds:
        - '{{InstanceId}}'
      PropertySelector: '$.Reservations[0].Instances[0].State.Name'
      DesiredValues:
        - running
    nextStep: patchInstance
  - name: verifyInstanceStopped
    action: 'aws:waitForAwsResourceProperty'
    timeoutSeconds: 120
    inputs:
      Service: ec2
      Api: DescribeInstances
      InstanceIds:
        - '{{InstanceId}}'
      PropertySelector: '$.Reservations[0].Instances[0].State.Name'
      DesiredValues:
        - stopped
      nextStep: startInstance
  - name: patchInstance
```

```
    action: 'aws:runCommand'
    onFailure: Abort
    timeoutSeconds: 5400
    inputs:
      DocumentName: 'AWS-RunPatchBaseline'
      InstanceIds:
      - '{{InstanceId}}'
      Parameters:
        SnapshotId: '{{SnapshotId}}'
        RebootOption: '{{RebootOption}}'
        Operation: '{{Operation}}'
```

JSON

```
{
         "name":"branchOnInstanceState",
         "action":"aws:branch",
         "onFailure":"Abort",
         "inputs":{
            "Choices":[
               {
                  "NextStep":"startInstance",
                  "Variable":"{{getInstanceState.instanceState}}",
                  "StringEquals":"stopped"
               },
               {
                  "Or":[
                     {
                        "Variable":"{{getInstanceState.instanceState}}",
                        "StringEquals":"stopping"
                     }
                  ],
                  "NextStep":"verifyInstanceStopped"
               },
               {
                  "NextStep":"patchInstance",
                  "Variable":"{{getInstanceState.instanceState}}",
                  "StringEquals":"running"
               }
            ]
         },
         "isEnd":true
      },
```

```
      {
         "name":"startInstance",
         "action":"aws:executeAwsApi",
         "onFailure":"Abort",
         "inputs":{
            "Service":"ec2",
            "Api":"StartInstances",
            "InstanceIds":[
               "{{InstanceId}}"
            ]
         },
         "nextStep":"verifyInstanceRunning"
      },
      {
         "name":"verifyInstanceRunning",
         "action":"aws:waitForAwsResourceProperty",
         "timeoutSeconds":120,
         "inputs":{
            "Service":"ec2",
            "Api":"DescribeInstances",
            "InstanceIds":[
               "{{InstanceId}}"
            ],
            "PropertySelector":"$.Reservations[0].Instances[0].State.Name",
            "DesiredValues":[
               "running"
            ]
         },
         "nextStep":"patchInstance"
      },
      {
         "name":"verifyInstanceStopped",
         "action":"aws:waitForAwsResourceProperty",
         "timeoutSeconds":120,
         "inputs":{
            "Service":"ec2",
            "Api":"DescribeInstances",
            "InstanceIds":[
               "{{InstanceId}}"
            ],
            "PropertySelector":"$.Reservations[0].Instances[0].State.Name",
            "DesiredValues":[
               "stopped"
            ],
```

```
            "nextStep":"startInstance"
         }
      },
      {
         "name":"patchInstance",
         "action":"aws:runCommand",
         "onFailure":"Abort",
         "timeoutSeconds":5400,
         "inputs":{
            "DocumentName":"AWS-RunPatchBaseline",
            "InstanceIds":[
               "{{InstanceId}}"
            ],
            "Parameters":{
               "SnapshotId":"{{SnapshotId}}",
               "RebootOption":"{{RebootOption}}",
               "Operation":"{{Operation}}"
            }
         }
      },
```

4. After the patching operation completes, Emily wants the automation to return the target instance to the same state it was in before the automation started. She does this by again using the output from the first action. The automation branches based on the original state of the target instance using the `aws:branch` action. If the instance was previously in any state other than `running`, the instance is stopped. Otherwise, if the instance state is `running`, the automation ends.

   YAML

```
- name: branchOnOriginalInstanceState
    action: 'aws:branch'
    onFailure: Abort
    inputs:
      Choices:
        - NextStep: stopInstance
          Not:
            Variable: '{{getInstanceState.instanceState}}'
            StringEquals: running
    isEnd: true
  - name: stopInstance
    action: 'aws:executeAwsApi'
    onFailure: Abort
```

```
    inputs:
      Service: ec2
      Api: StopInstances
      InstanceIds:
        - '{{InstanceId}}'
```

JSON

```
{
        "name":"branchOnOriginalInstanceState",
        "action":"aws:branch",
        "onFailure":"Abort",
        "inputs":{
           "Choices":[
              {
                 "NextStep":"stopInstance",
                 "Not":{
                    "Variable":"{{getInstanceState.instanceState}}",
                    "StringEquals":"running"
                 }
              }
           ]
        },
        "isEnd":true
     },
     {
        "name":"stopInstance",
        "action":"aws:executeAwsApi",
        "onFailure":"Abort",
        "inputs":{
           "Service":"ec2",
           "Api":"StopInstances",
           "InstanceIds":[
              "{{InstanceId}}"
           ]
        }
     }
  ]
}
```

5. Emily reviews the completed child runbook content and creates the runbook in the same Amazon Web Services account and Amazon Web Services Region as the target instances. Now

she's ready to continue with the creation of the parent runbook's content. The following is the completed child runbook content.

YAML

```
schemaVersion: '0.3'
description: 'An example of an Automation runbook that patches groups of Amazon
 EC2 instances in stages.'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: >-
      '(Optional) The Amazon Resource Name (ARN) of the IAM role that allows
 Automation to perform the
      actions on your behalf. If no role is specified, Systems Manager
      Automation uses your IAM permissions to operate this runbook.'
    default: ''
  InstanceId:
    type: String
    description: >-
      '(Required) The instance you want to patch.'
  SnapshotId:
    type: String
    description: '(Optional) The snapshot ID to use to retrieve a patch baseline
 snapshot.'
    default: ''
  RebootOption:
    type: String
    description: '(Optional) Reboot behavior after a patch Install operation. If
 you choose NoReboot and patches are installed, the instance is marked as non-
compliant until a subsequent reboot and scan.'
    allowedValues:
      - NoReboot
      - RebootIfNeeded
    default: RebootIfNeeded
  Operation:
    type: String
    description: '(Optional) The update or configuration to perform on the
 instance. The system checks if patches specified in the patch baseline are
 installed on the instance. The install operation installs patches missing from
 the baseline.'
    allowedValues:
      - Install
```

```
      - Scan
    default: Install
mainSteps:
  - name: getInstanceState
    action: 'aws:executeAwsApi'
    onFailure: Abort
    inputs:
      inputs:
      Service: ec2
      Api: DescribeInstances
      InstanceIds:
        - '{{InstanceId}}'
    outputs:
      - Name: instanceState
        Selector: '$.Reservations[0].Instances[0].State.Name'
        Type: String
    nextStep: branchOnInstanceState
  - name: branchOnInstanceState
    action: 'aws:branch'
    onFailure: Abort
    inputs:
      Choices:
        - NextStep: startInstance
          Variable: '{{getInstanceState.instanceState}}'
          StringEquals: stopped

            ]
         }
      }
   ]
}
```

For more information about the automation actions used in this example, see the Systems Manager Automation actions reference.

Create the parent runbook

This example runbook continues the scenario described in the previous section. Now that Emily has created the child runbook, she begins authoring the content for the parent runbook as follows:

1. First, she provides values for the schema and description of the runbook, and defines the input parameters for the parent runbook.

By using the `AutomationAssumeRole` parameter, Emily and her colleagues can use an existing IAM role that allows Automation to perform the actions in the runbook on their behalf. Emily uses the `PatchGroupPrimaryKey` and `PatchGroupPrimaryValue` parameters to specify the tag associated with the primary group of database instances that will be patched. She uses the `PatchGroupSecondaryKey` and `PatchGroupSecondaryValue` parameters to specify the tag associated with the secondary group of database instances that will be patched.

YAML

```
description: 'An example of an Automation runbook that patches groups of Amazon
 EC2 instances in stages.'
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Optional) The Amazon Resource Name (ARN) of the IAM role that
 allows Automation to perform the actions on your behalf. If no role is specified,
 Systems Manager Automation uses your IAM permissions to operate this runbook.'
    default: ''
  PatchGroupPrimaryKey:
    type: String
    description: '(Required) The key of the tag for the primary group of instances
 you want to patch.''
  PatchGroupPrimaryValue:
    type: String
    description: '(Required) The value of the tag for the primary group of
 instances you want to patch.'
  PatchGroupSecondaryKey:
    type: String
    description: '(Required) The key of the tag for the secondary group of
 instances you want to patch.'
  PatchGroupSecondaryValue:
    type: String
    description: '(Required) The value of the tag for the secondary group of
 instances you want to patch.'
```

JSON

```
{
   "schemaVersion": "0.3",
```

```
  "description": "An example of an Automation runbook that patches groups of
 Amazon EC2 instances in stages.",
  "assumeRole": "{{AutomationAssumeRole}}",
  "parameters": {
     "AutomationAssumeRole": {
        "type": "String",
        "description": "(Optional) The Amazon Resource Name (ARN) of the IAM
 role that allows Automation to perform the actions on your behalf. If no role is
 specified, Systems Manager Automation uses your IAM permissions to operate this
 runbook.",
        "default": ""
     },
     "PatchGroupPrimaryKey": {
        "type": "String",
        "description": "(Required) The key of the tag for the primary group of
 instances you want to patch."
     },
     "PatchGroupPrimaryValue": {
        "type": "String",
        "description": "(Required) The value of the tag for the primary group of
 instances you want to patch."
     },
     "PatchGroupSecondaryKey": {
        "type": "String",
        "description": "(Required) The key of the tag for the secondary group of
 instances you want to patch."
     },
     "PatchGroupSecondaryValue": {
        "type": "String",
        "description": "(Required) The value of the tag for the secondary group
 of instances you want to patch."
     }
  }
},
```

2. With the top-level elements defined, Emily proceeds with authoring the actions that make up the `mainSteps` of the runbook.

   The first action starts a rate control automation using the child runbook she just created that targets instances associated with the tag specified in the `PatchGroupPrimaryKey` and `PatchGroupPrimaryValue` input parameters. She uses the values provided to the input parameters to specify the key and value of the tag associated with the primary group of database instances she wants to patch.

After the first automation completes, the second action starts another rate control automation using the child runbook that targets instances associated with the tag specified in the `PatchGroupSecondaryKey` and `PatchGroupSecondaryValue` input parameters. She uses the values provided to the input parameters to specify the key and value of the tag associated with the secondary group of database instances she wants to patch.

YAML

```
mainSteps:
  - name: patchPrimaryTargets
    action: 'aws:executeAutomation'
    onFailure: Abort
    timeoutSeconds: 7200
    inputs:
      DocumentName: RunbookTutorialChildAutomation
      Targets:
        - Key: 'tag:{{PatchGroupPrimaryKey}}'
          Values:
            - '{{PatchGroupPrimaryValue}}'
      TargetParameterName: 'InstanceId'
  - name: patchSecondaryTargets
    action: 'aws:executeAutomation'
    onFailure: Abort
    timeoutSeconds: 7200
    inputs:
      DocumentName: RunbookTutorialChildAutomation
      Targets:
        - Key: 'tag:{{PatchGroupSecondaryKey}}'
          Values:
            - '{{PatchGroupSecondaryValue}}'
      TargetParameterName: 'InstanceId'
```

JSON

```
"mainSteps":[
      {
         "name":"patchPrimaryTargets",
         "action":"aws:executeAutomation",
         "onFailure":"Abort",
         "timeoutSeconds":7200,
         "inputs":{
            "DocumentName":"RunbookTutorialChildAutomation",
```

```
            "Targets":[
               {
                  "Key":"tag:{{PatchGroupPrimaryKey}}",
                  "Values":[
                     "{{PatchGroupPrimaryValue}}"
                  ]
               }
            ],
            "TargetParameterName":"InstanceId"
         }
      },
      {
         "name":"patchSecondaryTargets",
         "action":"aws:executeAutomation",
         "onFailure":"Abort",
         "timeoutSeconds":7200,
         "inputs":{
            "DocumentName":"RunbookTutorialChildAutomation",
            "Targets":[
               {
                  "Key":"tag:{{PatchGroupSecondaryKey}}",
                  "Values":[
                     "{{PatchGroupSecondaryValue}}"
                  ]
               }
            ],
            "TargetParameterName":"InstanceId"
         }
      }
   ]
}
```

3. Emily reviews the completed parent runbook content and creates the runbook in the same Amazon Web Services account and Amazon Web Services Region as the target instances. Now, she is ready to test her runbooks to make sure the automation operates as desired before implementing them into her production environment. The following is the completed parent runbook content.

   YAML

```
description: An example of an Automation runbook that patches groups of Amazon EC2
 instances in stages.
schemaVersion: '0.3'
```

```
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Optional) The Amazon Resource Name (ARN) of the IAM role that
 allows Automation to perform the actions on your behalf. If no role is specified,
 Systems Manager Automation uses your IAM permissions to operate this runbook.'
    default: ''
  PatchGroupPrimaryKey:
    type: String
    description: (Required) The key of the tag for the primary group of instances
 you want to patch.
  PatchGroupPrimaryValue:
    type: String
    description: '(Required) The value of the tag for the primary group of
 instances you want to patch. '
  PatchGroupSecondaryKey:
    type: String
    description: (Required) The key of the tag for the secondary group of
 instances you want to patch.
  PatchGroupSecondaryValue:
    type: String
    description: '(Required) The value of the tag for the secondary group of
 instances you want to patch.  '
mainSteps:
  - name: patchPrimaryTargets
    action: 'aws:executeAutomation'
    onFailure: Abort
    timeoutSeconds: 7200
    inputs:
      DocumentName: RunbookTutorialChildAutomation
      Targets:
        - Key: 'tag:{{PatchGroupPrimaryKey}}'
          Values:
            - '{{PatchGroupPrimaryValue}}'
      TargetParameterName: 'InstanceId'
  - name: patchSecondaryTargets
    action: 'aws:executeAutomation'
    onFailure: Abort
    timeoutSeconds: 7200
    inputs:
      DocumentName: RunbookTutorialChildAutomation
      Targets:
        - Key: 'tag:{{PatchGroupSecondaryKey}}'
```

```
          Values:
            - '{{PatchGroupSecondaryValue}}'
      TargetParameterName: 'InstanceId'
```

JSON

```

         }
      }
   ]
}
```

For more information about the automation actions used in this example, see the Systems Manager Automation actions reference.

Example 2: Scripted runbook

This example runbook addresses the following scenario. Emily is a Systems Engineer at AnyCompany Consultants, LLC. She previously created two runbooks that are used in a parent-child relationship to patch groups of Amazon Elastic Compute Cloud (Amazon EC2) instances that host primary and secondary databases. Applications access these databases 24 hours a day, so one of the database instances must always be available.

Based on this requirement, she built a solution that patches the instances in stages using the `AWS-RunPatchBaseline` Systems Manager (SSM) document. By using this SSM document, her colleagues can review the associated patch compliance information after the patching operation completes.

The primary group of database instances are patched first, followed by the secondary group of database instances. Also, to avoid incurring additional costs by leaving instances running that were previously stopped, Emily made sure that the automation returned the patched instances to their original state before the patching occurred. Emily used tags that are associated with the primary and secondary groups of database instances to identify which instances should be patched in her desired order.

Her existing automated solution works, but she wants to improve her solution if possible. To help with the maintenance of the runbook content and to ease troubleshooting efforts, she would like to condense the automation into a single runbook and simplify the number of input parameters. Also, she would like to avoid creating multiple child automations.

After Emily reviews the available automation actions, she determines that she can improve her solution by using the `aws:executeScript` action to run her custom Python scripts. She now begins authoring the content for the runbook as follows:

1. First, she provides values for the schema and description of the runbook, and defines the input parameters for the parent runbook.

   By using the `AutomationAssumeRole` parameter, Emily and her colleagues can use an existing IAM role that allows Automation to perform the actions in the runbook on their behalf. Unlike Example 1, the `AutomationAssumeRole` parameter is now required rather than optional. Because this runbook includes `aws:executeScript` actions, an Amazon Identity and Access Management (IAM) service role (or assume role) is always required. This requirement is necessary because some of the Python scripts specified for the actions call Amazon API operations.

Emily uses the `PrimaryPatchGroupTag` and `SecondaryPatchGroupTag` parameters to specify the tags associated with the primary and secondary group of database instances that will be patched. To simplify the required input parameters, she decides to use `StringMap` parameters rather than using multiple `String` parameters as she used in the Example 1 runbook. Optionally, the `Operation`, `RebootOption`, and `SnapshotId` parameters can be used to provide values to document parameters for `AWS-RunPatchBaseline`. To prevent invalid values from being provided to those document parameters, she defines the `allowedValues` as needed.

YAML

```
description: 'An example of an Automation runbook that patches groups of Amazon
 EC2 instances in stages.'
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Required) The Amazon Resource Name (ARN) of the IAM role that
 allows Automation to perform the actions on your behalf. If no role is specified,
 Systems Manager Automation uses your IAM permissions to operate this runbook.'
  PrimaryPatchGroupTag:
    type: StringMap
    description: '(Required) The tag for the primary group of instances you want
 to patch. Specify a key-value pair. Example: {"key" : "value"}'
  SecondaryPatchGroupTag:
    type: StringMap
    description: '(Required) The tag for the secondary group of instances you want
 to patch. Specify a key-value pair. Example: {"key" : "value"}'
  SnapshotId:
    type: String
    description: '(Optional) The snapshot ID to use to retrieve a patch baseline
 snapshot.'
    default: ''
  RebootOption:
    type: String
    description: '(Optional) Reboot behavior after a patch Install operation. If
 you choose NoReboot and patches are installed, the instance is marked as non-
compliant until a subsequent reboot and scan.'
    allowedValues:
      - NoReboot
      - RebootIfNeeded
```

```
    default: RebootIfNeeded
 Operation:
    type: String
    description: '(Optional) The update or configuration to perform on the
instance. The system checks if patches specified in the patch baseline are
installed on the instance. The install operation installs patches missing from
the baseline.'
    allowedValues:
      - Install
      - Scan
    default: Install
```

JSON

```
{
   "description":"An example of an Automation runbook that patches groups of
 Amazon EC2 instances in stages.",
   "schemaVersion":"0.3",
   "assumeRole":"{{AutomationAssumeRole}}",
   "parameters":{
      "AutomationAssumeRole":{
         "type":"String",
         "description":"(Required) The Amazon Resource Name (ARN) of the IAM role
 that allows Automation to perform the actions on your behalf. If no role is
 specified, Systems Manager Automation uses your IAM permissions to operate this
 runbook."
      },
      "PrimaryPatchGroupTag":{
         "type":"StringMap",
         "description":"(Required) The tag for the primary group of instances you
 want to patch. Specify a key-value pair. Example: {\"key\" : \"value\"}"
      },
      "SecondaryPatchGroupTag":{
         "type":"StringMap",
         "description":"(Required) The tag for the secondary group of instances
 you want to patch. Specify a key-value pair. Example: {\"key\" : \"value\"}"
      },
      "SnapshotId":{
         "type":"String",
         "description":"(Optional) The snapshot ID to use to retrieve a patch
 baseline snapshot.",
         "default":""
      },
```

```
      "RebootOption":{
         "type":"String",
         "description":"(Optional) Reboot behavior after a patch Install
 operation. If you choose NoReboot and patches are installed, the instance is
 marked as non-compliant until a subsequent reboot and scan.",
         "allowedValues":[
            "NoReboot",
            "RebootIfNeeded"
         ],
         "default":"RebootIfNeeded"
      },
      "Operation":{
         "type":"String",
         "description":"(Optional) The update or configuration to perform on
 the instance. The system checks if patches specified in the patch baseline are
 installed on the instance. The install operation installs patches missing from
 the baseline.",
         "allowedValues":[
            "Install",
            "Scan"
         ],
         "default":"Install"
      }
   }
},
```

2. With the top-level elements defined, Emily proceeds with authoring the actions that make up the `mainSteps` of the runbook. The first step gathers the IDs of all instances associated with the tag specified in the `PrimaryPatchGroupTag` parameter and outputs a `StringMap` parameter containing the instance ID and the current state of the instance. The output of this action is used in later actions.

   Note that the `script` input parameter isn't supported for JSON runbooks. JSON runbooks must provide script content using the `attachment` input parameter.

   YAML

```
mainSteps:
  - name: getPrimaryInstanceState
    action: 'aws:executeScript'
    timeoutSeconds: 120
    onFailure: Abort
    inputs:
```

```
      Runtime: python3.11
      Handler: getInstanceStates
      InputPayload:
        primaryTag: '{{PrimaryPatchGroupTag}}'
      Script: |-
        def getInstanceStates(events,context):
          import boto3

          #Initialize client
          ec2 = boto3.client('ec2')
          tag = events['primaryTag']
          tagKey, tagValue = list(tag.items())[0]
          instanceQuery = ec2.describe_instances(
          Filters=[
              {
                  "Name": "tag:" + tagKey,
                  "Values": [tagValue]
              }]
          )
          if not instanceQuery['Reservations']:
              noInstancesForTagString = "No instances found for specified tag."
              return({ 'noInstancesFound' : noInstancesForTagString })
          else:
              queryResponse = instanceQuery['Reservations']
              originalInstanceStates = {}
              for results in queryResponse:
                  instanceSet = results['Instances']
                  for instance in instanceSet:
                      instanceId = instance['InstanceId']
                      originalInstanceStates[instanceId] = instance['State']
['Name']
              return originalInstanceStates
    outputs:
      - Name: originalInstanceStates
        Selector: $.Payload
        Type: StringMap
    nextStep: verifyPrimaryInstancesRunning
```

JSON

```
"mainSteps":[
      {
         "name":"getPrimaryInstanceState",
```

```
         "action":"aws:executeScript",
         "timeoutSeconds":120,
         "onFailure":"Abort",
         "inputs":{
            "Runtime":"python3.11",
            "Handler":"getInstanceStates",
            "InputPayload":{
               "primaryTag":"{{PrimaryPatchGroupTag}}"
            },
            "Script":"..."
         },
         "outputs":[
            {
               "Name":"originalInstanceStates",
               "Selector":"$.Payload",
               "Type":"StringMap"
            }
         ],
         "nextStep":"verifyPrimaryInstancesRunning"
      },
```

3. Emily uses the output from the previous action in another `aws:executeScript` action to verify all instances associated with the tag specified in the `PrimaryPatchGroupTag` parameter are in a `running` state.

   If the instance state is already `running` or `shutting-down`, the script continues to loop through the remaining instances.

   If the instance state is `stopping`, the script polls for the instance to reach the `stopped` state and starts the instance.

   If the instance state is `stopped`, the script starts the instance.

   YAML

```
- name: verifyPrimaryInstancesRunning
    action: 'aws:executeScript'
    timeoutSeconds: 600
    onFailure: Abort
    inputs:
      Runtime: python3.11
      Handler: verifyInstancesRunning
      InputPayload:
```

```
        targetInstances: '{{getPrimaryInstanceState.originalInstanceStates}}'
      Script: |-
        def verifyInstancesRunning(events,context):
          import boto3

          #Initialize client
          ec2 = boto3.client('ec2')
          instanceDict = events['targetInstances']
          for instance in instanceDict:
            if instanceDict[instance] == 'stopped':
                print("The target instance " + instance + " is stopped. The
 instance will now be started.")
                ec2.start_instances(
                    InstanceIds=[instance]
                    )
            elif instanceDict[instance] == 'stopping':
                print("The target instance " + instance + " is stopping. Polling
 for instance to reach stopped state.")
                while instanceDict[instance] != 'stopped':
                    poll = ec2.get_waiter('instance_stopped')
                    poll.wait(
                        InstanceIds=[instance]
                    )
                ec2.start_instances(
                    InstanceIds=[instance]
                )
            else:
              pass
    nextStep: waitForPrimaryRunningInstances
```

JSON

```
{
         "name":"verifyPrimaryInstancesRunning",
         "action":"aws:executeScript",
         "timeoutSeconds":600,
         "onFailure":"Abort",
         "inputs":{
            "Runtime":"python3.11",
            "Handler":"verifyInstancesRunning",
            "InputPayload":{

 "targetInstances":"{{getPrimaryInstanceState.originalInstanceStates}}"
```

```
            },
            "Script":"..."
         },
         "nextStep":"waitForPrimaryRunningInstances"
      },
```

4. Emily verifies that all instances associated with the tag specified in the `PrimaryPatchGroupTag` parameter were started or already in a `running` state. Then she uses another script to verify that all instances, including those that were started in the previous action, have reached the `running` state.

   YAML

```
- name: waitForPrimaryRunningInstances
    action: 'aws:executeScript'
    timeoutSeconds: 300
    onFailure: Abort
    inputs:
      Runtime: python3.11
      Handler: waitForRunningInstances
      InputPayload:
        targetInstances: '{{getPrimaryInstanceState.originalInstanceStates}}'
      Script: |-
        def waitForRunningInstances(events,context):
          import boto3

          #Initialize client
          ec2 = boto3.client('ec2')
          instanceDict = events['targetInstances']
          for instance in instanceDict:
              poll = ec2.get_waiter('instance_running')
              poll.wait(
                  InstanceIds=[instance]
              )
    nextStep: returnPrimaryTagKey
```

   JSON

```
{
         "name":"waitForPrimaryRunningInstances",
         "action":"aws:executeScript",
         "timeoutSeconds":300,
         "onFailure":"Abort",
```

```
         "inputs":{
            "Runtime":"python3.11",
            "Handler":"waitForRunningInstances",
            "InputPayload":{

 "targetInstances":"{{getPrimaryInstanceState.originalInstanceStates}}"
            },
            "Script":"..."
         },
         "nextStep":"returnPrimaryTagKey"
      },
```

5. Emily uses two more scripts to return individual `String` values of the key and value of the tag specified in the `PrimaryPatchGroupTag` parameter. The values returned by these actions allows her to provide values directly to the `Targets` parameter for the `AWS-RunPatchBaseline` document. The automation then proceeds with patching the instance with the `AWS-RunPatchBaseline` document using the `aws:runCommand` action.

   YAML

```
- name: returnPrimaryTagKey
    action: 'aws:executeScript'
    timeoutSeconds: 120
    onFailure: Abort
    inputs:
      Runtime: python3.11
      Handler: returnTagValues
      InputPayload:
        primaryTag: '{{PrimaryPatchGroupTag}}'
      Script: |-
        def returnTagValues(events,context):
          tag = events['primaryTag']
          tagKey = list(tag)[0]
          stringKey = "tag:" + tagKey
          return {'tagKey' : stringKey}
    outputs:
      - Name: Payload
        Selector: $.Payload
        Type: StringMap
      - Name: primaryPatchGroupKey
        Selector: $.Payload.tagKey
        Type: String
    nextStep: returnPrimaryTagValue
```

```
  - name: returnPrimaryTagValue
    action: 'aws:executeScript'
    timeoutSeconds: 120
    onFailure: Abort
    inputs:
      Runtime: python3.11
      Handler: returnTagValues
      InputPayload:
        primaryTag: '{{PrimaryPatchGroupTag}}'
      Script: |-
        def returnTagValues(events,context):
          tag = events['primaryTag']
          tagKey = list(tag)[0]
          tagValue = tag[tagKey]
          return {'tagValue' : tagValue}
    outputs:
      - Name: Payload
        Selector: $.Payload
        Type: StringMap
      - Name: primaryPatchGroupValue
        Selector: $.Payload.tagValue
        Type: String
    nextStep: patchPrimaryInstances
  - name: patchPrimaryInstances
    action: 'aws:runCommand'
    onFailure: Abort
    timeoutSeconds: 7200
    inputs:
      DocumentName: AWS-RunPatchBaseline
      Parameters:
        SnapshotId: '{{SnapshotId}}'
        RebootOption: '{{RebootOption}}'
        Operation: '{{Operation}}'
      Targets:
        - Key: '{{returnPrimaryTagKey.primaryPatchGroupKey}}'
          Values:
            - '{{returnPrimaryTagValue.primaryPatchGroupValue}}'
      MaxConcurrency: 10%
      MaxErrors: 10%
    nextStep: returnPrimaryToOriginalState
```

JSON

```
{
         "name":"returnPrimaryTagKey",
         "action":"aws:executeScript",
         "timeoutSeconds":120,
         "onFailure":"Abort",
         "inputs":{
            "Runtime":"python3.11",
            "Handler":"returnTagValues",

               "Type":"StringMap"
            },
            {
               "Name":"primaryPatchGroupValue",
               "Selector":"$.Payload.tagValue",
               "Type":"String"
            }
         ],
         "nextStep":"patchPrimaryInstances"
      },
      {
         "name":"patchPrimaryInstances",
         "action":"aws:runCommand",
         "onFailure":"Abort",
         "timeoutSeconds":7200,
         "inputs":{
            "DocumentName":"AWS-RunPatchBaseline",
            "Parameters":{
               "SnapshotId":"{{SnapshotId}}",
               "RebootOption":"{{RebootOption}}",
               "Operation":"{{Operation}}"
            },
            "Targets":[
               {
                  "Key":"{{returnPrimaryTagKey.primaryPatchGroupKey}}",
                  "Values":[
                     "{{returnPrimaryTagValue.primaryPatchGroupValue}}"
                  ]
               }
            ],
            "MaxConcurrency":"10%",
            "MaxErrors":"10%"
         },
         "nextStep":"returnPrimaryToOriginalState"
      },
```

6. After the patching operation completes, Emily wants the automation to return the target instances associated with the tag specified in the `PrimaryPatchGroupTag` parameter to the same state they were before the automation started. She does this by again using the output from the first action in a script. Based on the original state of the target instance, if the instance

was previously in any state other than `running`, the instance is stopped. Otherwise, if the instance state is `running`, the script continues to loop through the remaining instances.

YAML

```
- name: returnPrimaryToOriginalState
    action: 'aws:executeScript'
    timeoutSeconds: 600
    onFailure: Abort
    inputs:
      Runtime: python3.11
      Handler: returnToOriginalState
      InputPayload:
        targetInstances: '{{getPrimaryInstanceState.originalInstanceStates}}'
      Script: |-

8. Emily reviews the completed scripted runbook content and creates the runbook in the same Amazon Web Services account and Amazon Web Services Region as the target instances. Now she's ready to test her runbook to make sure the automation operates as desired before implementing it into her production environment. The following is the completed scripted runbook content.

   YAML

```
description: An example of an Automation runbook that patches groups of Amazon EC2
 instances in stages.
schemaVersion: '0.3'
assumeRole: '{{AutomationAssumeRole}}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Required) The Amazon Resource Name (ARN) of the IAM role that
 allows Automation to perform the actions on your behalf. If no role is specified,
 Systems Manager Automation uses your IAM permissions to operate this runbook.'
  PrimaryPatchGroupTag:
    type: StringMap
    description: '(Required) The tag for the primary group of instances you want
 to patch. Specify a key-value pair. Example: {"key" : "value"}'
  SecondaryPatchGroupTag:
    type: StringMap
    description: '(Required) The tag for the secondary group of instances you want
 to patch. Specify a key-value pair. Example: {"key" : "value"}'
  SnapshotId:
    type: String
    description: '(Optional) The snapshot ID to use to retrieve a patch baseline
 snapshot.'
    default: ''
  RebootOption:
    type: String
    description: '(Optional) Reboot behavior after a patch Install operation. If
 you choose NoReboot and patches are installed, the instance is marked as non-
compliant until a subsequent reboot and scan.'
    allowedValues:
```

```
      - NoReboot
      - RebootIfNeeded
    default: RebootIfNeeded
  Operation:
    type: String
    description: '(Optional) The update or configuration to perform on the
 instance. The system checks if patches specified in the patch baseline are
 installed on the instance. The install operation installs patches missing from
 the baseline.'
    allowedValues:
      - Install
      - Scan
    default: Install
mainSteps:
  - name: getPrimaryInstanceState

For more information about the automation actions used in this example, see the Systems Manager Automation actions reference.

Additional runbook examples

The following example runbook demonstrate how you can use Amazon Systems Manager automation actions to automate common deployment, troubleshooting, and maintenance tasks.

> **Note**
>
> The example runbooks in this section are provided to demonstrate how you can create custom runbooks to support your specific operational needs. These runbooks aren't meant for use in production environments as is. However, you can customize them for your own use.

Examples

- Deploy VPC architecture and Microsoft Active Directory domain controllers
- Restore a root volume from the latest snapshot
- Create an AMI and cross-Region copy

Deploy VPC architecture and Microsoft Active Directory domain controllers

To increase efficiency and standardize common tasks, you might choose to automate deployments. This is useful if you regularly deploy the same architecture across multiple accounts and Amazon Web Services Regions. Automating architecture deployments can also reduce the potential for human error that can occur when deploying architecture manually. Amazon Systems Manager Automation actions can help you accomplish this. Automation is a tool in Amazon Systems Manager.

The following example Amazon Systems Manager runbook performs these actions:

- Retrieves the latest Windows Server 2016 Amazon Machine Image (AMI) using Systems Manager Parameter Store to use when launching the EC2 instances that will be configured as domain controllers. Parameter Store is a tool in Amazon Systems Manager.
- Uses the `aws:executeAwsApi` automation action to call several Amazon API operations to create the VPC architecture. The domain controller instances are launched in private subnets, and connect to the internet using a NAT gateway. This allows the SSM Agent on the instances to access the requisite Systems Manager endpoints.
- Uses the `aws:waitForAwsResourceProperty` automation action to confirm the instances launched by the previous action are `Online` for Amazon Systems Manager.
- Uses the `aws:runCommand` automation action to configure the instances launched as Microsoft Active Directory domain controllers.

Restore a root volume from the latest snapshot

The operating system on a root volume can become corrupted for various reasons. For example, following a patching operation, instances might fail to boot successfully due to a corrupted kernel or registry. Automating common troubleshooting tasks, like restoring a root volume from the latest snapshot taken before the patching operation, can reduce downtime and expedite your troubleshooting efforts. Amazon Systems Manager Automation actions can help you accomplish this. Automation is a tool in Amazon Systems Manager.

The following example Amazon Systems Manager runbook performs these actions:

- Uses the `aws:executeAwsApi` automation action to retrieve details from the root volume of the instance.
- Uses the `aws:executeScript` automation action to retrieve the latest snapshot for the root volume.
- Uses the `aws:branch` automation action to continue the automation if a snapshot is found for the root volume.

YAML

Create an AMI and cross-Region copy

Creating an Amazon Machine Image (AMI) of an instance is a common process used in backup and recovery. You might also choose to copy an AMI to another Amazon Web Services Region as part of a disaster recovery architecture. Automating common maintenance tasks can reduce downtime if an issue requires failover. Amazon Systems Manager Automation actions can help you accomplish this. Automation is a tool in Amazon Systems Manager.

The following example Amazon Systems Manager runbook performs these actions:

- Uses the `aws:executeAwsApi` automation action to create an AMI.
- Uses the `aws:waitForAwsResourceProperty` automation action to confirm the availability of the AMI.

- Uses the `aws:executeScript` automation action to copy the AMI to the destination Region.

              "Handler": "crossRegionImageCopy",
              "InputPayload": {
                 "newImageId": "{{ createImage.newImageId }}"
              },
              "Attachment": "crossRegionImageCopy.py"
           }
        }
     ],
     "files": {
          "crossRegionImageCopy.py": {
              "checksums": {
                  "sha256": "sampleETagValue"
              }
          }
      }
  }
```

Creating input parameters that populate Amazon resources

Automation populates Amazon resources in the Amazon Web Services Management Console that match the resource type you define for an input parameter. Resources in your Amazon Web Services account that match the resource type are displayed in a dropdown list for you to choose. You can define input parameter types for Amazon Elastic Compute Cloud (Amazon EC2) instances, Amazon Simple Storage Service (Amazon S3) buckets, and Amazon Identity and Access Management (IAM) roles. The supported type definitions and the regular expressions used to locate matching resources are as follows:

- `AWS::EC2::Instance::Id` - `^m?i-([a-z0-9]{8}|[a-z0-9]{17})$`
- `List<AWS::EC2::Instance::Id>` - `^m?i-([a-z0-9]{8}|[a-z0-9]{17})$`
- `AWS::S3::Bucket::Name` - `^[0-9a-z][a-z0-9\\-\\.]{3,63}$`
- `List<AWS::S3::Bucket::Name>` - `^[0-9a-z][a-z0-9\\-\\.]{3,63}$`

- AWS::IAM::Role::Arn - ^arn:(aws|aws-cn|aws-us-gov|aws-iso|aws-iso-b):iam::[0-9]{12}:role/.*$
- List<AWS::IAM::Role::Arn> - ^arn:(aws|aws-cn|aws-us-gov|aws-iso|aws-iso-b):iam::[0-9]{12}:role/.*$

The following is an example of input parameter types defined in runbook content.

YAML

```
description: Enables encryption on an Amazon S3 bucket
schemaVersion: '0.3'
assumeRole: '{{ AutomationAssumeRole }}'
parameters:
  BucketName:
    type: 'AWS::S3::Bucket::Name'
    description: (Required) The name of the Amazon S3 bucket you want to encrypt.
  SSEAlgorithm:
    type: String
    description: (Optional) The server-side encryption algorithm to use for the
 default encryption.
    default: AES256
  AutomationAssumeRole:
    type: 'AWS::IAM::Role::Arn'
    description: (Optional) The Amazon Resource Name (ARN) of the role that allows
 Automation to perform the actions on your behalf.
    default: ''
mainSteps:
  - name: enableBucketEncryption
    action: 'aws:executeAwsApi'
    inputs:
      Service: s3
      Api: PutBucketEncryption
      Bucket: '{{BucketName}}'
      ServerSideEncryptionConfiguration:
        Rules:
          - ApplyServerSideEncryptionByDefault:
              SSEAlgorithm: '{{SSEAlgorithm}}'
    isEnd: true
```

JSON

```
{
```

```
  "description": "Enables encryption on an Amazon S3 bucket",
  "schemaVersion": "0.3",

```
}
```

Using Document Builder to create runbooks

If the Amazon Systems Manager public runbooks don't support all the actions you want to perform on your Amazon resources, you can create your own runbooks. To create a custom runbook, you can manually create a local YAML or JSON format file with the appropriate automation actions. Alternatively, you can use Document Builder in the Systems Manager Automation console to build a custom runbook.

Using Document Builder, you can add automation actions to your custom runbook and provide the required parameters without having to use JSON or YAML syntax. After you add steps and create the runbook, the system converts the actions you've added into the YAML format that Systems Manager can use to run automation.

Runbooks support the use of Markdown, a markup language, which lets you add wiki-style descriptions to runbooks and individual steps within the runbook. For more information about using Markdown, see Using Markdown in Amazon.

Create a runbook using Document Builder

Before you begin

We recommend that you read about the different actions that you can use within a runbook. For more information, see Systems Manager Automation actions reference.

To create a runbook using Document Builder

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. Choose **Create automation**.
4. For **Name**, enter a descriptive name for the runbook.
5. For **Document description**, provide the markdown style description for the runbook. You can provide instructions for using the runbook, numbered steps, or any other type of information to describe the runbook. Refer to the default text for information about formatting your content.

> **Tip**
>
> Toggle between **Hide preview** and **Show preview** to see what your description content looks like as you compose.

6. (Optional) For **Assume role**, enter the name or ARN of a service role to perform actions on your behalf. If you don't specify a role, Automation uses the access permissions of the user who runs the automation.

> **Important**
>
> For runbooks not owned by Amazon that use the `aws:executeScript` action, a role must be specified. For information, see Permissions for using runbooks.

7. (Optional) For **Outputs**, enter any outputs for the automation of this runbook to make available for other processes.

   For example, if your runbook creates a new AMI, you might specify ["CreateImage.ImageId"], and then use this output to create new instances in a subsequent automation.

8. (Optional) Expand the **Input parameters** section and do the following.

   1. For **Parameter name**, enter a descriptive name for the runbook parameter you're creating.
   2. For **Type**, choose a type for the parameter, such as `String` or `MapList`.
   3. For **Required**, do one of the following:
      - Choose **Yes** if a value for this runbook parameter must be supplied at runtime.
      - Choose **No** if the parameter isn't required, and (optional) enter a default parameter value in **Default value**.
   4. For **Description**, enter a description for the runbook parameter.

> **Note**
>
> To add more runbook parameters, choose **Add a parameter**. To remove a runbook parameter, choose the **X** (Remove) button.

9. (Optional) Expand the **Target type** section and choose a target type to define the kinds of resources the automation can run on. For example, to use a runbook on EC2 instances, choose `/AWS::EC2::Instance`.

   > **Note**
   >
   > If you specify a value of '/', the runbook can run on all types of resources. For a list of valid resource types, see Amazon Resource Types Reference in the *Amazon CloudFormation User Guide*.

10. (Optional) Expand the **Document tags** section and enter one or more tag key-value pairs to apply to the runbook. Tags make it easier to identify, organize, and search for resources.

11. In the **Step 1** section, provide the following information.

    - For **Step name**, enter a descriptive name for the first step of the automation.
    - For **Action type**, select the action type to use for this step.

      For a list and information about the available action types, see Systems Manager Automation actions reference.
    - For **Description**, enter a description for the automation step. You can use Markdown to format your text.
    - Depending on the **Action type** selected, enter the required inputs for the action type in the **Step inputs** section. For example, if you selected the action `aws:approve`, you must specify a value for the `Approvers` property.

      For information about the step input fields, see the entry in Systems Manager Automation actions reference for the action type you selected. For example: `aws:executeStateMachine` – Run an Amazon Step Functions state machine.
    - (Optional) For **Additional inputs**, provide any additional input values needed for your runbook. The available input types depend on the action type you selected for the step. (Note that some action types require input values.)

      > **Note**
      >
      > To add more inputs, choose **Add optional input**. To remove an input, choose the **X** (Remove) button.

- (Optional) For **Outputs**, enter any outputs for this step to make available for other processes.

  > **Note**
  >
  > **Outputs** isn't available for all action types.

- (Optional) Expand the **Common properties** section and specify properties for the actions that are common to all automation actions. For example, for **Timeout seconds**, you can provide a value in seconds to specify how long the step can run before it's stopped.

  For more information, see Properties shared by all actions.

> **Note**
>
> To add more steps, select **Add step** and repeat the procedure for creating a step. To remove a step, choose **Remove step**.

12. Choose **Create automation** to save the runbook.

Create a runbook that runs scripts

The following procedure shows how to use Document Builder in the Amazon Systems Manager Automation console to create a custom runbook that runs a script.

The first step of the runbook you create runs a script to launch an Amazon Elastic Compute Cloud (Amazon EC2) instance. The second step runs another script to monitor for the instance status check to change to ok. Then, an overall status of `Success` is reported for the automation.

Before you begin

Make sure you have completed the following steps:

- Verify that you have administrator privileges, or that you have been granted the appropriate permissions to access Systems Manager in Amazon Identity and Access Management (IAM).

  For information, see Verifying user access for runbooks.

- Verify that you have an IAM service role for Automation (also known as an *assume role*) in your Amazon Web Services account. The role is required because this walkthrough uses the `aws:executeScript` action.

  For information about creating this role, see Configuring a service role (assume role) access for automations.

  For information about the IAM service role requirement for running `aws:executeScript`, see Permissions for using runbooks.
- Verify that you have permission to launch EC2 instances.

  For information, see IAM and Amazon EC2 in the *Amazon EC2 User Guide*.

To create a custom runbook that runs scripts using Document Builder

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. Choose **Create automation**.
4. For **Name**, type this descriptive name for the runbook: **`LaunchInstanceAndCheckStatus`**.
5. (Optional) For **Document description**, replace the default text with a description for this runbook, using Markdown. The following is an example.

```
##Title: LaunchInstanceAndCheckState
    -----
    **Purpose**: This runbook first launches an EC2 instance using the AMI
 ID provided in the parameter ```imageId```. The second step of this runbook
 continuously checks the instance status check value for the launched instance
 until the status ```ok``` is returned.

    ##Parameters:
    -----
    Name | Type | Description | Default Value
    ------------- | ------------- | ------------- | -------------
    assumeRole | String | (Optional) The ARN of the role that allows Automation to
 perform the actions on your behalf. | -
    imageId  | String | (Optional) The AMI ID to use for launching the instance.
 The default value uses the latest Amazon Linux 2023 AMI ID available. | {{ ssm:/
aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64 }}
```

6. For **Assume role**, enter the ARN of the IAM service role for Automation (Assume role) for the automation, in the format **`arn:aws-cn:iam::111122223333:role/AutomationServiceRole`**. Substitute your Amazon Web Services account ID for 111122223333.

   The role you specify is used to provide the permissions needed to start the automation.

   > **Important**
   >
   > For runbooks not owned by Amazon that use the `aws:executeScript` action, a role must be specified. For information, see Permissions for using runbooks.

7. Expand **Input parameters** and do the following.

   1. For **Parameter name**, enter **`imageId`**.
   2. For **Type**, choose **`String`**.
   3. For **Required**, choose No.
   4. For **Default value**, enter the following.

      ```
      {{ ssm:/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64 }}
      ```

      > **Note**
      >
      > This value launches an Amazon EC2 instance using the latest Amazon Linux 2023 Amazon Machine Image (AMI) ID. If you want to use a different AMI, replace the value with your AMI ID.

   5. For **Description**, enter the following.

      ```
      (Optional) The AMI ID to use for launching the instance. The default value uses
       the latest released Amazon Linux 2023 AMI ID.
      ```

8. Choose **Add a parameter** to create the second parameter, **`tagValue`**, and enter the following.

   1. For **Parameter name**, enter **`tagValue`**.
   2. For **Type**, choose **`String`**.
   3. For **Required**, choose No.

4. For **Default value**, enter **`LaunchedBySsmAutomation`**. This adds the tag key-pair value `Name:LaunchedBySsmAutomation` to the instance.
5. For **Description**, enter the following.

```
(Optional) The tag value to add to the instance. The default value is
 LaunchedBySsmAutomation.
```

9. Choose **Add a parameter** to create the third parameter, **`instanceType`**, and enter the following information.
   1. For **Parameter name**, enter **`instanceType`**.
   2. For **Type**, choose **`String`**.
   3. For **Required**, choose No.
   4. For **Default value**, enter **`t2.micro`**.
   5. For **Parameter description**, enter the following.

```
(Optional) The instance type to use for the instance. The default value is
 t2.micro.
```

10. Expand **Target type** and choose **`"/"`**.
11. (Optional) Expand **Document tags** to apply resource tags to your runbook. For **Tag key**, enter **`Purpose`**, and for **Tag value**, enter **`LaunchInstanceAndCheckState`**.
12. In the **Step 1** section, complete the following steps.
    1. For **Step name**, enter this descriptive step name for the first step of the automation: **`LaunchEc2Instance`**.
    2. For **Action type**, choose **Run a script** (**`aws:executeScript`**).
    3. For **Description**, enter a description for the automation step, such as the following.

```
**About This Step**

   This step first launches an EC2 instance using the ```aws:executeScript```
 action and the provided script.
```

    4. Expand **Inputs**.
    5. For **Runtime**, choose the runtime language to use to run the provided script.

6. For **Handler**, enter **`launch_instance`**. This is the function name declared in the following script.

   > **Note**
   >
   > This is not required for PowerShell.

7. For **Script**, replace the default contents with the following. Be sure to match the script with the corresponding runtime value.

   Python

   ```
   def launch_instance(events, context):
         import boto3
         ec2 = boto3.client('ec2')

         image_id = events['image_id']
         tag_value = events['tag_value']
         instance_type = events['instance_type']

         tag_config = {'ResourceType': 'instance', 'Tags': [{'Key':'Name',
    'Value':tag_value}]}

         res = ec2.run_instances(ImageId=image_id, InstanceType=instance_type,
    MaxCount=1, MinCount=1, TagSpecifications=[tag_config])

         instance_id = res['Instances'][0]['InstanceId']

         print('[INFO] 1 EC2 instance is successfully launched', instance_id)

         return { 'InstanceId' : instance_id }
   ```

   PowerShell

   ```
   Install-Module AWS.Tools.EC2 -Force
       Import-Module AWS.Tools.EC2

       $payload = $env:InputPayload | ConvertFrom-Json

       $imageid = $payload.image_id

       $tagvalue = $payload.tag_value
   ```

```
    $instanceType = $payload.instance_type

    $type = New-Object Amazon.EC2.InstanceType -ArgumentList $instanceType

    $resource = New-Object Amazon.EC2.ResourceType -ArgumentList 'instance'

    $tag = @{Key='Name';Value=$tagValue}

    $tagSpecs = New-Object Amazon.EC2.Model.TagSpecification

    $tagSpecs.ResourceType = $resource

    $tagSpecs.Tags.Add($tag)

    $res = New-EC2Instance -ImageId $imageId -MinCount 1 -MaxCount 1 -
InstanceType $type -TagSpecification $tagSpecs

    return @{'InstanceId'=$res.Instances.InstanceId}
```

8. Expand **Additional inputs**.
9. For **Input name**, choose **InputPayload**. For **Input value**, enter the following YAML data.

```
image_id: "{{ imageId }}"
    tag_value: "{{ tagValue }}"
    instance_type: "{{ instanceType }}"
```

13. Expand **Outputs** and do the following:
    - For **Name**, enter **`payload`**.
    - For **Selector**, enter **`$.Payload`**.
    - For **Type**, choose `StringMap`.
14. Choose **Add step** to add a second step to the runbook. The second step queries the status of the instance launched in Step 1 and waits until the status returned is ok.
15. In the **Step 2** section, do the following.
    1. For **Step name**, enter this descriptive name for the second step of the automation: **`WaitForInstanceStatusOk`**.
    2. For **Action type**, choose **Run a script (`aws:executeScript`)**.
    3. For **Description**, enter a description for the automation step, such as the following.

```
**About This Step**

   The script continuously polls the instance status check value for the
 instance launched in Step 1 until the ```ok``` status is returned.
```

4. For **Runtime**, choose the runtime language to be used for executing the provided script.
5. For **Handler**, enter **`poll_instance`**. This is the function name declared in the following script.

> **Note**
>
> This is not required for PowerShell.

6. For **Script**, replace the default contents with the following. Be sure to match the script with the corresponding runtime value.

   Python

```
def poll_instance(events, context):
      import boto3
      import time

      ec2 = boto3.client('ec2')

      instance_id = events['InstanceId']

      print('[INFO] Waiting for instance status check to report ok',
 instance_id)

      instance_status = "null"

      while True:
        res = ec2.describe_instance_status(InstanceIds=[instance_id])

        if len(res['InstanceStatuses']) == 0:
          print("Instance status information is not available yet")
          time.sleep(5)
          continue

        instance_status = res['InstanceStatuses'][0]['InstanceStatus']
['Status']
```

```
        print('[INFO] Polling to get status of the instance', instance_status)

        if instance_status == 'ok':
          break

        time.sleep(10)

      return {'Status': instance_status, 'InstanceId': instance_id}
```

PowerShell

```
Install-Module AWS.Tools.EC2 -Force

$inputPayload = $env:InputPayload | ConvertFrom-Json

$instanceId = $inputPayload.payload.InstanceId

$status = Get-EC2InstanceStatus -InstanceId $instanceId

while ($status.Status.Status -ne 'ok'){
   Write-Host 'Polling get status of the instance', $instanceId

   Start-Sleep -Seconds 5

   $status = Get-EC2InstanceStatus -InstanceId $instanceId
}

return @{Status = $status.Status.Status; InstanceId = $instanceId}
```

7. Expand **Additional inputs**.
8. For **Input name**, choose **InputPayload**. For **Input value**, enter the following:

```
{{ LaunchEc2Instance.payload }}
```

16. Choose **Create automation** to save the runbook.

Using scripts in runbooks

Automation runbooks support running scripts as part of the automation. Automation is a tool in Amazon Systems Manager. By using runbooks, you can run scripts directly in Amazon without creating a separate compute environment to run your scripts. Because runbooks can run script

steps along with other automation step types, such as approvals, you can manually intervene in critical or ambiguous situations. You can send the output from `aws:executeScript` actions in your runbooks to Amazon CloudWatch Logs. For more information, see Logging Automation action output with CloudWatch Logs.

Permissions for using runbooks

To use a runbook, Systems Manager must use the permissions of an Amazon Identity and Access Management (IAM) role. The method that Automation uses to determine which role's permissions to use depends on a few factors, and whether a step uses the `aws:executeScript` action.

For runbooks that don't use `aws:executeScript`, Automation uses one of two sources of permissions:

- The permissions of an IAM service role, or Assume role, that is specified in the runbook or passed in as a parameter.
- If no IAM service role is specified, the permissions of the user who started the automation.

When a step in a runbook includes the `aws:executeScript` action, however, an IAM service role (Assume role) is always required if the Python or PowerShell script specified for the action is calling any Amazon API operations. Automation checks for this role in the following order:

- The permissions of an IAM service role, or Assume role, that is specified in the runbook or passed in as a parameter.
- If no role is found, Automation attempts to run the Python or PowerShell script specified for `aws:executeScript` without any permissions. If the script is calling an Amazon API operation (for example the Amazon EC2 `CreateImage` operation), or attempting to act on an Amazon resource (such as an EC2 instance), the step containing the script fails, and Systems Manager returns an error message reporting the failure.

Adding scripts to runbooks

You can add scripts to your runbooks by including the script inline as part of a step in the runbook. You can also attach scripts to the runbook by uploading the scripts from your local machine or by specifying an Amazon Simple Storage Service (Amazon S3) bucket where the scripts are located. After a step that runs a script is complete, the output of the script is available as a JSON object, which you can then use as input for subsequent steps in your runbook. For more

information about the `aws:executeScript` action and how to use attachments for scripts, see `aws:executeScript` – Run a script.

Script constraints for runbooks

Runbooks enforce a limit of five file attachments. Scripts can either be in the form of a Python script (.py), a PowerShell Core script (.ps1), or attached as contents within a .zip file.

Using conditional statements in runbooks

By default, the steps that you define in the `mainSteps` section of a runbook run in sequential order. After one action is completed, the next action specified in the `mainSteps` section begins. Furthermore, if an action fails to run, the entire automation fails (by default). You can use the `aws:branch` automation action and the runbook options described in this section to create automations that perform *conditional branching*. This means that you can create automations that jump to a different step after evaluating different choices or that dynamically respond to changes when a step is complete. Here is a list of options that you can use to create dynamic automations:

- **`aws:branch`**: This automation action lets you create a dynamic automation that evaluates multiple choices in a single step and then jumps to a different step in the runbook based on the results of that evaluation.
- **`nextStep`**: This option specifies which step in an automation to process next after successfully completing a step.
- **`isEnd`**: This option stops an automation at the end of a specific step. The default value for this option is false.
- **`isCritical`**: This option designates a step as critical for the successful completion of the automation. If a step with this designation fails, then Automation reports the final status of the automation as `Failed`. The default value for this option is `true`.
- **`onFailure`**: This option indicates whether the automation should stop, continue, or go to a different step on failure. The default value for this option is abort.

The following section describes the `aws:branch` automation action. For more information about the `nextStep`, `isEnd`, `isCritical`, and `onFailure` options, see Example `aws:branch` runbooks.

Working with the aws:branch action

The aws:branch action offers the most dynamic conditional branching options for automations. As noted earlier, this action allows your automation to evaluate multiple conditions in a single step and then jump to a new step based on the results of that evaluation. The aws:branch action functions like an IF-ELIF-ELSE statement in programming.

Here is a YAML example of an aws:branch step.

```
- name: ChooseOSforCommands
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runPowerShellCommand
      Variable: "{{GetInstance.platform}}"
      StringEquals: Windows
    - NextStep: runShellCommand
      Variable: "{{GetInstance.platform}}"
      StringEquals: Linux
    Default:
      PostProcessing
```

When you specify the aws:branch action for a step, you specify Choices that the automation must evaluate. The automation can evaluate Choices based on the value of a parameter that you specified in the Parameters section of the runbook. The automation can also evaluate Choices based on output from a previous step.

The automation evaluates each choice by using a Boolean expression. If the evaluation determines that the first choice is true, then the automation jumps to the step designated for that choice. If the evaluation determines that the first choice is false, then the automation evaluates the next choice. If your step includes three or more Choices, then the automation evaluates each choice in sequential order until it evaluates a choice that is true. The automation then jumps to the designated step for the true choice.

If none of the Choices are true, the automation checks to see if the step contains a Default value. A Default value defines a step that the automation should jump to if none of the choices are true. If no Default value is specified for the step, then the automation processes the next step in the runbook.

Here is an aws:branch step in YAML named **chooseOSfromParameter**. The step includes two Choices: (NextStep: runWindowsCommand) and (NextStep: runLinuxCommand). The

automation evaluates these `Choices` to determine which command to run for the appropriate operating system. The `Variable` for each choice uses `{{OSName}}`, which is a parameter that the runbook author defined in the `Parameters` section of the runbook.

```
mainSteps:
- name: chooseOSfromParameter
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runWindowsCommand
      Variable: "{{OSName}}"
      StringEquals: Windows
    - NextStep: runLinuxCommand
      Variable: "{{OSName}}"
      StringEquals: Linux
```

Here is an `aws:branch` step in YAML named **chooseOSfromOutput**. The step includes two `Choices`: (`NextStep: runPowerShellCommand`) and (`NextStep: runShellCommand`). The automation evaluates these `Choices` to determine which command to run for the appropriate operating system. The `Variable` for each choice uses `{{GetInstance.platform}}`, which is the output from an earlier step in the runbook. This example also includes an option called `Default`. If the automation evaluates both `Choices`, and neither choice is `true`, then the automation jumps to a step called `PostProcessing`.

```
mainSteps:
- name: chooseOSfromOutput
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runPowerShellCommand
      Variable: "{{GetInstance.platform}}"
      StringEquals: Windows
    - NextStep: runShellCommand
      Variable: "{{GetInstance.platform}}"
      StringEquals: Linux
    Default:
      PostProcessing
```

Creating an aws:branch step in a runbook

When you create an `aws:branch` step in a runbook, you define the `Choices` the automation should evaluate to determine which step the automation should jump to next. As noted earlier, `Choices` are evaluated by using a Boolean expression. Each choice must define the following options:

- **NextStep**: The next step in the runbook to process if the designated choice is `true`.
- **Variable**: Specify either the name of a parameter that is defined in the `Parameters` section of the runbook, a variable defined in the `Variables` section, or specify an output object from a previous step.

  Specify variable values by using the following form.

  ```
  Variable: "{{variable name}}"
  ```

  Specify parameter values by using the following form.

  ```
  Variable: "{{parameter name}}"
  ```

  Specify output object variables by using the following form.

  ```
  Variable: "{{previousStepName.outputName}}"
  ```

  > **Note**
  >
  > Creating the output variable is described in more detail in the next section, About creating the output variable.

- **Operation**: The criteria used to evaluate the choice, such as `StringEquals: Linux`. The `aws:branch` action supports the following operations:

  String operations

  - StringEquals
  - EqualsIgnoreCase
  - StartsWith
  - EndsWith
  - Contains

Numeric operations

- NumericEquals
- NumericGreater
- NumericLesser
- NumericGreaterOrEquals
- NumericLesser
- NumericLesserOrEquals

Boolean operation

- BooleanEquals

> **Important**
>
> When you create a runbook, the system validates each operation in the runbook. If an operation isn't supported, the system returns an error when you try to create the runbook.

- **Default**: Specify a fallback step that the automation should jump to if none of the `Choices` are `true`.

> **Note**
>
> If you don't want to specify a `Default` value, then you can specify the `isEnd` option. If none of the `Choices` are `true` and no `Default` value is specified, then the automation stops at the end of the step.

Use the following templates to help you construct the `aws:branch` step in your runbook. Replace each *`example resource placeholder`* with your own information.

YAML

```
mainSteps:
- name: step name
  action: aws:branch
  inputs:
```

```
    Choices:
    - NextStep: step to jump to if evaluation for this choice is true
      Variable: "{{parameter name or output from previous step}}"
      Operation type: Operation value
    - NextStep: step to jump to if evaluation for this choice is true
      Variable: "{{parameter name or output from previous step}}"
      Operation type: Operation value
    Default:
      step to jump to if all choices are false
```

JSON

```
{
   "mainSteps":[
      {
         "name":"a name for the step",
         "action":"aws:branch",
         "inputs":{
            "Choices":[
               {
                  "NextStep":"step to jump to if evaluation for this choice is
 true",
                  "Variable":"{{parameter name or output from previous step}}",
                  "Operation type":"Operation value"
               },
               {
                  "NextStep":"step to jump to if evaluation for this choice is
 true",
                  "Variable":"{{parameter name or output from previous step}}",
                  "Operation type":"Operation value"
               }
            ],
            "Default":"step to jump to if all choices are false"
         }
      }
   ]
}
```

About creating the output variable

To create an `aws:branch` choice that references the output from a previous step, you need to identify the name of the previous step and the name of the output field. You then combine the names of the step and the field by using the following format.

`Variable: "{{previousStepName.outputName}}"`

For example, the first step in the following example is named `GetInstance`. And then, under `outputs`, there is a field called `platform`. In the second step (`ChooseOSforCommands`), the author wants to reference the output from the platform field as a variable. To create the variable, simply combine the step name (GetInstance) and the output field name (platform) to create `Variable: "{{GetInstance.platform}}"`.

```
mainSteps:
- Name: GetInstance
  action: aws:executeAwsApi
  inputs:
    Service: ssm
    Api: DescribeInstanceInformation
    Filters:
    - Key: InstanceIds
      Values: ["{{ InstanceId }}"]
  outputs:
  - Name: myInstance
    Selector: "$.InstanceInformationList[0].InstanceId"
    Type: String
  - Name: platform
    Selector: "$.InstanceInformationList[0].PlatformType"
    Type: String
- name: ChooseOSforCommands
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runPowerShellCommand
      Variable: "{{GetInstance.platform}}"
      StringEquals: Windows
    - NextStep: runShellCommand
      Variable: "{{GetInstance.platform}}"
      StringEquals: Linux
    Default:
      Sleep
```

Here is an example that shows how *"Variable": "{{ describeInstance.Platform }}"* is created from the previous step and the output.

```
- name: describeInstance
  action: aws:executeAwsApi
  onFailure: Abort
  inputs:
    Service: ec2
    Api: DescribeInstances
    InstanceIds:
    - "{{ InstanceId }}"
  outputs:
  - Name: Platform
    Selector: "$.Reservations[0].Instances[0].Platform"
    Type: String
  nextStep: branchOnInstancePlatform
- name: branchOnInstancePlatform
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runEC2RescueForWindows
      Variable: "{{ describeInstance.Platform }}"
      StringEquals: windows
    Default: runEC2RescueForLinux
```

Example `aws:branch` runbooks

Here are some example runbooks that use `aws:branch`.

Example 1: Using `aws:branch` with an output variable to run commands based on the operating system type

In the first step of this example (`GetInstance`), the runbook author uses the `aws:executeAwsApi` action to call the `ssm DescribeInstanceInformation` API operation. The author uses this action to determine the type of operating system being used by an instance. The `aws:executeAwsApi` action outputs the instance ID and the platform type.

In the second step (`ChooseOSforCommands`), the author uses the `aws:branch` action with two `Choices` (`NextStep: runPowerShellCommand`) and (`NextStep: runShellCommand`). The automation evaluates the operating system of the instance by using the output from the previous step (`Variable: "{{GetInstance.platform}}"`). The automation jumps to a step for the designated operating system.

```
---
schemaVersion: '0.3'
assumeRole: "{{AutomationAssumeRole}}"
parameters:
  AutomationAssumeRole:
    default: ""
    type: String
mainSteps:
- name: GetInstance
  action: aws:executeAwsApi
  inputs:
    Service: ssm
    Api: DescribeInstanceInformation
  outputs:
  - Name: myInstance
    Selector: "$.InstanceInformationList[0].InstanceId"
    Type: String
  - Name: platform
    Selector: "$.InstanceInformationList[0].PlatformType"
    Type: String
- name: ChooseOSforCommands
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runPowerShellCommand
      Variable: "{{GetInstance.platform}}"
      StringEquals: Windows
    - NextStep: runShellCommand
      Variable: "{{GetInstance.platform}}"
      StringEquals: Linux
    Default:
      Sleep
- name: runShellCommand
  action: aws:runCommand
  inputs:
    DocumentName: AWS-RunShellScript
    InstanceIds:
    - "{{GetInstance.myInstance}}"
    Parameters:
      commands:
      - ls
  isEnd: true
- name: runPowerShellCommand
```

```
  action: aws:runCommand
  inputs:
    DocumentName: AWS-RunPowerShellScript
    InstanceIds:
    - "{{GetInstance.myInstance}}"
    Parameters:
      commands:
      - ls
  isEnd: true
- name: Sleep
  action: aws:sleep
  inputs:
    Duration: PT3S
```

Example 2: Using aws:branch with a parameter variable to run commands based on the operating system type

The runbook author defines several parameter options at the beginning of the runbook in the `parameters` section. One parameter is named `OperatingSystemName`. In the first step (`ChooseOS`), the author uses the `aws:branch` action with two `Choices` (`NextStep: runWindowsCommand`) and (`NextStep: runLinuxCommand`). The variable for these `Choices` references the parameter option specified in the parameters section (`Variable: "{{OperatingSystemName}}"`). When the user runs this runbook, they specify a value at runtime for `OperatingSystemName`. The automation uses the runtime parameter during the `Choices` evaluation. The automation jumps to a step for the designated operating system based on the runtime parameter specified for `OperatingSystemName`.

```
---
schemaVersion: '0.3'
assumeRole: "{{AutomationAssumeRole}}"
parameters:
  AutomationAssumeRole:
    default: ""
    type: String
  OperatingSystemName:
    type: String
  LinuxInstanceId:
    type: String
  WindowsInstanceId:
    type: String
mainSteps:
- name: ChooseOS
```

```
  action: aws:branch
  inputs:
    Choices:
    - NextStep: runWindowsCommand
      Variable: "{{OperatingSystemName}}"
      StringEquals: windows
    - NextStep: runLinuxCommand
      Variable: "{{OperatingSystemName}}"
      StringEquals: linux
    Default:
      Sleep
- name: runLinuxCommand
  action: aws:runCommand
  inputs:
    DocumentName: "AWS-RunShellScript"
    InstanceIds:
    - "{{LinuxInstanceId}}"
    Parameters:
      commands:
      - ls
  isEnd: true
- name: runWindowsCommand
  action: aws:runCommand
  inputs:
    DocumentName: "AWS-RunPowerShellScript"
    InstanceIds:
    - "{{WindowsInstanceId}}"
    Parameters:
      commands:
      - date
  isEnd: true
- name: Sleep
  action: aws:sleep
  inputs:
    Duration: PT3S
```

Creating complex branching automations with operators

You can create complex branching automations by using the `And`, `Or`, and `Not` operators in your `aws:branch` steps.

The 'And' operator

Use the And operator when you want multiple variables to be `true` for a choice. In the following example, the first choice evaluates if an instance is `running` and uses the `Windows` operating system. If the evaluation of *both* of these variables is true, then the automation jumps to the `runPowerShellCommand` step. If one or more of the variables is `false`, then the automation evaluates the variables for the second choice.

```
mainSteps:
- name: switch2
  action: aws:branch
  inputs:
    Choices:
    - And:
      - Variable: "{{GetInstance.pingStatus}}"
        StringEquals: running
      - Variable: "{{GetInstance.platform}}"
        StringEquals: Windows
      NextStep: runPowerShellCommand

    - And:
      - Variable: "{{GetInstance.pingStatus}}"
        StringEquals: running
      - Variable: "{{GetInstance.platform}}"
        StringEquals: Linux
      NextStep: runShellCommand
    Default:
      sleep3
```

The 'Or' operator

Use the `Or` operator when you want *any* of multiple variables to be true for a choice. In the following example, the first choice evaluates if a parameter string is `Windows` and if the output from an Amazon Lambda step is true. If the evaluation determines that *either* of these variables is true, then the automation jumps to the `RunPowerShellCommand` step. If both variables are false, then the automation evaluates the variables for the second choice.

```
- Or:
  - Variable: "{{parameter1}}"
    StringEquals: Windows
  - Variable: "{{BooleanParam1}}"
    BooleanEquals: true
  NextStep: RunPowershellCommand
- Or:
```

```
  - Variable: "{{parameter2}}"
    StringEquals: Linux
  - Variable: "{{BooleanParam2}}"
    BooleanEquals: true
  NextStep: RunShellScript
```

The 'Not' operator

Use the `Not` operator when you want to jump to a step defined when a variable is *not* true. In the following example, the first choice evaluates if a parameter string is `Not Linux`. If the evaluation determines that the variable isn't Linux, then the automation jumps to the `sleep2` step. If the evaluation of the first choice determines that it *is* Linux, then the automation evaluates the next choice.

```
mainSteps:
- name: switch
  action: aws:branch
  inputs:
    Choices:
    - NextStep: sleep2
      Not:
        Variable: "{{testParam}}"
        StringEquals: Linux
    - NextStep: sleep1
      Variable: "{{testParam}}"
      StringEquals: Windows
    Default:
      sleep3
```

Examples of how to use conditional options

This section includes different examples of how to use dynamic options in a runbook. Each example in this section extends the following runbook. This runbook has two actions. The first action is named `InstallMsiPackage`. It uses the `aws:runCommand` action to install an application on a Windows Server instance. The second action is named `TestInstall`. It uses the `aws:invokeLambdaFunction` action to perform a test of the installed application if the application installed successfully. Step one specifies on`Failure: Abort`. This means that if the application didn't install successfully, the automation stops before step two.

Example 1: Runbook with two linear actions

```
---
schemaVersion: '0.3'
description: Install MSI package and run validation.
assumeRole: "{{automationAssumeRole}}"
parameters:
  automationAssumeRole:
    type: String
    description: "(Required) Assume role."
  packageName:
    type: String
    description: "(Required) MSI package to be installed."
  instanceIds:
    type: String
    description: "(Required) Comma separated list of instances."
mainSteps:
- name: InstallMsiPackage
  action: aws:runCommand
  maxAttempts: 2
  onFailure: Abort
  inputs:
    InstanceIds:
    - "{{instanceIds}}"
    DocumentName: AWS-RunPowerShellScript
    Parameters:
      commands:
      - msiexec /i {{packageName}}
- name: TestInstall
  action: aws:invokeLambdaFunction
  maxAttempts: 1
  timeoutSeconds: 500
  inputs:
    FunctionName: TestLambdaFunction
...
```

Creating a dynamic automation that jumps to different steps by using the onFailure option

The following example uses the onFailure: step:*step name*, nextStep, and isEnd options to create a dynamic automation. With this example, if the InstallMsiPackage action fails, then the automation jumps to an action called *PostFailure* (onFailure: step:PostFailure) to run an Amazon Lambda function to perform some action in the event the install failed. If the install succeeds, then the automation jumps to the TestInstall action (nextStep: TestInstall). Both

the `TestInstall` and the `PostFailure` steps use the `isEnd` option (`isEnd: true`) so that the automation finishes when either of those steps is completed.

> **Note**
>
> Using the `isEnd` option in the last step of the `mainSteps` section is optional. If the last step doesn't jump to other steps, then the automation stops after running the action in the last step.

Example 2: A dynamic automation that jumps to different steps

```
mainSteps
- name: InstallMsiPackage
  action: aws:runCommand
  onFailure: step:PostFailure
  maxAttempts: 2
  inputs:
    InstanceIds:
    - "{{instanceIds}}"
    DocumentName: AWS-RunPowerShellScript
    Parameters:
      commands:
      - msiexec /i {{packageName}}
  nextStep: TestInstall
- name: TestInstall
  action: aws:invokeLambdaFunction
  maxAttempts: 1
  timeoutSeconds: 500
  inputs:
    FunctionName: TestLambdaFunction
  isEnd: true
- name: PostFailure
  action: aws:invokeLambdaFunction
  maxAttempts: 1
  timeoutSeconds: 500
  inputs:
    FunctionName: PostFailureRecoveryLambdaFunction
  isEnd: true
...
```

> **Note**
>
> Before processing a runbook, the system verifies that the runbook doesn't create an infinite loop. If an infinite loop is detected, Automation returns an error and a circle trace showing which steps create the loop.

Creating a dynamic automation that defines critical steps

You can specify that a step is critical for the overall success of the automation. If a critical step fails, then Automation reports the status of the automation as `Failed`, even if one or more steps ran successfully. In the following example, the user identifies the *VerifyDependencies* step if the *InstallMsiPackage* step fails (on`Failure: step:VerifyDependencies`). The user specifies that the `InstallMsiPackage` step isn't critical (`isCritical: false`). In this example, if the application failed to install, Automation processes the `VerifyDependencies` step to determine if one or more dependencies is missing, which therefore caused the application install to fail.

Example 3: Defining critical steps for the automation

```
---
name: InstallMsiPackage
action: aws:runCommand
onFailure: step:VerifyDependencies
isCritical: false
maxAttempts: 2
inputs:
  InstanceIds:
  - "{{instanceIds}}"
  DocumentName: AWS-RunPowerShellScript
  Parameters:
    commands:
    - msiexec /i {{packageName}}
nextStep: TestPackage
...
```

Using action outputs as inputs

Several automation actions return pre-defined outputs. You can pass these outputs as inputs to later steps in your runbook using the format {{*stepName*.*outputName*}}. You can also define custom outputs for automation actions in your runbooks. This lets you run scripts, or invoke API

operations for other Amazon Web Services services once so you can reuse the values as inputs in later actions. Parameter types in runbooks are static. This means the parameter type can't be changed after it's defined. To define a step output provide the following fields:

- Name: (Required) The output name which is used to reference the output value in later steps.
- Selector: (Required) The JSONPath expression that is used to determine the output value.
- Type: (Optional) The data type of the value returned by the selector field. Valid type values are `String`, `Integer`, `Boolean`, `StringList`, `StringMap`, `MapList`. The default value is `String`.

If the value of an output doesn't match the data type you've specified, Automation tries to convert the data type. For example, if the value returned is an `Integer`, but the `Type` specified is `String`, the final output value is a `String` value. The following type conversions are supported:

- `String` values can be converted to `StringList`, `Integer` and `Boolean`.
- `Integer` values can be converted to `String` and `StringList`.
- `Boolean` values can be converted to `String` and `StringList`.
- `StringList`, `IntegerList`, or `BooleanList` values containing one element can be converted to `String`, `Integer`, or `Boolean`.

When using parameters or outputs with automation actions, the data type can't be dynamically changed within an action's input.

Here is an example runbook that demonstrates how to define action outputs, and reference the value as input for a later action. The runbooks does the following:

- Uses the `aws:executeAwsApi` action to call the Amazon EC2 DescribeImages API operation to get the name of a specific Windows Server 2016 AMI. It outputs the image ID as `ImageId`.
- Uses the `aws:executeAwsApi` action to call the Amazon EC2 RunInstances API operation to launch one instance that uses the `ImageId` from the previous step. It outputs the instance ID as `InstanceId`.
- Uses the `aws:waitForAwsResourceProperty` action to poll the Amazon EC2 DescribeInstanceStatus API operation to wait for the instance to reach the `running` state. The action times out in 60 seconds. The step times out if the instance state failed to reach `running` after 60 seconds of polling.

- Uses the `aws:assertAwsResourceProperty` action to call the Amazon EC2 `DescribeInstanceStatus` API operation to assert that the instance is in the `running` state. The step fails if the instance state isn't `running`.

```
---
description: Sample runbook using Amazon API operations
schemaVersion: '0.3'
assumeRole: "{{ AutomationAssumeRole }}"
parameters:
  AutomationAssumeRole:
    type: String
    description: "(Optional) The ARN of the role that allows Automation to perform the
 actions on your behalf."
    default: ''
  ImageName:
    type: String
    description: "(Optional) Image Name to launch EC2 instance with."
    default: "Windows_Server-2022-English-Full-Base*"
mainSteps:
- name: getImageId
  action: aws:executeAwsApi
  inputs:
    Service: ec2
    Api: DescribeImages
    Filters:
    - Name: "name"
      Values:
      - "{{ ImageName }}"
  outputs:
  - Name: ImageId
    Selector: "$.Images[0].ImageId"
    Type: "String"
- name: launchOneInstance
  action: aws:executeAwsApi
  inputs:
    Service: ec2
    Api: RunInstances
    ImageId: "{{ getImageId.ImageId }}"
    MaxCount: 1
    MinCount: 1
  outputs:
  - Name: InstanceId
```

```
    Selector: "$.Instances[0].InstanceId"
    Type: "String"
- name: waitUntilInstanceStateRunning
  action: aws:waitForAwsResourceProperty
  timeoutSeconds: 60
  inputs:
    Service: ec2
    Api: DescribeInstanceStatus
    InstanceIds:
    - "{{ launchOneInstance.InstanceId }}"
    PropertySelector: "$.InstanceStatuses[0].InstanceState.Name"
    DesiredValues:
    - running
- name: assertInstanceStateRunning
  action: aws:assertAwsResourceProperty
  inputs:
    Service: ec2
    Api: DescribeInstanceStatus
    InstanceIds:
    - "{{ launchOneInstance.InstanceId }}"
    PropertySelector: "$.InstanceStatuses[0].InstanceState.Name"
    DesiredValues:
    - running
outputs:
- "launchOneInstance.InstanceId"
...
```

Each of the previously described automation actions lets you call a specific API operation by specifying the service namespace, the API operation name, the input parameters, and the output parameters. Inputs are defined by the API operation that you choose. You can view the API operations (also called methods) by choosing a service in the left navigation on the following Services Reference page. Choose a method in the **Client** section for the service that you want to invoke. For example, all API operations (methods) for Amazon Relational Database Service (Amazon RDS) are listed on the following page: Amazon RDS methods.

You can view the schema for each automation action in the following locations:

- `aws:assertAwsResourceProperty` – Assert an Amazon resource state or event state
- `aws:executeAwsApi` – Call and run Amazon API operations
- `aws:waitForAwsResourceProperty` – Wait on an Amazon resource property

The schemas include descriptions of the required fields for using each action.

Using the Selector/PropertySelector fields

Each Automation action requires that you specify either an output `Selector` (for `aws:executeAwsApi`) or a `PropertySelector` (for `aws:assertAwsResourceProperty` and `aws:waitForAwsResourceProperty`). These fields are used to process the JSON response from an Amazon API operation. These fields use the JSONPath syntax.

Here is an example to help illustrate this concept for the `aws:executeAwsAPi` action.

```
---
mainSteps:
- name: getImageId
  action: aws:executeAwsApi
  inputs:
    Service: ec2
    Api: DescribeImages
    Filters:
      - Name: "name"
        Values:
          - "{{ ImageName }}"
  outputs:
    - Name: ImageId
      Selector: "$.Images[0].ImageId"
      Type: "String"
...
```

In the `aws:executeAwsApi` step `getImageId`, the automation invokes the `DescribeImages` API operation and receives a response from `ec2`. The automation then applies `Selector - "$.Images[0].ImageId"` to the API response and assigns the selected value to the output `ImageId` variable. Other steps in the same automation can use the value of `ImageId` by specifying `"{{ getImageId.ImageId }}"`.

Here is an example to help illustrate this concept for the `aws:waitForAwsResourceProperty` action.

```
---
- name: waitUntilInstanceStateRunning
  action: aws:waitForAwsResourceProperty
  # timeout is strongly encouraged for action - aws:waitForAwsResourceProperty
  timeoutSeconds: 60
```

```
  inputs:
    Service: ec2
    Api: DescribeInstanceStatus
    InstanceIds:
    - "{{ launchOneInstance.InstanceId }}"
    PropertySelector: "$.InstanceStatuses[0].InstanceState.Name"
    DesiredValues:
    - running
...
```

In the `aws:waitForAwsResourceProperty` step `waitUntilInstanceStateRunning`, the automation invokes the `DescribeInstanceStatus` API operation and receives a response from `ec2`. The automation then applies `PropertySelector - "$.InstanceStatuses[0].InstanceState.Name"` to the response and checks if the specified returned value matches a value in the `DesiredValues` list (in this case `running`). The step repeats the process until the response returns an instance state of `running`.

Using JSONPath in runbooks

A JSONPath expression is a string beginning with "$." that is used to select one of more components within a JSON element. The following list includes information about JSONPath operators that are supported by Systems Manager Automation:

- **Dot-notated child (.)**: Use with a JSON object. This operator selects the value of a specific key.
- **Deep-scan (..)**: Use with a JSON element. This operator scans the JSON element level by level and selects a list of values with the specific key. The return type of this operator is always a JSON array. In the context of an automation action output type, the operator can be either StringList or MapList.
- **Array-Index ([ ])**: Use with a JSON array. This operator gets the value of a specific index.
- **Filter ([?(*expression*)])**: Use with a JSON array. This operator filters JSON array values that match the criteria defined in the filter expression. Filter expressions can only use the following operators: ==, !=, >, <, >=, or <=. Combining multiple filter expressions with AND (&&) or OR (||) is not supported. The return type of this operator is always a JSON array.

To better understand JSONPath operators, review the following JSON response from the ec2 `DescribeInstances` API operation. Following this response are several examples that show different results by applying different JSONPath expressions to the response from the `DescribeInstances` API operation.

```
{
    "NextToken": "abcdefg",
    "Reservations": [
        {
            "OwnerId": "123456789012",
            "ReservationId": "r-abcd12345678910",
            "Instances": [
                {
                    "ImageId": "ami-12345678",
                    "BlockDeviceMappings": [
                        {
                            "Ebs": {
                                "DeleteOnTermination": true,
                                "Status": "attached",
                                "VolumeId": "vol-000000000000"
                            },
                            "DeviceName": "/dev/xvda"
                        }
                    ],
                    "State": {
                        "Code": 16,
                        "Name": "running"
                    }
                }
            ],
            "Groups": []
        },
        {
            "OwnerId": "123456789012",
            "ReservationId": "r-12345678910abcd",
            "Instances": [
                {
                    "ImageId": "ami-12345678",
                    "BlockDeviceMappings": [
                        {
                            "Ebs": {
                                "DeleteOnTermination": true,
                                "Status": "attached",
                                "VolumeId": "vol-111111111111"
                            },
                            "DeviceName": "/dev/xvda"
                        }
                    ],
```

```
                    "State": {
                        "Code": 80,
                        "Name": "stopped"
                    }
                }
            ],
            "Groups": []
        }
    ]
}
```

JSONPath Example 1: Get a specific String from a JSON response

```
JSONPath:
$.Reservations[0].Instances[0].ImageId

Returns:
"ami-12345678"

Type: String
```

JSONPath Example 2: Get a specific Boolean from a JSON response

```
JSONPath:
$.Reservations[0].Instances[0].BlockDeviceMappings[0].Ebs.DeleteOnTermination

Returns:
true

Type: Boolean
```

JSONPath Example 3: Get a specific Integer from a JSON response

```
JSONPath:
$.Reservations[0].Instances[0].State.Code

Returns:
16

Type: Integer
```

JSONPath Example 4: Deep scan a JSON response, then get all of the values for VolumeId as a StringList

```
JSONPath:
$.Reservations..BlockDeviceMappings..VolumeId

Returns:
[
   "vol-000000000000",
   "vol-111111111111"
]

Type: StringList
```

JSONPath Example 5: Get a specific BlockDeviceMappings object as a StringMap

```
JSONPath:
$.Reservations[0].Instances[0].BlockDeviceMappings[0]

Returns:
{
   "Ebs" : {
      "DeleteOnTermination" : true,
      "Status" : "attached",
      "VolumeId" : "vol-000000000000"
   },
   "DeviceName" : "/dev/xvda"
}

Type: StringMap
```

JSONPath Example 6: Deep scan a JSON response, then get all of the State objects as a MapList

```
JSONPath:
$.Reservations..Instances..State

Returns:
[
   {
      "Code" : 16,
      "Name" : "running"
   },
```

```
   {
      "Code" : 80,
      "Name" : "stopped"
   }
]

Type: MapList
```

JSONPath Example 7: Filter for instances in the `running` state

```
JSONPath:
$.Reservations..Instances[?(@.State.Name == 'running')]

Returns:
[
  {
    "ImageId": "ami-12345678",
    "BlockDeviceMappings": [
      {
        "Ebs": {
          "DeleteOnTermination": true,
          "Status": "attached",
          "VolumeId": "vol-000000000000"
        },
        "DeviceName": "/dev/xvda"
      }
    ],
    "State": {
      "Code": 16,
      "Name": "running"
    }
  }
]

Type: MapList
```

JSONPath Example 8: Return the `ImageId` of instances which aren't in the `running` state

```
JSONPath:
$.Reservations..Instances[?(@.State.Name != 'running')].ImageId

Returns:
[
```

```
  "ami-12345678"
]

Type: StringList | String
```

Creating webhook integrations for Automation

To send messages using webhooks during an automation, create an integration. Integrations can be invoked during an automation by using the `aws:invokeWebhook` action in your runbook. If you haven't already created a webhook, see Creating webhooks for integrations. To learn more about the `aws:invokeWebhook` action, see `aws:invokeWebhook` – Invoke an Automation webhook integration.

As shown in the following procedures, you can create an integration by using either the Systems Manager Automation console or your preferred command line tool.

Creating integrations (console)

To create an integration for Automation (console)

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Automation**.
3. Choose the **Integrations** tab.
4. Select **Add integration**, and choose **Webhook**.
5. Enter the required values and any optional values you want to include for the integration.
6. Choose **Add** to create the integration.

Creating integrations (command line)

To create an integration using command line tools, you must create the required `SecureString` parameter for an integration. Automation uses a reserved namespace in Parameter Store to store information about your integration. If you create an integration using the Amazon Web Services Management Console, Automation handles this process for you. Following the namespace, you must specify the type of integration you want to create and then the name of your integration. Currently, Automation supports `webhook` type integrations.

The supported fields for `webhook` type integrations are as follows:

- Description
- headers
- payload
- URL

Before you begin

If you haven't already, install and configure the Amazon Command Line Interface (Amazon CLI) or the Amazon Tools for PowerShell. For information, see Installing or updating the latest version of the Amazon CLI and Installing the Amazon Tools for PowerShell.

To create an integration for Automation (command line)

- Run the following commands to create the required `SecureString` parameter for an integration. Replace each *example resource placeholder* with your own information. The `/d9d01087-4a3f-49e0-b0b4-d568d7826553/ssm/integrations/webhook/` namespace is reserved in Parameter Store for integrations. The name of your parameter must use this namespace followed by the name of your integration. For example `/d9d01087-4a3f-49e0-b0b4-d568d7826553/ssm/integrations/webhook/`*myWebhookIntegration*.

  Linux & macOS

  ```
  aws ssm put-parameter \
      --name "/d9d01087-4a3f-49e0-b0b4-d568d7826553/ssm/integrations/
  webhook/myWebhookIntegration" \
      --type "SecureString" \
      --data-type "aws:ssm:integration" \
      --value '{"description": "My first webhook integration for Automation.",
   "url": "myWebHookURL"}'
  ```

  Windows

  ```
  aws ssm put-parameter ^
      --name "/d9d01087-4a3f-49e0-b0b4-d568d7826553/ssm/integrations/
  webhook/myWebhookIntegration" ^
      --type "SecureString" ^
      --data-type "aws:ssm:integration" ^
  ```

```
    --value  "{\"description\":\"My first webhook integration for Automation.\",
\"url\":\"myWebHookURL\"}"
```

PowerShell

```
Write-SSMParameter `
    -Name "/d9d01087-4a3f-49e0-b0b4-d568d7826553/ssm/integrations/
webhook/myWebhookIntegration" `
    -Type "SecureString"
    -DataType "aws:ssm:integration"
    -Value '{"description": "My first webhook integration for Automation.",
 "url": "myWebHookURL"}'
```

Creating webhooks for integrations

When creating webhooks with your provider, note the following:

- Protocol must be HTTPS.
- Custom request headers are supported.
- A default request body can be specified.
- The default request body can be overridden when an integration is invoked by using the `aws:invokeWebhook` action.

Handling timeouts in runbooks

The `timeoutSeconds` property is shared by all automation actions. You can use this property to specify the execution timeout value for an action. Further, you can change how an action timing out affects the automation and overall execution status. You can accomplish this by also defining the `onFailure` and `isCritical` shared properties for an action.

For example, depending on your use case, you might want your automation to continue to a different action and not affect the overall status of the automation if an action times out. In this example, you specify the length of time to wait before the action times out using the `timeoutSeconds` property. Then you specify the action, or step, the automation should go to if there is a timeout. Specify a value using the format `step:`*`step name`* for the `onFailure` property rather than the default value of `Abort`. By default, if an action times out, the automation execution status will be `Timed Out`. To prevent a timeout from affecting the automation execution status, specify `false` for the `isCritical` property.

The following example shows how to define the shared properties for an action described in this scenario.

YAML

```
- name: verifyImageAvailability
  action: 'aws:waitForAwsResourceProperty'
  timeoutSeconds: 600
  isCritical: false
  onFailure: 'step:getCurrentImageState'
  inputs:
    Service: ec2
    Api: DescribeImages
    ImageIds:
      - '{{ createImage.newImageId }}'
    PropertySelector: '$.Images[0].State'
    DesiredValues:
      - available
  nextStep: copyImage
```

JSON

```
{
    "name": "verifyImageAvailability",
    "action": "aws:waitForAwsResourceProperty",
    "timeoutSeconds": 600,
    "isCritical": false,
    "onFailure": "step:getCurrentImageState",
    "inputs": {
        "Service": "ec2",
        "Api": "DescribeImages",
        "ImageIds": [
            "{{ createImage.newImageId }}"
        ],
        "PropertySelector": "$.Images[0].State",
        "DesiredValues": [
            "available"
        ]
    },
    "nextStep": "copyImage"
}
```

For more information about properties shared by all automation actions, see Properties shared by all actions.

Systems Manager Automation Runbook Reference

To help you get started quickly, Amazon Systems Manager provides predefined runbooks. These runbooks are maintained by Amazon Web Services, Amazon Web Services Support, and Amazon Config. The Runbook Reference describes each of the predefined runbooks provided by Systems Manager, Amazon Web Services Support, and Amazon Config. For more information, see Systems Manager Automation Runbook Reference.

Tutorials

The following tutorials help you to use Amazon Systems Manager Automation to address common use cases. These tutorials demonstrate how to use your own runbooks, predefined runbooks provided by Automation, and other Systems Manager tools with other Amazon Web Services services.

This section includes the following topics.

- Update a Linux AMI
- Update a Windows Server AMI
- Using Amazon Web Services Support self-service runbooks
- Reset passwords and SSH keys on EC2 instances

Updating AMIs

The following tutorials explain how to update Amazon Machine Image (AMIs) to include the latest patches.

Update a Linux AMI

This Systems Manager Automation walkthrough shows you how to use the console or Amazon CLI and the `AWS-UpdateLinuxAmi` runbook to update a Linux AMI with the latest patches of packages that you specify. Automation is a tool in Amazon Systems Manager. The `AWS-UpdateLinuxAmi` runbook also automates the installation of additional site-specific packages and configurations. You can update a variety of Linux distributions using this walkthrough, including Ubuntu Server, Red Hat Enterprise Linux (RHEL), or Amazon Linux AMIs. For a full list of supported Linux versions, see Patch Manager prerequisites.

The `AWS-UpdateLinuxAmi` runbook lets you automate image maintenance tasks without having to author the runbook in JSON or YAML. You can use the `AWS-UpdateLinuxAmi` runbook to perform the following types of tasks.

- Upgrade all distribution packages and Amazon software on an Amazon Linux, Red Hat Enterprise Linux, or Ubuntu Server Amazon Machine Image (AMI). This is the default runbook behavior.
- Install Amazon Systems Manager SSM Agent on an existing image to enable Systems Manager tools, such as running remote commands using Amazon Systems Manager Run Command or software inventory collection using Inventory.
- Install additional software packages.

Before you begin

Before you begin working with runbooks, configure roles and, optionally, EventBridge for Automation. For more information, see Setting up Automation. This walkthrough also requires that you specify the name of an Amazon Identity and Access Management (IAM) instance profile. For more information about creating an IAM instance profile, see Configure instance permissions required for Systems Manager.

The `AWS-UpdateLinuxAmi` runbook accepts the following input parameters.

Parameter	Type	Description
SourceAmiId	String	(Required) The source AMI ID.
IamInstanceProfileName	String	(Required) The name of the IAM instance profile role you created in Configure instance permissions required for Systems Manager. The instance profile role gives Automation permission to perform actions on your instances, such as running commands or starting and stopping services. The runbook uses only the name

Parameter	Type	Description
		of the instance profile role. If you specify the Amazon Resource Name (ARN), the automation fails.
AutomationAssumeRole	String	(Required) The name of the IAM service role you created in Setting up Automation. The service role (also called an assume role) gives Automatio n permission to assume your IAM role and perform actions on your behalf. For example, the service role allows Automation to create a new AMI when running the `aws:createImage` action in a runbook. For this parameter, the complete ARN must be specified.
TargetAmiName	String	(Optional) The name of the new AMI after it is created. The default name is a system-generated string that includes the source AMI ID, and the creation time and date.
InstanceType	String	(Optional) The type of instance to launch as the workspace host. Instance types vary by region. The default type is t2.micro.

Parameter	Type	Description
PreUpdateScript	String	(Optional) URL of a script to run before updates are applied. Default (\"none\") is to not run a script.
PostUpdateScript	String	(Optional) URL of a script to run after package updates are applied. Default (\"none\") is to not run a script.
IncludePackages	String	(Optional) Only update these named packages. By default (\"all\"), all available updates are applied.
ExcludePackages	String	(Optional) Names of packages to hold back from updates, under all conditions. By default (\"none\"), no package is excluded.

Automation Steps

The `AWS-UpdateLinuxAmi` runbook includes the following automation actions, by default.

Step 1: launchInstance (`aws:runInstances` action)

This step launches an instance using Amazon Elastic Compute Cloud (Amazon EC2) userdata and an IAM instance profile role. Userdata installs the appropriate SSM Agent, based on the operating system. Installing SSM Agent lets you use Systems Manager tools such as Run Command, State Manager, and Inventory.

Step 2: updateOSSoftware (`aws:runCommand` action)

This step runs the following commands on the launched instance:

- Downloads an update script from Amazon S3.
- Runs an optional pre-update script.

- Updates distribution packages and Amazon software.
- Runs an optional post-update script.

The execution log is stored in the /tmp folder for the user to view later.

If you want to upgrade a specific set of packages, you can supply the list using the `IncludePackages` parameter. When provided, the system attempts to update only these packages and their dependencies. No other updates are performed. By default, when no *include* packages are specified, the program updates all available packages.

If you want to exclude upgrading a specific set of packages, you can supply the list to the `ExcludePackages` parameter. If provided, these packages remain at their current version, independent of any other options specified. By default, when no *exclude* packages are specified, no packages are excluded.

Step 3: stopInstance (`aws:changeInstanceState` action)

This step stops the updated instance.

Step 4: createImage (`aws:createImage` action)

This step creates a new AMI with a descriptive name that links it to the source ID and creation time. For example: "AMI Generated by EC2 Automation on {{global:DATE_TIME}} from {{SourceAmiId}}" where DATE_TIME and SourceID represent Automation variables.

Step 5: terminateInstance (`aws:changeInstanceState` action)

This step cleans up the automation by terminating the running instance.

Output

The automation returns the new AMI ID as output.

> **Note**
>
> By default, when Automation runs the `AWS-UpdateLinuxAmi` runbook, the system creates a temporary instance in the default VPC (172.30.0.0/16). If you deleted the default VPC, you receive the following error:
> `VPC not defined 400`
> To solve this problem, you must make a copy of the `AWS-UpdateLinuxAmi` runbook and specify a subnet ID. For more information, see VPC not defined 400.

To create a patched AMI using Automation (Amazon Systems Manager)

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Automation**.
3. Choose **Execute automation**.
4. In the **Automation document** list, choose **`AWS-UpdateLinuxAmi`**.
5. In the **Document details** section, verify that **Document version** is set to **Default version at runtime**.
6. Choose **Next**.
7. In the **Execution mode** section, choose **Simple Execution**.
8. In the **Input parameters** section, enter the information you collected in the **Before you begin** section.
9. Choose **Execute**. The console displays the status of the Automation execution.

After the automation finishes, launch a test instance from the updated AMI to verify changes.

> **Note**
>
> If any step in the automation fails, information about the failure is listed on the **Automation Executions** page. The automation is designed to terminate the temporary instance after successfully completing all tasks. If a step fails, the system might not terminate the instance. So if a step fails, manually terminate the temporary instance.

Update a Linux AMI (Amazon CLI)

This Amazon Systems Manager Automation walkthrough shows you how to use the Amazon Command Line Interface (Amazon CLI) and the Systems Manager `AWS-UpdateLinuxAmi` runbook to automatically patch a Linux Amazon Machine Image (AMI) with the latest versions of packages that you specify. Automation is a tool in Amazon Systems Manager. The `AWS-UpdateLinuxAmi` runbook also automates the installation of additional site-specific packages and configurations. You can update a variety of Linux distributions using this walkthrough, including Ubuntu Server, Red Hat Enterprise Linux (RHEL), or Amazon Linux AMIs. For a full list of supported Linux versions, see Patch Manager prerequisites.

The `AWS-UpdateLinuxAmi` runbook lets you automate image-maintenance tasks without having to author the runbook in JSON or YAML. You can use the `AWS-UpdateLinuxAmi` runbook to perform the following types of tasks.

- Upgrade all distribution packages and Amazon software on an Amazon Linux, RHEL, or Ubuntu Server Amazon Machine Image (AMI). This is the default runbook behavior.
- Install Amazon Systems Manager SSM Agent on an existing image to enable Systems Manager capabilities, such as running remote commands using Amazon Systems Manager Run Command or software inventory collection using Inventory.
- Install additional software packages.

Before you begin

Before you begin working with runbooks, configure roles and, optionally, EventBridge for Automation. For more information, see Setting up Automation. This walkthrough also requires that you specify the name of an Amazon Identity and Access Management (IAM) instance profile. For more information about creating an IAM instance profile, see Configure instance permissions required for Systems Manager.

The `AWS-UpdateLinuxAmi` runbook accepts the following input parameters.

Parameter	Type	Description
SourceAmiId	String	(Required) The source AMI ID. You can automatically reference the latest ID of an Amazon EC2 AMI for Linux by using a Amazon Systems Manager Parameter Store *public* parameter. For more information, see Query for the latest Amazon Linux AMI IDs using Amazon Systems Manager Parameter Store.
IamInstanceProfileName	String	(Required) The name of the IAM instance profile role

Parameter	Type	Description
		you created in Configure instance permissions required for Systems Manager. The instance profile role gives Automation permission to perform actions on your instances, such as running commands or starting and stopping services. The runbook uses only the name of the instance profile role.
AutomationAssumeRole	String	(Required) The name of the IAM service role you created in Setting up Automation. The service role (also called an assume role) gives Automation permission to assume your IAM role and perform actions on your behalf. For example, the service role allows Automation to create a new AMI when running the `aws:createImage` action in a runbook. For this parameter, the complete ARN must be specified.
TargetAmiName	String	(Optional) The name of the new AMI after it is created. The default name is a system-generated string that includes the source AMI ID, and the creation time and date.

Parameter	Type	Description
InstanceType	String	(Optional) The type of instance to launch as the workspace host. Instance types vary by Region. The default type is t2.micro.
PreUpdateScript	String	(Optional) URL of a script to run before updates are applied. Default (\"none\") is to not run a script.
PostUpdateScript	String	(Optional) URL of a script to run after package updates are applied. Default (\"none\") is to not run a script.
IncludePackages	String	(Optional) Only update these named packages. By default (\"all\"), all available updates are applied.
ExcludePackages	String	(Optional) Names of packages to hold back from updates, under all conditions. By default (\"none\"), no package is excluded.

Automation Steps

The `AWS-UpdateLinuxAmi` runbook includes the following steps, by default.

Step 1: launchInstance (`aws:runInstances` action)

This step launches an instance using Amazon Elastic Compute Cloud (Amazon EC2) user data and an IAM instance profile role. User data installs the appropriate SSM Agent, based on

the operating system. Installing SSM Agent lets you use Systems Manager tools such as Run Command, State Manager, and Inventory.

Step 2: updateOSSoftware (`aws:runCommand` action)

This step runs the following commands on the launched instance:

- Downloads an update script from Amazon Simple Storage Service (Amazon S3).
- Runs an optional pre-update script.
- Updates distribution packages and Amazon software.
- Runs an optional post-update script.

The execution log is stored in the /tmp folder for the user to view later.

If you want to upgrade a specific set of packages, you can supply the list using the `IncludePackages` parameter. When provided, the system attempts to update only these packages and their dependencies. No other updates are performed. By default, when no *include* packages are specified, the program updates all available packages.

If you want to exclude upgrading a specific set of packages, you can supply the list to the `ExcludePackages` parameter. If provided, these packages remain at their current version, independent of any other options specified. By default, when no *exclude* packages are specified, no packages are excluded.

Step 3: stopInstance (`aws:changeInstanceState` action)

This step stops the updated instance.

Step 4: createImage (`aws:createImage` action)

This step creates a new AMI with a descriptive name that links it to the source ID and creation time. For example: "AMI Generated by EC2 Automation on {{global:DATE_TIME}} from {{SourceAmiId}}" where DATE_TIME and SourceID represent Automation variables.

Step 5: terminateInstance (`aws:changeInstanceState` action)

This step cleans up the automation by terminating the running instance.

Output

The automation returns the new AMI ID as output.

> **Note**
>
> By default, when Automation runs the `AWS-UpdateLinuxAmi` runbook, the system creates a temporary instance in the default VPC (172.30.0.0/16). If you deleted the default VPC, you receive the following error:
> `VPC not defined 400`
> To solve this problem, you must make a copy of the `AWS-UpdateLinuxAmi` runbook and specify a subnet ID. For more information, see VPC not defined 400.

To create a patched AMI using Automation

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.

2. Run the following command to run the `AWS-UpdateLinuxAmi` runbook. Replace each *example resource placeholder* with your own information.

```
aws ssm start-automation-execution \
    --document-name "AWS-UpdateLinuxAmi" \
    --parameters \
    SourceAmiId=AMI ID, \
    IamInstanceProfileName=IAM instance profile, \
    AutomationAssumeRole='arn:aws-cn:iam::
{{global:ACCOUNT_ID}}:role/AutomationServiceRole'
```

   The command returns an execution ID. Copy this ID to the clipboard. Use this ID to view the status of the automation.

```
{
    "AutomationExecutionId": "automation execution ID"
}
```

3. To view the automation using the Amazon CLI, run the following command:

```
aws ssm describe-automation-executions
```

4. To view details about the automation progress, run the following command. Replace *automation execution ID* with your own information.

```
aws ssm get-automation-execution --automation-execution-id automation execution ID
```

   The update process can take 30 minutes or more to complete.

   > **Note**
   >
   > You can also monitor the status of the automation in the console. In the list, choose the automation you just ran and then choose the **Steps** tab. This tab shows you the status of the automation actions.

After the automation finishes, launch a test instance from the updated AMI to verify changes.

> **Note**
>
> If any step in the automation fails, information about the failure is listed on the **Automation Executions** page. The automation is designed to terminate the temporary instance after successfully completing all tasks. If a step fails, the system might not terminate the instance. So if a step fails, manually terminate the temporary instance.

Update a Windows Server AMI

The `AWS-UpdateWindowsAmi` runbook lets you automate image maintenance tasks on your Amazon Windows Amazon Machine Image (AMI) without having to author the runbook in JSON or YAML. This runbook is supported for Windows Server 2008 R2 or later. You can use the `AWS-UpdateWindowsAmi` runbook to perform the following types of tasks.

- Install all Windows updates and upgrade Amazon software (default behavior).
- Install specific Windows updates and upgrade Amazon software.
- Customize an AMI using your scripts.

Before you begin

Before you begin working with runbooks, configure roles for Automation to add an `iam:PassRole` policy that references the ARN of the instance profile you want to grant access to. Optionally, configure Amazon EventBridge for Automation. For more information, see Setting up Automation. This walkthrough also requires that you specify the name of an Amazon Identity and Access Management (IAM) instance profile. For more information about creating an IAM instance profile, see Configure instance permissions required for Systems Manager.

> **Note**
>
> Updates to Amazon Systems Manager SSM Agent are typically rolled out to different regions at different times. When you customize or update an AMI, use only source AMIs published for the region that you are working in. This will make sure that you are working with the latest SSM Agent released for that region and avoid compatibility issues.

The `AWS-UpdateWindowsAmi` runbook accepts the following input parameters.

Parameter	Type	Description
SourceAmiId	String	(Required) The source AMI ID. You can automatically reference the latest Windows Server AMI ID by using a Systems Manager Parameter Store *public* parameter. For more information, see Query for the latest Windows AMI IDs using Amazon Systems Manager Parameter Store.
SubnetId	String	(Optional) The subnet you want to launch the temporary instance into. You must specify a value for this parameter if you've deleted your default VPC.

Parameter	Type	Description
IamInstanceProfileName	String	(Required) The name of the IAM instance profile role you created in Configure instance permissions required for Systems Manager. The instance profile role gives Automation permission to perform actions on your instances, such as running commands or starting and stopping services. The runbook uses only the name of the instance profile role.
AutomationAssumeRole	String	(Required) The name of the IAM service role you created in Setting up Automation. The service role (also called an assume role) gives Automatio n permission to assume your IAM role and perform actions on your behalf. For example, the service role allows Automation to create a new AMI when running the `aws:createImage` action in a runbook. For this parameter, the complete ARN must be specified.

Parameter	Type	Description
TargetAmiName	String	(Optional) The name of the new AMI after it is created. The default name is a system-generated string that includes the source AMI ID, and the creation time and date.
InstanceType	String	(Optional) The type of instance to launch as the workspace host. Instance types vary by region. The default type is t2.medium.
PreUpdateScript	String	(Optional) A script to run before updating the AMI. Enter a script in the runbook or at runtime as a parameter.
PostUpdateScript	String	(Optional) A script to run after updating the AMI. Enter a script in the runbook or at runtime as a parameter.
IncludeKbs	String	(Optional) Specify one or more Microsoft Knowledge Base (KB) article IDs to include. You can install multiple IDs using comma-separated values. Valid formats: KB9876543 or 9876543.

Parameter	Type	Description
ExcludeKbs	String	(Optional) Specify one or more Microsoft Knowledge Base (KB) article IDs to exclude. You can exclude multiple IDs using comma-separated values. Valid formats: KB9876543 or 9876543.
Categories	String	(Optional)Specify one or more update categories. You can filter categories using comma-separated values. Options: Critical Update, Security Update, Definition Update, Update Rollup, Service Pack, Tool, Update, or Driver. Valid formats include a single entry, for example: Critical Update. Or, you can specify a comma separated list: Critical Update,Security Update,Definition Update.
SeverityLevels	String	(Optional) Specify one or more MSRC severity levels associated with an update. You can filter severity levels using comma-separated values. Options: Critical, Important, Low, Moderate or Unspecified. Valid formats include a single entry, for example: Critical. Or, you can specify a comma separated list: Critical,Important,Low.

Automation Steps

The `AWS-UpdateWindowsAmi` runbook includes the following steps, by default.

Step 1: launchInstance (`aws:runInstances` action)

This step launches an instance with an IAM instance profile role from the specified `SourceAmiID`.

Step 2: runPreUpdateScript (`aws:runCommand` action)

This step lets you specify a script as a string that runs before updates are installed.

Step 3: updateEC2Config (`aws:runCommand` action)

This step uses the `AWS-InstallPowerShellModule` runbook to download an Amazon public PowerShell module. Systems Manager verifies the integrity of the module by using an SHA-256 hash. Systems Manager then checks the operating system to determine whether to update EC2Config or EC2Launch. EC2Config runs on Windows Server 2008 R2 through Windows Server 2012 R2. EC2Launch runs on Windows Server 2016.

Step 4: updateSSMAgent (`aws:runCommand` action)

This step updates SSM Agent by using the `AWS-UpdateSSMAgent` runbook.

Step 5: updateAWSPVDriver (`aws:runCommand` action)

This step updates Amazon PV drivers by using the `AWS-ConfigureAWSPackage` runbook.

Step 6: updateAwsEnaNetworkDriver (`aws:runCommand` action)

This step updates Amazon ENA Network drivers by using the `AWS-ConfigureAWSPackage` runbook.

Step 7: installWindowsUpdates (`aws:runCommand` action)

This step installs Windows updates by using the `AWS-InstallWindowsUpdates` runbook. By default, Systems Manager searches for and installs all missing updates. You can change the default behavior by specifying one of the following parameters: `IncludeKbs`, `ExcludeKbs`, `Categories`, or `SeverityLevels`.

Step 8: runPostUpdateScript (`aws:runCommand` action)

This step lets you specify a script as a string that runs after the updates have been installed.

Step 9: runSysprepGeneralize (`aws:runCommand` action)

This step uses the `AWS-InstallPowerShellModule` runbook to download an Amazon public PowerShell module. Systems Manager verifies the integrity of the module by using an SHA-256 hash. Systems Manager then runs sysprep using Amazon-supported methods for either EC2Launch (Windows Server 2016) or EC2Config (Windows Server 2008 R2 through 2012 R2).

Step 10: stopInstance (`aws:changeInstanceState` action)

This step stops the updated instance.

Step 11: createImage (`aws:createImage` action)

This step creates a new AMI with a descriptive name that links it to the source ID and creation time. For example: "AMI Generated by EC2 Automation on {{global:DATE_TIME}} from {{SourceAmiId}}" where DATE_TIME and SourceID represent Automation variables.

Step 12: TerminateInstance (`aws:changeInstanceState` action)

This step cleans up the automation by terminating the running instance.

Output

This section lets you designate the outputs of various steps or values of any parameter as the Automation output. By default, the output is the ID of the updated Windows AMI created by the automation.

> **Note**
>
> By default, when Automation runs the `AWS-UpdateWindowsAmi` runbook and creates a temporary instance, the system uses the default VPC (172.30.0.0/16). If you deleted the default VPC, you receive the following error:
> VPC not defined 400
> To solve this problem, you must make a copy of the `AWS-UpdateWindowsAmi` runbook and specify a subnet ID. For more information, see VPC not defined 400.

To create a patched Windows AMI by using Automation

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

For information, see Installing or updating the latest version of the Amazon CLI.

2. Run the following command to run the `AWS-UpdateWindowsAmi` runbook. Replace each *example resource placeholder* with your own information. The example command below uses a recent Amazon EC2 AMI to minimize the number of patches that need to be applied. If you run this command more than once, you must specify a unique value for `targetAMIname`. AMI names must be unique.

```
aws ssm start-automation-execution \
    --document-name="AWS-UpdateWindowsAmi" \
    --parameters SourceAmiId='AMI ID',IamInstanceProfileName='IAM
 instance profile',AutomationAssumeRole='arn:aws-cn:iam::
{{global:ACCOUNT_ID}}:role/AutomationServiceRole'
```

The command returns an execution ID. Copy this ID to the clipboard. Use this ID to view the status of the automation.

```
{
    "AutomationExecutionId": "automation execution ID"
}
```

3. To view the automation using the Amazon CLI, run the following command:

```
aws ssm describe-automation-executions
```

4. To view details about the automation progress, run the following command.

```
aws ssm get-automation-execution
    --automation-execution-id automation execution ID
```

Note

Depending on the number of patches applied, the Windows patching process run in this sample automation can take 30 minutes or more to complete.

Update a golden AMI using Automation, Amazon Lambda, and Parameter Store

The following example uses the model where an organization maintains and periodically patches their own, proprietary AMIs rather than building from Amazon Elastic Compute Cloud (Amazon EC2) AMIs.

The following procedure shows how to automatically apply operating system (OS) patches to an AMI that is already considered to be the most up-to-date or *latest* AMI. In the example, the default value of the parameter `SourceAmiId` is defined by a Amazon Systems Manager Parameter Store parameter called `latestAmi`. The value of `latestAmi` is updated by an Amazon Lambda function invoked at the end of the automation. Because of this Automation process, the time and effort spent patching AMIs is minimized because patching is always applied to the most up-to-date AMI. Parameter Store and Automation are tools of Amazon Systems Manager.

Before you begin

Configure Automation roles and, optionally, Amazon EventBridge for Automation. For more information, see Setting up Automation.

Contents

- Task 1: Create a parameter in Systems Manager Parameter Store
- Task 2: Create an IAM role for Amazon Lambda
- Task 3: Create an Amazon Lambda function
- Task 4: Create a runbook and patch the AMI

Task 1: Create a parameter in Systems Manager Parameter Store

Create a string parameter in Parameter Store that uses the following information:

- **Name**: `latestAmi`.
- **Value**: An AMI ID. For example: `ami-188d6e0e`.

For information about how to create a Parameter Store string parameter, see Creating Parameter Store parameters in Systems Manager.

Task 2: Create an IAM role for Amazon Lambda

Use the following procedure to create an IAM service role for Amazon Lambda. These policies give Lambda permission to update the value of the `latestAmi` parameter using a Lambda function and Systems Manager.

To create an IAM service role for Lambda

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Policies**, and then choose **Create policy**.
3. Choose the **JSON** tab.
4. Replace the default contents with the following policy. Replace each *example resource placeholder* with your own information.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "logs:CreateLogGroup",
            "Resource": "arn:aws-cn:logs:us-east-1:111122223333:*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogStream",
                "logs:PutLogEvents"
            ],
            "Resource": [
                "arn:aws-cn:logs:us-east-1:111122223333:log-group:/aws/
lambda/function name:*"
            ]
        }
    ]
}
```

5. Choose **Next: Tags**.

6. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this policy.
7. Choose **Next: Review**.
8. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as **`amiLambda`**.
9. Choose **Create policy**.
10. Repeat steps 2 and 3.
11. Paste the following policy. Replace each *`example resource placeholder`* with your own information.

    JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ssm:PutParameter",
            "Resource": "arn:aws-cn:ssm:us-
east-1:111122223333:parameter/latestAmi"
        },
        {
            "Effect": "Allow",
            "Action": "ssm:DescribeParameters",
            "Resource": "*"
        }
    ]
}
```

12. Choose **Next: Tags**.
13. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this policy.
14. Choose **Next: Review**.
15. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as **`amiParameter`**.
16. Choose **Create policy**.
17. In the navigation pane, choose **Roles**, and then choose **Create role**.
18. Immediately under **Use case**, choose **Lambda**, and then choose **Next**.

19. On the **Add permissions** page, use the **Search** field to locate the two policies you created earlier.
20. Select the check box next to the policies, and then choose **Next**.
21. For **Role name**, enter a name for your new role, such as **`lambda-ssm-role`** or another name that you prefer.

    > **Note**
    >
    > Because various entities might reference the role, you cannot change the name of the role after it has been created.

22. (Optional) Add one or more tag key-value pairs to organize, track, or control access for this role, and then choose **Create role**.

Task 3: Create an Amazon Lambda function

Use the following procedure to create a Lambda function that automatically updates the value of the `latestAmi` parameter.

To create a Lambda function

1. Sign in to the Amazon Web Services Management Console and open the Amazon Lambda console at https://console.amazonaws.cn/lambda/.
2. Choose **Create function**.
3. On the **Create function** page, choose **Author from scratch**.
4. For **Function name**, enter **`Automation-UpdateSsmParam`**.
5. For **Runtime**, choose **Python 3.11**.
6. For **Architecture**, select the type of computer processor for Lambda to use to run the function, **x86_64** or **arm64**,
7. In the **Permissions** section, expand **Change default execution role**.
8. Choose **Use an existing role**, and then choose the service role for Lambda that you created in Task 2.
9. Choose **Create function**.
10. In the **Code source** area, on the **lambda_function** tab, delete the pre-populated code in the field, and then paste the following code sample.

```
from __future__ import print_function

import json
import boto3

print('Loading function')

#Updates an SSM parameter
#Expects parameterName, parameterValue
def lambda_handler(event, context):
    print("Received event: " + json.dumps(event, indent=2))

    # get SSM client
    client = boto3.client('ssm')

    #confirm  parameter exists before updating it
    response = client.describe_parameters(
       Filters=[
          {
           'Key': 'Name',
           'Values': [ event['parameterName'] ]
          },
        ]
    )

    if not response['Parameters']:
        print('No such parameter')
        return 'SSM parameter not found.'

    #if parameter has a Description field, update it PLUS the Value
    if 'Description' in response['Parameters'][0]:
        description = response['Parameters'][0]['Description']

        response = client.put_parameter(
          Name=event['parameterName'],
          Value=event['parameterValue'],
          Description=description,
          Type='String',
          Overwrite=True
        )

    #otherwise just update Value
```

```
    else:
        response = client.put_parameter(
          Name=event['parameterName'],
          Value=event['parameterValue'],
          Type='String',
          Overwrite=True
        )

    responseString = 'Updated parameter %s with value %s.' %
 (event['parameterName'], event['parameterValue'])

    return responseString
```

11. Choose **File, Save**.
12. To test the Lambda function, from the **Test** menu, choose **Configure test event**.
13. For **Event name**, enter a name for the test event, such as **`MyTestEvent`**.
14. Replace the existing text with the following JSON. Replace *`AMI ID`* with your own information to set your `latestAmi` parameter value.

```
{
   "parameterName":"latestAmi",
   "parameterValue":"AMI ID"
}
```

15. Choose **Save**.
16. Choose **Test** to test the function. On the **Execution result** tab, the status should be reported as **Succeeded**, along with other details about the update.

Task 4: Create a runbook and patch the AMI

Use the following procedure to create and run a runbook that patches the AMI you specified for the **latestAmi** parameter. After the automation completes, the value of **latestAmi** is updated with the ID of the newly-patched AMI. Subsequent automations use the AMI created by the previous execution.

To create and run the runbook

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.

3. For **Create document**, choose **Automation**.
4. For **Name**, enter **`UpdateMyLatestWindowsAmi`**.
5. Choose the **Editor** tab, and then choose **Edit**.
6. Choose **OK** when prompted.
7. In the **Document editor** field, replace the default content with the following YAML sample runbook content.

```
---
description: Systems Manager Automation Demo - Patch AMI and Update ASG
schemaVersion: '0.3'
assumeRole: '{{ AutomationAssumeRole }}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Required) The ARN of the role that allows Automation to perform
 the actions on your behalf. If no role is specified, Systems Manager Automation
 uses your IAM permissions to execute this document.'
    default: ''
  SourceAMI:
    type: String
    description: The ID of the AMI you want to patch.
    default: '{{ ssm:latestAmi }}'
  SubnetId:
    type: String
    description: The ID of the subnet where the instance from the SourceAMI
 parameter is launched.
  SecurityGroupIds:
    type: StringList
    description: The IDs of the security groups to associate with the instance
 that's launched from the SourceAMI parameter.
  NewAMI:
    type: String
    description: The name of of newly patched AMI.
    default: 'patchedAMI-{{global:DATE_TIME}}'

outputs:
- createImage.ImageId
```

8. Choose **Create automation**.
9. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
10. In the **Choose document** page, choose the **Owned by me** tab.
11. Search for the **UpdateMyLatestWindowsAmi** runbook, and select the button in the **UpdateMyLatestWindowsAmi** card.
12. Choose **Next**.
13. Choose **Simple execution**.
14. Specify values for the input parameters.
15. Choose **Execute**.
16. After the automation completes, choose **Parameter Store** in the navigation pane and confirm that the new value for `latestAmi` matches the value returned by the automation. You can also verify the new AMI ID matches the Automation output in the **AMIs** section of the Amazon EC2 console.

Updating AMIs using Automation and Jenkins

If your organization uses Jenkins software in a CI/CD pipeline, you can add Automation as a post-build step to pre-install application releases into Amazon Machine Images (AMIs). Automation is a tool in Amazon Systems Manager. You can also use the Jenkins scheduling feature to call Automation and create your own operating system (OS) patching cadence.

The example below shows how to invoke Automation from a Jenkins server that is running either on-premises or in Amazon Elastic Compute Cloud (Amazon EC2). For authentication, the Jenkins server uses Amazon credentials based on an IAM policy that you create in the example and attach to your instance profile.

> **Note**
>
> Be sure to follow Jenkins security best practices when configuring your instance.

Before you begin

Complete the following tasks before you configure Automation with Jenkins:

- Complete the Update a golden AMI using Automation, Amazon Lambda, and Parameter Store example. The following example uses the **UpdateMyLatestWindowsAmi** runbook created in that example.
- Configure IAM roles for Automation. Systems Manager requires an instance profile role and a service role ARN to process automations. For more information, see Setting up Automation.

To create an IAM policy for the Jenkins server

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Policies**, and then choose **Create policy**.
3. Choose the **JSON** tab.
4. Replace each *example resource placeholder* with your own information.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ssm:StartAutomationExecution",
            "Resource": [
                "arn:aws-cn:ssm:us-
east-1:111122223333:document/UpdateMyLatestWindowsAmi",
                "arn:aws-cn:ssm:us-east-1:111122223333:automation-execution/
*"
            ]
        }
    ]
```

```
}
```

5. Choose **Review policy**.
6. On the **Review policy** page, for **Name**, enter a name for the inline policy, such as **`JenkinsPolicy`**.
7. Choose **Create policy**.
8. In the navigation pane, choose **Roles**.
9. Choose the instance profile that's attached to your Jenkins server.
10. In the **Permissions** tab, select **Add permissions** and choose **Attach policies**.
11. In the **Other permissions policies** section, enter the name of policy you created in the previous steps. For example, **JenkinsPolicy**.
12. Select the check box next to your policy, and choose **Attach policies**.

Use the following procedure to configure the Amazon CLI on your Jenkins server.

To configure the Jenkins server for Automation

1. Connect to your Jenkins server on port 8080 using your preferred browser to access the management interface.
2. Enter the password found in `/var/lib/jenkins/secrets/initialAdminPassword`. To display your password, run the following command.

```
sudo cat /var/lib/jenkins/secrets/initialAdminPassword
```

3. The Jenkins installation script directs you to the **Customize Jenkins** page. Select **Install suggested plugins**.
4. Once the installation is complete, choose **Administrator Credentials**, select **Save Credentials**, and then select **Start Using Jenkins**.
5. In the left navigation pane, choose **Manage Jenkins**, and then choose **Manage Plugins**.
6. Choose the **Available** tab, and then enter **`Amazon EC2 plugin`**.
7. Select the check box for **`Amazon EC2 plugin`**, and then select **Install without restart**.
8. When the installation completes, select **Go back to the top page**.
9. Choose **Manage Jenkins**, and then choose **Manage nodes and clouds**.
10. In the **Configure Clouds** section, select **Add a new cloud**, and then choose **Amazon EC2**.

11. Enter your information in the remaining fields. Make sure you select the **Use EC2 instance profile to obtain credentials** option.

Use the following procedure to configure your Jenkins project to invoke Automation.

To configure your Jenkins server to invoke Automation

1. Open the Jenkins console in a web browser.
2. Choose the project that you want to configure with Automation, and then choose **Configure**.
3. On the **Build** tab, choose **Add Build Step**.
4. Choose **Execute shell** or **Execute Windows batch command** (depending on your operating system).
5. In the **Command** field, run an Amazon CLI command like the following. Replace each *example resource placeholder* with your own information.

```
aws ssm start-automation-execution \
        --document-name runbook name \
        --region Amazon Web Services Region of your source AMI \
        --parameters runbook parameters
```

The following example command uses the **UpdateMyLatestWindowsAmi** runbook and the Systems Manager Parameter `latestAmi` created in Update a golden AMI using Automation, Amazon Lambda, and Parameter Store.

```
aws ssm start-automation-execution \
        --document-name UpdateMyLatestWindowsAmi \
        --parameters \
            "sourceAMIid='{{ssm:latestAmi}}'"
        --region region
```

In Jenkins, the command looks like the example in the following screenshot.

6. In the Jenkins project, choose **Build Now**. Jenkins returns output similar to the following example.

```
Console Output

Started by user admin
Building in workspace /var/lib/jenkins/workspace/Build AMI
[Build AMI] $ /bin/sh -xe /tmp/hudson3259912997441414819.sh
+ aws --region us-east-1 ssm start-automation-execution --document-name UpdateMyLatestWindowsAmi --parameters 'sourceAMIid='\''{{ssm:latestAmi}}'\'''
{
    "AutomationExecutionId": "7badf13a-ff8c-11e6-9503-9d48daa849f3"
}
Finished: SUCCESS
```

Updating AMIs for Auto Scaling groups

The following example updates an Auto Scaling group with a newly patched AMI. This approach ensures that new images are automatically made available to different computing environments that use Auto Scaling groups.

The final step of the automation in this example uses a Python function to create a new launch template that uses the newly patched AMI. Then the Auto Scaling group is updated to use the new launch template. In this type of Auto Scaling scenario, users could terminate existing instances in the Auto Scaling group to force a new instance to launch that uses the new image. Or, users could wait and allow scale-in or scale-out events to naturally launch newer instances.

Before you begin

Complete the following tasks before you begin this example.

- Configure IAM roles for Automation. Systems Manager requires an instance profile role and a service role ARN to process automations. For more information, see Setting up Automation.

Create the PatchAMIAndUpdateASG runbook

Use the following procedure to create the **PatchAMIAndUpdateASG** runbook that patches the AMI you specify for the **SourceAMI** parameter. The runbook also updates an Auto Scaling group to use the latest, patched AMI.

To create and run the runbook

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. In the **Create document** dropdown, choose **Automation**.
4. In the **Name** field, enter **`PatchAMIAndUpdateASG`**.
5. Choose the **Editor** tab, and choose the **Edit**.
6. Choose **OK** when prompted, and delete the content in the **Document editor** field.
7. In the **Document editor** field, paste the following YAML sample runbook content.

```
---
description: Systems Manager Automation Demo - Patch AMI and Update ASG
schemaVersion: '0.3'
assumeRole: '{{ AutomationAssumeRole }}'
parameters:
  AutomationAssumeRole:
    type: String
    description: '(Required) The ARN of the role that allows Automation to perform
 the actions on your behalf. If no role is specified, Systems Manager Automation
 uses your IAM permissions to execute this document.'
    default: ''
  SourceAMI:
    type: String
    description: '(Required) The ID of the AMI you want to patch.'
  SubnetId:
    type: String
    description: '(Required) The ID of the subnet where the instance from the
 SourceAMI parameter is launched.'
  SecurityGroupIds:
    type: StringList
    description: '(Required) The IDs of the security groups to associate with the
 instance launched from the SourceAMI parameter.'
  NewAMI:
```

```
    type: String
    description: '(Optional) The name of of newly patched AMI.'
    default: 'patchedAMI-{{global:DATE_TIME}}'
  TargetASG:
    type: String
    description: '(Required) The name of the Auto Scaling group you want to
 update.'
  InstanceProfile:
    type: String
    description: '(Required) The name of the IAM instance profile you want the
 source instance to use.'
  SnapshotId:
    type: String
    description: (Optional) The snapshot ID to use to retrieve a patch baseline
 snapshot.
    default: ''
  RebootOption:
    type: String
    description: '(Optional) Reboot behavior after a patch Install operation. If
 you choose NoReboot and patches are installed, the instance is marked as non-
compliant until a subsequent reboot and scan.'
    allowedValues:
      - NoReboot
      - RebootIfNeeded
    default: RebootIfNeeded
  Operation:
    type: String
    description: (Optional) The update or configuration to perform on the instance.
 The system checks if patches specified in the patch baseline are installed on the
 instance. The install operation installs patches missing from the baseline.
    allowedValues:
      - Install
      - Scan
    default: Install
mainSteps:
  - name: startInstances

 volume_size, 'VolumeType': volume_type}}
                mappings.append(device)

            # create new launch template using details returned from instance in
 the ASG and specify the newly patched AMI
            time_stamp = time.time()
            time_stamp_string =
 datetime.datetime.fromtimestamp(time_stamp).strftime('%m-%d-%Y_%H-%M-%S')
            new_template_name = f'{new_ami}_{time_stamp_string}'
            try:
                ec2.create_launch_template(
                    LaunchTemplateName=new_template_name,
                    LaunchTemplateData={
                        'BlockDeviceMappings': mappings,
```

```
                        'ImageId': new_ami,
                        'InstanceType': source_instance['InstanceType'],
                        'IamInstanceProfile': {
                            'Arn': source_instance['IamInstanceProfile']['Arn']
                        },
                        'KeyName': source_instance['KeyName'],
                        'SecurityGroupIds': security_groups
                    }
                )
            except Exception as e:
                return f'Exception caught: {str(e)}'
            else:
                # update ASG to use new launch template
                asg.update_auto_scaling_group(
                    AutoScalingGroupName=target_asg,
                    LaunchTemplate={
                        'LaunchTemplateName': new_template_name
                    }
                )
                return f'Updated ASG {target_asg} with new launch template
 {new_template_name} which uses AMI {new_ami}.'
outputs:
- createImage.ImageId
```

8. Choose **Create automation**.
9. In the navigation pane, choose **Automation**, and then choose **Execute automation**.
10. In the **Choose document** page, choose the **Owned by me** tab.
11. Search for the **PatchAMIAndUpdateASG** runbook, and select the button in the **PatchAMIAndUpdateASG** card.
12. Choose **Next**.
13. Choose **Simple execution**.
14. Specify values for the input parameters. Be sure the `SubnetId` and `SecurityGroupIds` you specify allow access to the public Systems Manager endpoints, or your interface endpoints for Systems Manager.
15. Choose **Execute**.
16. After automation completes, in the Amazon EC2 console, choose **Auto Scaling**, and then choose **Launch Templates**. Verify that you see the new launch template, and that it uses the new AMI.

17. Choose **Auto Scaling**, and then choose **Auto Scaling Groups**. Verify that the Auto Scaling group uses the new launch template.
18. Terminate one or more instances in your Auto Scaling group. Replacement instances will be launched using the new AMI.

Using Amazon Web Services Support self-service runbooks

This section describes how to use some of the self-service automations created by the Amazon Web Services Support team. These automations help you manage your Amazon resources.

Support Automation Workflows

Support Automation Workflows (SAW) are automation runbooks written and maintained by the Amazon Web Services Support team. These runbooks help you troubleshoot common issues with your Amazon resources, proactively monitor and identify network issues, collect and analyze logs, and more.

SAW runbooks use the **`AWSSupport`** prefix. For example, `AWSSupport-ActivateWindowsWithAmazonLicense`.

Additionally, customers with Business Support+ and higher Amazon Support plans also have access to runbooks that use the **`AWSPremiumSupport`** prefix. For example, `AWSPremiumSupport-TroubleshootEC2DiskUsage`.

To learn more about Amazon Web Services Support, see Getting started with Amazon Web Services Support.

Run the EC2Rescue tool on unreachable instances

EC2Rescue can help you diagnose and troubleshoot problems on Amazon Elastic Compute Cloud (Amazon EC2) instances for Linux and Windows Server. You can run the tool manually, as described in Using EC2Rescue for Linux Server and Using EC2Rescue for Windows Server. Or, you can run the tool automatically by using Systems Manager Automation and the **`AWSSupport-ExecuteEC2Rescue`** runbook. Automation is a tool in Amazon Systems Manager. The **`AWSSupport-ExecuteEC2Rescue`** runbook is designed to perform a combination of Systems Manager actions and Amazon CloudFormation actions that automate the steps normally required to use EC2Rescue.

You can use the **AWSSupport-ExecuteEC2Rescue** runbook to troubleshoot and potentially remediate different types of operating system (OS) issues. Instances with encypted root volumes are not supported. See the following topics for a complete list:

Windows: See *Rescue Action* in Using EC2Rescue for Windows Server with the Command Line.

Linux and **macOS**: Some EC2Rescue for Linux modules detect and attempt to remediate issues. For more information, see the aws-ec2rescue-linux documentation for each module on GitHub.

How it works

Troubleshooting an instance with Automation and the **AWSSupport-ExecuteEC2Rescue** runbook works as follows:

- You specify the ID of the unreachable instance and start the runbook.
- The system creates a temporary VPC by deploying the EC2Rescue Amazon CloudFormation stack.
- The system identifies a subnet for your temporary VPC in the same Availability Zone as your original instance.
- The system launches a temporary, SSM-enabled helper instance.
- The system stops your original instance, and creates a backup. It then attaches the original root volume to the helper instance.
- The system uses Run Command to run EC2Rescue on the helper instance. EC2Rescue identifies and attempts to fix issues on the attached, original root volume. When finished, EC2Rescue reattaches the root volume back to the original instance.
- The system restarts your original instance, and terminates the temporary instance. The system also terminates the temporary VPC and deletes the EC2Rescue Amazon CloudFormation stack created at the start of the automation.

Before you begin

Before you run the following Automation, do the following:

- Copy the instance ID of the unreachable instance. Specify this ID in the procedure.
- Optionally, collect the ID of a subnet in the same availability zone as your unreachable instance. The EC2Rescue instance will be created in this subnet. If you don't specify a subnet, then Automation creates a new temporary VPC in your Amazon Web Services account. Verify that your Amazon Web Services account has at least one VPC available. By default, you can create five VPCs in a Region. If you already created five VPCs in the Region, the automation fails without

making changes to your instance. For more information about Amazon VPC quotas, see VPC and Subnets in the *Amazon VPC User Guide*.

- Optionally, you can create and specify an Amazon Identity and Access Management (IAM) role for Automation. If you don't specify this role, then Automation runs in the context of the user who ran the automation.

Granting `AWSSupport-EC2Rescue` permissions to perform actions on your instances

EC2Rescue needs permission to perform a series of actions on your instances during the automation. These actions invoke the IAM, Amazon EC2, and Amazon CloudFormation services to safely and securely attempt to remediate issues with your instances. If you have Administrator-level permissions in your Amazon Web Services account and/or VPC, you might be able to run the automation without configuring permissions, as described in this section. If you don't have Administrator-level permissions, then you or an administrator must configure permissions as described in Granting permissions by using IAM policies.

Granting permissions by using IAM policies

You can either attach the following IAM policy to your user, group, or role as an inline policy; or, you can create a new IAM managed policy and attach it to your user, group, or role. For more information about adding an inline policy to your user, group, or role see Working With Inline Policies. For more information about creating a new managed policy, see Working With Managed Policies.

> **Note**
>
> Attach the **AmazonSSMAutomationRole** managed policy alongside the following policy, whether you add the following policy inline or as a new managed policy. The automation depends on permissions that **AmazonSSMAutomationRole** grants and the following policy doesn't, including the Systems Manager API permissions, `ec2:RunInstances`, and the Amazon CloudFormation permissions used to create and delete the temporary EC2Rescue stack.

> **Note**
>
> This policy assumes that you specify an existing instance profile in the `HelperInstanceProfileName` parameter when you run the automation.

The IAM role inside that instance profile is a separate identity from the one you attach the following policy to. It must trust `ec2.amazonaws.com` and have the **AmazonSSMManagedInstanceCore** policy attached, so that the EC2Rescue helper instance can register with Systems Manager and receive commands. Don't attach **AmazonSSMAutomationRole** to it, because the helper instance doesn't call those APIs. If you set `LogDestination`, that role additionally needs `s3:ListBucket` on the bucket, and `s3:PutObject` with `s3:AbortMultipartUpload` on the `AWSSupport-ExecuteEC2Rescue` prefix within it. If you leave `HelperInstanceProfileName` empty, the automation creates a helper IAM role and instance profile on your behalf, which requires permissions to create and configure IAM resources that this policy doesn't grant.

IAM Policy for AWSSupport-EC2Rescue

Replace *account ID*, *EC2RescueHelperRole*, and *EC2RescueAutomationRole* with your own information.

    ]
}
```

Running the Automation

> **Important**
>
> The following automation stops the unreachable instance. Stopping the instance can result in lost data on attached instance store volumes (if present). Stopping the instance can also cause the public IP to change, if no Elastic IP is associated.

To run the `AWSSupport-ExecuteEC2Rescue` Automation

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Automation**.
3. Choose **Execute automation**.
4. In the **Automation document** section, choose **Owned by Amazon** from the list.
5. In the runbooks list, choose the button in the card for **`AWSSupport-ExecuteEC2Rescue`**, and then choose **Next**.
6. In the **Execute automation document** page, choose **Simple execution**.
7. In the **Document details** section, verify that **Document version** is set to the highest default version. For example, **$DEFAULT** or **3 (default)**.
8. In the **Input parameters** section, specify the following parameters:
   a. For **UnreachableInstanceId**, specify the ID of the unreachable instance.
   b. (Optional) For **EC2RescueInstanceType**, specify an instance type for the EC2Rescue instance. The default instance type is `t2.medium`.
   c. For **AutomationAssumeRole**, choose the ARN of the IAM role that you granted the permissions described in Granting permissions by using IAM policies. If you leave this empty, the automation runs with the permissions of your own user or role, which must then include those same permissions.
   d. For **HelperInstanceProfileName**, enter the name of the instance profile that you prepared for the EC2Rescue helper instance.
   e. (Optional) For **LogDestination**, specify an S3 bucket if you want to collect operating system-level logs while troubleshooting your instance. Logs are automatically uploaded to the specified bucket.

f. For **SubnetId**, specify a subnet in an existing VPC in the same availability zone as the unreachable instance. By default, Systems Manager creates a new VPC, but you can specify a subnet in an existing VPC if you want.

> **Note**
>
> If you don't see the option to specify a bucket or a subnet ID, verify that you are using the latest **Default** version of the runbook.

9. (Optional) In the **Tags** area, apply one or more tag key name/value pairs to help identify the automation, for example `Key=Purpose,Value=EC2Rescue`.
10. Choose **Execute**.

The runbook creates a backup AMI as part of the automation. All other resources created by the automation are automatically deleted, but this AMI remains in your account. The AMI is named using the following convention:

Backup AMI: AWSSupport-EC2Rescue:*UnreachableInstanceId*

You can locate this AMI in the Amazon EC2 console by searching on the Automation execution ID.

Reset passwords and SSH keys on EC2 instances

You can use the `AWSSupport-ResetAccess` runbook to automatically re-enable local Administrator password generation on Amazon Elastic Compute Cloud (Amazon EC2) instances for Windows Server and to generate a new SSH key on EC2 instances for Linux. The `AWSSupport-ResetAccess` runbook is designed to perform a combination of Amazon Systems Manager actions and Amazon CloudFormation actions that automate the steps normally required to reset the local administrator password.

You can use Automation with the `AWSSupport-ResetAccess` runbook to solve the following problems:

Windows

You lost the EC2 key pair: To resolve this problem, you can use the **AWSSupport-ResetAccess** runbook to create a password-enabled AMI from your current instance, launch a new instance from the AMI, and select a key pair you own.

You lost the local Administrator password: To resolve this problem, you can use the `AWSSupport-ResetAccess` runbook to generate a new password that you can decrypt with the current EC2 key pair.

Linux

You lost your EC2 key pair, or you configured SSH access to the instance with a key you lost: To resolve this problem, you can use the `AWSSupport-ResetAccess` runbook to create a new SSH key for your current instance, which lets you connect to the instance again.

> **Note**
>
> If your EC2 instance for Windows Server is configured for Systems Manager, you can also reset your local Administrator password by using EC2Rescue and Amazon Systems Manager Run Command. For more information, see Using EC2Rescue for Windows Server with Systems Manager Run Command in the *Amazon EC2 User Guide*.

Related information

Connect to your Linux instance from Windows using PuTTY in the *Amazon EC2 User Guide*

How it works

Troubleshooting an instance with Automation and the `AWSSupport-ResetAccess` runbook works as follows:

- You specify the ID of the instance and run the runbook.
- The system creates a temporary VPC by deploying the EC2Rescue Amazon CloudFormation stack.
- The system identifies a subnet for your temporary VPC in the same Availability Zone as your original instance.
- The system launches a temporary, SSM-enabled helper instance.
- The system stops your original instance, and creates a backup. It then attaches the original root volume to the helper instance.
- The system uses Run Command to run EC2Rescue on the helper instance. On Windows, EC2Rescue enables password generation for the local Administrator by using EC2Config or EC2Launch on the attached, original root volume. On Linux, EC2Rescue generates and injects a

new SSH key and saves the private key, encrypted, in Parameter Store. When finished, EC2Rescue reattaches the root volume back to the original instance.

- The system creates a new Amazon Machine Image (AMI) of your instance, now that password generation is enabled. You can use this AMI to create a new EC2 instance, and associate a new key pair if needed.
- The system restarts your original instance, and terminates the temporary instance. The system also terminates the temporary VPC and deletes the EC2Rescue Amazon CloudFormation stack created at the start of the automation.
- **Windows**: Your instance generates a new password you can decode from the Amazon EC2 console using the current key pair assigned to the instance.

  Linux: You can SSH to the instance by using the SSH key stored in Systems Manager Parameter Store as **/ec2rl/openssh/*instance ID*/key**.

Before you begin

Before you run the following Automation, do the following:

- Copy the instance ID of the instance on which you want to reset the Administrator password. Specify this ID in the procedure.
- Optionally, collect the ID of a subnet in the same availability zone as your unreachable instance. The EC2Rescue instance will be created in this subnet. If you don't specify a subnet, then Automation creates a new temporary VPC in your Amazon Web Services account. Verify that your Amazon Web Services account has at least one VPC available. By default, you can create five VPCs in a Region. If you already created five VPCs in the Region, the automation fails without making changes to your instance. For more information about Amazon VPC quotas, see VPC and Subnets in the *Amazon VPC User Guide*.
- Optionally, you can create and specify an Amazon Identity and Access Management (IAM) role for Automation. If you don't specify this role, then Automation runs in the context of the user who ran the automation.

Granting AWSSupport-EC2Rescue permissions to perform actions on your instances

EC2Rescue needs permission to perform a series of actions on your instances during the automation. These actions invoke the IAM, Amazon EC2, and Amazon CloudFormation services to safely and securely attempt to remediate issues with your instances. If you have Administrator-

level permissions in your Amazon Web Services account and/or VPC, you might be able to run the automation without configuring permissions, as described in this section. If you don't have Administrator-level permissions, then you or an administrator must configure permissions as described in Granting permissions by using IAM policies.

Granting permissions by using IAM policies

You can either attach the following IAM policy to your user, group, or role as an inline policy; or, you can create a new IAM managed policy and attach it to your user, group, or role. For more information about adding an inline policy to your user, group, or role see Working With Inline Policies. For more information about creating a new managed policy, see Working With Managed Policies.

> **Note**
>
> Attach the **AmazonSSMAutomationRole** managed policy alongside the following policy, whether you add the following policy inline or as a new managed policy. The automation depends on permissions that **AmazonSSMAutomationRole** grants and the following policy doesn't, including the Systems Manager API permissions, `ec2:RunInstances`, and the Amazon CloudFormation permissions used to create and delete the temporary EC2Rescue stack.

> **Note**
>
> This policy assumes that you specify an existing instance profile in the `HelperInstanceProfileName` parameter when you run the automation.
> The IAM role inside that instance profile is a separate identity from the one you attach the following policy to. It must trust `ec2.amazonaws.com` and have the **AmazonSSMManagedInstanceCore** policy attached, so that the EC2Rescue helper instance can register with Systems Manager and receive commands. Don't attach **AmazonSSMAutomationRole** to it, because the helper instance doesn't call those APIs.
> To reset an SSH key on a Linux instance, that role additionally needs `ssm:PutParameter` on `arn:aws-cn:ssm:*:`*`account ID`*`:parameter/ec2rl/openssh/*/key`, and `kms:Encrypt` with `kms:GenerateDataKey` so that the parameter can be written as a `SecureString`. If you leave `HelperInstanceProfileName` empty, the automation

creates a helper IAM role and instance profile on your behalf, which requires permissions to create and configure IAM resources that this policy doesn't grant.

IAM Policy for AWSSupport-ResetAccess

Replace *account ID*, *EC2RescueHelperRole*, and *EC2RescueAutomationRole* with your own information.

```

Running the Automation

The following procedure describes how to run the `AWSSupport-ResetAccess` runbook by using the Amazon Systems Manager console.

> **Important**
>
> The following automation stops the instance. Stopping the instance can result in lost data on attached instance store volumes (if present). Stopping the instance can also cause the public IP to change, if no Elastic IP is associated. To avoid these configuration changes, use Run Command to reset access. For more information, see Using EC2Rescue for Windows Server with Systems Manager Run Command in the *Amazon EC2 User Guide*.

To run the AWSSupport-ResetAccess Automation

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Automation**.
3. Choose **Execute automation**.
4. In the **Automation document** section, choose **Owned by Amazon** from the list.
5. In the runbooks list, choose the button in the card for **AWSSupport-ResetAccess**, and then choose **Next**.
6. In the **Execute automation document** page, choose **Simple execution**.
7. In the **Document details** section, verify that **Document version** is set to the highest default version. For example, **$DEFAULT** or **3 (default)**.
8. In the **Input parameters** section, specify the following parameters:

   a. For **InstanceId**, specify the ID of the unreachable instance.

   b. For **SubnetId**, specify a subnet in an existing VPC in the same availability zone as the instance you specified. By default, Systems Manager creates a new VPC, but you can specify a subnet in an existing VPC if you want.

   > **Note**
   >
   > If you don't see the option to specify a subnet ID, verify that you are using the latest **Default** version of the runbook.

   c. For **EC2RescueInstanceType**, specify an instance type for the EC2Rescue instance. The default instance type is `t3.medium`.

   d. For **HelperInstanceProfileName**, specify the name of an existing IAM instance profile for the EC2Rescue helper instance. If you leave this empty, the automation attempts to create a helper IAM role and instance profile on your behalf, which requires additional permissions. For the permissions that instance profile needs, see Granting permissions by using IAM policies.

   e. For **AutomationAssumeRole**, choose the ARN of the IAM role that you granted the permissions described in Granting permissions by using IAM policies. If you leave this empty, the automation runs with the permissions of your own user or role, which must then include those same permissions.

9. (Optional) In the **Tags** area, apply one or more tag key name/value pairs to help identify the automation, for example `Key=Purpose,Value=ResetAccess`.
10. Choose **Execute**.
11. To monitor the automation progress, choose the running automation, and then choose the **Steps** tab. When the automation is finished, choose the **Descriptions** tab, and then choose **View output** to view the results. To view the output of individual steps, choose the **Steps** tab, and then choose **View Outputs** next to a step.

The runbook creates a backup AMI and a password-enabled AMI as part of the automation. All other resources created by the automation are automatically deleted, but these AMIs remain in your account. The AMIs are named using the following conventions:

- Backup AMI: `AWSSupport-EC2Rescue:`*`InstanceID`*
- Password-enabled AMI: AWSSupport-EC2Rescue: Password-enabled AMI from *`Instance ID`*

You can locate these AMIs by searching on the Automation execution ID.

For Linux, the new SSH private key for your instance is saved, encrypted, in Parameter Store. The parameter name is **/ec2rl/openssh/*`instance ID`*/key**.

Passing data to Automation using input transformers

This Amazon Systems Manager Automation tutorial shows how to use the input transformer feature of Amazon EventBridge to extract the `instance-id` of an Amazon Elastic Compute Cloud (Amazon EC2) instance from an instance state change event. Automation is a tool in Amazon Systems Manager. We use the input transformer to pass that data to the `AWS-CreateImage` runbook target as the `InstanceId` input parameter. The rule is triggered when any instance changes to the `stopped` state.

For more information about working with input transformers, see Tutorial: Use Input Transformer to Customize What is Passed to the Event Target in the *Amazon EventBridge User Guide*.

Before you begin

Verify that you added the required permissions and trust policy for EventBridge to your Systems Manager Automation service role. For more information, see Overview of Managing Access Permissions to Your EventBridge Resources in the *Amazon EventBridge User Guide*.

To use input transformers with Automation

1. Open the Amazon EventBridge console at https://console.amazonaws.cn/events/.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule.

   A rule can't have the same name as another rule in the same Region and on the same event bus.
5. For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to respond to matching events that come from your own Amazon Web Services account, select **default**. When an Amazon Web Services service in your account emits an event, it always goes to your account's default event bus.
6. For **Rule type**, choose **Rule with an event pattern**.
7. Choose **Next**.
8. For **Event source**, choose **Amazon events or EventBridge partner events**.
9. In the **Event pattern** section, choose **Use pattern form**.
10. For **Event source**, choose **Amazon services**.
11. For **Amazon service**, choose **EC2**.
12. For **Event type**, choose **EC2 Instance State-change Notification**.
13. For **Event Type Specification 1**, select **Specific state(s)**, and then choose **stopped**.
14. For **Event Type Specification 2**, select **Any instance**, or select **Specific instance Id(s)** and enter the IDs of the instances to monitor.
15. Choose **Next**.
16. For **Target types**, choose **Amazon service**.
17. For **Select a target**, choose **Systems Manager Automation**.
18. For **Document**, choose **AWS-CreateImage**.
19. In the **Configure automation parameter(s)** section, choose **Input Transformer**.
20. For **Input path**, enter **`{"instance":"$.detail.instance-id"}`**.
21. For **Template**, enter **`{"InstanceId":[<instance>]}`**.
22. For **Execution role**, choose **Use existing role** and choose your Automation service role.

23. Choose **Next**.
24. (Optional) Enter one or more tags for the rule. For more information, see Tagging Your Amazon EventBridge Resources in the *Amazon EventBridge User Guide*.
25. Choose **Next**.
26. Review the details of the rule and choose **Create rule**.

Learn about statuses returned by Systems Manager Automation

Amazon Systems Manager Automation reports detailed status information about the various statuses an automation action or step goes through when you run an automation and for the overall automation. Automation is a tool in Amazon Systems Manager. You can monitor automation statuses using the following methods:

- Monitor the **Execution status** in the Systems Manager Automation console.
- Use your preferred command line tools. For the Amazon Command Line Interface (Amazon CLI), you can use describe-automation-step-executions or get-automation-execution. For the Amazon Tools for Windows PowerShell, you can use Get-SSMAutomationStepExecution or Get-SSMAutomationExecution.
- Configure Amazon EventBridge to respond to action or automation status changes.

For more information about handling timeouts in an automation, see Handling timeouts in runbooks.

About automation statuses

Automation reports status details for individual automation actions besides the overall automation.

The overall automation status can be different than the status reported by an individual action or step as noted in the following tables.

Detailed status for actions

Status	Details
Pending	The step hasn't started running. If your automation uses conditional actions, steps remain in this state after an automation has

Status	Details
	completed if the condition wasn't met to run the step. Steps also remain in this state if the automation is canceled before the step runs.
InProgress	The step is running.
Waiting	The step is waiting for input.
Success	The step completed successfully. This is a terminal state.
TimedOut	A step or approval wasn't completed before the specified timeout period. This is a terminal state.
Cancelling	The step is currently stopping after being canceled by a requester.
Cancelled	The step was stopped by a requester before it completed. This is a terminal state.
Failed	The step didn't complete successfully. This is a terminal state.
Exited	Only returned by the `aws:loop` action. The loop didn't fully complete. A step inside the loop moved to an outside step using the `nextStep`, `onCancel`, or `onFailure` properties.

Detailed status for an automation

Status	Details
Pending	The automation hasn't started running.
InProgress	The automation is running.

Status	Details
Waiting	The automation is waiting for input.
Success	The automation completed successfully. This is a terminal state.
TimedOut	A step or approval wasn't completed before the specified timeout period. This is a terminal state.
Cancelling	The automation is currently stopping after being canceled by a requester.
Cancelled	The automation was stopped by a requester before it completed. This is a terminal state.
Failed	The automation didn't complete successfully. This is a terminal state.

Troubleshooting Systems Manager Automation

Use the following information to help you troubleshoot problems with Amazon Systems Manager Automation. This topic includes specific tasks to resolve issues based on Automation error messages.

Common Automation errors

This section includes information about common Automation errors.

VPC not defined 400

By default, when Automation runs either the `AWS-UpdateLinuxAmi` runbook or the `AWS-UpdateWindowsAmi` runbook, the system creates a temporary instance in the default VPC (172.30.0.0/16). If you deleted the default VPC, you receive the following error:

```
VPC not defined 400
```

To solve this problem, you must specify a value for the `SubnetId` input parameter.

Automation execution failed to start

An automation can fail with an access denied error or an invalid assume role error if you haven't properly configured Amazon Identity and Access Management (IAM) roles, and policies for Automation.

Access denied

The following examples describe situations when an automation failed to start with an access denied error.

Access Denied to Systems Manager API

Error message: `User: user arn isn't authorized to perform: ssm:StartAutomationExecution on resource: document arn (Service: AWSSimpleSystemsManagement; Status Code: 400; Error Code: AccessDeniedException; Request ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx)`

- Possible cause 1: The user attempting to start the automation doesn't have permission to invoke the `StartAutomationExecution` API. To resolve this issue, attach the required IAM policy to the user that was used to start the automation.
- Possible cause 2: The user attempting to start the automation has permission to invoke the `StartAutomationExecution` API but doesn't have permission to invoke the API by using the specific runbook. To resolve this issue, attach the required IAM policy to the user that was used to start the automation.

Access denied due to missing PassRole permissions

Error message: `User: user arn isn't authorized to perform: iam:PassRole on resource: automation assume role arn (Service: AWSSimpleSystemsManagement; Status Code: 400; Error Code: AccessDeniedException; Request ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx)`

The user attempting to start the automation doesn't have PassRole permission for the assume role. To resolve this issue, attach the iam:PassRole policy to the role of the user attempting to start the automation. For more information, see Task 2: Attach the iam:PassRole policy to your Automation role.

Invalid assume role

When you run an Automation, an assume role is either provided in the runbook or passed as a parameter value for the runbook. Different types of errors can occur if the assume role isn't specified or configured properly.

Malformed Assume Role

Error message: `The format of the supplied assume role ARN isn't valid.` The assume role is improperly formatted. To resolve this issue, verify that a valid assume role is specified in your runbook or as a runtime parameter when starting the automation.

Assume role can't be assumed

Error message: `The defined assume role is unable to be assumed. (Service: AWSSimpleSystemsManagement; Status Code: 400; Error Code: InvalidAutomationExecutionParametersException; Request ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx)`

- Possible cause 1: The assume role doesn't exist. To resolve this issue, create the role. For more information, see the section called “Setting up Automation”. Specific details for creating this role are described in the following topic, Task 1: Create a service role for Automation.
- Possible cause 2: The assume role doesn't have a trust relationship with the Systems Manager service. To resolve this issue, create the trust relationship. For more information, see I Can't Assume A Role in the *IAM User Guide*.

Execution started, but status is failed

Action-specific failures

Runbooks contain steps and steps run in order. Each step invokes one or more Amazon Web Services service APIs. The APIs determine the inputs, behavior, and outputs of the step. There are multiple places where an error can cause a step to fail. Failure messages indicate when and where an error occurred.

To see a failure message in the Amazon Elastic Compute Cloud (Amazon EC2) console, choose the **View Outputs** link of the failed step. To see a failure message from the Amazon CLI, call `get-automation-execution` and look for the `FailureMessage` attribute in a failed `StepExecution`.

In the following examples, a step associated with the `aws:runInstance` action failed. Each example explores a different type of error.

Missing Image

Error message: `Automation Step Execution fails when it's launching the instance(s). Get Exception from RunInstances API of ec2 Service. Exception Message from RunInstances API: [The image id '[ami id]' doesn't exist (Service: AmazonEC2; Status Code: 400; Error Code: InvalidAMIID.NotFound; Request ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx)]. Please refer to Automation Service Troubleshooting Guide for more diagnosis details.`

The `aws:runInstances` action received input for an `ImageId` that doesn't exist. To resolve this problem, update the runbook or parameter values with the correct AMI ID.

Assume role policy lacks sufficient permissions

Error message: `Automation Step Execution fails when it's launching the instance(s). Get Exception from RunInstances API of ec2 Service. Exception Message from RunInstances API: [You aren't authorized to perform this operation. Encoded authorization failure message: xxxxxx (Service: AmazonEC2; Status Code: 403; Error Code: UnauthorizedOperation; Request ID: xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx)]. Please refer to Automation Service Troubleshooting Guide for more diagnosis details.`

The assume role doesn't have sufficient permission to invoke the `RunInstances` API on EC2 instances. To resolve this problem, attach an IAM policy to the assume role that has permission to invoke the `RunInstances` API. For more information, see the Create the service roles for Automation using the console.

Unexpected State

Error message: `Step fails when it's verifying launched instance(s) are ready to be used. Instance i-xxxxxxxxx entered unexpected state: shutting-down. Please refer to Automation Service Troubleshooting Guide for more diagnosis details.`

- Possible cause 1: There is a problem with the instance or the Amazon EC2 service. To resolve this problem, login to the instance or review the instance system log to understand why the instance started shutting down.

- Possible cause 2: The user data script specified for the `aws:runInstances` action has a problem or incorrect syntax. Verify the syntax of the user data script. Also, verify that the user data scripts doesn't shut down the instance, or invoke other scripts that shut down the instance.

Action-Specific Failures Reference

When a step fails, the failure message might indicate which service was being invoked when the failure occurred. The following table lists the services invoked by each action. The table also provides links to information about each service.

Action	Amazon Web Services services invoked by this action	For information about this service	Troubleshooting content
`aws:runInstances`	Amazon EC2	Amazon EC2 User Guide	Troubleshooting EC2 Instances
`aws:changeInstanceState`	Amazon EC2	Amazon EC2 User Guide	Troubleshooting EC2 instances
`aws:runCommand`	Systems Manager	Amazon Systems Manager Run Command	Troubleshooting Systems Manager Run Command
`aws:createImage`	Amazon EC2	Amazon Machine Images	
`aws:createStack`	Amazon CloudFormation	Amazon CloudFormation User Guide	Troubleshooting Amazon CloudFormation
`aws:deleteStack`	Amazon CloudFormation	Amazon CloudFormation User Guide	Troubleshooting Amazon CloudFormation
`aws:deleteImage`	Amazon EC2	Amazon Machines Images	

Action	Amazon Web Services services invoked by this action	For information about this service	Troubleshooting content
`aws:copyImage`	Amazon EC2	Amazon Machine Images	
`aws:createTag`	Amazon EC2, Systems Manager	EC2 Resource and Tags	
`aws:invokeLambdaFunction`	Amazon Lambda	Amazon Lambda Developer Guide	Troubleshooting Lambda

Automation service internal error

Error message: `Internal Server Error. Please refer to Automation Service Troubleshooting Guide for more diagnosis details.`

A problem with the Automation service is preventing the specified runbook from running correctly. To resolve this issue, contact Amazon Web Services Support. Provide the execution ID and customer ID, if available.

Execution started, but timed out

Error message: `Step timed out while step is verifying launched instance(s) are ready to be used. Please refer to Automation Service Troubleshooting Guide for more diagnosis details.`

A step in the `aws:runInstances` action timed out. This can happen if the step action takes longer to run than the value specified for `timeoutSeconds` in the step. To resolve this issue, specify a longer value for the `timeoutSeconds` parameter in the `aws:runInstances` action. If that doesn't solve the problem, investigate why the step takes longer to run than expected

Amazon Systems Manager Change Calendar

With Change Calendar, you can set up date and time ranges when actions you specify (for example, in Systems Manager Automation runbooks) might or might not be performed in your Amazon Web

Services account. In Change Calendar, these ranges are called *events*. When you create a Change Calendar entry, you're creating a Systems Manager document of the type `ChangeCalendar`. In Change Calendar, the document stores iCalendar 2.0 data in plaintext format. Events that you add to the Change Calendar entry become part of the document. To get started with Change Calendar, open the Systems Manager console. In the navigation pane, choose **Change Calendar**.

You can create a calendar and its events in the Systems Manager console. You can also import an iCalendar (`.ics`) file that you have exported from a supported third-party calendar provider to add its events to your calendar. Supported providers include Google Calendar, Microsoft Outlook, and iCloud Calendar.

A Change Calendar entry can be one of two types:

`DEFAULT_OPEN`, or Open by default

All actions can run by default, except during calendar events. During events, the state of a `DEFAULT_OPEN` calendar is `CLOSED` and events are blocked from running.

`DEFAULT_CLOSED`, or Closed by default

All actions are blocked by default, except during calendar events. During events, the state of a `DEFAULT_CLOSED` calendar is `OPEN` and actions are permitted to run.

You can choose to have all scheduled Automation workflows, maintenance windows, and State Manager associations added automatically to a calendar. You can also remove any of those individual types from the calendar display.

Who should use Change Calendar?

Change Manager availability change

Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

- Amazon customers who perform the following action types:
  - Create or run Automation runbooks.
  - Create change requests in Change Manager.

- Run maintenance windows.
- Create associations in State Manager.

  Automation, Change Manager, Maintenance Windows, and State Manager are all tools Amazon Systems Manager. By integrating these tools with Change Calendar, you can allow or block these action types depending on the current state of the change calendar you associate with each one.
- Administrators who are responsible for keeping the configurations of Systems Manager managed nodes consistent, stable, and functional.

Benefits of Change Calendar

The following are some benefits of Change Calendar.

- **Review changes before they're applied**

  A Change Calendar entry can help make sure that potentially destructive changes to your environment are reviewed before they're applied.
- **Apply changes only during appropriate times**

  Change Calendar entries help keep your environment stable during event times. For example, you can create a Change Calendar entry to block changes when you expect high demand on your resources, such as during a conference or public marketing promotion. A calendar entry can also block changes when you expect limited administrator support, such as during vacations or holidays. You can use a calendar entry to allow changes except for certain times of the day or week when there is limited administrator support to troubleshoot failed actions or deployments.
- **Get the current or upcoming state of the calendar**

  You can run the Systems Manager `GetCalendarState` API operation to show you the current state of the calendar, the state at a specified time, or the next time that the calendar state is scheduled to change.

  > **Note**
  >
  > The `GetCalendarState` API has a quota of 10 requests per second. For more information about Systems Manager quotas, see Systems Manager service quotas in the *Amazon Web Services General Reference*.
- **EventBridge support**

This Systems Manager tool is supported as an *event* type in Amazon EventBridge rules. For information, see Monitoring Systems Manager events with Amazon EventBridge and Reference: Amazon EventBridge event patterns and types for Systems Manager.

Topics

- Setting up Change Calendar
- Working with Change Calendar
- Adding Change Calendar dependencies to Automation runbooks
- Troubleshooting Change Calendar

Setting up Change Calendar

Complete the following before using Change Calendar.

Install latest command line tools

Install the latest command line tools to get state information about calendars.

Requirement	Description
Amazon CLI	(Optional) To use the Amazon Command Line Interface (Amazon CLI) to get state informati on about calendars, install the newest release of the Amazon CLI on your local computer. For more information about how to install or upgrade the CLI, see Installing, updating, and uninstalling the Amazon CLI in the *Amazon Command Line Interface User Guide*.
Amazon Tools for PowerShell	(Optional) To use the Tools for PowerShell to get state information about calendars, install the newest release of Tools for PowerShell on your local computer. For more information about how to install or upgrade the Tools for PowerShell, see Installin

Requirement	Description
	g the Amazon Tools for PowerShell in the *Amazon Tools for PowerShell User Guide*.

Set up permissions

If your user, group, or role is assigned administrator permissions, then you have full access to Change Calendar. If you don't have administrator permissions, then an administrator must give you permission by either assigning the `AmazonSSMFullAccess` managed policy, or assigning a policy that provides the necessary permissions to your user, group, or role.

The following permissions are required to work with Change Calendar.

Change Calendar entries

To create, update, or delete a Change Calendar entry, including adding and removing events from the entry, a policy attached to your user, group, or role must allow the following actions:

- `ssm:CreateDocument`
- `ssm:DeleteDocument`
- `ssm:DescribeDocument`
- `ssm:DescribeDocumentPermission`
- `ssm:GetCalendar`
- `ssm:ListDocuments`
- `ssm:ModifyDocumentPermission`
- `ssm:PutCalendar`
- `ssm:UpdateDocument`
- `ssm:UpdateDocumentDefaultVersion`

Calendar state

To get information about the current or upcoming state of the calendar, a policy attached to your user, group, or role must allow the following action:

- `ssm:GetCalendarState`

Operational events

To view operational events, such as maintenance windows, associations, and planned automations, the policy attached to your user, group, or role must allow the following actions:

- `ssm:DescribeMaintenanceWindows`
- `ssm:DescribeMaintenanceWindowExecution`
- `ssm:DescribeAutomationExecutions`
- `ssm:ListAssociations`

> **Note**
>
> Change Calendar entries that are owned by (that is, created by) accounts other than yours are read-only, even if they're shared with your account. Maintenance windows, State Manager associations, and automations aren't shared.

Working with Change Calendar

You can use the Amazon Systems Manager console to add, manage, or delete entries in Change Calendar, a tool in Amazon Systems Manager. You can also import events from supported third-party calendar providers by importing an iCalendar (`.ics`) file that you exported from the source calendar. And, you can use the `GetCalendarState` API operation or the `get-calendar-state` Amazon Command Line Interface (Amazon CLI) command to get information about the state of Change Calendar at a specific time.

Topics

- Creating a change calendar
- Creating and managing events in Change Calendar
- Importing and managing events from third-party calendars
- Updating a change calendar
- Sharing a change calendar
- Deleting a change calendar
- Getting the state of a change calendar

Creating a change calendar

When you create an entry in Change Calendar, you're creating a Systems Manager document (SSM document) that uses the `text` format.

To create a change calendar

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Calendar**.
3. Choose **Create calendar**.

   -or-

   If the **Change Calendar** home page opens first, choose **Create change calendar**.
4. On the **Create calendar** page, in **Calendar details**, enter a name for your calendar entry. Calendar entry names can contain letters, numbers, periods, dashes, and underscores. The name should be specific enough to identify the purpose of the calendar entry at a glance. An example is **`support-off-hours`**. You can't update this name after you create the calendar entry.
5. (Optional) For **Description**, enter a description for your calendar entry.
6. (Optional) In the **Import calendar** area, choose **Choose file** to select an iCalendar (`.ics`) file that you have exported from a third-party calendar provider. Importing the file will add its events to your calendar.

   Supported providers include Google Calendar, Microsoft Outlook, and iCloud Calendar.

   For more information, see Importing events from third-party calendar providers.
7. In **Calendar type**, choose one of the following.

   - **Open by default** - The calendar is open (Automation actions can run until an event starts), then closed for the duration of an associated event.
   - **Closed by default** - The calendar is closed (Automation actions can't run until an event starts) but open for the duration of an associated event.
8. (Optional) In **Change management events**, select **Add change management events to the calendar**. This selection displays all scheduled maintenance windows, State Manager associations, Automation workflows, and Change Manager change requests in your monthly calendar display.

> **Tip**
>
> If later you want to permanently remove these events types from the calendar display, edit the calendar, clear this check box, and then choose **Save**.

9. Choose **Create calendar**.

   After the calendar entry is created, Systems Manager displays your calendar entry in the **Change Calendar** list. The columns show the calendar version and the calendar owner's Amazon Web Services account number. Your calendar entry can't prevent or allow any actions until you have created or imported at least one event. For information about creating an event, see Creating a Change Calendar event. For information about importing events, see Importing events from third-party calendar providers.

Creating and managing events in Change Calendar

After you create a calendar in Amazon Systems Manager Change Calendar, you can create, update, and delete events that are included in your open or closed calendar. Change Calendar is a tool in Amazon Systems Manager.

> **Tip**
>
> As an alternative to creating events directly in the Systems Manager console, you can import an iCalendar (`.ics`) file from a supported third-party calendar application. For information, see Importing and managing events from third-party calendars.

Topics

- Creating a Change Calendar event
- Updating a Change Calendar event
- Deleting a Change Calendar event

Creating a Change Calendar event

When you add an event to an entry in Change Calendar, you specify a period of time when the default action of the calendar entry is suspended. For example, if the calendar entry type is closed

by default, the calendar is open to changes during events. You can also create an advisory event, which serves an informational role on the calendar only.

Currently, you can only create a Change Calendar event by using the console. Events are added to the Change Calendar document that you create when you create a Change Calendar entry.

To create a Change Calendar event

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar entry to which you want to add an event.
4. On the calendar entry's details page, choose **Create event**.
5. On the **Create scheduled event** page, in **Event details**, enter a display name for your event. Event names can contain letters, numbers, periods, dashes, and underscores. The name should be specific enough to identify the purpose of the event. An example is **`nighttime-hours`**.
6. For **Description**, enter a description for your event. For example, **`The support team isn't available during these hours`**.
7. (Optional) If you want this event to serve as a visual notification or reminder only, select the **Advisory** check box. Advisory events play no functional role on your calendar. They serve informational purposes only for those who view your calendar.
8. For **Event start date**, enter or choose a day in the format `MM/DD/YYYY` to start the event, and enter a time on the specified day in the format `hh:mm:ss` (hours, minutes, and seconds) to start the event.
9. For **Event end date**, enter or choose a day in the format `MM/DD/YYYY` to end the event, and enter a time on the specified day in the format `hh:mm:ss` (hours, minutes, and seconds) to end the event.
10. For **Schedule time zone**, choose a time zone that applies to the start and end times of the event. You can enter part of a city name or time zone difference from Greenwich Mean Time (GMT) to find a time zone faster. The default is Coordinated Universal Time (UTC).
11. (Optional) To create an event that recurs daily, weekly, or monthly, turn on **Recurrence**, and then specify the frequency and optional end date for the recurrence.
12. Choose **Create scheduled event**. The new event is added to your calendar entry, and is displayed on the **Events** tab of the calendar entry's details page.

Updating a Change Calendar event

Use the following procedure to update a Change Calendar event in the Amazon Systems Manager console. Change Calendar is a tool in Amazon Systems Manager.

To update a Change Calendar event

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar entry for which you want to edit an event.
4. On the calendar entry's details page, choose **Events**.
5. In the calendar page, choose the event that you want to edit.

   > **Tip**
   >
   > Use the buttons on the upper left to move back or forward one year, or back or forward one month. Change the time zone, if required, by choosing the correct time zone from the list on the upper right.

6. In **Event details**, choose **Edit**.

   To change the event name and description, add to or replace the current text values.

7. To change the **Event start date** value, choose the current start date, and then choose a new date from the calendar. To change the start time, choose the current start time, and then choose a new time from the list.
8. To change the **Event end date** value, choose the current date, and then choose a new end date from the calendar. To change the end time, choose the current end time, and then choose a new time from the list.
9. To change the **Schedule time zone** value, choose a time zone to apply to the start and end times of the event. You can enter part of a city name or time zone difference from Greenwich Mean Time (GMT) to find a time zone faster. The default is Coordinated Universal Time (UTC).
10. (Optional) If you want this event to serve as a visual notification or reminder only, select the **Advisory** check box. Advisory events play no functional role on your calendar. They serve informational purposes only for those who view your calendar.

11. Choose **Save**. Your changes are displayed on the **Events** tab of the calendar entry's details page. Choose the event that you updated to view your changes.

Deleting a Change Calendar event

You can delete one event at a time in Change Calendar by using the Amazon Web Services Management Console.

> **Tip**
>
> If you selected **Add change management events to the calendar** when you created the calendar, you can do the following:
>
> - To *temporarily* hide a change management event type from the calendar display, choose the **X** for the type at the top of the monthly preview.
> - To *permanently* remove these types from the calendar display, edit the calendar, clear the **Add change management events to the calendar** check box, and then choose **Save**. Removing the types from the calendar display doesn't delete them from your account.

To delete a Change Calendar event

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar entry from which you want to delete an event.
4. On the calendar entry's details page, choose **Events**.
5. In the calendar page, choose the event that you want to delete.

> **Tip**
>
> Use the buttons on the upper left to move the calendar back or forward one year, or back or forward one month. Change the time zone, if required, by choosing the correct time zone from the list on the upper right.

6. On the **Event details** page, choose **Delete**. When you're prompted to confirm that you want to delete the event, choose **Confirm**.

Importing and managing events from third-party calendars

As an alternative to creating events directly in the Amazon Systems Manager console, you can import an iCalendar (`.ics`) file from a supported third-party calendar application. Your calendar can include both imported events and events that you create in Change Calendar, which is a tool in Amazon Systems Manager.

Before you begin

Before you attempt to import a calendar file, review the following requirements and constraints:

Calendar file format

Only valid iCalendar files (`.ics`) are supported.

Supported calendar providers

Only `.ics` files exported from the following third-party calendar providers are supported:

- Google Calendar (Export instructions)
- Microsoft Outlook (Export instructions)
- iCloud Calendar (Export instructions)

File size

You can import any number of valid `.ics` files. However, the total size of all imported files for each calendar can't exceed 64KB.

> **Tip**
>
> To minimize the size of the `.ics` file, ensure that you are exporting only basic details about your calendar entries. If necessary, reduce the length of the time period that you are exporting.

Time zone

In addition to a calendar name, a calendar provider, and at least one event, your exported `.ics` file should also indicate the time zone for the calendar. If it does not, or there is a problem identifying the time zone, you are prompted to specify one after you import the file.

Recurring event limitation

Your exported `.ics` file can include recurring events. However, if one or more occurrences of a recurring event had been deleted in the source calendar, the import fails.

Topics

- Importing events from third-party calendar providers
- Updating all events from a third-party calendar provider
- Deleting all events imported from a third-party calendar

Importing events from third-party calendar providers

Use the following procedure to import an iCalendar (`.ics`) file from a supported third-party calendar application. The events contained in the file are incorporated into the rules for your open or closed calendar. You can import the file into a new calendar or into an existing calendar.

After you import the `.ics` file, you can remove individual events from it using the Change Calendar interface. For information, see Deleting a Change Calendar event. You can also delete all events from the source calendar by deleting the `.ics` file. For information, see Deleting all events imported from a third-party calendar.

To import events from third-party calendar providers

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Calendar**.
3. To start with a new calendar, choose **Create calendar**. In the **Import calendar** area, choose **Choose file**. For information about other steps to create a new calendar, see Creating a change calendar.

   -or-

To import third-party events into an existing calendar, choose the name of an existing calendar to open it.

4. Choose **Actions, Edit**, and then in the **Import calendar** area, choose **Choose file**.
5. Navigate to and select the exported `.ics` file on your local computer.
6. If prompted, for **Select a time zone**, select which time zone applies to the calendar.
7. Choose **Save**.

Updating all events from a third-party calendar provider

If several events are added to or removed from your source calendar after you have imported its iCalendar `.ics` file, you can reflect those changes in Change Calendar. First, re-export the source calendar, and then import the new file into Change Calendar, which is a tool in Amazon Systems Manager. Events in your change calendar will be updated to reflect the contents of the newer file.

To update all events from a third-party calendar provider

1. In your third-party calendar, add or remove events as you want them to be reflected in Change Calendar, and then re-export the calendar to a new `.ics` file.
2. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
3. In the navigation pane, choose **Change Calendar**.
4. From the list of calendars, choose the calendar name from the list.
5. On the **Actions** menu, choose **Edit**.
6. In the **Import calendar** section, choose **Choose file**.
7. Navigate to and select the replacement `.ics` file.
8. Choose **Save**.

Deleting all events imported from a third-party calendar

If you no longer want events that you imported from a third-party provider, you can delete the imported iCalendar `.ics` file.

To delete all events imported from a third-party calendar

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Calendar**.
3. From the list of calendars, choose the calendar name from the list.
4. On the **Actions** menu, choose **Edit**.
5. In the **Import calendar** section, under **My imported calendars**, choose the X next to the name of the calendar.
6. Choose **Save**.

Updating a change calendar

You can update the description of a change calendar, but not its name. Although you can change the default state of a calendar, be aware that this reverses the behavior of change actions during events that are associated with the calendar. For example, if you change the state of a calendar from **Open by default** to **Closed by default**, unwanted changes might be made during event periods when the users who created the associated events aren't expecting changes.

When you update a change calendar, you're editing the Change Calendar document that you created when you created the entry. Change Calendar is a tool in Amazon Systems Manager.

To update a change calendar

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar that you want to update.
4. On the calendar's details page, choose **Actions, Edit**.
5. In **Description**, you can change the description text. You can't edit the name of a change calendar.
6. To change the calendar state, in **Calendar type**, choose a different value. Be aware that this reverses the behavior of change actions during events that are associated with the calendar. Before you change the calendar type, you should verify with other Change Calendar users that changing the calendar type doesn't allow unwanted changes during events that they have created.

- **Open by default** – The calendar is open (Automation actions can run until an event starts) then closed for the duration of an associated event.
- **Closed by default** – The calendar is closed (Automation actions can't run until an event starts) but open for the duration of an associated event.

7. Choose **Save**.

   Your calendar can't prevent or allow any actions until you add at least one event. For information about how to add an event, see Creating a Change Calendar event.

Sharing a change calendar

You can share a calendar in Change Calendar with other Amazon Web Services accounts by using the Amazon Systems Manager console. When you share a calendar, the calendar is read-only to users in the shared account. Maintenance windows, State Manager associations, and automations aren't shared.

To share a change calendar

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar that you want to share.
4. On the calendar's details page, choose the **Sharing** tab.
5. Choose **Actions, Share**.
6. In **Share calendar**, for **Account ID**, enter the ID number of a valid Amazon Web Services account, and then choose **Share**.

   Users of the shared account can read the change calendar, but they can't make changes.

Deleting a change calendar

You can delete a calendar in Change Calendar by using either the Systems Manager console or the Amazon Command Line Interface (Amazon CLI). Deleting a change calendar deletes all associated events.

To delete a change calendar

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Calendar**.
3. In the list of calendars, choose the name of the calendar that you want to delete.
4. On the calendar's details page, choose **Actions, Delete**. When you're prompted to confirm that you want to delete the calendar, choose **Delete**.

Getting the state of a change calendar

You can get the overall state of a calendar or the state of a calendar at a specific time in Change Calendar. You can also show the next time that the calendar state changes from `OPEN` to `CLOSED`, or the reverse.

> **Note**
>
> For information about integrating Change Calendar with Amazon EventBridge for automated monitoring of calendar state changes, see the section called "Change Calendar integration with Amazon EventBridge". EventBridge integration provides event-driven notifications when calendar states transition, complementing the polling-based approach of the `GetCalendarState` API action.

You can do this task only by using the `GetCalendarState` API operation. The procedure in this section uses the Amazon Command Line Interface (Amazon CLI).

To get the state of a change calendar

- Run the following command to show the state of one or more calendars at a specific time. The `--calendar-names` parameter is required, but `--at-time` is optional. Replace each *`example resource placeholder`* with your own information.

  Linux & macOS

```
aws ssm get-calendar-state \
    --calendar-names "Calendar_name_or_document_ARN_1"
 "Calendar_name_or_document_ARN_2" \
```

```
    --at-time "ISO_8601_time_format"
```

The following is an example.

```
aws ssm get-calendar-state \
    --calendar-names "arn:aws:ssm:us-east-2:123456789012:document/
MyChangeCalendarDocument" "arn:aws:ssm:us-east-2:123456789012:document/
SupportOffHours" \
    --at-time "2020-07-30T11:05:14-0700"
```

Windows

```
aws ssm get-calendar-state ^
    --calendar-names "Calendar_name_or_document_ARN_1"
 "Calendar_name_or_document_ARN_2" ^
    --at-time "ISO_8601_time_format"
```

The following is an example.

```
aws ssm get-calendar-state ^
    --calendar-names "arn:aws:ssm:us-east-2:123456789012:document/
MyChangeCalendarDocument" "arn:aws:ssm:us-east-2:123456789012:document/
SupportOffHours" ^
    --at-time "2020-07-30T11:05:14-0700"
```

The command returns information like the following.

```
{
    "State": "OPEN",
    "AtTime": "2020-07-30T16:18:18Z",
    "NextTransitionTime": "2020-07-31T00:00:00Z"
}
```

The results show the state of the calendar (whether the calendar is of type `DEFAULT_OPEN` or `DEFAULT_CLOSED`) for the specified calendar entries that are owned by or shared with your account, at the time specified as the value of `--at-time`, and the time of the next transition. If you don't add the `--at-time` parameter, the current time is used.

> **Note**
>
> If you specify more than one calendar in a request, the command returns the status of OPEN only if all calendars in the request are open. If one or more calendars in the request are closed, the status returned is CLOSED.

Adding Change Calendar dependencies to Automation runbooks

To make Automation actions adhere to Change Calendar, add a step in an Automation runbook that uses the aws:assertAwsResourceProperty action. Configure the action to run GetCalendarState to verify that a specified calendar entry is in the state that you want (OPEN or CLOSED). The Automation runbook is only allowed to continue to the next step if the calendar state is OPEN. The following is a YAML-based sample excerpt of an Automation runbook that can't advance to the next step, LaunchInstance, unless the calendar state matches OPEN, the state specified in DesiredValues.

The following is an example.

```
mainSteps:
  - name: MyCheckCalendarStateStep
    action: 'aws:assertAwsResourceProperty'
    inputs:
      Service: ssm
      Api: GetCalendarState
      CalendarNames: ["arn:aws:ssm:us-east-2:123456789012:document/SaleDays"]
      PropertySelector: '$.State'
      DesiredValues:
      - OPEN
    description: "Use GetCalendarState to determine whether a calendar is open or
 closed."
    nextStep: LaunchInstance
  - name: LaunchInstance
    action: 'aws:executeScript'
    inputs:
      Runtime: python3.11
...
```

Troubleshooting Change Calendar

Use the following information to help you troubleshoot problems with Change Calendar, a tool in Amazon Systems Manager.

Topics

- 'Calendar import failed' error

'Calendar import failed' error

Problem: When importing an iCalendar (`.ics`) file, the system reports that the calendar import failed.

- **Solution 1** – Make sure that you are importing a file that was exported from a supported third-party calendar provider, which include the following:
  - Google Calendar (Export instructions)
  - Microsoft Outlook (Export instructions)
  - iCloud Calendar (Export instructions)
- **Solution 2** – If your source calendar contains any recurring events, make sure that no individual occurrences of the event have been canceled or deleted. Currently, Change Calendar doesn't support importing recurring events with individual cancellations. To resolve the issue, remove the recurring event from the source calendar, re-export the calendar and re-import it into Change Calendar, and then add the recurring event using the Change Calendar interface. For information, see Creating a Change Calendar event.
- **Solution 3** – Make sure that your source calendar contains at least one event. Uploads of `.ics` files that don't contain events don't succeed.
- **Solution 4** – If the system reports that the import failed because the `.ics` is too large, make sure that you are exporting only basic details about your calendar entries. If necessary, reduce the length of the time period that you export.
- **Solution 5** – If Change Calendar is unable to determine the time zone of your exported calendar when you attempt to import it from the **Events** tab, you might receive this message: "Calendar import failed. Change Calendar couldn't locate a valid time zone. You can import the calendar from the Edit menu." In this case, choose **Actions, Edit**, and then try importing the file from the **Edit calendar** page.

- **Solution 6** – Don't edit the `.ics` file before import. Attempting to modify the contents of the file can corrupt the calendar data. If you have modified the file before attempting the import, export the calendar from the source calendar again, and then re-attempt the upload.

Amazon Systems Manager Change Manager

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

Change Manager is an enterprise change management framework for requesting, approving, implementing, and reporting on operational changes to your application configuration and infrastructure. From a single *delegated administrator account*, if you use Amazon Organizations, you can manage changes across multiple Amazon Web Services accounts and across Amazon Web Services Regions. Alternatively, using a *local account*, you can manage changes for a single Amazon Web Services account. Use Change Manager for managing changes to both Amazon resources and on-premises resources. To get started with Change Manager, open the Systems Manager console. In the navigation pane, choose **Change Manager**.

With Change Manager, you can use pre-approved *change templates* to help automate change processes for your resources and help avoid unintentional results when making operational changes. Each change template specifies the following:

- One or more Automation runbooks for a user to choose from when creating a change request. The changes that are made to your resources are defined in Automation runbooks. You can include custom runbooks or Amazon managed runbooks in the change templates you create. When a user creates a change request, they can choose which one of the available runbooks to include in the request. Additionally, you can create change templates that let the user making the request specify any runbook in the change request.
- The users in the account who must review change requests that were made using that change template.
- The Amazon Simple Notification Service (Amazon SNS) topic that is used to notify assigned approvers that a change request is ready for review.

- The Amazon CloudWatch alarm that is used to monitor the runbook workflow.
- The Amazon SNS topic that is used to send notifications about status changes for change requests that are created using the change template.
- The tags to apply to the change template for use in categorizing and filtering your change templates.
- Whether change requests created from the change template can be run without an approval step (auto-approved requests).

Through its integration with Change Calendar, which is another tool in Systems Manager, Change Manager also helps you safely implement changes while avoiding schedule conflicts with important business events. Change Manager integration with Amazon Organizations and Amazon IAM Identity Center helps you manage changes across your organization from a single account using your existing identity management system. You can monitor change progress from Change Manager and audit operational changes across your organization, providing improved visibility and accountability.

Change Manager complements the safety controls of your continuous integration (CI) practices and continuous delivery (CD) methodology. Change Manager isn't intended for changes made as part of an automated release process, such as a CI/CD pipeline, unless there is an exception or approval required.

How Change Manager works

When the need for a standard or emergency operational change is identified, someone in the organization creates a change request that is based on one of the change templates created for use in your organization or account.

If the requested change requires manual approvals, Change Manager notifies the designated approvers through an Amazon SNS notification that a change request is ready for their review. You can designate approvers for change requests in the change template, or let users designate approvers in the change request itself. You can assign different reviewers to different templates. For example, assign one user, user group, or Amazon Identity and Access Management (IAM) role who must approve requests for changes to managed nodes, and another user, group, or IAM role for database changes. If the change template allows auto-approvals, and a requester's user policy doesn't prohibit it, the user can also choose to run the Automation runbook for their request without a review step (with the exception of change freeze events).

For each change template, you can add up to five levels of approvers. For example, you might require technical reviewers to approve a change request created from a change template first, and then require a second level of approvals from one or more managers.

Change Manager is integrated with Amazon Systems Manager Change Calendar. When a requested change is approved, the system first determines whether the request conflicts with other scheduled business activities. If a conflict is detected, Change Manager can block the change or require additional approvals before starting the runbook workflow. For example, you might allow changes only during business hours to make sure that teams are available to manage any unexpected problems. For any changes requested to run outside those hours, you can require higher-level management approval in the form of *change freeze approvers*. For emergency changes, Change Manager can skip the step of checking Change Calendar for conflicts or blocking events after a change request is approved.

When it's time to implement an approved change, Change Manager runs the Automation runbook that is specified in the associated change request. Only the operations defined in approved change requests are permitted when runbook workflows run. This approach helps you avoid unintentional results while changes are being implemented.

In addition to restricting the changes that can be made when a runbook workflow runs, Change Manager helps you control concurrency and error thresholds. You choose how many resources a runbook workflow can run on at once and how many accounts it can run in simultaneously. You also set how many failures to allow before the process stops and, if the runbook includes a rollback script, rolls back. You can monitor progress by using CloudWatch alarms.

After a runbook workflow has completed, you can review details about the changes made. These details include the reason for a change request, which change template was used, who requested and approved the changes, and how the changes were implemented.

More info

Introducing Amazon Systems Manager Change Manager on the *Amazon News Blog*

How can Change Manager benefit my operations?

Benefits of Change Manager include the following:

- **Reduce risk of service disruption and downtime**

Change Manager can make operational changes safer by ensuring that only approved changes are implemented when a runbook workflow runs. You can block unplanned and unreviewed changes. Change Manager helps you avoid the types of unintentional results caused by human error that require costly hours of research and backtracking.

- **Get detailed auditing and reporting on change histories**

  Change Manager provides accountability with a consistent way to report and audit changes made across your organization, the intent of the changes, and details about who approved and implemented them.

- **Avoid schedule conflicts or violations**

  Change Manager can detect schedule conflicts such as holiday events or new product launches, based on the active change calendar for your organization. You can allow runbook workflows to run only during business hours, or allow them only with additional approvals.

- **Adapt change requirements to your changing business**

  During different business periods, you can implement different change management requirements. For example, during end-of-month reporting, tax season, or other critical business periods, you can block changes or require director-level approval for changes that could introduce unnecessary operational risks.

- **Centrally manage changes across accounts**

  Through its integration with Organizations, Change Manager makes it possible for you to manage changes throughout all of your organizational units (OUs) from a single delegated administrator account. You can turn on Change Manager for use with your entire organization or with only some of your OUs.

Who should use Change Manager?

Change Manager is appropriate for the following Amazon customers and organizations:

- Any Amazon customer who wants to improve the safety and governance of operational changes made to their cloud or on-premises environments.
- Organizations that want to increase collaboration and visibility across teams, improve application availability by avoiding downtime, and reduce the risk associated with manual and repetitive tasks.

- Organizations that must comply with best practices for change management.
- Customers who need a fully auditable history of changes made to their application configuration and infrastructure.

What are the main features of Change Manager?

Primary features of Change Manager include the following:

- **Integrated support for change management best practices**

  With Change Manager, you can apply select change management best practices to your operations. You can choose to turn on the following options:

  - Check Change Calendar to see if events are currently restricted so changes are made only during open calendar periods.
  - Allow changes during restricted events with extra approvals from change freeze approvers.
  - Require CloudWatch alarms to be specified for all change templates.
  - Require all change templates created in your account to be reviewed and approved before they can be used to create change requests.
- **Different approval paths for closed calendar periods and emergency change requests**

  You can allow an option to check Change Calendar for restricted events and block approved change requests until the event is complete. However, you can also designate a second group of approvers, change freeze approvers, who can permit the change to be made even if the calendar is closed. You can also create emergency change templates. Change requests created from an emergency change template still require regular approvals but aren't subject to calendar restrictions and don't require change freeze approvals.
- **Control how and when runbook workflows are started**

  Runbook workflows can be started according to a schedule, or as soon as approvals are complete (subject to calendar restriction rules).
- **Built-in notification support**

  Specify who in your organization should review and approve change templates and change requests. Assign an Amazon SNS topic to a change template to send notifications to the topic's subscribers about status changes for change requests created with that change template.
- **Integration with Amazon Systems Manager Change Calendar**

Change Manager allows administrators to restrict scheduling changes during specified time periods. For instance, you can create a policy that allows changes only during business hours to make sure that the team is available to handle any issues. You can also restrict changes during important business events. For example, retail businesses might restrict changes during large sales events. You can also require additional approvals during restricted periods.

- **Integration with Amazon IAM Identity Center and Active Directory support**

  With IAM Identity Center integration, members of your organization can access Amazon Web Services accounts and manage their resources using Systems Manager based on a common user identity. Using IAM Identity Center, you can assign your users access to accounts across Amazon.

  Integration with Active Directory makes it possible to assign users in your Active Directory account as approvers for change templates created for your Change Manager operations.

- **Integration with Amazon CloudWatch alarms**

  Change Manager is integrated with CloudWatch alarms. Change Manager listens for CloudWatch alarms during the runbook workflow and takes any actions, including sending notifications, that are defined for the alarm.

- **Integration with Amazon CloudTrail Lake**

  By creating an event data store in Amazon CloudTrail Lake, you can view auditable information about the changes made by change requests that run in your account or organization. The event information stored includes such details as the following:

  - The API actions that were run
  - Tthe request parameters included for those actions
  - The user that ran the action
  - The resources that were updated during the process

- **Integration with Amazon Organizations**

  Using the cross-account capabilities provided by Organizations, you can use a delegated administrator account for managing Change Manager operations in OUs in your organization. In your Organizations management account, you can specify which account is to be the delegated administrator account. You can also control which of your OUs Change Manager can be used in.

Is there a charge to use Change Manager?

Yes. Change Manager is priced on a pay-per-use basis. You pay only for what you use. For more information, see Amazon Systems Manager Pricing.

What are the primary components of Change Manager?

Change Manager components that you use to manage the change process in your organization or account include the following:

Delegated administrator account

If you use Change Manager across an organization, you use a delegated administrator account. This is the Amazon Web Services account designated as the account for managing operations activities across Systems Manager, including Change Manager. The delegated administrator account manages change activities across your organization. When you set up your organization for use with Change Manager, you specify which of your accounts serves in this role. The delegated administrator account must be the only member of the organizational unit (OU) to which it's assigned. The delegated administrator account isn't required if you use Change Manager with a single Amazon Web Services account only.

> **Important**
>
> If you use Change Manager across an organization, we recommend always making changes from the delegated administrator account. Although you can make changes from other accounts in the organization, those changes won't be reported in or viewable from the delegated administrator account.

Change template

A change template is a collection of configuration settings in Change Manager that define such things as required approvals, available runbooks, and notification options for change requests.

You can require that the change templates created by users in your organization or account go through an approval process before they can be used.

Change Manager supports two types of change templates. For an approved change request that is based on an *emergency change template*, the requested change can be made even if there are

blocking events in Change Calendar. For an approved change request that is based on a *standard change template*, the requested change can't be made if there are blocking events in Change Calendar unless additional approvals are received from designated *change freeze event* approvers.

Change request

A change request is a request in Change Manager to run an Automation runbook that updates one or more resources in your Amazon or on-premises environments. A change request is created using a change template.

When you create a change request, one or more approvers in your organization or account must review and approve the request. Without the required approvals, the runbook workflow, which applies the changes you request, isn't permitted to run.

In the system, change requests are a type of OpsItem in Amazon Systems Manager OpsCenter. However, OpsItems of the type `/aws/changerequest` aren't displayed in OpsCenter. As OpsItems, change requests are subject to the same enforced quotas as other types of OpsItems.

Additionally, to create a change request programmatically, you don't call the `CreateOpsItem` API operation. Instead, you use the `StartChangeRequestExecution` API operation. But rather than running immediately, the change request must be approved, and there must not any blocking events in Change Calendar to prevent the workflow from running. When approvals have been received and the calendar isn't blocked (or permission has been given to bypass blocking calendar events), the `StartChangeRequestExecution` action can complete.

Runbook workflow

A runbook workflow is the process of requested changes being made to the targeted resources in your cloud or on-premises environment. Each change request designates a single Automation runbook to use to make the requested change. The runbook workflow occurs after all required approvals have been granted and there are no blocking events in Change Calendar. If the change has been scheduled for a specific date and time, the runbook workflow doesn't begin until scheduled, even if all approvals have been received and the calendar isn't blocked.

- Troubleshooting Change Manager

Setting up Change Manager

Change Manager availability change

Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

You can use Change Manager to manage changes for an entire organization, as configured in Amazon Organizations, or for a single Amazon Web Services account.

If you're using Change Manager with an organization, begin with the topic Setting up Change Manager for an organization (management account), and then proceed to Configuring Change Manager options and best practices.

If you're using Change Manager with a single account, proceed directly to Configuring Change Manager options and best practices.

Note

If you begin using Change Manager with a single account, but that account is later added to an organizational unit for which Change Manager is allowed, your single account settings are disregarded.

Setting up Change Manager for an organization (management account)

Change Manager availability change

Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

The tasks in this topic apply if you're using Change Manager with an organization that is set up in Amazon Organizations. If you want to use Change Manager only with a single Amazon Web Services account, skip to the topic Configuring Change Manager options and best practices.

Perform the tasks in this section in an Amazon Web Services account that is serving as the *management account* in Organizations. For information about the management account and other Organizations concepts, see Amazon Organizations terminology and concepts.

If you need to turn on Organizations and specify your account as the management account before proceeding, see Creating and managing an organization in the *Amazon Organizations User Guide*.

Note

This setup process can't be performed in the following Amazon Web Services Regions:

- Europe (Milan) (eu-south-1)
- Middle East (Bahrain) (me-south-1)
- Africa (Cape Town) (af-south-1)
- Asia Pacific (Hong Kong) (ap-east-1)

Make sure that you're working in a different Region in your management account for this procedure.

During the setup procedure, you perform the following major tasks in Quick Setup, a tool in Amazon Systems Manager.

- **Task 1: Register the delegated administrator account for your organization**

The change-related tasks that are performed using Change Manager are managed in one of your member accounts, which you specify to be the *delegated administrator account*. The delegated administrator account you register for Change Manager becomes the delegated administrator account for all your Systems Manager operations. (You might have delegated administrator accounts for other Amazon Web Services services). Your delegated administrator account for Change Manager, which isn't the same as your management account, manages change activities across your organization, including change templates, change requests, and approvals for each. In the delegated administrator account, you also specify other configuration options for your Change Manager operations.

> **Important**
>
> The delegated administrator account must be the only member of the organizational unit (OU) to which it's assigned in Organizations.

- **Task 2: Define and specify runbook access policies for change requester roles, or custom job functions, that you want to use for your Change Manager operations**

  To create change requests in Change Manager, users in your member accounts must be granted Amazon Identity and Access Management (IAM) permissions that allow them to access only the Automation runbooks and change templates you choose to make available to them.

  > **Note**
  >
  > When a user creates a change request, they first select a change template. This change template might make multiple runbooks available, but the user can select only one runbook for each change request. Change templates can also be configured to allow users to include any available runbook in their requests.

  To grant the needed permissions, Change Manager uses the concept of *job functions*, which is also used by IAM. However, unlike the Amazon managed policies for job functions in IAM, you specify both the names of your Change Manager job functions and the IAM permissions for those job functions.

  When you configure a job function, we recommend creating a custom policy and providing only the permissions needed to perform change management tasks. For instance, you might specify

permissions that limit users to that specific set of runbooks based on *job functions* that you define.

For example, you might create a job function with the name `DBAdmin`. For this job function, you might grant only permissions needed for runbooks related to Amazon DynamoDB databases, such as `AWS-CreateDynamoDbBackup` and `AWSConfigRemediation-DeleteDynamoDbTable`.

As another example, you might want to grant some users only the permissions needed to work with runbooks related to Amazon Simple Storage Service (Amazon S3) buckets, such as `AWS-ConfigureS3BucketLogging` and `AWSConfigRemediation-ConfigureS3BucketPublicAccessBlock`.

The configuration process in Quick Setup for Change Manager also makes a set of full Systems Manager administrative permissions available for you to apply to an administrative role you create.

Each Change Manager Quick Setup configuration you deploy creates a job function in your delegated administrator account with permissions to run Change Manager templates and Automation runbooks in the organizational units you have selected. You can create up to 15 Quick Setup configurations for Change Manager.

- **Task 3: Choose which member accounts in your organization to use with Change Manager**

  You can use Change Manager with all the member accounts in all your organizational units that are set up in Organizations, and in all the Amazon Web Services Regions they operate in. If you prefer, you can instead use Change Manager with only some of your organizational units.

> **Important**
>
> We strongly recommend, before you begin this procedure, that you read through its steps to understand the configuration choices you're making and the permissions you're granting. In particular, plan the custom job functions you will create and the permissions you assign to each job function. This ensures that when later you attach the job function policies you create to individual users, user groups, or IAM roles, they're being granted only the permissions you intend for them to have.
>
> As a best practice, begin by setting up the delegated administrator account using the login for an Amazon Web Services account administrator. Then configure job functions and their

permissions after you have created change templates and identified the runbooks that each one uses.

To set up Change Manager for use with an organization, perform the following task in the Quick Setup area of the Systems Manager console.

You repeat this task for each job function you want to create for your organization. Each job function you create can have permissions for a different set of organizational units.

To set up an organization for Change Manager in the Organizations management account

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Change Manager** card, choose **Create**.
4. For **Delegated administrator account**, enter the ID of the Amazon Web Services account you want to use for managing change templates, change requests, and runbook workflows in Change Manager.

   If you have previously specified a delegated administrator account for Systems Manager, its ID is already reported in this field.

   > **Important**
   >
   > The delegated administrator account must be the only member of the organizational unit (OU) to which it's assigned in Organizations.
   > If the delegated administrator account you register is later deregistered from that role, the system removes its permissions for managing Systems Manager operations at the same time. Keep in mind that it will be necessary for you return to Quick Setup, designate a different delegated administrator account, and specify all job functions and permissions again.
   > If you use Change Manager across an organization, we recommend always making changes from the delegated administrator account. Although you can make changes from other accounts in the organization, those changes won't be reported in or viewable from the delegated administrator account.

5. In the **Permissions to request and make changes** section, do the following.

> **Note**
>
> Each deployment configuration you create provides the permissions policy for just one job function. You can return to Quick Setup later to create more job functions when you have created change templates to use in your operations.

To create an administrative role – For an administrator job function that has IAM permissions for all Amazon actions, do the following.

> **Important**
>
> Granting users full administrative permissions should be done sparingly, and only if their roles require full Systems Manager access. For important information about security considerations for Systems Manager access, see Identity and access management for Amazon Systems Manager and Security best practices for Systems Manager.

1. For **Job function**, enter a name to identify this role and its permissions, such as **`MyAmazonAdmin`**.
2. For **Role and permissions option**, choose **Administrator permissions**.

To create other job functions – To create a non-administrative role, do the following:

1. For **Job function**, enter a name to identify this role and suggest its permissions. The name you choose should represent scope of the runbooks for which you provide permissions, such as `DBAdmin` or `S3Admin`.
2. For **Role and permissions option**, choose **Custom permissions**.
3. In the **Permissions policy editor**, enter the IAM permissions, in JSON format, to grant to this job function.

> **Tip**
>
> We recommend that you use the IAM policy editor to construct your policy and then paste the policy JSON into the **Permissions policy** field.

Sample policy: DynamoDB database management

For example, you might begin with policy content that provides permissions for working with the Systems Manager documents (SSM documents) the job function needs access to. Here is a sample policy content that grants access to all the Amazon managed Automation runbooks related to DynamoDB databases and two change templates that have been created in the sample Amazon Web Services account `123456789012`, in the US East (Ohio) Region (`us-east-2`).

The policy also includes permission for the StartChangeRequestExecution operation, which is required for creating a change request in Change Calendar.

> **Note**
>
> This example isn't comprehensive. Additional permissions might be needed for working with other Amazon resources, such as databases and nodes.

*"
            ]
        }
    ]
}
```

For more information about IAM policies, see Access management for Amazon resources and Creating IAM policies in the *IAM User Guide.*

6. In the **Targets** section, choose whether to grant permissions for the job function you're creating to your entire organization or only some of your organizational units.

   If you choose **Entire organization**, continue to step 9.

   If you choose **Custom**, continue to step 8.

7. In the **Target OUs** section, select the check boxes of the organizational units to use with Change Manager.

8. Choose **Create**.

After the system finishes setting up Change Manager for your organization, it displays a summary of your deployments. This summary information includes the name of the role that was created for the job function you configured. For example, `AWS-QuickSetup-SSMChangeMgr-DBAdminInvocationRole`.

> **Note**
>
> Quick Setup uses Amazon CloudFormation StackSets to deploy your configurations. You can also view information about a completed deployment configuration in the Amazon CloudFormation console. For information about StackSets, see Working with Amazon CloudFormation StackSets in the *Amazon CloudFormation User Guide*.

Your next step is to configure additional Change Manager options. You can complete this task in either your delegated administrator account or any account in an organization unit that you have allowed for use with Change Manager. You configure options such as choosing a user identity management option, specifying which users can review and approve or reject change templates and change requests, and choosing which best practice options to allow for your organization. For information, see Configuring Change Manager options and best practices.

Configuring Change Manager options and best practices

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

The tasks in this section must be performed whether you're using Change Manager, a tool in Amazon Systems Manager, across an organization or in a single Amazon Web Services account.

If you're using Change Manager for an organization, you can perform the following tasks in either your delegated administrator account or any account in an organization unit that you have allowed for use with Change Manager.

Topics

- Task 1: Configuring Change Manager user identity management and template reviewers
- Task 2: Configuring Change Manager change freeze event approvers and best practices
- Configuring Amazon SNS topics for Change Manager notifications

Task 1: Configuring Change Manager user identity management and template reviewers

Perform the task in this procedure the first time you access Change Manager. You can update these configuration settings later by returning to Change Manager and choosing **Edit** on the **Settings** tab.

To configure Change Manager user identity management and template reviewers

1. Sign in to the Amazon Web Services Management Console.

   If you're using Change Manager for an organization, sign in using your credentials for your delegated administrator account. The user must have the necessary Amazon Identity and Access Management (IAM) permissions for making updates to your Change Manager settings.
2. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
3. In the navigation pane, choose **Change Manager**.

4. On the service home page, depending on the available options, do one of the following:

   - If you're using Change Manager with Amazon Organizations , choose **Set up delegated account**.
   - If you're using Change Manager with a single Amazon Web Services account, choose **Set up Change Manager**.

     -or-

     Choose **Create sample change request**, **Skip**, and then choose the **Settings** tab.

5. For **User identity management**, choose one of the following.

   - **Amazon Identity and Access Management (IAM)** – Identify the users who make and approve requests and perform other actions in Change Manager by using your existing user, groups, and roles.
   - **Amazon IAM Identity Center (IAM Identity Center)** – Allow IAM Identity Center to create and manage identities, or connect to your existing identity source to identify the users who perform actions in Change Manager.

6. In the **Template reviewer notification** section, specify the Amazon Simple Notification Service (Amazon SNS) topics to use to notify template reviewers that a new change template or change template version is ready for review. Make sure that the Amazon SNS topic you choose is configured to send notifications to your template reviewers.

   For information about creating and configuring Amazon SNS topics for change template reviewer notifications, see Configuring Amazon SNS topics for Change Manager notifications.

   1. To specify the Amazon SNS topic for template reviewer notification, choose one of the following:

      - **Enter an SNS Amazon Resource Name (ARN)** – For **Topic ARN**, enter the ARN of an existing Amazon SNS topic. This topic can be in any of your organization's accounts.
      - **Select an existing SNS topic** – For **Target notification topic**, select the ARN of an existing Amazon SNS topic in your current Amazon Web Services account. (This option isn't available if you haven't yet created any Amazon SNS topics in your current Amazon Web Services account and Amazon Web Services Region.)

> **Note**
>
> The Amazon SNS topic you select must be configured to specify the notifications it sends and the subscribers they're sent to. Its access policy must also grant permissions to Systems Manager so Change Manager can send notifications. For information, see Configuring Amazon SNS topics for Change Manager notifications.

2. Choose **Add notification**.

7. In the **Change template reviewers** section, select the users in your organization or account to review new change templates or change template versions before they can be used in your operations.

   Change template reviewers are responsible for verifying the suitability and security of templates other users have submitted for use in Change Manager runbook workflows.

   Select change template reviewers by doing the following:

   1. Choose **Add**.
   2. Select the check box next to the name of each user, group, or IAM role you want to assign as a change template reviewer.
   3. Choose **Add approvers**.

8. Choose **Submit**.

After you complete this initial setup process, configure additional Change Manager settings and best practices by following the steps in Task 2: Configuring Change Manager change freeze event approvers and best practices.

Task 2: Configuring Change Manager change freeze event approvers and best practices

After you complete the steps in Task 1: Configuring Change Manager user identity management and template reviewers, you can designate extra reviewers for change requests during *change freeze events* and specify which available best practices you want to allow for your Change Manager operations.

A change freeze event means that restrictions are in place in the current change calendar (the calendar state in Amazon Systems Manager Change Calendar is CLOSED). In these cases, in addition to regular approvers for change requests, or if the change request is created using a template that

allow auto-approvals, change freeze approvers must grant permission for this change request to run. If they don't, the change won't be processed until the calendar state is again OPEN.

To configure Change Manager change freeze event approvers and best practices

1. In the navigation pane, choose **Change Manager**.
2. Choose the **Settings** tab, and then choose **Edit**.
3. In the **Approvers for change freeze events** section, select the users in your organization or account who can approve changes to run even when the calendar in use in Change Calendar is currently CLOSED.

   > **Note**
   >
   > To allow change freeze reviews, you must turn on the **Check Change Calendar for restricted change events** option in **Best practices**.

   Select approvers for change freeze events by doing the following:

   1. Choose **Add**.
   2. Select the check box next to the name of each user, group, or IAM role you want to assign as an approver for change freeze events.
   3. Choose **Add approvers**.
4. In the **Best practices** section near the bottom of the page, turn on the best practices you want to enforce for each of the following options.

   - Option: **Check Change Calendar for restricted change events**

     To specify that Change Manager checks a calendar in Change Calendar to make sure changes aren't blocked by scheduled events, first select the **Enabled** check box, and then select the calendar to check for restricted events from the **Change Calendar** list.

     For more information about Change Calendar, see Amazon Systems Manager Change Calendar.

   - Option: **SNS topic for approvers for closed events**

     1. Choose one of the following to specify the Amazon Simple Notification Service (Amazon SNS) topic in your account to use for sending notifications to approvers during change

freeze events. (Note that you must also specify approvers in the **Approvers for change freeze events** section above **Best practices**.)

- **Enter an SNS Amazon Resource Name (ARN)** – For **Topic ARN**, enter the ARN of an existing Amazon SNS topic. This topic can be in any of your organization's accounts.
- **Select an existing SNS topic** – For **Target notification topic**, select the ARN of an existing Amazon SNS topic in your current Amazon Web Services account. (This option isn't available if you haven't yet created any Amazon SNS topics in your current Amazon Web Services account and Amazon Web Services Region.)

> **Note**
>
> The Amazon SNS topic you select must be configured to specify the notifications it sends and the subscribers they're sent to. Its access policy must also grant permissions to Systems Manager so Change Manager can send notifications. For information, see Configuring Amazon SNS topics for Change Manager notifications.

2. Choose **Add notification**.

- Option: **Require monitors for all templates**

  If you want to make sure that all templates for your organization or account specify an Amazon CloudWatch alarm to monitor your change operation, select the **Enabled** check box.

- Option: **Require template review and approval before use**

  To make sure that no change requests are created, and no runbook workflows run, without being based on a template that has been reviewed and approved, select the **Enabled** check box.

5. Choose **Save**.

Configuring Amazon SNS topics for Change Manager notifications

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that

date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

You can configure Change Manager to send notifications to an Amazon Simple Notification Service (Amazon SNS) topic for events related to change requests and change templates. Complete the following tasks to receive notifications for the Change Manager events you add a topic to.

Topics

- Task 1: Create and subscribe to an Amazon SNS topic
- Task 2: Update the Amazon SNS access policy
- Task 3: (Optional) Update the Amazon Key Management Service access policy

Task 1: Create and subscribe to an Amazon SNS topic

First, you must create and subscribe to an Amazon SNS topic. For more information, see Creating a Amazon SNS topic and Subscribing to an Amazon SNS topic in the *Amazon Simple Notification Service Developer Guide*.

> **Note**
>
> To receive notifications, you must specify the Amazon Resource Name (ARN) of an Amazon SNS topic that is in the same Amazon Web Services Region and Amazon Web Services account as the delegated administrator account.

Task 2: Update the Amazon SNS access policy

Use the following procedure to update the Amazon SNS access policy so that Systems Manager can publish Change Manager notifications to the Amazon SNS topic you created in Task 1. Without completing this task, Change Manager doesn't have permission to send notifications for the events you add the topic for.

1. Sign in to the Amazon Web Services Management Console and open the Amazon SNS console at https://console.amazonaws.cn/sns/v3/home.
2. In the navigation pane, choose **Topics**.
3. Choose the topic you created in Task 1, and then choose **Edit**.

4. Expand **Access policy**.
5. Add and update the following `Sid` block to the existing policy and replace each *`user input placeholder`* with your own information .

```
{
    "Sid": "Allow Change Manager to publish to this topic",
    "Effect": "Allow",
    "Principal": {
        "Service": "ssm.amazonaws.com.cn"
    },
    "Action": "sns:Publish",
    "Resource": "arn:aws-cn:sns:region:account-id:topic-name",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": [
                "account-id"
            ]
        }
    }
}
```

   Enter this block after the existing `Sid` block, and replace *`region`*, *`account-id`*, and *`topic-name`* with the appropriate values for the topic you created.
6. Choose **Save changes**.

The system now sends notifications to the Amazon SNS topic when the event type you add to topic for occurs.

> **Important**
>
> If you configured the Amazon SNS topic with an Amazon Key Management Service (Amazon KMS) server-side encryption key, then you must complete Task 3.

Task 3: (Optional) Update the Amazon Key Management Service access policy

If you turned on Amazon Key Management Service (Amazon KMS) server-side encryption for your Amazon SNS topic, then you must also update the access policy of the Amazon KMS key you chose when you configured the topic. Use the following procedure to update the access policy so that

Systems Manager can publish Change Manager approval notifications to the Amazon SNS topic you created in Task 1.

1. Open the Amazon KMS console at https://console.amazonaws.cn/kms.
2. In the navigation pane, choose **Customer managed keys**.
3. Choose the ID of the customer managed key you chose when you created the topic.
4. In the **Key policy** section, choose **Switch to policy view**.
5. Choose **Edit**.
6. Enter the following `Sid` block after one of the existing `Sid` blocks in the existing policy. Replace each *`user input placeholder`* with your own information.

```
{
    "Sid": "Allow Change Manager to decrypt the key",
    "Effect": "Allow",
    "Principal": {
        "Service": "ssm.amazonaws.com.cn"
    },
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey*"
    ],
    "Resource": "arn:aws-cn:kms:region:account-id:key/key-id",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": [
                "account-id"
            ]
        }
    }
}
```

7. Now enter the following `Sid` block after one of the existing `Sid` blocks in the resource policy to help prevent the cross-service confused deputy problem.

   This block uses the `aws:SourceArn` and `aws:SourceAccount` global condition context keys to limit the permissions that Systems Manager gives another service to the resource.

   Replace each *`user input placeholder`* with your own information.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Sid": "Configure confused deputy protection for Amazon KMS keys
 used in Amazon SNS topic when called from Systems Manager",
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com.cn"
            },
            "Action": [
                "sns:Publish"
            ],
            "Resource": "arn:aws-cn:sns:us-east-1:111122223333:topic-name",
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws-cn:ssm:us-
east-1:111122223333:*"
                },
                "StringEquals": {
                    "aws:SourceAccount": "111122223333"
                }
            }
        }
    ]
}
```

8. Choose **Save changes**.

Configuring roles and permissions for Change Manager

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

By default, Change Manager doesn't have permission to perform actions on your resources. You must grant access by using an Amazon Identity and Access Management (IAM) service role, or *assume role*. This role enables Change Manager to securely run the runbook workflows specified in an approved change request on your behalf. The role grants Amazon Security Token Service (Amazon STS) AssumeRole trust to Change Manager.

By providing these permissions to a role to act on behalf of users in an organization, users don't need to be granted that array of permissions themselves. The actions allowed by the permissions are limited to approved operations only.

When users in your account or organization create a change request, they can select this assume role to perform the change operations.

You can create a new assume role for Change Manager or update an existing role with the needed permissions.

If you need to create a service role for Change Manager, complete the following tasks.

Tasks

- Task 1: Creating an assume role policy for Change Manager
- Task 2: Creating an assume role for Change Manager
- Task 3: Attaching the iam:PassRole policy to other roles
- Task 4: Adding inline policies to an assume role to invoke other Amazon Web Services services
- Task 5: Configuring user access to Change Manager

Task 1: Creating an assume role policy for Change Manager

Use the following procedure to create the policy that you will attach to your Change Manager assume role.

To create an assume role policy for Change Manager

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Policies**, and then choose **Create Policy**.
3. On the **Create policy** page, choose the **JSON** tab and replace the default content with the following, which you will modify for your own Change Manager operations in following steps.

> **Note**
>
> If you're creating a policy to use with a single Amazon Web Services account, and not an organization with multiple accounts and Amazon Web Services Regions, you can omit the first statement block. The `iam:PassRole` permission isn't required in the case of a single account using Change Manager.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws-cn:iam::111122223333:role/AWS-
SystemsManager-job-functionAdministrationRole",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": "ssm.amazonaws.com.cn"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:DescribeDocument",
                "ssm:GetDocument",
                "ssm:StartChangeRequestExecution"
            ],
            "Resource": [
                "arn:aws-cn:ssm:us-east-1::document/template-name",
                "arn:aws-cn:ssm:us-east-1:111122223333:automation-execution/
*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
```

```
                "ssm:ListOpsItemEvents",
                "ssm:GetOpsItem",
                "ssm:ListDocuments",
                "ssm:DescribeOpsItems"
            ],
            "Resource": "*"
        }
    ]
}
```

4. For the `iam:PassRole` action, update the `Resource` value to include the ARNs of all job functions defined for your organization that you want to grant permissions to initiate runbook workflows.
5. Replace the *`region`*, *`account-id`*, *`template-name`*, *`delegated-admin-account-id`*, and *`job-function`* placeholders with values for your Change Manager operations.
6. For the second `Resource` statement, modify the list to include all change templates that you want to grant permissions for. Alternatively, specify `"Resource": "*"` to grant permissions for all change templates in your organization.
7. Choose **Next: Tags**.
8. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this policy.
9. Choose **Next: Review**.
10. On the **Review policy** page, enter a name in the **Name** box, such as **`MyChangeManagerAssumeRole`**, and then enter an optional description.
11. Choose **Create policy**, and continue to Task 2: Creating an assume role for Change Manager.

Task 2: Creating an assume role for Change Manager

Use the following procedure to create a Change Manager assume role, a type of service role, for Change Manager.

To create an assume role for Change Manager

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. For **Select trusted entity**, make the following choices:

    1. For **Trusted entity type**, choose **Amazon service**

2. For **Use cases for other Amazon Web Services services**, choose **Systems Manager**
3. Choose **Systems Manager**.

4. Choose **Next**.
5. On the **Attached permissions policy** page, search for the assume role policy you created in Task 1: Creating an assume role policy for Change Manager, such as **`MyChangeManagerAssumeRole`**.
6. Select the check box next to the assume role policy name, and then choose **Next: Tags**.
7. For **Role name**, enter a name for your new instance profile, such as **`MyChangeManagerAssumeRole`**.
8. (Optional) For **Description**, update the description for this instance role.
9. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this role.
10. Choose **Next: Review**.
11. (Optional) For **Tags**, add one or more tag-key value pairs to organize, track, or control access for this role, and then choose **Create role**. The system returns you to the **Roles** page.
12. Choose **Create role**. The system returns you to the **Roles** page.
13. On the **Roles** page, choose the role you just created to open the **Summary** page.

Task 3: Attaching the `iam:PassRole` policy to other roles

Use the following procedure to attach the `iam:PassRole` policy to an IAM instance profile or IAM service role. (The Systems Manager service uses IAM instance profiles to communicate with EC2 instances. For non-EC2 managed nodes in a hybrid and multicloud environment, an IAM service role is used instead.)

By attaching the `iam:PassRole` policy, the Change Manager service can pass assume role permissions to other services or Systems Manager tools when running runbook workflows.

To attach the `iam:PassRole` policy to an IAM instance profile or service role

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Roles**.
3. Search for the Change Manager assume role you created, such as **`MyChangeManagerAssumeRole`**, and choose its name.
4. In the **Summary** page for the assume role, choose the **Permissions** tab.

5. Choose **Add permissions, Create inline policy**.
6. On the **Create policy** page, choose the **Visual editor** tab.
7. Choose **Service**, and then choose **IAM**.
8. In the **Filter actions** text box, enter **`PassRole`**, and then choose the **PassRole** option.
9. Expand **Resources**. Verify that **Specific** is selected, and then choose **Add ARN**.
10. In the **Specify ARN for role** field, enter the ARN of the IAM instance profile role or IAM service role to which you want to pass assume role permissions. The system populates the **Account** and **Role name with path** fields.
11. Choose **Add**.
12. Choose **Review policy**.
13. For **Name**, enter a name to identify this policy, and then choose **Create policy**.

More info

- Configure instance permissions required for Systems Manager
- Create the IAM service role required for Systems Manager in hybrid and multicloud environments

Task 4: Adding inline policies to an assume role to invoke other Amazon Web Services services

When a change request invokes other Amazon Web Services services by using the Change Manager assume role, the assume role must be configured with permission to invoke those services. This requirement applies to all Amazon Automation runbooks (AWS-* runbooks) that might be used in a change request, such as the `AWS-ConfigureS3BucketLogging`, `AWS-CreateDynamoDBBackup`, and `AWS-RestartEC2Instance` runbooks. This requirement also applies to any custom runbooks you create that invoke other Amazon Web Services services by using actions that call other services. For example, if you use the `aws:executeAwsApi`, `aws:CreateStack`, or `aws:copyImage` actions, then you must configure the service role with permission to invoke those services. You can enable permissions to other Amazon Web Services services by adding an IAM inline policy to the role.

To add an inline policy to an assume role to invoke other Amazon Web Services services (IAM console)

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.

2. In the navigation pane, choose **Roles**.
3. In the list, choose the name of the assume role that you want to update, such as `MyChangeManagerAssumeRole`.
4. Choose the **Permissions** tab.
5. Choose **Add permissions, Create inline policy**.
6. Choose the **JSON** tab.
7. Enter a JSON policy document for the Amazon Web Services services you want to invoke. Here are two example JSON policy documents.

Amazon S3 `PutObject` and `GetObject` example

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetObject"
            ],
            "Resource": "arn:aws-cn:s3:::amzn-s3-demo-bucket/*"
        }
    ]
}
```

Amazon EC2 `CreateSnapshot` and `DescribeSnapShots` example

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":"ec2:CreateSnapshot",
```

```
            "Resource":"*"
        },
        {
            "Effect":"Allow",
            "Action":"ec2:DescribeSnapshots",
            "Resource":"*"
        }
    ]
}
```

For details about the IAM policy language, see IAM JSON policy reference in the *IAM User Guide*.

8. When you're finished, choose **Review policy**. The Policy Validator reports any syntax errors.
9. For **Name**, enter a name to identify the policy that you're creating. Review the policy **Summary** to see the permissions that are granted by your policy. Then choose **Create policy** to save your work.
10. After you create an inline policy, it's automatically embedded in your role.

Task 5: Configuring user access to Change Manager

If your user, group, or role is assigned administrator permissions, then you have access to Change Manager. If you don't have administrator permissions, then an administrator must assign the `AmazonSSMFullAccess` managed policy, or a policy that provides comparable permissions, to your user, group, or role.

Use the following procedure to configure a user to use Change Manager. The user you choose will have permission to configure and run Change Manager.

Depending on the identity application that you are using in your organization, you can select any of the three options available to configure user access. While configuring the user access, assign or add the following:

1. Assign the `AmazonSSMFullAccess` policy or a comparable policy that gives permission to access Systems Manager.
2. Assign the `iam:PassRole` policy.
3. Add the ARN for the Change Manager assume role you copied at the end of Task 2: Creating an assume role for Change Manager.

To provide access, add permissions to your users, groups, or roles:

- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.

- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

You have finished configuring the required roles for Change Manager. You can now use the Change Manager assume role ARN in your Change Manager operations.

Controlling access to auto-approval runbook workflows

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

In each change template created for your organization or account, you can specify whether change requests created from that template can run as auto-approved change requests, meaning that they run automatically without a review step (with the exception of change freeze events).

However, you might want to prevent certain users, groups, or Amazon Identity and Access Management (IAM) roles from running auto-approved change requests even if a change template allows it. You can do this through the use of the `ssm:AutoApprove` condition key for the `StartChangeRequestExecution` operation in an IAM policy assigned to the user, group, or IAM role.

You can add the following policy as an inline policy, where the condition is specified as `false`, to prevent users from running auto-approvable change requests.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
            {
            "Effect": "Allow",
            "Action": "ssm:StartChangeRequestExecution",
            "Resource": "*",
            "Condition": {
                "BoolIfExists": {
                    "ssm:AutoApprove": "false"
                }
            }
        }
    ]
}
```

For information about specifying inline policies, see Inline policies and Adding and removing IAM identity permissions in the *IAM User Guide*.

For more information about condition keys for Systems Manager policies, see Condition keys for Systems Manager.

Working with Change Manager

Change Manager availability change

Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

With Change Manager, users across your organization or in a single Amazon Web Services account can perform change-related tasks for which they have been granted the necessary permissions. Change Manager tasks include the following:

- Create, review, and approve or reject change templates.

A change template is a collection of configuration settings in Change Manager that define such things as required approvals, available runbooks, and notification options for change requests.

- Create, review, and approve or reject change requests.

  A change request is a request in Change Manager to run an Automation runbook that updates one or more resources in your Amazon or on-premises environments. A change request is created using a change template.

- Specify which users in your organization or account can be made reviewers for change templates and change requests.
- Edit configuration settings, such as how user identities are managed in Change Manager and which of the available *best practice* options are enforced in your Change Manager operations. For information about configuring these settings, see Configuring Change Manager options and best practices.

Topics

- Working with change templates
- Working with change requests

- Viewing aggregated counts of change requests (command line)

Working with change templates

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

A change template is a collection of configuration settings in Change Manager that define such things as required approvals, available runbooks, and notification options for change requests.

Note

Amazon provides a sample Hello World change template you can use to try out Change Manager, a tool in Amazon Systems Manager. However, you create your own change templates to define the changes you want to allow to the resources in your organization or account.

The changes that are made when a runbook workflow runs are based on the contents an Automation runbook. In each change template you create, you can include one or more Automation runbooks that the user making a change request can choose from to run during the update. You can also create change templates that allow requesters to choose any available Automation runbook for the change request.

To create a change template, you can use the **Builder** option in the **Create template** console page to build a change template. Alternatively, using the **Editor** option, you can manually author JSON or YAML content with the configuration you want for your runbook workflow. You can also use a command line tool to create a change template, with JSON content for the change template stored in an external file.

Topics

- Try out the Amazon managed Hello World change template
- Creating change templates
- Reviewing and approving or rejecting change templates
- Deleting change templates

Try out the Amazon managed `Hello World` change template

Change Manager availability change

Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

You can use the sample change template `AWS-HelloWorldChangeTemplate`, which uses the sample Automation runbook `AWS-HelloWorld`, to test the review and approval process after you have finished setting up Change Manager. This template is designed for testing or verifying your configured permissions, approver assignments, and approval process. Approval to use this change template in your organization or account has already been provided by Amazon. Any change request based on this change template, however, must still be approved by reviewers in your organization or account.

Rather than make changes to a resource, the result of the runbook workflow associated with this template is to print a message in the output of an Automation step.

Before you begin

Before you begin, make sure you have completed the following tasks:

- If you're using Amazon Organizations to manage change across an organization, complete the organization setup tasks described in Setting up Change Manager for an organization (management account).
- Configure Change Manager for your delegated administrator account or single account, as described in Configuring Change Manager options and best practices.

> **Note**
>
> If you turned on the best practice option **Require monitors for all templates** in your Change Manager settings, turn it off temporarily while you test the Hello World change template.

To try out the Amazon managed Hello World change template

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Manager**.
3. Choose **Create request**.
4. Choose the change template named `AWS-HelloWorldChangeTemplate`, and then choose **Next**.
5. For **Name**, enter a name for the change request that makes its purpose easy to identify, such as **`MyChangeRequestTest`**.

6. For the remainder of the steps to create your change request, see Creating change requests.

Next steps

For information about approving change requests, see Reviewing and approving or rejecting change requests.

To view the status and results of your change request, choose the name of your change request on the **Requests** tab in Change Manager.

Creating change templates

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

A change template is a collection of configuration settings in Change Manager that define such things as required approvals, available runbooks, and notification options for change requests.

You can create change templates for your operations in Change Manager, a tool in Amazon Systems Manager, using the console, which includes Builder and Editor options, or command line tools.

- Creating change templates using Builder
- Creating change templates using Editor
- Creating change templates using command line tools

About approvals in your change templates

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

For each change template that you create, you can specify up to five approval *levels* for change requests created from it. For each of those levels, you can designate up to five potential *approvers*. An approver isn't limited to a single user. You can also specify an IAM group or IAM role as an individual approver. For IAM groups and IAM roles, one or more users belonging to the group or role can provide approvals toward receiving the total number of approvals required for a change request. You can also specify more approvers than your change template requires.

Change Manager supports two main approaches to approvals: *per-level approvals* and *per-line approvals*. A combination of the two types is also possible in some situations. We recommend using only per-level approvals in your Change Manager operations.

Per-level approvals

Recommended. As of January 23, 2023, Change Manager supports per-level approvals. In this model, for each approval level in your change template, you first specify how many approvals are required for that level. Then you specify at least that many approvers for the level and can specify more approvers. However, only the number of per-level approvers that you specify need to approve the change request. For example, you could specify five approvers but require three approvals.

For console-view and JSON samples of this approval type, see the section called “Sample per-level approval configuration”.

Per-line approvals

Supported for backward compatibility. The original release of Change Manager supported only per-line approvals. In this model, every approver specified for an approval level is represented as an approval line. Each approver had to approve a change request for it to be approved at that level. Prior to January 23, 2023, this was the only supported model for approvals. Change

templates created before this date continue to support per-line approvals, but we recommend using per-level approvals instead.

For console-view and JSON samples of this approval type, see the section called “Sample per-line approval configuration”.

Combined per-line and per-level approvals

Not recommended. In the console, the **Builder** tab no longer supports adding per-line approvals. However, in some cases you might end up with both per-line and per-level approvals in a change template. This can occur if you update a change template that was created before January 23, 2023, or if you create or update a change template by editing its YAML content manually,

For console-view and JSON samples of this approval type, see the section called “Sample combined per-level and per-line approval configuration”.

Important

Although it's possible to create a change template that combines per-line and per-level approvals, this configuration isn't recommended or necessary. Whichever approval type requires more approvals (per-line or per-level approvals) takes precedence. For example:

- If a change template specifies three per-level approvals but five per-line approvals, then five approvals are required.
- If a change template specifies four per-level approvals but two per-line approvals, then four approvals are required.

You can create a level that includes both per-line and per-level approvals by editing the YAML or JSON content manually. Then, the **Builder** tab displays controls for specifying the required number of approvals for both the level and for individual lines. However, new levels that you add using the console still support only per-level approval configurations.

Change request notifications and rejections

Amazon SNS notifications

When a change request is created using your change template, notifications are sent to subscribers of the Amazon Simple Notification Service (Amazon SNS) topic that has been

designated for approval notifications at that level. You can specify the notification topic in the change template or allow the user creating the change request to specify one.

After the minimum number of required approvals is received at one level, notifications are sent to approvers subscribed to the Amazon SNS topic for the next level, and so on.

> **Important**
>
> Make sure that the IAM roles, groups, and users you designate together provide enough approvers to meet the required number of approvals you specify. For example, if you designate only a single IAM group as an approver that contains three users, you can't specify that five approvals are mandatory at that level, only three or less.

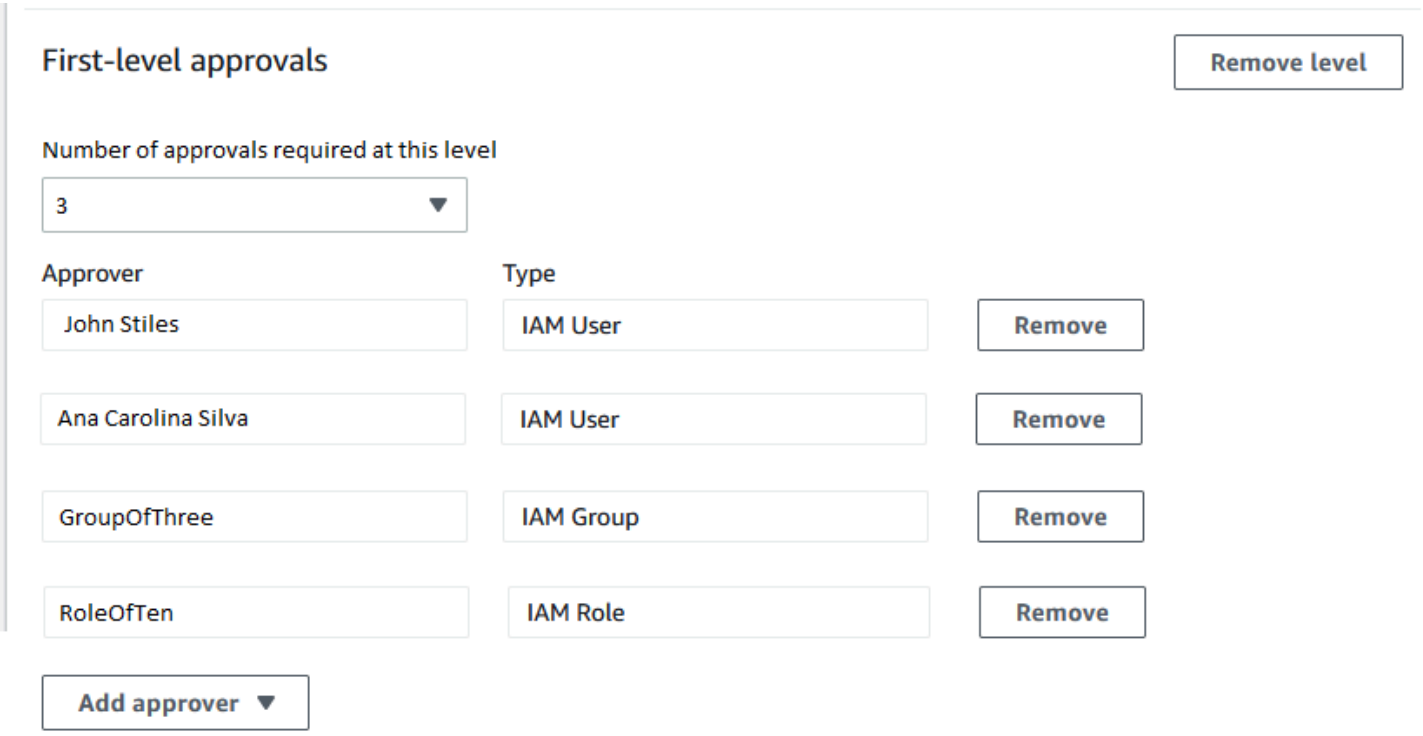
Change request rejections

No matter how many approval levels and approvers you specify, only one rejection to a change request is required to prevent the runbook workflow for that request from occurring.

Change Manager approval type examples

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

The following samples demonstrate the console view and JSON content for the three types of approval types in Change Manager.



Topics

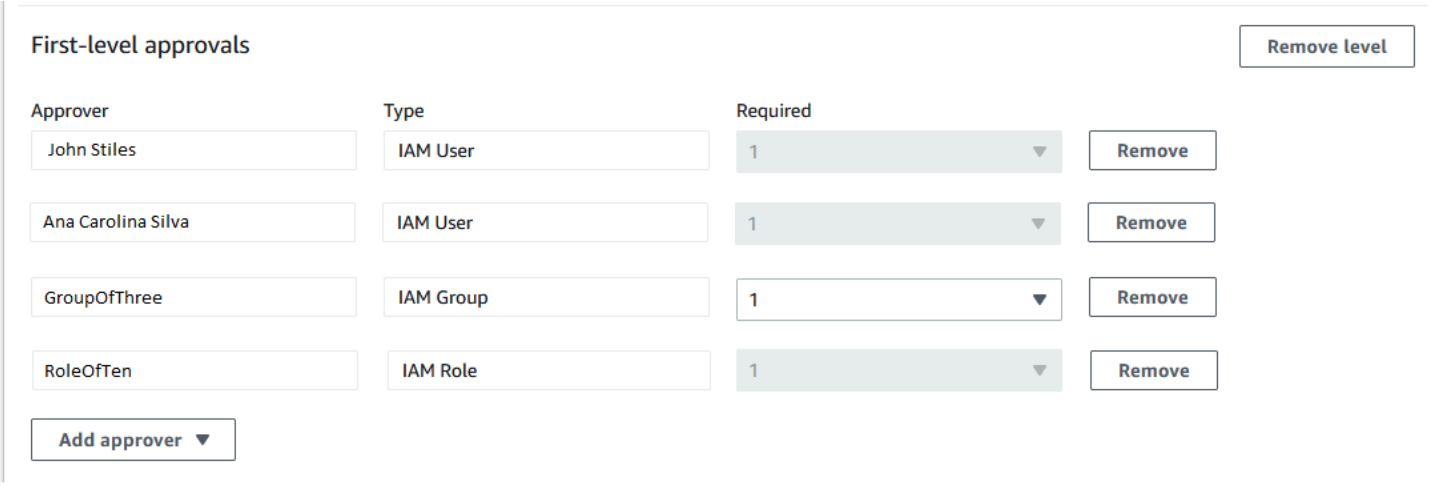
- Sample per-level approval configuration
- Sample per-line approval configuration
- Sample combined per-level and per-line approval configuration

Sample per-level approval configuration

In the per-level approval level setup shown in the following image, three approvals are required. Those approvals can come from any combination of IAM users, groups, and roles that are specified as approvers. Specified approvers include two IAM users (John Stiles and Ana Carolina Silva), a user group that contains three members (`GroupOfThree`), and a user role that represents ten users (`RoleOfTen`).

If all three users in the `GroupOfThree` group approve the change request, it is approved for that level. It's not necessary to receive an approval from each user, group, or role. The minimum number of approvals can come from any combination of specified approvers. We recommend per-level approvals for your Change Manager operations.

The following sample illustrates part of the YAML code for this configuration.



> **Note**
>
> This version of the YAML code include an additional input, `MinRequiredApprovals` (with an initial capital `M`). The value for this input indicates how many approvals are required from among all available reviewers. Note also that the `minRequiredApprovals`

(lowercase initial `m`) value for each approver in the `Approvers` list is `0` (zero). This indicates that the approver can contribute to the overall approvals but is not required to do so.

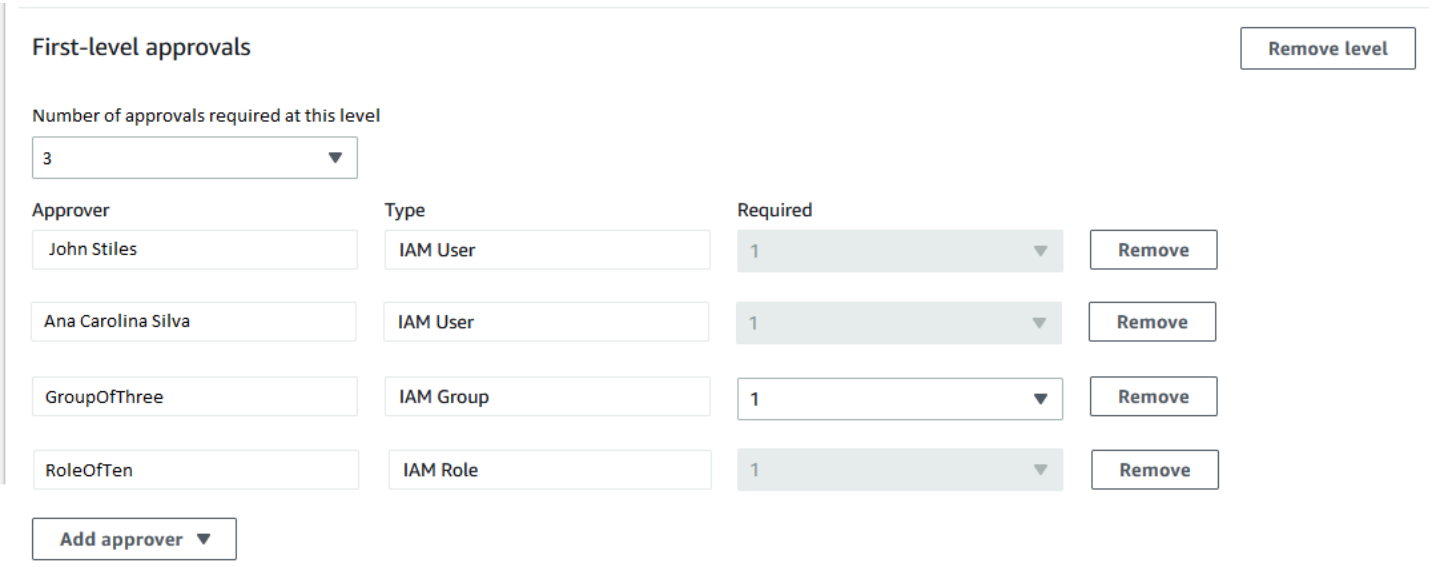
```
schemaVersion: "0.3"
emergencyChange: false
autoApprovable: false
mainSteps:
  - name: ApproveAction1
    action: aws:approve
    timeoutSeconds: 604800
    inputs:
      Message: Please approve this change request
      MinRequiredApprovals: 3
      EnhancedApprovals:
        Approvers:
          - approver: John Stiles
            type: IamUser
            minRequiredApprovals: 0
          - approver: Ana Carolina Silva
            type: IamUser
            minRequiredApprovals: 0
          - approver: GroupOfThree
            type: IamGroup
            minRequiredApprovals: 0
          - approver: RoleOfTen
            type: IamRole
            minRequiredApprovals: 0
templateInformation: >
  #### What is the purpose of this change?
    //truncated
```

Sample per-line approval configuration

In the approval level setup shown in the following image, four approvers are specified. These include two IAM users (John Stiles and Ana Carolina Silva), a user group that contains three members (`GroupOfThree`), and a user role that represents ten users (`RoleOfTen`). Per-line approvals are supported for backwards compatibility but not recommended.

For the change request to be approved in this per-line approval configuration, it must be approved by all approver lines: John Stiles, Ana Carolina Silva, one member of the `GroupOfThree` group, and one member of the `RoleOfTen` role.

The following sample illustrates part of the YAML code for this configuration.



> **Note**
>
> Observe that the value for each `minRequiredApprovals` approver is 1. This indicates that one approval is required from each approver.

```
schemaVersion: "0.3"
emergencyChange: false
autoApprovable: false
mainSteps:
  - name: ApproveAction1
    action: aws:approve
    timeoutSeconds: 10000
    inputs:
      Message: Please approve this change request
      EnhancedApprovals:
        Approvers:
          - approver: John Stiles
            type: IamUser
            minRequiredApprovals: 1
          - approver: Ana Carolina Silva
            type: IamUser
            minRequiredApprovals: 1
```

```
          - approver: GroupOfThree
            type: IamGroup
            minRequiredApprovals: 1
          - approver: RoleOfTen
            type: IamRole
            minRequiredApprovals: 1
executableRunBooks:
  - name: AWS-HelloWorld
    version: $DEFAULT
templateInformation: >
  #### What is the purpose of this change?
    //truncated
```

Sample combined per-level and per-line approval configuration

In the combined per-level and per-line approval setup shown in the following image, three approvals are specified for the level, but four approvals are specified for the line-item approvals. Whichever approval type requires more approvals takes precedence over the other, so four approvals are required by this configuration. Combined per-level and per-line approval are not recommended.

```
schemaVersion: "0.3"
emergencyChange: false
autoApprovable: false
mainSteps:
  - name: ApproveAction1
    action: aws:approve
```

```
    timeoutSeconds: 604800
    inputs:
      Message: Please approve this change request
      MinRequiredApprovals: 3
      EnhancedApprovals:
        Approvers:
          - approver: John Stiles
            type: IamUser
            minRequiredApprovals: 1
          - approver: Ana Carolina Silva
            type: IamUser
            minRequiredApprovals: 1
          - approver: GroupOfThree
            type: IamGroup
            minRequiredApprovals: 1
          - approver: RoleOfTen
            type: IamRole
            minRequiredApprovals: 1
templateInformation: >
  #### What is the purpose of this change?
    //truncated
```

Creating change templates using Builder

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

Using the Builder for change templates in Change Manager, you can configure the runbook workflow defined in your change template without having to use JSON or YAML syntax. After you

specify your options, the system converts your input into the YAML format that Systems Manager can use to run runbook workflows.

To create a change template using Builder

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Manager**.
3. Choose **Create template**.
4. For **Name**, enter a name for the template that makes its purpose easy to identify, such as **`UpdateEC2LinuxAMI`**.
5. In the **Change template details** section, do the following:

   - For **Description**, provide a brief explanation of how and when the change template you're creating is to be used.

     This description helps users who create change requests determine whether they're using the correct change template. It helps those who review change requests understand whether the request should be approved.
   - For **Change template type**, specify whether you're creating a standard change template or an emergency change template.

     An emergency change template is used for situations when a change must be made even if changes are otherwise blocked by an event in the calendar in use by Amazon Systems Manager Change Calendar. Change requests created from an emergency change template must still be approved by its designated approvers, but the requested changes can still run even when the calendar is blocked.
   - For **Runbook options**, specify the runbooks that users can choose from when creating a change request. You can add a single runbook or multiple runbooks. Alternatively, you can allow requesters to specify which runbook to use. In any of these cases, only one runbook can be included in the change request.
   - For **Runbook**, select the names of the runbooks and the versions of those runbooks that users can choose from for their change requests. No matter how many runbooks you add to the change template, only one can be selected per change request.

     You don't specify a runbook if you chose **Any runbook can be used** earlier.

> **Tip**
>
> Select a runbook and runbook version, and then choose **View** to examine the contents of the runbook in the Systems Manager Documents interface.

6. In the **Template information** section, use Markdown to enter information for users who create change requests from this change template. We have provided a set of questions that you can include for users who create change requests, or you can add other information and questions instead.

> **Note**
>
> Markdown is a markup language that lets you add wiki-style descriptions to documents and individual steps within the document. For more information about using Markdown, see Using Markdown in Amazon.

We recommend providing questions for users to answer about their change requests to help approvers decide whether to grant each change request, such as listing any manual steps required to run as part of the change and a rollback plan.

> **Tip**
>
> Toggle between **Hide preview** and **Show preview** to see what your content looks like as you compose.

7. In the **Change request approvals** section, do the following:

- (Optional) If you want to allow change requests that are created from this change template to run automatically, without review by any approvers (with the exception of change freeze events), select **Enable auto-approval**.

> **Note**
>
> Enabling auto-approvals in a change template provides users with the *option* of bypassing reviewers. They can still choose to specify reviewers when creating a

change request. Therefore, you must still specify reviewer options in the change template.

> **Important**
>
> If you enable auto-approval for a change template, users can submit change requests using that template that do not require review by reviewers before they run (with the exception of change freeze event approvers). If you want to restrict a particular user, group, or IAM role from submitting auto-approval requests, you can use a condition in an IAM policy for this purpose. For more information, see Controlling access to auto-approval runbook workflows.

- For **Number of approvals required at this level**, choose the number of approvals that change requests created from this change template must receive for this level.
- To add mandatory first-level approvers, choose **Add approver**, and then choose from the following:
  - **Template specified approvers** – Choose one or more users, groups, or Amazon Identity and Access Management (IAM) roles from your account to approve change requests created from this change template. Any change requests that are created using this template must be reviewed and approved by each approver you specify.
  - **Request specified approvers** – The user who makes the change request specifies reviewers at the time they make the request and can choose from a list of users in your account.

    The number you enter in the **Required** column determines how many reviewers must be specified by a change request that uses this change template.

> **Important**
>
> Prior to January 23, 2023, the **Builder** tab supported specifying per-line approvals only. New change templates and new levels you add to existing change templates using the **Builder** tab support per-level approvals only. We recommend using only per-level approvals in your Change Manager operations.
> For more information, see About approvals in your change templates.

- For **SNS topic to notify approvers**, do the following:

1. Choose one of the following to specify the Amazon Simple Notification Service (Amazon SNS) topic in your account to use for sending notifications to approvers that a change request is ready for their review:

   - **Enter an SNS Amazon Resource Name (ARN)** – For **Topic ARN**, enter the ARN of an existing Amazon SNS topic. This topic can be in any of your organization's accounts.
   - **Select an existing SNS topic** – For **Target notification topic**, select the ARN of an existing Amazon SNS topic in your current Amazon Web Services account. (This option isn't available if you haven't yet created any Amazon SNS topics in your current Amazon Web Services account and Amazon Web Services Region.)
   - **Specify SNS topic when the change request is created** – The user who creates a change request can specify the Amazon SNS topic to use for notifications.

   > **Note**
   >
   > The Amazon SNS topic you select must be configured to specify the notifications it sends and the subscribers they're sent to. Its access policy must also grant permissions to Systems Manager so Change Manager can send notifications. For information, see Configuring Amazon SNS topics for Change Manager notifications.

2. Choose **Add notification**.

8. (Optional) To add an additional level of approvers, choose **Add approval level** and choose between template-specified approvers and request-specified approvers for this level. Then choose an SNS topic to notify this level of approvers.

   After all approvals have been received by first-level approvers, second-level approvers are notified, and so on.

   You can add a maximum of five levels of approvers in each template. You might, for example, require approvals from users in technical roles for the first level, then managerial approval for the second level.

9. In the **Monitoring** section, for **CloudWatch alarm to monitor**, enter the name of an Amazon CloudWatch alarm in the current account to monitor the progress of runbook workflows that are based on this template.

> **Tip**
>
> To create a new alarm, or to review the settings of an alarm you want to specify, choose **Open the Amazon CloudWatch console**. For information about working with CloudWatch alarms, see Using CloudWatch Alarms in the *Amazon CloudWatch User Guide*.

10. In the **Notifications** section, do the following:

    1. Choose one of the following to specify the Amazon SNS topic in your account to use for sending notifications about change requests that are created using this change template:

       - **Enter an SNS Amazon Resource Name (ARN)** – For **Topic ARN**, enter the ARN of an existing Amazon SNS topic. This topic can be in any of your organization's accounts.
       - **Select an existing SNS topic** – For **Target notification topic**, select the ARN of an existing Amazon SNS topic in your current Amazon Web Services account. (This option isn't available if you haven't yet created any Amazon SNS topics in your current Amazon Web Services account and Amazon Web Services Region.)

       > **Note**
       >
       > The Amazon SNS topic you select must be configured to specify the notifications it sends and the subscribers they're sent to. Its access policy must also grant permissions to Systems Manager so Change Manager can send notifications. For information, see Configuring Amazon SNS topics for Change Manager notifications.

    2. Choose **Add notification**.

11. (Optional) In the **Tags** section, apply one or more tag key name/value pairs to the change template.

    Tags are optional metadata that you assign to a resource. By using tags, you can categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a change template to identify the type of change it makes and the environment it runs in. In this case, you could specify the following key name/value pairs:

    - `Key=TaskType,Value=InstanceRepair`
    - `Key=Environment,Value=Production`

12. Choose **Save and preview**.
13. Review the details of the change template you're creating.

    If you want to make change to the change template before submitting it for review, choose **Actions, Edit**.

    If you're satisfied with the contents of the change template, choose **Submit for review**. The users in your organization or account who have been specified as template reviewers on the **Settings** tab in Change Manager are notified that a new change template is pending their review.

    If an Amazon SNS topic has been specified for change templates, notifications are sent when the change template is rejected or approved. If you don't receive notifications related to this change template, you can return to Change Manager later to check on its status.

Creating change templates using Editor

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

Use the steps in this topic to configure a change template in Change Manager by entering JSON or YAML instead of using the console controls.

To create a change template using Editor

1. In the navigation pane, choose **Change Manager**.
2. Choose **Create template**.
3. For **Name**, enter a name for the template that makes its purpose easy to identify, such as **`RestartEC2LinuxInstance`**.
4. Above **Change template details**, choose **Editor**.
5. In the **Document editor** section, choose **Edit**, and then enter the JSON or YAML content for your change template.

The following is an example.

> **Note**
>
> The parameter `minRequiredApprovals` is used to specify how many reviewers at a specified level must approve a change request that is created using this template. This example demonstrates two levels of approvals. You can specify up to five levels of approvals, but only one level is required.
> In the first level, the specific user "John-Doe" must approve each change request. After that, any three members of the IAM role `Admin` must approve the change request.
> For more information about approvals for change templates, see About approvals in your change templates.

YAML

```
description: >-
  This change template demonstrates the feature set available for creating
  change templates for Change Manager. This template starts a Runbook workflow

            "EnhancedApprovals": {
               "NotificationArn": "{{ ApproverSnsTopicArn }}",
               "Approvers": [
                  {
                     "approver": "Admin",
                     "type": "IamRole",
                     "minRequiredApprovals": 3
                  }
               ]
            }
         }
      }
   ]
```

```
}
```

6. Choose **Save and preview**.
7. Review the details of the change template you're creating.

   If you want to make change to the change template before submitting it for review, choose **Actions, Edit**.

   If you're satisfied with the contents of the change template, choose **Submit for review**. The users in your organization or account who have been specified as template reviewers on the **Settings** tab in Change Manager are notified that a new change template is pending their review.

   If an Amazon Simple Notification Service (Amazon SNS) topic has been specified for change templates, notifications are sent when the change template is rejected or approved. If you don't receive notifications related to this change template, you can return to Change Manager later to check on its status.

Creating change templates using command line tools

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

The following procedures describe how to use the Amazon Command Line Interface (Amazon CLI) (on Linux, macOS, or Windows Server) or Amazon Tools for Windows PowerShell to create a change request in Change Manager.

To create a change template

1. Install and configure the Amazon CLI or the Amazon Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI and Installing the Amazon Tools for PowerShell.

2. Create a JSON file on your local machine with a name such as `MyChangeTemplate.json`, and then paste the content for your change template into it.

> **Note**
>
> Change templates use a version of schema 0.3 that doesn't include all the same support as for Automation runbooks.

The following is an example.

> **Note**
>
> The parameter `minRequiredApprovals` is used to specify how many reviewers at a specified level must approve a change request that is created using this template. This example demonstrates two levels of approvals. You can specify up to five levels of approvals, but only one level is required.
> In the first level, the specific user "John-Doe" must approve each change request. After that, any three members of the IAM role `Admin` must approve the change request.
> For more information about approvals for change templates, see About approvals in your change templates.

```
{
   "description": "This change template demonstrates the feature set available for
 creating
  change templates for Change Manager. This template starts a Runbook workflow
  for the Automation runbook called AWS-HelloWorld",
   "templateInformation": "### Document Name: HelloWorldChangeTemplate\n\n
    ## What does this document do?\n
    This change template demonstrates the feature set available for creating change
 templates for Change Manager.
    This template starts a Runbook workflow for the Automation runbook called AWS-
HelloWorld.\n\n
    ## Input Parameters\n* ApproverSnsTopicArn: (Required) Amazon Simple
 Notification Service ARN for approvers.\n
    * Approver: (Required) The name of the approver to send this request to.\n
    * ApproverType: (Required) The type of reviewer.  * Allowed Values: IamUser,
 IamGroup, IamRole, SSOGroup, SSOUser\n\n
```

```
   ## Output Parameters\nThis document has no outputs\n",

```
      },
        {
         "name": "ApproveAction2",
         "action": "aws:approve",
         "timeoutSeconds": 3600,
         "inputs": {
            "Message": "A sample change request has been submitted for your review
 in Change Manager. You can approve or reject this request.",
            "EnhancedApprovals": {
               "NotificationArn": "{{ ApproverSnsTopicArn }}",
               "Approvers": [
                  {
                     "approver": "Admin",
                     "type": "IamRole",
                     "minRequiredApprovals": 3
                  }
               ]
            }
         }
      }
   ]
}
```

3. Run the following command to create the change template.

   Linux & macOS

   ```
   aws ssm create-document \
       --name MyChangeTemplate \
       --document-format JSON \
       --document-type Automation.ChangeTemplate \
       --content file://MyChangeTemplate.json \
       --tags Key=tag-key,Value=tag-value
   ```

   Windows

   ```
   aws ssm create-document ^
       --name MyChangeTemplate ^
       --document-format JSON ^
       --document-type Automation.ChangeTemplate ^
       --content file://MyChangeTemplate.json ^
       --tags Key=tag-key,Value=tag-value
   ```

PowerShell

```
$json = Get-Content -Path "C:\path\to\file\MyChangeTemplate.json" | Out-String
New-SSMDocument `
    -Content $json `
    -Name "MyChangeTemplate" `
    -DocumentType "Automation.ChangeTemplate" `
    -Tags "Key=tag-key,Value=tag-value"
```

For information about other options you can specify, see create-document.

The system returns information like the following.

```
{
   "DocumentDescription":{
      "CreatedDate":1.585061751738E9,
      "DefaultVersion":"1",
      "Description":"Use this template to update an EC2 Linux AMI. Requires one
      approver specified in the template and an approver specified in the
 request.",

      "Tags":[

      ]
   }
}
```

The users in your organization or account who have been specified as template reviewers on the **Settings** tab in Change Manager are notified that a new change template is pending their review.

If an Amazon Simple Notification Service (Amazon SNS) topic has been specified for change templates, notifications are sent when the change template is rejected or approved. If you don't receive notifications related to this change template, you can return to Change Manager later to check on its status.

Reviewing and approving or rejecting change templates

Change Manager availability change

Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

If you're specified as a reviewer for change templates in Change Manager, a tool in Amazon Systems Manager, you're notified when a new change template, or new version of a change template is awaiting your review. An Amazon Simple Notification Service (Amazon SNS) topic sends the notifications.

> **Note**
>
> This functionality depends on whether your account has been configured to use an Amazon SNS topic to send change template review notifications. For information about specifying a template reviewer notification topic, see Task 1: Configuring Change Manager user identity management and template reviewers.

To review the change template, follow the link in your notification, sign in to the Amazon Web Services Management Console, and follow the steps in this procedure.

To review and approve or reject a change template

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Manager**.
3. In the **Change templates** section at the bottom of the **Overview** tab, choose the number in **Pending review**.
4. In the **Change templates** list, locate and choose the name of change template to review.
5. In the summary page, review the proposed content of the change template and do one of the following:
   - To approve the change template, which allows it to be used in change requests, choose **Approve**.
   - To reject the change template, which prevents it from being used in change requests, choose **Reject**.

Deleting change templates

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

This topic describes how to delete templates that you have created in Change Manager. If you are using Change Manager for an organization, this procedure is performed in your delegated administrator account.

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Manager**.
3. Choose the **Templates** tab.
4. Choose the name of the template to delete.
5. Choose **Actions, Delete template**.
6. In the confirmation dialog, enter the word **DELETE**, and then choose **Delete**.

Working with change requests

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

A change request is a request in Change Manager to run an Automation runbook that updates one or more resources in your Amazon or on-premises environments. A change request is created using a change template.

When you create a change request in Change Manager, one or more approvers in your organization or account must review and approve the request. Without the required approvals, the runbook workflow, which makes the changes you request, isn't permitted to run.

Topics

- Creating change requests
- Reviewing and approving or rejecting change requests

Creating change requests

Change Manager availability change

Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

When you create a change request in Change Manager, the change template you select typically does the following:

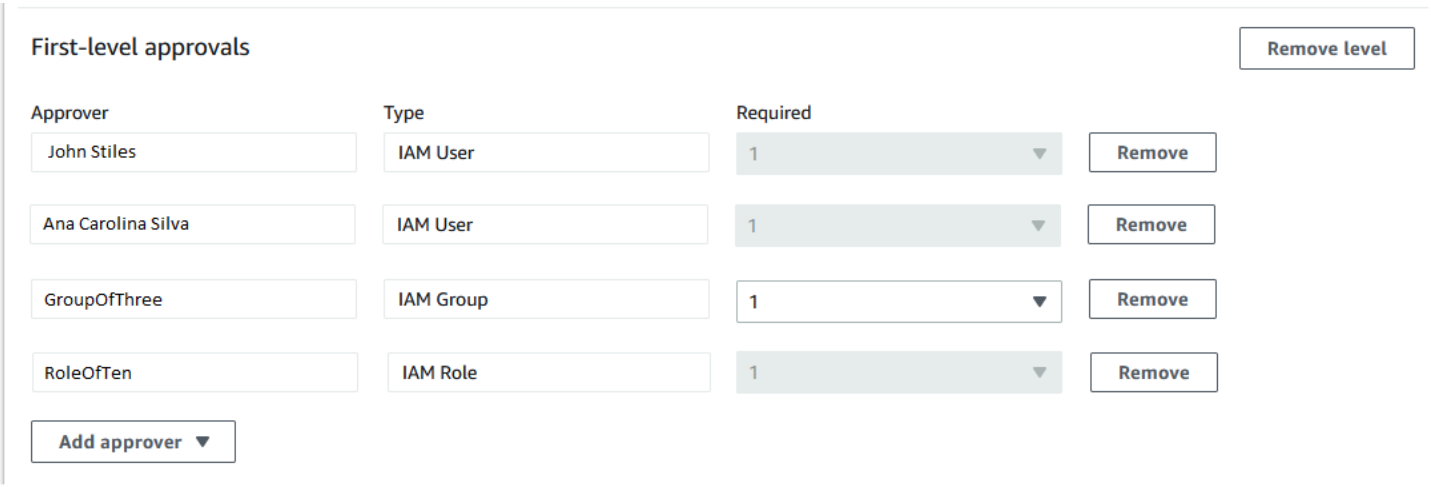
- Designates approvers for the change request or specifies how many approvals are required
- Specifies the Amazon Simple Notification Service (Amazon SNS) topic to use to notify approvers about your change request
- Specifies an Amazon CloudWatch alarm to monitor the runbook workflow for the change request
- Identifies which Automation runbooks you can choose from to make the requested change

In some cases, a change template might be configured so you specify your own Automation runbook to use, and to specify who should review and approve the request.

Important

If you use Change Manager across an organization, we recommend always making changes from the delegated administrator account. Although you can make changes from other accounts in the organization, those changes won't be reported in or viewable from the delegated administrator account.

Topics



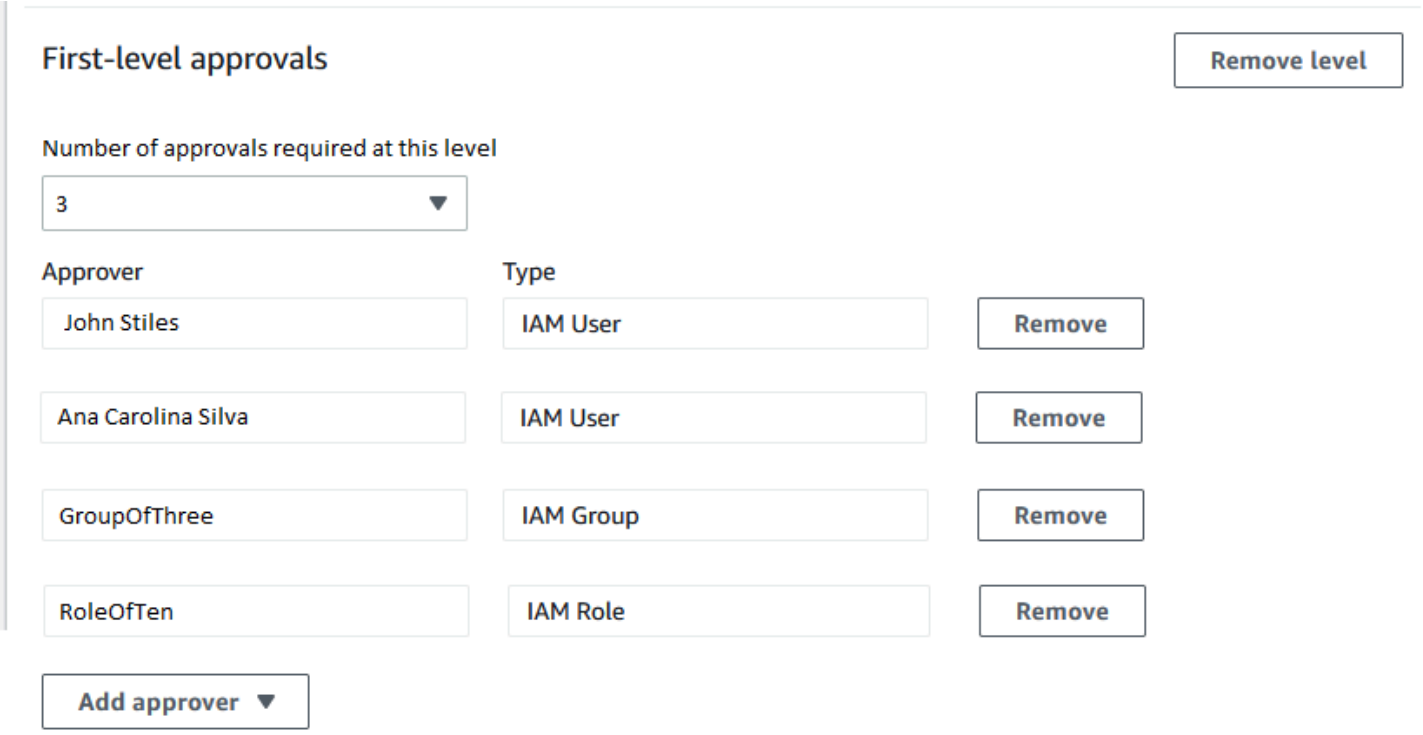
- About change request approvals
- Creating change requests (console)
- Creating change requests (Amazon CLI)

About change request approvals

Depending on the requirements specified in a change template, change requests that you create from it can require approvals from up to five *levels* before the runbook workflow for the request can occur. For each of those levels, the template creator could specify up to five potential *approvers*. An approver isn't limited to a single user. An approver in this sense can also be an IAM group or IAM role. For IAM groups and IAM roles, one or more users belonging to the group or role can provide approvals toward receiving the total number of approvals required for a change request. Template creators can also specify more approvers than the change template requires.

Original approval workflows and updated and/or approvals

Using change templates created before January 23, 2023, an approval must be received from each specified approver for the change request to be approved at that level. For example, in the approval level setup shown in the following image, four approvers are specified. Specified approvers include two users (John Stiles and Ana Carolina Silva), a user group that contains three members (GroupOfThree), and a user role that represents ten users (RoleOfTen).



For the change request to be approved at this level, it must be approved by John Stiles, Ana Carolina Silva, one member of the `GroupOfThree` group, and one member of the `RoleOfTen` role.

Using change templates created on or after January 23, 2023, for each approval level, template creators can specify an overall total number of required approvals. Those approvals can come from any combination of users, groups, and roles that have been specified as approvers. A change template could require only one approval for a level but specify, for example, two individual users, two groups, and one role as potential approvers.

For example, in the approval level area shown in the following image, three approvals are required. The template-specified approvers include two users (John Stiles and Ana Carolina Silva), a user

group that contains three members (`GroupOfThree`), and a user role that represents ten users (`RoleOfTen`).

If all three users in the `GroupOfThree` group approve your change request, it is approved for that level. It's not necessary to receive an approval from each user, group, or role. The minimum number of approvals can come from any combination of potential approvers.

When your change request is created, notifications are sent to subscribers of the Amazon SNS topic that has been specified for approval notifications at that level. The change template creator might have specified the notification topic that must be used or allowed you to specify one.

After the minimum number of required approvals is received at one level, notifications are sent to approvers that are subscribed to the Amazon SNS topic for the next level, and so on.

No matter how many approval levels and approvers are specified, only one rejection to a change request is required to prevent the runbook workflow for that request from occurring.

Creating change requests (console)

The following procedure describes how to create a change request by using the Systems Manager console.

To create a change request (console)

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Manager**.
3. Choose **Create request**.
4. Search for and select a change template that you want to use for this change request.
5. Choose **Next**.
6. For **Name**, enter a name for the change request that makes its purpose easy to identify, such as **`UpdateEC2LinuxAMI-us-east-2`**.
7. For **Runbook**, select the runbook you want to use to make your requested change.

   > **Note**
   >
   > If the option to select a runbook isn't available, the change template author has specified which runbook must be used.

8. For **Change request information**, use Markdown to provide additional information about the change request to help reviewers decide whether to approve or reject the change request. The author of the template you're using might have provided instructions or questions for you to answer.

   > **Note**
   >
   > Markdown is a markup language that lets you add wiki-style descriptions to documents and individual steps within the document. For more information about using Markdown, see Using Markdown in Amazon.

9. In the **Workflow start time** section, choose one of the following:

   - **Run the operation at a scheduled time** – For **Requested start time**, enter the date and time you propose for running the runbook workflow for this request. For **Estimated end time**, enter the date and time that you expect the runbook workflow to complete. (This time is an estimate only that you're providing for reviewers.)

> **Tip**
>
> Choose **View Change Calendar** to check for any blocking events for the time you specify.

- **Run the operation as soon as possible after approval** – If the change request is approved, the runbook workflow runs as soon as there is a non-restricted period when changes can be made.

10. In the **Change request approvals** section, do the following:

    1. If **Approval type** options are presented, choose one of the following:

       - **Automatic approval** – The change template you selected is configured to allow change requests to run automatically without review by any approvers. Continue to Step 11.

         > **Note**
         >
         > The permissions specified in the IAM policies that govern your use of Systems Manager must not restrict you from submitting auto-approval change requests for them to run automatically.

       - **Specify approvers** – You must add one or more users, groups, or IAM roles to review and approve this change request.

         > **Note**
         >
         > You can choose to specify reviewers even if the permissions specified in the IAM policies that govern your use of Systems Manager allow you to run auto-approval change requests.

    2. Choose **Add approver**, and then select one or more users, groups, or Amazon Identity and Access Management (IAM) roles from the lists of available reviewers.

       > **Note**
       >
       > One or more approvers might already be specified. This means that mandatory approvers are already specified in the change template you have selected. These approvers can't be removed from the request. If the **Add approver** button isn't

available, the template you have chosen doesn't allow additional reviewers to be added to requests.

For more information about approvals for change requests, see About change request approvals.

3. Under **SNS topic to notify approvers**, choose one of the following to specify the Amazon SNS topic in your account to use for sending notifications to the approvers you are adding to this change request.

> **Note**
>
> If the option to specify an Amazon SNS topic isn't available, the change template you selected already specifies the Amazon SNS topic to use.

- **Enter an SNS Amazon Resource Name (ARN)** – For **Topic ARN**, enter the ARN of an existing Amazon SNS topic. This topic can be in any of your organization's accounts.
- **Select an existing SNS topic** – For **Target notification topic**, select the ARN of an existing Amazon SNS topic in your current account. (This option isn't available if you haven't yet created any Amazon SNS topics in your current Amazon Web Services account and Amazon Web Services Region.)

> **Note**
>
> The Amazon SNS topic you select must be configured to specify the notifications it sends and the subscribers they're sent to. Its access policy must also grant permissions to Systems Manager so Change Manager can send notifications. For information, see Configuring Amazon SNS topics for Change Manager notifications.

4. Choose **Add notification**.

11. Choose **Next**.
12. For **IAM role**, select an IAM role *in your current account* that has the permissions needed to run the runbooks that are specified for this change request.

    This role is also referred to as the service role, or assume role, for Automation. For more information about this role, see Setting up Automation.

13. In the **Deployment location** section, choose one of the following:

> **Note**
>
> If you're using Change Manager with a single Amazon Web Services account only and not with an organization set up in Amazon Organizations, you don't need to specify a deployment location.

- **Apply change to this account** – The runbook workflow runs in the current account only. For an organization, this means the delegated administrator account.
- **Apply change to multiple organizational units (OUs)** – Do the following:
  1. For **Accounts and organizational units (OUs)**, enter the ID of a member account in your organization, in the format **123456789012**, or the ID of an organizational unit, in the format **o-o96EXAMPLE**.
  2. (Optional) For **Execution role name**, enter the name of the IAM role *in the target account* or OU that has the permissions needed to run the runbooks that are specified for this change request. All accounts in any OU you specify should use the same name for this role.
  3. (Optional) Choose **Add another target location** for each additional account or OU you want to specify and repeat steps a and b.
  4. For **Target Amazon Web Services Region**, select the Region to make the change in, such as `Ohio (us-east-2)` for the US East (Ohio) Region.
  5. Expand **Rate control**.

     For **Concurrency**, enter a number, then from the list select whether this represents the number or percentage of accounts the runbook workflow can run in at the same time.

     For **Error threshold**, enter a number, then from the list select whether this represents the number or percentage of accounts where runbook workflow can fail before the operation is stopped.

14. In the **Deployment targets** section, do the following:

    1. Choose one of the following:

- **Single resource** – The change is to be made for just one resource. For example, a single node or a single Amazon Machine Image (AMI), depending on the operation defined in the runbooks for this change request.
- **Multiple resources** – For **Parameter**, select from the available parameters from the runbooks for this change request. This selection reflects the type of resource being updated.

  For example, if the runbook for this change request is `AWS-RetartEC2Instance`, you might choose `InstanceId`, and then define which instances are updated by selecting from the following:

  - **Specify tags** – Enter a key-value pair that all resources to be updated are tagged with.
  - **Choose a resource group** – Choose the name of the resource group that all resources to be updated belong to.
  - **Specify parameter values** – Identify the resources to update in the **Runbook parameters** section.
  - **Target all instances** – Make the change on all managed nodes in the target locations.

2. If you chose **Multiple resources**, expand **Rate control**.

   For **Concurrency**, enter a number, then from the list select whether this represents the number or percentage of targets the runbook workflow can update at the same time.

   For **Error threshold**, enter a number, then from the list select whether this represents the number or percentage of targets where the update can fail before the operation is stopped.

15. If you chose **Specify parameter values** to update multiple resources in the previous step: In the **Runbook parameters** section, specify values for the required input parameters. The parameter values you must supply are based on the contents of the Automation runbooks associated with the change template you chose.

    For example, if the change template uses the `AWS-RetartEC2Instance` runbook, then you must enter one or more instance IDs for the **InstanceId** parameter. Alternatively, choose **Show interactive instance picker** and select available instances one by one.

16. Choose **Next**.

17. In the **Review and submit** page, double-check the resources and options you have specified for this change request.

    Choose the **Edit** button for any section you want to make changes to.

When you're satisfied with the change request details, choose **Submit for approval**.

If an Amazon SNS topic has been specified in the change template you chose for the request, notifications are sent when the request is rejected or approved. If you don't receive notifications for the request, you can return to Change Manager to check the status of your request.

Creating change requests (Amazon CLI)

You can create a change request using the Amazon Command Line Interface (Amazon CLI) by specifying options and parameters for the change request in a JSON file and using the `--cli-input-json` option to include it in your command.

To create a change request (Amazon CLI)

1. Install and configure the Amazon CLI or the Amazon Tools for PowerShell, if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI and Installing the Amazon Tools for PowerShell.

2. Create a JSON file on your local machine with a name such as `MyChangeRequest.json` and paste the following content into it.

   Replace *`placeholders`* with values for your change request.

   > **Note**
   >
   > This sample JSON creates a change request using the `AWS-HelloWorldChangeTemplate` change template and `AWS-HelloWorld` runbook. To help you adapt this sample for your own change requests, see StartChangeRequestExecution in the *Amazon Systems Manager API Reference* for information about all available parameters
   > For more information about approvals for change requests, see About change request approvals.

                ]
            }
        }
    ],
    "ChangeDetails": "### Document Name: HelloWorldChangeTemplate\n\n## What does
 this document do?\nThis change template demonstrates the feature set available
 for creating change templates for Change Manager. This template starts a Runbook
 workflow for the Automation document called AWS-HelloWorld.\n\n## Input Parameters
\n* ApproverSnsTopicArn: (Required) Amazon Simple Notification Service ARN for
 approvers.\n* Approver: (Required) The name of the approver to send this request
 to.\n* ApproverType: (Required) The type of reviewer.\n  * Allowed Values:
 IamUser, IamGroup, IamRole, SSOGroup, SSOUser\n\n## Output Parameters\nThis
 document has no outputs \n"
}
```

3. In the directory where you created the JSON file, run the following command.

```
aws ssm start-change-request-execution --cli-input-json file://MyChangeRequest.json
```

The system returns information like the following.

```
{
    "AutomationExecutionId": "b3c1357a-5756-4839-8617-2d2a4EXAMPLE"
}
```

Reviewing and approving or rejecting change requests

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

If you're specified as a reviewer for a change request in Change Manager, a tool in Amazon Systems Manager, you're notified through an Amazon Simple Notification Service (Amazon SNS) topic when a new change request is awaiting your review.

> **Note**
>
> This functionality depends on whether an Amazon SNS was specified in the change template for sending review notifications. For information, see Configuring Amazon SNS topics for Change Manager notifications.

To review the change request, you can follow the link in your notification, or sign in to the Amazon Web Services Management Console directly and follow the steps in this procedure.

> **Note**
>
> If an Amazon SNS topic is assigned for reviewers in a change template, notifications are sent to the topic's subscribers when the change request changes status.

For more information about approvals for change requests, see About change request approvals.

Reviewing and approving or rejecting change requests (console)

The following procedures describe how to use the Systems Manager console to review and approve or reject change requests.

To review and approve or reject a single change request

1. Open the link in the email notification you received and sign in to the Amazon Web Services Management Console, which directs you to the change request for your review.
2. In the summary page, review the proposed content of the change request.

   To approve the change request, choose **Approve**. In the dialog box, provide any comments you want to add for this approval, and then choose **Approve**. The runbook workflow represented by this request starts to run either when scheduled, or as soon as changes aren't blocked by any restrictions.

   -or-

   To reject the change request, choose **Reject**. In the dialog box, provide any comments you want to add for this rejection, and then choose **Reject**.

To review and approve or reject change requests in bulk

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Change Manager**.
3. Choose the **Approvals** tab.
4. (Optional) Review the details of requests pending your approval by choosing the name of each request, and then return to the **Approvals** tab.
5. Select the check box of each change request that you want to approve.

   -or-

   Select the check box of each change request that you want to reject.

6. In the dialog box, provide any comments you want to add for this approval or rejection.
7. Depending on whether you're approving or rejecting the selected change requests, choose **Approve** or **Reject**.

Reviewing and approving or rejecting a change request (command line)

The following procedure describes how to use the Amazon Command Line Interface (Amazon CLI) (on Linux, macOS, or Windows Server) to review and approve or reject a change request.

To review and approve or reject a change request

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.
2. Create a JSON file on your local machine that specifies the parameters for your Amazon CLI call.

```
{
  "OpsItemFilters":
  [
    {
      "Key": "OpsItemType",
      "Values": ["/aws/changerequest"],
      "Operator": "Equal"
    }
  ],
  "MaxResults": number
}
```

   You can filter the results for a specific approver by specifying the approver's Amazon Resource Name (ARN) in the JSON file. Here is an example.

```
{
  "OpsItemFilters":
  [
    {
      "Key": "OpsItemType",
      "Values": ["/aws/changerequest"],
      "Operator": "Equal"
```

```
    },
    {
      "Key": "ChangeRequestByApproverArn",
      "Values": ["arn:aws-cn:iam::account-id:user/user-name"],
      "Operator": "Equal"
    }
  ],
  "MaxResults": number
}
```

3. Run the following command to view the maximum number of change requests you specified in the JSON file.

   Linux & macOS

   ```
   aws ssm describe-ops-items \
   --cli-input-json file://filename.json
   ```

   Windows

   ```
   aws ssm describe-ops-items ^
   --cli-input-json file://filename.json
   ```

4. Run the following command to approve or reject a change request.

   Linux & macOS

   ```
   aws ssm send-automation-signal \
       --automation-execution-id ID \
       --signal-type Approve_or_Reject \
       --payload Comment="message"
   ```

   Windows

   ```
   aws ssm send-automation-signal ^
   --automation-execution-id ID ^
       --signal-type Approve_or_Reject ^
       --payload Comment="message"
   ```

If an Amazon SNS topic has been specified in the change template you chose for the request, notifications are sent when the request is rejected or approved. If you don't receive notifications for the request, you can return to Change Manager to check the status of your request. For information about other options when using this command, see send-automation-signal in the Amazon Systems Manager section of the *Amazon CLI Command Reference*.

Reviewing change request details, tasks, and timelines (console)

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

You can view information about a change request, including requests for which changes have already been processed, in the dashboard of Change Manager, a tool in Amazon Systems Manager. These details include a link to the Automation operation that runs the runbooks that make the change. An Automation execution ID is generated when the request is created, but the process doesn't run until all approvals have been given and no restrictions are in place to block the change.

To review change request details, tasks, and timelines

1. In the navigation pane, choose **Change Manager**.
2. Choose the **Requests** tab.
3. In the **Change requests** section, search for the change request you want to review.

   You can use the **Create date range** options to limit results to a specific time period.

   You can filter requests by the following properties:

   - `Status`
   - `Request ID`
   - `Approver`
   - `Requester`

For example, to view details about all change requests that have completed successfully in the past 24 hours, do the following:

1. For **Create date range**, choose **1d**.
2. In the search box, select **Status, CompletedWithSuccess**.
3. In the results, choose the name of the successfully completed change request to review results for.

4. View information about the change request on the following tabs:

- **Request details** – View basic details about the change request, including the requester, the change template, and the Automation runbooks selected for the change. You can also follow a link to the Automation operation details and view information about any runbook parameters specified in the request, Amazon CloudWatch alarms assigned to the change request, and approvals and comments provided for the request.
- **Task** – View information about the task in the change, including task status for completed change requests, the targeted resources, the steps in the associated Automation runbooks, and concurrency and error threshold details.
- **Timeline** – View a summary of all events associated with the change request, listed by date and time. The summary indicates when the change request was created, actions by assigned approvers, a note of when approved change requests are scheduled to run, runbook workflow details, and status changes for the overall change process and each step in the runbook.
- **Associated events** – View auditable details about change requests that are recorded in Amazon CloudTrail Lake. Details include which API actions were run, the request parameters included for those actions, the user account that ran the action, the resources updated during the process, and more.

  When you enable CloudTrail Lake event tracking, CloudTrail Lake creates an event data store for events related to your change requests. The event details are available for the account or organization where the change request ran. You can turn on CloudTrail Lake event tracking from any change request in your account or organization. For information about enabling CloudTrail Lake integration and creating an event data store, see Monitoring your change request events.

> **Note**
>
> There is a charge to use **CloudTrail Lake**. For details, see Amazon CloudTrail pricing.

Viewing aggregated counts of change requests (command line)

> **Change Manager availability change**
>
> Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

You can view aggregated counts of change requests in Change Manager, a tool in Amazon Systems Manager, by using the GetOpsSummary API operation. This API operation can return counts for a single Amazon Web Services account in a single Amazon Web Services Region or for multiple accounts and multiple Regions.

> **Note**
>
> If you want to view aggregated counts of change requests for multiple Amazon Web Services accounts and multiple Amazon Web Services Regions, you must set up and configure a resource data sync. For more information, see Creating a resource data sync for Inventory.

The following procedure describes how to use the Amazon Command Line Interface (Amazon CLI) (on Linux, macOS, or Windows Server) to view aggregated counts of change requests.

To view aggregated counts of change requests

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.
2. Run one of the following commands.

Single account and Region

This command returns a count of all change requests for the Amazon Web Services account and Amazon Web Services Region for which your Amazon CLI session is configured.

Linux & macOS

```
aws ssm get-ops-summary \
--filters Key=AWS:OpsItem.OpsItemType,Values="/aws/changerequests",Type=Equal \
--aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem
```

Windows

```
aws ssm get-ops-summary ^
--filters Key=AWS:OpsItem.OpsItemType,Values="/aws/changerequests",Type=Equal ^
--aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem
```

The call returns information like the following.

```
{
    "Entities": [
        {
            "Data": {
                "AWS:OpsItem": {
                    "Content": [
                        {
                            "Count": "38",
                            "Status": "Open"
                        }
                    ]
                }
            }
        }
    ]
}
```

Multiple accounts and/or Regions

This command returns a count of all change requests for the Amazon Web Services accounts and Amazon Web Services Regions specified in the resource data sync.

Linux & macOS

```
aws ssm get-ops-summary \
    --sync-name resource_data_sync_name \
    --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal \
    --aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem
```

Windows

```
aws ssm get-ops-summary ^
    --sync-name resource_data_sync_name ^
    --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal ^
    --aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem
```

The call returns information like the following.

```
{
    "Entities": [
        {
            "Data": {
                "AWS:OpsItem": {
                    "Content": [
                        {
                            "Count": "43",
                            "Status": "Open"
                        },
                        {
                            "Count": "2",
                            "Status": "Resolved"
                        }
                    ]
                }
            }
        }
    ]
```

```
}
```

Multiple accounts and a specific Region

This command returns a count of all change requests for the Amazon Web Services accounts specified in the resource data sync. However, it only returns data from the Region specified in the command.

Linux & macOS

```
aws ssm get-ops-summary \
    --sync-name resource_data_sync_name \
    --filters Key=AWS:OpsItem.SourceRegion,Values='Region',Type=Equal
 Key=AWS:OpsItem.OpsItemType,Values="/aws/changerequests",Type=Equal \
    --aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem
```

Windows

```
aws ssm get-ops-summary ^
    --sync-name resource_data_sync_name ^
    --filters Key=AWS:OpsItem.SourceRegion,Values='Region',Type=Equal
 Key=AWS:OpsItem.OpsItemType,Values="/aws/changerequests",Type=Equal ^
    --aggregators AggregatorType=count,AttributeName=Status,TypeName=AWS:OpsItem
```

Multiple accounts and Regions with output grouped by Region

This command returns a count of all change requests for the Amazon Web Services accounts and Amazon Web Services Regions specified in the resource data sync. The output displays count information per Region.

Linux & macOS

```
aws ssm get-ops-summary \
    --sync-name resource_data_sync_name \
    --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal \
    --aggregators
 '[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"Status","Aggregat
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceRegion"}]}]'
```

Windows

```
aws ssm get-ops-summary ^
    --sync-name resource_data_sync_name ^
    --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal ^
    --aggregators
 '[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"Status","Aggregat
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceRegion"}]}]'
```

The call returns information like the following.

```
{
        "Entities": [
            {
                "Data": {
                    "AWS:OpsItem": {
                        "Content": [
                            {
                                "Count": "38",
                                "SourceRegion": "us-east-1",
                                "Status": "Open"
                            },
                            {
                                "Count": "4",
                                "SourceRegion": "us-east-2",
                                "Status": "Open"
                            },
                            {
                                "Count": "1",
                                "SourceRegion": "us-west-1",
                                "Status": "Open"
                            },
                            {
                                "Count": "2",
                                "SourceRegion": "us-east-2",
                                "Status": "Resolved"
                            }
                        ]
                    }
                }
```

```
            }
        ]
    }
```

Multiple accounts and Regions with output grouped by accounts and Regions

This command returns a count of all change requests for the Amazon Web Services accounts and Amazon Web Services Regions specified in the resource data sync. The output groups the count information by accounts and Regions.

Linux & macOS

```
aws ssm get-ops-summary \
    --sync-name resource_data_sync_name \
    --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal \
    --aggregators
 '[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"Status","Aggregat
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceAccountId","A
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceRegion"}]}]}]
```

Windows

```
aws ssm get-ops-summary ^
    --sync-name resource_data_sync_name ^
    --filters Key=AWS:OpsItem.OpsItemType,Values="/aws/
changerequests",Type=Equal ^
    --aggregators
 '[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"Status","Aggregat
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceAccountId","A
[{"AggregatorType":"count","TypeName":"AWS:OpsItem","AttributeName":"SourceRegion"}]}]}]
```

The call returns information like the following.

```
{
    "Entities": [
        {
            "Data": {
                "AWS:OpsItem": {
                    "Content": [
```

```
                        {
                            "Count": "38",
                            "SourceAccountId": "123456789012",
                            "SourceRegion": "us-east-1",
                            "Status": "Open"
                        },
                        {
                            "Count": "4",
                            "SourceAccountId": "111122223333",
                            "SourceRegion": "us-east-2",
                            "Status": "Open"
                        },
                        {
                            "Count": "1",
                            "SourceAccountId": "111122223333",
                            "SourceRegion": "us-west-1",
                            "Status": "Open"
                        },
                        {
                            "Count": "2",
                            "SourceAccountId": "444455556666",
                            "SourceRegion": "us-east-2",
                            "Status": "Resolved"
                        },
                        {
                            "Count": "1",
                            "SourceAccountId": "222222222222",
                            "SourceRegion": "us-east-1",
                            "Status": "Open"
                        }
                    ]
                }
            }
        }
    ]
}
```

Auditing and logging Change Manager activity

Change Manager availability change

Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

You can audit activity in Change Manager by using Amazon CloudWatch and Amazon CloudTrail alarms.

For more information about auditing and logging options for Systems Manager, see Logging and monitoring in Amazon Systems Manager.

Audit Change Manager activity using CloudWatch alarms

You can configure and assign a CloudWatch alarm to a change template. If any conditions defined in the alarm are met, the actions specified for the alarm are taken. In the alarm configuration, you can specify an Amazon Simple Notification Service (Amazon SNS) topic to notify when an alarm condition is met.

For information about creating a Change Manager template, see Working with change templates.

For information about creating CloudWatch alarms, see Using CloudWatch Alarms in the *Amazon CloudWatch User Guide*.

Audit Change Manager activity using CloudTrail

CloudTrail captures API calls made in the Systems Manager console, the Amazon Command Line Interface (Amazon CLI), and the Systems Manager SDK. You can view the information in the CloudTrail console or in an Amazon Simple Storage Service (Amazon S3) bucket, where it's stored. One bucket is used for all CloudTrail logs for your account.

Logs of Change Manager actions show change template document creation, change template and change request approvals and rejections, activity generated by Automation runbooks, and more. For more information about viewing and using CloudTrail logs of Systems Manager activity, see Logging Amazon Systems Manager API calls with Amazon CloudTrail.

Troubleshooting Change Manager

Change Manager availability change

Amazon Systems Manager Change Manager will no longer be open to new customers starting November 7, 2025. If you would like to use Change Manager, sign up prior to that date. Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Change Manager availability change.

Use the following information to help you troubleshoot problems with Change Manager, a tool in Amazon Systems Manager.

Topics

- "Group {GUID} not found" error during change request approvals when using Active Directory (groups

"Group *{GUID}* not found" error during change request approvals when using Active Directory (groups

Problem: When Amazon IAM Identity Center (IAM Identity Center) is used for user identity management, a member of an Active Directory group who is granted approval permissions in Change Manager receives a "not authorized" or "group not found" error.

- **Solution**: When you select Active Directory groups in IAM Identity Center for access to the Amazon Web Services Management Console, the system schedules a periodic synchronization that copies information from those Active Directory groups into IAM Identity Center. This process must complete before users authorized through Active Directory group membership can successfully approve a request. For more information, see Connect to your Microsoft AD directory in the *Amazon IAM Identity Center User Guide*.

Amazon Systems Manager Documents

An Amazon Systems Manager document (SSM document) defines the actions that Systems Manager performs on your managed instances. Systems Manager includes more than 100 pre-configured documents that you can use by specifying parameters at runtime. You can find pre-configured documents in the Systems Manager Documents console by choosing the **Owned by**

Amazon tab, or by specifying Amazon for the `Owner` filter when calling the `ListDocuments` API operation. Documents use JavaScript Object Notation (JSON) or YAML, and they include steps and parameters that you specify.

For enhanced security, as of July 14th, 2025, SSM documents support environment variable interpolation when processing parameters. This feature, available in schema version 2.2 and with SSM Agent version 3.3.2746.0 or higher, helps prevent command injection attacks.

To get started with SSM documents, open the Systems Manager console. In the navigation pane, choose **Documents**.

> **Important**
>
> In Systems Manager, an *Amazon-owned* SSM document is a document created and managed by Amazon Web Services itself. *Amazon-owned* documents include a prefix like `AWS-*` in the document name. The owner of the document is considered to be Amazon, not a specific user account within Amazon. These documents are publicly available for all to use.

How can the Documents tool benefit my organization?

Documents offers these benefits:

- **Document categories**

  To help you find the documents you need, choose a category depending on the type of document you're searching for. To broaden your search, you can choose multiple categories of the same document type. Choosing categories of different document types is not supported. Categories are only supported for documents owned by Amazon.

- **Document versions**

  You can create and save different versions of documents. You can then specify a default version for each document. The default version of a document can be updated to a newer version or reverted to an older version of the document. When you change the content of a document, Systems Manager automatically increments the version of the document. You can retrieve or use any version of a document by specifying the document version in the console, Amazon Command Line Interface (Amazon CLI) commands, or API calls.

- **Customize documents for your needs**

If you want to customize the steps and actions in a document, you can create your own. The system stores the document with your Amazon Web Services account in the Amazon Web Services Region you create it in. For more information about how to create an SSM document, see Creating SSM document content.

- **Tag documents**

  You can tag your documents to help you quickly identify one or more documents based on the tags you've assigned to them. For example, you can tag documents for specific environments, departments, users, groups, or periods. You can also restrict access to documents by creating an Amazon Identity and Access Management (IAM) policy that specifies the tags that a user or group can access.

- **Share documents**

  You can make your documents public or share them with specific Amazon Web Services accounts in the same Amazon Web Services Region. Sharing documents between accounts can be useful if, for example, you want all of the Amazon Elastic Compute Cloud (Amazon EC2) instances that you supply to customers or employees to have the same configuration. In addition to keeping applications or patches on the instances up to date, you might want to restrict customer instances from certain activities. Or you might want to make sure that the instances used by employee accounts throughout your organization are granted access to specific internal resources. For more information, see Sharing SSM documents.

Who should use Documents?

- Any Amazon customer who wants to use Systems Manager tools to improve their operational efficiency at scale, reduce errors associated with manual intervention, and reduce time to resolution of common issues.
- Infrastructure experts who want to automate deployment and configuration tasks.
- Administrators who want to reliably resolve common issues, improve troubleshooting efficiency, and reduce repetitive operations.
- Users who want to automate a task they normally perform manually.

What are the types of SSM documents?

The following table describes the different types of SSM documents and their uses.

Type	Use with	Details
ApplicationConfiguration ApplicationConfigurationSchema	Amazon AppConfig	Amazon AppConfig lets you create, manage, and quickly deploy application configurations. You can store configuration data in an SSM document by creating a document that uses the `ApplicationConfiguration` document type. For more information, see Freeform configurations in the *Amazon AppConfig User Guide*. If you create a configuration in an SSM document, then you must specify a corresponding JSON Schema. The schema uses the `ApplicationConfigurationSchema` document type and, like a set of rules, defines the allowable properties for each application configuration setting. For more information, see About validators in the *Amazon AppConfig User Guide*.
Automation runbook	Automation State Manager Maintenance Windows	Use Automation runbooks when performing common maintenance and deployment tasks such as creating or updating an Amazon Machine Image (AMI). State Manager

Type	Use with	Details
		uses Automation runbooks to apply a configuration. These actions can be run on one or more targets at any point during the lifecycle of an instance. Maintenance Windows uses Automation runbooks to perform common maintenance and deployment tasks based on the specified schedule. All Automation runbooks that are supported for Linux-based operating systems are also supported on EC2 instances for macOS.
Change Calendar document	Change Calendar	Change Calendar uses the `ChangeCalendar` document type. A Change Calendar document stores a calendar entry and associated events that can allow or prevent Automation actions from changing your environment. In Change Calendar, a document stores iCalendar 2.0 data in plaintext format. Change Calendar isn't supported on EC2 instances for macOS.

Type	Use with	Details
Amazon CloudFormation template	Amazon CloudFormation	Amazon CloudFormation templates describe the resources that you want to provision in your CloudFormation stacks. By storing CloudFormation templates as Systems Manager documents, you can benefit from Systems Manager document features. These include creating and comparing multiple versions of your template, and sharing your template with other accounts in the same Amazon Web Services Region. You can create and edit CloudFormation templates and stacks by using Application Manager. For more information, see Working with Amazon CloudFormation templates and stacks in Application Manager.

Type	Use with	Details
Command document	Run Command State Manager Maintenance Windows	Run Command uses Command documents to run commands. State Manager uses command documents to apply a configuration. These actions can be run on one or more targets at any point during the lifecycle of an instance. Maintenance Windows uses Command documents to apply a configuration based on the specified schedule. Most Command documents are supported on all Linux and Windows Server operating systems supported by Systems Manager. The following Command documents are supported on EC2 instances for macOS: • `AWS-ConfigureAWSPackage` • `AWS-RunPatchBaseline` • `AWS-RunPatchBaselineAssociation` • `AWS-RunShellScript`

Type	Use with	Details
Amazon Config conformance pack template	Amazon Config	Amazon Config conformance pack templates are YAML formatted documents used to create conformance packs that contains the list of Amazon Config managed or custom rules and remediation actions. For more information, see Conformance Packs.
Package document	Distributor	In Distributor, a package is represented by an SSM document. A package document includes attached ZIP archive files that contain software or assets to install on managed instances . Creating a package in Distributor creates the package document. Distributor isn't supported on Oracle Linux and macOS managed instances.

Type	Use with	Details
Policy document	State Manager	Inventory uses the `AWS-GatherSoftwareInventory` Policy document with a State Manager association to collect inventory data from managed instances. When creating your own SSM documents, Automation runbooks and Command documents are the preferred method for enforcing a policy on a managed instance. Systems Manager Inventory and the `AWS-GatherSoftwareInventory` Policy document are supported on all operating systems supported by Systems Manager.
Post-incident analysis template	Incident Manager post-incident analysis	Incident Manager uses the post-incident analysis template to create an analysis based on Amazon operations management best practices. Use the template to create an analysis that your team can use to identify improvements to your incident response.

Type	Use with	Details
Session document	Session Manager	Session Manager uses Session documents to determine which type of session to start. Examples include port forwarding sessions, interactive command sessions, and SSH tunnels. Session documents are supported on all Linux and Windows Server operating systems supported by Systems Manager. The following Command documents are supported on EC2 instances for macOS: • `AWS-PasswordReset` • `AWS-StartInteractiveCommand` • `AWS-StartPortForwardingSession` • `AWS-StartPortForwardingSessionToSocket` • `AWS-StartSSHSession`

SSM document quotas

For information about SSM document quotas, see Systems Manager service quotas in the *Amazon Web Services General Reference*.

Document components

This section includes information about the components that make up SSM documents.

Contents

- Schemas, features, and examples
- Data elements and parameters
- Command document plugin reference

Schemas, features, and examples

Amazon Systems Manager (SSM) documents use the following schema versions.

- Documents of type `Command` can use schema version 1.2, 2.0, and 2.2. If you use schema 1.2 documents, we recommend that you create documents that use schema version 2.2.
- Documents of type `Policy` must use schema version 2.0 or later.
- Documents of type `Automation` must use schema version 0.3.
- Documents of type `Session` must use schema version 1.0.
- You can create documents in JSON or YAML.

For more information about `Session` document schema, see Session document schema.

By using the latest schema version for `Command` and `Policy` documents, you can take advantage of the following features.

Schema version 2.2 document features

Feature	Details
Document editing	Documents can now be updated. With version 1.2, any update to a document required that you save it with a different name.

Feature	Details
Automatic versioning	Any update to a document creates a new version. This isn't a schema version, but a version of the document.
Default version	If you have multiple versions of a document, you can specify which version is the default document.
Sequencing	Plugins or *steps* in a document run in the order that you specified.
Cross-platform support	Cross-platform support lets you specify different operating systems for different plugins within the same SSM document. Cross-platform support uses the `precondition` parameter within a step.
Parameter interpolation	Interpolation means to insert or substitute a variable value into a string. Think of it as filling in a blank space with actual values before the string is used. In the context of SSM documents, parameter interpolation allows string parameters to be interpolated into environment variables before command execution, providing better security against command injections. When set to `ENV_VAR`, the agent creates an environment variable named `SSM_`*`parameter-name`* that contains the parameter's value.

Note

You must keep Amazon Systems Manager SSM Agent on your instances updated with the latest version to use new Systems Manager features and SSM document features. For more information, see Updating the SSM Agent using Run Command.

The following table lists the differences between major schema versions.

Version 1.2	Version 2.2 (latest version)	Details
runtimeConfig	mainSteps	In version 2.2, the `mainSteps` section replaces `runtimeConfig`. The `mainSteps` section allows Systems Manager to run steps in sequence.
properties	inputs	In version 2.2, the `inputs` section replaces the `properties` section. The `inputs` section accepts parameters for steps.
commands	runCommand	In version 2.2, the `inputs` section takes the `runCommand` parameter instead of the `commands` parameter.
id	action	In version 2.2, `Action` replaces `ID`. This is just a name change.
not applicable	name	In version 2.2, `name` is any user-defined name for a step.

Using the precondition parameter

With schema version 2.2 or later, you can use the `precondition` parameter to specify the target operating system for each plugin or to validate input parameters you've defined in your SSM document. The `precondition` parameter supports referencing your SSM document's input parameters, and `platformType` using values of `Linux`, `MacOS`, and `Windows`. Only the `StringEquals` operator is supported.

For documents that use schema version 2.2 or later, if `precondition` isn't specified, each plugin is either run or skipped based on the plugin's compatibility with the operating system. Plugin compatibility with the operating system is evaluated before the `precondition`. For documents that use schema 2.0 or earlier, incompatible plugins throw an error.

For example, in a schema version 2.2 document, if `precondition` isn't specified and the `aws:runShellScript` plugin is listed, the step runs on Linux instances but is skipped on Windows Server instances. This is because `aws:runShellScript` isn't compatible with Windows Server. In a schema version 2.0 document, specifying `aws:runShellScript` and running the document on a Windows Server instance causes the execution to fail.

Schema version 2.2

Top-level elements

The following example shows the top-level elements of an SSM document using schema version 2.2.

YAML

```
---
schemaVersion: "2.2"
description: A description of the document.
parameters:
  parameter 1:
    property 1: "value"
    property 2: "value"
  parameter 2:
    property 1: "value"
    property 2: "value"
mainSteps:
  - action: Plugin name
    name: A name for the step.
    inputs:
      input 1: "value"
```

```
      input 2: "value"
      input 3: "{{ parameter 1 }}"
```

JSON

```
{
   "schemaVersion": "2.2",
   "description": "A description of the document.",
   "parameters": {
       "parameter 1": {
          "property 1": "value",
          "property 2": "value"
       },
       "parameter 2":{
          "property 1": "value",
          "property 2": "value"
       }
    },
   "mainSteps": [
      {
         "action": "Plugin name",
         "name": "A name for the step.",
         "inputs": {
            "input 1": "value",
            "input 2": "value",
            "input 3": "{{ parameter 1 }}"
         }
      }
   ]
}
```

Schema version 2.2 example

The following example uses the `aws:runPowerShellScript` plugin to run a PowerShell command on the target instances.

YAML

```
---
schemaVersion: "2.2"
description: "Example document"
parameters:
```

```
  Message:
    type: "String"
    description: "Example parameter"
    default: "Hello World"
    allowedValues:
    - "Hello World"
mainSteps:
  - action: "aws:runPowerShellScript"
    name: "example"
    inputs:
      timeoutSeconds: '60'
      runCommand:
      - "Write-Output {{Message}}"
```

JSON

```
{
   "schemaVersion": "2.2",
   "description": "Example document",
   "parameters": {
      "Message": {
         "type": "String",
         "description": "Example parameter",
         "default": "Hello World",
         "allowedValues": ["Hello World"]
      }
   },
   "mainSteps": [
      {
         "action": "aws:runPowerShellScript",
         "name": "example",
         "inputs": {
            "timeoutSeconds": "60",
            "runCommand": [
               "Write-Output {{Message}}"
            ]
         }
      }
   ]
}
```

Schema version 2.2 precondition parameter examples

Schema version 2.2 provides cross-platform support. This means that within a single SSM document you can specify different operating systems for different plugins. Cross-platform support uses the `precondition` parameter within a step, as shown in the following example. You can also use the `precondition` parameter to validate input parameters you've defined in your SSM document. You can see this in the second of the following examples.

YAML

```
---
schemaVersion: '2.2'
description: cross-platform sample
mainSteps:
- action: aws:runPowerShellScript
  name: PatchWindows
  precondition:
    StringEquals:
    - platformType
    - Windows
  inputs:
    runCommand:
    - cmds
- action: aws:runShellScript
  name: PatchLinux
  precondition:
    StringEquals:
    - platformType
    - Linux
  inputs:
    runCommand:
    - cmds
```

JSON

```
{
   "schemaVersion": "2.2",
   "description": "cross-platform sample",
   "mainSteps": [
      {
         "action": "aws:runPowerShellScript",
         "name": "PatchWindows",
         "precondition": {
            "StringEquals": [
```

```
                "platformType",
                "Windows"
            ]
         },
         "inputs": {
            "runCommand": [
               "cmds"
            ]
         }
      },
      {
         "action": "aws:runShellScript",
         "name": "PatchLinux",
         "precondition": {
            "StringEquals": [
               "platformType",
               "Linux"
            ]
         },
         "inputs": {
            "runCommand": [
               "cmds"
            ]
         }
      }
   ]
}
```

YAML

```
---
schemaVersion: '2.2'
parameters:
  action:
    type: String
    allowedValues:
    - Install
    - Uninstall
  confirmed:
    type: String
    allowedValues:
    - True
```

```
    - False
mainSteps:
- action: aws:runShellScript
  name: InstallAwsCLI
  precondition:
    StringEquals:
    - "{{ action }}"
    - "Install"
  inputs:
    runCommand:
    - sudo apt install aws-cli
- action: aws:runShellScript
  name: UninstallAwsCLI
  precondition:
    StringEquals:
    - "{{ action }} {{ confirmed }}"
    - "Uninstall True"
  inputs:
    runCommand:
    - sudo apt remove aws-cli
```

JSON

```
{
   "schemaVersion": "2.2",
   "parameters": {
      "action": {
         "type": "String",
         "allowedValues": [
            "Install",
            "Uninstall"
         ]
      },
      "confirmed": {
         "type": "String",
         "allowedValues": [
            true,
            false
         ]
      }
   },
   "mainSteps": [
      {
```

```
         "action": "aws:runShellScript",
         "name": "InstallAwsCLI",
         "precondition": {
            "StringEquals": [
               "{{ action }}",
               "Install"
            ]
         },
         "inputs": {
            "runCommand": [
               "sudo apt install aws-cli"
            ]
         }
      },
      {
         "action": "aws:runShellScript",
         "name": "UninstallAwsCLI",
         "precondition": {
            "StringEquals": [
               "{{ action }} {{ confirmed }}",
               "Uninstall True"
            ]
         },
         "inputs": {
            "runCommand": [
               "sudo apt remove aws-cli"
            ]
         }
      }
   ]
}
```

Schema version 2.2 interpolation example with SSM Agent versions before 3.3.2746.0

On SSM Agent versions prior to 3.3.2746.0, the agent ignores the `interpolationType` parameter and instead performs a raw string substitution. If you are referencing SSM_*parameter-name* explicitly, you must set this explicitly. In the following example for Linux, the SSM_Message environment variable is referenced explicitly.

```
{
    "schemaVersion": "2.2",
```

```
    "description": "An example document",
    "parameters": {
        "Message": {
            "type": "String",
            "description": "Message to be printed",
            "default": "Hello",
            "interpolationType" : "ENV_VAR",
      "allowedPattern: "^[^"]*$"

        }
    },
    "mainSteps": [{
        "action": "aws:runShellScript",
        "name": "printMessage",
        "inputs": {
            "runCommand": [
              "if [ -z "${SSM_Message+x}" ]; then",
              "    export SSM_Message=\"{{Message}}\"",
              "fi",
              "",
              "echo $SSM_Message"
            ]
        }
    }
}
```

Note

`allowedPattern` isn't technically required if an SSM document doesn't use double braces: `{{ }}`

Schema version 2.2 State Manager example

You can use the following SSM document with State Manager to download and install the ClamAV antivirus software. State Manager enforces a specific configuration, which means that each time the State Manager association is run, the system checks to see if the ClamAV software is installed. If not, State Manager reruns this document.

YAML

```
---
```

```
schemaVersion: '2.2'
description: State Manager Bootstrap Example
parameters: {}
mainSteps:
- action: aws:runShellScript
  name: configureServer
  inputs:
    runCommand:
    - sudo yum install -y httpd24
    - sudo yum --enablerepo=epel install -y clamav
```

JSON

```
{
   "schemaVersion": "2.2",
   "description": "State Manager Bootstrap Example",
   "parameters": {},
   "mainSteps": [
      {
         "action": "aws:runShellScript",
         "name": "configureServer",
         "inputs": {
            "runCommand": [
               "sudo yum install -y httpd24",
               "sudo yum --enablerepo=epel install -y clamav"
            ]
         }
      }
   ]
}
```

Schema version 2.2 Inventory example

You can use the following SSM document with State Manager to collect inventory metadata about your instances.

YAML

```
---
schemaVersion: '2.2'
description: Software Inventory Policy Document.
parameters:
```

```
  applications:
    type: String
    default: Enabled
    description: "(Optional) Collect data for installed applications."
    allowedValues:
    - Enabled
    - Disabled
  awsComponents:
    type: String
    default: Enabled
    description: "(Optional) Collect data for Amazon Components like amazon-ssm-
agent."
    allowedValues:
    - Enabled
    - Disabled
  networkConfig:
    type: String
    default: Enabled
    description: "(Optional) Collect data for Network configurations."
    allowedValues:
    - Enabled
    - Disabled
  windowsUpdates:
    type: String
    default: Enabled
    description: "(Optional) Collect data for all Windows Updates."
    allowedValues:
    - Enabled
    - Disabled
  instanceDetailedInformation:
    type: String
    default: Enabled
    description: "(Optional) Collect additional information about the instance,
 including
      the CPU model, speed, and the number of cores, to name a few."
    allowedValues:
    - Enabled
    - Disabled
  customInventory:
    type: String
    default: Enabled
    description: "(Optional) Collect data for custom inventory."
    allowedValues:
    - Enabled
```

```
    - Disabled
mainSteps:
- action: aws:softwareInventory
  name: collectSoftwareInventoryItems
  inputs:
    applications: "{{ applications }}"
    awsComponents: "{{ awsComponents }}"
    networkConfig: "{{ networkConfig }}"
    windowsUpdates: "{{ windowsUpdates }}"
    instanceDetailedInformation: "{{ instanceDetailedInformation }}"
    customInventory: "{{ customInventory }}"
```

JSON

```
{
   "schemaVersion": "2.2",
   "description": "Software Inventory Policy Document.",
   "parameters": {
      "applications": {
         "type": "String",
         "default": "Enabled",
         "description": "(Optional) Collect data for installed applications.",
         "allowedValues": [
            "Enabled",
            "Disabled"
         ]
      },
      "awsComponents": {
         "type": "String",
         "default": "Enabled",
         "description": "(Optional) Collect data for Amazon Components like amazon-
ssm-agent.",
         "allowedValues": [
            "Enabled",
            "Disabled"
         ]
      },
      "networkConfig": {
         "type": "String",
         "default": "Enabled",
         "description": "(Optional) Collect data for Network configurations.",
         "allowedValues": [
            "Enabled",
```

```
            "Disabled"
         ]
      },
      "windowsUpdates": {
         "type": "String",
         "default": "Enabled",
         "description": "(Optional) Collect data for all Windows Updates.",
         "allowedValues": [
            "Enabled",
            "Disabled"
         ]
      },
      "instanceDetailedInformation": {
         "type": "String",
         "default": "Enabled",
         "description": "(Optional) Collect additional information about the
instance, including\nthe CPU model, speed, and the number of cores, to name a
few.",
         "allowedValues": [
            "Enabled",
            "Disabled"
         ]
      },
      "customInventory": {
         "type": "String",
         "default": "Enabled",
         "description": "(Optional) Collect data for custom inventory.",
         "allowedValues": [
            "Enabled",
            "Disabled"
         ]
      }
   },
   "mainSteps": [
      {
         "action": "aws:softwareInventory",
         "name": "collectSoftwareInventoryItems",
         "inputs": {
            "applications": "{{ applications }}",
            "awsComponents": "{{ awsComponents }}",
            "networkConfig": "{{ networkConfig }}",
            "windowsUpdates": "{{ windowsUpdates }}",
            "instanceDetailedInformation": "{{ instanceDetailedInformation }}",
            "customInventory": "{{ customInventory }}"
```

```
        }
      }
   ]
}
```

Schema version 2.2 AWS-ConfigureAWSPackage example

The following example shows the AWS-ConfigureAWSPackage document. The mainSteps section includes the aws:configurePackage plugin in the action step.

> **Note**
>
> On Linux operating systems, only the AmazonCloudWatchAgent and AWSSupport-EC2Rescue packages are supported.

YAML

```
---
schemaVersion: '2.2'
description: 'Install or uninstall the latest version or specified version of an
 Amazon
  package. Available packages include the following: AWSPVDriver,
 AwsEnaNetworkDriver,
  AwsVssComponents, and AmazonCloudWatchAgent, and AWSSupport-EC2Rescue.'
parameters:
  action:
    description: "(Required) Specify whether to install or uninstall the package."
    type: String
    allowedValues:
    - Install
    - Uninstall
  name:
    description: "(Required) The package to install/uninstall."
    type: String
    allowedPattern: "^arn:[a-z0-9][-.a-z0-9]{0,62}:[a-z0-9][-.a-z0-9]{0,62}:([a-
z0-9][-.a-z0-9]{0,62})?:([a-z0-9][-.a-z0-9]{0,62})?:package\\/[a-zA-Z][a-zA-Z0-9\\-
_]{0,39}$|^[a-zA-Z][a-zA-Z0-9\\-_]{0,39}$"
  version:
    type: String
```

```
    description: "(Optional) A specific version of the package to install or
 uninstall."
mainSteps:
- action: aws:configurePackage
  name: configurePackage
  inputs:
    name: "{{ name }}"
    action: "{{ action }}"
    version: "{{ version }}"
```

JSON

```
{

```

Schema version 1.2

The following example shows the top-level elements of a schema version 1.2 document.

```
{
   "schemaVersion":"1.2",
   "description":"A description of the SSM document.",
   "parameters":{
      "parameter 1":{
         "one or more parameter properties"
      },
      "parameter 2":{
         "one or more parameter properties"
      },
      "parameter 3":{
         "one or more parameter properties"
      }
   },
   "runtimeConfig":{
      "plugin 1":{
         "properties":[
            {
               "one or more plugin properties"
            }
         ]
      }
   }
}
```

Schema version 1.2 `aws:runShellScript` example

The following example shows the `AWS-RunShellScript` SSM document. The **runtimeConfig** section includes the `aws:runShellScript` plugin.

```
{
    "schemaVersion":"1.2",
    "description":"Run a shell script or specify the commands to run.",
    "parameters":{
        "commands":{
            "type":"StringList",
            "description":"(Required) Specify a shell script or a command to run.",
            "minItems":1,
            "displayType":"textarea"
        },
        "workingDirectory":{
            "type":"String",
            "default":"",
            "description":"(Optional) The path to the working directory on your
 instance.",
            "maxChars":4096
        },
        "executionTimeout":{
            "type":"String",
            "default":"3600",
            "description":"(Optional) The time in seconds for a command to complete
 before it is considered to have failed. Default is 3600 (1 hour). Maximum is 172800
 (48 hours).",
            "allowedPattern":"([1-9][0-9]{0,3})|(1[0-9]{1,4})|(2[0-7][0-9]{1,3})|
(28[0-7][0-9]{1,2})|(28800)"
        }
    },
    "runtimeConfig":{
        "aws:runShellScript":{
            "properties":[
                {
                    "id":"0.aws:runShellScript",
                    "runCommand":"{{ commands }}",
                    "workingDirectory":"{{ workingDirectory }}",
                    "timeoutSeconds":"{{ executionTimeout }}"
                }
            ]
        }
    }
}
```

Schema version 0.3

Top-level elements

The following example shows the top-level elements of a schema version 0.3 Automation runbook in JSON format.

```
{
    "description": "document-description",
    "schemaVersion": "0.3",
    "assumeRole": "{{assumeRole}}",
    "parameters": {
        "parameter1": {
            "type": "String",
            "description": "parameter-1-description",
            "default": ""
        },
        "parameter2": {
            "type": "String",

```

YAML Automation runbook example

The following sample shows the contents of an Automation runbook, in YAML format. This working example of version 0.3 of the document schema also demonstrates the use of Markdown to format document descriptions.

```
description: >-
  ##Title: LaunchInstanceAndCheckState

  -----

  **Purpose**: This Automation runbook first launches an EC2 instance
  using the AMI ID provided in the parameter ```imageId```. The second step of
  this document continuously checks the instance status check value for the
  launched instance until the status ```ok``` is returned.

  ##Parameters:

  -----

  Name | Type | Description | Default Value

  ------------- | ------------- | ------------- | -------------
```

```
  assumeRole | String | (Optional) The ARN of the role that allows Automation to
  perform the actions on your behalf. | -

  imageId  | String | (Optional) The AMI ID to use for launching the instance.
  The default value uses the latest Amazon Linux AMI ID available. | {{
  ssm:/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-x86_64 }}
schemaVersion: '0.3'
assumeRole: 'arn:aws-cn:iam::111122223333::role/AutomationServiceRole'
parameters:
  imageId:
    type: String
    default: '{{ ssm:/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-
x86_64 }}'
    description: >-
      (Optional) The AMI ID to use for launching the instance. The default value
      uses the latest released Amazon Linux AMI ID.
  tagValue:
    type: String
    default: ' LaunchedBySsmAutomation'
    description: >-
      (Optional) The tag value to add to the instance. The default value is
      LaunchedBySsmAutomation.
  instanceType:
    type: String
    default: t2.micro
    description: >-
      (Optional) The instance type to use for the instance. The default value is
      t2.micro.
mainSteps:
  - name: LaunchEc2Instance
    action: 'aws:executeScript'
    outputs:
      - Name: payload
        Selector: $.Payload
        Type: StringMap
    inputs:
      Runtime: python3.11
      Handler: launch_instance
      Script: ''
      InputPayload:
        image_id: '{{ imageId }}'
        tag_value: '{{ tagValue }}'
        instance_type: '{{ instanceType }}'
      Attachment: launch.py
```

```
    description: >-
      **About This Step**

      This step first launches an EC2 instance using the ```aws:executeScript```
      action and the provided python script.
  - name: WaitForInstanceStatusOk
    action: 'aws:executeScript'
    inputs:
      Runtime: python3.11
      Handler: poll_instance
      Script: |-
        def poll_instance(events, context):
          import boto3
          import time

          ec2 = boto3.client('ec2')

          instance_id = events['InstanceId']

          print('[INFO] Waiting for instance status check to report ok', instance_id)

          instance_status = "null"

          while True:
            res = ec2.describe_instance_status(InstanceIds=[instance_id])

            if len(res['InstanceStatuses']) == 0:
              print("Instance status information is not available yet")
              time.sleep(5)
              continue

            instance_status = res['InstanceStatuses'][0]['InstanceStatus']['Status']

            print('[INFO] Polling to get status of the instance', instance_status)

            if instance_status == 'ok':
              break

            time.sleep(10)

          return {'Status': instance_status, 'InstanceId': instance_id}
      InputPayload: '{{ LaunchEc2Instance.payload }}'
    description: >-
```

```
      **About This Step**

      The python script continuously polls the instance status check value for
      the instance launched in Step 1 until the ```ok``` status is returned.

```

Secure parameter handling examples

The following examples demonstrate secure parameter handling using environment variable `interpolationType`.

Basic secure command execution

This example shows how to securely handle a command parameter:

> **Note**
>
> `allowedPattern` isn't technically required in SSM documents that don't use double braces: `{{ }}`

YAML

```
---

schemaVersion: '2.2'
description: An example document.
parameters:
  Message:
    type: String
    description: "Message to be printed"
    default: Hello
    interpolationType: ENV_VAR
    allowedPattern: "^[^"]*$"
mainSteps:
  - action: aws:runShellScript
    name: printMessage
    precondition:
      StringEquals:
```

```
        - platformType
        - Linux
    inputs:
      runCommand:
        - echo {{Message}}
```

JSON

```
{
    "schemaVersion": "2.2",
    "description": "An example document.",
    "parameters": {
        "Message": {
            "type": "String",
            "description": "Message to be printed",
            "default": "Hello",
            "interpolationType": "ENV_VAR",
            "allowedPattern": "^[^"]*$"
        }
    },
    "mainSteps": [{
        "action": "aws:runShellScript",
        "name": "printMessage",
        "precondition": {
           "StringEquals": ["platformType", "Linux"]
        },
        "inputs": {
            "runCommand": [
              "echo {{Message}}"
            ]
        }
    }]
}
```

Using parameters in interpreted languages

This example demonstrates secure parameter handling in Python:

YAML

```
---
schemaVersion: '2.2'
```

```
description: 'Secure Python script execution'
parameters:
  inputData:
    type: String
    description: 'Input data for processing'
    interpolationType: 'ENV_VAR'
mainSteps:
  - action: aws:runPowerShellScript
    name: runPython
    inputs:
      runCommand:
        - |
          python3 -c '
          import os
          import json

          # Safely access parameter through environment variable
          input_data = os.environ.get("SSM_inputData", "")

          # Process the data
          try:
              processed_data = json.loads(input_data)
              print(f"Successfully processed: {processed_data}")
          except json.JSONDecodeError:
              print("Invalid JSON input")
          '
```

Backwards compatibility example

This example shows how to handle parameters securely while maintaining backwards compatibility:

YAML

```
---
schemaVersion: '2.2'
description: 'Backwards compatible secure parameter handling'
parameters:
  userInput:
    type: String
    description: 'User input to process'
    interpolationType: 'ENV_VAR'
```

```
    allowedPattern: '^[^"]*$'

mainSteps:
  - action: aws:runShellScript
    name: processInput
    inputs:
      runCommand:
        - |
          # Handle both modern and legacy agent versions
          if [ -z "${SSM_userInput+x}" ]; then
              # Legacy agent - fall back to direct parameter reference
              export SSM_userInput="{{userInput}}"
          fi

          # Process the input securely
          echo "Processing input: $SSM_userInput"
```

> **Note**
>
> `allowedPattern` isn't technically required in SSM documents that don't use double braces: `{{ }}`

Parameter security best practices

Follow these best practices when handling parameters in SSM documents:

- **Use environment variable interpolation** - Always use `interpolationType: "ENV_VAR"` for string parameters that will be used in command execution.
- **Implement input validation** - Use `allowedPattern` to restrict parameter values to safe patterns.
- **Handle legacy systems** - Include fallback logic for older SSM Agent versions that don't support environment variable interpolation.
- **Escape special characters** - When using parameter values in commands, properly escape special characters to prevent interpretation by the shell.
- **Limit parameter scope** - Use the most restrictive parameter patterns possible for your use case.

Data elements and parameters

This topic describes the data elements used in SSM documents. The schema version used to create a document defines the syntax and data elements that the document accepts. We recommend that you use schema version 2.2 or later for Command documents. Automation runbooks use schema version 0.3. Additionally, Automation runbooks support the use of Markdown, a markup language, which lets you add wiki-style descriptions to documents and individual steps within the document. For more information about using Markdown, see Using Markdown in the Console in the *Amazon Web Services Management Console Getting Started Guide*.

The following section describes the data elements that you can include in a SSM document.

Top-level data elements

schemaVersion

The schema version to use.

Type: Version

Required: Yes

description

Information you provide to describe the purpose of the document. You can also use this field to specify whether a parameter requires a value for a document to run, or if providing a value for the parameter is optional. Required and optional parameters can be seen in the examples throughout this topic.

Type: String

Required: No

parameters

A structure that defines the parameters the document accepts.

For enhanced security when handling string parameters, you can use environment variable interpolation by specifying the `interpolationType` property. When set to `ENV_VAR`, the system creates an environment variable named `SSM_`*`parameter-name`* containing the parameter value.

The following includes an example of a parameter using environment variable `interpolationType`:

```
{
    "schemaVersion": "2.2",
    "description": "An example document.",
    "parameters": {
        "Message": {
            "type": "String",
            "description": "Message to be printed",
            "default": "Hello",
            "interpolationType" : "ENV_VAR",
            "allowedPattern": "^[^"]*$"

        }
    },
    "mainSteps": [{
        "action": "aws:runShellScript",
        "name": "printMessage",
        "precondition" : {
           "StringEquals" : ["platformType", "Linux"]
        },
        "inputs": {
            "runCommand": [
              "echo {{Message}}"
            ]
        }
    }
}
```

> **Note**
>
> `allowedPattern` isn't technically required in SSM documents that don't use double braces: `{{ }}`

For parameters that you use often, we recommend that you store those parameters in Parameter Store. Then, you can define parameters in your document that reference Parameter Store parameters as their default value. To reference a Parameter Store parameter, use the following syntax.

```
{{ssm:parameter-name}}
```

You can use a parameter that references a Parameter Store parameter the same way as any other document parameters. In the following example, the default value for the `commands` parameter is the Parameter Store parameter `myShellCommands`. By specifying the `commands` parameter as a `runCommand` string, the document runs the commands stored in the `myShellCommands` parameter.

YAML

```
---
schemaVersion: '2.2'
description: runShellScript with command strings stored as Parameter Store
 parameter
parameters:
  commands:
    type: StringList
    description: "(Required) The commands to run on the instance."
    default: ["{{ ssm:myShellCommands }}"],
            interpolationType : 'ENV_VAR'
            allowedPattern: '^[^"]*$'

mainSteps:
- action: aws:runShellScript
  name: runShellScriptDefaultParams
  inputs:
    runCommand:"{{ commands }}"
```

JSON

```
{
    "schemaVersion": "2.2",
    "description": "runShellScript with command strings stored as Parameter Store
 parameter",
    "parameters": {
      "commands": {
        "type": "StringList",
        "description": "(Required) The commands to run on the instance.",
        "default": ["{{ ssm:myShellCommands }}"],
        "interpolationType" : "ENV_VAR"
      }
    },
```

```
    "mainSteps": [
      {
        "action": "aws:runShellScript",
        "name": "runShellScriptDefaultParams",
        "inputs": {
            "runCommand": [
              "{{ commands }}"
          ]
        }
      }
    ]
  }
```

> **Note**
>
> You can reference `String` and `StringList` Parameter Store parameters in the `parameters` section of your document. You can't reference `SecureString` Parameter Store parameters.

For more information about Parameter Store, see Amazon Systems Manager Parameter Store.

Type: Structure

The `parameters` structure accepts the following fields and values:

- `type`: (Required) Allowed values include the following: `String`, `StringList`, `Integer` `Boolean`, `MapList`, and `StringMap`. To view examples of each type, see SSM document parameter `type` examples in the next section.

  > **Note**
  >
  > Command type documents only support the `String` and `StringList` parameter types.

- `description`: (Optional) A description of the parameter.
- `default`: (Optional) The default value of the parameter or a reference to a parameter in Parameter Store.

- `allowedValues`: (Optional) An array of values allowed for the parameter. Defining allowed values for the parameter validates the user input. If a user inputs a value that isn't allowed, the execution fails to start.

  YAML

  ```
  DirectoryType:
    type: String
    description: "(Required) The directory type to launch."
    default: AwsMad
    allowedValues:
    - AdConnector
    - AwsMad
    - SimpleAd
  ```

  JSON

  ```
  "DirectoryType": {
    "type": "String",
    "description": "(Required) The directory type to launch.",
    "default": "AwsMad",
    "allowedValues": [
      "AdConnector",
      "AwsMad",
      "SimpleAd"
    ]
  }
  ```

- `allowedPattern`: (Optional) A regular expression that validates whether the user input matches the defined pattern for the parameter. If the user input doesn't match the allowed pattern, the execution fails to start.

  > **Note**
  >
  > Systems Manager performs two validations for `allowedPattern`. The first validation is performed using the Java regex library at the API level when you use a document. The second validation is performed on SSM Agent by using the GO regexp library before processing the document.

YAML

```
InstanceId:
  type: String
  description: "(Required) The instance ID to target."
  allowedPattern: "^i-(?:[a-f0-9]{8}|[a-f0-9]{17})$"
  default: ''
```

JSON

```
"InstanceId": {
  "type": "String",
  "description": "(Required) The instance ID to target.",
  "allowedPattern": "^i-(?:[a-f0-9]{8}|[a-f0-9]{17})$",
  "default": ""
}
```

- `displayType`: (Optional) Used to display either a `textfield` or a `textarea` in the Amazon Web Services Management Console. `textfield` is a single-line text box. `textarea` is a multi-line text area.
- `minItems`: (Optional) The minimum number of items allowed.
- `maxItems`: (Optional) The maximum number of items allowed.
- `minChars`: (Optional) The minimum number of parameter characters allowed.
- `maxChars`: (Optional) The maximum number of parameter characters allowed.
- `interpolationType`: (Optional) Defines how parameter values are processed before command execution. When set to `ENV_VAR`, the parameter value is made available as an environment variable named `SSM_`*`parameter-name`*. This feature helps prevent command injection by treating parameter values as literal strings.

  Type: String

  Valid values: `ENV_VAR`

Required: No

variables

(Schema version 0.3 only) Values you can reference or update throughout the steps in an Automation runbook. Variables are similar to parameters, but differ in a very important way.

Parameter values are static in the context of a runbook, but the values of variables can be changed in the context of the runbook. When updating the value of a variable, the data type must match the defined data type. For information about updating variables values in an automation, see [aws:updateVariable – Updates a value for a runbook variable]

Type: Boolean | Integer | MapList | String | StringList | StringMap

Required: No

YAML

```
variables:
    payload:
        type: StringMap
        default: "{}"
```

JSON

```
{
    "variables": [
        "payload": {
            "type": "StringMap",
            "default": "{}"
        }
    ]
}
```

runtimeConfig

(Schema version 1.2 only) The configuration for the instance as applied by one or more Systems Manager plugins. Plugins aren't guaranteed to run in sequence.

Type: Dictionary<string,PluginConfiguration>

Required: No

mainSteps

(Schema version 0.3, 2.0, and 2.2 only) An object that can include multiple steps (plugins). Plugins are defined within steps. Steps run in sequential order as listed in the document.

Type: Dictionary<string,PluginConfiguration>

Required: Yes

outputs

(Schema version 0.3 only) Data generated by the execution of this document that can be used in other processes. For example, if your document creates a new AMI, you might specify "CreateImage.ImageId" as the output value, and then use this output to create new instances in a subsequent automation execution. For more information about outputs, see Using action outputs as inputs.

Type: Dictionary<string,OutputConfiguration>

Required: No

files

(Schema version 0.3 only) The script files (and their checksums) attached to the document and run during an automation execution. Applies only to documents that include the `aws:executeScript` action and for which attachments have been specified in one or more steps.

To learn about the runtimes supported by Automation runbooks, see `aws:executeScript` – Run a script. For more information about including scripts in Automation runbooks, see Using scripts in runbooks and Visual design experience for Automation runbooks.

When creating an Automation runbook with attachments, you must also specify attachment files using the `--attachments` option (for Amazon CLI) or `Attachments` (for API and SDK). You can specify the file location for SSM documents and files stored in Amazon Simple Storage Service (Amazon S3) buckets. For more information, see Attachments in the Amazon Systems Manager API Reference.

YAML

```
---
files:
  launch.py:
    checksums:
      sha256: 18871b1311b295c43d0f...
[truncated]...772da97b67e99d84d342ef4aEXAMPLE
```

JSON

```
"files": {
```

```
    "launch.py": {
        "checksums": {
            "sha256": "18871b1311b295c43d0f...
[truncated]...772da97b67e99d84d342ef4aEXAMPLE"
        }
    }
}
```

Type: Dictionary<string,FilesConfiguration>

Required: No

SSM document parameter `type` examples

Parameter types in SSM documents are static. This means the parameter type can't be changed after it's defined. When using parameters with SSM document plugins, the type of a parameter can't be dynamically changed within a plugin's input. For example, you can't reference an `Integer` parameter within the `runCommand` input of the `aws:runShellScript` plugin because this input accepts a string or list of strings. To use a parameter for a plugin input, the parameter type must match the accepted type. For example, you must specify a `Boolean` type parameter for the `allowDowngrade` input of the `aws:updateSsmAgent` plugin. If your parameter type doesn't match the input type for a plugin, the SSM document fails to validate and the system doesn't create the document. This is also true when using parameters downstream within inputs for other plugins or Amazon Systems Manager Automation actions. For example, you can't reference a `StringList` parameter within the `documentParameters` input of the `aws:runDocument` plugin. The `documentParameters` input accepts a map of strings even if the downstream SSM document parameter type is a `StringList` parameter and matches the parameter you're referencing.

When using parameters with Automation actions, parameter types aren't validated when you create the SSM document in most cases. Only when you use the `aws:runCommand` action are parameter types validated when you create the SSM document. In all other cases, the parameter validation occurs during the automation execution when an action's input is verified before running the action. For example, if your input parameter is a `String` and you reference it as the value for the `MaxInstanceCount` input of the `aws:runInstances` action, the SSM document is created. However, when running the document, the automation fails while validating the `aws:runInstances` action because the `MaxInstanceCount` input requires an `Integer`.

The following are examples of each parameter `type`.

String

A sequence of zero or more Unicode characters wrapped in quotation marks. For example, "i-1234567890abcdef0". Use backslashes to escape.

String parameters can include an optional `interpolationType` field with the value `ENV_VAR` to enable environment variable interpolation for improved security.

YAML

```
---
InstanceId:
  type: String
  description: "(Optional) The target EC2 instance ID."
  interpolationType: ENV_VAR
```

JSON

```
"InstanceId":{
  "type":"String",
  "description":"(Optional) The target EC2 instance ID.",
  "interpolationType": "ENV_VAR"
}
```

StringList

A list of String items separated by commas. For example, ["cd ~", "pwd"].

YAML

```
---
commands:
  type: StringList
  description: "(Required) Specify a shell script or a command to run."
  default: ""
  minItems: 1
  displayType: textarea
```

JSON

```
"commands":{
  "type":"StringList",
  "description":"(Required) Specify a shell script or a command to run.",
  "minItems":1,
```

```
  "displayType":"textarea"
}
```

Boolean

Accepts only `true` or `false`. Doesn't accept "true" or 0.

YAML

```
---
canRun:
  type: Boolean
  description: ''
  default: true
```

JSON

```
"canRun": {
  "type": "Boolean",
  "description": "",
  "default": true
}
```

Integer

Integral numbers. Doesn't accept decimal numbers, for example 3.14159, or numbers wrapped in quotation marks, for example "3".

YAML

```
---
timeout:
  type: Integer
  description: The type of action to perform.
  default: 100
```

JSON

```
"timeout": {
  "type": "Integer",
  "description": "The type of action to perform.",
  "default": 100
}
```

StringMap

A mapping of keys to values. Keys and values must be strings. For example, {"Env": "Prod"}.

YAML

```
---
notificationConfig:
  type: StringMap
  description: The configuration for events to be notified about
  default:
    NotificationType: 'Command'
    NotificationEvents:
    - 'Failed'
    NotificationArn: "$dependency.topicArn"
  maxChars: 150
```

JSON

```
"notificationConfig" : {
  "type" : "StringMap",
  "description" : "The configuration for events to be notified about",
  "default" : {
    "NotificationType" : "Command",
    "NotificationEvents" : ["Failed"],
    "NotificationArn" : "$dependency.topicArn"
  },
  "maxChars" : 150
}
```

MapList

A list of StringMap objects.

YAML

```
blockDeviceMappings:
  type: MapList
  description: The mappings for the create image inputs
  default:
  - DeviceName: "/dev/sda1"
    Ebs:
      VolumeSize: "50"
  - DeviceName: "/dev/sdm"
```

```
    Ebs:
      VolumeSize: "100"
  maxItems: 2
```

JSON

```
"blockDeviceMappings":{
  "type":"MapList",
  "description":"The mappings for the create image inputs",
  "default":[
    {
      "DeviceName":"/dev/sda1",
      "Ebs":{
        "VolumeSize":"50"
      }
    },
    {
      "DeviceName":"/dev/sdm",
      "Ebs":{
        "VolumeSize":"100"
      }
    }
  ],
  "maxItems":2
}
```

Viewing SSM Command document content

To preview the required and optional parameters for an Amazon Systems Manager (SSM) Command document, in addition to the actions the document runs, you can view the content of the document in the Systems Manager console.

To view SSM Command document content

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. In the search box, select **Document type**, and then select **Command**.
4. Choose the name of a document, and then choose the **Content** tab.
5. In the content field, review the available parameters and action steps for the document.

Command document plugin reference

This reference describes the plugins that you can specify in an Amazon Systems Manager (SSM) Command type document. These plugins can't be used in SSM Automation runbooks, which use Automation actions. For information about Amazon Systems Manager Automation actions, see Systems Manager Automation actions reference.

Systems Manager determines the actions to perform on a managed instance by reading the contents of an SSM document. Each document includes a code-execution section. Depending on the schema version of your document, this code-execution section can include one or more plugins or steps. For the purpose of this Help topic, plugins and steps are called *plugins*. This section includes information about each of the Systems Manager plugins. For more information about documents, including information about creating documents and the differences between schema versions, see Amazon Systems Manager Documents.

For plugins that accept String parameters, such as `aws:runShellScript` and `aws:runPowerShellScript`, the `interpolationType` parameter can be used to enhance security by treating parameter inputs as string literals rather than potentially executable commands. For example:

```
{
    "schemaVersion": "2.2",
    "description": "runShellScript with command strings stored as Parameter Store
 parameter",
    "parameters": {
      "commands": {
        "type": "StringList",
        "description": "(Required) The commands to run on the instance.",
        "default": ["{{ ssm:myShellCommands }}"],
        "interpolationType" : "ENV_VAR"
      }
    },
    //truncated
 }
```

> **Note**
>
> Some of the plugins described here run only on either Windows Server instances or Linux instances. Platform dependencies are noted for each plugin.

The following document plugins are supported on Amazon Elastic Compute Cloud (Amazon EC2) instances for macOS:

- `aws:refreshAssociation`
- `aws:runShellScript`
- `aws:runPowerShellScript`
- `aws:softwareInventory`
- `aws:updateSsmAgent`

Contents

- Shared inputs
- aws:applications
- aws:cloudWatch
- aws:configureDocker
- aws:configurePackage
- aws:domainJoin
- aws:downloadContent
- aws:psModule
- aws:refreshAssociation
- aws:runDockerAction
- aws:runDocument
- aws:runPowerShellScript
- aws:runShellScript
- aws:softwareInventory
- aws:updateAgent
- aws:updateSsmAgent

Shared inputs

With SSM Agent version 3.0.502 and later only, all plugins can use the following inputs:

finallyStep

The last step you want the document to run. If this input is defined for a step, it takes precedence over an `exit` value specified in the `onFailure` or `onSuccess` inputs. For a step with this input to run as expected, the step must be the last one defined in the `mainSteps` of your document.

Type: Boolean

Valid values: `true` | `false`

Required: No

onFailure

If you specify this input for a plugin with the `exit` value and the step fails, the step status reflects the failure and the document doesn't run any remaining steps unless a `finallyStep` has been defined. If you specify this input for a plugin with the `successAndExit` value and the step fails, the step status shows successful and the document doesn't run any remaining steps unless a `finallyStep` has been defined.

Type: String

Valid values: `exit` | `successAndExit`

Required: No

onSuccess

If you specify this input for a plugin and the step runs successfully, the document doesn't run any remaining steps unless a `finallyStep` has been defined.

Type: String

Valid values: `exit`

Required: No

YAML

```
---
schemaVersion: '2.2'
```

```
description: Shared inputs example
parameters:
  customDocumentParameter:
    type: String
    description: Example parameter for a custom Command-type document.
mainSteps:
- action: aws:runDocument
  name: runCustomConfiguration
  inputs:
    documentType: SSMDocument
    documentPath: "yourCustomDocument"
    documentParameters: '"documentParameter":{{customDocumentParameter}}'
    onSuccess: exit
- action: aws:runDocument
  name: ifConfigurationFailure
  inputs:
    documentType: SSMDocument
    documentPath: "yourCustomRepairDocument"
    onFailure: exit
- action: aws:runDocument
  name: finalConfiguration
  inputs:
    documentType: SSMDocument
    documentPath: "yourCustomFinalDocument"
    finallyStep: true
```

JSON

```
{
   "schemaVersion": "2.2",
   "description": "Shared inputs example",
   "parameters": {
      "customDocumentParameter": {
         "type": "String",
         "description": "Example parameter for a custom Command-type document."
      }
   },
   "mainSteps":[
      {
         "action": "aws:runDocument",
         "name": "runCustomConfiguration",
         "inputs": {
            "documentType": "SSMDocument",
```

```
            "documentPath": "yourCustomDocument",
            "documentParameters": "\"documentParameter\":
{{customDocumentParameter}}",
            "onSuccess": "exit"
         }
      },
      {
         "action": "aws:runDocument",
         "name": "ifConfigurationFailure",
         "inputs": {
            "documentType": "SSMDocument",
            "documentPath": "yourCustomRepairDocument",
            "onFailure": "exit"
         }
      },
      {
         "action": "aws:runDocument",
         "name":"finalConfiguration",
         "inputs": {
            "documentType": "SSMDocument",
            "documentPath": "yourCustomFinalDocument",
            "finallyStep": true
         }
      }
   ]
}
```

`aws:applications`

Install, repair, or uninstall applications on an EC2 instance. This plugin only runs on Windows Server operating systems.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:applications plugin
parameters:
```

```
  source:
    description: "(Required) Source of msi."
    type: String
mainSteps:
- action: aws:applications
  name: example
  inputs:
    action: Install
    source: "{{ source }}"
```

JSON

```
{
  "schemaVersion":"2.2",
  "description":"aws:applications",
  "parameters":{
    "source":{
    "description":"(Required) Source of msi.",
    "type":"String"
    }
  },
  "mainSteps":[
    {
      "action":"aws:applications",
      "name":"example",
      "inputs":{
        "action":"Install",
        "source":"{{ source }}"
      }
    }
  ]
}
```

Schema 1.2

YAML

```
---
runtimeConfig:
  aws:applications:
    properties:
    - id: 0.aws:applications
```

```
      action: "{{ action }}"
      parameters: "{{ parameters }}"
      source: "{{ source }}"
      sourceHash: "{{ sourceHash }}"
```

JSON

```
{
   "runtimeConfig":{
      "aws:applications":{
         "properties":[
            {
               "id":"0.aws:applications",
               "action":"{{ action }}",
               "parameters":"{{ parameters }}",
               "source":"{{ source }}",
               "sourceHash":"{{ sourceHash }}"
            }
         ]
      }
   }
}
```

Properties

action

The action to take.

Type: Enum

Valid values: `Install` | `Repair` | `Uninstall`

Required: Yes

parameters

The parameters for the installer.

Type: String

Required: No

source

The URL of the `.msi` file for the application.

Type: String

Required: Yes

sourceHash

The SHA256 hash of the `.msi` file.

Type: String

Required: No

`aws:cloudWatch`

Export data from Windows Server to Amazon CloudWatch or Amazon CloudWatch Logs and monitor the data using CloudWatch metrics. This plugin only runs on Windows Server operating systems. For more information about configuring CloudWatch integration with Amazon Elastic Compute Cloud (Amazon EC2), see Collecting metrics, logs, and traces with the CloudWatch agent in the *Amazon CloudWatch User Guide*.

> **Important**
>
> The unified CloudWatch agent has replaced SSM Agent as the tool for sending log data to Amazon CloudWatch Logs. The SSM Agent aws:cloudWatch plugin is not supported. We recommend using only the unified CloudWatch agent for your log collection processes. For more information, see the following topics:
>
> - Sending node logs to unified CloudWatch Logs (CloudWatch agent)
> - Migrate Windows Server node log collection to the CloudWatch agent
> - Collecting metrics, logs, and traces with the CloudWatch agent in the *Amazon CloudWatch User Guide*.

You can export and monitor the following data types:

ApplicationEventLog

Sends application event log data to CloudWatch Logs.

CustomLogs

Sends any text-based log file to Amazon CloudWatch Logs. The CloudWatch plugin creates a fingerprint for log files. The system then associates a data offset with each fingerprint. The plugin uploads files when there are changes, records the offset, and associates the offset with a fingerprint. This method is used to avoid a situation where a user turns on the plugin, associates the service with a directory that contains a large number of files, and the system uploads all of the files.

> **Warning**
>
> Be aware that if your application truncates or attempts to clean logs during polling, any logs specified for `LogDirectoryPath` can lose entries. If, for example, you want to limit log file size, create a new log file when that limit is reached, and then continue writing data to the new file.

ETW

Sends Event Tracing for Windows (ETW) data to CloudWatch Logs.

IIS

Sends IIS log data to CloudWatch Logs.

PerformanceCounter

Sends Windows performance counters to CloudWatch. You can select different categories to upload to CloudWatch as metrics. For each performance counter that you want to upload, create a **PerformanceCounter** section with a unique ID (for example, "PerformanceCounter2", "PerformanceCounter3", and so on) and configure its properties.

> **Note**
>
> If the Amazon Systems Manager SSM Agent or the CloudWatch plugin is stopped, performance counter data isn't logged in CloudWatch. This behavior is different than custom logs or Windows Event logs. Custom logs and Windows Event logs preserve

performance counter data and upload it to CloudWatch after SSM Agent or the CloudWatch plugin is available.

SecurityEventLog

Sends security event log data to CloudWatch Logs.

SystemEventLog

Sends system event log data to CloudWatch Logs.

You can define the following destinations for the data:

CloudWatch

The destination where your performance counter metric data is sent. You can add more sections with unique IDs (for example, "CloudWatch2", CloudWatch3", and so on), and specify a different Region for each new ID to send the same data to different locations.

CloudWatchLogs

The destination where your log data is sent. You can add more sections with unique IDs (for example, "CloudWatchLogs2", CloudWatchLogs3", and so on), and specify a different Region for each new ID to send the same data to different locations.

Syntax

```
"runtimeConfig":{
        "aws:cloudWatch":{
            "settings":{
                "startType":"{{ status }}"
            },
            "properties":"{{ properties }}"
        }
    }
```

Settings and properties

AccessKey

Your access key ID. This property is required unless you launched your instance using an IAM role. This property can't be used with SSM.

Type: String

Required: No

CategoryName

The performance counter category from Performance Monitor.

Type: String

Required: Yes

CounterName

The name of the performance counter from Performance Monitor.

Type: String

Required: Yes

CultureName

The locale where the timestamp is logged. If **CultureName** is blank, it defaults to the same locale used by your Windows Server instance.

Type: String

Valid values: For a list of supported values, see National Language Support (NLS) on the Microsoft website. The **div**, **div-MV**, **hu**, and **hu-HU** values aren't supported.

Required: No

DimensionName

A dimension for your Amazon CloudWatch metric. If you specify `DimensionName`, you must specify `DimensionValue`. These parameters provide another view when listing metrics. You can use the same dimension for multiple metrics so that you can view all metrics belonging to a specific dimension.

Type: String

Required: No

DimensionValue

A dimension value for your Amazon CloudWatch metric.

Type: String

Required: No

Encoding

The file encoding to use (for example, UTF-8). Use the encoding name, not the display name.

Type: String

Valid values: For a list of supported values, see Encoding Class in the Microsoft Learn Library.

Required: Yes

Filter

The prefix of log names. Leave this parameter blank to monitor all files.

Type: String

Valid values: For a list of supported values, see the FileSystemWatcherFilter Property in the MSDN Library.

Required: No

Flows

Each data type to upload, along with the destination for the data (CloudWatch or CloudWatch Logs). For example, to send a performance counter defined under `"Id": "PerformanceCounter"` to the CloudWatch destination defined under `"Id": "CloudWatch"`, enter **"PerformanceCounter,CloudWatch"**. Similarly, to send the custom log, ETW log, and system log to the CloudWatch Logs destination defined under `"Id": "ETW"`, enter **"(ETW),CloudWatchLogs"**. In addition, you can send the same performance counter or log file to more than one destination. For example, to send the application log to two different destinations that you defined under `"Id": "CloudWatchLogs"` and `"Id": "CloudWatchLogs2"`, enter **"ApplicationEventLog,(CloudWatchLogs, CloudWatchLogs2)"**.

Type: String

Valid values (source): `ApplicationEventLog` | `CustomLogs` | `ETW` | `PerformanceCounter` | `SystemEventLog` | `SecurityEventLog`

Valid values (destination): `CloudWatch` | `CloudWatchLogs` | `CloudWatch`*n* | `CloudWatchLogs`*n*

Required: Yes

FullName

The full name of the component.

Type: String

Required: Yes

Id

Identifies the data source or destination. This identifier must be unique within the configuration file.

Type: String

Required: Yes

InstanceName

The name of the performance counter instance. Don't use an asterisk (*) to indicate all instances because each performance counter component only supports one metric. You can, however use **_Total**.

Type: String

Required: Yes

Levels

The types of messages to send to Amazon CloudWatch.

Type: String

Valid values:

- **1** - Only error messages uploaded.
- **2** - Only warning messages uploaded.
- **4** - Only information messages uploaded.

You can add values together to include more than one type of message. For example, **3** means that error messages (**1**) and warning messages (**2**) are included. A value of **7** means that error messages (**1**), warning messages (**2**), and informational messages (**4**) are included.

Required: Yes

> **Note**
>
> Windows Security Logs should set Levels to 7.

LineCount

The number of lines in the header to identify the log file. For example, IIS log files have virtually identical headers. You could enter **3**, which would read the first three lines of the log file's header to identify it. In IIS log files, the third line is the date and time stamp, which is different between log files.

Type: Integer

Required: No

LogDirectoryPath

For CustomLogs, the path where logs are stored on your EC2 instance. For IIS logs, the folder where IIS logs are stored for an individual site (for example, **C:\\inetpub\\logs\\LogFiles\\W3SVC*n***). For IIS logs, only W3C log format is supported. IIS, NCSA, and Custom formats aren't supported.

Type: String

Required: Yes

LogGroup

The name for your log group. This name is displayed on the **Log Groups** screen in the CloudWatch console.

Type: String

Required: Yes

LogName

The name of the log file.

1. To find the name of the log, in Event Viewer, in the navigation pane, select **Applications and Services Logs**.
2. In the list of logs, open the context menu for the log you want to upload (for example, `Microsoft` > `Windows` > `Backup` > `Operational`), and then select **Create Custom View**.
3. In the **Create Custom View** dialog box, select the **XML** tab. The **LogName** is in the <Select Path=> tag (for example, `Microsoft-Windows-Backup`). Copy this text into the **LogName** parameter.

Type: String

Valid values: `Application` | `Security` | `System` | `Microsoft-Windows-WinINet/Analytic`

Required: Yes

LogStream

The destination log stream. If you use **{instance_id}**, the default, the instance ID of this instance is used as the log stream name.

Type: String

Valid values: `{instance_id}` | `{hostname}` | `{ip_address}` *`<log_stream_name>`*

If you enter a log stream name that doesn't already exist, CloudWatch Logs automatically creates it for you. You can use a literal string or predefined variables (**{instance_id}**, **{hostname}**, **{ip_address}**, or a combination of all three to define a log stream name.

The log stream name specified in this parameter is displayed on the **Log Groups > Streams for *`<YourLogStream>`*** screen in the CloudWatch console.

Required: Yes

MetricName

The CloudWatch metric that you want performance data to be included under.

> **Note**
>
> Don't use special characters in the name. If you do, the metric and associated alarms might not work.

Type: String

Required: Yes

NameSpace

The metric namespace where you want performance counter data to be written.

Type: String

Required: Yes

PollInterval

How many seconds must elapse before new performance counter and log data is uploaded.

Type: Integer

Valid values: Set this to 5 or more seconds. Fifteen seconds (00:00:15) is recommended.

Required: Yes

Region

The Amazon Web Services Region where you want to send log data. Although you can send performance counters to a different Region from where you send your log data, we recommend that you set this parameter to the same Region where your instance is running.

Type: String

Valid values: Regions IDs of the Amazon Web Services Regions supported by both Systems Manager and CloudWatch Logs, such as `us-east-2`, `eu-west-1`, and `ap-southeast-1`. For lists of Amazon Web Services Regions supported by each service, see Amazon CloudWatch Logs Service Endpoints and Systems Manager service endpoints in the *Amazon Web Services General Reference*.

Required: Yes

SecretKey

Your secret access key. This property is required unless you launched your instance using an IAM role.

Type: String

Required: No

startType

Turn on or turn off CloudWatch on the instance.

Type: String

Valid values: `Enabled` | `Disabled`

Required: Yes

TimestampFormat

The timestamp format you want to use. For a list of supported values, see Custom Date and Time Format Strings in the MSDN Library.

Type: String

Required: Yes

TimeZoneKind

Provides time zone information when no time zone information is included in your log's timestamp. If this parameter is left blank and if your timestamp doesn't include time zone information, CloudWatch Logs defaults to the local time zone. This parameter is ignored if your timestamp already contains time zone information.

Type: String

Valid values: `Local` | `UTC`

Required: No

Unit

The appropriate unit of measure for the metric.

Type: String

Valid values: Seconds | Microseconds | Milliseconds | Bytes | Kilobytes | Megabytes | Gigabytes | Terabytes | Bits | Kilobits | Megabits | Gigabits | Terabits | Percent | Count | Bytes/Second | Kilobytes/Second | Megabytes/Second | Gigabytes/Second | Terabytes/Second | Bits/Second | Kilobits/Second | Megabits/Second | Gigabits/Second | Terabits/Second | Count/Second | None

Required: Yes

`aws:configureDocker`

(Schema version 2.0 or later) Configure an instance to work with containers and Docker. This plugin is supported on most Linux variants and Windows Server operating systems.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:configureDocker
parameters:
  action:
    description: "(Required) The type of action to perform."
    type: String
    default: Install
    allowedValues:
    - Install
    - Uninstall
mainSteps:
- action: aws:configureDocker
  name: configureDocker
  inputs:
    action: "{{ action }}"
```

JSON

```
{
  "schemaVersion": "2.2",
  "description": "aws:configureDocker plugin",
  "parameters": {
    "action": {
      "description": "(Required) The type of action to perform.",
      "type": "String",
      "default": "Install",
      "allowedValues": [
        "Install",
```

```
        "Uninstall"
      ]
    }
  },
  "mainSteps": [
    {
      "action": "aws:configureDocker",
      "name": "configureDocker",
      "inputs": {
        "action": "{{ action }}"
      }
    }
  ]
}
```

Inputs

action

The type of action to perform.

Type: Enum

Valid values: `Install` | `Uninstall`

Required: Yes

`aws:configurePackage`

(Schema version 2.0 or later) Install or uninstall an Amazon Systems Manager Distributor package. You can install the latest version, default version, or a version of the package you specify. Packages provided by Amazon are also supported. This plugin runs on Windows Server and Linux operating systems, but not all the available packages are supported on Linux operating systems.

Available Amazon packages for Windows Server include the following: `AWSPVDriver`, `AWSNVMe`, `AwsEnaNetworkDriver`, `AwsVssComponents`, `AmazonCloudWatchAgent`, `CodeDeployAgent`, and `AWSSupport-EC2Rescue`.

Available Amazon packages for Linux operating systems include the following: `AmazonCloudWatchAgent`, `CodeDeployAgent`, and `AWSSupport-EC2Rescue`.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:configurePackage
parameters:
  name:
    description: "(Required) The name of the AWS package to install or uninstall."
    type: String
  action:
    description: "(Required) The type of action to perform."
    type: String
    default: Install
    allowedValues:
    - Install
    - Uninstall
  ssmParameter:
    description: "(Required) Argument stored in Parameter Store."
    type: String
    default: "{{ ssm:parameter_store_arg }}"
mainSteps:
- action: aws:configurePackage
  name: configurePackage
  inputs:
    name: "{{ name }}"
    action: "{{ action }}"
    additionalArguments:
      "{\"SSM_parameter_store_arg\": \"{{ ssmParameter }}\", \"SSM_custom_arg\":
 \"myValue\"}"
```

JSON

```
{
   "schemaVersion": "2.2",
   "description": "aws:configurePackage",
   "parameters": {
      "name": {
         "description": "(Required) The name of the AWS package to install or
 uninstall.",
```

```
            "type": "String"
         },
         "action": {
            "description": "(Required) The type of action to perform.",
            "type": "String",
            "default": "Install",
            "allowedValues": [
               "Install",
               "Uninstall"
            ]
         },
         "ssmParameter": {
            "description": "(Required) Argument stored in Parameter Store.",
            "type": "String",
            "default": "{{ ssm:parameter_store_arg }}"
         }
      },
      "mainSteps": [
         {
            "action": "aws:configurePackage",
            "name": "configurePackage",
            "inputs": {
               "name": "{{ name }}",
               "action": "{{ action }}",
               "additionalArguments": "{\"SSM_parameter_store_arg\":
 \"{{ ssmParameter }}\", \"SSM_custom_arg\": \"myValue\"}"
            }
         }
      ]
}
```

Inputs

name

The name of the Amazon package to install or uninstall. Available packages include the following: `AWSPVDriver`, `AwsEnaNetworkDriver`, `AwsVssComponents`, and `AmazonCloudWatchAgent`.

Type: String

Required: Yes

action

Install or uninstall a package.

Type: Enum

Valid values: `Install` | `Uninstall`

Required: Yes

installationType

The type of installation to perform. If you specify `Uninstall and reinstall`, the package is completely uninstalled, and then reinstalled. The application is unavailable until the reinstallation is complete. If you specify `In-place update`, only new or changed files are added to the existing installation according you instructions you provide in an update script. The application remains available throughout the update process. The `In-place update` option isn't supported for Amazon-published packages. `Uninstall and reinstall` is the default value.

Type: Enum

Valid values: `Uninstall and reinstall` | `In-place update`

Required: No

additionalArguments

A JSON string of the additional parameters to provide to your install, uninstall, or update scripts. Each parameter must be prefixed with `SSM_`. You can reference a Parameter Store parameter in your additional arguments by using the convention `{{ssm:`*`parameter-name`*`}}`. To use the additional parameter in your install, uninstall, or update script, you must reference the parameter as an environment variable using the syntax appropriate for the operating system. For example, in PowerShell, you reference the `SSM_arg` argument as `$Env:SSM_arg`. There is no limit to the number of arguments you define, but the additional argument input has a 4096 character limit. This limit includes all of the keys and values you define.

Type: StringMap

Required: No

version

A specific version of the package to install or uninstall. If installing, the system installs the latest published version, by default. If uninstalling, the system uninstalls the currently installed version, by default. If no installed version is found, the latest published version is downloaded, and the uninstall action is run.

Type: String

Required: No

`aws:domainJoin`

Join an EC2 instance to a domain. This plugin runs on Linux and Windows Server operating systems. This plugin changes the hostname for Linux instances to the format EC2AMAZ-*XXXXXXX*. For more information about joining EC2 instances, see Join an EC2 Instance to Your Amazon Managed Microsoft AD Directory in the *Amazon Directory Service Administration Guide*.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:domainJoin
parameters:
  directoryId:
    description: "(Required) The ID of the directory."
    type: String
  directoryName:
    description: "(Required) The name of the domain."
    type: String
  directoryOU:
    description: "(Optional) The organizational unit to assign the computer object
 to."
    type: String
  dnsIpAddresses:
    description: "(Required) The IP addresses of the DNS servers for your
 directory."
    type: StringList
```

```
  hostname:
    description: "(Optional) The hostname you want to assign to the node."
    type: String
mainSteps:
- action: aws:domainJoin
  name: domainJoin
  inputs:
    directoryId: "{{ directoryId }}"
    directoryName: "{{ directoryName }}"
    directoryOU: "{{ directoryOU }}"
    dnsIpAddresses: "{{ dnsIpAddresses }}"
    hostname: "{{ hostname }}"
```

JSON

```
{
  "schemaVersion": "2.2",
  "description": "aws:domainJoin",
  "parameters": {
    "directoryId": {
      "description": "(Required) The ID of the directory.",
      "type": "String"
    },
    "directoryName": {
      "description": "(Required) The name of the domain.",
      "type": "String"
    },
    "directoryOU": {
        "description": "(Optional) The organizational unit to assign the computer
 object to.",
        "type": "String"
      },
    "dnsIpAddresses": {
      "description": "(Required) The IP addresses of the DNS servers for your
 directory.",
      "type": "StringList"
    },
    "hostname": {
        "description": "(Optional) The hostname you want to assign to the node.",
        "type": "String"
      }
  },
  "mainSteps": [
```

```
    {
      "action": "aws:domainJoin",
      "name": "domainJoin",
      "inputs": {
        "directoryId": "{{ directoryId }}",
        "directoryName": "{{ directoryName }}",
        "directoryOU":"{{ directoryOU }}",
        "dnsIpAddresses":"{{ dnsIpAddresses }}",
        "hostname":"{{ hostname }}"
      }
    }
  ]
}
```

Schema 1.2

YAML

```
---
runtimeConfig:
  aws:domainJoin:
    properties:
      directoryId: "{{ directoryId }}"
      directoryName: "{{ directoryName }}"
      directoryOU: "{{ directoryOU }}"
      dnsIpAddresses: "{{ dnsIpAddresses }}"
```

JSON

```
{
   "runtimeConfig":{
      "aws:domainJoin":{
         "properties":{
            "directoryId":"{{ directoryId }}",
            "directoryName":"{{ directoryName }}",
            "directoryOU":"{{ directoryOU }}",
            "dnsIpAddresses":"{{ dnsIpAddresses }}"
         }
      }
   }
}
```

Properties

directoryId

The ID of the directory.

Type: String

Required: Yes

Example: "directoryId": "d-1234567890"

directoryName

The name of the domain.

Type: String

Required: Yes

Example: "directoryName": "example.com"

directoryOU

The organizational unit (OU).

Type: String

Required: No

Example: "directoryOU": "OU=test,DC=example,DC=com"

dnsIpAddresses

The IP addresses of the DNS servers.

Type: StringList

Required: Yes

Example: "dnsIpAddresses": ["198.51.100.1","198.51.100.2"]

hostname

The hostname you want to assign to the node. If not provided, there is no name change for Windows Server instances, while Linux instances will use the default naming pattern. If

provided, Windows Server instances will use the exact provided value, while for Linux instances it serves as a prefix (unless `keepHostName` is set to "true").

Type: String

Required: No

keepHostName

Determines whether the hostname is changed for Linux instances when joined to the domain. This is a Linux-only parameter. By default (without inputs to `hostname`, `hostnameNumAppendDigits`, and with `keepHostName` as "false"), Linux hosts will be renamed to the pattern EC2AMAZ-XXXXXX. When set to "true", it keeps the original hostname and ignores inputs to `hostname` and `hostnameNumAppendDigits`.

Type: Boolean

Required: No

hostnameNumAppendDigits

Defines the number of random numeric digits to append after the hostname value. This is a Linux-only parameter and is used together with the `hostname` parameter. It is ignored if `hostname` is not provided.

Type: String

Allowed values: 1 to 5

Required: No

Examples

For examples, see Join an Amazon EC2 Instance to your Amazon Managed Microsoft AD in the *Amazon Directory Service Administration Guide*.

`aws:downloadContent`

(Schema version 2.0 or later) Download SSM documents and scripts from remote locations. GitHub Enterprise repositories are not supported. This plugin is supported on Linux and Windows Server operating systems.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:downloadContent
parameters:
  sourceType:
    description: "(Required) The download source."
    type: String
  sourceInfo:
    description: "(Required) The information required to retrieve the content from
      the required source."
    type: StringMap
mainSteps:
- action: aws:downloadContent
  name: downloadContent
  inputs:
    sourceType: "{{ sourceType }}"
    sourceInfo: "{{ sourceInfo }}"
```

JSON

```
{
  "schemaVersion": "2.2",
  "description": "aws:downloadContent",
  "parameters": {
    "sourceType": {
    "description": "(Required) The download source.",
    "type": "String"
  },
  "sourceInfo": {
    "description": "(Required) The information required to retrieve the content from
 the required source.",
    "type": "StringMap"
    }
  },
  "mainSteps": [
    {
      "action": "aws:downloadContent",
```

```
      "name": "downloadContent",
      "inputs": {
        "sourceType":"{{ sourceType }}",
        "sourceInfo":"{{ sourceInfo }}"
      }
    }
  ]
}
```

Inputs

sourceType

The download source. Systems Manager supports the following source types for downloading scripts and SSM documents: `GitHub`, `Git`, `HTTP`, `S3`, and `SSMDocument`.

Type: String

Required: Yes

sourceInfo

The information required to retrieve the content from the required source.

Type: StringMap

Required: Yes

For sourceType `GitHub`, specify the following:

- owner: The repository owner.
- repository: The name of the repository.
- path: The path to the file or directory you want to download.
- getOptions: Extra options to retrieve content from a branch other than master or from a specific commit in the repository. getOptions can be omitted if you're using the latest commit in the master branch. If your repository was created after October 1, 2020 the default branch might be named main instead of master. In this case, you need to specify values for the getOptions parameter.

  This parameter uses the following format:

  - branch:refs/heads/*branch_name*

The default is `master`.

To specify a non-default branch use the following format:

branch:refs/heads/*branch_name*

- commitID:*commitID*

  The default is `head`.

  To use the version of your SSM document in a commit other than the latest, specify the full commit ID. For example:

```
"getOptions": "commitID:bbc1ddb94...b76d3bEXAMPLE",
```

- tokenInfo: The Systems Manager parameter (a SecureString parameter) where you store your GitHub access token information, in the format `{{ssm-secure:`*secure-string-token-name*`}}`.

> **Note**
>
> This `tokenInfo` field is the only SSM document plugin field that supports a SecureString parameter. SecureString parameters aren't supported for any other fields, nor for any other SSM document plugins.

```
{
    "owner":"TestUser",
    "repository":"GitHubTest",
    "path":"scripts/python/test-script",
    "getOptions":"branch:master",
    "tokenInfo":"{{ssm-secure:secure-string-token}}"
}
```

For sourceType `Git`, you must specify the following:

- repository

  The Git repository URL to the file or directory you want to download.

  Type: String

Additionally, you can specify the following optional parameters:

- getOptions

  Extra options to retrieve content from a branch other than master or from a specific commit in the repository. getOptions can be omitted if you're using the latest commit in the master branch.

  Type: String

  This parameter uses the following format:

  - branch:refs/heads/*branch_name*

    The default is `master`.

    `"branch"` is required only if your SSM document is stored in a branch other than `master`. For example:

    ```
    "getOptions": "branch:refs/heads/main"
    ```

  - commitID:*commitID*

    The default is `head`.

    To use the version of your SSM document in a commit other than the latest, specify the full commit ID. For example:

    ```
    "getOptions": "commitID:bbc1ddb94...b76d3bEXAMPLE",
    ```

- privateSSHKey

  The SSH key to use when connecting to the `repository` you specify. You can use the following format to reference a `SecureString` parameter for the value of your SSH key: `{{ssm-secure:`*`your-secure-string-parameter`*`}}`.

  Type: String

- skipHostKeyChecking

  Determines the value of the StrictHostKeyChecking option when connecting to the `repository` you specify. The default value is `false`.

Type: Boolean

- username

  The username to use when connecting to the `repository` you specify using HTTP. You can use the following format to reference a `SecureString` parameter for the value of your username: `{{ssm-secure:your-secure-string-parameter}}`.

  Type: String

- password

  The password to use when connecting to the `repository` you specify using HTTP. You can use the following format to reference a `SecureString` parameter for the value of your password: `{{ssm-secure:your-secure-string-parameter}}`.

  Type: String

For sourceType HTTP, you must specify the following:

- url

  The URL to the file or directory you want to download.

  Type: String

Additionally, you can specify the following optional parameters:

- allowInsecureDownload

  Determines whether a download can be performed over a connection that isn't encrypted with Secure Socket Layer (SSL) or Transport Layer Security (TLS). The default value is `false`. We don't recommend performing downloads without encryption. If you choose to do so, you assume all associated risks. SSM Agent follows HTTP redirects, which means an HTTPS URL can be redirected to an HTTP URL. Security is a shared responsibility between Amazon and you. This is described as the shared responsibility model. To learn more, see the shared responsibility model.

  Type: Boolean

- authMethod

  Determines whether a username and password are used for authentication when connecting to the `url` you specify. If you specify `Basic` or `Digest`, you must provide values for the

`username` and `password` parameters. To use the `Digest` method, SSM Agent version 3.0.1181.0 or later must be installed on your instance. The `Digest` method supports MD5 and SHA256 encryption.

Type: String

Valid values: None | `Basic` | `Digest`

- username

  The username to use when connecting to the `url` you specify using `Basic` authentication. You can use the following format to reference a `SecureString` parameter for the value of your username: `{{ssm-secure:`*`your-secure-string-parameter`*`}}`.

  Type: String

- password

  The password to use when connecting to the `url` you specify using `Basic` authentication. You can use the following format to reference a `SecureString` parameter for the value of your password: `{{ssm-secure:`*`your-secure-string-parameter`*`}}`.

  Type: String

For sourceType S3, specify the following:

- path: The URL to the file or directory you want to download from Amazon S3.

> **Note**
>
> When downloading a file from an S3 bucket, the .etag files are generated in the download directory.

```
{
    "path": "https://s3.amazonaws.com.cn/amzn-s3-demo-bucket/powershell/
helloPowershell.ps1"
}
```

For sourceType `SSMDocument`, specify *one* of the following:

- name: The name and version of the document in the following format: `name:version`. Version is optional.

```
{
    "name": "Example-RunPowerShellScript:3"
}
```

- name: The ARN for the document in the following format: `arn:aws-cn:ssm:region:account_id:document/document_name`

```
{
   "name":"arn:aws-cn:ssm:us-east-2:3344556677:document/MySharedDoc"
}
```

destinationPath

An optional local path on the instance where you want to download the file. If you don't specify a path, the content is downloaded to a path relative to your command ID.

Type: String

Required: No

`aws:psModule`

Install PowerShell modules on an Amazon EC2 instance. This plugin only runs on Windows Server operating systems.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:psModule
parameters:
  source:
    description: "(Required) The URL or local path on the instance to the
 application
     .zip file."
    type: String
```

```
mainSteps:
- action: aws:psModule
  name: psModule
  inputs:
    source: "{{ source }}"
```

JSON

```
{
  "schemaVersion": "2.2",
  "description": "aws:psModule",
  "parameters": {
    "source": {
      "description": "(Required) The URL or local path on the instance to the
 application .zip file.",
      "type": "String"
    }
  },
  "mainSteps": [
    {
      "action": "aws:psModule",
      "name": "psModule",
      "inputs": {
        "source": "{{ source }}"
      }
    }
  ]
}
```

Schema 1.2

YAML

```
---
runtimeConfig:
  aws:psModule:
    properties:
    - runCommand: "{{ commands }}"
      source: "{{ source }}"
      sourceHash: "{{ sourceHash }}"
      workingDirectory: "{{ workingDirectory }}"
      timeoutSeconds: "{{ executionTimeout }}"
```

JSON

```
{
   "runtimeConfig":{
      "aws:psModule":{
         "properties":[
            {
               "runCommand":"{{ commands }}",
               "source":"{{ source }}",
               "sourceHash":"{{ sourceHash }}",
               "workingDirectory":"{{ workingDirectory }}",
               "timeoutSeconds":"{{ executionTimeout }}"
            }
         ]
      }
   }
}
```

Properties

runCommand

The PowerShell command to run after the module is installed.

Type: StringList

Required: No

source

The URL or local path on the instance to the application `.zip` file.

Type: String

Required: Yes

sourceHash

The SHA256 hash of the `.zip` file.

Type: String

Required: No

timeoutSeconds

The time in seconds for a command to be completed before it's considered to have failed.

Type: String

Required: No

workingDirectory

The path to the working directory on your instance.

Type: String

Required: No

`aws:refreshAssociation`

(Schema version 2.0 or later) Refresh (force apply) an association on demand. This action will change the system state based on what is defined in the selected association or all associations bound to the targets. This plugin runs on Linux and Microsoft Windows Server operating systems.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:refreshAssociation
parameters:
  associationIds:
    description: "(Optional) List of association IDs. If empty, all associations
 bound
      to the specified target are applied."
    type: StringList
mainSteps:
- action: aws:refreshAssociation
  name: refreshAssociation
  inputs:
    associationIds:
```

```
    - "{{ associationIds }}"
```

JSON

```
{
  "schemaVersion": "2.2",
  "description": "aws:refreshAssociation",
  "parameters": {
    "associationIds": {
      "description": "(Optional) List of association IDs. If empty, all associations
 bound to the specified target are applied.",
      "type": "StringList"
    }
  },
  "mainSteps": [
    {
      "action": "aws:refreshAssociation",
      "name": "refreshAssociation",
      "inputs": {
        "associationIds": [
          "{{ associationIds }}"
        ]
      }
    }
  ]
}
```

Inputs

associationIds

List of association IDs. If empty, all associations bound to the specified target are applied.

Type: StringList

Required: No

`aws:runDockerAction`

(Schema version 2.0 or later) Run Docker actions on containers. This plugin runs on Linux and Microsoft Windows Server operating systems.

Syntax

Schema 2.2

YAML

```
---
mainSteps:
- action: aws:runDockerAction
  name: RunDockerAction
  inputs:
    action: "{{ action }}"
    container: "{{ container }}"
    image: "{{ image }}"
    memory: "{{ memory }}"
    cpuShares: "{{ cpuShares }}"
    volume: "{{ volume }}"
    cmd: "{{ cmd }}"
    env: "{{ env }}"
    user: "{{ user }}"
    publish: "{{ publish }}"
    workingDirectory: "{{ workingDirectory }}"
    timeoutSeconds: "{{ timeoutSeconds }}"
```

JSON

```
{
   "mainSteps":[
      {
         "action":"aws:runDockerAction",
         "name":"RunDockerAction",
         "inputs":{
            "action":"{{ action }}",
            "container":"{{ container }}",
            "image":"{{ image }}",
            "memory":"{{ memory }}",
            "cpuShares":"{{ cpuShares }}",
            "volume":"{{ volume }}",
            "cmd":"{{ cmd }}",
            "env":"{{ env }}",
            "user":"{{ user }}",
            "publish":"{{ publish }}",
            "workingDirectory": "{{ workingDirectory }}",
```

```
            "timeoutSeconds": "{{ timeoutSeconds }}"
         }
      }
   ]
}
```

Inputs

action

The type of action to perform.

Type: String

Required: Yes

container

The Docker container ID.

Type: String

Required: No

image

The Docker image name.

Type: String

Required: No

cmd

The container command.

Type: String

Required: No

memory

The container memory limit.

Type: String

Required: No

cpuShares

The container CPU shares (relative weight).

Type: String

Required: No

volume

The container volume mounts.

Type: StringList

Required: No

env

The container environment variables.

Type: String

Required: No

user

The container user name.

Type: String

Required: No

publish

The container published ports.

Type: String

Required: No

workingDirectory

The path to the working directory on your managed node.

Type: String

Required: No

timeoutSeconds

The time in seconds for a command to be completed before it's considered to have failed.

Type: String

Required: No

`aws:runDocument`

(Schema version 2.0 or later) Runs SSM documents stored in Systems Manager or on a local share. You can use this plugin with the `aws:downloadContent` plugin to download an SSM document from a remote location to a local share, and then run it. This plugin is supported on Linux and Windows Server operating systems. This plugin doesn't support running the `AWS-UpdateSSMAgent` document or any document that uses the `aws:updateSsmAgent` plugin.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:runDocument
parameters:
  documentType:
    description: "(Required) The document type to run."
    type: String
    allowedValues:
    - LocalPath
    - SSMDocument
mainSteps:
- action: aws:runDocument
  name: runDocument
  inputs:
    documentType: "{{ documentType }}"
```

JSON

```
{
  "schemaVersion": "2.2",
  "description": "aws:runDocument",
  "parameters": {
    "documentType": {
      "description": "(Required) The document type to run.",
      "type": "String",
      "allowedValues": [
        "LocalPath",
        "SSMDocument"
      ]
    }
  },
  "mainSteps": [
    {
      "action": "aws:runDocument",
      "name": "runDocument",
      "inputs": {
        "documentType": "{{ documentType }}"
      }
    }
  ]
}
```

Inputs

documentType

The document type to run. You can run local documents (`LocalPath`) or documents stored in Systems Manager (`SSMDocument`).

Type: String

Required: Yes

documentPath

The path to the document. If `documentType` is `LocalPath`, then specify the path to the document on the local share. If `documentType` is `SSMDocument`, then specify the name of the document.

Type: String

Required: No

documentParameters

Parameters for the document.

Type: StringMap

Required: No

`aws:runPowerShellScript`

Run PowerShell scripts or specify the path to a script to run. This plugin runs on Microsoft Windows Server and Linux operating systems.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:runPowerShellScript
parameters:
  commands:
    type: String
    description: "(Required) The commands to run or the path to an existing script
      on the instance."
    default: Write-Host "Hello World"
mainSteps:
- action: aws:runPowerShellScript
  name: runPowerShellScript
  inputs:
    timeoutSeconds: '60'
    runCommand:
    - "{{ commands }}"
```

JSON

```
{
```

```
  "schemaVersion": "2.2",
  "description": "aws:runPowerShellScript",
  "parameters": {
    "commands": {
      "type": "String",
      "description": "(Required) The commands to run or the path to an existing
 script on the instance.",
      "default": "Write-Host \"Hello World\""
    }
  },
  "mainSteps": [
    {
      "action": "aws:runPowerShellScript",
      "name": "runPowerShellScript",
      "inputs": {
        "timeoutSeconds": "60",
        "runCommand": [
          "{{ commands }}"
        ]
      }
    }
  ]
}
```

Schema 1.2

YAML

```
---
runtimeConfig:
  aws:runPowerShellScript:
    properties:
    - id: 0.aws:runPowerShellScript
      runCommand: "{{ commands }}"
      workingDirectory: "{{ workingDirectory }}"
      timeoutSeconds: "{{ executionTimeout }}"
```

JSON

```
{
   "runtimeConfig":{
      "aws:runPowerShellScript":{
```

```
         "properties":[
            {
               "id":"0.aws:runPowerShellScript",
               "runCommand":"{{ commands }}",
               "workingDirectory":"{{ workingDirectory }}",
               "timeoutSeconds":"{{ executionTimeout }}"
            }
         ]
      }
   }
}
```

Properties

runCommand

Specify the commands to run or the path to an existing script on the instance.

Type: StringList

Required: Yes

timeoutSeconds

The time in seconds for a command to be completed before it's considered to have failed. When the timeout is reached, Systems Manager stops the command execution.

Type: String

Required: No

workingDirectory

The path to the working directory on your instance.

Type: String

Required: No

`aws:runShellScript`

Run Linux shell scripts or specify the path to a script to run. This plugin only runs on Linux operating systems.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:runShellScript
parameters:
  commands:
    type: String
    description: "(Required) The commands to run or the path to an existing script
      on the instance."
    default: echo Hello World
mainSteps:
- action: aws:runShellScript
  name: runShellScript
  inputs:
    timeoutSeconds: '60'
    runCommand:
    - "{{ commands }}"
```

JSON

```
{
  "schemaVersion": "2.2",
  "description": "aws:runShellScript",
  "parameters": {
    "commands": {
      "type": "String",
      "description": "(Required) The commands to run or the path to an existing
 script on the instance.",
      "default": "echo Hello World"
    }
  },
  "mainSteps": [
    {
      "action": "aws:runShellScript",
      "name": "runShellScript",
      "inputs": {
        "timeoutSeconds": "60",
        "runCommand": [
```

```
          "{{ commands }}"
        ]
      }
    }
  ]
}
```

Schema 1.2

YAML

```
---
runtimeConfig:
  aws:runShellScript:
    properties:
    - runCommand: "{{ commands }}"
      workingDirectory: "{{ workingDirectory }}"
      timeoutSeconds: "{{ executionTimeout }}"
```

JSON

```
{
   "runtimeConfig":{
      "aws:runShellScript":{
         "properties":[
            {
               "runCommand":"{{ commands }}",
               "workingDirectory":"{{ workingDirectory }}",
               "timeoutSeconds":"{{ executionTimeout }}"
            }
         ]
      }
   }
}
```

Properties

runCommand

Specify the commands to run or the path to an existing script on the instance.

Type: StringList

Required: Yes

timeoutSeconds

The time in seconds for a command to be completed before it's considered to have failed. When the timeout is reached, Systems Manager stops the command execution.

Type: String

Required: No

workingDirectory

The path to the working directory on your instance.

Type: String

Required: No

`aws:softwareInventory`

(Schema version 2.0 or later) Gather metadata about applications, files, and configurations on your managed instances. This plugin runs on Linux and Microsoft Windows Server operating systems. When you configure inventory collection, you start by creating an Amazon Systems Manager State Manager association. Systems Manager collects the inventory data when the association is run. If you don't create the association first, and attempt to invoke the `aws:softwareInventory` plugin the system returns the following error:

```
The aws:softwareInventory plugin can only be invoked through ssm-associate.
```

An instance can have only one inventory association configured at a time. If you configure an instance with two or more associations, the inventory association doesn't run and no inventory data is collected. For more information about collecting inventory, see Amazon Systems Manager Inventory.

Syntax

Schema 2.2

YAML

```
---
mainSteps:
- action: aws:softwareInventory
  name: collectSoftwareInventoryItems
  inputs:
    applications: "{{ applications }}"
    awsComponents: "{{ awsComponents }}"
    networkConfig: "{{ networkConfig }}"
    files: "{{ files }}"
    services: "{{ services }}"
    windowsRoles: "{{ windowsRoles }}"
    windowsRegistry: "{{ windowsRegistry}}"
    windowsUpdates: "{{ windowsUpdates }}"
    instanceDetailedInformation: "{{ instanceDetailedInformation }}"
    customInventory: "{{ customInventory }}"
```

JSON

```
{
   "mainSteps":[
      {
         "action":"aws:softwareInventory",
         "name":"collectSoftwareInventoryItems",
         "inputs":{
            "applications":"{{ applications }}",
            "awsComponents":"{{ awsComponents }}",
            "networkConfig":"{{ networkConfig }}",
            "files":"{{ files }}",
            "services":"{{ services }}",
            "windowsRoles":"{{ windowsRoles }}",
            "windowsRegistry":"{{ windowsRegistry}}",
            "windowsUpdates":"{{ windowsUpdates }}",
            "instanceDetailedInformation":"{{ instanceDetailedInformation }}",
            "customInventory":"{{ customInventory }}"
         }
      }
   ]
```

```
}
```

Inputs

applications

(Optional) Collect metadata for installed applications.

Type: String

Required: No

awsComponents

(Optional) Collect metadata for Amazon components like amazon-ssm-agent.

Type: String

Required: No

files

(Optional, requires SSM Agent version 2.2.64.0 or later) Collect metadata for files, including file names, the time files were created, the time files were last modified and accessed, and file sizes, to name a few. For more information about collecting file inventory, see Working with file and Windows registry inventory.

Type: String

Required: No

networkConfig

(Optional) Collect metadata for network configurations.

Type: String

Required: No

billingInfo

(Optional) Collect metadata for platform details associated with the billing code of the AMI.

Type: String

Required: No

windowsUpdates

(Optional) Collect metadata for all Windows updates.

Type: String

Required: No

instanceDetailedInformation

(Optional) Collect more instance information than is provided by the default inventory plugin (`aws:instanceInformation`), including CPU model, speed, and the number of cores, to name a few.

Type: String

Required: No

services

(Optional, Windows OS only, requires SSM Agent version 2.2.64.0 or later) Collect metadata for service configurations.

Type: String

Required: No

windowsRegistry

(Optional, Windows OS only, requires SSM Agent version 2.2.64.0 or later) Collect Windows Registry keys and values. You can choose a key path and collect all keys and values recursively. You can also collect a specific registry key and its value for a specific path. Inventory collects the key path, name, type, and the value. For more information about collecting Windows Registry inventory, see Working with file and Windows registry inventory.

Type: String

Required: No

windowsRoles

(Optional, Windows OS only, requires SSM Agent version 2.2.64.0 or later) Collect metadata for Microsoft Windows role configurations.

Type: String

Required: No

customInventory

(Optional) Collect custom inventory data. For more information about custom inventory, see Working with custom inventory

Type: String

Required: No

customInventoryDirectory

(Optional) Collect custom inventory data from the specified directory. For more information about custom inventory, see Working with custom inventory

Type: String

Required: No

`aws:updateAgent`

Update the EC2Config service to the latest version or specify an older version. This plugin only runs on Microsoft Windows Server operating systems. For more information about the EC2Config service, see Configuring a Windows Instance using the EC2Config service (legacy) in the *Amazon EC2 User Guide*.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:updateAgent
mainSteps:
- action: aws:updateAgent
  name: updateAgent
  inputs:
```

```
    agentName: Ec2Config
    source: https://s3.{Region}.amazonaws.com.cn/aws-ssm-{Region}/manifest.json
```

JSON

```
{
  "schemaVersion": "2.2",
  "description": "aws:updateAgent",
  "mainSteps": [
    {
      "action": "aws:updateAgent",
      "name": "updateAgent",
      "inputs": {
        "agentName": "Ec2Config",
        "source": "https://s3.{Region}.amazonaws.com.cn/aws-ssm-{Region}/
manifest.json"
      }
    }
  ]
}
```

Schema 1.2

YAML

```
---
runtimeConfig:
  aws:updateAgent:
    properties:
      agentName: Ec2Config
      source: https://s3.{Region}.amazonaws.com.cn/aws-ssm-{Region}/manifest.json
      allowDowngrade: "{{ allowDowngrade }}"
      targetVersion: "{{ version }}"
```

JSON

```
{
   "runtimeConfig":{
      "aws:updateAgent":{
         "properties":{
            "agentName":"Ec2Config",
```

```
            "source":"https://s3.{Region}.amazonaws.com.cn/aws-ssm-{Region}/
manifest.json",
            "allowDowngrade":"{{ allowDowngrade }}",
            "targetVersion":"{{ version }}"
         }
      }
   }
}
```

Properties

agentName

EC2Config. This is the name of the agent that runs the EC2Config service.

Type: String

Required: Yes

allowDowngrade

Allow the EC2Config service to be downgraded to an earlier version. If set to false, the service can be upgraded to newer versions only (default). If set to true, specify the earlier version.

Type: Boolean

Required: No

source

The location where Systems Manager copies the version of EC2Config to install. You can't change this location.

Type: String

Required: Yes

targetVersion

A specific version of the EC2Config service to install. If not specified, the service will be updated to the latest version.

Type: String

Required: No

`aws:updateSsmAgent`

Update the SSM Agent to the latest version or specify an older version. This plugin runs on Linux and Windows Server operating systems. For more information, see Working with SSM Agent.

Syntax

Schema 2.2

YAML

```
---
schemaVersion: '2.2'
description: aws:updateSsmAgent
parameters:
  allowDowngrade:
    default: 'false'
    description: "(Optional) Allow the Amazon SSM Agent service to be downgraded to
      an earlier version. If set to false, the service can be upgraded to newer
 versions
      only (default). If set to true, specify the earlier version."
    type: String
    allowedValues:
    - 'true'
    - 'false'
mainSteps:
- action: aws:updateSsmAgent
  name: updateSSMAgent
  inputs:
    agentName: amazon-ssm-agent
    source: https://s3.{Region}.amazonaws.com.cn/amazon-ssm-{Region}/ssm-agent-
manifest.json
    allowDowngrade: "{{ allowDowngrade }}"
```

JSON

```
{
  "schemaVersion": "2.2",
  "description": "aws:updateSsmAgent",
  "parameters": {
    "allowDowngrade": {
```

```
      "default": "false",
      "description": "(Required) Allow the Amazon SSM Agent service to be downgraded
 to an earlier version. If set to false, the service can be upgraded to newer
 versions only (default). If set to true, specify the earlier version.",
      "type": "String",
      "allowedValues": [
        "true",
        "false"
      ]
    }
  },
  "mainSteps": [
    {
      "action": "aws:updateSsmAgent",
      "name": "awsupdateSsmAgent",
      "inputs": {
        "agentName": "amazon-ssm-agent",
        "source": "https://s3.{Region}.amazonaws.com.cn/amazon-ssm-{Region}/ssm-
agent-manifest.json",
        "allowDowngrade": "{{ allowDowngrade }}"
      }
    }
  ]
}
```

Schema 1.2

YAML

```
---
runtimeConfig:
  aws:updateSsmAgent:
    properties:
    - agentName: amazon-ssm-agent
      source: https://s3.{Region}.amazonaws.com.cn/aws-ssm-{Region}/manifest.json
      allowDowngrade: "{{ allowDowngrade }}"
```

JSON

```
{
   "runtimeConfig":{
      "aws:updateSsmAgent":{
```

```
         "properties":[
            {
               "agentName":"amazon-ssm-agent",
               "source":"https://s3.{Region}.amazonaws.com.cn/aws-ssm-{Region}/
manifest.json",
               "allowDowngrade":"{{ allowDowngrade }}"
            }
         ]
      }
   }
}
```

Properties

agentName

amazon-ssm-agent. This is the name of the Systems Manager agent that processes requests and runs commands on the instance.

Type: String

Required: Yes

allowDowngrade

Allow the SSM Agent to be downgraded to an earlier version. If set to false, the agent can be upgraded to newer versions only (default). If set to true, specify the earlier version.

Type: Boolean

Required: Yes

source

The location where Systems Manager copies the SSM Agent version to install. You can't change this location.

Type: String

Required: Yes

targetVersion

A specific version of SSM Agent to install. If not specified, the agent will be updated to the latest version.

Type: String

Required: No

Creating SSM document content

If the Amazon Systems Manager public documents don't perform all the actions you want to perform on your Amazon resources, you can create your own SSM documents. You can also clone SSM documents using the console. Cloning copies content from an existing document to a new document that you can modify. The content of the document must not exceed 64KB, including content specified for input parameters at runtime. For new `Command` or `Policy` documents, we recommend schema version 2.2 or later. This version supports document editing, automatic versioning, sequencing, and more.

Writing SSM document content

To create your own SSM document content, it's important to understand the different schemas, features, plugins, and syntax available for SSM documents. We recommend becoming familiar with the following resources.

- Writing your own Amazon Systems Manager documents
- Data elements and parameters
- Schemas, features, and examples
- Command document plugin reference
- Systems Manager Automation actions reference
- Automation system variables
- Additional runbook examples
- Working with Systems Manager Automation runbooks using the Amazon Toolkit for Visual Studio Code
- Visual design experience for Automation runbooks
- Using scripts in runbooks

Amazon pre-defined SSM documents might perform some of the actions you require. You can call these documents by using the `aws:runDocument`, `aws:runCommand`, or `aws:executeAutomation` plugins within your custom SSM document, depending on the

document type. You can also copy portions of those documents into a custom SSM document, and edit the content to meet your requirements.

Tip

When creating SSM document content, you might change the content and update your SSM document several times while testing. The following commands update the SSM document with your latest content, and update the document's default version to the latest version of the document.

Note

The Linux and Windows commands use the `jq` command line tool to filter the JSON response data.

Linux & macOS

```
latestDocVersion=$(aws ssm update-document \
    --content file://path/to/file/documentContent.json \
    --name "ExampleDocument" \
    --document-format JSON \
    --document-version '$LATEST' \
    | jq -r '.DocumentDescription.LatestVersion')

aws ssm update-document-default-version \
    --name "ExampleDocument" \
    --document-version $latestDocVersion
```

Windows

```
latestDocVersion=$(aws ssm update-document ^
    --content file://C:\path\to\file\documentContent.json ^
    --name "ExampleDocument" ^
    --document-format JSON ^
    --document-version "$LATEST" ^
    | jq -r '.DocumentDescription.LatestVersion')

aws ssm update-document-default-version ^
    --name "ExampleDocument" ^
```

```
    --document-version $latestDocVersion
```

PowerShell

```
$content = Get-Content -Path "C:\path\to\file\documentContent.json" | Out-
String
$latestDocVersion = Update-SSMDocument `
    -Content $content `
    -Name "ExampleDocument" `
    -DocumentFormat "JSON" `
    -DocumentVersion '$LATEST' `
    | Select-Object -ExpandProperty LatestVersion

Update-SSMDocumentDefaultVersion `
    -Name "ExampleDocument" `
    -DocumentVersion $latestDocVersion
```

Security best practices for SSM documents

When creating SSM documents, follow these security best practices to help prevent command injection and ensure secure parameter handling:

- Use environment variable interpolation for string parameters that will be used in commands or scripts. Add the `interpolationType` property with value `ENV_VAR` to your string parameters:

  ```
  {
      "command": {
          "type": "String",
          "description": "Command to execute",
          "interpolationType": "ENV_VAR"
      }
  }
  ```

  You can further improve the security of your SSM documents by specifying that double-quote marks aren't accepted in values delivered by interpolation:

  ```
  {
      "command": {
          "type": "String",
          "description": "Command to execute",
  ```

```
        "interpolationType": "ENV_VAR",
            "allowedPattern": "^[^"]*$"
    }
}
```

- When using interpreted languages like Python, Ruby, or Node.js, reference parameters using the appropriate environment variable syntax:

```
# Python example
import os
command = os.environ['SSM_Message']
```

- For backwards compatibility with older SSM Agent versions (prior to version 3.3.2746.0), include fallback logic for environment variables:

```
if [ -z "${SSM_command+x}" ]; then
    export SSM_command="{{command}}"
fi
```

- Combine environment variable interpolation with `allowedPattern` for additional input validation. In the following example, the `allowedPattern` value `^[^"]*$` specifically prevent double-quotes in the string value:

```
{
    "command": {
        "type": "String",
        "interpolationType": "ENV_VAR",
        "allowedPattern": "^[a-zA-Z0-9_-]+$"
    }
}
```

- Before implementing your SSM document, verify the following security considerations:
  - All string parameters that accept user input use environment variable interpolation when appropriate.
  - Input validation is implemented using `allowedPattern` where possible.
  - The document includes appropriate error handling for parameter processing.
  - Backwards compatibility is maintained for environments using older SSM Agent versions.

For information about Amazon service-owned resources that Systems Manager accesses and how to configure data perimeter policies, see Data perimeters in Amazon Systems Manager.

Cloning an SSM document

You can clone Amazon Systems Manager documents using the Systems Manager Documents console to create SSM documents. Cloning SSM documents copies content from an existing document to a new document that you can modify. You can't clone a document larger than 64KB.

To clone an SSM document

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. In the search box, enter the name of the document you want to clone.
4. Choose the name of the document you want to clone, and then choose **Clone document** in the **Actions** dropdown.
5. Modify the document as you prefer, and then choose **Create document** to save the document.

After writing your SSM document content, you can use your content to create an SSM document using one of the following methods.

Create SSM documents

- Creating composite documents

Creating composite documents

A *composite* Amazon Systems Manager (SSM) document is a custom document that performs a series of actions by running one or more secondary SSM documents. Composite documents promote *infrastructure as code* by allowing you to create a standard set of SSM documents for common tasks such as boot-strapping software or domain-joining instances. You can then share these documents across Amazon Web Services accounts in the same Amazon Web Services Region to reduce SSM document maintenance and ensure consistency.

For example, you can create a composite document that performs the following actions:

1. Installs all patches in the allow list.
2. Installs antivirus software.

3. Downloads scripts from GitHub and runs them.

In this example, your custom SSM document includes the following plugins to perform these actions:

1. The `aws:runDocument` plugin to run the `AWS-RunPatchBaseline` document, which installs all allow listed patches.
2. The `aws:runDocument` plugin to run the `AWS-InstallApplication` document, which installs the antivirus software.
3. The `aws:downloadContent` plugin to download scripts from GitHub and run them.

Composite and secondary documents can be stored in Systems Manager, GitHub (public and private repositories), or Amazon S3. Composite documents and secondary documents can be created in JSON or YAML.

> **Note**
>
> Composite documents can only run to a maximum depth of three documents. This means that a composite document can call a child document; and that child document can call one last document.

To create a composite document, add the `aws:runDocument` plugin in a custom SSM document and specify the required inputs. The following is an example of a composite document that performs the following actions:

1. Runs the `aws:downloadContent` plugin to download an SSM document from a GitHub public repository to a local directory called bootstrap. The SSM document is called StateManagerBootstrap.yml (a YAML document).
2. Runs the `aws:runDocument` plugin to run the StateManagerBootstrap.yml document. No parameters are specified.
3. Runs the `aws:runDocument` plugin to run the `AWS-ConfigureDocker pre-defined` SSM document. The specified parameters install Docker on the instance.

```

More info

- For information about rebooting servers and instances when using Run Command to call scripts, see Handling reboots when running commands.
- For more information about the plugins you can add to a custom SSM document, see Command document plugin reference.

- If you simply want to run a document from a remote location (without creating a composite document), see Running documents from remote locations.

Working with documents

This section includes information about how to use and work with SSM documents.

Topics

- Compare SSM document versions
- Create an SSM document
- Deleting custom SSM documents
- Running documents from remote locations
- Sharing SSM documents
- Searching for SSM documents

Compare SSM document versions

You can compare the differences in content between versions of Amazon Systems Manager (SSM) documents in the Systems Manager Documents console. When comparing versions of an SSM document, differences between the content of the versions are highlighted.

To compare SSM document content (console)

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. In the documents list, choose the document whose content you want to compare.
4. On the **Content** tab, select **Compare versions**, and choose the version of the document you want to compare the content to.

Create an SSM document

After you create the content for your custom SSM document, as described in Writing SSM document content, you can use the Systems Manager console to create an SSM document using your content.

To create an SSM document

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. Choose **Create command or session**.
4. Enter a descriptive name for the document.
5. (Optional) For **Target type**, specify the type of resources the document can run on.
6. In the **Document type** list, choose the type of document you want to create.
7. Delete the brackets in the **Content** field, and then paste the document content you created earlier.
8. (Optional) In the **Document tags** section, apply one or more tag key name/value pairs to the document.

   Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a document to identify the type of tasks it runs, the type of operating systems it targets, and the environment it runs in. In this case, you could specify the following key name/value pairs:

   - `Key=TaskType,Value=MyConfigurationUpdate`
   - `Key=OS,Value=AMAZON_LINUX_2`
   - `Key=Environment,Value=Production`
9. Choose **Create document** to save the document.

Deleting custom SSM documents

If you no longer want to use a custom SSM document, you can delete it using the Amazon Systems Manager console.

To delete an SSM document

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. Select the document you want to delete.

4. Select **Delete**. When prompted to delete the document, select **Delete**.

For examples using command line tools or SDKs to delete SSM documents, see Use `DeleteDocument` with an Amazon SDK or CLI.

Running documents from remote locations

You can run Amazon Systems Manager (SSM) documents from remote locations by using the `AWS-RunDocument` pre-defined SSM document. This document supports running SSM documents stored in the following locations:

- Public and private GitHub repositories (GitHub Enterprise is not supported)
- Amazon S3 buckets
- Systems Manager

While you can also run remote documents by using State Manager or Automation, tools in Amazon Systems Manager, the following procedure describes only how to run remote SSM documents by using Amazon Systems Manager Run Command in the Systems Manager console.

Note

`AWS-RunDocument` can be used to run only command-type SSM documents, not other types such as Automation runbooks. The `AWS-RunDocument` uses the `aws:downloadContent` plugin. For more information about the `aws:downloadContent` plugin, see `aws:downloadContent`.

Warning

`AWS-RunDocument` can execute document content from various sources (SSM documents, GitHub, S3, URLs). When executing remote documents, the IAM permissions evaluated are for `ssm:GetDocument` on the remote document and `ssm:SendCommand` on `AWS-RunDocument`. If you have IAM policies that deny access to specific SSM documents, users with `AWS-RunDocument` permissions can still execute those denied documents by passing the document content as parameters, which may not be subject to the same document-specific IAM restrictions.
To properly restrict document execution, use one of these approaches:

- **Allowlist approved sources**: If you need to use nested document execution, restrict access to only approved sources. Use IAM policies to control `ssm:GetDocument` for SSM document sources. Use IAM and Amazon S3 bucket policies for Amazon S3 sources. Use network settings (such as VPC endpoints or security groups) for public Internet sources.
- **Restrict access to AWS-RunDocument**: Deny `ssm:SendCommand` on `AWS-RunDocument` and any other documents that use the `aws:runDocument` plugin in your IAM policies to prevent nested document execution.
- **Use permission boundaries**: Implement IAM permission boundaries to set maximum permissions for users, preventing them from executing unauthorized documents regardless of the execution method.

For more information about IAM best practices and permission boundaries, see Permissions boundaries for IAM entities in the *Amazon Identity and Access Management User Guide*.

Before you begin

Before you run a remote document, you must complete the following tasks.

- Create an SSM Command document and save it in a remote location. For more information, see Creating SSM document content
- If you plan to run a remote document that is stored in a private GitHub repository, then you must create a Systems Manager `SecureString` parameter for your GitHub security access token. You can't access a remote document in a private GitHub repository by manually passing your token over SSH. The access token must be passed as a Systems Manager `SecureString` parameter. For more information about creating a `SecureString` parameter, see Creating Parameter Store parameters in Systems Manager.

Run a remote document (console)

To run a remote document

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.

4. In the **Document** list, choose **AWS-RunDocument**.
5. In **Command parameters**, for **Source Type**, choose an option.

   - If you choose **GitHub**, specify **Source Info** information in the following format:

     ```
     {
         "owner": "owner_name",
         "repository": "repository_name",
         "path": "path_to_document",
         "getOptions":"branch:branch_name",
         "tokenInfo": "{{ssm-secure:secure-string-token}}"
     }
     ```

     For example:

     ```
     {
         "owner":"TestUser",
         "repository":"GitHubTestExamples",
         "path":"scripts/python/test-script",
         "getOptions":"branch:exampleBranch",
         "tokenInfo":"{{ssm-secure:my-secure-string-token}}"
     }
     ```

     Note

     `getOptions` are extra options to retrieve content from a branch other than master, or from a specific commit in the repository. `getOptions` can be omitted if you are using the latest commit in the master branch. The `branch` parameter is required only if your SSM document is stored in a branch other than `master`.
     To use the version of your SSM document in a particular *commit* in your repository, use `commitID` with `getOptions` instead of `branch`. For example:

     ```
     "getOptions": "commitID:bbc1ddb94...b76d3bEXAMPLE",
     ```

   - If you choose **S3**, specify **Source Info** information in the following format:

     ```
     {"path":"URL_to_document_in_S3"}
     ```

For example:

```
{"path":"https://s3.amazonaws.com.cn/amzn-s3-demo-bucket/scripts/ruby/
mySSMdoc.json"}
```

- If you choose **SSMDocument**, specify **Source Info** information in the following format:

```
{"name": "document_name"}
```

For example:

```
{"name": "mySSMdoc"}
```

6. In the **Document Parameters** field, enter parameters for the remote SSM document. For example, if you run the `AWS-RunPowerShell` document, you could specify:

```
{"commands": ["date", "echo \"Hello World\""]}
```

If you run the `AWS-ConfigureAWSPack` document, you could specify:

```
{
   "action":"Install",
   "name":"AWSPVDriver"
}
```

7. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

> **Tip**
>
> If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

8. For **Other parameters**:

- For **Comment**, enter information about this command.
- For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.

9. For **Rate control**:

   - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

     > **Note**
     >
     > If you selected targets by specifying tags applied to managed nodes or by specifying Amazon resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

   - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

10. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

    > **Note**
    >
    > The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different Amazon Web Services account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

11. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

    For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

12. Choose **Run**.

> **Note**
>
> For information about rebooting servers and instances when using Run Command to call scripts, see Handling reboots when running commands.

Sharing SSM documents

You can share Amazon Systems Manager (SSM) documents with other accounts in the same Amazon Web Services Region in two ways. For new document sharing, we recommend using Amazon Resource Access Manager (Amazon RAM). With Amazon RAM, you can share a document with an entire organization or organizational unit (OU) in Amazon Organizations, or with individual Amazon Web Services accounts. You can also manage all of your shares from the Amazon RAM console. For more information, see Share an SSM document using Amazon RAM.

You can also share a document by using account permissions, the original sharing mechanism. With account permissions, you modify the document permissions directly to share a document privately with specific Amazon Web Services account IDs, or publicly with everyone. Account-permission sharing remains supported. For more information, see Share an SSM document using account permissions.

If you already share documents by using account permissions, you can migrate those shares to Amazon RAM. For more information, see Migrate an existing shared document to Amazon RAM.

You can't share a document publicly and privately at the same time. You also can't use Amazon RAM sharing and account-permission (`ModifyDocumentPermission`) sharing on the same document at the same time.

> **Warning**
>
> Use shared SSM documents only from trusted sources. When using any shared document, carefully review the contents of the document before using it so that you understand how it will change the configuration of your instance. For more information about shared document best practices, see Best practices for shared SSM documents.

Limitations

As you begin working with SSM documents, be aware of the following limitations.

- Only the owner can share a document.
- Documents can be shared with other accounts in the same Amazon Web Services Region only. Cross-Region sharing isn't supported.

> **Important**
>
> In Systems Manager, an *Amazon-owned* SSM document is a document created and managed by Amazon Web Services itself. *Amazon-owned* documents include a prefix like `AWS-*` in the document name. The owner of the document is considered to be Amazon, not a specific user account within Amazon. These documents are publicly available for all to use.

Contents

- Share an SSM document using Amazon RAM
- Share an SSM document using account permissions
- Using shared SSM documents

Best practices for shared SSM documents

Review the following guidelines before you share or use a shared document.

Use Amazon RAM to share documents (recommended)

For new document sharing, we recommend using Amazon Resource Access Manager (Amazon RAM) instead of the `ModifyDocumentPermission` API operation. When you share through Amazon RAM, you can share a document with an entire organization or organizational unit (OU) in Amazon Organizations instead of listing individual Amazon Web Services account IDs. You can also manage access with a resource-based policy, and view and audit all of your shares in one place in the Amazon RAM console. For steps, see Share an SSM document using Amazon RAM. Documents that you share with individual Amazon Web Services account IDs by using `ModifyDocumentPermission` are still supported. To move a document that you already share to Amazon RAM, see Migrate an existing shared document to Amazon RAM.

Remove sensitive information

Review your Amazon Systems Manager (SSM) document carefully and remove any sensitive information. For example, verify that the document doesn't include your Amazon credentials. If you share a document with specific individuals, those users can view the information in the document. If you share a document publicly, anyone can view the information in the document.

Block public sharing for documents

Review all publicly shared SSM documents in your account and confirm whether you want to continue sharing them. To stop sharing a document with the public, you must modify the document permission setting as described in the Modify permissions for a shared SSM document section of this topic. Turning on the block public sharing setting doesn't affect any documents you're currently sharing with the public. Unless your use case requires you to share documents with the public, we recommend turning on the block public sharing setting for your SSM documents in the **Preferences** section of the Systems Manager Documents console. Turning on this setting prevents unwanted access to your SSM documents. The block public sharing setting is an account level setting that can differ for each Amazon Web Services Region.

Restrict Run Command actions using an IAM trust policy

Create a restrictive Amazon Identity and Access Management (IAM) policy for users who will have access to the document. The IAM policy determines which SSM documents a user can see in either the Amazon Elastic Compute Cloud (Amazon EC2) console or by calling `ListDocuments` using the Amazon Command Line Interface (Amazon CLI) or Amazon Tools for Windows PowerShell. The policy also restricts the actions the user can perform with SSM documents. You can create a restrictive policy so that a user can only use specific documents. For more information, see Customer managed policy examples.

Use caution when using shared SSM documents

Review the contents of every document that is shared with you, especially public documents, to understand the commands that will be run on your instances. A document could intentionally or unintentionally have negative repercussions after it's run. If the document references an external network, review the external source before you use the document.

Send commands using the document hash

When you share a document, the system creates a Sha-256 hash and assigns it to the document. The system also saves a snapshot of the document content. When you send a command using a shared document, you can specify the hash in your command to make sure that the following conditions are true:

- You're running a command from the correct Systems Manager document
- The content of the document hasn't changed since it was shared with you.

If the hash doesn't match the specified document or if the content of the shared document has changed, the command returns an `InvalidDocument` exception. The hash can't verify document content from external locations.

Use the interpolation parameter to improve security

For `String` type parameters in your SSM documents, use the parameter and value `interpolationType": "ENV_VAR` to improve security against command injection attacks by treating parameter inputs as string literals rather than potentially executable commands. In this case, the agent creates an environment variable named `SSM_`*`parameter-name`* with the parameter's value. We recommend updating all your existing SSM documents that include `String` type parameters to include `"interpolationType": "ENV_VAR"`. For more information, see the section called “Writing SSM document content”.

Block public sharing for SSM documents

Before you begin, review all publicly shared SSM documents in your Amazon Web Services account and confirm whether you want to continue sharing them. To stop sharing an SSM document with the public, you must modify the document permission setting as described in the Modify permissions for a shared SSM document section of this topic. Turning on the block public sharing setting doesn't affect any SSM documents you're currently sharing with the public. With the block public sharing setting enabled, you won’t be able to share any additional SSM documents with the public.

Unless your use case requires you to share documents with the public, we recommend turning on the block public sharing setting for your SSM documents. Turning on this setting prevents unwanted access to your SSM documents. The block public sharing setting is an account level setting that can differ for each Amazon Web Services Region. Complete the following tasks to block public sharing for any SSM documents you're not currently sharing.

Block public sharing (console)

To block public sharing of your SSM documents

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.

2. In the navigation pane, choose **Documents**.
3. Choose **Preferences**, and then choose **Edit** in the **Block public sharing** section.
4. Select the **Block public sharing** check box, and then choose **Save**.

Block public sharing (command line)

Open the Amazon Command Line Interface (Amazon CLI) or Amazon Tools for Windows PowerShell on your local computer and run the following command to block public sharing of your SSM documents.

Linux & macOS

```
aws ssm update-service-setting  \
    --setting-id /ssm/documents/console/public-sharing-permission \
    --setting-value Disable \
    --region 'The Amazon Web Services Region you want to block public sharing in'
```

Windows

```
aws ssm update-service-setting ^
    --setting-id /ssm/documents/console/public-sharing-permission ^
    --setting-value Disable ^
    --region "The Amazon Web Services Region you want to block public sharing in"
```

PowerShell

```
Update-SSMServiceSetting `
    -SettingId /ssm/documents/console/public-sharing-permission `
    -SettingValue Disable `
    -Region The Amazon Web Services Region you want to block public sharing in
```

Confirm the setting value was updated using the following command.

Linux & macOS

```
aws ssm get-service-setting   \
    --setting-id /ssm/documents/console/public-sharing-permission \
    --region The Amazon Web Services Region you blocked public sharing in
```

Windows

```
aws ssm get-service-setting  ^
    --setting-id /ssm/documents/console/public-sharing-permission ^
    --region "The Amazon Web Services Region you blocked public sharing in"
```

PowerShell

```
Get-SSMServiceSetting `
    -SettingId /ssm/documents/console/public-sharing-permission `
    -Region The Amazon Web Services Region you blocked public sharing in
```

Restricting access to block public sharing with IAM

You can create Amazon Identity and Access Management (IAM) policies that restrict users from modifying the block public sharing setting. This prevents users from allowing unwanted access to your SSM documents.

The following is an example of an IAM policy that prevents users from updating the block public sharing setting. To use this example, you must replace the example Amazon Web Services account ID with your own account ID.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": "ssm:UpdateServiceSetting",
            "Resource": "arn:aws-cn:ssm:*:444455556666:servicesetting/ssm/
documents/console/public-sharing-permission"
        }
    ]
}
```

Share an SSM document using Amazon RAM

Amazon Resource Access Manager (Amazon RAM) is the recommended way to share Amazon Systems Manager (SSM) documents. With Amazon RAM, you create a resource share that grants access to your document, and you manage all of your shares from the Amazon RAM console. You can share an SSM document with the following three types of principals:

- An entire organization in Amazon Organizations.
- An organizational unit (OU) in Amazon Organizations.
- Individual Amazon Web Services accounts.

You can share a document only with accounts in the same Amazon Web Services Region, and only the document owner can share a document. For more information about sharing with Amazon RAM, see Getting started with Amazon RAM in the *Amazon Resource Access Manager User Guide*.

Important

When you share an SSM document by using Amazon RAM, you share all versions of the document, not only the default version.

Note

Amazon RAM supports private sharing only. To share a document publicly, use the procedure in Share an SSM document using account permissions instead.

Note

When you share a document with an Amazon Web Services account that is outside your organization, the consumer must accept the resource share invitation in Amazon RAM before they can access the document. When you share within an organization that has Amazon RAM sharing enabled, no invitation is required, and Amazon RAM grants access automatically.

Amazon RAM service quotas apply when you share SSM documents through Amazon RAM. For more information, see Service quotas for Amazon RAM in the *Amazon Resource Access Manager User Guide*.

To manage an existing share (for example, to update principals or stop sharing a document that you shared through Amazon RAM), see Working with shared Amazon resources in the *Amazon Resource Access Manager User Guide*.

Share a document using Amazon RAM (console)

To share a document using Amazon RAM

1. Open the Amazon RAM console at https://console.aws.amazon.com/ram/.
2. In the navigation pane, choose **Resource shares**, and then choose **Create resource share**.
3. For **Name**, enter a name for the resource share.
4. Under **Resources**, choose the resource type **SSM Documents**, and then select the document that you want to share.
5. (Optional) Under **Managed permissions**, review the managed permission that Amazon RAM applies to the shared document.
6. Choose **Next**. Under **Principals**, add the organization, OUs, or Amazon Web Services accounts that you want to share with. To share with your organization or an OU, you must enable sharing within Amazon Organizations.
7. Choose **Next**, review your choices, and then choose **Create resource share**.

Share a document using Amazon RAM (command line)

Open the Amazon Command Line Interface (Amazon CLI) or Amazon Tools for Windows PowerShell on your local computer and run the following command to share a document by creating an Amazon RAM resource share. For the `--principals` parameter, specify an organization ARN, an OU ARN, or an Amazon Web Services account ID.

Linux & macOS

```
aws ram create-resource-share \
    --name MyDocumentShare \
    --resource-arns arn:aws:ssm:region:account-id:document/document-name \
    --principals principal
```

Windows

```
aws ram create-resource-share ^
    --name MyDocumentShare ^
    --resource-arns arn:aws:ssm:region:account-id:document/document-name ^
    --principals principal
```

Note

After you create a share, Amazon RAM might take a few minutes to propagate the change before consuming accounts can see it.

Migrate an existing shared document to Amazon RAM

If you currently share a document by using account permissions (the `ModifyDocumentPermission` API operation), you can migrate it to an Amazon RAM resource share by running the `AWS-MigrateSSMDocumentSharingToRAM` runbook. This Amazon-owned Amazon Systems Manager Automation runbook migrates a document from account-permission sharing to an Amazon RAM resource share while preserving the document's existing consumers.

Note

Running the `AWS-MigrateSSMDocumentSharingToRAM` runbook uses Amazon Systems Manager Automation, which incurs charges. For more information, see Amazon Systems Manager pricing.

Note

You can't migrate a document that is shared publicly, because Amazon RAM supports private sharing only. If you specify a publicly shared document, the runbook fails. If you migrate all documents in the account, the runbook skips publicly shared documents. To migrate a publicly shared document, first stop sharing it publicly, and then share it with the accounts, organizational units (OUs), or organization that you want.

Important

After you migrate a document, you manage sharing for that document through Amazon RAM. The `ModifyDocumentPermission` and `DescribeDocumentPermission` API operations return a 4xx error for a migrated document. If the migration fails or is canceled, the runbook automatically rolls back the change.

To migrate a document from its Permissions view (console)

1. Open the Amazon Systems Manager console and, in the navigation pane, choose **Documents**.
2. Choose the document that you want to migrate.
3. Choose the **Details** tab.
4. In the **Permissions** section, choose **Migrate to RAM**. Systems Manager opens the **Migrate to RAM** page, which helps you start the migration.
5. For **Documents to migrate**, select the documents to migrate. Select individual documents, or choose **All documents** to migrate every document in the account that uses account-permission sharing.
6. For **AutomationAssumeRole**, choose the IAM role that Systems Manager Automation assumes to run the migration.
7. (Optional) For **Organizational units**, add an organization ID or organizational unit (OU) ID to share the documents with.
8. Choose **Start migration**.

For the full list of parameters, the IAM permissions required for the `AutomationAssumeRole` role, and step-by-step instructions for running the runbook, see AWS-MigrateSSMDocumentSharingToRAM in the Amazon Systems Manager Automation runbook reference.

Share an SSM document using account permissions

You can share Amazon Systems Manager (SSM) documents by modifying the document permissions to grant access to specific Amazon Web Services account IDs (private sharing) or to everyone (public sharing). You can share documents from the Systems Manager console, or programmatically by calling the `ModifyDocumentPermission` API operation using the Amazon Command Line Interface (Amazon CLI), Amazon Tools for Windows PowerShell, or the Amazon

SDK. When you share documents from the console, you can share only the default version of the document. Before you share a document, get the Amazon Web Services account IDs of the accounts that you want to share with. Specify these account IDs when you share the document.

> **Note**
>
> For new document sharing, we recommend using Amazon Resource Access Manager (Amazon RAM) instead. With Amazon RAM, you can share with an entire organization or OU and manage all of your shares in one place. For more information, see Share an SSM document using Amazon RAM.

Limitations

Be aware of the following limitations when you share a document by using account permissions.

- You must stop sharing a document before you can delete it. For more information, see Modify permissions for a shared SSM document.
- You can share a document with a maximum of 1,000 Amazon Web Services accounts. You can request an increase to this limit in the Amazon Web Services Support Center. For **Limit type**, choose *EC2 Systems Manager* and describe your reason for the request.
- You can publicly share a maximum of five SSM documents. You can request an increase to this limit in the Amazon Web Services Support Center. For **Limit type**, choose *EC2 Systems Manager* and describe your reason for the request.

For more information about Systems Manager service quotas, see Amazon Systems Manager Service Quotas.

Share a document (console)

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. In the documents list, choose the document you want to share, and then choose **View details**. On the **Permissions** tab, verify that you're the document owner. Only a document owner can share a document.
4. Choose **Edit**.

5. To share the command publicly, choose **Public** and then choose **Save**. To share the command privately, choose **Private**, enter the Amazon Web Services account ID, choose **Add permission**, and then choose **Save**.

Share a document (command line)

The following procedure requires that you specify an Amazon Web Services Region for your command line session.

1. Open the Amazon CLI or Amazon Tools for Windows PowerShell on your local computer and run the following command to specify your credentials.

   In the following command, replace *region* with your own information. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

   Linux & macOS

   ```
   aws config

   AWS Access Key ID: [your key]
   AWS Secret Access Key: [your key]
   Default region name: region
   Default output format [None]:
   ```

   Windows

   ```
   aws config

   AWS Access Key ID: [your key]
   AWS Secret Access Key: [your key]
   Default region name: region
   Default output format [None]:
   ```

   PowerShell

   ```
   Set-AWSCredentials –AccessKey your key –SecretKey your key
   Set-DefaultAWSRegion -Region region
   ```

2. Use the following command to view the permissions for the document.

Linux & macOS

```
aws ssm describe-document-permission \
    --name document name \
    --permission-type Share
```

Windows

```
aws ssm describe-document-permission ^
    --name document name ^
    --permission-type Share
```

PowerShell

```
Get-SSMDocumentPermission `
    -Name document name `
    -PermissionType Share
```

3. Use the following command to modify the permissions for the document and share it. You must be the owner of the document to edit the permissions. Optionally, for documents shared with specific Amazon Web Services account IDs, you can specify a version of the document you want to share using the `--shared-document-version` parameter. If you don't specify a version, the system shares the `Default` version of the document. If you share a document publicly (with `all`), all versions of the specified document are shared by default. The following example command privately shares the document with a specific individual, based on that person's Amazon Web Services account ID.

   Linux & macOS

   ```
   aws ssm modify-document-permission \
       --name document name \
       --permission-type Share \
       --account-ids-to-add Amazon Web Services account ID
   ```

   Windows

   ```
   aws ssm modify-document-permission ^
       --name document name ^
       --permission-type Share ^
   ```

```
    --account-ids-to-add Amazon Web Services account ID
```

PowerShell

```
Edit-SSMDocumentPermission `
    –Name document name `
    -PermissionType Share `
    -AccountIdsToAdd Amazon Web Services account ID
```

4. Use the following command to share a document publicly.

> **Note**
>
> If you share a document publicly (with `all`), all versions of the specified document are shared by default.

Linux & macOS

```
aws ssm modify-document-permission \
    --name document name \
    --permission-type Share \
    --account-ids-to-add 'all'
```

Windows

```
aws ssm modify-document-permission ^
    --name document name ^
    --permission-type Share ^
    --account-ids-to-add "all"
```

PowerShell

```
Edit-SSMDocumentPermission `
    -Name document name `
    -PermissionType Share `
    -AccountIdsToAdd ('all')
```

Modify permissions for a shared SSM document

If you share a command, users can view and use that command until you either remove access to the Amazon Systems Manager (SSM) document or delete the SSM document. However, you can't delete a document as long as it's shared. You must stop sharing it first and then delete it.

> **Note**
>
> This section applies to documents that you shared by using account permissions. To manage a document that you shared through Amazon RAM, see Share an SSM document using Amazon RAM.

Stop sharing a document (console)

Stop sharing a document

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. In the documents list, choose the document you want to stop sharing, and then choose the **Details**. In the **Permissions** section, verify that you're the document owner. Only a document owner can stop sharing a document.
4. Choose **Edit**.
5. Choose **X** to delete the Amazon Web Services account ID that should no longer have access to the command, and then choose **Save**.

Stop sharing a document (command line)

Open the Amazon CLI or Amazon Tools for Windows PowerShell on your local computer and run the following command to stop sharing a document.

Linux & macOS

```
aws ssm modify-document-permission \
    --name document name \
    --permission-type Share \
    --account-ids-to-remove 'Amazon Web Services account ID'
```

Windows

```
aws ssm modify-document-permission ^
    --name document name ^
    --permission-type Share ^
    --account-ids-to-remove "Amazon Web Services account ID"
```

PowerShell

```
Edit-SSMDocumentPermission `
    -Name document name `
    -PermissionType Share `
    –AccountIdsToRemove Amazon Web Services account ID
```

Using shared SSM documents

When you share an Amazon Systems Manager (SSM) document, the system generates an Amazon Resource Name (ARN) and assigns it to the command. If you select and run a shared document from the Systems Manager console, you don't see the ARN. However, if you want to run a shared SSM document using a method other than the Systems Manager console, you must specify the full ARN of the document for the `DocumentName` request parameter. You're shown the full ARN for an SSM document when you run the command to list documents.

> **Note**
>
> You aren't required to specify ARNs for Amazon public documents (documents that begin with `AWS-*`) or documents that you own.

Use a shared SSM document (command line)

To list all public SSM documents

Linux & macOS

```
aws ssm list-documents \
    --filters Key=Owner,Values=Public
```

Windows

```
aws ssm list-documents ^
    --filters Key=Owner,Values=Public
```

PowerShell

```
$filter = New-Object Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$filter.Key = "Owner"
$filter.Values = "Public"

Get-SSMDocumentList `
    -Filters @($filter)
```

To list private SSM documents that have been shared with you

Linux & macOS

```
aws ssm list-documents \
    --filters Key=Owner,Values=Private
```

Windows

```
aws ssm list-documents ^
    --filters Key=Owner,Values=Private
```

PowerShell

```
$filter = New-Object Amazon.SimpleSystemsManagement.Model.DocumentKeyValuesFilter
$filter.Key = "Owner"
$filter.Values = "Private"

Get-SSMDocumentList `
    -Filters @($filter)
```

To list all SSM documents available to you

Linux & macOS

```
aws ssm list-documents
```

Windows

```
aws ssm list-documents
```

PowerShell

```
Get-SSMDocumentList
```

To get information about an SSM document that has been shared with you

Linux & macOS

```
aws ssm describe-document \
    --name arn:aws-cn:ssm:us-east-2:12345678912:document/documentName
```

Windows

```
aws ssm describe-document ^
    --name arn:aws-cn:ssm:us-east-2:12345678912:document/documentName
```

PowerShell

```
Get-SSMDocumentDescription `
    -Name arn:aws-cn:ssm:us-east-2:12345678912:document/documentName
```

To run a shared SSM document

Linux & macOS

```
aws ssm send-command \
    --document-name arn:aws-cn:ssm:us-east-2:12345678912:document/documentName \
    --instance-ids ID
```

Windows

```
aws ssm send-command ^
    --document-name arn:aws-cn:ssm:us-east-2:12345678912:document/documentName ^
    --instance-ids ID
```

PowerShell

```
Send-SSMCommand `
    -DocumentName arn:aws-cn:ssm:us-east-2:12345678912:document/documentName `
    -InstanceIds ID
```

Searching for SSM documents

You can search the Amazon Systems Manager (SSM) document store for SSM documents by using either free text search or a filter-based search. You can also favorite documents to help you find frequently used SSM documents. The following sections describes how to use these features.

Using free text search

The search box on the Systems Manager **Documents** page supports free text search. Free text search compares the search term or terms that you enter against the document name in each SSM document. If you enter a single search term, for example **`ansible`**, then Systems Manager returns all SSM documents where this term was discovered. If you enter multiple search terms, then Systems Manager searches by using an `OR` statement. For example, if you specify **`ansible`** and **`linux`**, then search returns all documents with *either* keyword in their name.

If you enter a free text search term and choose a search option, such as **Platform type**, then search uses an `AND` statement and returns all documents with the keyword in their name and the specified platform type.

> **Note**
>
> Note the following details about free text search.
>
> - Free text search is *not* case sensitive.
> - Search terms require a minimum of three characters and have a maximum of 20 characters.

- Free text search accepts up to five search terms.
- If you enter a space between search terms, the system includes the space when searching.
- You can combine free text search with other search options such as **Document type** or **Platform type**.
- The **Document Name Prefix** filter and free text search can't be used together. they're mutually exclusive.

To search for an SSM document

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. Enter your search terms in the search box, and press Enter.

Performing free text document search by using the Amazon CLI

To perform a free text document search by using the CLI

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.
2. To perform free text document search with a single term, run the following command. In this command, replace *search_term* with your own information.

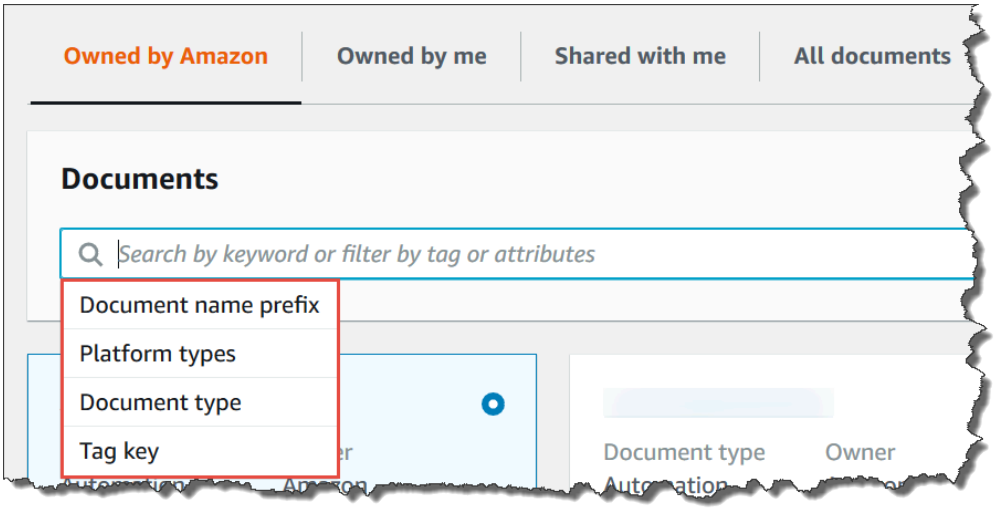
   ```
   aws ssm list-documents --filters Key="SearchKeyword",Values="search_term"
   ```

   Here's an example.

   ```
   aws ssm list-documents --filters Key="SearchKeyword",Values="aws-asg" --region us-east-2
   ```

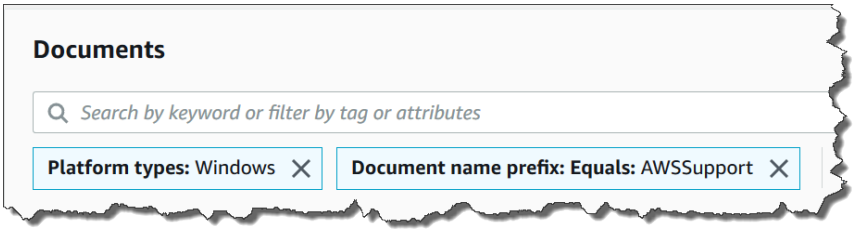
   To search using multiple terms that create an AND statement, run the following command. In this command, replace *search_term_1* and *search_term_2* with your own information.

```
aws ssm list-documents --filters
 Key="SearchKeyword",Values="search_term_1","search_term_2","search_term_3" --
region us-east-2
```



Here's an example.

```
aws ssm list-documents --filters Key="SearchKeyword",Values="aws-asg","aws-
ec2","restart" --region us-east-2
```



Using filters

The Systems Manager **Documents** page automatically displays the following filters when you choose the search box.

- Document name prefix
- Platform types
- Document type
- Tag key

You can search for SSM documents by using a single filter. If you want to return a more specific set of SSM documents, you can apply multiple filters. Here is an example of a search that uses the **Platform types** and the **Document name prefix** filters.

If you apply multiple filters, Systems Manager creates different search statements based on the filters you choose:

- If you apply the *same* filter multiple times, for example **Document name prefix**, then Systems Manager searches by using an OR statement. For example, if you specify one filter of **Document name prefix**=**AWS** and a second filter of **Document name prefix**=**Lambda**, then search returns all documents with the prefix "AWS" and all documents with the prefix "Lambda".
- If you apply *different* filters, for example **Document name prefix** and **Platform types**, then Systems Manager searches by using an AND statement. For example, if you specify a **Document name prefix**=**AWS** filter and a **Platform types**=**Linux** filter, then search returns all documents with the prefix "AWS" that are specific to the Linux platform.

> **Note**
>
> Searches that use filters are case sensitive.

Adding documents to your favorites

To help you find frequently used SSM documents, add documents to your favorites. You can favorite up to 20 documents per document type, per Amazon Web Services account and Amazon Web Services Region. You can choose, modify, and view your favorites from the documents Amazon Web Services Management Console. The following procedures describe how to choose, modify, and view your favorites.

To favorite an SSM document

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. Select the star icon next to the document name you want to favorite.

To remove an SSM document from your favorites

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. Deselect the star icon next to the document name you want to remove from your favorites.

To view your favorites from the documents Amazon Web Services Management Console

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Documents**.
3. Select the **Favorites** tab.

Troubleshooting parameter handling issues

Common parameter handling issues

Environment variables not available during execution

Problem: Commands fail because environment variables (SSM_*parameter-name*) are not found.

Possible causes:

- SSM Agent version doesn't support environment variable interpolation
- `interpolationType` is not set to `ENV_VAR`
- Parameter name doesn't match the expected environment variable name

Solution:

- Verify SSM Agent version is 3.3.2746.0 or later
- Add fallback logic for older agent versions:

```
if [ -z "${SSM_parameterName+x}" ]; then
    export SSM_parameterName="{{parameterName}}"
fi
```

Parameter values containing special characters

Problem: Commands fail when parameter values contain spaces, quotes, or other special characters.

Solution:

- Use proper quoting when referencing environment variables:

```
# Correct
echo "$SSM_parameter-name"

# Incorrect
echo $SSM_parameter-name
```

- Add input validation using `allowedPattern` to restrict special characters

Inconsistent behavior across platforms

Problem: Parameter handling works differently on Linux and Windows Server systems.

Solution:

- Use platform-specific environment variable syntax:

```
# PowerShell
$env:SSM_parameter-name

# Bash
$SSM_parameter-name
```

- Use platform-specific precondition checks in your document

Parameter values not properly escaped

Problem: Command injection vulnerabilities despite using environment variable interpolation.

Solution:

- Always use proper escaping when including parameter values in commands:

```
# Correct
mysql_command="mysql -u \"$SSM_username\" -p\"$SSM_password\""

# Incorrect
```

```
mysql_command="mysql -u $SSM_username -p$SSM_password"
```

Parameter validation tips

Use these techniques to validate your parameter handling:

1. Test environment variable availability:

```
#!/bin/bash
# Print all SSM_ environment variables
env | grep ^SSM_

# Test specific parameter
if [ -n "$SSM_parameter" ]; then
    echo "Parameter is available"
else
    echo "Parameter is not available"
fi
```

2. Verify parameter patterns:

```
parameters:
  myParameter:
    type: String
    allowedPattern: "^[a-zA-Z0-9_-]+$"
    description: "Test this pattern with sample inputs"
```

3. Include error handling:

```
if [[ ! "$SSM_parameter" =~ ^[a-zA-Z0-9_-]+$ ]]; then
    echo "Parameter validation failed"
    exit 1
fi
```

Amazon Systems Manager Maintenance Windows

Maintenance Windows helps you define a schedule for when to perform potentially disruptive actions on your nodes such as patching an operating system, updating drivers, or installing software or patches.

> **Note**
>
> State Manager and Maintenance Windows can perform some similar types of updates on your managed nodes. Which one you choose depends on whether you need to automate system compliance or perform high-priority, time-sensitive tasks during periods you specify.
> For more information, see Choosing between State Manager and Maintenance Windows.

With Maintenance Windows, you can schedule actions on numerous other Amazon resource types, such as Amazon Simple Storage Service (Amazon S3) buckets, Amazon Simple Queue Service (Amazon SQS) queues, Amazon Key Management Service (Amazon KMS) keys, and many more.

For a full list of supported resource types that you can include in a maintenance window target, see Resources you can use with Amazon Resource Groups and Tag Editor in the *Amazon Resource Groups User Guide*. To get started with Maintenance Windows, open the Systems Manager console. In the navigation pane, choose **Maintenance Windows**.

Each maintenance window has a schedule, a maximum duration, a set of registered targets (the managed nodes or other Amazon resources that are acted upon), and a set of registered tasks. You can add tags to your maintenance windows when you create or update them. (Tags are keys that help identify and sort your resources within your organization.) You can also specify dates that a maintenance window shouldn't run before or after, and you can specify the international time zone on which to base the maintenance window schedule.

For an explanation of how the various schedule-related options for maintenance windows relate to one another, see Maintenance window scheduling and active period options.

For more information about working with the `--schedule` option, see Reference: Cron and rate expressions for Systems Manager.

Supported task types

With maintenance windows, you can run four types of tasks:

- Commands in Run Command, a tool in Systems Manager

  For more information about Run Command, see Amazon Systems Manager Run Command.
- Workflows in Automation, a tool in Systems Manager

For more information about Automation workflows, see Amazon Systems Manager Automation.

- Functions in Amazon Lambda

  For more information about Lambda functions, see Getting started with Lambda in the *Amazon Lambda Developer Guide*.

- Tasks in Amazon Step Functions

> **Note**
>
> Maintenance window tasks support Step Functions Standard state machine workflows only. They don't support Express state machine workflows. For information about state machine workflow types, see Standard vs. Express Workflows in the *Amazon Step Functions Developer Guide*.

  For more information about Step Functions, see the *Amazon Step Functions Developer Guide*.

This means you can use maintenance windows to perform tasks such as the following on your selected targets.

- Install or update applications.
- Apply patches.
- Install or update SSM Agent.
- Run PowerShell commands and Linux shell scripts by using a Systems Manager Run Command task.
- Build Amazon Machine Images (AMIs), boot-strap software, and configure nodes by using a Systems Manager Automation task.
- Run Amazon Lambda functions that invokes additional actions, such as scanning your nodes for patch updates.
- Run Amazon Step Functions state machines to perform tasks such as removing a node from an Elastic Load Balancing environment, patching the node, and then adding the node back to the Elastic Load Balancing environment.
- Target nodes that are offline by specifying an Amazon resource group as the target.

> **Note**
>
> One or more targets must be specified for maintenance window Run Command-type tasks. Depending on the task, targets are optional for other maintenance window task types (Automation, Amazon Lambda, and Amazon Step Functions). For more information about running tasks that don't specify targets, see Registering maintenance window tasks without targets.

EventBridge support

This Systems Manager tool is supported as an *event* type in Amazon EventBridge rules. For information, see Monitoring Systems Manager events with Amazon EventBridge and Reference: Amazon EventBridge event patterns and types for Systems Manager.

Setting up Maintenance Windows

Before users in your Amazon Web Services account can create and schedule maintenance window tasks using Maintenance Windows, they must be granted the necessary permissions. In addition, you must create an IAM service role for maintenance windows and the IAM policy to attach to it.

Before you begin

In addition to the permissions you configure in this section, the IAM Entities (users, roles, or groups that will work with maintenance windows should already have general maintenance window permissions. You can grant these permissions by assigning the IAM policy `AmazonSSMFullAccess` to the Entities, or assigning a custom IAM policy that provides a smaller set of access permissions for Systems Manager that covers maintenance window tasks.

Topics

- Control access to maintenance windows using the console
- Control access to maintenance windows using the Amazon CLI

Control access to maintenance windows using the console

The following procedures describe how to use the Amazon Systems Manager console to create the required permissions and roles for maintenance windows.

Topics

- Task 1: Create a custom policy for your maintenance window service role using the console
- Task 2: Create a custom service role for maintenance windows using the console
- Task 3: Grant permissions to specified users to register maintenance window tasks using the console
- Task 4: Prevent specified users from registering maintenance window tasks using the console

Task 1: Create a custom policy for your maintenance window service role using the console

Maintenance window tasks require an IAM role to provide the permissions required to run on the target resources. The permissions are provided through an IAM policy attached to the role. The types of tasks you run and your other operational requirements determine the contents of this policy. We provide a base policy you can adapt to your needs. Depending on the tasks and types of tasks your maintenance windows run, you might not need all the permissions in this policy, and you might need to include additional permissions. You attach this policy to the role that you create later in Task 2: Create a custom service role for maintenance windows using the console.

To create a custom policy using the console

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Policies**, and then choose **Create policy**.
3. In the **Policy editor** area, choose **JSON**.
4. Replace the default contents with the following:

   JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:SendCommand",
                "ssm:CancelCommand",
                "ssm:ListCommands",
                "ssm:ListCommandInvocations",
                "ssm:GetCommandInvocation",
                "ssm:GetAutomationExecution",
                "ssm:StartAutomationExecution",
                "ssm:ListTagsForResource",
                "ssm:DescribeInstanceInformation",
                "ssm:GetParameters"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "states:DescribeExecution",
                "states:StartExecution"
            ],
            "Resource": [
                "arn:aws-cn:states:*:*:execution:*:*",
                "arn:aws-cn:states:*:*:stateMachine:*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "lambda:InvokeFunction"
            ],
            "Resource": [
                "arn:aws-cn:lambda:*:*:function:*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "resource-groups:ListGroups",
                "resource-groups:ListGroupResources"
            ],
```

```
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "tag:GetResources"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws-cn:iam::111122223333:role/maintenance-
window-role-name",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "ssm.amazonaws.com"
                    ]
                }
            }
        }
    ]
}
```

5. Modify the JSON content as needed for the maintenance tasks that you run in your account. The changes you make are specific to your planned operations.

   For example:

   - You can provide Amazon Resource Names (ARNs) for specific functions and state machines instead of using wildcard (*) qualifiers.
   - If you don't plan to run Amazon Step Functions tasks, you can remove the `states` permissions and (ARNs).
   - If you don't plan to run Amazon Lambda tasks, you can remove the `lambda` permissions and ARNs.
   - If you don't plan to run Automation tasks, you can remove the `ssm:GetAutomationExecution` and `ssm:StartAutomationExecution` permissions.

- Add additional permissions that might be needed for the tasks to run. For example, some Automation actions work with Amazon CloudFormation stacks. Therefore, the permissions `cloudformation:CreateStack`, `cloudformation:DescribeStacks`, and `cloudformation:DeleteStack` are required.

  For another example, the Automation runbook `AWS-CopySnapshot` requires permissions to create an Amazon Elastic Block Store (Amazon EBS) snapshot. Therefore, the service role needs the permission `ec2:CreateSnapshot`.

  For information about the role permissions needed by Automation runbooks, see the runbook descriptions in the Amazon Systems Manager Automation Runbook Reference.

6. After completing the policy revisions, choose **Next**.
7. For **Policy name**, enter a name that identifies this as the policy attached to the service role you create. For example: **`my-maintenance-window-role-policy`**.
8. (Optional) In the **Add tags** area, add one or more tag-key value pairs to organize, track, or control access for this policy.
9. Choose **Create policy**.

   Make a note of the name you specified for the policy. You refer to it in the next procedure, Task 2: Create a custom service role for maintenance windows using the console.

Task 2: Create a custom service role for maintenance windows using the console

The policy you created in the previous task is attached to the maintenance window service role you create in this task. When users register a maintenance window task, they specify this IAM role as part of the task configuration. The permissions in this role allow Systems Manager to run tasks in maintenance windows on your behalf.

> **Important**
>
> Previously, the Systems Manager console provided you with the ability to choose the Amazon managed IAM service-linked role `AWSServiceRoleForAmazonSSM` to use as the maintenance role for your tasks. Using this role and its associated policy, `AmazonSSMServiceRolePolicy`, for maintenance window tasks is no longer recommended. If you're using this role for maintenance window tasks now, we encourage you to stop using it. Instead, create your own IAM role that enables communication

between Systems Manager and other Amazon Web Services services when your maintenance window tasks run.

Use the following procedure to create a custom service role for Maintenance Windows, so that Systems Manager can run Maintenance Windows tasks on your behalf. You attach the policy you created in the previous task to the custom service role you create.

To create a custom service role for maintenance windows using the console

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Roles**, and then choose **Create role**.
3. For **Select trusted entity**, make the following choices:
   1. For **Trusted entity type**, choose **Amazon service**.
   2. For **Use case**, choose **Systems Manager**
   3. Choose **Systems Manager**.

   .
4. Choose **Next**.
5. In the **Permissions policies** area, in the search box, enter the name of the policy you created in Task 1: Create a custom policy for your maintenance window service role using the console, select the box next to its name, and then choose **Next**.
6. For **Role name**, enter a name that identifies this role as a Maintenance Windows role. For example: **`my-maintenance-window-role`**.
7. (Optional) Change the default role description to reflect the purpose of this role. For example: **`Performs maintenance window tasks on your behalf`**.
8. For **Step 1: Select trusted entities**, verify that the following policy is displayed in the **Trusted policy** box.

   JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "",
```

```
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

9. For **Step 2: Add permissions**, verify that policy you created in Task 1: Create a custom policy for your maintenance window service role using the console is present.
10. (Optional) In **Step 3: Add tags**, add one or more tag-key value pairs to organize, track, or control access for this role.
11. Choose **Create role**. The system returns you to the **Roles** page.
12. Choose the name of the IAM role you just created.
13. Copy or make a note of the role name and the **ARN** value in the **Summary** area. Users in your account specify this information when they create maintenance windows.

Task 3: Grant permissions to specified users to register maintenance window tasks using the console

Providing users with permissions to access the custom service role for maintenance windows lets them use it with their maintenance windows tasks. This is in addition to permissions that you've already given them to work with the Systems Manager API commands for the Maintenance Windows tool. This IAM role conveys the permissions need to run a maintenance window task. As a result, a user can't register tasks with a maintenance window using your custom service role without the ability to pass these IAM permissions.

When you register a task with a maintenance window, you specify a service role to run the actual task operations. This is the role that the service assumes when it runs tasks on your behalf. Before that, to register the task itself, assign the IAM `PassRole` policy to an IAM entity (such as a user or group). This allows the IAM entity to specify, as part of registering those tasks with the maintenance window, the role that should be used when running tasks. For information, see Grant a user permissions to pass a role to an Amazon Web Services service in the *IAM User Guide*.

To configure permissions to allow users to register maintenance window tasks

If an IAM entity (user, role, or group) is set up with administrator permissions, then the IAM user or role has access to Maintenance Windows. For IAM entities without administrator permissions,

an administrator must grant the following permissions to the IAM entity. These are the minimum permissions required to register tasks with a maintenance window:

- The `AmazonSSMFullAccess` managed policy, or a policy that provides comparable permissions.
- The following `iam:PassRole` and `iam:ListRoles`permissions.

  JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws-cn:iam::111122223333:role/my-maintenance-
window-role"
        },
        {
            "Effect": "Allow",
            "Action": "iam:ListRoles",
            "Resource": "arn:aws-cn:iam::111122223333:role/"
        },
        {
            "Effect": "Allow",
            "Action": "iam:ListRoles",
            "Resource": "arn:aws-cn:iam::111122223333:role/aws-service-role/
ssm.amazonaws.com.cn/"
        }
    ]
}
```

my-maintenance-window-role represents the name of the custom maintenance window service role you created earlier.

account-id represents the ID of your Amazon Web Services account. Adding this permission for the resource `arn:aws-cn:iam::`*account-id*`:role/` allows a user to view and choose from customer roles in the console when they create a maintenance window task. Adding this permission for `arn:aws-cn:iam::`*account-id*`:role/aws-service-role/ssm.amazonaws.com.cn/` allows a user to choose the Systems Manager service-linked role in the console when they create a maintenance window task.

To provide access, add permissions to your users, groups, or roles:

- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.

- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

To configure permissions for groups that are allowed to register maintenance window tasks using the console

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **User groups**.
3. In the list of groups, select the name of the group you want to assign the `iam:PassRole` permission to, or first create a new group if necessary
4. On the **Permissions** tab, choose **Add permissions, Create inline policy**.
5. In the **Policy editor** area, choose **JSON**, and replace the default contents of the box with the following.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws-cn:iam::111122223333:role/my-maintenance-
window-role"
        },
        {
            "Effect": "Allow",
            "Action": "iam:ListRoles",
```

```
            "Resource": "arn:aws-cn:iam::111122223333:role/"
        },
        {
            "Effect": "Allow",
            "Action": "iam:ListRoles",
            "Resource": "arn:aws-cn:iam::111122223333:role/aws-service-role/
ssm.amazonaws.com.cn/"
        }
    ]
}
```

my-maintenance-window-role represents the name of the custom maintenance window role you created earlier.

account-id represents the ID of your Amazon Web Services account. Adding this permission for the resource `arn:aws-cn:iam::`*account-id*`:role/` allows a user to view and choose from customer roles in the console when they create a maintenance window task. Adding this permission for `arn:aws-cn:iam::`*account-id*`:role/aws-service-role/ssm.amazonaws.com.cn/` allows a user to choose the Systems Manager service-linked role in the console when they create a maintenance window task.

6. Choose **Next**.
7. On the **Review and create** page, enter a name in the **Policy name** box to identify this `PassRole` policy, such as **`my-group-iam-passrole-policy`**, and then choose **Create policy**.

Task 4: Prevent specified users from registering maintenance window tasks using the console

You can deny the `ssm:RegisterTaskWithMaintenanceWindow` permission for the users in your Amazon Web Services account who you don't want to register tasks with maintenance windows. This provides an extra layer of prevention for users who shouldn't register maintenance window tasks.

To configure permissions for groups that aren't allowed to register maintenance window tasks using the console

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **User groups**.

3. In the list of groups, select the name of the group you want to deny the `ssm:RegisterTaskWithMaintenanceWindow` permission from, or first create a new group if necessary.
4. On the **Permissions** tab, choose **Add permissions, Create inline policy**.
5. In the **Policy editor** area, choose **JSON**, and then replace the default contents of the box with the following.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": "ssm:RegisterTaskWithMaintenanceWindow",
            "Resource": "*"
        }
    ]
}
```

6. Choose **Next**.
7. On the **Review and create** page, for **Policy name**, enter a name to identify this policy, such as **`my-groups-deny-mw-tasks-policy`**, and then choose **Create policy**.

Control access to maintenance windows using the Amazon CLI

The following procedures describe how to use the Amazon Command Line Interface (Amazon CLI) to create the required permissions and roles for Maintenance Windows.

Topics

- Task 1: Create trust policy and customer managed policy files in JSON format
- Task 2: Create and verify a custom service role for maintenance windows using the Amazon CLI
- Task 3: Grant permissions to specified users to register maintenance window tasks using the Amazon CLI
- Task 4: Prevent specified users from registering maintenance window tasks using the Amazon CLI

Task 1: Create trust policy and customer managed policy files in JSON format

Maintenance window tasks require an IAM role to provide the permissions required to run on the target resources. The permissions are provided through an IAM policy attached to the role. The types of tasks you run and your other operational requirements determine the contents of this policy. We provide a base policy you can adapt to your needs. Depending on the tasks and types of tasks your maintenance windows run, you might not need all the permissions in this policy, and you might need to include additional permissions.

In this task, you specify the permissions needed for your custom maintenance window role in a pair of JSON files. You attach this policy to the role that you create later in Task 2: Create and verify a custom service role for maintenance windows using the Amazon CLI.

To create trust policy and customer managed policy files

1. Copy and paste the following trust policy into a text file. Save this file with the following name and file extension: **`mw-role-trust-policy.json`**.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

2. Copy and paste the following JSON policy into a different text file. In the same directory where you created the first file, save this file with the following name and file extension: **`mw-role-custom-policy.json`**.

   JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:SendCommand",
                "ssm:CancelCommand",
                "ssm:ListCommands",
                "ssm:ListCommandInvocations",
                "ssm:GetCommandInvocation",
                "ssm:GetAutomationExecution",
                "ssm:StartAutomationExecution",
                "ssm:ListTagsForResource",
                "ssm:GetParameters"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "states:DescribeExecution",
                "states:StartExecution"
            ],
            "Resource": [
                "arn:aws-cn:states:*:*:execution:*:*",
                "arn:aws-cn:states:*:*:stateMachine:*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "lambda:InvokeFunction"
            ],
            "Resource": [
                "arn:aws-cn:lambda:*:*:function:*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "resource-groups:ListGroups",
                "resource-groups:ListGroupResources"
            ],
            "Resource": [
```

```
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "tag:GetResources"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws-cn:iam::111122223333:role/maintenance-
window-role-name",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "ssm.amazonaws.com"
                    ]
                }
            }
        }
    ]
}
```

3. Modify the the content of `mw-role-custom-policy.json` as needed for the maintenance tasks that you run in your account. The changes you make are specific to your planned operations.

   For example:

   - You can provide Amazon Resource Names (ARNs) for specific functions and state machines instead of using wildcard (*) qualifiers.
   - If you don't plan to run Amazon Step Functions tasks, you can remove the `states` permissions and (ARNs).
   - If you don't plan to run Amazon Lambda tasks, you can remove the `lambda` permissions and ARNs.

- If you don't plan to run Automation tasks, you can remove the `ssm:GetAutomationExecution` and `ssm:StartAutomationExecution` permissions.
- Add additional permissions that might be needed for the tasks to run. For example, some Automation actions work with Amazon CloudFormation stacks. Therefore, the permissions `cloudformation:CreateStack`, `cloudformation:DescribeStacks`, and `cloudformation:DeleteStack` are required.

  For another example, the Automation runbook `AWS-CopySnapshot` requires permissions to create an Amazon Elastic Block Store (Amazon EBS) snapshot. Therefore, the service role needs the permission `ec2:CreateSnapshot`.

  For information about the role permissions needed by Automation runbooks, see the runbook descriptions in the Amazon Systems Manager Automation Runbook Reference.

Save the file again after making any needed changes.

Task 2: Create and verify a custom service role for maintenance windows using the Amazon CLI

The policy you created in the previous task is attached to the maintenance window service role you create in this task. When users register a maintenance window task, they specify this IAM role as part of the task configuration. The permissions in this role allow Systems Manager to run tasks in maintenance windows on your behalf.

> **Important**
>
> Previously, the Systems Manager console provided you with the ability to choose the Amazon managed IAM service-linked role `AWSServiceRoleForAmazonSSM` to use as the maintenance role for your tasks. Using this role and its associated policy, `AmazonSSMServiceRolePolicy`, for maintenance window tasks is no longer recommended. If you're using this role for maintenance window tasks now, we encourage you to stop using it. Instead, create your own IAM role that enables communication between Systems Manager and other Amazon Web Services services when your maintenance window tasks run.

In this task, you run CLI commands to create your maintenance windows service role, adding the policy content from the JSON files you created.

Create a custom service role for maintenance windows using the Amazon CLI

1. Open the Amazon CLI and run the following command in the directory where you placed `mw-role-custom-policy.json` and `mw-role-trust-policy.json`. The command creates a maintenance window service role called `my-maintenance-window-role` and attaches the *trust policy* to it.

   Linux & macOS

   ```
   aws iam create-role \
       --role-name "my-maintenance-window-role" \
       --assume-role-policy-document file://mw-role-trust-policy.json
   ```

   Windows

   ```
   aws iam create-role ^
       --role-name "my-maintenance-window-role" ^
       --assume-role-policy-document file://mw-role-trust-policy.json
   ```

   The system returns information similar to the following.

   ```
   {
       "Role": {
           "AssumeRolePolicyDocument": {
               "Version": "2012-10-17",
               "Statement": [
                   {
                       "Action": "sts:AssumeRole",
                       "Effect": "Allow",
                       "Principal": {
                           "Service": "ssm.amazonaws.com"
                       }
                   }
               ]
           },
           "RoleId": "AROAIIZKPBKS2LEXAMPLE",
           "CreateDate": "2024-08-19T03:40:17.373Z",
           "RoleName": "my-maintenance-window-role",
           "Path": "/",
           "Arn": "arn:aws-cn:iam::123456789012:role/my-maintenance-window-role"
       }
   ```

```
}
```

> **Note**
>
> Make a note of the `RoleName` and the `Arn` values. You include them in the next command.

2. Run the following command to attach the *customer managed policy* to the role. Replace the *`account-id`* placeholder with your own Amazon Web Services account ID

   Linux & macOS

   ```
   aws iam attach-role-policy \
       --role-name "my-maintenance-window-role" \
       --policy-arn "arn:aws-cn:iam::account-id:policy/mw-role-custom-policy.json"
   ```

   Windows

   ```
   aws iam attach-role-policy ^
       --role-name "my-maintenance-window-role" ^
       --policy-arn "arn:aws-cn:iam::account-id:policy/mw-role-custom-policy.json"
   ```

3. Run the following command to verify that your role has been created, and that the trust policy has been attached.

   ```
   aws iam get-role --role-name my-maintenance-window-role
   ```

   The command returns information similar to the following:

   ```
   {
       "Role": {
           "Path": "/",
           "RoleName": "my-maintenance-window-role",
           "RoleId": "AROA123456789EXAMPLE",
           "Arn": "arn:aws-cn:iam::123456789012:role/my-maintenance-window-role",
           "CreateDate": "2024-08-19T14:13:32+00:00",
           "AssumeRolePolicyDocument": {
               "Version": "2012-10-17",
               "Statement": [
                   {
   ```

```
                    "Effect": "Allow",
                    "Principal": {
                        "Service": "ssm.amazonaws.com"
                    },
                    "Action": "sts:AssumeRole"
                }
            ]
        },
        "MaxSessionDuration": 3600,
        "RoleLastUsed": {
            "LastUsedDate": "2024-08-19T14:30:44+00:00",
            "Region": "us-east-2"
        }
    }
}
```

4. Run the following command to verify that the customer managed policy has been attached to the role.

```
aws iam list-attached-role-policies --role-name my-maintenance-window-role
```

The command returns information similar to the following:

```
{
    "AttachedPolicies": [
        {
            "PolicyName": "mw-role-custom-policy",
            "PolicyArn": "arn:aws:iam::123456789012:policy/mw-role-custom-policy"
        }
    ]
}
```

Task 3: Grant permissions to specified users to register maintenance window tasks using the Amazon CLI

Providing users with permissions to access the custom service role for maintenance windows lets them use it with their maintenance windows tasks. This is in addition to permissions that you've already given them to work with the Systems Manager API commands for the Maintenance Windows tool. This IAM role conveys the permissions need to run a maintenance window task.

As a result, a user can't register tasks with a maintenance window using your custom service role without the ability to pass these IAM permissions.

When you register a task with a maintenance window, you specify a service role to run the actual task operations. This is the role that the service assumes when it runs tasks on your behalf. Before that, to register the task itself, assign the IAM `PassRole` policy to an IAM entity (such as a user or group). This allows the IAM entity to specify, as part of registering those tasks with the maintenance window, the role that should be used when running tasks. For information, see Grant a user permissions to pass a role to an Amazon Web Services service in the *IAM User Guide*.

To configure permissions for users who are allowed to register maintenance window tasks using the Amazon CLI

1. Copy and paste the following Amazon Identity and Access Management (IAM) policy into a text editor and save it with the following name and file extension: `mw-passrole-policy.json`.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws-cn:iam::111122223333:role/my-maintenance-
window-role"
        },
        {
            "Effect": "Allow",
            "Action": "iam:ListRoles",
            "Resource": "arn:aws-cn:iam::111122223333:role/"
        },
        {
            "Effect": "Allow",
            "Action": "iam:ListRoles",
            "Resource": "arn:aws-cn:iam::111122223333:role/aws-service-role/
ssm.amazonaws.com.cn/"
        }
    ]
}
```

Replace *my-maintenance-window-role* with the name of the custom maintenance window role you created earlier.

Replace *account-id* with the ID of your Amazon Web Services account. Adding this permission for the resource `arn:aws-cn:iam::account-id:role/` allows users in the group to view and choose from customer roles in the console when they create a maintenance window task. Adding this permission for `arn:aws-cn:iam::account-id:role/aws-service-role/ssm.amazonaws.com.cn/` allows users in the group to choose the Systems Manager service-linked role in the console when they create a maintenance window task.

2. Open the Amazon CLI.
3. Depending on whether you're assigning the permission to an IAM entity (user or group), run one of the following commands.

- **For an IAM entity:**

  Linux & macOS

  ```
  aws iam put-user-policy \
      --user-name "user-name" \
      --policy-name "policy-name" \
      --policy-document file://path-to-document
  ```

  Windows

  ```
  aws iam put-user-policy ^
      --user-name "user-name" ^
      --policy-name "policy-name" ^
      --policy-document file://path-to-document
  ```

  For *user-name*, specify the user who assigns tasks to maintenance windows. For *policy-name*, specify the name you want to use to identify the policy, such as **my-iam-passrole-policy**. For *path-to-document*, specify the path to the file you saved in step 1. For example: `file://C:\Temp\mw-passrole-policy.json`

  > **Note**
  >
  > To grant access for a user to register tasks for maintenance windows using the Systems Manager console, you must also assign the `AmazonSSMFullAccess` policy

to your user (or an IAM policy that provides a smaller set of access permissions for Systems Manager that covers maintenance window tasks). Run the following command to assign the `AmazonSSMFullAccess` policy to your user.

Linux & macOS

```
aws iam attach-user-policy \
    --policy-arn "arn:aws-cn:iam::aws:policy/AmazonSSMFullAccess" \
    --user-name "user-name"
```

Windows

```
aws iam attach-user-policy ^
    --policy-arn "arn:aws-cn:iam::aws:policy/AmazonSSMFullAccess" ^
    --user-name "user-name"
```

- **For an IAM group:**

  Linux & macOS

  ```
  aws iam put-group-policy \
      --group-name "group-name" \
      --policy-name "policy-name" \
      --policy-document file://path-to-document
  ```

  Windows

  ```
  aws iam put-group-policy ^
      --group-name "group-name" ^
      --policy-name "policy-name" ^
      --policy-document file://path-to-document
  ```

  For *group-name*, specify the group whose members assign tasks to maintenance windows. For *policy-name*, specify the name you want to use to identify the policy, such as **my-iam-passrole-policy**. For *path-to-document*, specify the path to the file you saved in step 1. For example: `file://C:\Temp\mw-passrole-policy.json`

> **Note**
>
> To grant access for members of a group to register tasks for maintenance windows using the Systems Manager console, you must also assign the `AmazonSSMFullAccess` policy to your group. Run the following command to assign this policy to your group.
>
> Linux & macOS
>
> ```
> aws iam attach-group-policy \
>     --policy-arn "arn:aws-cn:iam::aws:policy/AmazonSSMFullAccess" \
>     --group-name "group-name"
> ```
>
> Windows
>
> ```
> aws iam attach-group-policy ^
>     --policy-arn "arn:aws-cn:iam::aws:policy/AmazonSSMFullAccess" ^
>     --group-name "group-name"
> ```

4. Run the following command to verify that the policy has been assigned to the group.

   Linux & macOS

   ```
   aws iam list-group-policies \
       --group-name "group-name"
   ```

   Windows

   ```
   aws iam list-group-policies ^
       --group-name "group-name"
   ```

Task 4: Prevent specified users from registering maintenance window tasks using the Amazon CLI

You can deny the `ssm:RegisterTaskWithMaintenanceWindow` permission for the users in your Amazon Web Services account who you don't want to register tasks with maintenance windows. This provides an extra layer of prevention for users who shouldn't register maintenance window tasks.

Depending on whether you're denying the `ssm:RegisterTaskWithMaintenanceWindow` permission for an individual user or a group, use one of the following procedures to prevent users from registering tasks with a maintenance window.

To configure permissions for users who aren't allowed to register maintenance window tasks using the Amazon CLI

1. Copy and paste the following IAM policy into a text editor and save it with the following name and file extension: **`deny-mw-tasks-policy.json`**.

   JSON

   ```
   {
       "Version":"2012-10-17",
       "Statement": [
           {
               "Effect": "Deny",
               "Action": "ssm:RegisterTaskWithMaintenanceWindow",
               "Resource": "*"
           }
       ]
   }
   ```

2. Open the Amazon CLI.
3. Depending on whether you're assigning the permission to an IAM entity (user or group), run one of the following commands.

   - **For a user:**

     Linux & macOS

     ```
     aws iam put-user-policy \
         --user-name "user-name" \
         --policy-name "policy-name" \
         --policy-document file://path-to-document
     ```

     Windows

     ```
     aws iam put-user-policy ^
         --user-name "user-name" ^
         --policy-name "policy-name" ^
     ```

```
    --policy-document file://path-to-document
```

For *user-name*, specify the user to prevent from assigning tasks to maintenance windows. For *policy-name*, specify the name you want to use to identify the policy, such as **my-deny-mw-tasks-policy**. For *path-to-document*, specify the path to the file you saved in step 1. For example: `file://C:\Temp\deny-mw-tasks-policy.json`

- **For a group:**

  Linux & macOS

  ```
  aws iam put-group-policy \
      --group-name "group-name" \
      --policy-name "policy-name" \
      --policy-document file://path-to-document
  ```

  Windows

  ```
  aws iam put-group-policy ^
      --group-name "group-name" ^
      --policy-name "policy-name" ^
      --policy-document file://path-to-document
  ```

  For *group-name*, specify the group whose to prevent from assigning tasks to maintenance windows. For *policy-name*, specify the name you want to use to identify the policy, such as **my-deny-mw-tasks-policy**. For *path-to-document*, specify the path to the file you saved in step 1. For example: `file://C:\Temp\deny-mw-tasks-policy.json`

4. Run the following command to verify that the policy has been assigned to the group.

   Linux & macOS

   ```
   aws iam list-group-policies \
       --group-name "group-name"
   ```

   Windows

   ```
   aws iam list-group-policies ^
       --group-name "group-name"
   ```

Create and manage maintenance windows using the console

This section describes how to create, configure, update, and delete maintenance windows using the Amazon Systems Manager console. This section also provides information about managing the targets and tasks of a maintenance window.

> **Important**
>
> We recommend that you initially create and configure maintenance windows in a test environment.

Before you begin

Before you create a maintenance window, you must configure access to Maintenance Windows, a tool in Amazon Systems Manager. For more information, see Setting up Maintenance Windows.

Topics

- Create a maintenance window using the console
- Assign targets to a maintenance window using the console
- Assign tasks to a maintenance window using the console
- Disable or enable a maintenance window using the console
- Update or delete maintenance window resources using the console

Create a maintenance window using the console

In this procedure, you create a maintenance window in Maintenance Windows, a tool in Amazon Systems Manager. You can specify its basic options, such as name, schedule, and duration. In later steps, you choose the targets, or resources, that it updates and the tasks that run when the maintenance window runs.

> **Note**
>
> For an explanation of how the various schedule-related options for maintenance windows relate to one another, see Maintenance window scheduling and active period options. For more information about working with the `--schedule` option, see Reference: Cron and rate expressions for Systems Manager.

To create a maintenance window using the console

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Maintenance Windows**.
3. Choose **Create maintenance window**.
4. For **Name**, enter a descriptive name to help you identify this maintenance window.
5. (Optional) For **Description**, enter a description to identify how this maintenance window will be used.
6. (Optional) If you want to allow a maintenance window task to run on managed nodes, even if you haven't registered those nodes as targets, choose **Allow unregistered targets**.

   If you choose this option, then you can choose the unregistered nodes (by node ID) when you register a task with the maintenance window.

   If you don't choose this option, then you must choose previously registered targets when you register a task with the maintenance window.
7. Specify a schedule for the maintenance window by using one of the three scheduling options.

   For information about building cron/rate expressions, see Reference: Cron and rate expressions for Systems Manager.
8. For **Duration**, enter the number of hours the maintenance window will run. The value you specify determines the specific end time for the maintenance window based on the time it begins. No maintenance window tasks are permitted to start after the resulting endtime minus the number of hours you specify for **Stop initiating tasks** in the next step.

   For example, if the maintenance window starts at 3 PM, the duration is three hours, and the **Stop initiating tasks** value is one hour, no maintenance window tasks can start after 5 PM.
9. For **Stop initiating tasks**, enter the number of hours before the end of the maintenance window that the system should stop scheduling new tasks to run.
10. (Optional) For **Window start date**, specify a date and time, in ISO-8601 Extended format, for when you want the maintenance window to become active. This lets you delay activation of the maintenance window until the specified future date.

> **Note**
>
> You can't specify a start date and time that occurs in the past.

11. (Optional) For **Window end date**, specify a date and time, in ISO-8601 Extended format, for when you want the maintenance window to become inactive. This lets you set a date and time in the future after which the maintenance window no longer runs.
12. (Optional) For **Schedule timezone**, specify the time zone to use as the basis for when scheduled maintenance windows run, in Internet Assigned Numbers Authority (IANA) format. For example: "America/Los_Angeles", "etc/UTC", or "Asia/Seoul".

    For more information about valid formats, see the Time Zone Database on the IANA website.
13. (Optional) For **Schedule offset**, enter the number of days to wait after the date and time specified by a cron or rate expression before running the maintenance window. You can specify between one and six days.

    > **Note**
    >
    > This option is available only if you specified a schedule by entering a cron or rate expression manually.
14. (Optional) In the **Manage tags** area, apply one or more tag key name/value pairs to the maintenance window.

    Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a maintenance window to identify the type of tasks it runs, the types of targets, and the environment it runs in. In this case, you could specify the following key name/value pairs:

    - `Key=TaskType,Value=AgentUpdate`
    - `Key=OS,Value=Windows`
    - `Key=Environment,Value=Production`
15. Choose **Create maintenance window**. The system returns you to the maintenance window page. The state of the maintenance window you just created is **Enabled**.

Assign targets to a maintenance window using the console

In this procedure, you register a target with a maintenance window. In other words, you specify which resources the maintenance window performs actions on.

> **Note**
>
> If a single maintenance window task is registered with multiple targets, its task invocations occur sequentially and not in parallel. If your task must run on multiple targets at the same time, register a task for each target individually and assign each task the same priority level.

To assign targets to a maintenance window using the console

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Maintenance Windows**.
3. In the list of maintenance windows, choose the maintenance window to add targets to.
4. Choose **Actions**, and then choose **Register targets**.
5. (Optional) For **Target name**, enter a name for the targets.
6. (Optional) For **Description**, enter a description.
7. (Optional) For **Owner information**, specify information to include in any Amazon EventBridge event raised while running tasks for these targets in this maintenance window.

   For information about using EventBridge to monitor Systems Manager events, see Monitoring Systems Manager events with Amazon EventBridge.
8. In the **Targets** area, choose one of the options described in the following table.

Option	Description
Specify instance tags	For the **Specify instance tags** boxes, specify one or more tag keys and (optional) values that have been or will be added to managed nodes in your account. When the maintenance window runs, it attempts to perform

Option	Description
	tasks on all of the managed nodes to which these tags have been added. If you specify more than one tag key, a node must be tagged with *all* the tag keys and values you specify to be included in the target group.
Choose instances manually	From the list, select the box for each node that you want to include in the maintenance window target. The list includes all nodes in your account that are configured for use with Systems Manager. If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips. For edge devices and on-premises servers and virtual machines (VMs), see Managing nodes in hybrid and multicloud environments with Systems Manager

Option	Description
Choose a resource group	For **Resource group**, choose the name of an existing resource group in your account from the list. For information about creating and working with resource groups, see the following topics: • What are resource groups? in the *Amazon Resource Groups User Guide* • Resource Groups and Tagging for Amazon in the *Amazon News Blog* (Optional) For **Resource types**, select up to five available resource types, or choose **All resource types**. If the tasks you assign to the maintenance window don't act on one of the resource types you added to the target, the system might report an error. Tasks for which a supported resource type is found continue to run despite these errors. For example, suppose you add the following resource types to this target: • `AWS::S3::Bucket` • `AWS::DynamoDB::Table` • `AWS::EC2::Instance` But later, when you add tasks to the maintenance window, you include only tasks that perform actions on nodes, such as applying a patch baseline or rebooting

Option	Description
	a node. In the maintenance window log, an error might be reported for no Amazon Simple Storage Service (Amazon S3) buckets or Amazon DynamoDB tables being found. However, the maintenance window still runs tasks on the nodes in your resource group.

9. Choose **Register target**.

If you want to assign more targets to this maintenance window, choose the **Targets** tab, and then choose **Register target**. With this option, you can choose a different means of targeting. For example, if you previously targeted nodes by node ID, you can register new targets and target nodes by specifying tags applied to managed nodes or choosing resource types from a resource group.

Assign tasks to a maintenance window using the console

In this procedure, you add a task to a maintenance window. Tasks are the actions performed when a maintenance window runs.

The following four types of tasks can be added to a maintenance window:

- Amazon Systems Manager Run Command commands
- Systems Manager Automation workflows
- Amazon Step Functions tasks
- Amazon Lambda functions

> **Important**
>
> The IAM policy for Maintenance Windows requires that you add the prefix `SSM` to Lambda function (or alias) names. Before you proceed to register this type of task, update its name in Amazon Lambda to include `SSM`. For example, if your Lambda function name is `MyLambdaFunction`, change it to `SSMMyLambdaFunction`.

To assign tasks to a maintenance window

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Maintenance Windows**.
3. In the list of maintenance windows, choose a maintenance window.
4. Choose **Actions**, and then choose the option for the type of task you want to register with the maintenance window.

   - **Register Run command task**
   - **Register Automation task**
   - **Register Lambda task**
   - **Register Step Functions task**

   > **Note**
   >
   > Maintenance window tasks support Step Functions Standard state machine workflows only. They don't support Express state machine workflows. For information about state machine workflow types, see Standard vs. Express Workflows in the *Amazon Step Functions Developer Guide*.

5. (Optional) For **Name**, enter a name for the task.
6. (Optional) For **Description**, enter a description.
7. For **New task invocation cutoff**, if you don't want any new task invocations to start after the maintenance window cutoff time is reached, choose **Enabled**.

   When this option is *not* enabled, the task continues running when the cutoff time is reached and starts new task invocations until completion.

   > **Note**
   >
   > The status for tasks that are not completed when you enable this option is `TIMED_OUT`.

8. For this step, follow the sub-steps for your selected task type.

Run Command

1. In the **Command document** list, choose the Systems Manager Command document (SSM document) that defines the tasks to run.
2. For **Document version**, choose the document version to use.
3. For **Task priority**, specify a priority for this task. Zero (`0`) is the highest priority. Tasks in a maintenance window are scheduled in priority order with tasks that have the same priority scheduled in parallel.

Automation

1. In the **Automation document** list, choose the Automation runbook that defines the tasks to run.
2. For **Document version**, choose the runbook version to use.
3. For **Task priority**, specify a priority for this task. Zero (`0`) is the highest priority. Tasks in a maintenance window are scheduled in priority order with tasks that have the same priority scheduled in parallel.

Lambda

1. In the **Lambda parameters** area, choose a Lambda function from the list.
2. (Optional) Provide any content for **Payload**, **Client Context**, or **Qualifier** that you want to include.

   > **Note**
   >
   > In some cases, you can use a *pseudo parameter* as part of your `Payload` value. Then when the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. For information, see Using pseudo parameters when registering maintenance window tasks.

3. For **Task priority**, specify a priority for this task. Zero (`0`) is the highest priority. Tasks in a maintenance window are scheduled in priority order with tasks that have the same priority scheduled in parallel.

Step Functions

1. In the **Step Functions parameters** area, choose a state machine from the list.
2. (Optional) Provide a name for the state machine execution and any content for **Input** that you want to include.

   > **Note**
   >
   > In some cases, you can use a *pseudo parameter* as part of your `Input` value. Then when the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. For information, see Using pseudo parameters when registering maintenance window tasks.

3. For **Task priority**, specify a priority for this task. Zero (`0`) is the highest priority. Tasks in a maintenance window are scheduled in priority order with tasks that have the same priority scheduled in parallel.

9. In the **Targets** area, choose one of the following:

   - **Selecting registered target groups**: Select one or more maintenance window targets you have registered with the current maintenance window.
   - **Selecting unregistered targets**: Choose available resources one by one as targets for the task.

     If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.
   - **Task target not required**: Targets for the task might already be specified in other functions for all but Run Command-type tasks.

     Specify one or more targets for maintenance window Run Command-type tasks. Depending on the task, targets are optional for other maintenance window task types (Automation, Amazon Lambda, and Amazon Step Functions). For more information about running tasks that don't specify targets, see Registering maintenance window tasks without targets.

> **Note**
>
> In many cases, you don't need to explicitly specify a target for an automation task. For example, say that you're creating an Automation-type task to update an Amazon Machine Image (AMI) for Linux using the `AWS-UpdateLinuxAmi` runbook. When the task runs, the AMI is updated with the latest available Linux distribution packages and Amazon software. New instances created from the AMI already have these updates installed. Because the ID of the AMI to be updated is specified in the input parameters for the runbook, there is no need to specify a target again in the maintenance window task.

10. *Automation tasks only:*

    In the **Input parameters** area, provide values for any required or optional parameters needed to run your task.

    > **Note**
    >
    > In some cases, you can use a *pseudo parameter* for certain input parameter values. Then when the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. For information, see Using pseudo parameters when registering maintenance window tasks.

11. For **Rate control**:

    - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

      > **Note**
      >
      > If you selected targets by specifying tags applied to managed nodes or by specifying Amazon resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

    - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three

errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

12. (Optional) For **IAM service role**, choose a role to provide permissions for Systems Manager to assume when running a maintenance window task.

    If you don't specify a service role ARN, Systems Manager uses a service-linked role in your account. This role is not listed in the drop-down menu. If no appropriate service-linked role for Systems Manager exists in your account, it's created when the task is registered successfully.

    > **Note**
    >
    > For an improved security posture, we strongly recommend creating a custom policy and custom service role for running your maintenance window tasks. The policy can be crafted to provide only the permissions needed for your particular maintenance window tasks. For more information, see Setting up Maintenance Windows.

13. *Run Command tasks only:*

    (Optional) For **Output options**, do the following:

    - Select the **Enable writing to S3** check box to save the command output to a file. Enter the bucket and prefix (folder) names in the boxes.
    - Select the **CloudWatch output** check box to write complete output to Amazon CloudWatch Logs. Enter the name of a CloudWatch Logs log group.

    > **Note**
    >
    > The permissions that grant the ability to write data to an S3 bucket or CloudWatch Logs are those of the instance profile assigned to the node, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager. In addition, if the specified S3 bucket or log group is in a different Amazon Web Services account, verify that the instance profile associated with the node has the necessary permissions to write to that bucket.

14. *Run Command tasks only:*

    In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

15. *Run Command tasks only:*

    In the **Parameters** area, specify parameters for the document.

    > **Note**
    >
    > In some cases, you can use a *pseudo parameter* for certain input parameter values. Then when the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. For information, see Using pseudo parameters when registering maintenance window tasks.

16. *Run Command and Automation tasks only:*

    (Optional) In the **CloudWatch alarm** area, for **Alarm name**, choose an existing CloudWatch alarm to apply to your task for monitoring.

    If the alarm activates, the task is stopped.

    > **Note**
    >
    > To attach a CloudWatch alarm to your task, the IAM principal that runs the task must have permission for the `iam:createServiceLinkedRole` action. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms.

17. Depending on your task type, choose one of the following:

    - **Register Run command task**
    - **Register Automation task**
    - **Register Lambda task**
    - **Register Step Functions task**

Disable or enable a maintenance window using the console

You can disable or enable a maintenance window in Maintenance Windows. You can choose one maintenance window at a time to either disable or enable the maintenance window from running. You can also select multiple or all maintenance windows to enable and disable.

This section describes how to disable or enable a maintenance window by using the Systems Manager console. For examples of how to do this by using the Amazon Command Line Interface (Amazon CLI), see Tutorial: Update a maintenance window using the Amazon CLI.

Topics

- Disable a maintenance window using the console
- Enable a maintenance window using the console

Disable a maintenance window using the console

You can disable a maintenance window to pause a task for a specified period, and it will remain available to enable again later.

To disable a maintenance window

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Maintenance Windows**.
3. Using the check box next to the maintenance window that you want to disable, select one or more maintenance windows.
4. Choose **Disable maintenance window** in the **Actions** menu. The system prompts you to confirm your actions.

Enable a maintenance window using the console

You can enable a maintenance window to resume a task.

> **Note**
>
> If the maintenance window uses a rate schedule and the start date is currently set to a past date and time, the current date and time is used as the start date for the maintenance window. You can change the start date of the maintenance window before or after

enabling it. For information, see Update or delete maintenance window resources using the console.

To enable a maintenance window

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Maintenance Windows**.
3. Select the check box next to the maintenance window to enable.
4. Choose **Actions, Enable maintenance window**. The system prompts you to confirm your actions.

Update or delete maintenance window resources using the console

You can update or delete a maintenance window in Maintenance Windows. You can also update or delete the targets or tasks of a maintenance window. If you edit the details of a maintenance window, you can change the schedule, targets, and tasks. You can also specify names and descriptions for windows, targets, and tasks, which helps you better understand their purpose, and makes it easier to manage your queue of windows.

This section describes how to update or delete a maintenance window, targets, and tasks by using the Systems Manager console. For examples of how to do this by using the Amazon Command Line Interface (Amazon CLI), see Tutorial: Update a maintenance window using the Amazon CLI.

Topics

- Updating or deleting a maintenance window using the console
- Updating or deregistering maintenance window targets using the console
- Updating or deregistering maintenance window tasks using the console

Updating or deleting a maintenance window using the console

You can update a maintenance window to change its name, description, and schedule, and whether the maintenance window should allow unregistered targets.

To update or delete a maintenance window

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Maintenance Windows**.
3. Select the button next to the maintenance window that you want to update or delete, and then do one of the following:

   - Choose **Delete**. The system prompts you to confirm your actions.
   - Choose **Edit**. On the **Edit maintenance window** page, change the values and options that you want, and then choose **Save changes**.

     For information about the configuration choices you can make, see Create a maintenance window using the console.

Updating or deregistering maintenance window targets using the console

You can update or deregister the targets of a maintenance window. If you choose to update a maintenance window target you can specify a new target name, description, and owner. You can also choose different targets.

To update or delete the targets of a maintenance window

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Maintenance Windows**.
3. Choose the name of the maintenance window that you want to update, choose the **Targets** tab, and then do one of the following:

   - To update targets, select the button next to the target to update, and then choose **Edit**.
   - To deregister targets, select the button next to the target to deregister, and then choose **Deregister target**. In the **Deregister maintenance windows target** dialog box, choose **Deregister**.

Updating or deregistering maintenance window tasks using the console

You can update or deregister the tasks of a maintenance window. If you choose to update, you can specify a new task name, description, and owner. For Run Command and Automation tasks, you

can choose a different SSM document for the tasks. You can't, however, edit a task to change its type. For example, if you created an Automation task, you can't edit that task and change it to a Run Command task.

To update or delete the tasks of a maintenance window using the console

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Maintenance Windows**.
3. Choose the name of the maintenance window that you want to update.
4. Choose the **Tasks** tab, and then select the button next to the task to update.
5. Do one of the following:

   - To deregister a task, choose **Deregister task**.
   - To edit the task, choose **Edit**. Change the values and options that you want, and then choose **Edit task**.

Tutorials

The tutorials in this section show you how to perform common tasks when working with maintenance windows.

Complete prerequisites

Before trying these tutorials, complete the following prerequisites.

- **Configure the Amazon CLI on your local machine** – Before you can run Amazon CLI commands, you must install and configure the CLI on your local machine. For information, see Installing or updating the latest version of the Amazon CLI and Installing the Amazon Tools for PowerShell.
- **Verify maintenance window roles and permissions** – An Amazon administrator in your account must grant you the Amazon Identity and Access Management (IAM) permissions you need to manage maintenance windows using the CLI. For information, see Setting up Maintenance Windows.
- **Create or configure an instance that is compatible with Systems Manager** – You need at least one Amazon Elastic Compute Cloud (Amazon EC2) instance that is configured for use with Systems Manager to complete the tutorials. This means that SSM Agent is installed on the instance, and an IAM instance profile for Systems Manager is attached to the instance.

We recommend launching an instance from one Amazon managed Amazon Machine Image (AMI) with the agent preinstalled. For more information, see Find AMIs with the SSM Agent preinstalled.

For information about installing SSM Agent on an instance, see the following topics:

- Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server
- Manually installing and uninstalling SSM Agent on EC2 instances for Linux

For information about configuring IAM permissions for Systems Manager to your instance, see Configure instance permissions required for Systems Manager.

- **Create additional resources as needed** – Run Command includes many tasks that don't require you to create resources other than those listed in this prerequisites topic. For that reason, we provide a simple Run Command task for you to use your first time through the tutorials. You also need an EC2 instance that is configured to use with Systems Manager, as described earlier in this topic. After you configure that instance, you can register a simple Run Command task.

  The Systems Manager Maintenance Windows tool supports running the following four types of tasks:

  - Run Command commands
  - Systems Manager Automation workflows
  - Amazon Lambda functions
  - Amazon Step Functions tasks

  In general, if a maintenance window task that you want to run requires additional resources, you should create them first. For example, if you want a maintenance window that runs an Amazon Lambda function, create the Lambda function before you begin; for a Run Command task, create the S3 bucket that you can save command output to (if you plan to do so); and so on.

Tutorials

- Tutorials: Create and manage maintenance windows using the Amazon CLI
- Tutorial: Create a maintenance window for patching using the console

Tutorials: Create and manage maintenance windows using the Amazon CLI

This section includes tutorials that help you learn how to use the Amazon Command Line Interface (Amazon CLI) to do the following:

- Create and configure a maintenance window
- View information about a maintenance window
- View information about maintenance windows tasks and task executions
- Update a maintenance window
- Delete a maintenance window

Keep track of resource IDs

As you complete the tasks in these Amazon CLI tutorials, keep track of resource IDs generated by the commands you run. You use many of these as input for subsequent commands. For example, when you create the maintenance window, the system provides you with a maintenance window ID in the following format.

```
{
   "WindowId":"mw-0c50858d01EXAMPLE"
}
```

Make a note of the following system-generated IDs because the tutorials in this section use them:

- `WindowId`
- `WindowTargetId`
- `WindowTaskId`
- `WindowExecutionId`
- `TaskExecutionId`
- `InvocationId`
- `ExecutionId`

You also need the ID of the EC2 instance that you plan to use in the tutorials. For example: `i-02573cafcfEXAMPLE`

Tutorial: Create and configure a maintenance window using the Amazon CLI

This tutorial demonstrates how to use the Amazon Command Line Interface (Amazon CLI) to create and configure a maintenance window, its targets, and its tasks. The main path through the tutorial consists of simple steps. You create a single maintenance window, identify a single target, and set up a simple task for the maintenance window to run. Along the way, we provide information you can use to try more complicated scenarios.

As you follow the steps in this tutorial, replace the values in italicized *red* text with your own options and IDs. For example, replace the maintenance window ID *mw-0c50858d01EXAMPLE* and the instance ID *i-02573cafcfEXAMPLE* with IDs of resources you create.

Contents

- Step 1: Create the maintenance window using the Amazon CLI
- Step 2: Register a target node with the maintenance window using the Amazon CLI
- Step 3: Register a task with the maintenance window using the Amazon CLI

Step 1: Create the maintenance window using the Amazon CLI

In this step, you create a maintenance window and specify its basic options, such as name, schedule, and duration. In later steps, you choose the instance it updates and the task it runs.

In our example, you create a maintenance window that runs every five minutes. Normally, you wouldn't run a maintenance window this frequently. However, with this rate you can see your tutorial results quickly. We will show you how to change to a less frequent rate after the task has run successfully.

> **Note**
>
> For an explanation of how the various schedule-related options for maintenance windows relate to one another, see Maintenance window scheduling and active period options.

For more information about working with the `--schedule` option, see Reference: Cron and rate expressions for Systems Manager.

To create a maintenance window using the Amazon CLI

1. Open the Amazon Command Line Interface (Amazon CLI) and run the following command on your local machine to create a maintenance window that does the following:

   - Runs every five minutes for up to two hours (as needed).
   - Prevents new tasks from starting within one hour of the end of the maintenance window operation.
   - Allows unassociated targets (instances that you haven't registered with the maintenance window).
   - Indicates through the use of custom tags that its creator intends to use it in a tutorial.

   Linux & macOS

   ```
   aws ssm create-maintenance-window \
       --name "My-First-Maintenance-Window" \
       --schedule "rate(5 minutes)" \
       --duration 2 \
       --cutoff 1 \
       --allow-unassociated-targets \
       --tags "Key=Purpose,Value=Tutorial"
   ```

   Windows

   ```
   aws ssm create-maintenance-window ^
       --name "My-First-Maintenance-Window" ^
       --schedule "rate(5 minutes)" ^
       --duration 2 ^
       --cutoff 1 ^
       --allow-unassociated-targets ^
       --tags "Key"="Purpose","Value"="Tutorial"
   ```

   The system returns information similar to the following.

```
{
   "WindowId":"mw-0c50858d01EXAMPLE"
}
```

2. Now run the following command to view details about this and any other maintenance windows already in your account.

```
aws ssm describe-maintenance-windows
```

The system returns information similar to the following.

```
{
   "WindowIdentities":[
      {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "My-First-Maintenance-Window",
            "Enabled": true,
            "Duration": 2,
            "Cutoff": 1,
            "NextExecutionTime": "2019-05-11T16:46:16.991Z"
      }
   ]
}
```

Continue to Step 2: Register a target node with the maintenance window using the Amazon CLI.

Step 2: Register a target node with the maintenance window using the Amazon CLI

In this step, you register a target with your new maintenance window. In this case, you specify which node to update when the maintenance window runs.

For an example of registering more than one node at a time using node IDs, examples of using tags to identify multiple nodes, and examples of specifying resource groups as targets, see Examples: Register targets with a maintenance window.

> **Note**
>
> You should already have created an Amazon Elastic Compute Cloud (Amazon EC2) instance to use in this step, as described in the Maintenance Windows tutorial prerequisites.

To register a target node with a maintenance window using the Amazon CLI

1. Run the following command on your local machine. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm register-target-with-maintenance-window \
       --window-id "mw-0c50858d01EXAMPLE" \
       --resource-type "INSTANCE" \
       --target "Key=InstanceIds,Values=i-02573cafcfEXAMPLE"
   ```

   Windows

   ```
   aws ssm register-target-with-maintenance-window ^
       --window-id "mw-0c50858d01EXAMPLE" ^
       --resource-type "INSTANCE" ^
       --target "Key=InstanceIds,Values=i-02573cafcfEXAMPLE"
   ```

   The system returns information similar to the following.

   ```
   {
      "WindowTargetId":"e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
   }
   ```

2. Now run the following command on your local machine to view details about your maintenance window target.

   Linux & macOS

   ```
   aws ssm describe-maintenance-window-targets \
       --window-id "mw-0c50858d01EXAMPLE"
   ```

   Windows

   ```
   aws ssm describe-maintenance-window-targets ^
       --window-id "mw-0c50858d01EXAMPLE"
   ```

   The system returns information similar to the following.

```
{
    "Targets": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "WindowTargetId": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE",
            "ResourceType": "INSTANCE",
            "Targets": [
                {
                    "Key": "InstanceIds",
                    "Values": [
                        "i-02573cafcfEXAMPLE"
                    ]
                }
            ]
        }
    ]
}
```

Continue to Step 3: Register a task with the maintenance window using the Amazon CLI.

Examples: Register targets with a maintenance window

You can register a single node as a target using its node ID, as demonstrated in Step 2: Register a target node with the maintenance window using the Amazon CLI. You can also register one or more nodes as targets using the command formats on this page.

In general, there are two methods for identifying the nodes you want to use as maintenance window targets: specifying individual nodes, and using resource tags. The resource tags method provides more options, as shown in examples 2-3.

You can also specify one or more resource groups as the target of a maintenance window. A resource group can include nodes and many other types of supported Amazon resources. Examples 4 and 5, next, demonstrate how to add resource groups to your maintenance window targets.

> **Note**
>
> If a single maintenance window task is registered with multiple targets, its task invocations occur sequentially and not in parallel. If your task must run on multiple targets at the same

time, register a task for each target individually and assign each task the same priority level.

For more information about creating and managing resource groups, see What are resource groups? in the *Amazon Resource Groups User Guide* and Resource Groups and Tagging for Amazon in the *Amazon News Blog*.

For information about quotas for Maintenance Windows, in addition to those specified in the following examples, see Systems Manager service quotas in the *Amazon Web Services General Reference*.

Example 1: Register multiple targets using node IDs

Run the following command on your local machine format to register multiple nodes as targets using their node IDs. Replace each *example resource placeholder* with your own information.

Linux & macOS

```
aws ssm register-target-with-maintenance-window \
    --window-id "mw-0c50858d01EXAMPLE" \
    --resource-type "INSTANCE" \
    --target
 "Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE,i-07782c72faEXAMPLE"
```

Windows

```
aws ssm register-target-with-maintenance-window ^
    --window-id "mw-0c50858d01EXAMPLE ^
    --resource-type "INSTANCE" ^
    --target
 "Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE,i-07782c72faEXAMPLE
```

Recommended use: Most useful when registering a unique group of nodes with any maintenance window for the first time and they do *not* share a common node tag.

Quotas: You can specify up to 50 nodes total for each maintenance window target.

Example 2: Register targets using resource tags applied to nodes

Run the following command on your local machine to register nodes that are all already tagged with a key-value pair you have assigned. Replace each *example resource placeholder* with your own information.

Linux & macOS

```
aws ssm register-target-with-maintenance-window \
    --window-id "mw-0c50858d01EXAMPLE" \
    --resource-type "INSTANCE" \
    --target "Key=tag:Region,Values=East"
```

Windows

```
aws ssm register-target-with-maintenance-window ^
    --window-id "mw-0c50858d01EXAMPLE" ^
    --resource-type "INSTANCE" ^
    --target "Key=tag:Region,Values=East"
```

Recommended use: Most useful when registering a unique group of nodes with any maintenance window for the first time and they *do* share a common node tag.

Quotas: You can specify up to five key-value pairs total for each target. If you specify more than one key-value pair, a node must be tagged with *all* the tag keys and values you specify to be included in the target group.

Note

You can tag a group of nodes with the tag-key `Patch Group` or `PatchGroup` and assign the nodes a common key value, such as `my-patch-group`. (You must use `PatchGroup`, without a space, if you have allowed tags in EC2 instance metadata.) Patch Manager, a tool in Systems Manager, evaluates the `Patch Group` or `PatchGroup` key on nodes to help determine which patch baseline applies to them. If your task will run the `AWS-RunPatchBaseline` SSM document (or the legacy `AWS-ApplyPatchBaseline` SSM document), you can specify the same `Patch Group` or `PatchGroup` key-value pair when you register targets with a maintenance window. For example: `--target "Key=tag:PatchGroup,Values=my-patch-group`. Doing so lets you use a

maintenance window to update patches on a group of nodes that are already associated with the same patch baseline. For more information, see Patch groups.

Example 3: Register targets using a group of tag keys (without tag values)

Run the following command on your local machine to register nodes that all have one or more tag keys assigned to them, regardless of their key values. Replace each *example resource placeholder* with your own information.

Linux & macOS

```
aws ssm register-target-with-maintenance-window \
    --window-id "mw-0c50858d01EXAMPLE" \
    --resource-type "INSTANCE" \
    --target "Key=tag-key,Values=Name,Instance-Type,CostCenter"
```

Windows

```
aws ssm register-target-with-maintenance-window ^
    --window-id "mw-0c50858d01EXAMPLE" ^
    --resource-type "INSTANCE" ^
    --target "Key=tag-key,Values=Name,Instance-Type,CostCenter"
```

Recommended use: Useful when you want to target nodes by specifying multiple tag *keys* (without their values) rather than just one tag-key or a tag key-value pair.

Quotas: You can specify up to five tag-keys total for each target. If you specify more than one tag key, a node must be tagged with *all* the tag keys you specify to be included in the target group.

Example 4: Register targets using a resource group name

Run the following command on your local machine to register a specified resource group, regardless of the type of resources it contains. Replace *mw-0c50858d01EXAMPLE* with your own information. If the tasks you assign to the maintenance window don't act on a type of resource included in this resource group, the system might report an error. Tasks for which a supported resource type is found continue to run despite these errors.

Linux & macOS

```
aws ssm register-target-with-maintenance-window \
    --window-id "mw-0c50858d01EXAMPLE" \
    --resource-type "RESOURCE_GROUP" \
    --target "Key=resource-groups:Name,Values=MyResourceGroup"
```

Windows

```
aws ssm register-target-with-maintenance-window ^
    --window-id "mw-0c50858d01EXAMPLE" ^
    --resource-type "RESOURCE_GROUP" ^
    --target "Key=resource-groups:Name,Values=MyResourceGroup"
```

Recommended use: Useful when you want to quickly specify a resource group as a target without evaluating whether all of its resource types will be targeted by a maintenance window, or when you know that the resource group contains only the resource types that your tasks perform actions on.

Quotas: You can specify only one resource group as a target.

Example 5: Register targets by filtering resource types in a resource group

Run the following command on your local machine to register only certain resource types that belong to a resource group that you specify. Replace *mw-0c50858d01EXAMPLE* with your own information. With this option, even if you add a task for a resource type that belongs to the resource group, the task won't run if you haven't explicitly added the resource type to the filter.

Linux & macOS

```
aws ssm register-target-with-maintenance-window \
    --window-id "mw-0c50858d01EXAMPLE" \
    --resource-type "RESOURCE_GROUP" \
    --target "Key=resource-groups:Name,Values=MyResourceGroup" \
    "Key=resource-
groups:ResourceTypeFilters,Values=AWS::EC2::Instance,AWS::ECS::Cluster"
```

Windows

```
aws ssm register-target-with-maintenance-window ^
    --window-id "mw-0c50858d01EXAMPLE" ^
```

```
    --resource-type "RESOURCE_GROUP" ^
    --target "Key=resource-groups:Name,Values=MyResourceGroup" ^
    "Key=resource-
groups:ResourceTypeFilters,Values=AWS::EC2::Instance,AWS::ECS::Cluster"
```

Recommended use: Useful when you want to maintain strict control over the types of Amazon resources your maintenance window can run actions on, or when your resource group contains a large number of resource types and you want to avoid unnecessary error reports in your maintenance window logs.

Quotas: You can specify only one resource group as a target.

Step 3: Register a task with the maintenance window using the Amazon CLI

In this step of the tutorial, you register an Amazon Systems Manager Run Command task that runs the `df` command on your Amazon Elastic Compute Cloud (Amazon EC2) instance for Linux. The results of this standard Linux command show how much space is free and how much is used on the disk file system of your instance.

-or-

If you're targeting an Amazon EC2 instance for Windows Server instead of Linux, replace **df** in the following command with **ipconfig**. Output from this command lists details about the IP address, subnet mask, and default gateway for adapters on the target instance.

When you're ready to register other task types, or use more of the available Systems Manager Run Command options, see Examples: Register tasks with a maintenance window. There, we provide more information about all four task types, and some of their most important options, to help you plan for more extensive real-world scenarios.

To register a task with a maintenance window

1. Run the following command on your local machine. Replace each *`example resource placeholder`* with your own information. The version to run from a local Windows machine includes the escape characters ("/") that you need to run the command from your command line tool.

   Linux & macOS

   ```
   aws ssm register-task-with-maintenance-window \
   ```

```
    --window-id mw-0c50858d01EXAMPLE \
    --task-arn "AWS-RunShellScript" \
    --max-concurrency 1 --max-errors 1 \
    --priority 10 \
    --targets "Key=InstanceIds,Values=i-0471e04240EXAMPLE" \
    --task-type "RUN_COMMAND" \
    --task-invocation-parameters '{"RunCommand":{"Parameters":{"commands":
["df"]}}}'
```

Windows

```
aws ssm register-task-with-maintenance-window ^
    --window-id mw-0c50858d01EXAMPLE ^
    --task-arn "AWS-RunShellScript" ^
    --max-concurrency 1 --max-errors 1 ^
    --priority 10 ^
    --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" ^
    --task-type "RUN_COMMAND" ^
    --task-invocation-parameters={\"RunCommand\":{\"Parameters\":{\"commands\":
[\"df\"]}}}
```

The system returns information similar to the following:

```
{
    "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE"
}
```

2. Now run the following command to view details about the maintenance window task you created.

   Linux & macOS

   ```
   aws ssm describe-maintenance-window-tasks \
       --window-id mw-0c50858d01EXAMPLE
   ```

   Windows

   ```
   aws ssm describe-maintenance-window-tasks ^
       --window-id mw-0c50858d01EXAMPLE
   ```

3. The system returns information similar to the following.

```
{
    "Tasks": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
            "TaskArn": "AWS-RunShellScript",
            "Type": "RUN_COMMAND",
            "Targets": [
                {
                    "Key": "InstanceIds",
                    "Values": [
                        "i-02573cafcfEXAMPLE"
                    ]
                }
            ],
            "TaskParameters": {},
            "Priority": 10,
            "ServiceRoleArn": "arn:aws-cn:iam::123456789012:role/
MyMaintenanceWindowServiceRole",
            "MaxConcurrency": "1",
            "MaxErrors": "1"
        }
    ]
}
```

4. Wait until the task has had time to run, based on the schedule you specified in Step 1: Create the maintenance window using the Amazon CLI. For example, if you specified **`--schedule "rate(5 minutes)"`**, wait five minutes. Then run the following command to view information about any executions that occurred for this task.

   Linux & macOS

   ```
   aws ssm describe-maintenance-window-executions \
       --window-id mw-0c50858d01EXAMPLE
   ```

   Windows

   ```
   aws ssm describe-maintenance-window-executions ^
       --window-id mw-0c50858d01EXAMPLE
   ```

The system returns information similar to the following.

```
{
    "WindowExecutions": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
            "Status": "SUCCESS",
            "StartTime": 1557593493.096,
            "EndTime": 1557593498.611
        }
    ]
}
```

Tip

After the task runs successfully, you can decrease the rate at which the maintenance window runs. For example, run the following command to decrease the frequency to once a week. Replace *mw-0c50858d01EXAMPLE* with your own information.

Linux & macOS

```
aws ssm update-maintenance-window \
    --window-id mw-0c50858d01EXAMPLE \
    --schedule "rate(7 days)"
```

Windows

```
aws ssm update-maintenance-window ^
    --window-id mw-0c50858d01EXAMPLE ^
    --schedule "rate(7 days)"
```

For information about managing maintenance window schedules, see Reference: Cron and rate expressions for Systems Manager and Maintenance window scheduling and active period options.

> For information about using the Amazon Command Line Interface (Amazon CLI) to modify a maintenance window, see Tutorial: Update a maintenance window using the Amazon CLI.

For practice running Amazon CLI commands to view more details about your maintenance window task and its executions, continue to Tutorial: View information about tasks and task executions using the Amazon CLI.

Accessing tutorial command output

It's beyond the scope of this tutorial to use the Amazon CLI to view the *output* of the Run Command command associated with your maintenance window task executions.

You can view this data using the Amazon CLI. You can also view the output in the Systems Manager console or in a log file stored in an Amazon Simple Storage Service (Amazon S3) bucket, if you configured the maintenance window to store output there. The output of the **df** command on an EC2 instance for Linux is similar to the following.

```
Filesystem 1K-blocks Used Available Use% Mounted on

devtmpfs 485716 0 485716 0% /dev

tmpfs 503624 0 503624 0% /dev/shm

tmpfs 503624 328 503296 1% /run

tmpfs 503624 0 503624 0% /sys/fs/cgroup

/dev/xvda1 8376300 1464160 6912140 18% /
```

The output of the **ipconfig** command on an EC2 instance for Windows Server is similar to the following:

```
Windows IP Configuration

Ethernet adapter Ethernet 2:

   Connection-specific DNS Suffix  . : example.com
   IPv4 Address. . . . . . . . . . . : 10.24.34.0/23
   Subnet Mask . . . . . . . . . . . : 255.255.255.255
```

```
   Default Gateway . . . . . . . . . : 0.0.0.0

Ethernet adapter Ethernet:

   Media State . . . . . . . . . . . : Media disconnected

   Media State . . . . . . . . . . . : Media disconnected
   Connection-specific DNS Suffix  . :

Wireless LAN adapter Wi-Fi:

   Connection-specific DNS Suffix  . :
   Link-local IPv6 Address . . . . . : fe80::100b:c234:66d6:d24f%4
   IPv4 Address. . . . . . . . . . . : 192.0.2.0
   Subnet Mask . . . . . . . . . . . : 255.255.255.0
   Default Gateway . . . . . . . . . : 192.0.2.0

Ethernet adapter Bluetooth Network Connection:

   Media State . . . . . . . . . . . : Media disconnected
   Connection-specific DNS Suffix  . :
```

Examples: Register tasks with a maintenance window

You can register a task in Run Command, with a maintenance window using the Amazon Command Line Interface (Amazon CLI), as demonstrated in Register tasks with the maintenance window. You can also register tasks for Systems Manager Automation workflows, Amazon Lambda functions, and Amazon Step Functions tasks, as demonstrated later in this topic.

> **Note**
>
> Specify one or more targets for maintenance window Run Command-type tasks. Depending on the task, targets are optional for other maintenance window task types (Automation, Amazon Lambda, and Amazon Step Functions). For more information about running tasks that don't specify targets, see Registering maintenance window tasks without targets.

In this topic, we provide examples of using the Amazon Command Line Interface (Amazon CLI) command `register-task-with-maintenance-window` to register each of the four supported

task types with a maintenance window. The examples are for demonstration only, but you can modify them to create working task registration commands.

Using the --cli-input-json option

To better manage your task options, you can use the command option `--cli-input-json`, with option values referenced in a JSON file.

To use the sample JSON file content we provide in the following examples, do the following on your local machine:

1. Create a file with a name such as `MyRunCommandTask.json`, `MyAutomationTask.json`, or another name that you prefer.
2. Copy the contents of our JSON sample into the file.
3. Modify the contents of the file for your task registration, and then save the file.
4. In the same directory where you stored the file, run the following command. Substitute your file name for *`MyFile.json`*.

   Linux & macOS

   ```
   aws ssm register-task-with-maintenance-window \
       --cli-input-json file://MyFile.json
   ```

   Windows

   ```
   aws ssm register-task-with-maintenance-window ^
       --cli-input-json file://MyFile.json
   ```

Pseudo parameters in maintenance window tasks

In some examples, we use *pseudo parameters* as the method to pass ID information to your tasks. For instance, `{{TARGET_ID}}` and `{{RESOURCE_ID}}` can be used to pass IDs of Amazon resources to Automation, Lambda, and Step Functions tasks. For more information about pseudo parameters in `--task-invocation-parameters` content, see Using pseudo parameters when registering maintenance window tasks.

More info

- Parameter options for the register-task-with-maintenance-windows command.

- register-task-with-maintenance-window in the *Amazon CLI Command Reference*
- RegisterTaskWithMaintenanceWindow in the *Amazon Systems Manager API Reference*

Task registration examples

The following sections provide a sample Amazon CLI command for registering a supported task type and a JSON sample that can be used with the `--cli-input-json` option.

Register a Systems Manager Run Command task

The following examples demonstrate how to register Systems Manager Run Command tasks with a maintenance window using the Amazon CLI.

Linux & macOS

```
aws ssm register-task-with-maintenance-window \
    --window-id mw-0c50858d01EXAMPLE \
    --task-arn "AWS-RunShellScript" \
    --max-concurrency 1 --max-errors 1 --priority 10 \
    --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" \
    --task-type "RUN_COMMAND" \
    --task-invocation-parameters '{"RunCommand":{"Parameters":{"commands":["df"]}}}'
```

Windows

```
aws ssm register-task-with-maintenance-window ^
    --window-id mw-0c50858d01EXAMPLE ^
    --task-arn "AWS-RunShellScript" ^
    --max-concurrency 1 --max-errors 1 --priority 10 ^
    --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" ^
    --task-type "RUN_COMMAND" ^
    --task-invocation-parameters "{\"RunCommand\":{\"Parameters\":{\"commands\":
[\"df\"]}}}"
```

JSON content to use with `--cli-input-json` file option:

```
{
    "TaskType": "RUN_COMMAND",
    "WindowId": "mw-0c50858d01EXAMPLE",
    "Description": "My Run Command task to update SSM Agent on an instance",
```

```
    "MaxConcurrency": "1",
    "MaxErrors": "1",
    "Name": "My-Run-Command-Task",

            "TimeoutSeconds": 3600
        }
    }
}
```

Register a Systems Manager Automation task

The following examples demonstrate how to register Systems Manager Automation tasks with a maintenance window using the Amazon CLI:

Amazon CLI command:

Linux & macOS

```
aws ssm register-task-with-maintenance-window \
    --window-id "mw-0c50858d01EXAMPLE" \
    --task-arn "AWS-RestartEC2Instance" \
```

```
    --service-role-arn arn:aws-cn:iam::123456789012:role/
MyMaintenanceWindowServiceRole \
    --task-type AUTOMATION \
    --task-invocation-parameters
 "Automation={DocumentVersion=5,Parameters={InstanceId='{{RESOURCE_ID}}'}}" \
    --priority 0 --name "My-Restart-EC2-Instances-Automation-Task" \
    --description "Automation task to restart EC2 instances"
```

Windows

```
aws ssm register-task-with-maintenance-window ^
    --window-id "mw-0c50858d01EXAMPLE" ^
    --task-arn "AWS-RestartEC2Instance" ^
    --service-role-arn arn:aws-cn:iam::123456789012:role/
MyMaintenanceWindowServiceRole ^
    --task-type AUTOMATION ^
    --task-invocation-parameters
 "Automation={DocumentVersion=5,Parameters={InstanceId='{{TARGET_ID}}'}}" ^
    --priority 0 --name "My-Restart-EC2-Instances-Automation-Task" ^
    --description "Automation task to restart EC2 instances"
```

JSON content to use with `--cli-input-json` file option:

```
{
    "WindowId": "mw-0c50858d01EXAMPLE",
        "TaskArn": "AWS-PatchInstanceWithRollback",
    "TaskType": "AUTOMATION","TaskInvocationParameters": {
        "Automation": {
            "DocumentVersion": "1",
            "Parameters": {
                "instanceId": [
                    "{{RESOURCE_ID}}"
                ]
            }
        }
    }
}
```

Register an Amazon Lambda task

The following examples demonstrate how to register Lambda function tasks with a maintenance window using the Amazon CLI.

> **Important**
>
> Lambda functions must be in the same Amazon Web Services account as the maintenance window when using the service-linked role (`AWSServiceRoleForAmazonSSM`). Cross-account Lambda invocation is not supported with the service-linked role. If you need to invoke a Lambda function in a different account, specify a custom service role using the `--service-role-arn` parameter with permissions explicitly scoped to the target account, and add a resource-based policy on the target Lambda function granting invoke access to your custom role.

For these examples, the user who created the Lambda function named it `SSMrestart-my-instances` and created two parameters called `instanceId` and `targetType`.

> **Important**
>
> The IAM policy for Maintenance Windows requires that you add the prefix `SSM` to Lambda function (or alias) names. Before you proceed to register this type of task, update its name in Amazon Lambda to include `SSM`. For example, if your Lambda function name is `MyLambdaFunction`, change it to `SSMMyLambdaFunction`.

Amazon CLI command:

Linux & macOS

> **Important**
>
> If you are using version 2 of the Amazon CLI, you must include the option `--cli-binary-format raw-in-base64-out` in the following command if your Lambda payload is not base64 encoded. The `cli_binary_format` option is available only in version 2. For information about this and other Amazon CLI `config` file settings, see Supported `config` file settings in the *Amazon Command Line Interface User Guide*.

```
aws ssm register-task-with-maintenance-window \
    --window-id "mw-0c50858d01EXAMPLE" \
    --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
```

```
    --priority 2 --max-concurrency 10 --max-errors 5 --name "My-Lambda-Example" \
    --description "A description for my LAMBDA example task" --task-type "LAMBDA" \
    --task-arn "arn:aws-cn:lambda:region:123456789012:function:serverlessrepo-
SSMrestart-my-instances-C4JF9EXAMPLE" \
    --task-invocation-parameters '{"Lambda":{"Payload":"{\"InstanceId\":
\"{{RESOURCE_ID}}\",\"targetType\":\"{{TARGET_TYPE}}\"}","Qualifier": "$LATEST"}}'
```

PowerShell

> **Important**
>
> If you are using version 2 of the Amazon CLI, you must include the option `--cli-binary-format raw-in-base64-out` in the following command if your Lambda payload is not base64 encoded. The `cli_binary_format` option is available only in version 2. For information about this and other Amazon CLI `config` file settings, see Supported `config` file settings in the *Amazon Command Line Interface User Guide*.

```
aws ssm register-task-with-maintenance-window `
    --window-id "mw-0c50858d01EXAMPLE" `
    --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" `
    --priority 2 --max-concurrency 10 --max-errors 5 --name "My-Lambda-Example" `
    --description "A description for my LAMBDA example task" --task-type "LAMBDA" `
    --task-arn "arn:aws-cn:lambda:region:123456789012:function:serverlessrepo-
SSMrestart-my-instances-C4JF9EXAMPLE" `
    --task-invocation-parameters '{\"Lambda\":{\"Payload\":\"{\\\"InstanceId\\\":\\
\"{{RESOURCE_ID}}\\\",\\\"targetType\\\":\\\"{{TARGET_TYPE}}\\\"}\",\"Qualifier\":
 \"$LATEST\"}}'
```

JSON content to use with `--cli-input-json` file option:

```
{
    "WindowId": "mw-0c50858d01EXAMPLE",
    "Targets": [
        {
            "Key": "WindowTargetIds",
            "Values": [
                "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
            ]
        }
```

```
    ],
    "TaskArn": "SSM_RestartMyInstances",
    "TaskType": "LAMBDA",
    "MaxConcurrency": "10",
    "MaxErrors": "10",
    "TaskInvocationParameters": {
        "Lambda": {
            "ClientContext": "ew0KICAi--truncated--0KIEXAMPLE",
            "Payload": "{ \"instanceId\": \"{{RESOURCE_ID}}\", \"targetType\":
 \"{{TARGET_TYPE}}\" }",
            "Qualifier": "$LATEST"
        }
    },
    "Name": "My-Lambda-Task",
    "Description": "A description for my LAMBDA task",
    "Priority": 5
}
```

Register a Step Functions task

The following examples demonstrate how to register Step Functions state machine tasks with a maintenance window using the Amazon CLI.

> **Important**
>
> Step Functions state machines must be in the same Amazon Web Services account as the maintenance window. Cross-account Step Functions invocation is not supported regardless of whether you use the service-linked role or a custom service role.

> **Note**
>
> Maintenance window tasks support Step Functions Standard state machine workflows only. They don't support Express state machine workflows. For information about state machine workflow types, see Standard vs. Express Workflows in the *Amazon Step Functions Developer Guide*.

For these examples, the user who created the Step Functions state machine created a state machine named `SSMMyStateMachine` with a parameter called `instanceId`.

> **Important**
>
> The Amazon Identity and Access Management (IAM) policy for Maintenance Windows requires that you prefix Step Functions state machine names with SSM. Before you proceed to register this type of task, you must update its name in Amazon Step Functions to include SSM. For example, if your state machine name is `MyStateMachine`, change it to `SSMMyStateMachine`.

Amazon CLI command:

Linux & macOS

```
aws ssm register-task-with-maintenance-window \
    --window-id "mw-0c50858d01EXAMPLE" \
    --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
    --task-arn arn:aws-cn:states:region:123456789012:stateMachine:SSMMyStateMachine-
MggiqEXAMPLE \
    --task-type STEP_FUNCTIONS \
    --task-invocation-parameters '{"StepFunctions":{"Input":"{\"InstanceId\":
\"{{RESOURCE_ID}}\"}", "Name":"{{INVOCATION_ID}}"}}' \
    --priority 0 --max-concurrency 10 --max-errors 5 \
    --name "My-Step-Functions-Task" --description "A description for my Step
 Functions task"
```

PowerShell

```
aws ssm register-task-with-maintenance-window `
    --window-id "mw-0c50858d01EXAMPLE" `
    --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" `
    --task-arn arn:aws-cn:states:region:123456789012:stateMachine:SSMMyStateMachine-
MggiqEXAMPLE `
    --task-type STEP_FUNCTIONS `
    --task-invocation-parameters '{\"StepFunctions\":{\"Input\":\"{\\\"InstanceId\\
\":\\\"{{RESOURCE_ID}}\\\"}\", \"Name\":\"{{INVOCATION_ID}}\"}}' `
    --priority 0 --max-concurrency 10 --max-errors 5 `
    --name "My-Step-Functions-Task" --description "A description for my Step
 Functions task"
```

JSON content to use with `--cli-input-json` file option:

```
{
    "WindowId": "mw-0c50858d01EXAMPLE",
    "Targets": [
        {
            "Key": "WindowTargetIds",
            "Values": [
                "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
            ]
        }
    ],
    "TaskArn": "SSM_MyStateMachine",
    "TaskType": "STEP_FUNCTIONS",
    "MaxConcurrency": "10",
    "MaxErrors": "10",
    "TaskInvocationParameters": {
        "StepFunctions": {
            "Input": "{ \"instanceId\": \"{{TARGET_ID}}\" }",
            "Name": "{{INVOCATION_ID}}"
        }
    },
    "Name": "My-Step-Functions-Task",
    "Description": "A description for my Step Functions task",
    "Priority": 5
}
```

Parameter options for the register-task-with-maintenance-windows command

The **register-task-with-maintenance-window** command provides several options for configuring a task according to your needs. Some are required, some are optional, and some apply to only a single maintenance window task type.

This topic provides information about some of these options to help you work with samples in this tutorial section. For information about all command options, see **register-task-with-maintenance-window** in the *Amazon CLI Command Reference*.

Command option: `--task-arn`

The option `--task-arn` is used to specify the resource that the task operates on. The value that you specify depends on the type of task you're registering, as described in the following table.

TaskArn formats for maintenance window tasks

Maintenance window task type	TaskArn value
RUN_COMMAND and **AUTOMATION**	TaskArn is the SSM document name or Amazon Resource Name (ARN). For example: `AWS-RunBatchShellScript` -or- `arn:aws-cn:ssm:` *`region`*`:11112222 3333:document/My-Document` .
LAMBDA	TaskArn is the function name or ARN. For example: `SSMMy-Lambda-Function` -or- `arn:aws-cn:lambda:` *`region`*`:11112222 3333:function:SSMMyLambdaFu nction` . **Important** The IAM policy for Maintenance Windows requires that you add the prefix `SSM` to Lambda function (or alias) names. Before you proceed to register this type of task, update its name in Amazon Lambda to include `SSM`. For example, if your Lambda function name is `MyLambdaF unction` , change it to `SSMMyLamb daFunction` .

Maintenance window task type	TaskArn value
	Note The Lambda function must be in the same account as the maintenance window when using the service-linked role. For cross-account invocation, use `--service-role-arn` with a custom role and add a resource-based policy on the target function.

Maintenance window task type	TaskArn value
STEP_FUNCTIONS	`TaskArn` is the state machine ARN. For example: `arn:aws:states:us-east-2:111122223333:stateMachine:SSMMyStateMachine` . **Important** The IAM policy for maintenance windows requires that you prefix Step Functions state machine names with `SSM`. Before you register this type of task, you must update its name in Amazon Step Functions to include `SSM`. For example, if your state machine name is `MyStateMachine` , change it to `SSMMyStateMachine` . **Note** The state machine must be in the same account as the maintenance window. You can't invoke a state machine across accounts.

Command option: `--service-role-arn`

The role for Amazon Systems Manager to assume when running the maintenance window task.

For more information, see Setting up Maintenance Windows

Command option: `--task-invocation-parameters`

The `--task-invocation-parameters` option is used to specify the parameters that are unique to each of the four task types. The supported parameters for each of the four task types are described in the following table.

> **Note**
>
> For information about using pseudo parameters in `--task-invocation-parameters` content, such as {{TARGET_ID}}, see Using pseudo parameters when registering maintenance window tasks.

Task invocation parameters options for maintenance window tasks

Maintenance window task type	Available parameters	Example
RUN_COMMAND	Comment DocumentHash DocumentHashType NotificationConfig OutputS3BucketName OutPutS3KeyPrefix Parameters ServiceRoleArn TimeoutSeconds	"TaskInvocationParameters": { "RunCommand": { "Comment": "My Run Command task comment", "DocumentHash": "6554ed3d--truncated--5EXAMPLE", "DocumentHashType": "Sha256", "NotificationConfig": { "NotificationArn": "arn:aws-cn:sns: *region*:123456789012:my-sns-topic-name", "NotificationEvents": ["FAILURE"],

Maintenance window task type	Available parameters	Example
		"NotificationType": "Invocation" }, "OutputS3BucketName": "amzn-s3-demo-bucket", "OutputS3KeyPrefix": " *S3-PREFIX* ", "Parameters": { "commands": ["Get-ChildItem$env:temp-Recurse|Remove-Item-Recurse-force"] }, "ServiceRoleArn": "arn:aws-cn:iam::123456789012:role/MyMaintenanceWindowServiceRole", "TimeoutSeconds": 3600 } }

Maintenance window task type	Available parameters	Example

AUTOMATION	DocumentVersion
	
	Parameters
		"TaskInvocationParameters": {
		"Automation": {
		"DocumentVersion": "3",
		"Parameters": {
		"instanceid": [
		"{{TARGET_ID}}"
		]
		}
		}
		}

LAMBDA	ClientContext
	
	Payload
	
	Qualifier
		"TaskInvocationParameters": {
		"Lambda": {
		"ClientContext": "ew0KICAi--truncated--0KIEXAMPLE",
		"Payload": "{ \"targetId\": \"{{TARGET_ID}}\", \"targetType\": \"{{TARGET_TYPE}}\" }",
		"Qualifier": "$LATEST"
		}
		}

Maintenance window task type	Available parameters	Example
STEP_FUNCTIONS	Input Name	"TaskInvocationParameters": { "StepFunctions": { "Input": "{ \"targetId\": \"{{TARGET_ID}}\" }", "Name": "{{INVOCATION_ID}}" } }

Tutorial: View information about maintenance windows using the Amazon CLI

This tutorial includes commands to help you update or get information about your maintenance windows, tasks, executions, and invocations. The examples are organized by command to demonstrate how to use command options to filter for the type of detail you want to see.

As you follow the steps in this tutorial, replace the values in italicized *red* text with your own options and IDs. For example, replace the maintenance window ID *mw-0c50858d01EXAMPLE* and the instance ID *i-02573cafcfEXAMPLE* with IDs of resources you create.

For information about setting up and configuring the Amazon Command Line Interface (Amazon CLI), see Installing, updating, and uninstalling the Amazon CLI and Configuring the Amazon CLI.

Command examples

- Examples for 'describe-maintenance-windows'
- Examples for 'describe-maintenance-window-targets'
- Examples for 'describe-maintenance-window-tasks'
- Examples for 'describe-maintenance-windows-for-target'
- Examples for 'describe-maintenance-window-executions'
- Examples for 'describe-maintenance-window-schedule'

Examples for 'describe-maintenance-windows'

List all maintenance windows in your Amazon Web Services account

Run the following command.

```
aws ssm describe-maintenance-windows
```

The system returns information similar to the following.

```
{
   "WindowIdentities":[
      {
         "WindowId":"mw-0c50858d01EXAMPLE",
         "Name":"My-First-Maintenance-Window",
         "Enabled":true,
         "Duration":2,
         "Cutoff":0,
         "NextExecutionTime": "2019-05-18T17:01:01.137Z"
      },
      {
         "WindowId":"mw-9a8b7c6d5eEXAMPLE",
         "Name":"My-Second-Maintenance-Window",
         "Enabled":true,
         "Duration":4,
         "Cutoff":1,
         "NextExecutionTime": "2019-05-30T03:30:00.137Z"
      },
   ]
}
```

List all enabled maintenance windows

Run the following command.

```
aws ssm describe-maintenance-windows --filters "Key=Enabled,Values=true"
```

The system returns information similar to the following.

```
{
   "WindowIdentities":[
```

```
      {
         "WindowId":"mw-0c50858d01EXAMPLE",
         "Name":"My-First-Maintenance-Window",
         "Enabled":true,
         "Duration":2,
         "Cutoff":0,
         "NextExecutionTime": "2019-05-18T17:01:01.137Z"
      },
      {
         "WindowId":"mw-9a8b7c6d5eEXAMPLE",
         "Name":"My-Second-Maintenance-Window",
         "Enabled":true,
         "Duration":4,
         "Cutoff":1,
         "NextExecutionTime": "2019-05-30T03:30:00.137Z"
      },
   ]
}
```

List all disabled maintenance windows

Run the following command.

```
aws ssm describe-maintenance-windows --filters "Key=Enabled,Values=false"
```

The system returns information similar to the following.

```
{
    "WindowIdentities": [
        {
            "WindowId": "mw-6e5c9d4b7cEXAMPLE",
            "Name": "My-Disabled-Maintenance-Window",
            "Enabled": false,
            "Duration": 2,
            "Cutoff": 1
        }
    ]
}
```

List all maintenance windows having names that start with a certain prefix

Run the following command.

```
aws ssm describe-maintenance-windows --filters "Key=Name,Values=My"
```

The system returns information similar to the following.

```
{
    "WindowIdentities": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "My-First-Maintenance-Window",
            "Enabled": true,
            "Duration": 2,
            "Cutoff": 0,
            "NextExecutionTime": "2019-05-18T17:01:01.137Z"
        },
        {
            "WindowId": "mw-9a8b7c6d5eEXAMPLE",
            "Name": "My-Second-Maintenance-Window",
            "Enabled": true,
            "Duration": 4,
            "Cutoff": 1,
            "NextExecutionTime": "2019-05-30T03:30:00.137Z"
        },
        {
            "WindowId": "mw-6e5c9d4b7cEXAMPLE",
            "Name": "My-Disabled-Maintenance-Window",
            "Enabled": false,
            "Duration": 2,
            "Cutoff": 1
        }
    ]
}
```

Examples for 'describe-maintenance-window-targets'

Display the targets for a maintenance window matching a specific owner information value

Run the following command.

Linux & macOS

```
aws ssm describe-maintenance-window-targets \
    --window-id "mw-6e5c9d4b7cEXAMPLE" \
```

```
    --filters "Key=OwnerInformation,Values=CostCenter1"
```

Windows

```
aws ssm describe-maintenance-window-targets ^
    --window-id "mw-6e5c9d4b7cEXAMPLE" ^
    --filters "Key=OwnerInformation,Values=CostCenter1"
```

> **Note**
>
> The supported filter keys are `Type`, `WindowTargetId` and `OwnerInformation`.

The system returns information similar to the following.

```
{
    "Targets": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "WindowTargetId": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE",
            "ResourceType": "INSTANCE",
            "Targets": [
                {
                    "Key": "tag:Name",
                    "Values": [
                        "Production"
                    ]
                }
            ],
            "OwnerInformation": "CostCenter1",
            "Name": "Target1"
        }
    ]
}
```

Examples for 'describe-maintenance-window-tasks'

Show all registered tasks that invoke the SSM command document `AWS-RunPowerShellScript`

Run the following command.

Linux & macOS

```
aws ssm describe-maintenance-window-tasks \
    --window-id "mw-0c50858d01EXAMPLE" \
    --filters "Key=TaskArn,Values=AWS-RunPowerShellScript"
```

Windows

```
aws ssm describe-maintenance-window-tasks ^
    --window-id "mw-0c50858d01EXAMPLE" ^
    --filters "Key=TaskArn,Values=AWS-RunPowerShellScript"
```

The system returns information similar to the following.

```
{
   "Tasks":[
      {
         "ServiceRoleArn": "arn:aws-cn:iam::111122223333:role/
MyMaintenanceWindowServiceRole",
         "MaxErrors":"1",
         "TaskArn":"AWS-RunPowerShellScript",
         "MaxConcurrency":"1",
         "WindowTaskId":"4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
         "TaskParameters":{
            "commands":{
               "Values":[
                  "driverquery.exe"
               ]
            }
         },
         "Priority":3,
         "Type":"RUN_COMMAND",
         "Targets":[
            {
               "TaskTargetId":"i-02573cafcfEXAMPLE",
               "TaskTargetType":"INSTANCE"
            }
         ]
      },
      {
         "ServiceRoleArn":"arn:aws-cn:iam::111122223333:role/
MyMaintenanceWindowServiceRole",
```

```
         "MaxErrors":"1",
         "TaskArn":"AWS-RunPowerShellScript",
         "MaxConcurrency":"1",
         "WindowTaskId":"4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
         "TaskParameters":{
            "commands":{
               "Values":[
                  "ipconfig"
               ]
            }
         },
         "Priority":1,
         "Type":"RUN_COMMAND",
         "Targets":[
            {
               "TaskTargetId":"i-02573cafcfEXAMPLE",
               "TaskTargetType":"WINDOW_TARGET"
            }
         ]
      }
   ]
}
```

Show all registered tasks that have a priority of "3"

Run the following command.

Linux & macOS

```
aws ssm describe-maintenance-window-tasks \
    --window-id "mw-9a8b7c6d5eEXAMPLE" \
    --filters "Key=Priority,Values=3"
```

Windows

```
aws ssm describe-maintenance-window-tasks ^
    --window-id "mw-9a8b7c6d5eEXAMPLE" ^
    --filters "Key=Priority,Values=3"
```

The system returns information similar to the following.

```
{
```

```
   "Tasks":[
      {
         "ServiceRoleArn":"arn:aws-cn:iam::111122223333:role/
MyMaintenanceWindowServiceRole",
         "MaxErrors":"1",
         "TaskArn":"AWS-RunPowerShellScript",
         "MaxConcurrency":"1",
         "WindowTaskId":"4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
         "TaskParameters":{
            "commands":{
               "Values":[
                  "driverquery.exe"
               ]
            }
         },
         "Priority":3,
         "Type":"RUN_COMMAND",
         "Targets":[
            {
               "TaskTargetId":"i-02573cafcfEXAMPLE",
               "TaskTargetType":"INSTANCE"
            }
         ]
      }
   ]
}
```

Show all registered tasks that have a priority of "1" and use Run Command

Run the following command.

Linux & macOS

```
aws ssm describe-maintenance-window-tasks \
    --window-id "mw-0c50858d01EXAMPLE" \
    --filters "Key=Priority,Values=1" "Key=TaskType,Values=RUN_COMMAND"
```

Windows

```
aws ssm describe-maintenance-window-tasks ^
    --window-id "mw-0c50858d01EXAMPLE" ^
    --filters "Key=Priority,Values=1" "Key=TaskType,Values=RUN_COMMAND"
```

The system returns information similar to the following.

```
{
    "Tasks": [
        {

        }
    ]
}
```

Examples for 'describe-maintenance-windows-for-target'

List information about the maintenance window targets or tasks associated with a specific node

Run the following command.

Linux & macOS

```
aws ssm describe-maintenance-windows-for-target \
    --resource-type INSTANCE \
    --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" \
    --max-results 10
```

Windows

```
aws ssm describe-maintenance-windows-for-target ^
    --resource-type INSTANCE ^
    --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE" ^
    --max-results 10
```

The system returns information similar to the following.

```
{
    "WindowIdentities": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "My-First-Maintenance-Window"
        },
        {
            "WindowId": "mw-9a8b7c6d5eEXAMPLE",
            "Name": "My-Second-Maintenance-Window"
        }
    ]
}
```

Examples for 'describe-maintenance-window-executions'

List all tasks run before a certain date

Run the following command.

Linux & macOS

```
aws ssm describe-maintenance-window-executions \
    --window-id "mw-9a8b7c6d5eEXAMPLE" \
    --filters "Key=ExecutedBefore,Values=2019-05-12T05:00:00Z"
```

Windows

```
aws ssm describe-maintenance-window-executions ^
    --window-id "mw-9a8b7c6d5eEXAMPLE" ^
    --filters "Key=ExecutedBefore,Values=2019-05-12T05:00:00Z"
```

The system returns information similar to the following.

```
{
    "WindowExecutions": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
            "Status": "FAILED",
            "StatusDetails": "The following SSM parameters are invalid: LevelUp",
            "StartTime": 1557617747.993,
            "EndTime": 1557617748.101
        },
        {
            "WindowId": "mw-9a8b7c6d5eEXAMPLE",
            "WindowExecutionId": "791b72e0-f0da-4021-8b35-f95dfEXAMPLE",
            "Status": "SUCCESS",
            "StartTime": 1557594085.428,
            "EndTime": 1557594090.978
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "WindowExecutionId": "ecec60fa-6bb0-4d26-98c7-140308EXAMPLE",
            "Status": "SUCCESS",
            "StartTime": 1557593793.483,
```

```
            "EndTime": 1557593798.978
        }
    ]
}
```

List all tasks run after a certain date

Run the following command.

Linux & macOS

```
aws ssm describe-maintenance-window-executions \
    --window-id "mw-9a8b7c6d5eEXAMPLE" \
    --filters "Key=ExecutedAfter,Values=2018-12-31T17:00:00Z"
```

Windows

```
aws ssm describe-maintenance-window-executions ^
    --window-id "mw-9a8b7c6d5eEXAMPLE" ^
    --filters "Key=ExecutedAfter,Values=2018-12-31T17:00:00Z"
```

The system returns information similar to the following.

```
{
    "WindowExecutions": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
            "Status": "FAILED",
            "StatusDetails": "The following SSM parameters are invalid: LevelUp",
            "StartTime": 1557617747.993,
            "EndTime": 1557617748.101
        },
        {
            "WindowId": "mw-9a8b7c6d5eEXAMPLE",
            "WindowExecutionId": "791b72e0-f0da-4021-8b35-f95dfEXAMPLE",
            "Status": "SUCCESS",
            "StartTime": 1557594085.428,
            "EndTime": 1557594090.978
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
```

```
            "WindowExecutionId": "ecec60fa-6bb0-4d26-98c7-140308EXAMPLE",
            "Status": "SUCCESS",
            "StartTime": 1557593793.483,
            "EndTime": 1557593798.978
        }
    ]
}
```

Examples for 'describe-maintenance-window-schedule'

Display the next ten scheduled maintenance window runs for a particular node

Run the following command.

Linux & macOS

```
aws ssm describe-maintenance-window-schedule \
    --resource-type INSTANCE \
    --targets "Key=InstanceIds,Values=i-07782c72faEXAMPLE" \
    --max-results 10
```

Windows

```
aws ssm describe-maintenance-window-schedule ^
    --resource-type INSTANCE ^
    --targets "Key=InstanceIds,Values=i-07782c72faEXAMPLE" ^
    --max-results 10
```

The system returns information similar to the following.

```
{
    "ScheduledWindowExecutions": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "My-First-Maintenance-Window",
            "ExecutionTime": "2019-05-18T23:35:24.902Z"
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "My-First-Maintenance-Window",
            "ExecutionTime": "2019-05-25T23:35:24.902Z"
        },
```

```
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "My-First-Maintenance-Window",
            "ExecutionTime": "2019-06-01T23:35:24.902Z"
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "My-First-Maintenance-Window",
            "ExecutionTime": "2019-06-08T23:35:24.902Z"
        },
        {
            "WindowId": "mw-9a8b7c6d5eEXAMPLE",
            "Name": "My-Second-Maintenance-Window",
            "ExecutionTime": "2019-06-15T23:35:24.902Z"
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "My-First-Maintenance-Window",
            "ExecutionTime": "2019-06-22T23:35:24.902Z"
        },
        {
            "WindowId": "mw-9a8b7c6d5eEXAMPLE",
            "Name": "My-Second-Maintenance-Window",
            "ExecutionTime": "2019-06-29T23:35:24.902Z"
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "My-First-Maintenance-Window",
            "ExecutionTime": "2019-07-06T23:35:24.902Z"
        },
        {
            "WindowId": "mw-9a8b7c6d5eEXAMPLE",
            "Name": "My-Second-Maintenance-Window",
            "ExecutionTime": "2019-07-13T23:35:24.902Z"
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "My-First-Maintenance-Window",
            "ExecutionTime": "2019-07-20T23:35:24.902Z"
        }
    ],
    "NextToken": "AAEABUXdceT92FvtKld/dGHELj5Mi+GKW/EXAMPLE"
}
```

Display the maintenance window schedule for nodes tagged with a certain key-value pair

Run the following command.

Linux & macOS

```
aws ssm describe-maintenance-window-schedule \
    --resource-type INSTANCE \
    --targets "Key=tag:prod,Values=rhel7"
```

Windows

```
aws ssm describe-maintenance-window-schedule ^
    --resource-type INSTANCE ^
    --targets "Key=tag:prod,Values=rhel7"
```

The system returns information similar to the following.

```
{
    "ScheduledWindowExecutions": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "DemoRateStartDate",
            "ExecutionTime": "2019-10-20T05:34:56-07:00"
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "DemoRateStartDate",
            "ExecutionTime": "2019-10-21T05:34:56-07:00"
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "DemoRateStartDate",
            "ExecutionTime": "2019-10-22T05:34:56-07:00"
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "Name": "DemoRateStartDate",
            "ExecutionTime": "2019-10-23T05:34:56-07:00"
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
```

```
            "Name": "DemoRateStartDate",
            "ExecutionTime": "2019-10-24T05:34:56-07:00"
        }
    ],
    "NextToken": "AAEABccwSXqQRGKiTZ1yzGELR6cxW4W/EXAMPLE"
}
```

Display start times for next four runs of a maintenance window

Run the following command.

Linux & macOS

```
aws ssm describe-maintenance-window-schedule \
    --window-id "mw-0c50858d01EXAMPLE" \
    --max-results "4"
```

Windows

```
aws ssm describe-maintenance-window-schedule ^
    --window-id "mw-0c50858d01EXAMPLE" ^
    --max-results "4"
```

The system returns information similar to the following.

```
{
    "WindowSchedule": [
        {
            "ScheduledWindowExecutions": [
                {
                    "ExecutionTime": "2019-10-04T10:10:10Z",
                    "Name": "My-First-Maintenance-Window",
                    "WindowId": "mw-0c50858d01EXAMPLE"
                },
                {
                    "ExecutionTime": "2019-10-11T10:10:10Z",

                    "WindowId": "mw-0c50858d01EXAMPLE"
                },
                {
                    "ExecutionTime": "2019-10-18T10:10:10Z",
                    "Name": "My-First-Maintenance-Window",
```

```
                "WindowId": "mw-0c50858d01EXAMPLE"
            },
            {
                "ExecutionTime": "2019-10-25T10:10:10Z",
                "Name": "My-First-Maintenance-Window",
                "WindowId": "mw-0c50858d01EXAMPLE"
            }
        ]
    }
]
}
```

Tutorial: View information about tasks and task executions using the Amazon CLI

This tutorial demonstrates how to use the Amazon Command Line Interface (Amazon CLI) to view details about your completed maintenance window tasks.

If you're continuing directly from Tutorial: Create and configure a maintenance window using the Amazon CLI, make sure you have allowed enough time for your maintenance window to run at least once in order to see its execution results.

As you follow the steps in this tutorial, replace the values in italicized *red* text with your own options and IDs. For example, replace the maintenance window ID *mw-0c50858d01EXAMPLE* and the instance ID *i-02573cafcfEXAMPLE* with IDs of resources you create.

To view information about tasks and task executions using the Amazon CLI

1. Run the following command to view a list of task executions for a specific maintenance window.

   Linux & macOS

   ```
   aws ssm describe-maintenance-window-executions \
       --window-id "mw-0c50858d01EXAMPLE"
   ```

   Windows

   ```
   aws ssm describe-maintenance-window-executions ^
       --window-id "mw-0c50858d01EXAMPLE"
   ```

   The system returns information similar to the following.

```
{
    "WindowExecutions": [
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
            "Status": "SUCCESS",
            "StartTime": 1557593793.483,
            "EndTime": 1557593798.978
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "WindowExecutionId": "791b72e0-f0da-4021-8b35-f95dfEXAMPLE",
            "Status": "SUCCESS",
            "StartTime": 1557593493.096,
            "EndTime": 1557593498.611
        },
        {
            "WindowId": "mw-0c50858d01EXAMPLE",
            "WindowExecutionId": "ecec60fa-6bb0-4d26-98c7-140308EXAMPLE",
            "Status": "SUCCESS",
            "StatusDetails": "No tasks to execute.",
            "StartTime": 1557593193.309,
            "EndTime": 1557593193.334
        }
    ]
}
```

2. Run the following command to get information about a maintenance window task execution.

   Linux & macOS

   ```
   aws ssm get-maintenance-window-execution \
       --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE"
   ```

   Windows

   ```
   aws ssm get-maintenance-window-execution ^
       --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE"
   ```

   The system returns information similar to the following.

```
{
    "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
    "TaskIds": [
        "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE"
    ],
    "Status": "SUCCESS",
    "StartTime": 1557593493.096,
    "EndTime": 1557593498.611
}
```

3. Run the following command to list the tasks run as part of a maintenance window execution.

   Linux & macOS

   ```
   aws ssm describe-maintenance-window-execution-tasks \
       --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE"
   ```

   Windows

   ```
   aws ssm describe-maintenance-window-execution-tasks ^
       --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE"
   ```

   The system returns information similar to the following.

   ```
   {
       "WindowExecutionTaskIdentities": [
           {
               "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
               "TaskExecutionId": "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE",
               "Status": "SUCCESS",
               "StartTime": 1557593493.162,
               "EndTime": 1557593498.57,
               "TaskArn": "AWS-RunShellScript",
               "TaskType": "RUN_COMMAND"
           }
       ]
   }
   ```

4. Run the following command to get the details of a task execution.

Linux & macOS

```
aws ssm get-maintenance-window-execution-task \
    --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE" \
    --task-id "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE"
```

Windows

```
aws ssm get-maintenance-window-execution-task ^
    --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE" ^
    --task-id "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE"
```

The system returns information similar to the following.

```
{
    "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
    "TaskExecutionId": "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE",
    "TaskArn": "AWS-RunShellScript",
    "ServiceRole": "arn:aws-cn:iam::111122223333:role/
MyMaintenanceWindowServiceRole",
    "Type": "RUN_COMMAND",
    "TaskParameters": [
        {
            "aws:InstanceId": {
                "Values": [
                    "i-02573cafcfEXAMPLE"
                ]
            },
            "commands": {
                "Values": [
                    "df"
                ]
            }
        }
    ],
    "Priority": 10,
    "MaxConcurrency": "1",
    "MaxErrors": "1",
    "Status": "SUCCESS",
    "StartTime": 1557593493.162,
```

```
    "EndTime": 1557593498.57
}
```

5. Run the following command to get the specific task invocations performed for a task execution.

   Linux & macOS

   ```
   aws ssm describe-maintenance-window-execution-task-invocations \
       --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE" \
       --task-id "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE"
   ```

   Windows

   ```
   aws ssm describe-maintenance-window-execution-task-invocations ^
       --window-execution-id "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE" ^
       --task-id "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE"
   ```

   The system returns information similar to the following.

   ```
   {
       "WindowExecutionTaskInvocationIdentities": [
           {
               "WindowExecutionId": "14bea65d-5ccc-462d-a2f3-e99c8EXAMPLE",
               "TaskExecutionId": "c9b05aba-197f-4d8d-be34-e73fbEXAMPLE",
               "InvocationId": "c336d2ab-09de-44ba-8f6a-6136cEXAMPLE",
               "ExecutionId": "76a5a04f-caf6-490c-b448-92c02EXAMPLE",
               "TaskType": "RUN_COMMAND",
               "Parameters": "{\"documentName\":\"AWS-RunShellScript\",\"instanceIds
   \":[\"i-02573cafcfEXAMPLE\"],\"maxConcurrency\":\"1\",\"maxErrors\":\"1\",
   \"parameters\":{\"commands\":[\"df\"]}}",
               "Status": "SUCCESS",
               "StatusDetails": "Success",
               "StartTime": 1557593493.222,
               "EndTime": 1557593498.466
           }
       ]
   }
   ```

Tutorial: Update a maintenance window using the Amazon CLI

This tutorial demonstrates how to use the Amazon Command Line Interface (Amazon CLI) to update a maintenance window. It also shows you how to update different task types, including those for Amazon Systems Manager Run Command and Automation, Amazon Lambda, and Amazon Step Functions.

The examples in this section use the following Systems Manager actions for updating a maintenance window:

- UpdateMaintenanceWindow
- UpdateMaintenanceWindowTarget
- UpdateMaintenanceWindowTask
- DeregisterTargetFromMaintenanceWindow

For information about using the Systems Manager console to update a maintenance window, see Update or delete maintenance window resources using the console.

As you follow the steps in this tutorial, replace the values in italicized *red* text with your own options and IDs. For example, replace the maintenance window ID *mw-0c50858d01EXAMPLE* and the instance ID *i-02573cafcfEXAMPLE* with IDs of resources you create.

To update a maintenance window using the Amazon CLI

1. Open the Amazon CLI and run the following command to update a target to include a name and a description.

   Linux & macOS

   ```
   aws ssm update-maintenance-window-target \
       --window-id "mw-0c50858d01EXAMPLE" \
       --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
       --name "My-Maintenance-Window-Target" \
       --description "Description for my maintenance window target"
   ```

   Windows

   ```
   aws ssm update-maintenance-window-target ^
       --window-id "mw-0c50858d01EXAMPLE" ^
   ```

```
    --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" ^
    --name "My-Maintenance-Window-Target" ^
    --description "Description for my maintenance window target"
```

The system returns information similar to the following.

```
{
    "WindowId": "mw-0c50858d01EXAMPLE",
    "WindowTargetId": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE",
    "Targets": [
        {
            "Key": "InstanceIds",
            "Values": [
                "i-02573cafcfEXAMPLE"
            ]
        }
    ],
    "Name": "My-Maintenance-Window-Target",
    "Description": "Description for my maintenance window target"
}
```

2. Run the following command to use the `replace` option to remove the description field and add an additional target. The description field is removed, because the update doesn't include the field (a null value). Be sure to specify an additional node that has been configured for use with Systems Manager.

   Linux & macOS

   ```
   aws ssm update-maintenance-window-target \
       --window-id "mw-0c50858d01EXAMPLE" \
       --window-target-id "d208dedf-3f6b-41ff-ace8-8e751EXAMPLE" \
       --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE" \
       --name "My-Maintenance-Window-Target" \
       --replace
   ```

   Windows

   ```
   aws ssm update-maintenance-window-target ^
       --window-id "mw-0c50858d01EXAMPLE" ^
       --window-target-id "d208dedf-3f6b-41ff-ace8-8e751EXAMPLE" ^
       --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE,i-0471e04240EXAMPLE" ^
   ```

```
    --name "My-Maintenance-Window-Target" ^
    --replace
```

The system returns information similar to the following.

```
{
    "WindowId": "mw-0c50858d01EXAMPLE",
    "WindowTargetId": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE",
    "Targets": [
        {
            "Key": "InstanceIds",
            "Values": [
                "i-02573cafcfEXAMPLE",
                "i-0471e04240EXAMPLE"
            ]
        }
    ],
    "Name": "My-Maintenance-Window-Target"
}
```

3. The `start-date` option lets you delay activation of a maintenance window until a specified future date. The `end-date` option lets you set a date and time in the future after which the maintenance window no longer runs. Specify the options in ISO-8601 Extended format.

   Run the following command to specify a date and time range for regularly scheduled maintenance window executions.

   Linux & macOS

   ```
   aws ssm update-maintenance-window \
       --window-id "mw-0c50858d01EXAMPLE" \
       --start-date "2020-10-01T10:10:10Z" \
       --end-date "2020-11-01T10:10:10Z"
   ```

   Windows

   ```
   aws ssm update-maintenance-window ^
       --window-id "mw-0c50858d01EXAMPLE" ^
       --start-date "2020-10-01T10:10:10Z" ^
       --end-date "2020-11-01T10:10:10Z"
   ```

4. Run the following command to update a Run Command task.

> **Tip**
>
> If your target is an Amazon Elastic Compute Cloud (Amazon EC2) instance for Windows Server, change `df` to `ipconfig`, and `AWS-RunShellScript` to `AWS-RunPowerShellScript` in the following command.

Linux & macOS

```
aws ssm update-maintenance-window-task \
    --window-id "mw-0c50858d01EXAMPLE" \
    --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" \
    --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
 \
    --task-arn "AWS-RunShellScript" \
    --service-role-arn "arn:aws-cn:iam::account-id:role/MaintenanceWindowsRole"
 \
    --task-invocation-parameters "RunCommand={Comment=Revising my Run Command
 task,Parameters={commands=df}}" \
    --priority 1 --max-concurrency 10 --max-errors 4 \
    --name "My-Task-Name" --description "A description for my Run Command task"
```

Windows

```
aws ssm update-maintenance-window-task ^
    --window-id "mw-0c50858d01EXAMPLE" ^
    --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" ^
    --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
 ^
    --task-arn "AWS-RunShellScript" ^
    --service-role-arn "arn:aws-cn:iam::account-id:role/MaintenanceWindowsRole"
 ^
    --task-invocation-parameters "RunCommand={Comment=Revising my Run Command
 task,Parameters={commands=df}}" ^
    --priority 1 --max-concurrency 10 --max-errors 4 ^
    --name "My-Task-Name" --description "A description for my Run Command task"
```

The system returns information similar to the following.

```
{
    "WindowId": "mw-0c50858d01EXAMPLE",
    "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
    "Targets": [
        {
            "Key": "WindowTargetIds",
            "Values": [
                "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
            ]
        }
    ],
    "TaskArn": "AWS-RunShellScript",
    "ServiceRoleArn": "arn:aws-cn:iam::111122223333:role/MaintenanceWindowsRole",
    "TaskParameters": {},
    "TaskInvocationParameters": {
        "RunCommand": {
            "Comment": "Revising my Run Command task",
            "Parameters": {
                "commands": [
                    "df"
                ]
            }
        }
    },
    "Priority": 1,
    "MaxConcurrency": "10",
    "MaxErrors": "4",
    "Name": "My-Task-Name",
    "Description": "A description for my Run Command task"
}
```

5. Adapt and run the following command to update a Lambda task.

   Linux & macOS

```
aws ssm update-maintenance-window-task \
    --window-id mw-0c50858d01EXAMPLE \
    --window-task-id 4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE \
    --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
 \
    --task-arn "arn:aws-cn:lambda:region:111122223333:function:SSMTestLambda" \
    --service-role-arn "arn:aws-cn:iam:account-id:role/MaintenanceWindowsRole" \
```

```
    --task-invocation-parameters '{"Lambda":{"Payload":"{\"InstanceId\":
\"{{RESOURCE_ID}}\",\"targetType\":\"{{TARGET_TYPE}}\"}"}}' \
    --priority 1 --max-concurrency 10 --max-errors 5 \
    --name "New-Lambda-Task-Name" \
    --description "A description for my Lambda task"
```

Windows

```
aws ssm update-maintenance-window-task ^
    --window-id mw-0c50858d01EXAMPLE ^
    --window-task-id 4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE ^
    --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
 ^
    --task-arn --task-arn "arn:aws-
cn:lambda:region:111122223333:function:SSMTestLambda" ^
    --service-role-arn "arn:aws-cn:iam:account-id:role/MaintenanceWindowsRole" ^
    --task-invocation-parameters '{"Lambda":{"Payload":"{\"InstanceId\":
\"{{RESOURCE_ID}}\",\"targetType\":\"{{TARGET_TYPE}}\"}"}}' ^
    --priority 1 --max-concurrency 10 --max-errors 5 ^
    --name "New-Lambda-Task-Name" ^
    --description "A description for my Lambda task"
```

The system returns information similar to the following.

```
{
    "WindowId": "mw-0c50858d01EXAMPLE",
    "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
    "Targets": [
        {
            "Key": "WindowTargetIds",
            "Values": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
        }
    ],
    "TaskArn": "arn:aws:lambda:us-east-2:111122223333:function:SSMTestLambda",
    "ServiceRoleArn": "arn:aws:iam::111122223333:role/MaintenanceWindowsRole",
    "TaskParameters": {},
    "TaskInvocationParameters": {
        "Lambda": {
            "Payload": "e30="
        }
    },
    "Priority": 1,
```

```
    "MaxConcurrency": "10",
    "MaxErrors": "5",
    "Name": "New-Lambda-Task-Name",
    "Description": "A description for my Lambda task"
}
```

6. If you're updating a Step Functions task, adapt and run the following command to update its task-invocation-parameters.

   Linux & macOS

   ```
   aws ssm update-maintenance-window-task \
       --window-id "mw-0c50858d01EXAMPLE" \
       --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" \
       --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
    \
       --task-arn "arn:aws-cn:states:region:execution:SSMStepFunctionTest" \
       --service-role-arn "arn:aws-cn:iam:account-id:role/MaintenanceWindowsRole" \
       --task-invocation-parameters '{"StepFunctions":{"Input":"{\"InstanceId\":
   \"{{RESOURCE_ID}}\"}"}}' \
       --priority 0 --max-concurrency 10 --max-errors 5 \
       --name "My-Step-Functions-Task" \
       --description "A description for my Step Functions task"
   ```

   Windows

   ```
   aws ssm update-maintenance-window-task ^
       --window-id "mw-0c50858d01EXAMPLE" ^
       --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" ^
       --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
    ^
       --task-arn "arn:aws-cn:states:region:execution:SSMStepFunctionTest" ^
       --service-role-arn "arn:aws-cn:iam:account-id:role/MaintenanceWindowsRole" ^
       --task-invocation-parameters '{"StepFunctions":{"Input":"{\"InstanceId\":
   \"{{RESOURCE_ID}}\"}"}}' ^
       --priority 0 --max-concurrency 10 --max-errors 5 ^
       --name "My-Step-Functions-Task" ^
       --description "A description for my Step Functions task"
   ```

   The system returns information similar to the following.

```
{
    "WindowId": "mw-0c50858d01EXAMPLE",
    "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
    "Targets": [
        {
            "Key": "WindowTargetIds",
            "Values": [
                "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
            ]
        }
    ],
    "TaskArn": "arn:aws:states:us-
east-2:111122223333:execution:SSMStepFunctionTest",
    "ServiceRoleArn": "arn:aws:iam::111122223333:role/MaintenanceWindowsRole",
    "TaskParameters": {},
    "TaskInvocationParameters": {
        "StepFunctions": {
            "Input": "{\"instanceId\":\"{{RESOURCE_ID}}\"}"
        }
    },
    "Priority": 0,
    "MaxConcurrency": "10",
    "MaxErrors": "5",
    "Name": "My-Step-Functions-Task",
    "Description": "A description for my Step Functions task"
}
```

7. Run the following command to unregister a target from a maintenance window. This example uses the `safe` parameter to determine if the target is referenced by any tasks and therefore safe to unregister.

   Linux & macOS

   ```
   aws ssm deregister-target-from-maintenance-window \
       --window-id "mw-0c50858d01EXAMPLE" \
       --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
       --safe
   ```

   Windows

   ```
   aws ssm deregister-target-from-maintenance-window ^
   ```

```
    --window-id "mw-0c50858d01EXAMPLE" ^
    --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" ^
    --safe
```

The system returns information similar to the following.

```
An error occurred (TargetInUseException) when calling the
 DeregisterTargetFromMaintenanceWindow operation:
This Target cannot be deregistered because it is still referenced in Task:
 4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE
```

8. Run the following command to unregister a target from a maintenance window even if the target is referenced by a task. You can force the unregister operation by using the `no-safe` parameter.

   Linux & macOS

   ```
   aws ssm deregister-target-from-maintenance-window \
       --window-id "mw-0c50858d01EXAMPLE" \
       --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" \
       --no-safe
   ```

   Windows

   ```
   aws ssm deregister-target-from-maintenance-window ^
       --window-id "mw-0c50858d01EXAMPLE" ^
       --window-target-id "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE" ^
       --no-safe
   ```

   The system returns information similar to the following.

   ```
   {
       "WindowId": "mw-0c50858d01EXAMPLE",
       "WindowTargetId": "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
   }
   ```

9. Run the following command to update a Run Command task. This example uses a Systems Manager Parameter Store parameter called `UpdateLevel`, which is formatted as follows: `'{{ssm:UpdateLevel}}'`

Linux & macOS

```
aws ssm update-maintenance-window-task \
    --window-id "mw-0c50858d01EXAMPLE" \
    --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" \
    --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE"  \
    --task-invocation-parameters "RunCommand={Comment=A comment for my task
 update,Parameters={UpdateLevel='{{ssm:UpdateLevel}}'}}"
```

Windows

```
aws ssm update-maintenance-window-task ^
    --window-id "mw-0c50858d01EXAMPLE" ^
    --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" ^
    --targets "Key=InstanceIds,Values=i-02573cafcfEXAMPLE"  ^
    --task-invocation-parameters "RunCommand={Comment=A comment for my task
 update,Parameters={UpdateLevel='{{ssm:UpdateLevel}}'}}"
```

The system returns information similar to the following.

```
{
    "WindowId": "mw-0c50858d01EXAMPLE",
    "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
    "Targets": [
        {
            "Key": "InstanceIds",
            "Values": [
                "i-02573cafcfEXAMPLE"
            ]
        }
    ],
    "TaskArn": "AWS-RunShellScript",
    "ServiceRoleArn": "arn:aws:iam::111122223333:role/
MyMaintenanceWindowServiceRole",
    "TaskParameters": {},
    "TaskInvocationParameters": {
        "RunCommand": {
            "Comment": "A comment for my task update",
            "Parameters": {
                "UpdateLevel": [
```

```
                    "{{ssm:UpdateLevel}}"
                ]
            }
        }
    },
    "Priority": 10,
    "MaxConcurrency": "1",
    "MaxErrors": "1"
}
```

10. Run the following command to update an Automation task to specify `WINDOW_ID` and `WINDOW_TASK_ID` parameters for the `task-invocation-parameters` parameter:

    Linux & macOS

    ```
    aws ssm update-maintenance-window-task \
        --window-id "mw-0c50858d01EXAMPLE" \
        --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" \
        --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE \
        --task-arn "AutoTestDoc" \
        --service-role-arn "arn:aws-cn:iam:account-id:role/
    MyMaintenanceWindowServiceRole \
        --task-invocation-parameters
     "Automation={Parameters={InstanceId='{{RESOURCE_ID}}',initiator='{{WINDOW_ID}}.Task-
    {{WINDOW_TASK_ID}}'}}" \
        --priority 3 --max-concurrency 10 --max-errors 5
    ```

    Windows

    ```
    aws ssm update-maintenance-window-task ^
        --window-id "mw-0c50858d01EXAMPLE" ^
        --window-task-id "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE" ^
        --targets "Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE ^
        --task-arn "AutoTestDoc" ^
        --service-role-arn "arn:aws-cn:iam:account-id:role/
    MyMaintenanceWindowServiceRole ^
        --task-invocation-parameters
     "Automation={Parameters={InstanceId='{{RESOURCE_ID}}',initiator='{{WINDOW_ID}}.Task-
    {{WINDOW_TASK_ID}}'}}" ^
        --priority 3 --max-concurrency 10 --max-errors 5
    ```

The system returns information similar to the following.

```
{
    "WindowId": "mw-0c50858d01EXAMPLE",
    "WindowTaskId": "4f7ca192-7e9a-40fe-9192-5cb15EXAMPLE",
    "Targets": [
        {
            "Key": "WindowTargetIds",
            "Values": [
                "e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE"
            ]
        }
    ],
    "TaskArn": "AutoTestDoc",
    "ServiceRoleArn": "arn:aws-cn:iam::111122223333:role/
MyMaintenanceWindowServiceRole",
    "TaskParameters": {},
    "TaskInvocationParameters": {
        "Automation": {
            "Parameters": {
                "multi": [
                    "{{WINDOW_TASK_ID}}"
                ],
                "single": [
                    "{{WINDOW_ID}}"
                ]
            }
        }
    },
    "Priority": 0,
    "MaxConcurrency": "10",
    "MaxErrors": "5",
    "Name": "My-Automation-Task",
    "Description": "A description for my Automation task"
}
```

Tutorial: Delete a maintenance window using the Amazon CLI

To delete a maintenance window you created in these tutorials, run the following command.

```
aws ssm delete-maintenance-window --window-id "mw-0c50858d01EXAMPLE"
```

The system returns information similar to the following.

```
{
   "WindowId":"mw-0c50858d01EXAMPLE"
}
```

Tutorial: Create a maintenance window for patching using the console

> **Important**
>
> You can continue to use this legacy topic to create a maintenance window for patching. However, we recommend that you use a patch policy instead. For more information, see Patch policy configurations in Quick Setup and Configure patching for instances in an organization using a Quick Setup patch policy.

To minimize the impact on your server availability, we recommend that you configure a maintenance window to run patching during times that won't interrupt your business operations.

You must configure roles and permissions for Maintenance Windows before beginning this procedure. For more information, see Setting up Maintenance Windows.

To create a maintenance window for patching

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Maintenance Windows**.
3. Choose **Create maintenance window**.
4. For **Name**, enter a name that designates this as a maintenance window for patching critical and important updates.
5. (Optional) For **Description**, enter a description.
6. Choose **Allow unregistered targets** if you want to allow a maintenance window task to run on managed nodes, even if you haven't registered those nodes as targets.

   If you choose this option, then you can choose the unregistered nodes (by node ID) when you register a task with the maintenance window.

If you don't choose this option, then you must choose previously-registered targets when you register a task with the maintenance window.

7. In the top of the **Schedule** section, specify a schedule for the maintenance window by using one of the three scheduling options.

   For information about building cron/rate expressions, see Reference: Cron and rate expressions for Systems Manager.

8. For **Duration**, enter the number of hours the maintenance window will run. The value you specify determines the specific end time for the maintenance window based on the time it begins. No maintenance window tasks are permitted to start after the resulting endtime minus the number of hours you specify for **Stop initiating tasks** in the next step.

   For example, if the maintenance window starts at 3 PM, the duration is three hours, and the **Stop initiating tasks** value is one hour, no maintenance window tasks can start after 5 PM.

9. For **Stop initiating tasks**, enter the number of hours before the end of the maintenance window that the system should stop scheduling new tasks to run.

10. (Optional) For **Window start date**, specify a date and time, in ISO-8601 Extended format, for when you want the maintenance window to become active. This lets you delay activation of the maintenance window until the specified future date.

11. (Optional) For **Window end date**, specify a date and time, in ISO-8601 Extended format, for when you want the maintenance window to become inactive. This lets you set a date and time in the future after which the maintenance window no longer runs.

12. (Optional) For **Schedule timezone**, specify the time zone to base scheduled maintenance window executions on, in Internet Assigned Numbers Authority (IANA) format. For example: "America/Los_Angeles", "etc/UTC", or "Asia/Seoul".

    For more information about valid formats, see the Time Zone Database on the IANA website.

13. (Optional) In the **Manage tags** area, apply one or more tag key name/value pairs to the maintenance window.

    Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag this maintenance window to identify the type of tasks it runs. In this case, you could specify the following key name/value pair:

    - `Key=TaskType,Value=Patching`

14. Choose **Create maintenance window**.
15. In the maintenance windows list, choose the maintenance window you just created, and then choose **Actions**, **Register targets**.
16. (Optional) In the **Maintenance window target details** section, provide a name, a description, and owner information (your name or alias) for this target.
17. For **Target selection**, choose **Specify instance tags**.
18. For **Specify instance tags**, enter a tag key and a tag value to identify the nodes to register with the maintenance window, and then choose **Add**.
19. Choose **Register target**. The system creates a maintenance window target.
20. In the details page of the maintenance window you created, choose **Actions**, **Register Run command task**.
21. (Optional) For **Maintenance window task details**, provide a name and description for this task.
22. For **Command document**, choose `AWS-RunPatchBaseline`.
23. For **Task priority**, choose a priority. Zero (`0`) is the highest priority.
24. For **Targets**, under **Target by**, choose the maintenance window target you created earlier in this procedure.
25. For **Rate control**:

    - For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

      > **Note**
      >
      > If you selected targets by specifying tags applied to managed nodes or by specifying Amazon resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

    - For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

26. (Optional) For **IAM service role**, choose a role to provide permissions for Systems Manager to assume when running a maintenance window task.

If you don't specify a service role ARN, Systems Manager uses a service-linked role in your account. If no appropriate service-linked role for Systems Manager exists in your account, it's created when the task is registered successfully.

> **Note**
>
> For an improved security posture, we strongly recommend creating a custom policy and custom service role for running your maintenance window tasks. The policy can be crafted to provide only the permissions needed for your particular maintenance window tasks. For more information, see Setting up Maintenance Windows.

27. (Optional) For **Output options**, to save the command output to a file, select the **Enable writing output to S3** box. Enter the bucket and prefix (folder) names in the boxes.

> **Note**
>
> The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile assigned to the managed node, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different Amazon Web Services account, verify that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

To stream the output to an Amazon CloudWatch Logs log group, select the **CloudWatch output** box. Enter the log group name in the box.

28. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

29. For **Parameters**:

- For **Operation**, choose **Scan** to scan for missing patches, or choose **Install** to scan for and install missing patches.

- You don't need to enter anything in the **Snapshot Id** field. This system automatically generates and provides this parameter.
- You don't need to enter anything in the **Install Override List** field unless you want Patch Manager to use a different patch set than is specified for the patch baseline. For information, see Parameter name: `InstallOverrideList`.
- For **RebootOption**, specify whether you want nodes to reboot if patches are installed during the `Install` operation, or if Patch Manager detects other patches that were installed since the last node reboot. For information, see Parameter name: `RebootOption`.
- (Optional) For **Comment**, enter a tracking note or reminder about this command.
- For **Timeout (seconds)**, enter the number of seconds the system should wait for the operation to finish before it is considered unsuccessful.

30. Choose **Register Run command task**.

After the maintenance window task is complete, you can view patch compliance details in the Systems Manager console in the Fleet Manager tool.

You can also view compliance information in the Patch Manager tool, on the **Compliance reporting** tab.

You can also use the DescribePatchGroupState and DescribeInstancePatchStatesForPatchGroup APIs to view compliance details. For information about patch compliance data, see About patch compliance.

Patching schedules using maintenance windows

After you configure a patch baseline (and optionally a patch group), you can apply patches to your node by using a maintenance window. A maintenance window can reduce the impact on server availability by letting you specify a time to perform the patching process that doesn't interrupt business operations. A maintenance window works like this:

1. Create a maintenance window with a schedule for your patching operations.
2. Choose the targets for the maintenance window by specifying the `Patch Group` or `PatchGroup` tag for the tag name, and any value for which you have defined Amazon Elastic Compute Cloud (Amazon EC2) tags, for example, "web servers" or "US-EAST-PROD. (You must use `PatchGroup`, without a space, if you have allowed tags in EC2 instance metadata.
3. Create a new maintenance window task, and specify the `AWS-RunPatchBaseline` document.

When you configure the task, you can choose to either scan nodes or scan and install patches on the nodes. If you choose to scan nodes, Patch Manager, a tool in Amazon Systems Manager, scans each node and generates a list of missing patches for you to review.

If you choose to scan and install patches, Patch Manager scans each node and compares the list of installed patches against the list of approved patches in the baseline. Patch Manager identifies missing patches, and then downloads and installs all missing and approved patches.

If you want to perform a one-time scan or install to fix an issue, you can use Run Command to call the `AWS-RunPatchBaseline` document directly.

> **Important**
>
> After installing patches, Systems Manager reboots each node. The reboot is required to ensure patches are installed correctly and to make sure that the system didn't leave the node in a potentially bad state. (Exception: If the `RebootOption` parameter is set to `NoReboot` in the `AWS-RunPatchBaseline` document, the managed node isn't rebooted after Patch Manager runs. For more information, see Parameter name: `RebootOption`.)

Using pseudo parameters when registering maintenance window tasks

When you register a task in Maintenance Windows, you specify the parameters that are unique to each of the four task types. (In CLI commands, these are provided using the `--task-invocation-parameters` option.)

You can also reference certain values using *pseudo parameter* syntax, such as `{{RESOURCE_ID}}`, `{{TARGET_TYPE}}`, and `{{WINDOW_TARGET_ID}}`. When the maintenance window task runs, it passes the correct values instead of the pseudo parameter placeholders. The full list of pseudo parameters you can use is provided later in this topic in Supported pseudo parameters.

> **Important**
>
> For the target type `RESOURCE_GROUP`, depending on the ID format needed for the task, you can choose between using `{{TARGET_ID}}` and `{{RESOURCE_ID}}` to reference the resource when your task runs. `{{TARGET_ID}}` returns the full ARN of the resource. `{{RESOURCE_ID}}` returns only a shorter name or ID of the resource, as shown in these examples.

- {{TARGET_ID}} format: arn:aws:ec2:us-east-1:123456789012:instance/i-02573cafcfEXAMPLE
- {{RESOURCE_ID}} format: i-02573cafcfEXAMPLE

For target type INSTANCE, both the {{TARGET_ID}} and {{RESOURCE_ID}} parameters yield the instance ID only. For more information, see Supported pseudo parameters. {{TARGET_ID}} and {{RESOURCE_ID}} can be used to pass IDs of Amazon resources only to Automation, Lambda, and Step Functions tasks. These two pseudo parameters can't be used with Run Command tasks.

Pseudo parameter examples

Suppose that your payload for an Amazon Lambda task needs to reference an instance by its ID.

Whether you're using an INSTANCE or a RESOURCE_GROUP maintenance window target, this can be achieved by using the {{RESOURCE_ID}} pseudo parameter. For example:

```
"TaskArn": "arn:aws:lambda:us-east-2:111122223333:function:SSMTestFunction",
    "TaskType": "LAMBDA",
    "TaskInvocationParameters": {
        "Lambda": {
            "ClientContext": "ew0KICAi--truncated--0KIEXAMPLE",
            "Payload": "{ \"instanceId\": \"{{RESOURCE_ID}}\" }",
            "Qualifier": "$LATEST"
        }
    }
```

If your Lambda task is intended to run against another supported target type in addition to Amazon Elastic Compute Cloud (Amazon EC2) instances, such as an Amazon DynamoDB table, the same syntax can be used, and {{RESOURCE_ID}} yields the name of the table only. However, if you require the full ARN of the table, use {{TARGET_ID}}, as shown in the following example.

```
"TaskArn": "arn:aws:lambda:us-east-2:111122223333:function:SSMTestFunction",
    "TaskType": "LAMBDA",
    "TaskInvocationParameters": {
        "Lambda": {
            "ClientContext": "ew0KICAi--truncated--0KIEXAMPLE",
```

```
            "Payload": "{ \"tableArn\": \"{{TARGET_ID}}\" }",
            "Qualifier": "$LATEST"
        }
    }
```

The same syntax works for targeting instances or other resource types. When multiple resource types have been added to a resource group, the task runs against each of the appropriate resources.

> **Important**
>
> Not all resource types that might be included in a resource group yield a value for the `{{RESOURCE_ID}}` parameter. For a list of supported resource types, see Supported pseudo parameters.

As another example, to run an Automation task that stops your EC2 instances, you specify the `AWS-StopEC2Instance` Systems Manager document (SSM document) as the `TaskArn` value and use the `{{RESOURCE_ID}}` pseudo parameter:

```
"TaskArn": "AWS-StopEC2Instance",
    "TaskType": "AUTOMATION"
    "TaskInvocationParameters": {
        "Automation": {
            "DocumentVersion": "1",
            "Parameters": {
                "instanceId": [
                    "{{RESOURCE_ID}}"
                ]
            }
        }
    }
```

To run an Automation task that copies a snapshot of an Amazon Elastic Block Store (Amazon EBS) volume, you specify the `AWS-CopySnapshot` SSM document as the `TaskArn` value and use the `{{RESOURCE_ID}}` pseudo parameter.

```
"TaskArn": "AWS-CopySnapshot",
    "TaskType": "AUTOMATION"
    "TaskInvocationParameters": {
```

```
        "Automation": {
            "DocumentVersion": "1",
            "Parameters": {
                "SourceRegion": "us-east-2",
                "targetType":"RESOURCE_GROUP",
                "SnapshotId": [
                    "{{RESOURCE_ID}}"
                ]
            }
        }
    }
```

Supported pseudo parameters

The following list describes the pseudo parameters that you can specify using the {{*PSEUDO_PARAMETER*}} syntax in the `--task-invocation-parameters` option.

- **`WINDOW_ID`**: The ID of the target maintenance window.
- **`WINDOW_TASK_ID`**: The ID of the window task that is running.
- **`WINDOW_TARGET_ID`**: The ID of the window target that includes the target (target ID).
- **`WINDOW_EXECUTION_ID`**: The ID of the current window execution.
- **`TASK_EXECUTION_ID`**: The ID of the current task execution.
- **`INVOCATION_ID`**: The ID of the current invocation.
- **`TARGET_TYPE`**: The type of target. Supported types include `RESOURCE_GROUP` and `INSTANCE`.
- **`TARGET_ID`**:

  If the target type you specify is `INSTANCE`, the `TARGET_ID` pseudo parameter is replaced by the ID of the instance. For example, `i-078a280217EXAMPLE`.

  If the target type you specify is `RESOURCE_GROUP`, the value referenced for the task execution is the full ARN of the resource. For example: `arn:aws:ec2:us-east-1:123456789012:instance/i-078a280217EXAMPLE`. The following table provides sample `TARGET_ID` values for particular resource types in a resource group.

  > **Note**
  >
  > `TARGET_ID` isn't supported for Run Command tasks.

Resource type	Example TARGET_ID	
AWS::CloudWatch::Alarm	arn:aws:cloudwatch:us-east-1:123456789012:alarm:MyCloudWatchAlarm i-078a280217EXAMPLE	
AWS::DynamoDB::Table	arn:aws:dynamodb:us-east-1:123456789012:table/MyTable	
AWS::EC2::Instance	arn:aws:ec2:us-east-1:123456789012:instance/ i-078a280217EXAMPLE	
AWS::EC2::Image	arn:aws:ec2:us-east-1:123456789012:image/ami-02250b3732EXAMPLE	
AWS::EC2::SecurityGroup	arn:aws:ec2:us-east-1:123456789012:security-group/sg-cEXAMPLE	
AWS::EC2::Snapshot	arn:aws:ec2:us-east-1:123456789012:snapshot/snap-03866bf003EXAMPLE	
AWS::EC2::Volume	arn:aws:ec2:us-east-1:123456789012:volume/vol-0912e04d78EXAMPLE	

Resource type	Example TARGET_ID
AWS::ECS::Service	arn:aws:ecs:us-east-1:123456789012:service/my-ecs-service
AWS::RDS::DBCluster	arn:aws:rds:us-east-2:123456789012:cluster:My-Cluster
AWS::RDS::DBInstance	arn:aws:rds:us-east-1:123456789012:db:My-SQL-Instance
AWS::S3::Bucket	arn:aws:s3:::amzn-s3-demo-bucket
AWS::SSM::ManagedInstance	arn:aws:ssm:us-east-1:123456789012:managed-instance/mi-0feadcf2d9EXAMPLE

- **RESOURCE_ID**: The short ID of a resource type contained in a resource group. The following table provides sample RESOURCE_ID values for particular resource types in a resource group.

> **Note**
>
> RESOURCE_ID isn't supported for Run Command tasks.

Resource type	Example RESOURCE_ID
AWS::CloudWatch::Alarm	MyCloudWatchAlarm
AWS::DynamoDB::Table	MyTable

Resource type	Example RESOURCE_ID	
AWS::EC2::Instance	i-078a280217EXAMPLE	
AWS::EC2::Image	ami-02250b3732EXAMPLE	
AWS::EC2::SecurityGroup	sg-cEXAMPLE	
AWS::EC2::Snapshot	snap-03866bf003EXAMPLE	
AWS::EC2::Volume	vol-0912e04d78EXAMPLE	
AWS::ECS::Service	my-ecs-service	
AWS::RDS::DBCluster	My-Cluster	
AWS::RDS::DBInstance	My-SQL-Instance	
AWS::S3::Bucket	amzn-s3-demo-bucket	
AWS::SSM::ManagedInstance	mi-0feadcf2d9EXAMPLE	

Note

If the Amazon resource group you specify includes resource types that don't yield a RESOURCE_ID value, and aren't listed in the preceding table, then the RESOURCE_ID parameter isn't populated. An execution invocation will still occur for that resource. In these cases, use the TARGET_ID pseudo parameter instead, which will be replaced with the full ARN of the resource.

Maintenance window scheduling and active period options

When you create a maintenance window, you must specify how often the maintenance window runs by using a Cron or rate expression. Optionally, you can specify a date range during which the maintenance window can run on its regular schedule and a time zone on which to base that regular schedule.

Be aware, however, that the time zone option and the start date and end date options don't influence each other. Any start date and end date times that you specify (with or without an offset for your time zone) determine only the *valid period* during which the maintenance window can run on its schedule. A time zone option determines the international time zone that the maintenance window schedule is based on *during* its valid period.

> **Note**
>
> You specify start and end dates in ISO-8601 timestamp format. For example: `2021-04-07T14:29:00-08:00`
> You specify time zones in Internet Assigned Numbers Authority (IANA) format. For example: `America/Chicago`, `Europe/Berlin` or `Asia/Tokyo`

Examples

- Example 1: Specify a maintenance window start date
- Example 2: Specify a maintenance window start date and end date
- Example 3: Create a maintenance window that runs only once
- Example 4: Specify the number of schedule offset days for a maintenance window

Example 1: Specify a maintenance window start date

Say that you use the Amazon Command Line Interface (Amazon CLI) to create a maintenance window with the following options:

- `--start-date 2021-01-01T00:00:00-08:00`
- `--schedule-timezone "America/Los_Angeles"`
- `--schedule "cron(0 09 ? * WED *)"`

For example:

Linux & macOS

```
aws ssm create-maintenance-window \
    --name "My-LAX-Maintenance-Window" \
    --allow-unassociated-targets \
    --duration 3 \
    --cutoff 1 \
    --start-date 2021-01-01T00:00:00-08:00 \
    --schedule-timezone "America/Los_Angeles" \
    --schedule "cron(0 09 ? * WED *)"
```

Windows

```
aws ssm create-maintenance-window ^
    --name "My-LAX-Maintenance-Window" ^
    --allow-unassociated-targets ^
    --duration 3 ^
    --cutoff 1 ^
    --start-date 2021-01-01T00:00:00-08:00 ^
    --schedule-timezone "America/Los_Angeles" ^
    --schedule "cron(0 09 ? * WED *)"
```

This means that the first run of the maintenance window won't occur until *after* its specified start date and time, which is at 12:00 AM US Pacific Time on Friday, January 1, 2021. (This time zone is eight hours behind UTC time.) In this case, the start date and time of the window period don't represent when the maintenance windows first runs. Taken together, the `--schedule-timezone` and `--schedule` values mean that the maintenance window runs at 9 AM every Wednesday in the US Pacific Time Zone (represented by "America/Los Angeles" in IANA format). The first execution in the allowed period will be on Wednesday, January 4, 2021, at 9 AM US Pacific Time.

Example 2: Specify a maintenance window start date and end date

Suppose that next you create a maintenance window with these options:

- `--start-date 2019-01-01T00:03:15+09:00`
- `--end-date 2019-06-30T00:06:15+09:00`
- `--schedule-timezone "Asia/Tokyo"`
- `--schedule "rate(7 days)"`

For example:

Linux & macOS

```
aws ssm create-maintenance-window \
    --name "My-NRT-Maintenance-Window" \
    --allow-unassociated-targets \
    --duration 3 \
    --cutoff 1 \
    --start-date 2019-01-01T00:03:15+09:00 \
    --end-date 2019-06-30T00:06:15+09:00 \
    --schedule-timezone "Asia/Tokyo" \
    --schedule "rate(7 days)"
```

Windows

```
aws ssm create-maintenance-window ^
    --name "My-NRT-Maintenance-Window" ^
    --allow-unassociated-targets ^
    --duration 3 ^
    --cutoff 1 ^
    --start-date 2019-01-01T00:03:15+09:00 ^
    --end-date 2019-06-30T00:06:15+09:00 ^
    --schedule-timezone "Asia/Tokyo" ^
    --schedule "rate(7 days)"
```

The allowed period for this maintenance window begins at 3:15 AM Japan Standard Time on January 1, 2019. The valid period for this maintenance window ends at 6:15 AM Japan Standard Time on Sunday, June 30, 2019. (This time zone is nine hours ahead of UTC time.) Taken together, the `--schedule-timezone` and `--schedule` values mean that the maintenance window runs at 3:15 AM every Tuesday in the Japan Standard Time Zone (represented by "Asia/Tokyo" in IANA format). This is because the maintenance window runs every seven days, and it becomes active at 3:15 AM on Tuesday, January 1. The last execution is at 3:15 AM Japan Standard Time on Tuesday, June 25, 2019. This is the last Tuesday before the allowed maintenance window period ends five days later.

Example 3: Create a maintenance window that runs only once

Now you create a maintenance window with this option:

- `--schedule "at(2020-07-07T15:55:00)"`

For example:

Linux & macOS

```
aws ssm create-maintenance-window \
    --name "My-One-Time-Maintenance-Window" \
    --schedule "at(2020-07-07T15:55:00)" \
    --duration 5 \
    --cutoff 2 \
    --allow-unassociated-targets
```

Windows

```
aws ssm create-maintenance-window ^
    --name "My-One-Time-Maintenance-Window" ^
    --schedule "at(2020-07-07T15:55:00)" ^
    --duration 5 ^
    --cutoff 2 ^
    --allow-unassociated-targets
```

This maintenance window runs just once, at 3:55 PM UTC time on July 7, 2020. The maintenance window is allowed to run up to five hours, as needed, but new tasks are prevented from starting two hours before the end of the maintenance window period.

Example 4: Specify the number of schedule offset days for a maintenance window

Now you create a maintenance window with this option:

```
--schedule-offset 2
```

For example:

Linux & macOS

```
aws ssm create-maintenance-window \
    --name "My-Cron-Offset-Maintenance-Window" \
    --schedule "cron(0 30 23 ? * TUE#3 *)" \
    --duration 4 \
    --cutoff 1 \
    --schedule-offset 2 \
    --allow-unassociated-targets
```

Windows

```
aws ssm create-maintenance-window ^
    --name "My-Cron-Offset-Maintenance-Window" ^
    --schedule "cron(0 30 23 ? * TUE#3 *)" ^
    --duration 4 ^
    --cutoff 1 ^
    --schedule-offset 2 ^
    --allow-unassociated-targets
```

A schedule offset is the number of days to wait after the date and time specified by a CRON expression before running the maintenance window.

In the preceding example, the CRON expression schedules a maintenance window to run the third Tuesday of every month at 11:30 PM:

```
--schedule "cron(0 30 23 ? * TUE#3 *)
```

However, including `--schedule-offset 2` means that the maintenance window won't run until 11:30 PM two days *after* the third Tuesday of each month.

Schedule offsets are supported for CRON expressions only.

- CreateMaintenanceWindow in the *Amazon Systems Manager API Reference*
- create-maintenance-window in the *Amazon Systems Manager section of the Amazon CLI Command Reference*
- Time Zone Database on the IANA website

Registering maintenance window tasks without targets

For each maintenance window you create, you can specify one or more tasks to perform when the maintenance window runs. In most cases, you must specify the resources, or targets, that the task is to run on. In some cases, however, you don't need to specify targets explicitly in the task.

One or more targets must be specified for maintenance window Systems Manager Run Command-type tasks. Depending on the nature of the task, targets are optional for other maintenance window task types (Systems Manager Automation, Amazon Lambda, and Amazon Step Functions).

For Lambda and Step Functions task types, whether a target is required depends on the content of the function or state machine you have created.

> **Note**
>
> When a task has registered targets, Automation, Amazon Lambda, and Amazon Step Functions tasks resolve the targets from resource groups and tags and send one invocation per resolved resource, which results in multiple task invocations. But say, for example, that you want only one invocation for a Lambda task that's registered with a resource group containing more than one instance. In this case, if you are working in the Amazon Web Services Management Console, choose the option **Task target not required** in the **Register Lambda task** or **Edit Lambda task** page. If you are using the Amazon CLI command, do not specify targets using the `--targets` parameter when running the register-task-with-maintenance-window command or update-maintenance-window-task command.

In many cases, you don't need to explicitly specify a target for an automation task. For example, say that you're creating an Automation-type task to update an Amazon Machine Image (AMI) for Linux using the `AWS-UpdateLinuxAmi` runbook. When the task runs, the AMI is updated with the latest available Linux distribution packages and Amazon software. New instances created from the AMI already have these updates installed. Because the ID of the AMI to be updated is specified in the input parameters for the runbook, there is no need to specify a target again in the maintenance window task.

Similarly, suppose you're using the Amazon Command Line Interface (Amazon CLI) to register a maintenance window Automation task that uses the `Amazon-RestartEC2Instance` runbook. Because the node to restart is specified in the `--task-invocation-parameters` argument, you don't need to also specify a `--targets` option.

> **Note**
>
> For maintenance window tasks without a target specified, you can't supply values for `--max-errors` and `--max-concurrency`. Instead, the system inserts a placeholder value of 1, which might be reported in the response to commands such as describe-maintenance-

window-tasks and get-maintenance-window-task. These values don't affect the running of your task and can be ignored.

The following example demonstrates omitting the `--targets`, `--max-errors`, and `--max-concurrency` options for a targetless maintenance window task.

Linux & macOS

```
aws ssm register-task-with-maintenance-window \
    --window-id "mw-ab12cd34eEXAMPLE" \
    --service-role-arn "arn:aws-cn:iam::123456789012:role/
MaintenanceWindowAndAutomationRole" \
    --task-type "AUTOMATION" \
    --name "RestartInstanceWithoutTarget" \
    --task-arn "AWS-RestartEC2Instance" \
    --task-invocation-parameters "{\"Automation\":{\"Parameters\":{\"InstanceId\":
[\"i-02573cafcfEXAMPLE\"]}}}" \
    --priority 10
```

Windows

```
aws ssm register-task-with-maintenance-window ^
    --window-id "mw-ab12cd34eEXAMPLE" ^
    --service-role-arn "arn:aws-cn:iam::123456789012:role/
MaintenanceWindowAndAutomationRole" ^
    --task-type "AUTOMATION" ^
    --name "RestartInstanceWithoutTarget" ^
    --task-arn "AWS-RestartEC2Instance" ^
    --task-invocation-parameters "{\"Automation\":{\"Parameters\":{\"InstanceId\":
[\"i-02573cafcfEXAMPLE\"]}}}" ^
    --priority 10
```

Note

For maintenance window tasks registered before December 23, 2020: If you specified targets for the task and one is no longer required, you can update that task to remove the targets using the Systems Manager console or the update-maintenance-window-task Amazon CLI command.

More info

- Error messages: "Maintenance window tasks without targets don't support MaxConcurrency values" and "Maintenance window tasks without targets don't support MaxErrors values"

Troubleshooting maintenance windows

Use the following information to help you troubleshoot problems with maintenance windows.

Topics

- Edit task error: On the page for editing a maintenance window task, the IAM role list returns an error message: "We couldn't find the IAM maintenance window role specified for this task. It might have been deleted, or it might not have been created yet."
- Not all maintenance window targets are updated
- Task fails with task invocation status: "The provided role does not contain the correct SSM permissions."
- Task fails with error message: "Step fails when it is validating and resolving the step inputs"
- Error messages: "Maintenance window tasks without targets don't support MaxConcurrency values" and "Maintenance window tasks without targets don't support MaxErrors values"

Edit task error: On the page for editing a maintenance window task, the IAM role list returns an error message: "We couldn't find the IAM maintenance window role specified for this task. It might have been deleted, or it might not have been created yet."

Problem 1: The Amazon Identity and Access Management (IAM) maintenance window role you originally specified was deleted after you created the task.

Possible fix: 1) Select a different IAM maintenance window role, if one exists in your account, or create a new one and select it for the task.

Problem 2: If the task was created using the Amazon Command Line Interface (Amazon CLI), Amazon Tools for Windows PowerShell, or an Amazon SDK, a non-existent IAM maintenance window role name could have been specified. For example, the IAM maintenance window role could have been deleted before you created the task, or the role name could have been typed incorrectly, such as **`myrole`** instead of **`my-role`**.

Possible fix: Select the correct name of the IAM maintenance window role you want to use, or create a new one to specify for the task.

Not all maintenance window targets are updated

Problem: You notice that maintenance window tasks didn't run on all the resources targeted by your maintenance window. For example, in the maintenance window run results, the task for that resource is marked as failed or timed out.

Solution: The most common reasons for a maintenance window task not running on a target resource involve connectivity and availability. For example:

- Systems Manager lost connection to the resource before or during the maintenance window operation.
- The resource was offline or stopped during the maintenance window operation.

You can wait for the next scheduled maintenance window time to run tasks on the resources. You can manually run the maintenance window tasks on the resources that weren't available or were offline.

Task fails with task invocation status: "The provided role does not contain the correct SSM permissions."

Problem: You have specified a maintenance window service role for a task, but the task fails to run successfully and the task invocation status reports that "The provided role does not contain the correct SSM permissions."

- **Solution**: In Task 1: Create a custom policy for your maintenance window service role using the console, we provide a basic policy you can attach to your custom maintenance window service role. The policy includes the permissions needed for many task scenarios. However, due to the wide variety of tasks you can run, you might need to provide additional permissions in the policy for your maintenance window role.

  For example, some Automation actions work with Amazon CloudFormation stacks. Therefore, you might need to add the additional permissions `cloudformation:CreateStack`, `cloudformation:DescribeStacks`, and `cloudformation:DeleteStack` to the policy for your maintenance window service role.

  For another example, the Automation runbook `AWS-CopySnapshot` requires permissions to create an Amazon Elastic Block Store (Amazon EBS) snapshot. Therefore, you might need to add the permission `ec2:CreateSnapshot`.

For information about the role permissions needed by an Amazon managed Automation runbook, see the runbook descriptions in the Amazon Systems Manager Automation Runbook Reference.

For information about the role permissions needed by an Amazon managed SSM document, review the content of the document in the Documents section Systems Manager console.

For information about the role permissions needed for Step Functions tasks, Lambda tasks, and custom Automation runbooks and SSM documents, verify permission requirements with the author of those resources.

Task fails with error message: "Step fails when it is validating and resolving the step inputs"

Problem: An Automation runbook or Systems Manager Command document you're using in a task requires that you specify inputs such as `InstanceId` or `SnapshotId`, but a value isn't supplied or isn't supplied correctly.

- **Solution 1**: If your task is targeting a single resource, such as a single node or single snapshot, enter its ID in the input parameters for the task.
- **Solution 2**: If your task is targeting multiple resources, such as creating images from multiple nodes when you use the runbook `AWS-CreateImage`, you can use one of the pseudo parameters supported for maintenance window tasks in the input parameters to represent node IDs in the command.

  The following commands register a Systems Manager Automation task with a maintenance window using the Amazon CLI. The `--targets` value indicates a maintenance window target ID. Also, even though the `--targets` parameter specifies a window target ID, parameters of the Automation runbook require that a node ID be provided. In this case, the command uses the pseudo parameter `{{RESOURCE_ID}}` as the `InstanceId` value.

  Amazon CLI command:

  Linux & macOS

  The following example command restarts Amazon Elastic Compute Cloud (Amazon EC2) instances that belong to the maintenance window target group with the ID e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE.

  ```
  aws ssm register-task-with-maintenance-window \
  ```

```
    --window-id "mw-0c50858d01EXAMPLE" \
    --targets Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE \
    --task-arn "AWS-RestartEC2Instance" \
    --service-role-arn arn:aws-cn:iam::123456789012:role/
MyMaintenanceWindowServiceRole \
    --task-type AUTOMATION \
    --task-invocation-parameters
 "Automation={DocumentVersion=5,Parameters={InstanceId='{{RESOURCE_ID}}'}}" \
    --priority 0 --max-concurrency 10 --max-errors 5 --name "My-Restart-EC2-
Instances-Automation-Task" \
    --description "Automation task to restart EC2 instances"
```

Windows

```
aws ssm register-task-with-maintenance-window ^
    --window-id "mw-0c50858d01EXAMPLE" ^
    --targets Key=WindowTargetIds,Values=e32eecb2-646c-4f4b-8ed1-205fbEXAMPLE ^
    --task-arn "AWS-RestartEC2Instance" ^
    --service-role-arn arn:aws-cn:iam::123456789012:role/
MyMaintenanceWindowServiceRole ^
    --task-type AUTOMATION ^
    --task-invocation-parameters
 "Automation={DocumentVersion=5,Parameters={InstanceId='{{RESOURCE_ID}}'}}" ^
    --priority 0 --max-concurrency 10 --max-errors 5 --name "My-Restart-EC2-
Instances-Automation-Task" ^
    --description "Automation task to restart EC2 instances"
```

For more information about working with pseudo parameters for maintenance window tasks, see Using pseudo parameters when registering maintenance window tasks and Task registration examples.

Error messages: "Maintenance window tasks without targets don't support MaxConcurrency values" and "Maintenance window tasks without targets don't support MaxErrors values"

Problem: When you register a Run Command-type task, you must specify at least one target for the task to run on. For other task types (Automation, Amazon Lambda, and Amazon Step Functions), depending on the nature of the task, targets are optional. The options `MaxConcurrency` (the number of resources to run a task on at the same time) and `MaxErrors` (the number of failures to run the task on target resources before the task fails) aren't required or

supported for maintenance window tasks that don't specify targets. The system generates these error messages if values are specified for either of these options when no task target is specified.

Solution: If you receive either of these errors, remove the values for concurrency and error threshold before continuing to register or update the maintenance window task.

For more information about running tasks that don't specify targets, see Registering maintenance window tasks without targets in the *Amazon Systems Manager User Guide*.

Amazon Systems Manager Quick Setup

Use Quick Setup to quickly configure frequently used Amazon Web Services services and features with recommended best practices. Quick Setup simplifies setting up services, including Systems Manager, by automating common or recommended tasks. These tasks include, for example, creating required Amazon Identity and Access Management (IAM) instance profile roles and setting up operational best practices, such as periodic patch scans and inventory collection. There is no cost to use Quick Setup. However, costs can be incurred based on the type of services you set up and the usage limits with no fees for the services used to set up your service. To get started with Quick Setup, open the Systems Manager console. In the navigation pane, choose **Quick Setup**.

This section includes the following topics.

- Deregister a delegated administrator for Quick Setup
- Troubleshooting Quick Setup results
- Using a delegated administrator for Quick Setup
- Configuration for Assume Role for Systems Manager
- Register a delegated administrator for Quick Setup
- Using the Quick Setup API to manage configurations and deployments
- Getting started with Quick Setup
- Learn Quick Setup terminology and details
- Supported Quick Setup configuration types

> **Note**
>
> If you were directed to Quick Setup to help you configure your instances to be managed by Systems Manager, complete the procedure in Set up Amazon EC2 host management using Quick Setup.

What are the benefits of Quick Setup?

Benefits of Quick Setup include the following:

- **Simplify service and feature configuration**

  Quick Setup walks you through configuring operational best practices and automatically deploys those configurations. The Quick Setup dashboard displays a real-time view of your configuration deployment status.

- **Deploy configurations automatically across multiple accounts**

  You can use Quick Setup in an individual Amazon Web Services account or across multiple Amazon Web Services accounts and Amazon Web Services Regions by integrating with Amazon Organizations. Using Quick Setup across multiple accounts helps to make sure that your organization maintains consistent configurations.

- **Eliminate configuration drift**

  Configuration drift occurs whenever a user makes any change to a service or feature that conflicts with the selections made through Quick Setup. Quick Setup periodically checks for configuration drift and attempts to remediate it.

Who should use Quick Setup?

Quick Setup is most beneficial for customers who already have some experience with the services and features they're setting up, and want to simplify their setup process. If you're unfamiliar with the Amazon Web Services service you're configuring with Quick Setup, we recommend that you learn more about the service. Review the content in the relevant User Guide before you create a configuration with Quick Setup.

Availability of Quick Setup in Amazon Web Services Regions

In the following Amazon Web Services Regions, you can use all Quick Setup configuration types for an entire organization, as configured in Amazon Organizations, or for only the organizational accounts and Regions you choose. You can also use Quick Setup with just a single account in these Regions.

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Stockholm)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- South America (São Paulo)

In the following Regions, only the Host Management configuration type is available for individual accounts:

- Europe (Milan)
- Asia Pacific (Hong Kong)
- Middle East (Bahrain)
- China (Beijing)
- China (Ningxia)
- Amazon GovCloud (US-East)

- Amazon GovCloud (US-West)

For a list of all supported Regions for Systems Manager, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

Getting started with Quick Setup

Use the information in this topic to help you prepare to use Quick Setup.

IAM roles and permissions for Quick Setup onboarding

Quick Setup launched a new console experience and a new API. Now you can interact with this API using the console, Amazon CLI, Amazon CloudFormation, and SDKs. If you opt in to the new experience, your existing configurations are recreated using the new API. Depending on the number of existing configurations in your account, this process can take several minutes.

To use the new Quick Setup console, you must have permissions for the following actions:

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",

service-role/stacksets.cloudformation.amazonaws.com/
AWSServiceRoleForCloudFormationStackSetsOrgAdmin"
        }
    ]
}
```

To restrict users to read-only permissions, only allow `ssm-quicksetup:List*` and `ssm-quicksetup:Get*` operations for the Quick Setup API.

During onboarding, Quick Setup creates the following Amazon Identity and Access Management (IAM) roles on your behalf:

- `AWS-QuickSetup-LocalExecutionRole` – Grants Amazon CloudFormation permissions to use any template, excluding the patch policy template, and create the necessary resources.
- `AWS-QuickSetup-LocalAdministrationRole` – Grants permissions to Amazon CloudFormation to assume `AWS-QuickSetup-LocalExecutionRole`.
- `AWS-QuickSetup-PatchPolicy-LocalExecutionRole` – Grants permissions to Amazon CloudFormation to use the patch policy template, and create the necessary resources.
- `AWS-QuickSetup-PatchPolicy-LocalAdministrationRole` – Grants permissions to Amazon CloudFormation to assume `AWS-QuickSetup-PatchPolicy-LocalExecutionRole`.

If you're onboarding a management account—the account that you use to create an organization in Amazon Organizations—Quick Setup also creates the following roles on your behalf:

- `AWS-QuickSetup-SSM-RoleForEnablingExplorer` – Grants permissions to the `AWS-EnableExplorer` automation runbook. The `AWS-EnableExplorer` runbook configures Explorer, a tool in Systems Manager to display information for multiple Amazon Web Services accounts and Amazon Web Services Regions.
- `AWSServiceRoleForAmazonSSM` – A service-linked role that grants access to Amazon resources managed and used by Systems Manager.
- `AWSServiceRoleForAmazonSSM_AccountDiscovery` – A service-linked role that grants permissions to Systems Manager to call Amazon Web Services services to discover Amazon Web Services account information when synchronizing data. For more information, see Using roles to collect Amazon Web Services account information for OpsCenter and Explorer.

When onboarding a management account, Quick Setup enables trusted access between Amazon Organizations and CloudFormation to deploy Quick Setup configurations across your organization. To enable trusted access, your management account must have administrator permissions. After onboarding, you no longer need administrator permissions. For more information, see Enable trusted access with Organizations.

For information about Amazon Organizations account types, see Amazon Organizations terminology and concepts in the *Amazon Organizations User Guide*.

> **Note**
>
> Quick Setup uses Amazon CloudFormation StackSets to deploy your configurations across Amazon Web Services accounts and Regions. If the number of target accounts multiplied by the number of Regions exceeds 10,000, the configuration fails to deploy. We recommend reviewing your use case and creating configurations that use fewer targets to accommodate the growth of your organization. Stack instances aren't deployed to your organization's management account. For more information, see Considerations when creating a stack set with service-managed permissions.

Manual onboarding for working with Quick Setup API programmatically

If you use the console to work with Quick Setup, the service handles onboarding steps for you. If you plan to use SDKs or the Amazon CLI to work with the Quick Setup API, you can still use the console to complete onboarding steps for you so you don't have to perform them manually. However, some customers need to complete onboarding steps for Quick Setup programmatically

without interacting with the console. If this method fits your use case, you must complete the following steps. All of these steps must be completed from your Amazon Organizations management account.

To complete manual onboarding for Quick Setup

1. Activate trusted access for Amazon CloudFormation with Organizations. This provides the management account with the permissions needed to create and manage StackSets for your organization. You can use Amazon CloudFormation's `ActivateOrganizationsAccess` API action to complete this step. For more information, see ActivateOrganizationsAccess in the *Amazon CloudFormation API Reference*.
2. Enable the integration of Systems Manager with Organizations. This allows Systems Manager to create a service-linked role in all the accounts in your organization. This also allows Systems Manager to perform operations on your behalf in your organization and its accounts. You can use Amazon Organizations's `EnableAWSServiceAccess` API action to complete this step. The service principal for Systems Manager is `ssm.amazonaws.com`.For more information, see EnableAWSServiceAccess in the *Amazon Organizations API Reference*.
3. Create the required IAM role for Explorer. This allows Quick Setup to create dashboards for your configurations so you can view deployment and association statuses. Create an IAM role and attach the `AWSSystemsManagerEnableExplorerExecutionPolicy` managed policy. Modify the trust policy for the role to match the following. Replace each *`account ID`* with your information.

   JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333"
                },
                "ArnLike": {
```

```
                    "aws:SourceArn": "arn:*:ssm:*:111122223333:automation-
execution/*"
                }
            }
        }
    ]
}
```

4. Update the Quick Setup service setting for Explorer. You can use Quick Setup's `UpdateServiceSettings` API action to complete this step. Specify the ARN for the IAM role you created in the previous step for the `ExplorerEnablingRoleArn` request parameter. For more information, see UpdateServiceSettings in the *Quick Setup API Reference*.
5. Create the required IAM roles for Amazon CloudFormation StackSets to use. You must create an *execution* role and an *administration* role.

   a. Create the execution role. The execution role should have at least one of the `AWSQuickSetupDeploymentRolePolicy` or `AWSQuickSetupPatchPolicyDeploymentRolePolicy` managed policies attached. If you're only creating patch policy configurations, you can use `AWSQuickSetupPatchPolicyDeploymentRolePolicy` managed policy. All other configurations use the `AWSQuickSetupDeploymentRolePolicy` policy. Modify the trust policy for the role to match the following. Replace each *`account ID`* and *`administration role name`* with your information.

      JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws-cn:iam::111122223333:role/administration
 role name"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

b. Create the administration role. The permissions policy must match the following. Replace each *account ID* and *execution role name* with your information.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Action": [
                "sts:AssumeRole"
            ],
            "Resource": "arn:*:iam::111122223333:role/execution role
 name",
            "Effect": "Allow"
        }
    ]
}
```

Modify the trust policy for the role to match the following. Replace each *account ID* with your information.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "cloudformation.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "111122223333"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws-
cn:cloudformation:*:111122223333:stackset/AWS-QuickSetup-*"
```

```
                }
            }
        }
    ]
}
```

Configuration for Assume Role for Systems Manager

To create an assume role for Systems Manager Quick Setup:

Systems Manager Quick Setup requires a role that allows Systems Manager to securely perform actions in your account. This role grants Systems Manager the permissions needed to run commands on your instances and configure EC2 instances, IAM roles, and other Systems Manager resources on your behalf.

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose **Policies**, and then **Create Policy**
3. Add the `SsmOnboardingInlinePolicy` policy using the JSON below. This policy enables actions required to attach instance profile permissions to instances you specify. For example, it lets you create instance profiles and associate them with EC2 instances.
4. After completing this step, in the navigation pane, choose **Roles**, and then choose **Create role**.
5. For **Trusted entity type**, keep it as default (service).
6. Under **Use case**, choose **Systems Manager**, then choose **Next**.
7. On the **Add permissions** page:
8. Add the `SsmOnboardingInlinePolicy` policy
9. Choose **Next**
10. For **Role name**, enter a descriptive name (for example, `AmazonSSMRoleForAutomationAssumeQuickSetup`).
11. (Optional) Add tags to help identify and organize the role.
12. Choose **Create role**.

> **Important**
>
> The role must include a trust relationship with `ssm.amazonaws.com`. This is automatically configured when you select Systems Manager as the service in step 4.

After creating the role, you can select it when configuring Quick Setup. The role enables Systems Manager to manage EC2 instances, IAM roles, and other Systems Manager resources and run commands on your behalf while maintaining security through specific, limited permissions.

Permissions Policies

`SsmOnboardingInlinePolicy`

The following policy defines the permissions for Systems Manager Quick Setup:

```
{
    "Version": "2012-10-17"        ,
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:CreateInstanceProfile",
                "iam:ListInstanceProfilesForRole",
                "ec2:DescribeIamInstanceProfileAssociations",
                "iam:GetInstanceProfile",
                "iam:AddRoleToInstanceProfile"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:AssociateIamInstanceProfile"
            ],
            "Resource": "arn:aws:ec2:*:*:instance/*",
            "Condition": {
                "Null": {
                    "ec2:InstanceProfile": "true"
                },
                "ArnLike": {
                    "ec2:NewInstanceProfile": "arn:aws:iam::*:instance-profile/
[INSTANCE_PROFILE_ROLE_NAME]"
```

```
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": "arn:aws:iam::*:role/[INSTANCE_PROFILE_ROLE_NAME]",
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": "ec2.amazonaws.com"
                }
            }
        }
    ]
        }
```

Trust Relationship

This is added automatically through the preceding steps

```
{
    "Version": "2012-10-17"        ,
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
     ]
        }
```

Using a delegated administrator for Quick Setup

After you register a delegated administrator account for Quick Setup, users with the appropriate permissions in that account can create, update, view, and delete configuration managers that target organizational units within your Amazon Organizations structure. This delegated administrator account can also manage configuration managers previously created by your organization's management account.

The management account in Organizations can designate one account within your organization as a delegated administrator. When you register an account as a delegated administrator for Quick Setup, this account also becomes a delegated administrator for Amazon CloudFormation StackSets and Systems Manager Explorer. These services are needed to deploy and monitor Quick Setup configurations.

> **Note**
>
> Currently, the patch policy configuration type isn't supported by the delegated administrator for Quick Setup. Patch policy configurations for an organization must be created and maintained in the management account for an organization. For more information, see Creating a patch policy.

The following topics describe how to register and deregister a delegated administrator for Quick Setup.

Register a delegated administrator for Quick Setup

Use the following procedure to register a delegated administrator for Quick Setup.

To register a Quick Setup delegated administrator

1. Log into your Amazon Organizations management account.
2. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
3. In the navigation pane, choose **Quick Setup**.
4. Choose **Settings**.
5. In the **Delegated administrator for Quick Setup** section, verify that you have configured the required service-linked role and service access options. If necessary, choose the **Create role** and **Enable access** buttons to configure these options.
6. For **Account ID**, enter the Amazon Web Services account ID. This account must be a member account in Amazon Organizations.
7. Choose **Register delegated administrator**.

Deregister a delegated administrator for Quick Setup

Use the following procedure to deregister a delegated administrator for Quick Setup.

To deregister a Quick Setup delegated administrator

1. Log into your Amazon Organizations management account.
2. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
3. In the navigation pane, choose **Quick Setup**.
4. Choose **Settings**.
5. In the **Delegated administrator for Quick Setup** section, choose **Deregister** from the **Actions** dropdown.
6. Select **Confirm**.

Learn Quick Setup terminology and details

Quick Setup displays the results of all configuration managers you've created across all Amazon Web Services Regions in the **Configuration managers** table on the Quick Setup home page. From this page, you can **View details** of each configuration, delete configurations from the **Actions** drop down, or **Create** configurations. The **Configuration managers** table contains the following information:

- **Name** – The name of the configuration manager if provided when created.
- **Configuration type** – The configuration type chosen when creating the configuration.
- **Version** – The version of the configuration type currently deployed.
- **Organizational units** – Displays the organizational units (OUs) that the configuration is deployed to if you chose a **Custom** set of targets. Organizational units and custom targets are only available to the management account of your organization. The management account is the account that you use to create an organization in Amazon Organizations.
- **Deployment type** – Indicates whether the deployment applies to the entire organization (`Organizational`) or only your account (`Local`).
- **Regions** – The Regions that the configuration is deployed to if you chose a **Custom** set of targets or targets within your **Current account**.
- **Deployment status** – The deployment status indicates if Amazon CloudFormation successfully deployed the target or stack instance. The target and stack instances contain the configuration options that you chose during configuration creation.

- **Association status** – The association status is the state of all associations created by the configuration that you created. The associations for all targets must run successfully; otherwise, the status is **Failed**.

  Quick Setup creates and runs a State Manager association for each configuration target. State Manager is a tool in Amazon Systems Manager.

To view configurations deployed to the Region you're currently browsing, select the **Configurations** tab.

Configuration details

The **Configuration details** page displays information about the deployment of the configuration and its related associations. From this page, you can edit configuration options, update targets, or delete the configuration. You can also view the details of each configuration deployment to get more information about the associations.

Depending on the type of configuration, one or more of the following status graphs are displayed:

Configuration deployment status

Displays the number of deployments that have succeeded, failed, or are running or pending. Deployments occur in the specified target accounts and Regions that contain nodes affected by the configuration.

Configuration association status

Displays the number of State Manager associations that have succeeded, failed, or are pending. Quick Setup creates an association in each deployment for the configuration options selected.

Setup status

Displays the number of actions performed by the configuration type and their current statuses.

Resource compliance

Displays the number of resources that are compliant to the configurations specified policy.

The **Configuration details** table displays information about the deployment of your configuration. You can view more details about each deployment by selecting the deployment and then choosing **View details**. The details page of each deployment displays the associations deployed to the nodes in that deployment.

Editing and deleting your configuration

You can edit configuration options of a configuration from the **Configuration details** page by choosing **Actions** and then **Edit configuration options**. When you add new options to the configuration, Quick Setup runs your deployments and creates new associations. When you remove options from a configuration, Quick Setup runs your deployments and removes any related associations.

> **Note**
>
> You can edit Quick Setup configurations for your account at anytime. To edit an **Organization** configuration, the **Configuration status** must be **Success** or **Failed**.

You can also update the targets included in your configurations by choosing **Actions** and **Add OUs**, **Add Regions**, **Remove OUs**, or **Remove Regions**. If your account isn't configured as the management account or you created the configuration for only the current account, you can't update the target organizational units (OUs). Removing a Region or OU removes the associations from those Regions or OUs.

Periodically, Quick Setup releases new versions of configurations. You can select the **Upgrade configuration** option to upgrade your configuration to the latest version.

You can delete a configuration from Quick Setup by choosing the configuration, then **Actions**, and then **Delete configuration**. Or, you can delete the configuration from the **Configuration details** page under the **Actions** dropdown and then **Delete configuration**. Quick Setup then prompts you to **Remove all OUs and Regions** which might take some time to complete. Deleting a configuration also deletes all related associations. This two-step deletion process removes all deployed resources from all accounts and Regions and then deletes the configuration.

Configuration compliance

You can view whether your instances are compliant with the associations created by your configurations in either Explorer or Compliance, which are both tools in Amazon Systems Manager. To learn more about compliance, see Learn details about Compliance. To learn more about viewing compliance in Explorer, see Amazon Systems Manager Explorer.

Using the Quick Setup API to manage configurations and deployments

You can use the API provided by Quick Setup to create and manage configurations and deployments using the Amazon CLI or your preferred SDK. You can also use Amazon CloudFormation to create a configuration manager resource that deploys configurations. Using the API, you create configuration managers that deploy configuration *definitions*. Configuration definitions contain all of the necessary information to deploy a particular configuration type. For more information about the Quick Setup API, see the Quick Setup API Reference.

The following examples demonstrate how to create configuration managers using the Amazon CLI and Amazon CloudFormation.

Amazon CLI

```
aws ssm-quicksetup create-configuration-manager \
--name configuration manager name \
--description Description of your configuration manager
--configuration-definitions JSON string containing configuration defintion
```

The following is an example JSON string containing a configuration definition for patch policy.

```
'{"Type":"AWSQuickSetupType-
PatchPolicy","LocalDeploymentAdministrationRoleArn":"arn:aws:iam::123456789012:role/

Supported Quick Setup configuration types

Supported configuration types

Quick Setup walks you through configuring operational best practices for several Systems Manager and other Amazon Web Services services, and automatically deploying those configurations. The Quick Setup dashboard displays a real-time view of your configuration deployment status.

You can use Quick Setup in an individual Amazon Web Services account or across multiple Amazon Web Services accounts and Regions by integrating with Amazon Organizations. Using Quick Setup across multiple accounts helps to make sure that your organization maintains consistent configurations.

Quick Setup provides support for the following configuration types.

- Set up Amazon EC2 host management using Quick Setup
- Set up the Default Host Management Configuration for an organization using Quick Setup
- Create an Amazon Config configuration recorder using Quick Setup
- Deploy Amazon Config conformance pack using Quick Setup
- Configure patching for instances in an organization using a Quick Setup patch policy
- Change Manager organization setup
- Set up DevOps Guru using Quick Setup
- Deploy Distributor packages using Quick Setup
- Stop and start EC2 instances automatically on a schedule using Quick Setup
- OpsCenter organization setup
- Configure Amazon Resource Explorer using Quick Setup

Set up Amazon EC2 host management using Quick Setup

Use Quick Setup to quickly configure required security roles and commonly used Systems Manager tools on your Amazon Elastic Compute Cloud (Amazon EC2) instances. You can use Quick Setup in an individual account or across multiple accounts and Amazon Web Services Regions by integrating

with Amazon Organizations. These tools help you manage and monitor the health of your instances while providing the minimum required permissions to get started.

If you're unfamiliar with Systems Manager services and features, we recommend that you review the *Amazon Systems Manager User Guide* before creating a configuration with Quick Setup. For more information about Systems Manager, see What is Amazon Systems Manager?.

Important

Quick Setup might not be the right tool to use for EC2 management if either of the following applies to you:

- You're trying to create an EC2 instance for the first time to try out Amazon capabilities.
- You're still new to EC2 instance management.

Instead, we recommend that you explore the following content:

- Getting Started with Amazon EC2
- Launch an instance using the new launch instance wizard in the *Amazon EC2 User Guide*
- Tutorial: Get started with Amazon EC2 Linux instances in the *Amazon EC2 User Guide*

If you're already familiar with EC2 instance management and want to streamline configuration and management for multiple EC2 instances, use Quick Setup. Whether your organization has dozens, thousands, or millions of EC2 instances, use the following Quick Setup procedure to configure multiple options for them, all at once.

Note

This configuration type lets you set multiple options for an entire organization defined in Amazon Organizations, only some organizational accounts and Regions, or a single account. One of these options is to check for and apply updates to SSM Agent every two weeks. If you are an organization administrator, you can also choose to update *all* EC2 instances in your organization with agent updates every two weeks using the Default Host Management Configuration type. For information, see Set up the Default Host Management Configuration for an organization using Quick Setup.

Configuring host management options for EC2 instances

To set up host management, perform the following tasks in the Amazon Systems Manager Quick Setup console.

To open the Host Management configuration page

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Host Management** card, choose **Create**.

> **Tip**
>
> If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

To configure Systems Manager host management options

- To configure Systems Manager functionality, in the **Configuration options** section, choose the options in the **Systems Manager** group that you want to enable for your configuration:

  Update Systems Manager (SSM) Agent every two weeks

  Enables Systems Manager to check every two weeks for a new version of the agent. If there is a new version, then Systems Manager automatically updates the agent on your managed node to the latest released version. Quick Setup doesn't install the agent on instances where it's not already present. For information about which AMIs have SSM Agent preinstalled, see Find AMIs with the SSM Agent preinstalled.

  We encourage you to choose this option to make sure that your nodes are always running the most up-to-date version of SSM Agent. For more information about SSM Agent, including information about how to manually install the agent, see Working with SSM Agent.

Collect inventory from your instances every 30 minutes

Enables Quick Setup to configure collection of the following types of metadata:

- **Amazon components** – EC2 driver, agents, versions, and more.
- **Applications** – Application names, publishers, versions, and more.
- **Node details** – System name, operating system (OS) name, OS version, last boot, DNS, domain, work group, OS architecture, and more.
- **Network configuration** – IP address, MAC address, DNS, gateway, subnet mask, and more.
- **Services** – Name, display name, status, dependent services, service type, start type, and more (Windows Server nodes only).
- **Windows roles** – Name, display name, path, feature type, installed state, and more (Windows Server nodes only).
- **Windows updates** – Hotfix ID, installed by, installed date, and more (Windows Server nodes only).

For more information about Inventory, see Amazon Systems Manager Inventory.

> **Note**
>
> The **Inventory collection** option can take up to 10 minutes to complete, even if you only selected a few nodes.

Scan instances for missing patches daily

Enables Patch Manager to scan your nodes daily and generate a report in the **Compliance** page. The report shows how many nodes are patch-compliant according to the *default patch baseline*. The report includes a list of each node and its compliance status.

For information about patching operations and patch baselines, see Amazon Systems Manager Patch Manager.

For information about patch compliance, see the Systems Manager Compliance page.

For information about patching managed nodes in multiple accounts and Regions in one configuration, see Patch policy configurations in Quick Setup and Configure patching for instances in an organization using a Quick Setup patch policy.

> **Important**
>
> Systems Manager supports several methods for scanning managed nodes for patch compliance. If you implement more than one of these methods at a time, the patch compliance information you see is always the result of the most recent scan. Results from previous scans are overwritten. If the scanning methods use different patch baselines, with different approval rules, the patch compliance information can change unexpectedly. For more information, see Identifying the execution that created patch compliance data.

To configure Amazon CloudWatch host management options

- To configure CloudWatch functionality, in the **Configuration options** section, choose the options in the **Amazon CloudWatch** group that you want to enable for your configuration:

Install and configure the CloudWatch agent

Installs the basic configuration of the unified CloudWatch agent on your Amazon EC2 instances. The agent collects metrics and log files from your instances for Amazon CloudWatch. This information is consolidated so you can quickly determine the health of your instances. For more information about the CloudWatch agent basic configuration, see CloudWatch agent predefined metric sets. There might be added cost. For more information, see Amazon CloudWatch pricing.

Update the CloudWatch agent once every 30 days

Enables Systems Manager to check every 30 days for a new version of the CloudWatch agent. If there is a new version, Systems Manager updates the agent on your instance. We encourage you to choose this option to make sure that your instances are always running the most up-to-date version of the CloudWatch agent.

To configure Amazon EC2 Launch Agent host management options

- To configure Amazon EC2 Launch Agent functionality, in the **Configuration options** section, choose the options in the **Amazon EC2 Launch Agent** group that you want to enable for your configuration:

  Update the EC2 launch agent once every 30 days

  Enables Systems Manager to check every 30 days for a new version of the launch agent installed on your instance. If a new version is available, Systems Manager updates the agent on your instance. We encourage you to choose this option to make sure that your instances are always running the most up-to-date version of the applicable launch agent. For Amazon EC2 Windows instances, this option supports EC2Launch, EC2Launch v2, and EC2Config. For Amazon EC2 Linux instances, this option supports `cloud-init`. For Amazon EC2 Mac instances, this option supports `ec2-macos-init`. Quick Setup doesn't support updating launch agents that are installed on operating systems not supported by the launch agent, or on AL2023.

  For more information about these initialization agents see the following topics:

  - Configure a Windows instance using EC2Launch v2
  - Configure a Windows instance using EC2Launch
  - Configure a Windows instance using the EC2Config service
  - cloud-init Documentation
  - ec2-macos-init

To select the EC2 instances to be updated by the host management configuration

- In the **Targets** section, choose the method to determine the accounts and Regions where the configuration is to be deployed:

  > **Note**
  >
  > You can't create multiple Quick Setup Host Management configurations that target the same Amazon Web Services Region.

Entire organization

Your configuration is deployed to all organizational units (OUs) and Amazon Web Services Regions in your organization.

> **Note**
>
> The **Entire organization** option is only available if you're configuring host management from your organization's management account.

Custom

1. In the **Target OUs** section, select the OUs where you want to deploy this host management configuration.
2. In the **Target Regions** section, select the Regions where you want to deploy this host management configuration.

Current account

Choose one of the Region options and follow the steps for that option.

Current Region

Choose how to target instances in the current Region only:

- **All instances** – The host management configuration automatically targets every EC2 in the current Region.
- **Tag** – Choose **Add** and enter the key and optional value that is added to the instances to be targeted.
- **Resource group** – For **Resource group**, select an existing resource group that contains the EC2 instances to be targeted.
- **Manual** – In the **Instances** section, select the check box of each EC2 instance to be targeted.

Choose Regions

Choose how to target instances in the Region you specify by choosing one of the following:

- **All instances** – All instances in the Regions you specify are targeted.
- **Tag** – Choose **Add** and enter the key and optional value that has been added to the instances to be targeted.

In the **Target Regions** section, select the Regions where you want to deploy this host management configuration.

To specify an instance profile option

- ***Entire organization*** *and* ***Custom*** *targets only.*

  In the **Instance profile options** section, choose whether you want to add the required IAM policies to the existing instance profiles attached to your instances, or to allow Quick Setup to create the IAM policies and instance profiles with the permissions needed for the configuration you choose.

After specifying all your configuration choices, choose **Create**.

Set up the Default Host Management Configuration for an organization using Quick Setup

With Quick Setup, you can activate Default Host Management Configuration for all accounts and Regions that have been added to your organization in Amazon Organizations. This ensures that SSM Agent is kept up to date on all Amazon Elastic Compute Cloud (EC2) instances in the organization, and that they can connect to Systems Manager.

Before you begin

Make sure that the following requirements are met before enabling this setting.

- The latest version of SSM Agent is already installed on all EC2 instances to be managed in your organization.
- Your EC2 instances to be managed are using Instance Metadata Service Version 2 (IMDSv2).

- You are signed in to the management account for your organization, as specified in Amazon Organizations, using an Amazon Identity and Access Management (IAM) identity (user, role, or group) with administrator permissions.

Using the default EC2 instance management role

Default Host Management Configuration makes use of the `default-ec2-instance-management-role` service setting for Systems Manager. This is a role with permissions that you want made available to all accounts in your organization to allow communication between SSM Agent on the instance and the Systems Manager service in the cloud.

If you have already set this role using the update-service-setting CLI command, Default Host Management Configuration uses that role. If you have not set this role yet, Quick Setup will create and apply the role for you.

To check whether this role has already been specified for your organization, use the get-service-setting command.

Enable automatic updates of SSM Agent every two weeks

Use the following procedure to enable the Default Host Management Configuration option for your entire Amazon Organizations organization.

To enable automatic updates of SSM Agent every two weeks

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Default Host Management Configuration** card, choose **Create**.

   > **Tip**
   >
   > If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Configuration options** section, select **Enable automatic updates of SSM Agent every two weeks**.
5. Choose **Create**

Create an Amazon Config configuration recorder using Quick Setup

With Quick Setup, you can quickly create a configuration recorder powered by Amazon Config. Use the configuration recorder to detect changes in your resource configurations and capture the changes as configuration items. If you're unfamiliar with Amazon Config, we recommend learning more about the service by reviewing the content in the *Amazon Config Developer Guide* before creating a configuration with Quick Setup. For more information about Amazon Config, see What is Amazon Config? in the *Amazon Config Developer Guide*.

By default, the configuration recorder records all supported resources in the Amazon Web Services Region where Amazon Config is running. You can customize the configuration so that only the resource types you specify are recorded. For more information, see Selecting which resources Amazon Config records in the *Amazon Config Developer Guide*.

You're charged service usage fees when Amazon Config starts recording configurations. For pricing information, see Amazon Config pricing.

> **Note**
>
> If you've already created a configuration recorder, Quick Setup doesn't stop recording or make any changes to resource types that you're already recording. If you choose to record additional resource types using Quick Setup, the service appends them to your existing recorder groups. Deleting the Quick Setup **Config recording** configuration type doesn't stop the configuration recorder. Changes continue to be recorded, and service usage fees apply until you stop the configuration recorder. To learn more about managing the configuration recorder, see Managing the Configuration Recorder in the *Amazon Config Developer Guide*.

To set up Amazon Config recording, perform the following tasks in the Amazon Systems Manager console.

To set up Amazon Config recording with Quick Setup

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Config Recording** card, choose **Create**.

> **Tip**
>
> If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Configuration options** section, do the following:

   a. For **Choose the Amazon resource types to record**, specify whether to record all supported resources or only the resource types you choose.

   b. For **Delivery settings, specify whether to create a new Amazon Simple Storage Service (Amazon S3) bucket, or choose an existing bucket to send configuration snapshots to.**

   c. For **Notification options**, choose the notification option you prefer. Amazon Config uses Amazon Simple Notification Service (Amazon SNS) to notify you about important Amazon Config events related to your resources. If you choose the **Use existing SNS topics** option, you must provide the Amazon Web Services account ID and name of the existing Amazon SNS topic in that account you want to use. If you target multiple Amazon Web Services Regions, the topic names must be identical in each Region.

5. In the **Schedule** section, choose how frequently you want Quick Setup to remediate changes made to resources that differ from your configuration. The **Default** option runs once. If you don't want Quick Setup to remediate changes made to resources that differ from your configuration, choose **Disable remediation** under **Custom**.

6. In the **Targets** section, choose one of the following to identify the accounts and Regions for recording.

> **Note**
>
> If you are working in a single account, options for working with organizations and organizational units (OUs) are not available. You can choose whether to apply this configuration to all Amazon Web Services Regions in your account or only the Regions you select.

   - **Entire organization** – All accounts and Regions in your organization.
   - **Custom** – Only the OUs and Regions that you specify.
     - In the **Target OUs** section, select the OUs where you want to allow recording.

- In the **Target Regions** section, select the Regions where you want to allow recording.
- **Current account** – Only the Regions you specify in the account you are currently signed into are targeted. Choose one of the following:
  - **Current Region** – Only managed nodes in the Region selected in the console are targeted.
  - **Choose Regions** – Choose the individual Regions to apply the recording configuration to.

7. Choose **Create**.

Deploy Amazon Config conformance pack using Quick Setup

A conformance pack is a collection of Amazon Config rules and remediation actions. With Quick Setup, you can deploy a conformance pack as a single entity in an account and an Amazon Web Services Region or across an organization in Amazon Organizations. This helps you manage configuration compliance of your Amazon resources at scale, from policy definition to auditing and aggregated reporting, by using a common framework and packaging model.

To deploy conformance packs, perform the following tasks in the Amazon Systems Manager Quick Setup console.

> **Note**
>
> You must enable Amazon Config recording before deploying this configuration. For more information, see Conformance packs in the *Amazon Config Developer Guide*.

To deploy conformance packs with Quick Setup

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Conformance Packs** card, choose **Create**.

   > **Tip**
   >
   > If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Choose conformance packs** section, choose the conformance packs you want to deploy.

5. In the **Schedule** section, choose how frequently you want Quick Setup to remediate changes made to resources that differ from your configuration. The **Default** option runs once. If you don't want Quick Setup to remediate changes made to resources that differ from your configuration, choose **Disabled** under **Custom**.
6. In the **Targets** section, choose whether to deploy conformance packs to your entire organization, some Amazon Web Services Regions, or the account you're currently logged in to.

   If you choose **Entire organization**, continue to step 8.

   If you choose **Custom**, continue to step 7.
7. In the **Target Regions** section, select the check boxes of the Regions you want to deploy conformance packs to.
8. Choose **Create**.

Configure patching for instances in an organization using a Quick Setup patch policy

With Quick Setup, you can create patch policies powered by Patch Manager. A patch policy defines the schedule and baseline to use when automatically patching your Amazon Elastic Compute Cloud (Amazon EC2) instances and other managed nodes. Using a single patch policy configuration, you can define patching for all accounts in multiple Amazon Web Services Regions in your organization, for only the accounts and Regions you choose, or for a single account-Region pair. For more information about patch policies, see Patch policy configurations in Quick Setup.

Prerequisite

To define a patch policy for a node using Quick Setup, the node must be a *managed node*. For more information about managing your nodes, see Setting up Systems Manager unified console for an organization.

> **Important**
>
> **Patch compliance scanning methods** – Systems Manager supports several methods for scanning managed nodes for patch compliance. If you implement more than one of these methods at a time, the patch compliance information you see is always the result of the most recent scan. Results from previous scans are overwritten. If the scanning methods use different patch baselines, with different approval rules, the patch compliance information

can change unexpectedly. For more information, see Identifying the execution that created patch compliance data.

Association compliance status and patch policies – The patching status for a managed node that's under a Quick Setup patch policy matches the status of the State Manager association execution for that node. If the association execution status is `Compliant`, the patching status for the managed node is also marked `Compliant`. If the association execution status is `Non-Compliant`, the patching status for the managed node is also marked `Non-Compliant`.

Supported Regions for patch policy configurations

Patch policy configurations in Quick Setup are currently supported in the following Regions:

- US East (Ohio) (us-east-2)
- US East (N. Virginia) (us-east-1)
- US West (N. California) (us-west-1)
- US West (Oregon) (us-west-2)
- Asia Pacific (Mumbai) (ap-south-1)
- Asia Pacific (Seoul) (ap-northeast-2)
- Asia Pacific (Singapore) (ap-southeast-1)
- Asia Pacific (Sydney) (ap-southeast-2)
- Asia Pacific (Tokyo) (ap-northeast-1)
- Canada (Central) (ca-central-1)
- Europe (Frankfurt) (eu-central-1)
- Europe (Ireland) (eu-west-1)
- Europe (London) (eu-west-2)
- Europe (Paris) (eu-west-3)
- Europe (Stockholm) (eu-north-1)
- South America (São Paulo) (sa-east-1)

Permissions for the patch policy S3 bucket

When you create a patch policy, Quick Setup creates an Amazon S3 bucket that contains a file named `baseline_overrides.json`. This file stores information about the patch baselines that you specified for your patch policy.

The S3 bucket is named in the format `aws-quicksetup-patchpolicy-`*`account-id`*`-`*`quick-setup-configuration-id`*.

For example: `aws-quicksetup-patchpolicy-123456789012-abcde`

If you're creating a patch policy for an organization, the bucket is created in your organization's management account.

There are two use cases when you must provide other Amazon resources with permission to access this S3 bucket using Amazon Identity and Access Management (IAM) policies:

- Case 1: Use your own instance profile or service role with your managed nodes instead of one provided by Quick Setup
- Case 2: Use VPC endpoints to connect to Systems Manager

The permissions policy you need in either case is located in the section below, Policy permissions for Quick Setup S3 buckets.

Case 1: Use your own instance profile or service role with your managed nodes instead of one provided by Quick Setup

Patch policy configurations include an option to **Add required IAM policies to existing instance profiles attached to your instances**.

If you don't choose this option but want Quick Setup to patch your managed nodes using this patch policy, you must make sure that the following are implemented:

- The IAM managed policy `AmazonSSMManagedInstanceCore` must be attached to the IAM instance profile or IAM service role that's used to provide Systems Manager permissions to your managed nodes.
- You must add permissions to access your patch policy bucket as an inline policy to the IAM instance profile or IAM service role. You can provide wildcard access to all `aws-quicksetup-patchpolicy` buckets or only the specific bucket created for your organization or account, as shown in the earlier code samples.

- You must tag your IAM instance profile or IAM service role with the following key-value pair.

  `Key: QSConfigId-`*`quick-setup-configuration-id`*`, Value: `*`quick-setup-configuration-id`*

  `quick-setup-configuration-id` represents the value of the parameter applied to the Amazon CloudFormation stack that is used in creating your patch policy configuration. To retrieve this ID, do the following:

  1. Open the Amazon CloudFormation console at https://console.amazonaws.cn/cloudformation.
  2. Select the name of the stack that is used to create your patch policy. The name is in a format such as `StackSet-AWS-QuickSetup-PatchPolicy-LA-q4bkg-52cd2f06-d0f9-499e-9818-d887cEXAMPLE`.
  3. Choose the **Parameters** tab.
  4. In the **Parameters** list, in the **Key** column, locate the key **QSConfigurationId**. In the **Value** column for its row, locate the configuration ID, such as `abcde`.

     In this example, for the tag to apply to your instance profile or service role, the key is `QSConfigId-abcde`, and the value is `abcde`.

For information about adding tags to an IAM role, see Tagging IAM roles and Managing tags on instance profiles (Amazon CLI or Amazon API) in the *IAM User Guide*.

Case 2: Use VPC endpoints to connect to Systems Manager

If you use VPC endpoints to connect to Systems Manager, your VPC endpoint policy for S3 must allow access to your Quick Setup patch policy S3 bucket.

For information about adding permissions to a VPC endpoint policy for S3, see Controlling access from VPC endpoints with bucket policies in the *Amazon S3 User Guide*.

Policy permissions for Quick Setup S3 buckets

You can provide wildcard access to all `aws-quicksetup-patchpolicy` buckets or only the specific bucket created for your organization or account. To provide the necessary permissions for the two cases described below, use either format.

All patch policy buckets

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AccessToAllPatchPolicyRelatedBuckets",
      "Effect": "Allow",
      "Action": "s3:GetObject",
      "Resource": "arn:aws-cn:s3:::aws-quicksetup-patchpolicy-*"
    }
  ]
}
```

Specific patch policy bucket

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Sid": "AccessToMyPatchPolicyRelatedBucket",
      "Effect": "Allow",
      "Action": "s3:GetObject",
      "Resource": "arn:aws-cn:s3:::aws-quicksetup-
patchpolicy-111122223333-quick-setup-configuration-id"
    }
  ]
}
```

Note

After the patch policy configuration is created, you can locate the full name of your bucket in the S3 console. For example: `aws-quicksetup-patchpolicy-123456789012-abcde`

Random patch baseline IDs in patch policy operations

Patching operations for patch policies use the `BaselineOverride` parameter in the `AWS-RunPatchBaseline` SSM Command document.

When you use `AWS-RunPatchBaseline` for patching *outside* of a patch policy, you can use `BaselineOverride` to specify a list of patch baselines to use during the operation that are different from the specified defaults. You create this list in a file named `baseline_overrides.json` and manually add it to an Amazon S3 bucket that you own, as explained in Using the BaselineOverride parameter.

For patching operations based on patch policies, however, Systems Manager automatically creates an S3 bucket and adds a `baseline_overrides.json` file to it. Then, every time Quick Setup runs a patching operation (using the Run Command tool, the system generates a random ID for each patch baseline. This ID is different for every patch policy patching operation, and the patch baseline it represents is not stored or accessible to you in your account.

As a result, the ID of the patch baseline selected in your configuration in patching logs. This applies to both Amazon managed patch baselines and custom patch baselines you might have selected. The baseline ID reported in the log is instead that one that was generated for that specific patching operation.

In addition, if you attempt to view details in Patch Manager about a patch baseline that was generated with a random ID, the system reports that the patch baseline doesn't exist. This is expected behavior and can be ignored.

Creating a patch policy

To create a patch policy, perform the following tasks in the Systems Manager console.

To create a patch policy with Quick Setup

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.

   If you are setting up patching for an organization, make sure you are signed in to the management account for the organization. You can't set up the policy using the delegated administrator account or a member account.

2. In the navigation pane, choose **Quick Setup**.

3. On the **Patch Manager** card, choose **Create**.

> **Tip**
>
> If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. For **Configuration name**, enter a name to help identify the patch policy.
5. In the **Scanning and installation** section, under **Patch operation**, choose whether the patch policy will **Scan** the specified targets or **Scan and install** patches on the specified targets.
6. Under **Scanning schedule**, choose **Use recommended defaults** or **Custom scan schedule**. The default scan schedule will scan your targets daily at 1:00 AM UTC.

   - If you choose **Custom scan schedule**, select the **Scanning frequency**.
   - If you choose **Daily**, enter the time, in UTC, that you want to scan your targets.
   - If you choose **Custom CRON Expression**, enter the schedule as a **CRON expression**. For more information about formatting CRON expressions for Systems Manager, see Reference: Cron and rate expressions for Systems Manager.

     Also, select **Wait to scan targets until first CRON interval**. By default, Patch Manager immediately scans nodes as they become targets.
7. If you chose **Scan and install**, choose the **Installation schedule** to use when installing patches to the specified targets. If you choose **Use recommended defaults**, Patch Manager will install weekly patches at 2:00 AM UTC on Sunday.

   - If you choose **Custom install schedule**, select the **Installation Frequency**.
   - If you choose **Daily**, enter the time, in UTC, that you want to install updates on your targets.
   - If you choose **Custom CRON expression**, enter the schedule as a **CRON expression**. For more information about formatting CRON expressions for Systems Manager, see Reference: Cron and rate expressions for Systems Manager.

     Also, clear **Wait to install updates until first CRON interval** to immediately install updates on nodes as they become targets. By default, Patch Manager waits until the first CRON interval to install updates.
   - Choose **Reboot if needed** to reboot the nodes after patch installation. Rebooting after installation is recommended but can cause availability issues.

8. In the **Patch baseline** section, choose the patch baselines to use when scanning and updating your targets.

   By default, Patch Manager uses the predefined patch baselines. For more information, see Predefined baselines.

   If you choose **Custom patch baseline**, change the selected patch baseline for operating systems that you don't want to use a predefined Amazon patch baseline.

   > **Note**
   >
   > If you use VPC endpoints to connect to Systems Manager, make sure your VPC endpoint policy for S3 allows access to this S3 bucket. For more information, see Permissions for the patch policy S3 bucket.

   > **Important**
   >
   > If you are using a patch policy configuration in Quick Setup, updates you make to custom patch baselines are synchronized with Quick Setup once an hour.
   > If a custom patch baseline that was referenced in a patch policy is deleted, a banner displays on the Quick Setup **Configuration details** page for your patch policy. The banner informs you that the patch policy references a patch baseline that no longer exists, and that subsequent patching operations will fail. In this case, return to the Quick Setup **Configurations** page, select the Patch Manager configuration , and choose **Actions**, **Edit configuration**. The deleted patch baseline name is highlighted, and you must select a new patch baseline for the affected operating system.

9. (Optional) In the **Patching log storage** section, select **Write output to S3 bucket** to store patching operation logs in an Amazon S3 bucket.

   > **Note**
   >
   > If you are setting up a patch policy for an organization, the management account for your organization must have at least read-only permissions for this bucket. All organization units included in the policy must have write-access to the bucket. For information about granting bucket access to different accounts, see Example 2: Bucket

owner granting cross-account bucket permissions in the *Amazon Simple Storage Service User Guide*.

10. Choose **Browse S3** to select the bucket that you want to store patch log output in. The management account must have read access to this bucket. All non-management accounts and targets configured in the **Targets** section must have write access to the provided S3 bucket for logging.
11. In the **Targets** section, choose one of the following to identify the accounts and Regions for this patch policy operation.

> **Note**
>
> If you are working in a single account, options for working with organizations and organizational units (OUs) are not available. You can choose whether to apply this configuration to all Amazon Web Services Regions in your account or only the Regions you select.
> If you previously specified a Home Region for you account and haven't onboarded to the new Quick Setup console experience, you can't exclude that Region from the **Targets** configuration.

- **Entire organization** – All accounts and Regions in your organization.
- **Custom** – Only the OUs and Regions that you specify.
  - In the **Target OUs** section, select the OUs where you want to set up the patch policy.
  - In the **Target Regions** section, select the Regions where you want to apply the patch policy.
- **Current account** – Only the Regions you specify in the account you are currently signed into are targeted. Choose one of the following:
  - **Current Region** – Only managed nodes in the Region selected in the console are targeted.
  - **Choose Regions** – Choose the individual Regions to apply the patch policy to.

12. For **Choose how you want to target instances**, choose one of the following to identify the nodes to patch:

- **All managed nodes** – All managed nodes in the selected OUs and Regions.

- **Specify the resource group** – Choose the name of a resource group from the list to target its associated resources.

  > **Note**
  >
  > Currently, selecting resource groups is supported only for single account configurations. To patch resources in multiple accounts, choose a different targeting option.

- **Specify a node tag** – Only nodes tagged with the key-value pair that you specify are patched in all accounts and Regions you have targeted.
- **Manual** – Choose managed nodes from all specified accounts and Regions manually from a list.

  > **Note**
  >
  > This option currently supports only Amazon EC2 instances. You can add a maximum of 25 instances manually in a patch policy configuration.

13. In the **Rate control** section, do the following:

    - For **Concurrency**, enter a number or percentage of nodes to run the patch policy on at the same time.
    - For **Error threshold**, enter the number or percentage of nodes that can experience an error before the patch policy fails.

14. (Optional) Select the **Add required IAM policies to existing instance profiles attached to your instances** check box.

    This selection applies the IAM policies created by this Quick Setup configuration to nodes that already have an instance profile attached (EC2 instances) or a service role attached (hybrid-activated nodes). We recommend this selection when your managed nodes already have an instance profile or service role attached, but it doesn't contain all the permissions required for working with Systems Manager.

    Your selection here is applied to managed nodes created later in the accounts and Regions that this patch policy configuration applies to.

> **Important**
>
> If you don't select this check box but want Quick Setup to patch your managed nodes using this patch policy, you must do the following:
> Add permissions to your IAM instance profile or IAM service role to access the S3 bucket created for your patch policy
> Tag your IAM instance profile or IAM service role with a specific key-value pair.
> For information, see Case 1: Use your own instance profile or service role with your managed nodes instead of one provided by Quick Setup.

15. Choose **Create**.

    To review patching status after the patch policy is created, you can access the configuration from the Quick Setup page.

Set up DevOps Guru using Quick Setup

> **Important**
>
> End of support notice: Amazon DevOps Guru will stop accepting new customers on October 29, 2026. Current customers will not be impacted and can continue using Amazon DevOps Guru until September 30, 2027. After September 30, 2027 you will no longer be able to access Amazon DevOps Guru. For more information, see Amazon DevOps Guru end of support.

You can quickly configure DevOps Guru options by using Quick Setup. Amazon DevOps Guru is a machine learning (ML) powered service that makes it easy to improve an application's operational performance and availability. DevOps Guru detects behaviors that are different from normal operating patterns so you can identify operational issues long before they impact your customers. DevOps Guru automatically ingests operational data from your Amazon applications and provides a single dashboard to visualize issues in your operational data. You can get started with DevOps Guru to improve application availability and reliability with no manual setup or machine learning expertise.

Configuring DevOps Guru with Quick Setup is available in the following Amazon Web Services Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (Oregon)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (Stockholm)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)

For pricing information, see Amazon DevOps Guru pricing.

To set up DevOps Guru, perform the following tasks in the Amazon Systems Manager Quick Setup console.

To set up DevOps Guru with Quick Setup

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. On the **DevOps Guru** card, choose **Create**.

   > **Tip**
   >
   > If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Configuration options** section, choose the Amazon resource types you want to analyze and your notification preferences.

   If you don't select the **Analyze all Amazon resources in all the accounts in my organization** option, you can choose Amazon resources to analyze later in the DevOps Guru console. DevOps Guru analyzes different Amazon resource types (such as Amazon Simple Storage Service (Amazon S3) buckets and Amazon Elastic Compute Cloud (Amazon EC2) instances), which are categorized into two pricing groups. You pay for the Amazon resource hours

analyzed, for each active resource. A resource is only active if it produces metrics, events, or log entries within an hour. The rate you're charged for a specific Amazon resource type depends on the price group.

If you select the **Enable SNS notifications** option, an Amazon Simple Notification Service (Amazon SNS) topic is created in each Amazon Web Services account in the organizational units (OUs) you target with your configuration. DevOps Guru uses the topic to notify you about important DevOps Guru events, such as the creation of a new insight. If you don't enable this option, you can add a topic later in the DevOps Guru console.

If you select the **Enable Amazon Systems Manager OpsItems** option, operational work items (OpsItems) will be created for related Amazon EventBridge events and Amazon CloudWatch alarms.

5. In the **Schedule** section, choose how frequently you want Quick Setup to remediate changes made to resources that differ from your configuration. The **Default** option runs once. If you don't want Quick Setup to remediate changes made to resources that differ from your configuration, choose **Disabled** under **Custom**.
6. In the **Targets** section, choose whether to allow DevOps Guru to analyze resources in some of your organizational units (OUs), or the account you're currently logged in to.

   If you choose **Custom**, continue to step 8.

   If you choose **Current account**, continue to step 9.
7. In the **Target OUs** and **Target Regions** sections, select the check boxes of the OUs and Regions where you want to use DevOps Guru.
8. Choose the Regions where you want to use DevOps Guru in the current account.
9. Choose **Create**.

Deploy Distributor packages using Quick Setup

Distributor is a tool in Amazon Systems Manager. A Distributor package is a collection of installable software or assets that can be deployed as a single entity. With Quick Setup, you can deploy a Distributor package in an Amazon Web Services account and an Amazon Web Services Region or across an organization in Amazon Organizations. Currently, only the EC2Launch v2 agent, Amazon Elastic File System (Amazon EFS) utilities package and Amazon CloudWatch agent can be deployed with Quick Setup. For more information about Distributor, see Amazon Systems Manager Distributor.

To deploy Distributor packages, perform the following tasks in the Amazon Systems Manager Quick Setup console.

To deploy Distributor packages with Quick Setup

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Distributor** card, choose **Create**.

   > **Tip**
   >
   > If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Configuration options** section, choose the package you want to deploy.
5. In the **Targets** section, choose whether to deploy the package to your entire organization, some of your organizational units (OUs), or the account you're currently logged in to.

   If you choose **Entire organization**, continue to step 8.

   If you choose **Custom**, continue to step 7.
6. In the **Target OUs** section, select the check boxes of the OUs and Regions you want to deploy the package to.
7. Choose **Create**.

Stop and start EC2 instances automatically on a schedule using Quick Setup

With Quick Setup, you can configure Resource Scheduler to automate the starting and stopping of Amazon Elastic Compute Cloud (Amazon EC2) instances.

This Quick Setup configuration helps you reduce operational costs by starting and stopping instances according to the schedule that you specify. This tool helps you avoid incurring unnecessary costs for running instances when they're not needed.

For example, you currently might leave your instances running constantly, even though they're only used 10 hours a day, 5 days a week. Instead, you can schedule your instances to stop every day after business hours. As a result, there would be 70 percent savings for those instances because the

running time is reduced from 168 hours to 50 hours. There is no cost to use Quick Setup. However, costs can be incurred by the resources you set up and the usage limits with no fees for the services used to set up your configuration.

Using Resource Scheduler, you can choose to automatically stop and start instances across multiple Amazon Web Services Regions and Amazon Web Services accounts according to a schedule you define. The Quick Setup configuration targets Amazon EC2 instances using the tag key and value that you specify. Only the instances with a tag matching the value that you specify in your configuration are stopped or started by Resource Scheduler. Note that if the Amazon EBS volumes attached to the instance are encrypted, you must add the required permissions for the Amazon KMS key to the IAM role for Resource Scheduler to start the instance.

Maximum instances per configuration

An individual configuration supports scheduling up to 5,000 instances per Region. If your case requires more than 5,000 instances to be scheduled in a given Region, you must create multiple configurations. Tag your instances accordingly so each configuration is managing up to 5,000 instances. When creating multiple Resource Scheduler Quick Setup configurations, you must specify different tag key values. For example, one configuration can use the tag key `Environment` with the value `Production`, while another uses `Environment` and `Development`.

Scheduling behaviors

The following points describe certain behaviors of schedule configurations:

- Resource Scheduler starts the tagged instances only if they are in the `Stopped` state. Similarly, instances are only stopped if they are in the `running` state. Resource Scheduler operates on an event driven model and only starts or stops instances at the times that you specify. For example, you create a schedule that starts instances at 9 AM. Resource Scheduler starts all instances associated with the tag you specify that are in the `Stopped` state at 9 AM. If the instances are manually stopped at a later time, Resource Scheduler will not start them again to maintain the `Running` state. Similarly, if an instance is started manually after it was stopped according to your schedule, Resource Scheduler will not stop the instance again.
- If you create a schedule with a start time that is later in a 24-hour day than the stop time, Resource Scheduler assumes your instances are to run overnight. For example, you create a schedule that starts instances at 9 PM, and stops instances at 7 AM. Resource Scheduler starts all instances associated with the tag you specify that are in the `Stopped` state at 9 PM, and stops them at 7 AM the following day. For overnight schedules, the start time applies to the days you select for your schedule. However, the stop time applies to the following day in your schedule.

- When you create a schedule configuration, the current state of your instances might be changed to match the requirements of the schedule.

  For example, say that today is a Wednesday, and you specify a schedule for your managed instances to start at 9 AM and stop at 5 PM on Tuesdays and Thursdays *only*. Because your current time is outside of the prescribed hours for the instances to be running, they will be stopped after the configuration is created. The instances won't run again until the next prescribed hour, 9 AM on Thursday.

  If your instances are currently in a `Stopped` state, and you specify a schedule in which they would be running at the current time, Resource Scheduler starts them after the configuration is created.

If you delete your configuration, instances are no longer stopped and started according to the previously defined schedule. In rare cases, instances might not successfully stop or start due to API operation failures.

To set up scheduling for Amazon EC2 instances, perform the following tasks in the Amazon Systems Manager Quick Setup console.

To set up instance scheduling with Quick Setup

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Resource Scheduler** card, choose **Create**.

   > **Tip**
   >
   > If you already have one or more configurations in your account, first choose the **Library** tab or the **Create** button in the **Configurations** section to view the cards.

4. In the **Instance tag** section, specify the tag key and value applied to the instances you want to associate with your schedule.
5. In the **Schedule options** section, specify the time zone, days, and times you want to start and stop your instances.
6. In the **Targets** section, choose whether to set scheduling for a **Custom** group of organizational units (OUs), or the **Current account** you're signed in to:

- **Custom** – In the **Target OUs** section, select the OUs where you want to set up scheduling. Next, in the **Target Regions** section, select the Regions where you want to set up scheduling.
- **Current account** – Select **Current Region** or **Choose Regions**. If you selected **Choose Regions**, choose the **Target Regions** where you want to set up scheduling.

7. Verify the schedule information in the **Summary** section.
8. Choose **Create**.

Configure Amazon Resource Explorer using Quick Setup

With Quick Setup, you can quickly configure Amazon Resource Explorer to search and discover resources in your Amazon Web Services account or across an entire Amazon organization. You can search for your resources using metadata like names, tags, and IDs. Amazon Resource Explorer provides fast responses to your search queries by using *indexes*. Resource Explorer creates and maintains indexes using a variety of data sources to gather information about resources in your Amazon Web Services account.

Quick Setup for Resource Explorer automates the index configuration process. For more information about Amazon Resource Explorer, see What is Amazon Resource Explorer? in the Amazon Resource Explorer User Guide.

During Quick Setup, Resource Explorer does the following:

- Creates an index in every Amazon Web Services Region in your Amazon Web Services account.
- Updates the index in the Region you specify to be the aggregator index for the account.
- Creates a default view in the aggregator index Region. This view has no filters so it returns all resources found in the index.

Minimum permissions

To perform the steps in the following procedure, you must have the following permissions:

- **Action**: `resource-explorer-2:*` – **Resource**: no specific resource (*)
- **Action**: `iam:CreateServiceLinkedRole` – **Resource**: no specific resource (*)

To configure Resource Explorer

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Resource Explorer** card, choose **Create**.
4. In the **Aggregator Index Region** section, choose which Region you want to contain the **aggregator index**. You should select the Region that is appropriate for the geographic location for your users.
5. (Optional) Select the **Replace existing aggregator indexes in Regions other than the one selected above** check box.
6. In the **Targets** section, choose the target **organization** or specific **Organizational Units (OUs)** containing the resources you want to discover.
7. In the **Regions** section, choose which **Regions** to include in the configuration.
8. Review the configuration summary, and then choose **Create**.

On the **Resource Explorer** page, you can monitor the configuration status.

Troubleshooting Quick Setup results

Use the following information to help you troubleshoot problems with Quick Setup, a tool in Amazon Systems Manager. This topic includes specific tasks to resolve issues based on the type of Quick Setup issue.

Issue: Failed deployment

A deployment fails if the CloudFormation stack set failed during creation. Use the following steps to investigate a deployment failure.

1. Navigate to the Amazon CloudFormation console.
2. Choose the stack created by your Quick Setup configuration. The **Stack name** includes `QuickSetup` followed by the type of configuration you chose, such as `SSMHostMgmt`.

> **Note**
>
> CloudFormation sometimes deletes failed stack deployments. If the stack isn't available in the **Stacks** table, choose **Deleted** from the filter list.

3. View the **Status** and **Status reason**. For more information about stack statuses, see Stack status codes in the *Amazon CloudFormation User Guide*.
4. To understand the exact step that failed, view the **Events** tab and review each event's **Status**.
5. Review Troubleshooting in the *Amazon CloudFormation User Guide*.
6. If you are unable to resolve the deployment failure using the CloudFormation troubleshooting steps, delete the configuration and reconfigure it.

Issue: Failed association

The **Configuration details** table on the **Configuration details** page of your configuration shows a **Configuration status** of **Failed** if any of the associations failed during set up. Use the following steps to troubleshoot a failed association.

1. In the **Configuration details** table, choose the failed configuration and then choose **View Details**.
2. Copy the **Association name**.
3. Navigate to **State Manager** and paste the association name into the search field.
4. Choose the association and choose the **Execution history** tab.
5. Under **Execution ID**, choose the association execution that failed.
6. The **Association execution targets** page lists all of the nodes where the association ran. Choose the **Output** button for an execution that failed to run.
7. In the **Output** page, choose **Step - Output** to view the error message for that step in the command execution. Each step can display a different error message. Review the error messages for all steps to help troubleshoot the issue.

If viewing the step output doesn't solve the problem, then you can try to recreate the association. To recreate the association, first delete the failing association in State Manager.

After deleting the association, edit the configuration and choose the option you deleted and choose **Update**.

> **Note**
>
> To investigate **Failed** associations for an **Organization** configuration, you must sign in to the account with the failed association and use the following failed association procedure, previously described. The **Association ID** isn't a hyperlink to the target account when viewing results from the management account.

Issue: Drift status

When viewing a configuration's details page, you can view the drift status of each deployment. Configuration drift occurs whenever a user makes any change to a service or feature that conflicts with the selections made through Quick Setup. If an association has changed after the initial configuration, the table displays a warning icon that indicates the number of items that have drifted. You can determine what caused the drift by hovering over the icon.

When an association is deleted in State Manager, the related deployments display a drift warning. To fix this, edit the configuration and choose the option that was removed when the association was deleted. Choose **Update** and wait for the deployment to complete.

Amazon Systems Manager application tools

Application tools are a suite of capabilities that help you manage your applications running in Amazon.

Topics

- Amazon AppConfig
- Amazon Systems Manager Application Manager
- Amazon Systems Manager Parameter Store

Amazon AppConfig

Information about Amazon AppConfig has been moved into separate guides. For more information, see the following:

- Amazon AppConfig User Guide
- Amazon AppConfig API Reference

Amazon Systems Manager Application Manager

> **Note**
>
> Amazon Systems Manager Application Manager is no longer open to new customers. For capabilities similar to Amazon Systems Manager Application Manager, explore alternatives Amazon Systems Manager Application Manager availability change.

Application Manager helps DevOps engineers investigate and remediate issues with their Amazon resources in the context of their applications and clusters. Application Manager aggregates operations information from multiple Amazon Web Services services and Systems Manager tools to a single Amazon Web Services Management Console.

In Application Manager, an *application* is a logical group of Amazon resources that you want to operate as a unit. This logical group can represent different versions of an application, ownership boundaries for operators, or developer environments, to name a few. Application Manager support for container clusters includes both Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon Elastic Container Service (Amazon ECS) clusters.

The first time you open Application Manager, the **What Application Manager can do for you** page displays. When you choose **Get started**, Application Manager automatically imports metadata about your resources that were created in other Amazon Web Services services or Systems Manager tools. Application Manager then displays those resources in a list grouped by predefined categories.

For **Applications**, the list includes the following:

- Amazon CloudFormation stacks
- Custom applications
- Amazon Launch Wizard applications
- AppRegistry applications
- Amazon SAP Enterprise Workload applications
- Amazon ECS clusters

- Amazon EKS clusters

After you set up and configure Amazon Web Services services and Systems Manager tools, Application Manager displays the following types of information about your resources:

- Information about the current state, status, and Amazon EC2 Auto Scaling health of the Amazon Elastic Compute Cloud (Amazon EC2) instances in your application
- Alarms provided by Amazon CloudWatch
- Compliance information provided by Amazon Config and State Manager (a component of Systems Manager)
- Kubernetes cluster information provided by Amazon EKS
- Log data provided by Amazon CloudTrail and Amazon CloudWatch Logs
- OpsItems provided by Systems Manager OpsCenter
- Resource details provided by the Amazon Web Services services that host them.
- Container cluster information provided by Amazon ECS.

To help you remediate issues with components or resources, Application Manager also provides runbooks that you can associate with your applications. To get started with Application Manager, open the Systems Manager console. In the navigation pane, choose **Application Manager**.

What are the benefits of using Application Manager?

Application Manager reduces the time it takes for DevOps engineers to detect and investigate issues with Amazon resources. To do this, Application Manager displays many types of operations information in the context of an application in one console. Application Manager also reduces the time it takes to remediate issues by providing runbooks that perform common remediation tasks on Amazon resources.

What are the features of Application Manager?

Application Manager includes the following features:

- **Import your Amazon resources automatically**

  During initial setup, you can choose to have Application Manager automatically import and display resources in your Amazon Web Services account that are based on CloudFormation stacks, Amazon Resource Groups, Launch Wizard deployments, AppRegistry applications, and

Amazon ECS and Amazon EKS clusters. The system displays these resources in predefined application or cluster categories. Thereafter, whenever new resources of these types are added to your Amazon Web Services account, Application Manager automatically displays the new resources in the predefined application and cluster categories.

- **Create or edit CloudFormation stacks and templates**

  Application Manager helps you provision and manage resources for your applications by integrating with CloudFormation. You can create, edit, and delete Amazon CloudFormation templates and stacks in Application Manager. Application Manager also includes a template library where you can clone, create, and store templates. Application Manager and CloudFormation display the same information about the current status of a stack. Templates and template updates are stored in Systems Manager until you provision the stack, at which time the changes are also displayed in CloudFormation.

- **View information about your instances in the context of an application**

  Application Manager integrates with Amazon Elastic Compute Cloud (Amazon EC2) to display information about your instances in the context of an application. Application Manager displays instance state, status, and Amazon EC2 Auto Scaling health for a selected application in a graphical format. The **Instances** tab also includes a table with the following information for each instance in your application.

  - Instance state (Pending, Stopping, Running, Stopped)
  - Ping status for SSM Agent
  - Status and name of the last Systems Manager Automation runbook processed on the instance
  - A count of Amazon CloudWatch Logs alarms per state.
    - `ALARM` – The metric or expression is outside of the defined threshold.
    - `OK` – The metric or expression is within the defined threshold.
    - `INSUFFICIENT_DATA` – The alarm has just started, the metric is not available, or not enough data is available for the metric to determine the alarm state.
  - Auto Scaling group health for the parent and individual autoscaling groups

- **View operational metrics and alarms for an application or cluster**

  Application Manager integrates with Amazon CloudWatch to provide real-time operational metrics and alarms for an application or cluster. You can drill down into your application tree to view alarms at each component level, or view alarms for an individual cluster.

- **View log data for an application**

Application Manager integrates with Amazon CloudWatch Logs to provide log data in the context of your application without having to leave Systems Manager.

- **View and manage OpsItems for an application or cluster**

  Application Manager integrates with Amazon Systems Manager OpsCenter to provide a list of operational work items (OpsItems) for your applications and clusters. The list reflects automatically generated and manually created OpsItems. You can view details about the resource that created an OpsItem and the OpsItem status, source, and severity.

- **View resource compliance data for an application or cluster**

  Application Manager integrates with Amazon Config to provide compliance and history details about your Amazon resources according to rules you specify. Application Manager also integrates with Amazon Systems Manager State Manager to provide compliance information about the state you want to maintain for your Amazon Elastic Compute Cloud (Amazon EC2) instances.

- **View Amazon ECS and Amazon EKS cluster infrastructure information**

  Application Manager integrates with Amazon ECS and Amazon EKS to provide information about the health of your cluster infrastructures and a component runtime view of the compute, networking, and storage resources in a cluster.

  However, you can't manage or view operations information about your Amazon EKS pods or containers in Application Manager. You can only manage and view operations information about the infrastructure that is hosting your Amazon EKS resources.

- **View resource cost details for an application**

  Application Manager is integrated with Amazon Cost Explorer, a feature of Amazon Billing and Cost Management, through the **Cost** widget. After you enable Cost Explorer in the Billing and Cost Management console, the **Cost** widget in Application Manager shows cost data for a specific non-container application or application component. You can use filters in the widget to view cost data according to different time periods, granularities, and cost types in either a bar or line chart.

- **View detailed resource information in one console**

  Choose a resource name listed in Application Manager and view contextual information and operations information about that resource without having to leave Systems Manager.

- **Receive automatic resource updates for applications**

If you make changes to a resource in a service console, and that resource is part of an application in Application Manager, then Systems Manager automatically displays those changes. For example, if you update a stack in the Amazon CloudFormation console, and if that stack is part of an Application Manager application, then the stack updates are automatically reflected in Application Manager.

- **Discover Launch Wizard applications automatically**

  Application Manager is integrated with Amazon Launch Wizard. If you used Launch Wizard to deploy resources for an application, Application Manager can automatically import and display them in a Launch Wizard section.

- **Monitor application resources in Application Manager by using CloudWatch Application Insights**

  Application Manager integrates with Amazon CloudWatch Application Insights. Application Insights identifies and sets up key metrics, logs, and alarms across your application resources and technology stack. Application Insights continuously monitors metrics and logs to detect and correlate anomalies and errors. When the system detects errors or anomalies, Application Insights generates CloudWatch Events that you can use to set up notifications or take actions. You can enable and view Application Insights on the **Overview** and **Monitoring** tabs in Application Manager. For more information about Application Insights, see What is Amazon CloudWatch Application Insights in the *Amazon CloudWatch User Guide*.

- **Remediate issues with runbooks**

  Application Manager includes predefined Systems Manager runbooks for remediating common issues with Amazon resources. You can execute a runbook against all of the applicable resources in an application without having to leave Application Manager.

Is there a charge to use Application Manager?

Application Manager is available at no additional charge.

What are the resource quotas for Application Manager?

You can view quotas for all Systems Manager tools in the Systems Manager service quotas in the *Amazon Web Services General Reference*. Unless otherwise noted, each quota is Region specific.

Amazon Systems Manager Application Manager availability change

Amazon Systems Manager Application Manager is no longer open to new customers. SSM Application Manager is a console capability that enables DevOps teams to define or auto-discover applications, associate Amazon resources to those applications, apply tags for resource management and monitor applications' health.

Until further notice, existing SSM Application Manager customers can continue to use the service normally in established accounts. During this period, Amazon will maintain service availability and performance and continue to offer support through Amazon Support channels. Amazon will not add new features or expand the service into new Regions.

We have identified several alternatives to SSM Application Manager depending on your use case. Amazon Console for SAP Applications, Tagging, Amazon Resource Groups, and Amazon Resource Explorer are available at no additional cost. For observability use cases, Amazon CloudWatch Application Signals is a paid service that includes a free tier.

Alternatives to Application Manager

Amazon Console for SAP Applications

If your primary use case is to manage SAP HANA-based applications on Amazon, use Amazon Console for SAP Applications. This centralized experience provides an application-centric view to register and manage SAP HANA-based applications running on Amazon. The console offers a unified dashboard to view your registered SAP applications, understand your landing zone setup, and gain visibility into resources consumed by your SAP workloads. From the application details page, you can view application topology, associated resources, and perform operations including application-aware start/stop and automated validation. To learn more, see the Amazon Console for SAP Applications announcement.

Tagging

If your primary use case is to assign metadata to resources, add tags using customer-defined tag keys (e.g., application, project, or workload) to your account. Tagging is the foundation that not only Amazon Systems Manager builds on, but also many other Amazon management tools (services such as Resource Groups, Resource Explorer, Cost Explorer, CloudWatch, Config, and Security Hub all use tags to organize and filter your resources). By establishing a tagging strategy first, you gain the flexibility to adopt other alternatives over time. For example, after tagging your resources, you can use Amazon Resource Groups to create a logical grouping

for operations and visibility within your account and search those tagged resources cross-Region and cross-account using Amazon Resource Explorer. To learn more, see Best Practices for Tagging Amazon Resources.

Amazon Resource Groups

If your primary use case is resource organization and management, use Amazon Resource Groups to establish permanent and named groupings based on tags in a single Region. Resource Groups allow you to organize resources by application, environment, or any other tag-based category, making it easier to manage and operate your workloads. To learn more, see the Amazon Resource Groups User Guide.

Amazon Resource Explorer

If your primary use case is resource discovery, use Amazon Resource Explorer to search and discover a collection of resources by tag, cross-Region and cross-account. Resource Explorer provides a unified view of your Amazon resources, enabling you to search and filter by properties including tag, resource type, and Region. To learn more, see the Amazon Resource Explorer User Guide.

Amazon CloudWatch Application Signals Application Map

If your primary use case is application-level observability, use Amazon CloudWatch Application Signals for auto-discovery of applications with multi-Region and multi-account support. Application Signals is a paid service that includes a free tier and provides a comprehensive view of your application's health, performance, and dependencies. To learn more, see the Application Signals User Guide.

> **Note**
>
> The `awsApplication` tags and AppManager resource groups created through SSM Application Manager persist indefinitely and can continue to be used for resource grouping, cost allocation, and filtering. Customers can use their existing AppManager resource groups and `awsApplication` tags in combination with the recommended alternatives (Resource Groups, Resource Explorer, Application Signals). There is no requirement to remove or replace this tag as part of the transition to maintenance mode.

Frequently asked questions

Is Amazon Systems Manager Application Manager shut down?

No, Amazon Systems Manager Application Manager is entering maintenance mode. Amazon will continue to maintain service availability and offer support through Amazon Support channels. Amazon will not add new features or expand the service to additional Regions. Starting July 30, 2026, accounts that have not previously used Amazon Systems Manager Application Manager will no longer be able to access the service; existing customers are not affected.

Will my existing Amazon Systems Manager Application Manager applications continue to work?

Yes, existing Amazon Systems Manager Application Manager applications will continue to function as they do today. There is no disruption to your current setup, and no action is required on your part. No APIs are impacted by this change. Application Manager only uses existing SSM APIs.

What alternatives can customers explore?

Customers can explore different alternatives depending on their use cases: Amazon Console for SAP Applications, Tagging, Amazon Resource Groups, Amazon Resource Explorer, and, for observability use cases, Amazon CloudWatch Application Signals Application Map.

Is there a recommended tagging strategy or key naming convention to replace AppManager and awsApplication?

There is no single mandated tag key, giving customers the flexibility to select their own custom tag key for their use case. Common conventions include applications, projects, or workloads. The AppManager resource groups and `awsApplication` tags also remain usable for existing customers and do not need to be removed or replaced. In concert with this move of Application Manager to maintenance mode, `awsApplication` is also moving to maintenance mode.

If you have additional questions, contact us through the Amazon Support Center.

Topics

- Setting up related services
- Configuring permissions for Systems Manager Application Manager
- Adding applications and container clusters to Application Manager
- Working with applications

Setting up related services

Application Manager displays resources and information from other Amazon Web Services services and Systems Manager tools. To maximize the amount of operations information displayed in Application Manager, we recommend that you set up and configure these other services or tools *before* you use Application Manager.

Topics

- Set up tasks for importing resources
- Set up tasks for viewing operations information about resources

Set up tasks for importing resources

The following setup tasks help you view Amazon resources in Application Manager. After each of these tasks is completed, Systems Manager can automatically import resources into Application Manager. After your resources are imported, you can create applications in Application Manager and move your imported resources into them. This helps you view operations information in the context of an application.

(Optional) Organize your Amazon resources by using tags

You can assign metadata to your Amazon resources in the form of tags. Each tag is a label consisting of a user-defined key and value. Tags can help you manage, identify, organize, search for, and filter resources. You can create tags to categorize resources by purpose, owner, environment, or other criteria.

(Optional) Organizes your Amazon resources by using Amazon Resource Groups

You can use resource groups to organize your Amazon resources. Resource groups make it easier to manage, monitor, and automate tasks on many resources at one time.

Application Manager automatically imports all of your resource groups and lists them in the **Custom applications** category.

(Optional) Set up and deploy your Amazon resources by using Amazon CloudFormation

Amazon CloudFormation lets you create and provision Amazon infrastructure deployments predictably and repeatedly. It helps you use Amazon Web Services services such as Amazon EC2, Amazon Elastic Block Store (Amazon EBS), Amazon Simple Notification Service (Amazon SNS), Elastic Load Balancing, and Amazon Auto Scaling. With CloudFormation, you can build

reliable, scalable, cost-effective applications in the cloud without worrying about creating and configuring the underlying Amazon infrastructure.

Application Manager automatically imports all of your Amazon CloudFormation resources and lists them in the **Amazon CloudFormation stacks** category. You can create CloudFormation stacks and templates in Application Manager. Stack and template changes are automatically synchronized between Application Manager and CloudFormation. You can also create applications in Application Manager and move stacks into them. This helps you view operations information for resources in your stacks in the context of an application. For pricing information, see Amazon CloudFormation Pricing.

(Optional) Set up and deploy your applications by using Amazon Launch Wizard

Launch Wizard guides you through the process of sizing, configuring, and deploying Amazon resources for third-party applications without the need to manually identify and provision individual Amazon resources.

Application Manager automatically imports all of your Launch Wizard resources and lists them in the **Launch Wizard** category. For more information about Amazon Launch Wizard, see Getting started with Amazon Launch Wizard for SQL Server. Launch Wizard is available at no additional charge. You only pay for the Amazon resources that you provision to run your solution.

(Optional) Set up and deploy your containerized applications by using Amazon ECS and Amazon EKS

Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that makes it easy to run, stop, and manage containers on a cluster. Your containers are defined in a task definition that you use to run individual tasks or tasks within a service.

Amazon EKS is a managed service that helps you to run Kubernetes on Amazon without needing to install, operate, and maintain your own Kubernetes control plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

Application Manager automatically imports all of your Amazon ECS and Amazon EKS infrastructure resources and lists them on the **Container clusters** tab. However, you can't manage or view operations information about your Amazon EKS pods or containers in Application Manager. You can only manage and view operations information about the infrastructure that is hosting your Amazon EKS resources. For pricing information, see Amazon ECS Pricing and Amazon EKS Pricing.

Set up tasks for viewing operations information about resources

The following setup tasks help you view operations information about your Amazon resources in Application Manager.

(Recommended) Verify runbook permissions

You can remediate issues with Amazon resources from Application Manager by using Systems Manager Automation runbooks. To use this remediation tool, you must configure or verify permissions. For pricing information, see Amazon Systems Manager Pricing.

(Optional) Enable Cost Explorer

Amazon Cost Explorer is a feature of Amazon Cost Management that you can use to visualize your cost data for further analysis. When you enable Cost Explorer, you can view cost information, cost history, and cost optimization for your application's resources in the Application Manager console.

(Optional) Set up and configure Amazon CloudWatch logs and alarms

CloudWatch is a monitoring and management service that provides data and actionable insights for Amazon, hybrid, and multicloud applications and infrastructure resources. With CloudWatch, you can collect and access all your performance and operational data in the form of logs and metrics from a single platform. To view CloudWatch logs and alarms for your resources in Application Manager, you must set up and configure CloudWatch. For pricing information, see CloudWatch Pricing.

> **Note**
>
> CloudWatch Logs support applies to applications only, not to clusters.

(Optional) Set up and configure Amazon Config

Amazon Config provides a detailed view of the resources associated with your Amazon Web Services account, including how they're configured, how they're related to one another, and how the configurations and their relationships have changed over time. You can use Amazon Config to evaluate the configuration settings of your Amazon resources. You do this by creating Amazon Config rules, which represent your ideal configuration settings. While Amazon Config continually tracks the configuration changes that occur among your resources, it checks whether these changes violate any of the conditions in your rules. If a resource violates a rule,

Amazon Config flags the resource and the rule as *noncompliant*. Application Manager displays compliance information about Amazon Config rules. To view this data in Application Manager, you must set up and configure Amazon Config. For pricing information, see Amazon Config Pricing.

(Optional) Create State Manager associations

You can use Systems Manager State Manager to create a configuration that you assign to your managed nodes. The configuration, called an *association*, defines the state that you want to maintain on your nodes. To view association compliance data in Application Manager, you must configure one or more State Manager associations. State Manager is offered at no additional charge.

(Optional) Set up and configure OpsCenter

You can view operational work items (OpsItems) about your resources in Application Manager by using OpsCenter. You can configure Amazon CloudWatch and Amazon EventBridge to automatically send OpsItems to OpsCenter based on alarms and events. You can also enter OpsItems manually. For pricing information, see Amazon Systems Manager Pricing.

Configuring permissions for Systems Manager Application Manager

You can use all features of Application Manager if your Amazon Identity and Access Management (IAM) entity (such as a user, group, or role) has access to the API operations listed in this topic. The API operations are separated into two tables to help you understand the different functions they perform.

The following table lists the API operations that Systems Manager calls if you choose a resource in Application Manager because you want to view the resource details. For example, if Application Manager lists an Amazon EC2 Auto Scaling group, and if you choose that group to view its details, then Systems Manager calls the `autoscaling:DescribeAutoScalingGroups` API operations. If you don't have any Auto Scaling groups in your account, this API operation isn't called from Application Manager.

Note

You can restrict a user's ability to make changes to applications and resources in Application Manager by removing the following API operations from the IAM permissions policy attached to their user, group, or role. Removing these actions creates a read-only experience in Application Manager. The following are all of the APIs that allow users to make changes to the application or any other related resources.

```

```

For information about creating and editing IAM policies, see Creating IAM Policies in the *IAM User Guide*. For information about how to assign this policy to an IAM entity (such as a user, group, or role), see Adding and removing IAM identity permissions.

Adding applications and container clusters to Application Manager

Application Manager is a component of Amazon Systems Manager. In Application Manager, an *application* is a logical group of Amazon resources that you want to operate as a unit. This logical group can represent different versions of an application, ownership boundaries for operators, or developer environments, to name a few.

The first time you open Application Manager, the **What Application Manager can do for you** page displays. When you choose **Get started**, Application Manager automatically imports metadata about your resources that were created in other Amazon Web Services services or Systems Manager tools. Application Manager then displays those resources in a list grouped by predefined categories.

For **Applications**, the list includes the following:

- Amazon CloudFormation stacks
- Custom applications
- Amazon Launch Wizard applications
- AppRegistry applications
- Amazon SAP Enterprise Workload applications
- Amazon ECS clusters
- Amazon EKS clusters

After import is complete, you can view operations information for an application or a specific resource in these predefined categories. Or, if you want to provide more context about a collection of resources, you can manually create an application in Application Manager. You can then add resources or groups of resources into that application. After you create an application in Application Manager, you can view operations information about your resource in the context of an application.

Creating an application in Application Manager

Use the following procedure to create an application in Application Manager and add resources to that application.

To create an application in Application Manager

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. Choose choose **Create application**.
4. Choose an option from the drop-down list and complete the fields in the page that appears.

Working with applications

Application Manager is a component of Amazon Systems Manager. This section includes topics to help you work with Application Manager applications and view operations information about your Amazon resources.

Contents

- Application overview in Application Manager
- Managing your application EC2 instances
- Viewing resources associated with your application
- Managing your application compliance
- Using CloudWatch Application Insights to monitor an application
- Viewing OpsItems for an application
- Managing your application logs
- Use Automation runbooks to remediate application issues
- Tag resources in Application Manager

- Working with Amazon CloudFormation templates and stacks in Application Manager
- Working with clusters in Application Manager

Application overview in Application Manager

In Application Manager, a component of Amazon Systems Manager, the **Overview** tab displays a summary of Amazon CloudWatch alarms, operational work items (OpsItems), CloudWatch Application Insights, and runbook history. Choose **View all** for any card to open the corresponding tab where you can view all application insights, alarms, OpsItems, or runbook history.

About Application Insights

CloudWatch Application Insights identifies and sets up key metrics, logs, and alarms across your application resources and technology stack. Application Insights continuously monitors metrics and logs to detect and correlate anomalies and errors. When the system detects errors or anomalies, Application Insights generates CloudWatch Events that you can use to set up notifications or take actions. If you choose the **Edit configuration** button on the **Monitoring** tab, the system opens the CloudWatch Application Insights console. For more information about Application Insights, see What is Amazon CloudWatch Application Insights in the *Amazon CloudWatch User Guide*.

About Cost Explorer

Application Manager is integrated with Amazon Cost Explorer, a feature of Amazon Cost Management, through the **Cost** widget and **Cost** tab. After you enable Cost Explorer in the Cost Management console, the **Cost** widget and **Cost** tab in Application Manager shows cost data for a specific non-container application or application component. You can use filters in the widget, or tab, to view cost data according to different time periods, levels of granularity, and cost types in either a bar or line chart.

You can enable this feature by choosing the **Go to Amazon Cost Management console** button. By default, the data is filtered to the past three months. For a non-container application, if you choose the **View all** button, Application Manager opens the **Resources** tab. For container applications, the **View all** button opens the Amazon Cost Explorer console.

Actions you can perform on this page

You can turn on and access information about the following widgets on the **Overview** tab on this page. When a widget is enabled, choose its **View all** to see relevant application details for that area.

- In the **Insights and Alarms** section, choose the number for a severity to open the **Monitoring**, tab, where you can view more details about alarms of the chosen severity.
- In the **Cost** section, choose **View all** to open the **Resources** tab, where you can view cost data for a specific application or application component.
- In the **Compliance** section, choose **View all** to open the **Compliance** tab, where you can view compliance information from Amazon Config and State Manager associations.

> **Note**
>
> To view patch compliance details, choose the **Compliance** tab directly. Then you can view patch compliance details for the managed nodes used by the selected application.

- In the **Runbooks** section, choose a runbook to open it in the Systems Manager **Documents** page where you can view more details about the document.
- In the **OpsItems** section, choose a severity to open the **OpsItems** tab where you can view all OpsItems of the chosen severity.
- Choose a **View all** button to open the corresponding tab. You can view all alarms, OpsItems, or runbook history entries for the application.

To open the Overview tab

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.

Managing your application EC2 instances

Application Manager integrates with Amazon Elastic Compute Cloud (Amazon EC2) to display information about your instances in the context of an application. Application Manager displays instance state, status, and Amazon EC2 Auto Scaling health for a selected application in a graphical format. The **Instances** tab also includes a table with the following information for each instance in your application:

- Instance state (Pending, Stopping, Running, Stopped)
- Ping status for SSM Agent
- Status and name of the most recent Systems Manager Automation runbook processed on the instance
- A count of Amazon CloudWatch Logs alarms per state.
  - `ALARM` – The metric or expression is outside of the defined threshold.
  - `OK` – The metric or expression is within the defined threshold.
  - `INSUFFICIENT_DATA` – The alarm has just started, the metric is not available, or not enough data is available for the metric to determine the alarm state.
- Auto Scaling group health for the parent and individual autoscaling groups

If you choose an instance in the **All instances** table, Application Manager displays information about that instance on four tabs:

- **Details** – All of the instance details from Amazon EC2, including the Amazon Machine Image (AMI), DNS information, IP address information, and more.
- **Health** – The current status as provided by EC2 system and instance status checks.
- **Execution history** – Execution logs for Systems Manager Automation runbooks and API calls processed by the instance.
- **CloudWatch alarms** – The name, state, and more for any CloudWatch alarms raised by the instance.

Actions you can perform on this page

You can perform the following actions on this page:

- Start, stop, and terminate instances.
- Apply a Chef recipe.
- Attach instances to, or detach instances from, an Auto Scaling group.
- Enable automated updates for SSM Agent.

To open the Instances tab

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application that you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Instances** tab.

To view details for your application instances

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application that you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Instances** tab.
6. Select the button next to the instance whose details you want to view.
7. Review the instance details at the bottom of the page.

To automatically update SSM Agent

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application that you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Instances** tab.
6. In the **Agent actions** dropdown, choose **Configure SSM Agent update**.

7. Choose **All instances** to configure automatic SSM Agent updates for all managed instances. Alternatively, choose **Instance** to configure automation SSM Agent updates for a single instance in your application.
8. Select the **Enable automatic update** toggle.
9. In the **Specify schedule** dropdown, choose the schedule you want to use for SSM Agent updates.
10. Select **Configure**.

Viewing resources associated with your application

In Application Manager, a component of Amazon Systems Manager, the **Resources** tab displays the Amazon resources in your application. If you choose a top-level component, this page displays all resources for that component and any subcomponents. If you choose a subcomponent, this page shows only the resources assigned to that subcomponent.

Actions you can perform on this page

You can perform the following actions on this page:

- Choose a resource name to view information about it, including details provided by the console where it was created, tags, Amazon CloudWatch alarms, Amazon Config details, and Amazon CloudTrail log information.
- Choose the option button beside a resource name. Then, choose the **Resource timeline** button to open the Amazon Config console where you can view compliance information about a selected resource.
- If you enabled Amazon Cost Explorer, the **Cost Explorer** section shows cost data for a specific non-container application or application component. You can enable this feature by choosing the **Go to Amazon Cost Management console** button. Use the filters in this section to view cost information about your application.

To open the Resources tab

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.

3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Resources** tab.

Managing your application compliance

In Application Manager, a component of Amazon Systems Manager, the **Configurations** page displays Amazon Config resource and configuration rule compliance information. This page also displays Amazon Systems Manager State Manager association compliance information. You can choose a resource, a rule, or an association to open the corresponding console for more information. This page displays compliance information from the last 90 days.

Actions you can perform on this page

You can perform the following actions on this page:

- Choose a resource name to open the Amazon Config console where you can view compliance information about a selected resource.
- Choose the option button beside a resource name. Then, choose the **Resource timeline** button to open the Amazon Config console where you can view compliance information about a selected resource.
- In the **Config rules compliance** section, you can do the following:
  - Choose a rule name to open the Amazon Config console where you can view information about that rule.
  - Choose **Add rules** to open the Amazon Config console where you can create a rule.
  - Choose the option button beside a rule name, choose **Actions**, and then choose **Manage remediation** to change the remediation action for a rule.
  - Choose the option button beside a rule name, choose **Actions**, and then choose **Re-evaluate** to have Amazon Config run a compliance check on the selected rule.
- In the **Association compliance** section, you can do the following:
  - Choose an association name to open the **Associations** page where you can view information about that association.
  - Choose **Create association** to open Systems Manager State Manager where you can create an association.

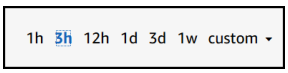
- Choose the option button beside an association name and choose **Apply association** to immediately start all actions specified in the association.

To open the Compliance tab

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Compliance** tab.

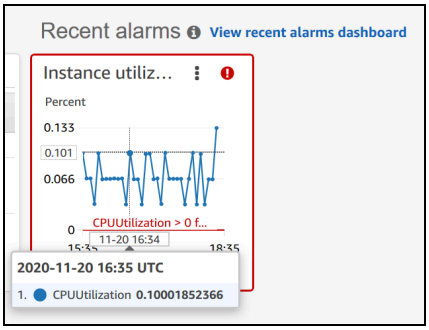
Using CloudWatch Application Insights to monitor an application

In Application Manager, a component of Amazon Systems Manager, the **Monitoring** tab displays Amazon CloudWatch Application Insights and alarm details for resources in an application.



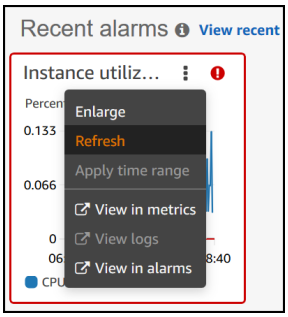
About Application Insights

CloudWatch Application Insights identifies and sets up key metrics, logs, and alarms across your application resources and technology stack. Application Insights continuously monitors metrics and logs to detect and correlate anomalies and errors. When the system detects errors or anomalies, Application Insights generates CloudWatch Events that you can use to set up notifications or take actions. If you choose the **Edit configuration** button on the **Monitoring** tab, the system opens the CloudWatch Application Insights console. For more information about Application Insights, see What is Amazon CloudWatch Application Insights in the *Amazon CloudWatch User Guide*.



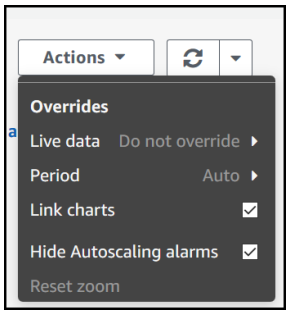
Actions you can perform on this page

You can perform the following actions on this page:



- Choose a service name in the **Alarms by Amazon service** section to open CloudWatch to the selected service and alarm.
- Adjust the time period for data displayed in widgets in the **Recent alarms** section by selecting one of the predefined time period values. You can choose **custom** to define your own time period.

- Hover your cursor over a widget in the **Recent alarms** section to view a data pop-up for a specific time.



- Choose the options menu in a widget to view display options. Choose **Enlarge** to expand a widget. Choose **Refresh** to update the data in a widget. Select a range in a widget data display to view a specific time range. You can then choose **Apply time range**.

- Choose the **Actions** menu to view alarm data **Override** options, which include the following:
  - Choose whether your widget displays live data. Live data is data published within the last minute that hasn't been fully aggregated. If live data is turned off, only data points with an aggregation period of at least one minute in the past are shown. For example, when using 5-minute periods, the data point for 12:35 would be aggregated from 12:35 to 12:40, and displayed at 12:41.

    If live data is turned on, the most recent data point is shown as soon as any data is published in the corresponding aggregation interval. Each time you refresh the display, the most recent data point might change as new data within that aggregation period is published.
  - Specify a time period for live data.
  - Link the charts in the **Recent alarms** section, so that when you zoom in or zoom out on one chart, the other chart zooms in or zooms out at the same time. You can unlink charts to limit zoom to one chart.

- Hide Auto Scaling alarms.

To open the Monitoring tab

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Monitoring** tab.

Viewing OpsItems for an application

In Application Manager, a component of Amazon Systems Manager, the **OpsItems** tab displays operational work items (OpsItems) for resources in the selected application. You can configure Systems Manager OpsCenter to automatically create OpsItems from Amazon CloudWatch alarms and Amazon EventBridge events. You can also manually create OpsItems.

Actions you can perform on this tab

You can perform the following actions on this page:

- Filter the list of OpsItems by using the search field. You can filter by OpsItem name, ID, source ID, or severity. You can also filter the list based on status. OpsItems support the following statuses: Open, In progress, Open and In progress, Resolved, or All.
- Change the status of an OpsItem by choosing the option button beside it and then choosing an option in the **Set status** menu.
- Open Systems Manager OpsCenter to create an OpsItem by choosing **Create OpsItem**.

To open the OpsItems tab

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **OpsItems** tab.

Managing your application logs

In Application Manager, a component of Amazon Systems Manager, the **Logs** tab displays a list of log groups from Amazon CloudWatch Logs.

Actions you can perform on this tab

You can perform the following actions on this page:

- Choose a log group name to open it in CloudWatch Logs. You can then choose a log stream to view logs for a resource in the context of an application.
- Choose **Create log groups** to create a log group in CloudWatch Logs.

To open the Logs tab

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Logs** tab.

Use Automation runbooks to remediate application issues

You can remediate issues with Amazon resources from Application Manager by using Automation runbooks. An Automation runbook defines the actions that Systems Manager performs on your

managed instances and other Amazon resources when an automation runs. Automation is a tool in Amazon Systems Manager. A runbook contains one or more steps that run in sequential order. Each step is built around a single action. Output from one step can be used as input in a later step.

When you choose **Start runbook** from an Application Manager application or cluster, the system displays a filtered list of available runbooks based on the type of resources in your application or cluster. When you choose the runbook you want to start, Systems Manager opens the **Execute automation document** page.

Application Manager includes the following enhancements for working with runbooks.

- If you choose the name of a resource in Application Manager and then choose **Execute runbook**, the system displays a filtered list of runbooks for that resource type.
- You can initiate an automation on all resources of the same type by choosing a runbook in the list and then choosing **Run for resources of same type**.

Before you begin

Before you start a runbook from Application Manager, do the following:

- Verify that you have the correct permissions for starting runbooks. For more information, see Setting up Automation.
- Review the Automation procedure documentation about starting runbooks. For more information, see Run an automated operation powered by Systems Manager Automation.

To start a runbook from Application Manager

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose **Start runbook**. Application Manager opens the **Automation widget** pop up. For information about the options in the **Automation widget**, see Run an automated operation powered by Systems Manager Automation.

Tag resources in Application Manager

You can quickly add or delete tags on applications and Amazon resources in Application Manager. Use the following procedure to add a tag to or delete a tag from an application and all Amazon resources in that application.

To add a tag to or delete a tag from an application and all resources in the application

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. In the **Application information** section, choose the number beneath **Application tags**. If no tags are assigned to the application, the number is zero.
6. To add a tag, choose **Add new tag**. Specify a key and an optional value. To delete a tag, choose **Remove**.
7. Choose **Save**.

Use the following procedure to add a tag to or delete a tag from a specific resource in Application Manager.

To add a tag to or delete a tag from a resource

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Applications** section, choose a category. If you want to open an application you created manually in Application Manager, choose **Custom applications**.
4. Choose the application in the list. Application Manager opens the **Overview** tab.
5. Choose the **Resources** tab.
6. Choose a resource name.
7. In the **Tags** section choose **Edit**.

8. To add a tag, choose **Add new tag**. Specify a key and an optional value. To delete a tag, choose **Remove**.
9. Choose **Save**.

Working with Amazon CloudFormation templates and stacks in Application Manager

Application Manager helps you provision and manage resources for your applications by integrating with Amazon CloudFormation. You can create, edit, and delete Amazon CloudFormation templates and stacks in Application Manager. A *stack* is a collection of Amazon resources that you can manage as a single unit. This means you can create, update, or delete a collection of Amazon resources by using CloudFormation stacks. A *template* is a formatted text file in JSON or YAML that specifies the resources you want to provision in your stacks.

Application Manager also includes a template library where you can clone, create, and store templates. Application Manager and CloudFormation display the same information about the current status of a stack. Templates and template updates are stored in Systems Manager until you provision the stack, at which time the changes are also displayed in CloudFormation.

After you create a stack in Application Manager, the **CloudFormation stacks** page displays helpful information about it. This includes the template used to create it, a count of OpsItems for resources in your stack, the stack status, and drift status.

About Cost Explorer

Application Manager is integrated with Amazon Cost Explorer, a feature of Amazon Cost Management, through the **Cost** widget. After you enable Cost Explorer in the Cost Management console, the **Cost** widget in Application Manager shows cost data for a specific non-container application or application component. You can use filters in the widget to view cost data according to different time periods, granularities, and cost types in either a bar or line chart.

You can enable this feature by choosing the **Go to Amazon Cost Management console** button. By default, the data is filtered to the past three months. For a non-container application, if you choose the **View all** button, Application Manager opens the **Resources** tab. For container applications, the **View all** button opens the Amazon Cost Explorer console.

> **Note**
>
> Cost Explorer uses tags to track your application costs. If your Amazon CloudFormation stack-based application isn't configured with the `AppManagerCFNStackKey` tag key,

Cost Explorer fails to present accurate cost data in Application Manager. When the `AppManagerCFNStackKey` tag key is not detected, you be prompted in the console to add the tag to your CloudFormation stack to enable cost tracking. Adding it maps the tag key to the Amazon Resource Name (ARN) of your stack and enables the **Cost** widget to display accurate cost data.

Important

Adding the `AppManagerCFNStackKey` tag will trigger a stack update. Any manual configurations that were performed after the stack was originally deployed will not be reflected after the user tag is added. For more information about resource update behaviors, see Update behaviors of stack resources in the *Amazon CloudFormation User Guide*

Before you begin

Use the following links to learn about CloudFormation concepts before you create, edit, or delete CloudFormation templates and stacks by using Application Manager.

- What is Amazon CloudFormation?
- Amazon CloudFormation best practices
- Learn template basics
- Working with Amazon CloudFormation stacks
- Working with Amazon CloudFormation templates
- Sample templates

Topics

- Using Application Manager to manage Amazon CloudFormation templates
- Using Application Manager to manage Amazon CloudFormation stacks

Using Application Manager to manage Amazon CloudFormation templates

Application Manager includes a template library and other tools to help you manage Amazon CloudFormation templates. This section includes the following information.

Topics

- Working with the template library
- Creating a template
- Editing a template

Working with the template library

The Application Manager template library provides tools to help you view, create, edit, delete, and clone templates. You can also provision stacks directly from the template library. Templates are stored as Systems Manager (SSM) documents of type `CloudFormation`. By storing templates as SSM documents, you can use version controls to work with different versions of a template. You can also set permissions and share templates. After you successfully provision a stack, the stack and template are available in Application Manager and CloudFormation.

Before you begin

We recommend that you read the following topics to learn more about SSM documents before you start working with CloudFormation templates in Application Manager.

- Amazon Systems Manager Documents
- Sharing SSM documents
- Best practices for shared SSM documents

To view the template library in Application Manager

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. Choose **CloudFormation Template Library**.

Creating a template

The following procedure describes how to create a CloudFormation template in Application Manager. When you create a template, you enter the stack details of the template in either JSON or YAML. If you're unfamiliar with JSON or YAML, you can use Amazon Infrastructure Composer, a tool for visually creating and modifying templates. For more information, see Create templates visually with Infrastructure Composer in the *Amazon CloudFormation User Guide*. For information about the

structure and syntax of a template, see Amazon CloudFormation template sections in the *Amazon CloudFormation User Guide*.

You can also construct a template from multiple template snippets. Template snippets are examples that demonstrate how to write templates for a particular resource. For example, you can view snippets for Amazon Elastic Compute Cloud (Amazon EC2) instances, Amazon Simple Storage Service (Amazon S3) domains, Amazon CloudFormation mappings, and more. Snippets are grouped by resource. You can find general-purpose Amazon CloudFormation snippets in the General template snippets section of the *Amazon CloudFormation User Guide*.

Creating a CloudFormation template in Application Manager (console)

Use the following procedure to create a CloudFormation template in Application Manager by using the Amazon Web Services Management Console.

To create a CloudFormation template in Application Manager

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. Choose **CloudFormation Template Library**, and then either choose **Create template** or choose an existing template and then choose **Actions**, **Clone**.
4. For **Name**, enter a name for the template that helps you identify the resources it creates or the purpose of the stack.
5. (Optional) For **Version name**, enter a name or a number to identity the template version.
6. In the **Code editor** section, choose either **YAML** or **JSON** and then either enter or copy and paste your template code.
7. (Optional) In the **Tags** section, apply one or more tag key name/value pairs to the template.
8. (Optional) In the **Permissions** section, enter an Amazon Web Services account ID and choose **Add account**. This action provides read permission to the template. The account owner can provision and clone the template, but they can't edit or delete it.
9. Choose **Create**. The template is saved in the Systems Manager (SSM) Document service.

Creating a CloudFormation template in Application Manager (command line)

After you create the content of your CloudFormation template in JSON or YAML, you can use the Amazon Command Line Interface (Amazon CLI) or Amazon Tools for PowerShell to save the

template as an SSM document. Replace each *example resource placeholder* with your own information.

Before you begin

Install and configure the Amazon CLI or the Amazon Tools for PowerShell if you have not already. For information, see Installing or updating the latest version of the Amazon CLI and Installing the Amazon Tools for PowerShell.

Linux & macOS

```
aws ssm create-document \
    --content file://path/to/template_in_json_or_yaml \
    --name "a_name_for_the_template" \
    --document-type "CloudFormation" \
    --document-format "JSON_or_YAML" \
    --tags "Key=tag-key,Value=tag-value"
```

Windows

```
aws ssm create-document ^
    --content file://C:\path\to\template_in_json_or_yaml ^
    --name "a_name_for_the_template" ^
    --document-type "CloudFormation" ^
    --document-format "JSON_or_YAML" ^
    --tags "Key=tag-key,Value=tag-value"
```

PowerShell

```
$json = Get-Content -Path "C:\path\to\template_in_json_or_yaml | Out-String
New-SSMDocument `
    -Content $json `
    -Name "a_name_for_the_template" `
    -DocumentType "CloudFormation" `
    -DocumentFormat "JSON_or_YAML" `
    -Tags "Key=tag-key,Value=tag-value"
```

If successful, the command returns a response similar to the following.

```
{
```

```
    "DocumentDescription": {
        "Hash": "c1d9640f15fbdba6deb41af6471d6ace0acc22f213bdd1449f03980358c2d4fb",
        "HashType": "Sha256",
        "Name": "MyTestCFTemplate",
        "Owner": "428427166869",
        "CreatedDate": "2021-06-04T09:44:18.931000-07:00",
        "Status": "Creating",
        "DocumentVersion": "1",
        "Description": "My test template",
        "PlatformTypes": [],
        "DocumentType": "CloudFormation",
        "SchemaVersion": "1.0",
        "LatestVersion": "1",
        "DefaultVersion": "1",
        "DocumentFormat": "YAML",
        "Tags": [
            {
                "Key": "Templates",
                "Value": "Test"
            }
        ]
    }
```

Editing a template

Use the following procedure to edit a CloudFormation template in Application Manager. Template changes are available in CloudFormation after you provision a stack that uses the updated template.

To edit a CloudFormation template in Application Manager

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. Choose **CloudFormation Template Library**
4. Choose a template, and then choose **Actions**, **Edit**. You can't change the name of a template, but you can change all other details.
5. Choose **Save**. The template is saved in the Systems Manager Document service.

Using Application Manager to manage Amazon CloudFormation stacks

Application Manager helps you provision and manage resources for your applications by integrating with Amazon CloudFormation. You can create, edit, and delete CloudFormation templates and stacks in Application Manager. A *stack* is a collection of Amazon resources that you can manage as a single unit. This means you can create, update, or delete a collection of Amazon resources by using CloudFormation stacks. A *template* is a formatted text file in JSON or YAML that specifies the resources you want to provision in your stacks. This section includes the following information.

Topics

- Creating a stack
- Updating a stack

Creating a stack

The following procedures describe how to create a CloudFormation stack by using Application Manager. A stack is based on a template. When you create a stack, you can either choose an existing template or create a new one. After you create the stack, the system immediately attempts to create the resources identified in the stack. After the system successfully provisions the resources, the template and the stack are available to view and edit in Application Manager and CloudFormation.

> **Note**
>
> There is no charge to use Application Manager to create a stack, but you are charged for Amazon resources created in the stack.

Creating a CloudFormation stack by using Application Manager (console)

Use the following procedure to create a stack by using Application Manager in the Amazon Web Services Management Console.

To create a CloudFormation stack

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.

2. In the navigation pane, choose **Application Manager**.
3. Choose **Create Application, CloudFormation Stack**.
4. In the **Prepare a template** section, choose an option. If you choose **Use an existing template**, you can use the tabs in the **Choose a template** section to locate the template you want. (If you choose one of the other options, complete the wizard to prepare a template.)
5. Select the button beside a template name, and then choose **Next**.
6. On the **Specify template details** page, verify the details of the template to make sure the process creates the resources you want.

   - (Optional) In the **Tags** section, apply one or more tag key name/value pairs to the template.
   - Tags are optional metadata that you assign to a resource. By using tags, you can categorize a resource in different ways, such as by purpose, owner, or environment.
   - Choose **Next**.
7. On the **Edit stack details** page, for **Stack name**, enter a name that helps you identify the resources created by the stack or its purpose.

   - The **Parameters** section includes all optional and required parameters specified in the template. Enter one or more parameters in each field.
   - (Optional) In the **Tags** section, apply one or more tag key name/value pairs to the stack.
   - (Optional) In the **Permissions** section, specify an Amazon Identity and Access Management (IAM) role name or an IAM Amazon Resource Name (ARN). The system uses the specified service role to create all resources specified in your stack. If you don't specify an IAM role, then Amazon CloudFormation uses a temporary session that the system generates from your user credentials. For more information about this IAM role, see Amazon CloudFormation service role in the *Amazon CloudFormation User Guide*.
   - Choose **Next**.
8. On the **Review and provision** page, review all the details of the stack. Choose an **Edit** button on this page to make change.
9. Choose **Provision stack**.

Application Manager displays the **CloudFormation stacks** page and the status of the stack creation and deployment. If CloudFormation fails to create and provision the stack, see the following topics in the *Amazon CloudFormation User Guide*.

- Stack status codes

- Troubleshooting Amazon CloudFormation

After your stack resources are provisioned and running, users can edit resources directly by using the underlying service that created the resource. For example, a user can use the Amazon Elastic Compute Cloud (Amazon EC2) console to update a server instance that was created as part of a CloudFormation stack. Some changes may be accidental, and some may be made intentionally to respond to time-sensitive operational events. Regardless, changes made outside of CloudFormation can complicate stack update or deletion operations. You can use drift detection or *drift status* to identify stack resources to which configuration changes have been made outside of CloudFormation management. For information about drift status, see Detecting unmanaged configuration changes to stacks and resources.

Creating a CloudFormation stack by using Application Manager (command line)

Use the following Amazon Command Line Interface (Amazon CLI) procedure to provision a stack by using a CloudFormation template that is stored as an SSM document in Systems Manager. Replace each *example resource placeholder* with your own information. For information about other Amazon CLI procedures for creating stacks, see Creating a stack in the *Amazon CloudFormation User Guide*.

Before you begin

Install and configure the Amazon CLI or the Amazon Tools for PowerShell if you have not already. For information, see Installing or updating the latest version of the Amazon CLI and Installing the Amazon Tools for PowerShell.

Linux & macOS

```
aws cloudformation create-stack \
    --stack-name a_name_for_the_stack \
    --template-url "ssm-doc://arn:aws-
cn:ssm:Region:account_ID:document/template_name" \
```

Windows

```
aws cloudformation create-stack ^
     --stack-name a_name_for_the_stack ^
     --template-url "ssm-doc://arn:aws-
cn:ssm:Region:account_ID:document/template_name" ^
```

PowerShell

```
New-CFNStack `
    -StackName "a_name_for_the_stack" `
    -TemplateURL "ssm-doc://arn:aws-cn:ssm:Region:account_ID:document/template_name"
 `
```

Updating a stack

You can deploy updates to a CloudFormation stack by directly editing the stack in Application Manager. With a direct update, you specify updates to a template or input parameters. After you save and deploy the changes, CloudFormation updates the Amazon resources according to the changes you specified.

You can preview the changes that CloudFormation will make to your stack before you update it by using change sets. For more information, see Updating stacks using change sets in the *Amazon CloudFormation User Guide*.

To update a CloudFormation stack in Application Manager

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. Select the radio button next to an application name, and then choose **Actions**, **Update stack**.
4. On the **Specify template source** page, choose one of the following options, and then choose **Next**.
   - Choose **Use the template code currently provisioned in the stack** to view a template. Choose a template version in the **Versions** list, and then choose **Next**.
   - Choose **Switch to a different template** to choose or create a new template for the stack.
5. After you finish making changes to the template, choose **Next**.
6. On the **Edit stack details** page, you can edit parameters, tags, and permissions. You can't change the stack name. Make your changes and choose **Next**.
7. On the **Review and provision** page, review all the details of the stack, and then choose **Provision stack**.

Working with clusters in Application Manager

This section includes topics to help you work with Amazon Elastic Container Service (Amazon ECS) and Amazon Elastic Kubernetes Service (Amazon EKS) container clusters in Application Manager, a component of Amazon Systems Manager.

Contents

- Working with Amazon ECS in Application Manager
- Working with Amazon EKS in Application Manager
- Working with runbooks for clusters

Working with Amazon ECS in Application Manager

With Application Manager, you can view and manage your Amazon Elastic Container Service (Amazon ECS) cluster infrastructure. Application Manager applies a tag to your Amazon ECS cluster using the Amazon Resource Name (ARN) of the cluster as the tag value. Application Manager provides a component runtime view of the compute, networking, and storage resources in a cluster.

> **Note**
>
> You can't manage or view operations information about your containers in Application Manager. You can only manage and view operations information about the infrastructure hosting your Amazon ECS resources.

Actions you can perform on this page

You can perform the following actions on this page:

- Choose **Manage cluster** to open the cluster in Amazon ECS.
- Choose **View all** to view a list of resources in your cluster.
- Choose **View in CloudWatch** to view resource alarms in Amazon CloudWatch.
- Choose **Manage nodes** or **Manage Fargate profiles** to view these resources in Amazon ECS.
- Choose a resource ID to view detailed information about it in the console where it was created.
- View a list of OpsItems related to your clusters.
- View a history of runbooks that have been run on your clusters.

To open an ECS cluster

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Container clusters** section, choose **ECS clusters**.
4. Choose a cluster in the list. Application Manager opens the **Overview** tab.

Working with Amazon EKS in Application Manager

Application Manager integrates with Amazon Elastic Kubernetes Service (Amazon EKS) to provide information about the health of your Amazon EKS cluster infrastructure. Application Manager applies a tag to your Amazon EKS cluster using the Amazon Resource Name (ARN) of the cluster as the tag value. Application Manager provides a component runtime view of the compute, networking, and storage resources in a cluster.

> **Note**
>
> You can't manage or view operations information about your Amazon EKS pods or containers in Application Manager. You can only manage and view operations information about the infrastructure hosting your Amazon EKS resources.

Actions you can perform on this page

You can perform the following actions on this page:

- Choose **Manage cluster** to open the cluster in Amazon EKS.
- Choose **View all** to view a list of resources in your cluster.
- Choose **View in CloudWatch** to view resource alarms in Amazon CloudWatch.
- Choose **Manage nodes** or **Manage Fargate profiles** to view these resources in Amazon EKS.
- Choose a resource ID to view detailed information about it in the console where it was created.
- View a list of OpsItems related to your clusters.
- View a history of runbooks that have been run on your clusters.

To open an EKS clusters application

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Container clusters** section, choose **EKS clusters**.
4. Choose a cluster in the list. Application Manager opens the **Overview** tab.

Working with runbooks for clusters

You can remediate issues with Amazon resources from Application Manager, a tool in Amazon Systems Manager, by using Systems Manager Automation runbooks. When you choose **Start runbook** from an Application Manager cluster, the system displays a filtered list of runbooks based on the type of resources in your cluster. When you choose the runbook you want to start, Systems Manager opens the **Execute automation document** page.

Before you begin

Before you start a runbook from Application Manager, do the following:

- Verify that you have the correct permissions for starting runbooks. For more information, see Setting up Automation.
- Review the Automation procedure documentation about starting runbooks. For more information, see Run an automated operation powered by Systems Manager Automation.
- If you intend to start runbooks on multiple resources at one time, review the documentation about using targets and rate controls. For more information, see Run automated operations at scale.

To start a runbook for clusters from Application Manager

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Application Manager**.
3. In the **Container clusters** section, choose a container type.
4. Choose the cluster in the list. Application Manager opens the **Overview** tab.

5. On the **Runbooks** tab, choose **Start runbook**. Application Manager opens the **Execute automation document** page in a new tab. For information about the options in the **Execute automation document** page, see Run an automated operation powered by Systems Manager Automation.

Amazon Systems Manager Parameter Store

Parameter Store is a centralized configuration data store for named values called parameters. A *parameter* is any piece of data stored in Parameter Store, such as a block of text, a list of names, an AMI ID, a license key, and so on. With Parameter Store, you can securely store, organize, and retrieve configuration data at scale.

Parameter Store simplifies configuration management across environments. You can standardize how applications access critical data at runtime without hardcoding values or relying on fragmented storage solutions. In this way, you maintain consistency, enforce governance, and build more secure and maintainable systems.

Parameter Store supports the following parameter types:

- `String`

  Use this type for plain text values, such as environment names, endpoint URLs, or resource identifiers.

- `StringList`

  Use this type for a comma-separated list of plain-text values. For example, you could store the value `subnet-123abc,subnet-456def,subnet-789ghi`.

- `SecureString`

  Use `SecureString` for configuration values that require encryption, such as service endpoints and account identifiers. For secrets such as database credentials, API keys, or tokens, we recommend Amazon Secrets Manager, which provides purpose built security controls including automatic rotation and cross-region replication.

  Parameter Store encrypts the values using Amazon Key Management Service.

For more information about parameter types, see Parameter Store reference.

Where should I store my application data?

Use the following table to choose a service for your application data.

> **Note**
>
> If you manage credentials such as usernames, passwords, or any other secrets, we recommend using Amazon Secrets Manager. Secrets Manager is purpose-built for managing secrets such as database credentials, API keys, and supported third-party software-vended secrets. For more information, see What is Amazon Secrets Manager? in the *Amazon Secrets Manager User Guide*.

Feature	Parameter Store	Amazon AppConfig	Amazon Secrets Manager
Use cases	• Static configuration • Key-value storage without deployment, with optional validation by data type. For more information, see Parameter data types in Parameter Store.	• Frequently changed application configuration • Zero-downtime deployments • Runtime experiments	• Credentials or any other secrets • Encrypted data requiring automatic rotation, cross-account access, or fine-grained audit logging
Typical data	• Approved AMI IDs • Environment variables • Endpoint URLs • Resource identifiers • Tuning parameters	• Feature flags • Operational toggles • Tunable parameters • Allow and deny lists	• Database credentials • API keys • OAuth tokens • Private keys and certificates
Encryption	Optional with `SecureString` and Amazon KMS	Amazon managed encryption at rest;	Amazon KMS encryption at rest with an

Feature	Parameter Store	Amazon AppConfig	Amazon Secrets Manager
		optional additional customer managed key	Amazon managed or customer managed key
Credential rotation	None	Not applicable	Automatic, with native database integrations
Cost	Standard tier free; advanced tier and higher throughput billed	Billed per configuration request	Billed per secret per month and per API call
Deployment	Versioning and value validation by data type, without gradual rollout or automatic rollback	Gradual rollout, pre-deployment validation, and automatic rollback on Amazon CloudWatch alarms	Versioning with staging labels

Parameter Store features

Parameter Store supports the following features:

- **Centralized configuration updates**

  Update your configuration without code changes or redeployments, improving operational agility and reducing risk. For example, you can update /myapp/prod/inventory-service-endpoint to point to a new endpoint after migrating the inventory service.

  > **Note**
  >
  > A parameter update takes effect on the next read. Parameter Store doesn't roll out the update gradually or revert it automatically, and it validates the new value only against the parameter's data type and any allowed pattern. For more information about data types, see Parameter data types in Parameter Store.
  > For configuration where a bad value could cause an outage, Amazon AppConfig adds a managed deployment workflow. It validates the change (using JSON Schema or Lambda),

rolls it out gradually, and monitors your Amazon CloudWatch alarms. If an alarm goes into the ALARM state, Amazon AppConfig automatically rolls back the change (this requires the necessary IAM permissions). See Working with deployment strategies.

- **High-performance throughput option**

  Parameter Store provides a default throughput suitable for lower-scale workloads. For large or latency-sensitive applications that need higher request rates, you can enable high-throughput mode for an additional cost.

  If your application retrieves parameters frequently or at scale, evaluate throughput settings early to avoid throttling. For information about enabling high throughput, see Managing Parameter Store throughput.

- **Hierarchical parameter management**

  Use parameter hierarchies to group related parameters, making it easier to discover, manage, and filter them across environments and applications. For example, you can create the naming convention /env/computer-type/app/data, and then create application-specific parameters such as /dev/webserver/linux/approved-ami and /dev/webserver/windows/approved-ami. You can retrieve the path /dev/webserver to find all web server parameters for development environments, or /dev/webserver/linux to find only Linux image parameters.

- **Versioning**

  Parameter Store retains the 100 most recent versions of each parameter. When you investigate operational issues, you can review and reconstruct previous values.

- **Integration with IAM**

  Use IAM policies to determine whether an application can read, write, list, or delete parameters. For example, you could write an application role that can read parameters prefixed with /myapp/prod/* but not /myapp/dev/*. You could also grant a role permission to decrypt an encrypted parameter.

- **Accessibility from other Amazon Web Services services**

  You can reference parameter values from other Amazon services. Here are some examples:

  - Lambda functions can retrieve parameters and secrets using the Parameters and Secrets Lambda Extension.

- Amazon Elastic Container Service and Amazon Fargate allow you to inject environmental variables whose values are managed centrally in Parameter Store.

  > **Note**
  >
  > Environment variables from Parameter Store are resolved when a task starts. A running task needs a new task or a forced deployment to pick up a changed value. For configuration that should update without replacing tasks, run the Amazon AppConfig Agent as an additional container to serve the latest values to your application. For secrets, use Amazon Secrets Manager. See What is Amazon AppConfig Agent?

- Amazon CloudFormation templates can reference parameter values.
- With Amazon AppConfig, you can create configuration profiles that reference a parameter in Parameter Store, adding deployment safety (gradual rollout, validation, and automatic rollback on a configured Amazon CloudWatch alarm) while Parameter Store remains your source.
- Amazon CodeBuild lets you define environmental variables whose values are dynamically retrieved from Parameter Store at build time.

- **Shared account access**

  Centralize configuration data in a single Amazon Web Services account and share parameters with other accounts that need access. For more information, see Working with shared parameters in Parameter Store.

- **OS patching**

  Amazon EC2 lets you specify the operating system for new instances by referencing a parameter instead of hardcoding an AMI (AMI) ID. This approach ensures your instances automatically use the latest patched and updated images. Amazon and operating system vendors provide public parameters that track current AMI versions, so you don't have to manage updates manually. You can also define your own parameters to reference a centrally managed golden AMI, making it easier to enforce consistent, approved configurations across your organization.

- **Events and notifications**

  Automate workflows in Parameter Store by subscribing to parameter change events. You can also use change events to enforce expiration and receive notifications when a parameter hasn't been rotated within a specified timeframe.

Parameter tiers in Parameter Store

Parameter Store offers different parameter tiers that control storage limits: the maximum number and size of your parameters in an Amazon account and Region. Configure each parameter individually to use either the standard tier or advanced tier.

You can mix standard and advanced parameters. For example, you can have up to 100,000 advanced parameters and 10,000 standard parameters in the same Amazon account and Region. The following table describes the different features supported for each parameter type.

The following table describes the differences between parameter tiers.

Feature or use case	Standard	Advanced
Use case	Best for most configuration data and low-scale workloads. This is the default.	Best when you need higher limits, larger values, or parameter policies.
Maximum parameters (per Amazon Web Services account and Amazon Web Services Region)	10,000	100,000
Maximum value size	4 KB	8 KB
Parameter policies	Not supported	Supported For more information, see Assigning parameter policies in Parameter Store.
Shareability across Amazon Web Services accounts	Not supported	Supported For more information, see Working with shared parameters in Parameter Store.

Feature or use case	Standard	Advanced
Data types	All data types except `url`, `json`, and `jsonc`	All data types For more information, see Parameter data types in Parameter Store.
Upgrade and downgrade capability	Upgradeable	Not downgradeable
Cost	No additional charge	Charges apply For more information, see Amazon Systems Manager Pricing for Parameter Store.

Use standard parameters for most configuration data. Use advanced parameters only when you need capabilities that standard parameters don't support.

For a detailed comparison of standard and advanced parameters, see Choosing parameter tiers.

Getting started with Parameter Store

In this tutorial, you learn how to create, retrieve, update, and delete Parameter Store parameters by using the Amazon CLI. The examples use a fictional application named `myapp`, the `dev` environment, account `111122223333`, and the `us-east-1` Region.

Prerequisites

Before you begin, make sure you have the following:

- An Amazon account.
- A place to run Amazon CLI commands. You can use Amazon CloudShell, a local client with the Amazon CLI installed and configured, or an Amazon EC2 instance that has the Amazon CLI installed.
- IAM permissions to create, retrieve, update, and delete Parameter Store parameters. For this tutorial, the principal running the commands needs IAM permissions such as `ssm:PutParameter`, `ssm:GetParameter`, `ssm:GetParameters`,

`ssm:GetParametersByPath`, `ssm:DeleteParameter`, and `ssm:DeleteParameters`. For more information, see Managing access to Parameter Store parameters using IAM policies

- Amazon KMS permissions if you create or retrieve `SecureString` parameters encrypted with a customer managed key. If you use the default Amazon managed key for Parameter Store, separate Amazon KMS permissions aren't required.

Step 1: Create a parameter

Run the `put-parameter` command to create a `String` parameter named `/myapp/dev/log-level` with the value `INFO`. Because you don't specify a tier in this example, Parameter Store creates this parameter in the default standard tier.

```
aws ssm put-parameter \
    --region us-east-1 \
    --name "/myapp/dev/log-level" \
    --type "String" \
    --value "INFO"
```

Step 2: Retrieve the parameter value

Run the get-parameter command to retrieve the value of a single parameter. The following example retrieves the value of the `/myapp/dev/log-level` parameter.

```
aws ssm get-parameter \
    --region us-east-1 \
    --name "/myapp/dev/log-level"
```

The following sample output prints the value of the parameter and related metadata.

```
{
    "Parameter": {
        "Name": "/myapp/dev/log-level",
        "Type": "String",
        "Value": "INFO",
        "Version": 1,
```

```
        "LastModifiedDate": "2026-06-25T17:20:26.517000+00:00",
        "ARN": "arn:aws:ssm:us-east-1:111122223333:parameter/myapp/dev/log-level",
        "DataType": "text"
    }
}
```

Step 3: Create a StringList parameter

Run the following command to create a `StringList` parameter named `/myapp/dev/subnet-ids` with three comma-separated subnet IDs.

```
aws ssm put-parameter \
    --region us-east-1 \
    --name "/myapp/dev/subnet-ids" \
    --type "StringList" \
    --value "subnet-123abc,subnet-456def,subnet-789ghi"
```

Step 4: Retrieve multiple parameters

Run the get-parameters command to specify up to 10 parameters in a list. The following example specifies the `/myapp/dev/log-level` and `/myapp/dev/subnet-ids` parameters by name.

```
aws ssm get-parameters \
    --region us-east-1 \
    --names "/myapp/dev/log-level" "/myapp/dev/subnet-ids"
```

Step 5: Create an encrypted parameter

Use `SecureString` for configuration values that require encryption, such as service endpoints and account identifiers. For secrets such as database credentials, API keys, or tokens, we recommend Amazon Secrets Manager, which provides purpose built security controls including automatic rotation and cross-region replication.

Run the following command to create a `SecureString` parameter named `/myapp/dev/vendor/merchant-id` with the encrypted value `merchant-739482`.

```
aws ssm put-parameter \
    --region us-east-1 \
    --name "/myapp/dev/vendor/merchant-id" \
    --type "SecureString" \
    --value "merchant-739482"
```

Note

If you manage credentials such as usernames, passwords, or any other secrets, we recommend using Amazon Secrets Manager. Secrets Manager is purpose-built for managing secrets such as database credentials, API keys, and supported third-party software-vended secrets. For more information, see What is Amazon Secrets Manager? in the *Amazon Secrets Manager User Guide*.

Run the following command to see what happens when you retrieve a `SecureString` value without decrypting it.

```
aws ssm get-parameter \
    --region us-east-1 \
    --name "/myapp/dev/vendor/merchant-id"
```

The output shows that encrypted value, not the plaintext.

```
{
    "Parameter": {
        "Name": "/myapp/dev/vendor/merchant-id",
        "Type": "SecureString",
        "Value": "AQICAHh1cV16RSGzfLARDIKV0croMvax6aMUDP1thWREL5ToawG6q+Xj8K...==",
        "Version": 1,
        "LastModifiedDate": "2026-06-25T17:27:56.401000+00:00",
        "ARN": "arn:aws:ssm:us-east-1:111122223333:parameter/myapp/dev/vendor/merchant-
id",
        "DataType": "text"
    }
}
```

Run the following command to retrieve the plaintext value of the `/myapp/dev/vendor/merchant-id` parameter. The `--with-decryption` option tells Parameter Store to return the decrypted value.

```
aws ssm get-parameter \
    --region us-east-1 \
    --name "/myapp/dev/vendor/merchant-id" \
    --with-decryption
```

The following output shows the plaintext value.

```
{
    "Parameter": {
        "Name": "/myapp/dev/vendor/merchant-id",
        "Type": "SecureString",
        "Value": "merchant-739482",
        "Version": 1,
        "LastModifiedDate": "2026-06-25T17:27:56.401000+00:00",
        "ARN": "arn:aws:ssm:us-east-1:111122223333:parameter/myapp/dev/vendor/merchant-
id",
        "DataType": "text"
    }
}
```

Step 6: Update a parameter

Run the following command to update the value of the `/myapp/dev/log-level` parameter from `INFO` to `DEBUG`. The `--overwrite` option allows the command to replace the existing value.

```
aws ssm put-parameter \
    --region us-east-1 \
    --name "/myapp/dev/log-level" \
    --type "String" \
    --value "DEBUG" \
    --overwrite
```

Parameter Store creates a new version of the parameter each time you update it, as shown in the output.

```
{
    "Version": 2,
    "Tier": "Standard"
}
```

Run the get-parameter-history command to view the history of the `/myapp/dev/log-level` parameter.

```
aws ssm get-parameter-history \
    --region us-east-1 \
    --name "/myapp/dev/log-level"
```

The response includes previous versions of the parameter, including the version number, value, type, and last modified date.

```
{
    "Parameters": [
        {
            "Name": "/myapp/dev/log-level",
            "Type": "String",
            "Value": "INFO",
            "Version": 1,
            "LastModifiedDate": "2026-06-25T15:30:00.000000-04:00",
            "DataType": "text"
        },
        {
            "Name": "/myapp/dev/log-level",
            "Type": "String",
            "Value": "DEBUG",
            "Version": 2,
            "LastModifiedDate": "2026-06-25T15:35:00.000000-04:00",
            "DataType": "text"
        }
    ]
}
```

Step 7: Retrieve parameters by path

Run the get-parameters-by-path command to retrieve parameters under the `/myapp/dev/` path. The `--recursive` option includes parameters in lower levels of the hierarchy.

```
aws ssm get-parameters-by-path \
    --region us-east-1 \
    --path "/myapp/dev/" \
    --recursive
```

The output shows both parameters that you created. The `SecureString` parameter is encrypted.

```
{
    "Parameters": [
        {
            "Name": "/myapp/dev/log-level",
            "Type": "String",
            "Value": "DEBUG",
            "Version": 2,
            "LastModifiedDate": "2026-06-25T17:35:39.184000+00:00",
            "ARN": "arn:aws:ssm:us-east-1:111122223333:parameter/myapp/dev/log-level",
            "DataType": "text"
        },
        {
            "Name": "/myapp/dev/vendor/merchant-id",
            "Type": "SecureString",
            "Value": "AQICAHh1cV16RSGzfLARDIKV0croMvax6aMUDP1thWREL5ToawG6q+Xj8K...==",
            "Version": 1,
            "LastModifiedDate": "2026-06-25T17:27:56.401000+00:00",
            "ARN": "arn:aws:ssm:us-east-1:111122223333:parameter/myapp/dev/vendor/
merchant-id",
            "DataType": "text"
        }
    ]
}
```

Run the following command to retrieve parameters under the `/myapp/dev/` path and return decrypted values for any `SecureString` parameters that the principal is authorized to decrypt.

```
aws ssm get-parameters-by-path \
    --region us-east-1 \
    --path "/myapp/dev/" \
    --recursive \
    --with-decryption
```

Step 8: Delete a parameter

Run the following command to delete the `/myapp/dev/log-level` parameter.

```
aws ssm delete-parameter \
    --region us-east-1 \
    --name "/myapp/dev/log-level"
```

Clean up

Run the following command to delete the remaining example parameters.

```
aws ssm delete-parameters \
    --region us-east-1 \
    --names "/myapp/dev/subnet-ids" "/myapp/dev/vendor/merchant-id"
```

Next steps

After you create your first parameters, consider the following next steps:

- Define a naming convention for applications, environments, and teams. For more information, see https://docs.amazonaws.cn/systems-manager/latest/userguide/sysman-paramstore-hierarchies.html#ps-hierarchy-examples.
- Use IAM policies to control who can read or update each parameter path.
- Use `SecureString` for configuration values that require encryption, such as service endpoints and account identifiers. For secrets such as database credentials, API keys, or tokens, we recommend Amazon Secrets Manager, which provides purpose built security controls including automatic rotation and cross-region replication.
- Use `Amazon AppConfig` for feature flags and dynamic application configuration.

> **Note**
>
> For feature flags and configuration that changes at runtime, Amazon AppConfig extends Parameter Store with several deployment safety features. These include validation

before deployment (JSON Schema or Lambda), gradual rollouts, automatic rollback on a configured Amazon CloudWatch alarm, and local caching through the Amazon AppConfig Agent. To learn more, see What is Amazon AppConfig?

Setting up Parameter Store

Before setting up parameters in Parameter Store, configure Amazon Identity and Access Management (IAM) policies that provide principals in your account with permission to perform the actions you specify.

In this section, you learn how to manually configure these policies using the IAM console, and how to assign them to users and user groups. You can also create and assign policies to control which parameter actions can be run on a managed node.

This section also explains how to create Amazon EventBridge rules that let you receive notifications about changes to Systems Manager parameters. You can use EventBridge rules to invoke other actions in Amazon based on changes in Parameter Store.

Contents

- Managing access to Parameter Store parameters using IAM policies
- Choosing parameter tiers in Parameter Store
- Managing Parameter Store throughput
- Setting up notifications or triggering actions based on Parameter Store events

Managing access to Parameter Store parameters using IAM policies

The IAM principal that accesses Amazon Systems Manager parameters must have permission to perform the required SSM actions. The principal can be an IAM user, IAM role, Amazon EC2 instance profile, Lambda execution role, Amazon ECS task role, CodeBuild service role, or another Amazon service role.

The following table describes the IAM permissions required for different Parameter Store actions.

Action	Required IAM privilege	Reference information
Create or update a parameter	`ssm:PutParameter`	PutParameter

Action	Required IAM privilege	Reference information
Retrieve one parameter	`ssm:GetParameter`	GetParameter
Retrieve multiple named parameters	`ssm:GetParameters`	GetParameters
Retrieve parameters under a path	`ssm:GetParametersByPath`	GetParametersByPath
View parameter metadata	`ssm:DescribeParameters`	DescribeParameters
View parameter version history	`ssm:GetParameterHistory`	GetParameterHistory
Delete one parameter	`ssm:DeleteParameter`	DeleteParameter
Delete multiple parameters	`ssm:DeleteParameters`	DeleteParameters

When using IAM policies to grant access to Systems Manager parameters, we recommend that you create and use *restrictive* IAM policies. For example, the following policy allows a principal to call the `DescribeParameters` and `GetParameters` API operations for a limited set of resources. The principal can get information about and use all parameters that begin with `prod-*`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:DescribeParameters"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
```

```
            "Action": [
                "ssm:GetParameters"
            ],
            "Resource": "arn:aws-cn:ssm:us-east-1:111122223333:parameter/prod-*"
        }
    ]
}
```

Note

The preceding policy allows `ssm:GetParameters` but not the other retrieval actions. Parameter Store authorizes each retrieval operation against its own IAM action, so allowing or denying one action doesn't affect the others. Before you rely on a policy to restrict which parameters a principal can read, see How Parameter Store authorizes parameter retrieval and Restricting access to specific parameters and paths.

Important

Parameter Store authorizes the `GetParametersByPath` operation against the path that you specify in the request, not against each parameter that the operation returns. A principal who is allowed to call `GetParametersByPath` for the path `/a` receives every parameter under that path, including `/a/b`. This is true even if the same policy explicitly denies access to `/a/b` for other actions.

To prevent a parameter from being returned by `GetParametersByPath`, deny the `ssm:GetParametersByPath` action on every ancestor path that could include the parameter in its results. For example, to prevent `/a/b` from being returned, deny `ssm:GetParametersByPath` for both `/a` and `/`.

For trusted administrators, you can provide access to all Systems Manager parameter API operations by using a policy similar to the following example. This policy gives the user full access to all production parameters that begin with `dbserver-prod-*`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:PutParameter",
                "ssm:DeleteParameter",
                "ssm:GetParameterHistory",
                "ssm:GetParametersByPath",
                "ssm:GetParameters",
                "ssm:GetParameter",
                "ssm:DeleteParameters"
            ],
            "Resource": "arn:aws-cn:ssm:us-east-1:111122223333:parameter/
dbserver-prod-*"
        },
        {
            "Effect": "Allow",
            "Action": "ssm:DescribeParameters",
            "Resource": "*"
        }
    ]
}
```

Denying permissions

Each API is unique and has distinct operations and permissions that you can allow or deny individually. An explicit deny in any policy overrides the allow.

> **Important**
>
> Because each operation is authorized against its own IAM action, denying a single action doesn't prevent a principal from retrieving the same parameter through another operation. For example, denying `ssm:GetParameter` alone has no effect on `ssm:GetParameters`, `ssm:GetParameterHistory`, or `ssm:GetParametersByPath`. Always deny every action

that can return the value. For a complete description of this behavior, see How Parameter Store authorizes parameter retrieval.

Note

The default Amazon Key Management Service (Amazon KMS) key has `Decrypt` permission for all IAM principals within the Amazon Web Services account. If you want different access levels to `SecureString` parameters in your account, we don't recommend that you use the default key. Restricting `kms:Decrypt` on a customer managed key prevents decryption of a `SecureString` value through any retrieval operation. For more information, see Restricting decryption of `SecureString` parameter values.

All four retrieval action names begin with `GetParameter`, so the single entry `ssm:GetParameter*` covers `ssm:GetParameter`, `ssm:GetParameters`, `ssm:GetParameterHistory`, and `ssm:GetParametersByPath`. The following example uses this pattern to deny all four actions for all parameters beginning with `prod-*`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "ssm:GetParameter*"
            ],
            "Resource": "arn:aws-cn:ssm:us-east-1:111122223333:parameter/prod-*"
        }
    ]
}
```

Note

In the preceding example, the deny on `ssm:GetParametersByPath` applies only to calls that *request* a path matching `prod-*`. It doesn't prevent a `prod-*` parameter

from being returned by a call that requests an ancestor path. To close that gap, deny `ssm:GetParametersByPath` on the ancestor paths as well. For more information, see Restricting access to specific parameters and paths.

The following example shows how to deny some commands while allowing the user to perform other commands on all parameters that begin with `prod-*`.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "ssm:PutParameter",
                "ssm:DeleteParameter",
                "ssm:DeleteParameters",
                "ssm:DescribeParameters"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetParametersByPath",
                "ssm:GetParameters",
                "ssm:GetParameter",
                "ssm:GetParameterHistory"
            ],
            "Resource": "arn:aws-cn:ssm:us-east-1:111122223333:parameter/prod-*"
        }
    ]
}
```

Note

The parameter history includes all parameter versions, including the current one. Therefore, if a user is denied permission for `GetParameter`, `GetParameters`, and

GetParametersByPath but is allowed permission for GetParameterHistory, they can see the current parameter, including SecureString parameters, using GetParameterHistory.

The same behavior applies to deletion. ssm:DeleteParameters is authorized independently of ssm:DeleteParameter, so denying only ssm:DeleteParameter doesn't prevent a principal from deleting the parameter with the DeleteParameters operation. Deny both actions, or use the pattern ssm:DeleteParameter*.

Encrypting and decrypting parameters using Amazon KMS keys

Parameter Store SecureString parameters use Amazon KMS keys for encryption. Amazon KMS encrypts the value by using either an Amazon managed key or a customer managed key. For more information about Amazon KMS and Amazon KMS key, see the *Amazon Key Management Service Developer Guide*.

All users within the customer account have access to the default Amazon managed key. You can locate the Amazon Resource Name (ARN) of the default key in the Amazon KMS console on the Amazon managed keys page. The default key is identified with aws/ssm in the **Alias** column. You might want to use the default key to encrypt SecureString parameters while preventing users from working with SecureString parameters. In this case, the IAM policies must explicitly deny access to the default key, as demonstrated in the following policy example.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": [
                "arn:aws-cn:kms:us-east-1:111122223333:key/abcd1234-ab12-cd34-
ef56-abcdeEXAMPLE"
            ]
```

```
        }
    ]
}
```

When using a customer managed key, the IAM policy that grants a principal access to a parameter or parameter path must provide explicit `kms:Encrypt` permissions for the key. For example, the following policy allows a principal to create, update, and view `SecureString` parameters that begin with `prod-` in the specified Amazon Web Services Region and Amazon Web Services account.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:PutParameter",
                "ssm:GetParameter",
                "ssm:GetParameters"
            ],
            "Resource": [
                "arn:aws-cn:ssm:us-east-1:111122223333:parameter/prod-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt",
                "kms:Encrypt",
                "kms:GenerateDataKey"
            ],
            "Resource": [
                "arn:aws-cn:kms:us-
east-1:111122223333:key/1234abcd-12ab-34cd-56ef-12345EXAMPLE"
            ]
        }
    ]
}
```

> **Note**
>
> The `kms:GenerateDataKey` permission is required for creating encrypted advanced parameters using the specified customer managed key.

If you require fine-grained access control over the `SecureString` parameters in your account, use a customer managed key to protect and restrict access to these parameters. We also recommend using Amazon CloudTrail to monitor `SecureString` parameter activities.

For more information, see the following topics:

- Policy evaluation logic in the *IAM User Guide*
- Using key policies in Amazon KMS in the *Amazon Key Management Service Developer Guide*
- Viewing events with CloudTrail Event history in the *Amazon CloudTrail User Guide*

Allowing managed nodes to access specific parameters

To control which Parameter Store parameters a managed node can retrieve, you can attach an IAM policy to the instance role. If you choose the `SecureString` parameter type when you create your parameter, Systems Manager uses Amazon KMS to encrypt the parameter value. You can view the Amazon managed key by running the following command from the Amazon CLI.

```
aws kms describe-key --key-id alias/aws/ssm
```

The following example allows nodes to get a parameter value only for parameters that begin with `prod-`. If the parameter is a `SecureString` parameter, then the node decrypts the string using Amazon KMS.

> **Note**
>
> Instance policies, like in the following example, are assigned to the instance role in IAM. For more information about configuring access to Systems Manager features, including how to assign policies to users and instances, see Managing EC2 instances with Systems Manager.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetParameters"
            ],
            "Resource": [
                "arn:aws-cn:ssm:us-east-1:111122223333:parameter/prod-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
            "Resource": [
                "arn:aws-cn:kms:us-east-1:111122223333:key/4914ec06-e888-4ea5-
a371-5b88eEXAMPLE"
            ]
        }
    ]
}
```

Choosing parameter tiers in Parameter Store

To control parameter storage attributes, Parameter Store includes *standard parameters* and *advanced parameters*. You configure each parameter individually for an account and Region. The parameter tier determines the maximum size of a parameter value, the number of parameters in a specific tier that you can create, whether you can use parameter policies, and whether charges apply.

Parameter tiers are different from parameter throughput. Tiers control parameter storage attributes, whereas throughput controls request rate.

Standard and advanced parameter tiers

The following table describes the differences between the tiers.

The following table describes the differences between parameter tiers.

Feature or use case	Standard	Advanced
Use case	Best for most configuration data and low-scale workloads. This is the default.	Best when you need higher limits, larger values, or parameter policies.
Maximum parameters (per Amazon Web Services account and Amazon Web Services Region)	10,000	100,000
Maximum value size	4 KB	8 KB
Parameter policies	Not supported	Supported For more information, see Assigning parameter policies in Parameter Store.
Shareability across Amazon Web Services accounts	Not supported	Supported For more information, see Working with shared parameters in Parameter Store.
Data types	All data types except `url`, `json`, and `jsonc`	All data types For more information, see Parameter data types in Parameter Store.
Upgrade and downgrade capability	Upgradeable	Not downgradeable
Cost	No additional charge	Charges apply

Feature or use case	Standard	Advanced
		For more information, see Amazon Systems Manager Pricing for Parameter Store.

For a complete list of Parameter Store quotas and limits, see Amazon Systems Manager endpoints and quotas in the *Amazon General Reference*.

Default tier and individual parameter tier settings

Parameter Store supports the following related settings:

- Default parameter tier for your Amazon Web Services account and Region

  This setting controls what tier Parameter Store uses when you create a new parameter and don't explicitly specify a tier. You can set the default to `Standard`, `Advanced`, or `Intelligent-Tiering`.

- Tier for an individual parameter

  You can specify the tier when you create or update an individual parameter. You can change a standard parameter to an advanced parameter, but you can't change an advanced parameter to a standard parameter.

  If you change the data type of an existing standard parameter to `url`, `json`, or `jsonc`, you must also change the parameter to the advanced tier, or the request fails. If you use Intelligent-Tiering, Parameter Store upgrades the parameter to the advanced tier automatically. On the console, you must choose **Switch to advanced**. For more information, see Supported data types.

The default parameter tier is separate from the tier of an individual parameter. Changing the default parameter tier affects only new parameters that you create without specifying a tier. Existing parameters aren't affected.

Viewing parameter tier settings

You can view the default tier setting for your Amazon Web Services account and Region, and the tier setting for each individual parameter.

View the default parameter tier

To view the default parameter tier for your Amazon Web Services account and Region, use the action. The following example retrieves the default parameter tier.

```
aws ssm get-service-setting \
    --region us-east-1 \
    --setting-id arn:aws:ssm:us-east-1:111122223333:servicesetting/ssm/parameter-store/
default-parameter-tier
```

The following example shows sample output.

```
{
    "ServiceSetting": {
        "SettingId": "/ssm/parameter-store/default-parameter-tier",
        "SettingValue": "Standard",
        "Status": "Default"
    }
}
```

View the tier for a specific parameter

To view the tier for a specific parameter, use the action. The following example returns the tier of parameter `/myapp/dev/log-level`.

```
aws ssm describe-parameters \
    --region us-east-1 \
    --parameter-filters "Key=Name,Option=Equals,Values=/myapp/dev/log-level" \
    --query "Parameters[0].Tier" \
    --output text
```

The command returns the parameter tier, such as `Standard` or `Advanced`.

Topics

- Specifying a default parameter tier for your Amazon Web Services account and Amazon Web Services Region
- Changing a standard parameter to an advanced parameter
- Limitations on changing tiers for individual parameters

Specifying a default parameter tier for your Amazon Web Services account and Amazon Web Services Region

If you create or update a parameter but don't specify a parameter tier in the command, the default tier setting determines the tier. By default, Parameter Store sets the default setting to the standard parameter tier.

Default parameter tier options

Standard parameters are available at no cost, but they have size and feature restrictions, as described in Standard and advanced parameter tiers. If your use case requires features or limits that standard parameters don't support, consider setting the advanced tier as the default. The advanced tier offers higher limits and extra features, at a cost. For more information, see Amazon Systems Manager Pricing for Parameter Store.

You can change Parameter Store default tier settings at any time using the UpdateServiceSetting API. Set the parameter tier default value to `Standard`, `Advanced`, or `Intelligent-Tiering`.

To maximize efficiency and reduce costs, consider setting `Intelligent-Tiering` as the default value. This setting determines whether to use the standard or advanced tier based on the request content. For example, if you create a parameter that meets the criteria for a standard parameter, intelligent tiering creates the parameter in the standard tier. If you create a parameter where one or more criteria don't meet the standard-tier requirements, intelligent tiering creates the parameter in the advanced tier.

Intelligent tiering offers the following benefits:

Cost control

Intelligent tiering helps control your parameter-related costs by always creating standard parameters unless the request requires the advanced tier.

Automatic upgrade to the advanced tier

When you make a change to your code that requires upgrading a standard parameter to an advanced parameter, intelligent tiering handles the conversion for you. You don't need to change your code to handle the upgrade. Sample use cases include the following:

- Your Amazon CloudFormation templates provision numerous parameters when they're run. When this process causes you to reach the 10,000 parameter quota in the standard-parameter tier, Intelligent-Tiering automatically upgrades you to the advanced-parameter tier, and your Amazon CloudFormation processes aren't interrupted.

- You store a certificate value in a parameter, rotate the certificate value regularly, and the content is less than the 4 KB quota of the standard-parameter tier. If a replacement certificate value exceeds 4 KB, Intelligent-Tiering automatically upgrades the parameter to the advanced-parameter tier.
- You want to associate numerous existing standard parameters to a parameter policy, which requires the advanced-parameter tier. Instead of including the `--tier Advanced` option in calls to update parameters, Intelligent-Tiering automatically upgrades parameters to the advanced tier.
- You create a parameter with, or change an existing parameter to, the `url`, `json`, or `jsonc` data type. These data types require the advanced tier, so Intelligent-Tiering automatically creates or upgrades the parameter as an advanced parameter.

Configuring permissions to specify a Parameter Store default tier

Verify that you have permission in Amazon Identity and Access Management (IAM) to change the default parameter tier in Parameter Store by doing one of the following:

- Make sure that you attach the `AdministratorAccess` policy to your IAM entity (such as user, group, or role).
- Make sure that you have permission to change the default tier setting by using the following API operations:
  - GetServiceSetting
  - UpdateServiceSetting
  - ResetServiceSetting

Grant the following permissions to the IAM entity to allow a user to view and change the default tier setting for parameters in a specific Amazon Web Services Region in an Amazon Web Services account.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
```

```
            "Action": [
                "ssm:GetServiceSetting"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ssm:UpdateServiceSetting"
            ],
            "Resource": "arn:aws-cn:ssm:us-east-1:111122223333:servicesetting/
ssm/parameter-store/default-parameter-tier"
        }
    ]
}
```

Administrators can specify read-only permission by assigning the following permissions.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetServiceSetting"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": [
                "ssm:ResetServiceSetting",
                "ssm:UpdateServiceSetting"
            ],
            "Resource": "*"
        }
    ]
}
```

To provide access, add permissions to your users, groups, or roles:

- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.

- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

Setting the Parameter Store default tier using the console, Amazon CLI, or PowerShell

By default, Parameter Store sets the default setting to the standard parameter tier. You can set the default parameter tier for your Amazon Web Services account and Region using the Systems Manager console, Amazon CLI, or PowerShell. For example, you can change the default tier to advanced and then back to standard.

Console

The following procedure shows how to use the Systems Manager console to set the default parameter tier for the current Amazon Web Services account and Amazon Web Services Region.

To set the Parameter Store default tier

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the **Settings** tab.
4. Choose **Manage settings**.
5. In the **Parameter default tier** section, choose an option. For information about these options, see Specifying a default parameter tier for your Amazon Web Services account and Amazon Web Services Region.
6. If prompted, select the option to approve the changes and authorize charges. Choose **Save settings**.

To change the default tier setting later, repeat the preceding steps and specify a different default tier option.

CLI

The following procedure shows how to use the Amazon CLI to set the default parameter tier for the current Amazon Web Services account and Amazon Web Services Region.

To set the Parameter Store default tier using the Amazon CLI

1. Open the Amazon CLI and run the following command to set the default parameter tier setting for a specific Amazon Web Services Region in an Amazon Web Services account.

```
aws ssm update-service-setting \
    --region region \
    --setting-id arn:aws-cn:ssm:region:account-id:servicesetting/ssm/parameter-
store/default-parameter-tier \
    --setting-value tier-option
```

region represents the identifier for an Amazon Web Services Region supported by Amazon Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

tier-option values include `Standard`, `Advanced`, and `Intelligent-Tiering`. For information about these options, see Specifying a default parameter tier for your Amazon Web Services account and Amazon Web Services Region.

There is no output if the command succeeds.

2. Run the following command to view the current default parameter tier service settings for Parameter Store in the current Amazon Web Services account and Amazon Web Services Region.

```
aws ssm get-service-setting \
    --region region \
    --setting-id arn:aws-cn:ssm:region:account-id:servicesetting/ssm/parameter-
store/default-parameter-tier
```

The command returns output similar to the following.

```
{
    "ServiceSetting": {
        "SettingId": "/ssm/parameter-store/default-parameter-tier",
        "SettingValue": "Advanced",
        "LastModifiedDate": 1556551683.923,
        "LastModifiedUser": "arn:aws:sts::123456789012:assumed-role/
Administrator/Jasper",
        "ARN": "arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/parameter-
store/default-parameter-tier",
        "Status": "Customized"
    }
}
```

To change the default tier setting again, repeat this procedure and specify a different `SettingValue` option.

PowerShell

The following procedure shows how to use the Tools for Windows PowerShell to set the default parameter tier for a specific Amazon Web Services Region in an Amazon Web Services account.

To set the Parameter Store default tier using PowerShell

1. Set the Parameter Store default tier in the current Amazon Web Services account and Amazon Web Services Region using the Amazon Tools for PowerShell (Tools for PowerShell).

```
Update-SSMServiceSetting -SettingId "arn:aws-cn:ssm:region:account-
id:servicesetting/ssm/parameter-store/default-parameter-tier" -SettingValue
 "tier-option" -Region region
```

`region` represents the identifier for an Amazon Web Services Region supported by Amazon Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *`region`* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

`tier-option` values include `Standard`, `Advanced`, and `Intelligent-Tiering`. For information about these options, see Specifying a default parameter tier for your Amazon Web Services account and Amazon Web Services Region.

There is no output if the command succeeds.

2. Run the following command to view the current default parameter tier service settings for Parameter Store in the current Amazon Web Services account and Amazon Web Services Region.

```
Get-SSMServiceSetting -SettingId "arn:aws-cn:ssm:region:account-
id:servicesetting/ssm/parameter-store/default-parameter-tier" -Region region
```

region represents the identifier for an Amazon Web Services Region supported by Amazon Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

The command returns output similar to the following.

```
ARN : arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/parameter-store/
default-parameter-tier
LastModifiedDate : 4/29/2019 3:35:44 PM
LastModifiedUser : arn:aws:sts::123456789012:assumed-role/Administrator/Jasper
SettingId        : /ssm/parameter-store/default-parameter-tier
SettingValue     : Advanced
Status           : Customized
```

To change the default tier setting again, repeat this procedure and specify a different `SettingValue` option.

Changing a standard parameter to an advanced parameter

Use the following procedure to change an existing standard parameter to an advanced parameter. For information about how to create a new advanced parameter, see Creating Parameter Store parameters in Systems Manager.

Console

To change a standard parameter to an advanced parameter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.

2. In the navigation pane, choose **Parameter Store**.
3. Choose a parameter, and then choose **Edit**.
4. For **Description**, enter information about this parameter.
5. Choose **Advanced**.
6. For **Value**, enter the value of this parameter. Advanced parameters have a maximum value limit of 8 KB.
7. Choose **Save changes**.

Amazon CLI

You can override the default setting by specifying the parameter tier using the `PutParameter` operation. For example, you might want to share the default AMI value across Amazon accounts. The following Amazon CLI example explicitly sets the parameter tier to `Advanced` for the `default-ami` parameter in Linux & macOS.

```
aws ssm put-parameter \
    --region us-east-1 \
    --name "default-ami" \
    --type "String" \
    --value "t3.micro" \
    --tier "Advanced"
```

Limitations on changing tiers for individual parameters

You can change a standard parameter to an advanced parameter at any time. You *can't* change an advanced parameter to a standard parameter for the following reasons:

- Changing the parameter to the standard tier would truncate the parameter value from 8 KB to 4 KB, resulting in data loss.
- Changing the parameter to the standard tier would remove any policies attached to the parameter.
- Advanced and standard parameters use a different form of encryption.

If you no longer need an advanced parameter, or if you no longer want to incur charges for an advanced parameter, delete it and recreate it as a new standard parameter.

The default parameter tier is a separate setting. You can change the default parameter tier for an Amazon Web Services account and Region from `Standard` to `Advanced`, and then change it back to `Standard`. The default tier setting affects only new parameters that you create without specifying a tier. Existing parameters aren't affected.

For example, you can create parameters while the default tier is `Standard`, and then set the default parameter tier to `Advanced`. New parameters that you create without specifying a tier use the `Advanced` tier. You can later change the default tier back to `Standard` without changing the tier of existing parameters.

Advanced parameters incur charges. For more information, see Amazon Systems Manager Pricing for Parameter Store.

Managing Parameter Store throughput

Parameter Store throughput defines the number of API transactions per second (TPS) that Systems Manager can process. The throughput setting applies to the Parameter Store as a whole rather than an individual API. By default, Parameter Store is configured with a standard throughput quota that is often suitable for low- to moderate-volume workloads. For higher-volume workloads, you can enable higher throughput, which increases the maximum number of supported transactions per second for your account and Region. You can enable and disable higher throughput as needed.

Throughput quotas in Parameter Store

The following table lists the transaction limits for different API categories using default and higher throughput. API actions include Amazon console usage, Amazon CLI commands, and application reads. For more information on quotas and rate limits, see Amazon Systems Manager endpoints and quotas.

API actions	Default throughput	Higher throughput
GetParameter, GetParameters, and GetParametersByPath	`40` TPS shared across all three API actions combined	GetParameter: `10,000` TPS; GetParameters: `1,000` TPS; GetParametersByPath: `100` TPS
DeleteParameter and DeleteParameters	`3` TPS	`5` TPS

API actions	Default throughput	Higher throughput
DescribeParameters, GetParameterHistory, LabelParameterVersion, UnlabelParameterVersion, and PutParameter	3 TPS	10 TPS

In this context, a transaction is one API action for an account in a single Region. For example, the following command creates a single transaction.

```
aws ssm get-parameter --name "/myapp/prod/log-level"
```

The API actions can be distributed among applications. For example, each of the following scenarios reaches the default throughput limit of 40 TPS:

- 1 application makes 40 `GetParameter` calls per second.
- 10 applications make 4 `GetParameter` calls per second.
- 40 applications make 1 `GetParameter` call per second.

A throughput limit applies to all APIs within a category. For example, the following combination of simultaneous parameter calls for an application meets the default limit of 40 TPS for parameter retrieval APIs:

- `GetParameter` makes 25 calls per second.
- `GetParameters` makes 10 calls per second.
- `GetParameterByPath` makes 5 calls per second.

The `DescribeParameters` calls have a separate throughput limit. An application can make the preceding calls while also making 3 `DescribeParameters` calls per second without exceeding the overall limit for standard throughput.

If your production requests exceed a throughput limit during standard operation or planned periods of high traffic, use the following optimization techniques.

Topics

- Optimizing throughput in Parameter Store
- Changing the throughput setting in Parameter Store

Optimizing throughput in Parameter Store

When Parameter Store receives multiple requests for parameters in a short interval, your application can experience *throttling*. For example, CloudWatch Logs or your application logs show `ThrottlingException` or `RateExceeded` errors raised by the SDK when it calls `GetParameter`, `GetParameters`, or `GetParametersByPath`. In other cases, application logic successfully retries API calls, but application latency increases. The result can be application outages, suboptimal user experience, failed deployments, complex workarounds, and lost developer time.

Multiple factors can lead to your application hitting Parameter Store quota limits, including the following:

- Your application scales out quickly because of a spike in traffic. For example, your application normally runs on 5 Amazon EC2 instances. When traffic increases suddenly, Amazon EC2 Auto Scaling launches 50 more instances. If each instance reads parameters when it starts, the combined requests can exceed the default request limit.
- Your container service starts many tasks at the same time. For example, an Amazon ECS service might start many replacement tasks during an update, and each task might read settings from Parameter Store when it starts.
- Your Lambda functions receive many requests at the same time. For example, Lambda might start many function environments to handle the increased traffic. Each function environment might read parameters when it starts.
- Your build or release process reads many parameters in a short time interval. For example, a build job might read settings for several applications or environments.
- Your application reads many parameters by path. For example, your application repeatedly reads all parameters under `/myapp/prod/` instead of reading only the specific parameters it needs. These repeated requests can exceed the default request limit.

You can address Parameter Store throttling in the following complementary ways:

- Reducing throughput

  Your application might be retrieving more data than it needs or retrieving it in an inefficient way.

- Enabling higher throughput

  You can increase application resilience by increasing throughput quota for a specified Region and account. You can enable and disable the higher-throughput setting at any time for periods of high traffic. For production workloads that regularly generate throttling errors, consider enabling the setting permanently.

Reducing throughput in Parameter Store

Whether you use standard or higher throughput, review the frequency and type of calls to Parameter Store. In some cases, you can reduce the number of requests without changing your parameters. Because cost is determined based on usage rather than on a subscription or tier model, the result is fewer billed API interactions.

- Cache parameter values in your application instead of reading the same values on every request.

  For example, if your application reads `/myapp/prod/log-level` many times per minute, the application can read the value once and reuse it for a short period of time. This technique reduces repeated calls to Parameter Store. Choose a shorter reuse period for values that change often, and a longer reuse period for values that rarely change.
- Use GetParameters when you know the names of multiple parameters.

  For example, instead of making separate GetParameter calls for the parameters `/myapp/prod/database/host`, `/myapp/prod/log-level`, and `/myapp/prod/vendor/merchant-id`, you can retrieve a list of these parameters in a single `GetParameters` request.
- Avoid reading more parameters than your application needs.

  If your application needs only a few known parameters, use `GetParameter` or `GetParameters` instead of repeatedly reading an entire path such as `/myapp/prod/`. Use GetParametersByPath when your application needs a group of parameters under a path. When you use higher throughput, the `GetParameter` quota is 100x the quota for `GetParametersByPath`.
- Spread out parameter reads when many resources start at the same time.

  For example, if many Amazon EC2 instances or Amazon ECS tasks start during an update, avoid having every resource read parameters at exactly the same time. The quotas are per-second. Where possible, read parameters once and cache their values to the application, or add a small delay so that requests do not all occur in the same second.
- For Lambda functions, consider using the Amazon Parameters and Secrets Lambda Extension.

The extension can store parameter values locally for reuse by the function. This technique can reduce the number of calls to Parameter Store and can also reduce the time needed to retrieve parameter values. For a sample walkthrough of this technique, see Using the Amazon Parameter and Secrets Lambda extension to cache parameters and secrets.

Increasing throughput

For higher-volume workloads, you can enable higher throughput. This setting increases the maximum number of supported transactions per second for your account and Region, at a cost. Consider higher throughput in the following scenarios:

- Your application has a temporary need for higher throughput.

  For example, a webstore might read parameters more often during a weekend sale. You can enable higher throughput before the sale begins, and then return to standard throughput after the sale ends. You can enable or disable higher throughput at any time from the Parameter Store **Settings** page or by using the Amazon CLI.
- Your production application regularly retrieves parameters concurrently and runs into throttling issues.

  Concurrent retrieval can happen when multiple instances, containers, functions, or build jobs read parameters from Parameter Store at the same time. Examples include the following:

  - Your application scales out quickly. For example, your application normally runs on 5 Amazon EC2 instances. When traffic increases suddenly, Amazon EC2 Auto Scaling launches 50 more instances. If each instance reads parameters when it starts, the combined requests can exceed the default request limit.
  - Your container service starts many tasks at the same time. For example, an Amazon ECS service might start many replacement tasks during an update, and each task might read settings from Parameter Store when it starts.
  - Your Lambda functions receive many requests at the same time. For example, Lambda might start many function environments to handle the increased traffic. Each function environment might read parameters when it starts.
  - Your build or release process reads many parameters in a short time interval. For example, a build job might read settings for several applications or environments.

Cost considerations for higher throughput

For the higher throughput option, additional charges apply. For current Parameter Store API pricing and examples, see Amazon Systems Manager Pricing.

Charges are based on Parameter Store API interactions. An API interaction is defined as an interaction between an API request and an individual parameter. For example, if a single `GetParameter` request returns 10 parameters, this request counts as 10 Parameter Store API interactions for billing purposes.

Consider a scenario where you want to switch to higher throughput for a short period of increased traffic. Your webstore holds a weekend sale and makes `1,000,000` Parameter Store API interactions during the sale. If the cost for higher throughput in this example is `$0.05` per `10,000` API interactions, the total additional cost is approximately `$5`. You can switch back to standard throughput at the end of the sale and stop incurring costs.

Combining throughput and parameter tiers

Throughput operates independently of parameter tiers. Whereas parameter tiers control storage limits and feature availability, throughput settings control request volume. To meet performance and scale requirements, you can use tiers and throughput together.

For example, to support simple and low-load applications, you can use standard parameters with default throughput. To support large-scale, high-frequency access patterns, you can combine advanced parameters with higher throughput. In general, increasing throughput is necessary when your application exceeds default TPS limits (for example, during bursts of concurrent reads or writes), regardless of which parameter tier you use.

For more information about maximum throughput and other Parameter Store quotas, see Amazon Systems Manager endpoints and quotas.

Changing the throughput setting in Parameter Store

The following procedures describe how to use Systems Manager to change the number of transactions per second that Parameter Store can process for the current Amazon Web Services account and Amazon Web Services Region. You can change the setting at any time.

Console

To change Parameter Store throughput using the console

> **Tip**
>
> If you haven't created a parameter yet, you can use the Amazon Command Line Interface (Amazon CLI) or Amazon Tools for Windows PowerShell to change throughput. For information, see Changing the throughput setting in Parameter Store.

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the **Settings** tab.
4. Choose the **Manage settings**.
5. In the **Parameter throughput** section, choose an option.
6. If prompted, select the option to approve the changes and authorize charges. Choose **Save settings**.

CLI

To change Parameter Store throughput using the Amazon CLI

1. Open the Amazon CLI and run the `aws ssm update-service-setting` command to increase or decrease the transactions per second that Parameter Store can process in the current Amazon Web Services account and Amazon Web Services Region. The following example increases the throughput to the high level.

```
aws ssm update-service-setting \
--setting-id arn:aws-cn:ssm:region:account-id:servicesetting/ssm/parameter-store/high-throughput-enabled \
--setting-value true
```

   There is no output if the command succeeds. To turn off high throughput, set `--setting-value` to `false`.

2. Run the following command to view the current throughput service settings for Parameter Store in the current Amazon Web Services account and Amazon Web Services Region.

```
aws ssm get-service-setting \
--setting-id arn:aws-cn:ssm:region:account-id:servicesetting/ssm/parameter-
store/high-throughput-enabled
```

The system returns information similar to the following:

```
{
    "ServiceSetting": {
        "SettingId": "/ssm/parameter-store/high-throughput-enabled",
        "SettingValue": "true",
        "LastModifiedDate": 1556551683.923,
        "LastModifiedUser": "arn:aws:sts::123456789012:assumed-role/
Administrator/Jasper",
        "ARN": "arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/parameter-
store/high-throughput-enabled",
        "Status": "Customized"
    }
}
```

PowerShell

To change Parameter Store throughput using PowerShell

1. Increase or decrease Parameter Store throughput in the current Amazon Web Services account and Amazon Web Services Region using the Amazon Tools for PowerShell (Tools for PowerShell). The following example set throughput to the high level.

```
Update-SSMServiceSetting -SettingId "arn:aws-cn:ssm:region:account-
id:servicesetting/ssm/parameter-store/high-throughput-enabled" -SettingValue
 "true" -Region region
```

There is no output if the command succeeds.

2. Run the following command to view the current throughput service settings for Parameter Store in the current Amazon Web Services account and Amazon Web Services Region.

```
Get-SSMServiceSetting -SettingId "arn:aws-cn:ssm:region:account-
id:servicesetting/ssm/parameter-store/high-throughput-enabled" -Region region
```

The system returns information similar to the following:

```
ARN              : arn:aws:ssm:us-east-2:123456789012:servicesetting/ssm/
parameter-store/high-throughput-enabled
LastModifiedDate : 4/29/2019 3:35:44 PM
LastModifiedUser : arn:aws:sts::123456789012:assumed-role/Administrator/Jasper
SettingId        : /ssm/parameter-store/high-throughput-enabled
SettingValue     : true
Status           : Customized
```

Setting up notifications or triggering actions based on Parameter Store events

You can use Amazon EventBridge and Amazon Simple Notification Service (Amazon SNS) to notify you about changes to Amazon Systems Manager parameters. Events are emitted on a best effort basis. For example, you can create rules that do the following:

- Notify you when a parameter or a parameter label version is created, updated, or deleted.
- Notify you of changes or status related to parameter policies, such as when a parameter expires, is going to expire, or hasn't changed for a specified period of time.

> **Note**
>
> Parameter policies are available for parameters that use the advanced parameters tier. Charges apply. For more information, see Assigning parameter policies in Parameter Store and Choosing parameter tiers in Parameter Store.

- Initiate other actions on a target for specific parameter events. For example, you can run an Amazon Lambda function to recreate a parameter automatically when it expires or is deleted. You can set up a notification to invoke a Lambda function when a parameter that stores an approved AMI ID is updated. The Lambda function can update a launch template or start a deployment workflow that uses the new AMI ID.

EventBridge also supports running Run Command commands and Automation executions, and actions in many other Amazon Web Services services. Run Command and Automation are both tools in Amazon Systems Manager. For more information, see the *Amazon EventBridge User Guide*.

Before You Begin

Create any resources you need to specify the target action for the rule you create. For example, if the rule you create is for sending a notification, first create an Amazon SNS topic. For more information, see Getting started with Amazon SNS in the *Amazon Simple Notification Service Developer Guide*.

Configuring EventBridge rules for parameters and parameter policies

This topic explains the following:

- How to create an EventBridge rule that invokes a target based on events that happen to one or more parameters in your Amazon Web Services account.
- How to create EventBridge rules that invoke targets based on events that happen to one or more parameter policies in your Amazon Web Services account. When you create an advanced parameter, you specify when a parameter expires, when to receive notification before a parameter expires, and how long to wait before notification should be sent that a parameter hasn't changed. You set up notification for these events using the following procedure. For more information, see Assigning parameter policies in Parameter Store and Choosing parameter tiers in Parameter Store.

To configure an EventBridge rule for a Systems Manager parameter or parameter policy

1. Open the Amazon EventBridge console at https://console.amazonaws.cn/events/.
2. Choose **EventBridge Rule with event pattern** and then **Create rule**.
3. Choose **Advanced builder** if it is not already selected.
4. Enter a name and description for the rule. Then choose **Next**.

   A rule can't have the same name as another rule in the same Region and on the same event bus.
5. For **Event bus**, choose the event bus that you want to associate with this rule. If you want this rule to initiate on matching events that come from your own Amazon Web Services account, select **default**. When an Amazon Web Services service in your account emits an event, it always goes to your account's default event bus.

6. For **Rule type**, leave the default **Rule with an event pattern** selected.
7. Choose **Next**.
8. For **Event source**, leave the default **Amazon events or EventBridge partner events** selected. You can skip the **Sample event** section.
9. For **Event pattern**, do the following:

   - Choose **Custom patterns (JSON editor)**.
   - For **Event pattern**, paste one of the following content in the box, depending on whether you are creating a rule for a parameter or a parameter policy:

     Parameter

```
{
    "source": [
        "aws.ssm"
    ],
    "detail-type": [
        "Parameter Store Change"
    ],
    "detail": {
        "name": [
            "parameter-1-name",
            "/parameter-2-name/level-2",
            "/parameter-3-name/level-2/level-3"
        ],
        "operation": [
            "Create",
            "Update",
            "Delete",
            "LabelParameterVersion"
        ]
    }
}
```

     Parameter policy

```
{
    "source": [
        "aws.ssm"
    ],
    "detail-type": [
```

```
        "Parameter Store Policy Action"
    ],
    "detail": {
        "parameter-name": [
            "parameter-1-name",
            "/parameter-2-name/level-2",
            "/parameter-3-name/level-2/level-3"
        ],
        "policy-type": [
            "Expiration",
            "ExpirationNotification",
            "NoChangeNotification"
        ]
    }
}
```

- Modify the contents for the parameters and the operations you want to act on, as shown in the following samples.

  Parameter

  With this example, an action is taken when either of the parameters named `/Oncall` and `/Project/Teamlead` are updated:

```
{
    "source": [
        "aws.ssm"
    ],
    "detail-type": [
        "Parameter Store Change"
    ],
    "detail": {
        "name": [
            "/Oncall",
            "/Project/Teamlead"
        ],
        "operation": [
            "Update"
        ]
    }
}
```

Parameter policy

With this example, an action is taken whenever the parameter named `/OncallDuties` expires and is deleted:

```
{
    "source": [
        "aws.ssm"
    ],
    "detail-type": [
        "Parameter Store Policy Action"
    ],
    "detail": {
        "parameter-name": [
            "/OncallDuties"
        ],
        "policy-type": [
            "Expiration"
        ]
    }
}
```

10. Choose **Next**.
11. For **Target 1**, choose a target type and a supported resource. For example, if you choose **Amazon service** and then **SNS topic**, make a selection for **Topic**. If you choose **CodePipeline**, enter a pipeline ARN for **Pipeline ARN**. Provide additional configuration values as required.

> **Tip**
>
> Choose **Add another target** if you require additional targets for the rule.

12. Choose **Next**.
13. (Optional) Enter one or more tags for the rule. For more information, see Amazon EventBridge tags in the *Amazon EventBridge User Guide*.
14. Choose **Next**.
15. Choose **Create rule**.

Working with Parameter Store

Parameter Store lets you create, organize, and manage configuration data and secrets that your applications use at runtime.

In this section, you learn how to work with parameters throughout their lifecycle–creating and organizing them, applying policies, managing versions and labels, and controlling access. You can perform these tasks using the Amazon Web Services Management Console, the Amazon Command Line Interface, or Amazon Tools for Windows PowerShell.

Parameter Store centralizes configuration data such as environment variables, service endpoint URLs, resource identifiers, approved AMI IDs, and application tuning parameters, so you can update values without modifying application code. Parameters are stored as key-value pairs, can be organized hierarchically, and support versioning and optional encryption with Amazon Key Management Service.

Topics

- Creating Parameter Store parameters in Systems Manager
- Searching for Parameter Store parameters in Systems Manager
- Assigning parameter policies in Parameter Store
- Working with parameter hierarchies in Parameter Store
- Preventing access to Parameter Store API operations
- Working with parameter labels in Parameter Store
- Working with parameter versions in Parameter Store
- Working with shared parameters in Parameter Store
- Working with parameters in Parameter Store using Run Command commands
- Parameter data types in Parameter Store

- Using native parameter support in Parameter Store for Amazon Machine Image IDs
- Deleting parameters from Parameter Store

Creating Parameter Store parameters in Systems Manager

A *parameter* is any piece of data stored in Parameter Store, such as a block of text, a list of names, an AMI ID, a license key, and so on. You can centrally and securely reference this data in your scripts, commands, and SSM documents.

Parameter Store provides support for the following parameter types:

- `String`
- `StringList`
- `SecureString`

For more information about the preceding types, see Parameter Store reference.

In the following sections, you learn how to create Parameter Store parameters using the Amazon Web Services Management Console, the Amazon Command Line Interface (Amazon CLI), or Amazon Tools for Windows PowerShell (Tools for Windows PowerShell).

Topics

- Creating a Parameter Store parameter using the console
- Creating a Parameter Store parameter using the Amazon CLI
- Creating a Parameter Store parameter using Tools for Windows PowerShell

Creating a Parameter Store parameter using the console

You can use the Amazon Systems Manager console to create and run `String`, `StringList`, and `SecureString` parameter types. After deleting a parameter, wait for at least 30 seconds to create a parameter with the same name.

> **Note**
>
> Parameters are only available in the Amazon Web Services Region where they were created.

The following procedure walks you through the process of creating a parameter in the Parameter Store console. You can create `String`, `StringList`, and `SecureString` parameter types from the console.

To create a parameter

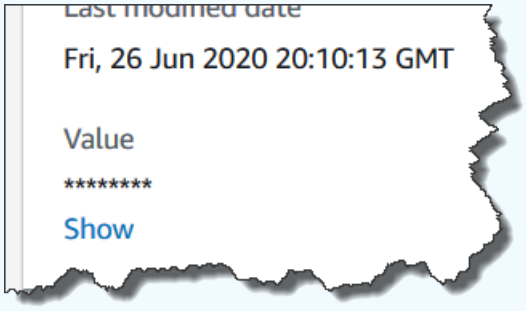
1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. Choose **Create parameter**.
4. In the **Name** box, enter a hierarchy and a name. For example, enter **`/Test/helloWorld`**.

   For more information about parameter hierarchies, see Working with parameter hierarchies in Parameter Store.
5. In the **Description** box, type a description that identifies this parameter as a test parameter.
6. For **Parameter tier** choose either **Standard** or **Advanced**. For more information about advanced parameters, see Choosing parameter tiers in Parameter Store.
7. For **Type**, choose **String**, **StringList**, or **SecureString**.

   - For **Data type**, choose a data type to validate the parameter value. This field is available for all three parameter types. Not every data type supports every parameter type. For example, choose `aws:ec2:image` for an AMI ID, `integer` for an integer value, or `json` for a JSON document. The `url`, `json`, and `jsonc` data types require the advanced tier. If you choose one of these data types, make sure that you chose **Advanced** for **Parameter tier**. If you don't need validation, keep the default `text` selected. For the full list of supported data types, see Parameter data types in Parameter Store.
   - If you choose **SecureString,** the **KMS Key ID** field is displayed. If you don't provide an Amazon Key Management Service Amazon KMS key ID, an Amazon KMS key Amazon Resource Name (ARN), an alias name, or an alias ARN, then the system uses `alias/aws/ssm`, which is the Amazon managed key for Systems Manager. If you don't want to use this key, then you can use a customer managed key. For more information about Amazon managed keys and customer managed keys, see Amazon Key Management Service Concepts in the *Amazon Key Management Service Developer Guide*. For more information about Parameter Store and Amazon KMS encryption, see How Amazon Systems Manager Parameter Store Uses Amazon KMS.

> **Important**
>
> Parameter Store only supports symmetric encryption KMS keys. You can't use an asymmetric encryption KMS key to encrypt your parameters. For help determining whether a KMS key is symmetric or asymmetric, see Identifying symmetric and asymmetric KMS keys in the *Amazon Key Management Service Developer Guide*

- When creating a `SecureString` parameter in the console by using the `key-id` parameter with either a customer managed key alias name or an alias ARN, specify the prefix `alias/` before the alias. Following is an ARN example.



```
arn:aws:kms:us-east-2:123456789012:alias/abcd1234-ab12-cd34-ef56-abcdeEXAMPLE
```

Following is an alias name example.

```
alias/MyAliasName
```

8. In the **Value** box, type a value. For example, type **`This is my first parameter`** or **`ami-0dbf5ea29aEXAMPLE`**.

> **Note**
>
> Parameters can't be referenced or nested in the values of other parameters. You can't include `{{}}` or `{{ssm:parameter-name}}` in a parameter value.
> If you chose **SecureString**, the value of the parameter is masked by default ("******") when you view it later on the parameter **Overview** tab, as shown in the following illustration. Choose **Show** to display the parameter value.

9. (Optional) In the **Tags** area, apply one or more tag key-value pairs to the parameter.

Tags are optional metadata that you assign to a resource. Tags allow you to categorize a resource in different ways, such as by purpose, owner, or environment. For example, you might want to tag a Systems Manager parameter to identify the type of resource to which it applies, the environment, or the type of configuration data referenced by the parameter. In this case, you could specify the following key-value pairs:

- `Key=Resource,Value=S3bucket`
- `Key=OS,Value=Windows`
- `Key=ParameterType,Value=LicenseKey`

10. Choose **Create parameter**.
11. In the parameters list, choose the name of the parameter you just created. Verify the details on the **Overview** tab. If you created a `SecureString` parameter, choose **Show** to view the unencrypted value.

> **Note**
>
> You can't change an advanced parameter to a standard parameter. If you no longer need an advanced parameter, or if you no longer want to incur charges for an advanced parameter, delete it and recreate it as a new standard parameter.

> **Note**
>
> You can't change the type of an existing parameter (for example, from `String` to `SecureString`) using the console. To change a parameter's type, you must use the Amazon CLI or s with the `--overwrite` option. For more information, see Creating a Parameter Store parameter using the Amazon CLI.

Creating a Parameter Store parameter using the Amazon CLI

You can use the Amazon Command Line Interface (Amazon CLI) to create `String`, `StringList`, and `SecureString` parameter types. After deleting a parameter, wait for at least 30 seconds to create a parameter with the same name.

Parameters can't be referenced or nested in the values of other parameters. You can't include {{}} or {{ssm:*parameter-name*}} in a parameter value.

> **Note**
>
> Parameters are only available in the Amazon Web Services Region where they were created.

Topics

- Creating a String parameter using the Amazon CLI
- Creating a StringList parameter using the Amazon CLI
- Creating a SecureString parameter using the Amazon CLI
- Creating a multi-line parameter using the Amazon CLI

Creating a `String` parameter using the Amazon CLI

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.

2. Run the following command to create a `String`-type parameter. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm put-parameter \
       --name "parameter-name" \
       --value "parameter-value" \
       --type String \
       --tags "Key=tag-key,Value=tag-value"
   ```

   Windows

   ```
   aws ssm put-parameter ^
       --name "parameter-name" ^
       --value "parameter-value" ^
       --type String ^
       --tags "Key=tag-key,Value=tag-value"
   ```

-or-

Run the following command to create a parameter that contains an Amazon Machine Image (AMI) ID as the parameter value.

Linux & macOS

```
aws ssm put-parameter \
    --name "parameter-name" \
    --value "an-AMI-id" \
    --type String \
    --data-type "aws:ec2:image" \
    --tags "Key=tag-key,Value=tag-value"
```

Windows

```
aws ssm put-parameter ^
    --name "parameter-name" ^
    --value "an-AMI-id" ^
    --type String ^
    --data-type "aws:ec2:image" ^
    --tags "Key=tag-key,Value=tag-value"
```

The `--name` option supports hierarchies. For information about hierarchies, see Working with parameter hierarchies in Parameter Store.

The `--data-type` option specifies how Parameter Store validates the parameter value. For example, use `aws:ec2:image` to validate an AMI ID or `integer` to validate an integer value. If you don't specify a data type, the default is `text`, which performs no validation. For the full list of supported data types, see Parameter data types in Parameter Store.

Important

If successful, the command returns the version number of the parameter. **Exception**: If you have specified `aws:ec2:image` as the data type, a new version number in the response doesn't mean that the parameter value has been validated yet. For more

information, see Using native parameter support in Parameter Store for Amazon Machine Image IDs.

The following example adds two key-value pair tags to a parameter.

Linux & macOS

```
aws ssm put-parameter \
    --name parameter-name \
    --value "parameter-value" \
    --type "String" \
    --tags '[{"Key":"Region","Value":"East"},{"Key":"Environment",
 "Value":"Production"}]'
```

Windows

```
aws ssm put-parameter ^
    --name parameter-name ^
    --value "parameter-value" ^
    --type "String" ^
    --tags [{\"Key\":\"Region1\",\"Value\":\"East1\"},{\"Key\":\"Environment1\",
\"Value\":\"Production1\"}]
```

The following example uses a parameter hierarchy in the name to create a plaintext `String` parameter. It returns the version number of the parameter. For more information about parameter hierarchies, see Working with parameter hierarchies in Parameter Store.

Linux & macOS

Parameter not in a hierarchy

```
aws ssm put-parameter \
    --name "golden-ami" \
    --type "String" \
    --value "ami-12345abcdeEXAMPLE"
```

Parameter in a hierarchy

```
aws ssm put-parameter \
    --name "/amis/linux/golden-ami" \
    --type "String" \
    --value "ami-12345abcdeEXAMPLE"
```

Windows

Parameter not in a hierarchy

```
aws ssm put-parameter ^
    --name "golden-ami" ^
    --type "String" ^
    --value "ami-12345abcdeEXAMPLE"
```

Parameter in a hierarchy

```
aws ssm put-parameter ^
    --name "/amis/windows/golden-ami" ^
    --type "String" ^
    --value "ami-12345abcdeEXAMPLE"
```

3. Run the following command to view the latest parameter value and verify the details of your new parameter.

```
aws ssm get-parameters --names "/Test/IAD/helloWorld"
```

The system returns information like the following.

```
{
    "InvalidParameters": [],
    "Parameters": [
        {
            "Name": "/Test/IAD/helloWorld",
            "Type": "String",
            "Value": "My updated parameter value",
            "Version": 2,
            "LastModifiedDate": "2020-02-25T15:55:33.677000-08:00",
            "ARN": "arn:aws:ssm:us-east-2:123456789012:parameter/Test/IAD/
helloWorld"
        }
```

```
    ]
}
```

Run the following command to change the parameter value. It returns the version number of the parameter.

```
aws ssm put-parameter --name "/Test/IAD/helloWorld" --value "My updated 1st parameter"
 --type String --overwrite
```

Run the following command to view the parameter value history.

```
aws ssm get-parameter-history --name "/Test/IAD/helloWorld"
```

Run the following command to use this parameter in a command.

```
aws ssm send-command --document-name "AWS-RunShellScript" --parameters '{"commands":
["echo {{ssm:/Test/IAD/helloWorld}}"]}' --targets "Key=instanceids,Values=instance-ids"
```

Run the following command if you only want to retrieve the parameter Value.

```
aws ssm get-parameter --name testDataTypeParameter --query "Parameter.Value"
```

Run the following command if you only want to retrieve the parameter Value using `get-parameters`.

```
aws ssm get-parameters --names "testDataTypeParameter" --query "Parameters[*].Value"
```

Run the following command to view the parameter metadata.

```
aws ssm describe-parameters --filters "Key=Name,Values=/Test/IAD/helloWorld"
```

> **Note**
>
> *Name* must be capitalized.

The system returns information like the following.

```
{
    "Parameters": [
        {
            "Name": "helloworld",
            "Type": "String",
            "LastModifiedUser": "arn:aws:iam::123456789012:user/JohnDoe",
            "LastModifiedDate": 1494529763.156,
            "Version": 1,
            "Tier": "Standard",
            "Policies": []
        }
    ]
}
```

Creating a StringList parameter using the Amazon CLI

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.

2. Run the following command to create a parameter. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm put-parameter \
       --name "parameter-name" \
       --value "a-comma-separated-list-of-values" \
       --type StringList \
       --tags "Key=tag-key,Value=tag-value"
   ```

   Windows

   ```
   aws ssm put-parameter ^
       --name "parameter-name" ^
       --value "a-comma-separated-list-of-values" ^
       --type StringList ^
       --tags "Key=tag-key,Value=tag-value"
   ```

> **Note**
>
> If successful, the command returns the version number of the parameter.

This example adds two key-value pair tags to a parameter. (Depending on the operating system type on your local machine, run one of the following commands. The version to run from a local Windows machine includes the escape characters ("\") that you need to run the command from your command line tool.)

Here is a `StringList` example that uses a parameter hierarchy.

Linux & macOS

```
aws ssm put-parameter \
    --name /IAD/ERP/Oracle/addUsers \
    --value "Milana,Mariana,Mark,Miguel" \
    --type StringList
```

Windows

```
aws ssm put-parameter ^
    --name /IAD/ERP/Oracle/addUsers ^
    --value "Milana,Mariana,Mark,Miguel" ^
    --type StringList
```

> **Note**
>
> Items in a `StringList` must be separated by a comma (,). You can't use other punctuation or special characters to escape items in the list. If you have a parameter value that requires a comma, then use the `String` type.

3. Run the `get-parameters` command to verify the details of the parameter. For example:

```
aws ssm get-parameters --name "/IAD/ERP/Oracle/addUsers"
```

Creating a SecureString parameter using the Amazon CLI

Use the following procedure to create a `SecureString` parameter. Replace each *`example resource placeholder`* with your own information.

Only the *value* of a `SecureString` parameter is encrypted. Parameter names, descriptions, and other properties aren't encrypted.

> **Important**
>
> Parameter Store only supports symmetric encryption KMS keys. You can't use an asymmetric encryption KMS key to encrypt your parameters. For help determining whether a KMS key is symmetric or asymmetric, see Identifying symmetric and asymmetric KMS keys in the *Amazon Key Management Service Developer Guide*

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.

2. Run **one** of the following commands to create a parameter that uses the `SecureString` data type.

   Linux & macOS

   Create a `SecureString` parameter using the default Amazon managed key

   ```
   aws ssm put-parameter \
       --name "parameter-name" \
       --value "parameter-value" \
       --type "SecureString"
   ```

   Create a `SecureString` parameter that uses a customer managed key

   ```
   aws ssm put-parameter \
       --name "parameter-name" \
       --value "a-parameter-value, for example merchant-739482" \
       --type "SecureString"
       --tags "Key=tag-key,Value=tag-value"
   ```

Create a `SecureString` parameter that uses a custom Amazon KMS key

```
aws ssm put-parameter \
    --name "parameter-name" \
    --value "a-parameter-value, for example merchant-739482" \
    --type "SecureString" \
    --key-id "your-account-ID/the-custom-Amazon KMS-key" \
    --tags "Key=tag-key,Value=tag-value"
```

Windows

Create a `SecureString` parameter using the default Amazon managed key

```
aws ssm put-parameter ^
    --name "parameter-name" ^
    --value "parameter-value" ^
    --type "SecureString"
```

Create a `SecureString` parameter that uses a customer managed key

```
aws ssm put-parameter ^
    --name "parameter-name" ^
    --value "a-parameter-value, for example merchant-739482" ^
    --type "SecureString" ^
    --tags "Key=tag-key,Value=tag-value"
```

Create a `SecureString` parameter that uses a custom Amazon KMS key

```
aws ssm put-parameter ^
    --name "parameter-name" ^
    --value "a-parameter-value, for example merchant-739482" ^
    --type "SecureString" ^
    --key-id " ^
    --tags "Key=tag-key,Value=tag-value"account-ID/the-custom-Amazon KMS-key"
```

If you create a `SecureString` parameter by using the Amazon managed key key in your account and Region, then you *don't* have to provide a value for the `--key-id` parameter.

> **Note**
>
> To use the Amazon KMS key assigned to your Amazon Web Services account and Amazon Web Services Region, remove the `key-id` parameter from the command. For more information about Amazon KMS keys, see Amazon Key Management Service Concepts in the *Amazon Key Management Service Developer Guide*.

To use a customer managed key instead of the Amazon managed key assigned to your account, specify the key by using the `--key-id` parameter. The parameter supports the following KMS parameter formats.

- Key Amazon Resource Name (ARN) example:

  `arn:aws:kms:us-east-2:123456789012:key/key-id`

- Alias ARN example:

  `arn:aws:kms:us-east-2:123456789012:alias/alias-name`

- Key ID example:

  `12345678-1234-1234-1234-123456789012`

- Alias Name example:

  `alias/MyAliasName`

You can create a customer managed key by using the Amazon Web Services Management Console or the Amazon KMS API. The following Amazon CLI commands create a customer managed key in the current Amazon Web Services Region of your Amazon Web Services account.

```
aws kms create-key
```

Use a command in the following format to create a `SecureString` parameter using the key you just created.

The following example uses a parameter named `/myapp/prod/vendor/merchant-id` with a merchant ID as the encrypted value and an Amazon KMS key.

Linux & macOS

```
aws ssm put-parameter \
    --name /myapp/prod/vendor/merchant-id \
    --value "merchant-739482" \
    --type SecureString \
    --key-id arn:aws:kms:us-
east-2:123456789012:key/1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d5e
```

Windows

```
aws ssm put-parameter ^
    --name /myapp/prod/vendor/merchant-id ^
    --value "merchant-739482" ^
    --type SecureString ^
    --key-id arn:aws:kms:us-
east-2:123456789012:key/1a2b3c4d-1a2b-1a2b-1a2b-1a2b3c4d5e
```

3. Run the following command to verify the details of the parameter.

   If you don't specify the `with-decryption` parameter, or if you specify the `no-with-decryption` parameter, the command returns an encrypted GUID.

   Linux & macOS

   ```
   aws ssm get-parameters \
       --name "the-parameter-name-you-specified" \
       --with-decryption
   ```

   Windows

   ```
   aws ssm get-parameters ^
       --name "the-parameter-name-you-specified" ^
       --with-decryption
   ```

4. Run the following command to view the parameter metadata.

   Linux & macOS

   ```
   aws ssm describe-parameters \
   ```

```
    --filters "Key=Name,Values=the-name-that-you-specified"
```

Windows

```
aws ssm describe-parameters ^
    --filters "Key=Name,Values=the-name-that-you-specified"
```

5. Run the following command to change the parameter value if you're **not** using a customer managed Amazon KMS key.

   Linux & macOS

   ```
   aws ssm put-parameter \
       --name "the-name-that-you-specified" \
       --value "a-new-parameter-value" \
       --type "SecureString" \
       --overwrite
   ```

   Windows

   ```
   aws ssm put-parameter ^
       --name "the-name-that-you-specified" ^
       --value "a-new-parameter-value" ^
       --type "SecureString" ^
       --overwrite
   ```

   -or-

   Run one of the following commands to change the parameter value if you **are** using a customer managed Amazon KMS key.

   Linux & macOS

   ```
   aws ssm put-parameter \
       --name "the-name-that-you-specified" \
       --value "a-new-parameter-value" \
       --type "SecureString" \
       --key-id "the-KMSkey-ID" \
       --overwrite
   ```

```
aws ssm put-parameter \
    --name "the-name-that-you-specified" \
    --value "a-new-parameter-value" \
    --type "SecureString" \
    --key-id "account-alias/the-KMSkey-ID" \
    --overwrite
```

Windows

```
aws ssm put-parameter ^
    --name "the-name-that-you-specified" ^
    --value "a-new-parameter-value" ^
    --type "SecureString" ^
    --key-id "the-KMSkey-ID" ^
    --overwrite
```

```
aws ssm put-parameter ^
    --name "the-name-that-you-specified" ^
    --value "a-new-parameter-value" ^
    --type "SecureString" ^
    --key-id "account-alias/the-KMSkey-ID" ^
    --overwrite
```

6. Run the following command to view the latest parameter value.

   Linux & macOS

   ```
   aws ssm get-parameters \
       --name "the-name-that-you-specified" \
       --with-decryption
   ```

   Windows

   ```
   aws ssm get-parameters ^
       --name "the-name-that-you-specified" ^
       --with-decryption
   ```

7. Run the following command to view the parameter value history.

Linux & macOS

```
aws ssm get-parameter-history \
    --name "the-name-that-you-specified"
```

Windows

```
aws ssm get-parameter-history ^
    --name "the-name-that-you-specified"
```

Note

You can manually create a parameter with an encrypted value. In this case, because the value is already encrypted, you don't need to choose the `SecureString` parameter type. If you choose `SecureString`, your parameter is doubly encrypted.

By default, all `SecureString` values are displayed as cipher-text. To decrypt a `SecureString` value, a user must have permission to call the Amazon KMS Decrypt API operation. For information about configuring Amazon KMS access control, see Authentication and Access Control for Amazon KMS in the *Amazon Key Management Service Developer Guide*.

Important

If you change the KMS key alias for the KMS key used to encrypt a parameter, you must also update the key alias that the parameter uses to reference Amazon KMS. This only applies to the KMS key alias; the key ID that an alias attaches to stays the same unless you delete the whole key.

Creating a multi-line parameter using the Amazon CLI

You can use the Amazon CLI to create a parameter with line breaks. Use line breaks to break up the text in longer parameter values for better legibility or, for example, update multi-paragraph parameter content for a web page. You can include the content in a JSON file and use the `--cli-input-json` option, using line break characters like \n, as shown in the following example.

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.

2. Run the following command to create a multi-line parameter.

   Linux & macOS

   ```
   aws ssm put-parameter \
       --name "MultiLineParameter3" \
       -type String \
       -value "{ \"Value\": \"LineOne\nLineTwo\nLine3\nLine4\"}"
   ```

   Windows

   ```
   aws ssm put-parameter ^
       -name "MultiLineParameter3" ^
       -type String ^
       -value "{ \"Value\": \"LineOne\nLineTwo\nLine3\nLine4\"}"
   ```

   Linux & macOS

   ```
   aws ssm put-parameter \
       --name "MultiLineParameter" \
       --type String \
       --cli-input-json file://MultiLineParameter.json
   ```

   Windows

   ```
   aws ssm put-parameter ^
       --name "MultiLineParameter" ^
       --type String ^
       --cli-input-json file://MultiLineParameter.json
   ```

   The following example shows the contents of the file `MultiLineParameter.json`.

   ```
   {
   ```

```
    "Value": "<para>Paragraph One</para>\n<para>Paragraph Two</para>
\n<para>Paragraph Three</para>"
}
```

The saved parameter value is stored as follows.

```
<para>Paragraph One</para>
<para>Paragraph Two</para>
<para>Paragraph Three</para>
```

Creating a Parameter Store parameter using Tools for Windows PowerShell

You can use Amazon Tools for Windows PowerShell to create `String`, `StringList`, and `SecureString` parameter types. After deleting a parameter, wait for at least 30 seconds to create a parameter with the same name.

Parameters can't be referenced or nested in the values of other parameters. You can't include `{{}}` or `{{ssm:parameter-name}}` in a parameter value.

> **Note**
>
> Parameters are only available in the Amazon Web Services Region where they were created.

Topics

- Creating a String parameter (Tools for Windows PowerShell)
- Creating a StringList parameter (Tools for Windows PowerShell)
- Creating a SecureString parameter (Tools for Windows PowerShell)

Creating a String parameter (Tools for Windows PowerShell)

1. Install and configure the Amazon Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

   For information, see Installing the Amazon Tools for PowerShell.
2. Run the following command to create a parameter that contains a plain text value. Replace each *example resource placeholder* with your own information.

```
Write-SSMParameter `
    -Name "parameter-name" `
    -Value "parameter-value" `
    -Type "String"
```

-or-

Run the following command to create a parameter that contains an Amazon Machine Image (AMI) ID as the parameter value.

> **Note**
>
> To create a parameter with a tag, first create an `Amazon.SimpleSystemsManagement.Model.Tag` object as a variable. The following is an example.
>
> ```
> $tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
> $tag.Key = "tag-key"
> $tag.Value = "tag-value"
> ```

```
Write-SSMParameter `
    -Name "parameter-name" `
    -Value "an-AMI-id" `
    -Type "String" `
    -DataType "aws:ec2:image" `
    -Tags $tag
```

The `-DataType` parameter specifies how Parameter Store validates the parameter value. For example, use `aws:ec2:image` to validate an AMI ID or `integer` to validate an integer value. If you don't specify a data type, the default is `text`, which performs no validation. For the full list of supported data types, see Parameter data types in Parameter Store. For more information about the `aws:ec2:image` data type, see Using native parameter support in Parameter Store for Amazon Machine Image IDs.

Here is an example that uses a parameter hierarchy.

```
Write-SSMParameter `
```

```
    -Name "/IAD/Web/SQL/IPaddress" `
    -Value "99.99.99.999" `
    -Type "String" `
    -Tags $tag
```

3. Run the following command to verify the details of the parameter.

```
(Get-SSMParameterValue -Name "the-parameter-name-you-specified").Parameters
```

Creating a StringList parameter (Tools for Windows PowerShell)

1. Install and configure the Amazon Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

   For information, see Installing the Amazon Tools for PowerShell.

2. Run the following command to create a StringList parameter. Replace each *example resource placeholder* with your own information.

> **Note**
>
> To create a parameter with a tag, first create an `Amazon.SimpleSystemsManagement.Model.Tag` object as a variable. The following is an example.
>
> ```
> $tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
> $tag.Key = "tag-key"
> $tag.Value = "tag-value"
> ```

```
Write-SSMParameter `
    -Name "parameter-name" `
    -Value "a-comma-separated-list-of-values" `
    -Type "StringList" `
    -Tags $tag
```

If successful, the command returns the version number of the parameter.

Here is an example.

```
Write-SSMParameter `
    -Name "stringlist-parameter" `
    -Value "Milana,Mariana,Mark,Miguel" `
    -Type "StringList" `
    -Tags $tag
```

> **Note**
>
> Items in a `StringList` must be separated by a comma (,). You can't use other punctuation or special characters to escape items in the list. If you have a parameter value that requires a comma, then use the `String` type.

3. Run the following command to verify the details of the parameter.

```
(Get-SSMParameterValue -Name "the-parameter-name-you-specified").Parameters
```

Creating a SecureString parameter (Tools for Windows PowerShell)

Before you create a `SecureString` parameter, read about the requirements for this type of parameter. For more information, see Creating a SecureString parameter using the Amazon CLI.

Only the *value* of a `SecureString` parameter is encrypted. Parameter names, descriptions, and other properties aren't encrypted.

> **Important**
>
> Parameter Store only supports symmetric encryption KMS keys. You can't use an asymmetric encryption KMS key to encrypt your parameters. For help determining whether a KMS key is symmetric or asymmetric, see Identifying symmetric and asymmetric KMS keys in the *Amazon Key Management Service Developer Guide*

1. Install and configure the Amazon Tools for PowerShell (Tools for Windows PowerShell), if you haven't already.

   For information, see Installing the Amazon Tools for PowerShell.

2. Run the following command to create a parameter. Replace each *example resource placeholder* with your own information.

> **Note**
>
> To create a parameter with a tag, first create an `Amazon.SimpleSystemsManagement.Model.Tag` object as a variable. The following is an example.
>
> ```
> $tag = New-Object Amazon.SimpleSystemsManagement.Model.Tag
> $tag.Key = "tag-key"
> $tag.Value = "tag-value"
> ```

```
Write-SSMParameter `
    -Name "parameter-name" `
    -Value "parameter-value" `
    -Type "SecureString"  `
    -KeyId "an Amazon KMS key ID, an Amazon KMS key ARN, an alias name, or an alias
 ARN" `
    -Tags $tag
```

If successful, the command returns the version number of the parameter.

> **Note**
>
> To use the Amazon managed key assigned to your account, remove the `-KeyId` parameter from the command.

The following example creates a `SecureString` parameter named `/myapp/dev/vendor/merchant-id` with a merchant ID as the encrypted value and an Amazon managed key.

```
Write-SSMParameter `
    -Name "/myapp/dev/vendor/merchant-id" `
    -Value "merchant-739482" `
    -Type "SecureString"`
    -Tags $tag
```

3. Run the following command to verify the details of the parameter.

```
(Get-SSMParameterValue -Name "the-parameter-name-you-specified" -WithDecryption
 $true).Parameters
```

By default, all `SecureString` values are displayed as cipher-text. To decrypt a `SecureString` value, a user must have permission to call the Amazon KMS Decrypt API operation. For information about configuring Amazon KMS access control, see Authentication and Access Control for Amazon KMS in the *Amazon Key Management Service Developer Guide*.

> **Important**
>
> If you change the KMS key alias for the KMS key used to encrypt a parameter, then you must also update the key alias the parameter uses to reference Amazon KMS. This only applies to the KMS key alias; the key ID that an alias attaches to stays the same unless you delete the whole key.

Searching for Parameter Store parameters in Systems Manager

When you have a lot of parameters in your account, it can be difficult to find information about a single or several parameters at a time. In this case, you can use filter tools to search for the ones you need information about, according to search criteria you specify. You can use the Amazon Systems Manager console, the Amazon Command Line Interface (Amazon CLI), the Amazon Tools for PowerShell, or the DescribeParameters API to search for parameters.

Topics

- Searching for a parameter using the console
- Searching for a parameter using the Amazon CLI

Searching for a parameter using the console

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. Select in the search box and choose how you want to search. For example, `Type` or `Name`.

4. Provide information for the search type you selected. For example:

   - If you're searching by `Type`, choose from `String`, `StringList`, or `SecureString`.
   - If you're searching by `Name`, choose `contains`, `equals`, or `begins-with`, and then enter all or part of a parameter name.

   > **Note**
   >
   > In the console, the default search type for `Name` is `contains`.

5. Press **Enter**.

The list of parameters is updated with the results of your search.

> **Note**
>
> Your search might contain more results than are displayed on the first page of results. Use the right arrow (**>**) at the topic of the parameter list (if available) to view the next set of results.

Searching for a parameter using the Amazon CLI

Use the `describe-parameters` command to view information about one or more parameters in the Amazon CLI.

The following examples demonstrate various options you can use to view information about the parameters in your Amazon Web Services account. For more information about these options, see describe-parameters in the *Amazon Command Line Interface User Guide*.

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.

2. Replace the sample values in the following commands with values reflecting parameters that have been created in your account.

Linux & macOS

```
aws ssm describe-parameters \
    --parameter-filters "Key=Name,Values=MyParameterName"
```

Windows

```
aws ssm describe-parameters ^
    --parameter-filters "Key=Name,Values=MyParameterName"
```

> **Note**
>
> For `describe-parameters`, the default search type for `Name` is `Equals`. In your parameter filters, specifying `"Key=Name,Values=MyParameterName"` is the same as specifying `"Key=Name,Option=Equals,Values=MyParameterName"`.

```
aws ssm describe-parameters \
    --parameter-filters "Key=Name,Option=Contains,Values=Product"
```

```
aws ssm describe-parameters \
    --parameter-filters "Key=Type,Values=String"
```

```
aws ssm describe-parameters \
    --parameter-filters "Key=Path,Values=/Production/West"
```

```
aws ssm describe-parameters \
    --parameter-filters "Key=Tier,Values=Standard"
```

```
aws ssm describe-parameters \
    --parameter-filters "Key=tag:tag-key,Values=tag-value"
```

```
aws ssm describe-parameters \
    --parameter-filters "Key=KeyId,Values=key-id"
```

> **Note**
>
> In the last example, *key-id* represents the ID of an Amazon Key Management Service (Amazon KMS) key used to encrypt a `SecureString` parameter created in your account. Alternatively, you can enter **alias/aws/ssm** to use the default Amazon KMS key for your account. For more information, see Creating a SecureString parameter using the Amazon CLI.

If successful, the command returns output similar to the following.

```
{
    "Parameters": [
        {
            "Name": "/Production/West/Manager",
            "Type": "String",
            "LastModifiedDate": 1573438580.703,
            "LastModifiedUser": "arn:aws:iam::111122223333:user/Mateo.Jackson",
            "Version": 1,
            "Tier": "Standard",
            "Policies": []
        },
        {
            "Name": "/Production/West/TeamLead",
            "Type": "String",
            "LastModifiedDate": 1572363610.175,
            "LastModifiedUser": "arn:aws:iam::111122223333:user/Mateo.Jackson",
            "Version": 1,
            "Tier": "Standard",
            "Policies": []
        },
        {
            "Name": "/Production/West/HR",
            "Type": "String",
            "LastModifiedDate": 1572363680.503,
            "LastModifiedUser": "arn:aws:iam::111122223333:user/Mateo.Jackson",
            "Version": 1,
            "Tier": "Standard",
            "Policies": []
        }
    ]
```

```
}
```

Assigning parameter policies in Parameter Store

Parameter policies help you manage a growing set of parameters by allowing you to assign specific criteria to a parameter such as an expiration date or *time to live*. Parameter policies are especially helpful in forcing you to update or delete configuration data stored in Parameter Store, a tool in Amazon Systems Manager. Parameter Store offers the following types of policies: `Expiration`, `ExpirationNotification`, and `NoChangeNotification`.

If you manage credentials that require automatic rotation, cross-account access, or fine-grained audit logging, we recommend using Amazon Secrets Manager. Secrets Manager is purpose-built for managing secrets such as database credentials, API keys, and supported third-party software-vended secrets. For more information, see What is Amazon Secrets Manager? in the *Amazon Secrets Manager User Guide*.

Parameter Store enforces parameter policies by using asynchronous, periodic scans. After you create a policy, you don't need to perform additional actions to enforce the policy. Parameter Store independently performs the action defined by the policy according to the criteria you specified.

> **Note**
>
> Parameter policies are available for parameters that use the advanced parameters tier. For more information, see Choosing parameter tiers in Parameter Store.

A parameter policy is a JSON array, as shown in the following table. You can assign a policy when you create a new advanced parameter, or you can apply a policy by updating a parameter. Parameter Store supports the following types of parameter policies.

Policy	Details	Examples
Expiration	This policy deletes the parameter. You can specify a specific date and time by using either the `ISO_INSTANT` format or the `ISO_OFFSET_DATE_TI`	`{ "Type": "Expiration", "Version": "1.0", "Attributes": {`

Policy	Details	Examples
	ME format. To change when you want the parameter to be deleted, update the policy. Updating a *parameter* doesn't affect the expiration date or time of the policy attached to it. When the expiration date and time is reached, Parameter Store deletes the parameter. **Note** This example uses the ISO_INSTANT format. You can also specify a date and time by using the ISO_OFFSET_DATE_TIME format. Here is an example: 2019-11-01T22:13:48.87+10:30:00 .	"Timestamp": "2018-12-02T21:34:33.000Z" } }

ExpirationNotification	This policy initiates an event in Amazon EventBridge (EventBridge) that notifies you about the expiration. By using this policy, you can receive notifications before the expiration time is reached, in units of days or hours.	{
		"Type": "ExpirationNotification",
		"Version": "1.0",
		"Attributes": {
		"Before": "15",
		"Unit": "Days"
		}
		}

Policy	Details	Examples
NoChangeNotification	This policy initiates an event in EventBridge if a parameter has *not* been modified for a specified period of time. This policy type is useful when, for example, an approved AMI ID needs to be reviewed or updated within a period of time. This policy determines when to send a notification by reading the `LastModifiedTime` attribute of the parameter. If you change or edit a parameter, the system resets the notification time period based on the new value of `LastModifiedTime` .	`{ "Type": "NoChangeNotification", "Version": "1.0", "Attributes": { "After": "20", "Unit": "Days" } }`

You can assign multiple policies to a parameter. For example, you can assign `Expiration` and `ExpirationNotification` policies so that the system initiates an EventBridge event to notify you about the impending deletion of a parameter. You can assign a maximum of ten (10) policies to a parameter.

The following example shows the request syntax for a PutParameter API request that assigns four policies to a new `SecureString` parameter named `/myapp/prod/vendor/merchant-id`.

```
{
    "Name": "/myapp/prod/vendor/merchant-id",
    "Description": "Parameter with policies",
    "Value": "merchant-739482",
    "Type": "SecureString",
    "Overwrite": "True",
    "Policies": [
```

```
        {
            "Type": "Expiration",
            "Version": "1.0",
            "Attributes": {
                "Timestamp": "2018-12-02T21:34:33.000Z"
            }
        },
        {
            "Type": "ExpirationNotification",
            "Version": "1.0",
            "Attributes": {
                "Before": "30",
                "Unit": "Days"
            }
        },
        {
            "Type": "ExpirationNotification",
            "Version": "1.0",
            "Attributes": {
                "Before": "15",
                "Unit": "Days"
            }
        },
        {
            "Type": "NoChangeNotification",
            "Version": "1.0",
            "Attributes": {
                "After": "20",
                "Unit": "Days"
            }
        }
    ]
}
```

Adding policies to an existing parameter

This section includes information about how to add policies to an existing parameter by using the Amazon Systems Manager console, the Amazon Command Line Interface (Amazon CLI), and Amazon Tools for Windows PowerShell. For information about how to create a new parameter that includes policies, see Creating Parameter Store parameters in Systems Manager.

Topics

- Adding policies to an existing parameter using the console

- Adding policies to an existing parameter using the Amazon CLI
- Adding policies to an existing parameter (Tools for Windows PowerShell)

Adding policies to an existing parameter using the console

Use the following procedure to add policies to an existing parameter by using the Systems Manager console.

To add policies to an existing parameter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the option next to the parameter that you want to update to include policies, and then choose **Edit**.
4. Choose **Advanced**.
5. (Optional) In the **Parameter policies** section, choose **Enabled**. You can specify an expiration date and one or more notification policies for this parameter.
6. Choose **Save changes**.

> **Important**
>
> - Parameter Store preserves policies on a parameter until you either overwrite the policies with new policies or remove the policies.
> - To remove all policies from an existing parameter, edit the parameter and apply an empty policy by using brackets and curly braces, as follows: `[{}]`
> - If you add a new policy to a parameter that already has policies, then Systems Manager overwrites the policies attached to the parameter. The existing policies are deleted. If you want to add a new policy to a parameter that already has one or more policies, copy and paste the original policies, type the new policy, and then save your changes.

Adding policies to an existing parameter using the Amazon CLI

Use the following procedure to add policies to an existing parameter by using the Amazon CLI.

To add policies to an existing parameter

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.

2. Run the following command to add policies to an existing parameter. Replace each *example resource placeholder* with your own information.

   Linux & macOS

   ```
   aws ssm put-parameter
       --name "parameter name" \
       --value 'parameter value' \
       --type parameter type \
       --overwrite \
       --policies "[{policies-enclosed-in-brackets-and-curly-braces}]"
   ```

   Windows

   ```
   aws ssm put-parameter
       --name "parameter name" ^
       --value 'parameter value' ^
       --type parameter type ^
       --overwrite ^
       --policies "[{policies-enclosed-in-brackets-and-curly-braces}]"
   ```

   The following example includes an expiration policy that deletes the parameter after 15 days. The example also includes a notification policy that generates an EventBridge event five (5) days before the parameter is deleted. Last, it includes a `NoChangeNotification` policy if no changes are made to this parameter after 60 days. The example uses a parameter named `/myapp/prod/vendor/merchant-id` with a merchant ID as the encrypted value and an Amazon Key Management Service Amazon KMS key. For more information about Amazon KMS keys, see Amazon Key Management Service Concepts in the *Amazon Key Management Service Developer Guide*.

Linux & macOS

```
aws ssm put-parameter \
    --name "/myapp/prod/vendor/merchant-id" \
    --value "merchant-739482" \
    --type "SecureString" \
    --overwrite \
    --policies "[{\"Type\":\"Expiration\",\"Version\":\"1.0\",\"Attributes\":
{\"Timestamp\":\"2020-05-13T00:00:00.000Z\"}},{\"Type\":\"ExpirationNotification
\",\"Version\":\"1.0\",\"Attributes\":{\"Before\":\"5\",\"Unit\":\"Days\"}},
{\"Type\":\"NoChangeNotification\",\"Version\":\"1.0\",\"Attributes\":{\"After
\":\"60\",\"Unit\":\"Days\"}}]"
```

Windows

```
aws ssm put-parameter ^
    --name "/myapp/prod/vendor/merchant-id" ^
    --value "merchant-739482" ^
    --type "SecureString" ^
    --overwrite ^
    --policies "[{\"Type\":\"Expiration\",\"Version\":\"1.0\",\"Attributes\":
{\"Timestamp\":\"2020-05-13T00:00:00.000Z\"}},{\"Type\":\"ExpirationNotification
\",\"Version\":\"1.0\",\"Attributes\":{\"Before\":\"5\",\"Unit\":\"Days\"}},
{\"Type\":\"NoChangeNotification\",\"Version\":\"1.0\",\"Attributes\":{\"After
\":\"60\",\"Unit\":\"Days\"}}]"
```

3. Run the following command to verify the details of the parameter. Replace *parameter name* with your own information.

Linux & macOS

```
aws ssm describe-parameters  \
    --parameter-filters "Key=Name,Values=parameter name"
```

Windows

```
aws ssm describe-parameters  ^
    --parameter-filters "Key=Name,Values=parameter name"
```

Important

- Parameter Store retains policies for a parameter until you either overwrite the policies with new policies or remove the policies.
- To remove all policies from an existing parameter, edit the parameter and apply an empty policy of brackets and curly braces. Replace each *example resource placeholder* with your own information. For example:

  Linux & macOS

  ```
  aws ssm put-parameter \
      --name parameter name \
      --type parameter type  \
      --value 'parameter value' \
      --policies "[{}]"
  ```

  Windows

  ```
  aws ssm put-parameter ^
      --name parameter name ^
      --type parameter type  ^
      --value 'parameter value' ^
      --policies "[{}]"
  ```

- If you add a new policy to a parameter that already has policies, then Systems Manager overwrites the policies attached to the parameter. The existing policies are deleted. If you want to add a new policy to a parameter that already has one or more policies, copy and paste the original policies, type the new policy, and then save your changes.

Adding policies to an existing parameter (Tools for Windows PowerShell)

Use the following procedure to add policies to an existing parameter by using Tools for Windows PowerShell. Replace each *example resource placeholder* with your own information.

To add policies to an existing parameter

1. Open Tools for Windows PowerShell and run the following command to specify your credentials. You must either have administrator permissions in Amazon Elastic Compute Cloud

(Amazon EC2), or you must have been granted the appropriate permission in Amazon Identity and Access Management (IAM).

```
Set-AWSCredentials `
    -AccessKey access-key-name `
    -SecretKey secret-key-name
```

2. Run the following command to set the Region for your PowerShell session. The example uses the US East (Ohio) Region (us-east-2).

```
Set-DefaultAWSRegion `
    -Region us-east-2
```

3. Run the following command to add policies to an existing parameter. Replace each *example resource placeholder* with your own information.

```
Write-SSMParameter `
    -Name "parameter name" `
    -Value "parameter value" `
    -Type "parameter type" `
    -Policies "[{policies-enclosed-in-brackets-and-curly-braces}]" `
    -Overwrite
```

The following example includes an expiration policy that deletes the parameter at midnight (GMT) on May 13, 2020. The example also includes a notification policy that generates an EventBridge event five (5) days before the parameter is deleted. Last, it includes a NoChangeNotification policy if no changes are made to this parameter after 60 days. The example uses a parameter named /myapp/prod/vendor/merchant-id with a merchant ID as the encrypted value and an Amazon managed key.

```
Write-SSMParameter `
    -Name "/myapp/prod/vendor/merchant-id" `
    -Value "merchant-739482" `
    -Type "SecureString" `
    -Policies "[{\"Type\":\"Expiration\",\"Version\":\"1.0\",\"Attributes\":
{\"Timestamp\":\"2018-05-13T00:00:00.000Z\"}},{\"Type\":\"ExpirationNotification
\",\"Version\":\"1.0\",\"Attributes\":{\"Before\":\"5\",\"Unit\":\"Days\"}},{\"Type
\":\"NoChangeNotification\",\"Version\":\"1.0\",\"Attributes\":{\"After\":\"60\",
\"Unit\":\"Days\"}}]" `
    -Overwrite
```

4. Run the following command to verify the details of the parameter. Replace *parameter name* with your own information.

```
(Get-SSMParameterValue -Name "parameter name").Parameters
```

Important

- Parameter Store preserves policies on a parameter until you either overwrite the policies with new policies or remove the policies.
- To remove all policies from an existing parameter, edit the parameter and apply an empty policy of brackets and curly braces. For example:

```
Write-SSMParameter `
    -Name "parameter name" `
    -Value "parameter value" `
    -Type "parameter type" `
    -Policies "[{}]"
```

- If you add a new policy to a parameter that already has policies, then Systems Manager overwrites the policies attached to the parameter. The existing policies are deleted. If you want to add a new policy to a parameter that already has one or more policies, copy and paste the original policies, type the new policy, and then save your changes.

Working with parameter hierarchies in Parameter Store

Managing dozens or hundreds of parameters as a flat list is time consuming and prone to errors. It can also be difficult to identify the correct parameter for a task. This means you might accidentally use the wrong parameter, or you might create multiple parameters that use the same configuration data.

You can use parameter hierarchies to help you organize and manage parameters. A hierarchy is a parameter name that includes a path that you define by using forward slashes (/).

Topics

- Understanding parameter hierarchy through examples
- Querying parameters in a hierarchy

- Managing parameters using hierarchies using the Amazon CLI

Understanding parameter hierarchy through examples

The following example uses three hierarchy levels in the name to identify the following:

`/Environment/Type of computer/Application/Data`

`/Dev/WebServer/Linux/approved-ami`

You can create a hierarchy with a maximum of 15 levels. We suggest that you create hierarchies that reflect an existing hierarchical structure in your environment, as shown in the following examples:

- Your Continuous integration and Continuous delivery environment (CI/CD workflows)

  `/Dev/WebServer/Linux/approved-ami`

  `/Staging/WebServer/Linux/approved-ami`

  `/Prod/WebServer/Linux/approved-ami`
- Your applications that use containers

  ```
  /MyApp/.NET/Images/approved-ami
  ```
- Your business organization

  `/Finance/Accountants/UserList`

  `/Finance/Analysts/UserList`

  `/HR/Employees/EU/UserList`

Parameter hierarchies standardize the way you create parameters and make it easier to manage parameters over time. A parameter hierarchy can also help you identify the correct parameter for a configuration task. This helps you to avoid creating multiple parameters with the same configuration data.

You can create a hierarchy that lets you share parameters across different environments, as shown in the following examples that use approved AMI IDs in development and staging environments.

`/DevTest/MyApp/images/approved-ami`

You could then create a unique approved AMI ID for your production environment, as shown in the following example:

`/prod/MyApp/images/approved-ami`

You aren't required to specify a parameter hierarchy. You can create parameters at level one. These are called *root* parameters. For backward compatibility, all parameters created in Parameter Store before hierarchies were released are root parameters. The systems treats both of the following parameters as root parameters.

`/parameter-name`

`parameter-name`

Querying parameters in a hierarchy

Another benefit of using hierarchies is the ability to query for all parameters *under* a certain level in a hierarchy by using the GetParametersByPath API operation. For example, if you run the following command from the Amazon Command Line Interface (Amazon CLI), the system returns all parameters under the `Oncall` level:

```
aws ssm get-parameters-by-path --path /Dev/Web/Oncall
```

Sample output:

```
{
    "Parameters": [
        {
            "Name": "/Dev/Web/Oncall/Week1",
            "Type": "String",
            "Value": "John Doe",
            "Version": 1,
            "LastModifiedDate": "2024-11-22T07:18:53.510000-08:00",
            "ARN": "arn:aws:ssm:us-east-2:123456789012:parameter/Dev/Web/Oncall/Week1",
            "DataType": "text"
        },
        {
            "Name": "/Dev/Web/Oncall/Week2",
            "Type": "String",
```

```
            "Value": "Mary Major",
            "Version": 1,
            "LastModifiedDate": "2024-11-22T07:21:25.325000-08:00",
            "ARN": "arn:aws:ssm:us-east-2:123456789012:parameter/Dev/Web/Oncall/Week2",
            "DataType": "text"
        }
    ]
}
```

To view decrypted `SecureString` parameters in a hierarchy, you specify the path and the `--with-decryption` parameter, as shown in the following example.

```
aws ssm get-parameters-by-path --path /Prod/ERP/SAP --with-decryption
```

Managing parameters using hierarchies using the Amazon CLI

This procedure shows how to work with parameters and parameter hierarchies by using the Amazon CLI.

To manage parameters using hierarchies

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.

2. Run the following command to create a parameter that uses the `allowedPattern` parameter and the `String` parameter type. The allowed pattern in this example means the value for the parameter must be between 1 and 4 digits long.

   Linux & macOS

   ```
   aws ssm put-parameter \
       --name "/MyService/Test/MaxConnections" \
       --value 100 --allowed-pattern "\d{1,4}" \
       --type String
   ```

   Windows

   ```
   aws ssm put-parameter ^
       --name "/MyService/Test/MaxConnections" ^
   ```

```
    --value 100 --allowed-pattern "\d{1,4}" ^
    --type String
```

The command returns the version number of the parameter.

3. Run the following command to *attempt* to overwrite the parameter you just created with a new value.

   Linux & macOS

   ```
   aws ssm put-parameter \
       --name "/MyService/Test/MaxConnections" \
       --value 10,000 \
       --type String \
       --overwrite
   ```

   Windows

   ```
   aws ssm put-parameter ^
       --name "/MyService/Test/MaxConnections" ^
       --value 10,000 ^
       --type String ^
       --overwrite
   ```

   The system returns the following error because the new value doesn't meet the requirements of the allowed pattern you specified in the previous step.

   ```
   An error occurred (ParameterPatternMismatchException) when calling the PutParameter
    operation: Parameter value, cannot be validated against allowedPattern: \d{1,4}
   ```

4. Run the following command to create a `SecureString` parameter that uses an Amazon managed key. The allowed pattern in this example validates that the parameter value is an AMI ID.

   Linux & macOS

   ```
   aws ssm put-parameter \
       --name "/MyService/Test/approved-ami" \
       --value "ami-0abcdef1234567890" \
       --allowed-pattern "ami-[a-f0-9]{17}" \
   ```

```
    --type SecureString
```

Windows

```
aws ssm put-parameter ^
    --name "/MyService/Test/approved-ami" ^
    --value "ami-0abcdef1234567890" ^
    --allowed-pattern "ami-[a-f0-9]{17}" ^
    --type SecureString
```

5. Run the following commands to create more parameters that use the hierarchy structure from the previous step.

Linux & macOS

```
aws ssm put-parameter \
    --name "/MyService/Test/DBname" \
    --value "SQLDevDb" \
    --type String
```

```
aws ssm put-parameter \
    --name "/MyService/Test/user" \
    --value "SA" \
    --type String
```

```
aws ssm put-parameter \
    --name "/MyService/Test/userType" \
    --value "SQLuser" \
    --type String
```

Windows

```
aws ssm put-parameter ^
    --name "/MyService/Test/DBname" ^
    --value "SQLDevDb" ^
    --type String
```

```
aws ssm put-parameter ^
    --name "/MyService/Test/user" ^
    --value "SA" ^
```

```
    --type String
```

```
aws ssm put-parameter ^
    --name "/MyService/Test/userType" ^
    --value "SQLuser" ^
    --type String
```

6. Run the following command to get the value of two parameters.

   Linux & macOS

   ```
   aws ssm get-parameters \
       --names "/MyService/Test/user" "/MyService/Test/userType"
   ```

   Windows

   ```
   aws ssm get-parameters ^
       --names "/MyService/Test/user" "/MyService/Test/userType"
   ```

7. Run the following command to query for all parameters under a single level.

   Linux & macOS

   ```
   aws ssm get-parameters-by-path \
       --path "/MyService/Test"
   ```

   Windows

   ```
   aws ssm get-parameters-by-path ^
       --path "/MyService/Test"
   ```

8. Run the following command to delete two parameters.

   Linux & macOS

   ```
   aws ssm delete-parameters \
       --names "/IADRegion/Dev/user" "/IADRegion/Dev/userType"
   ```

   Windows

   ```
   aws ssm delete-parameters ^
   ```

```
    --names "/IADRegion/Dev/user" "/IADRegion/Dev/userType"
```

Preventing access to Parameter Store API operations

Using service-specific *conditions* supported by Systems Manager for Amazon Identity and Access Management (IAM) policies, you can explicity allow or deny access to Parameter Store API operations and content. By using these conditions, you can allow only certain IAM Entities (users and roles) in your organization to call certain API actions, or prevent certain IAM Entities from running them. This includes actions run through the Parameter Store console, the Amazon Command Line Interface (Amazon CLI), and SDKs.

Before you write a policy that denies access to particular parameters, review How Parameter Store authorizes parameter retrieval. Parameter Store authorizes each retrieval operation independently, so a policy that denies only one action might not produce the result you intend.

Topics

- How Parameter Store authorizes parameter retrieval
- Restricting access to specific parameters and paths
- Restricting decryption of SecureString parameter values
- Condition keys specific to Parameter Store
- Preventing changes to existing parameters using ssm:Overwrite
- Preventing creation or updates to parameters that use a parameter policy using ssm:Policies

How Parameter Store authorizes parameter retrieval

Four Parameter Store operations can return a parameter value, and each one is authorized against its own IAM action. Three of them authorize against the parameters named in the request. `GetParametersByPath` is the exception: it authorizes against the path in the request rather than against the parameters it returns.

Operation	IAM action authorized	Resource authorized against
GetParameter	`ssm:GetParameter`	The requested parameter
GetParameters	`ssm:GetParameters`	Each requested parameter

Operation	IAM action authorized	Resource authorized against
GetParameterHistory	`ssm:GetParameterHistory`	The requested parameter
GetParametersByPath	`ssm:GetParametersByPath`	The path specified in the request, *not* the parameters returned

Two consequences of this model are important when you design restrictive policies.

Each action is authorized independently

Parameter Store authorizes each retrieval operation against its own IAM action. Denying `ssm:GetParameter` has no effect on calls to `ssm:GetParameters`, `ssm:GetParametersByPath`, or `ssm:GetParameterHistory`. To restrict access to a parameter value, deny every action that can return it.

Because all four action names begin with `GetParameter`, the wildcard pattern `ssm:GetParameter*` covers them in a single statement. For examples, see Denying permissions.

`GetParametersByPath` is authorized against the requested path

This means resource-level denies on an individual parameter don't limit what a path query returns. If you use parameter hierarchies to separate environments or application tiers, apply your controls to the paths themselves.

> **Important**
>
> Parameter Store authorizes the `GetParametersByPath` operation against the path that you specify in the request, not against each parameter that the operation returns. A principal who is allowed to call `GetParametersByPath` for the path `/a` receives every parameter under that path, including `/a/b`. This is true even if the same policy explicitly denies access to `/a/b` for other actions.
>
> To prevent a parameter from being returned by `GetParametersByPath`, deny the `ssm:GetParametersByPath` action on every ancestor path that could include the parameter in its results. For example, to prevent `/a/b` from being returned, deny `ssm:GetParametersByPath` for both `/a` and `/`.

The same pattern applies to deletion. DeleteParameters is authorized against `ssm:DeleteParameters`, not against `ssm:DeleteParameter`. To prevent a principal from deleting a parameter, deny both actions.

> **Note**
>
> Parameter Store operations are recorded in Amazon CloudTrail. If you want to review which operations have been used to retrieve a parameter in your account, see Auditing and logging Parameter Store activity.

Restricting access to specific parameters and paths

Use the following approach to restrict access to a parameter or a set of parameters. This approach reflects the authorization behavior described in How Parameter Store authorizes parameter retrieval.

To restrict access to specific parameters or paths

1. **Prefer granting narrow access over denying broad access.** Where you can, scope `Allow` statements to the smallest set of parameters a principal needs, rather than granting broad access and then subtracting from it. An `Allow` statement that never grants access to a parameter doesn't depend on you enumerating every action correctly.
2. **Separate sensitive parameters into their own path.** Restricting access is simpler when sensitive parameters don't share a path with parameters that principals are allowed to read. For example, store restricted values under `/myapp/restricted/` rather than alongside general configuration under `/myapp/config/`. For more information about organizing parameters, see Working with parameter hierarchies in Parameter Store.
3. **When you deny access, deny every action that can return the value.** Include `ssm:GetParameter`, `ssm:GetParameters`, `ssm:GetParameterHistory`, and `ssm:GetParametersByPath`, or use `ssm:GetParameter*` to match all four.
4. **For `GetParametersByPath`, deny every ancestor path.** A deny on the parameter's own ARN doesn't stop the parameter from being returned by a call against a path above it. To protect `/myapp/restricted/db-password`, deny `ssm:GetParametersByPath` for `/myapp/restricted`, `/myapp`, and `/`.
5. **For `SecureString` parameters, restrict `kms:Decrypt` on the KMS key.** Retrieving a decrypted `SecureString` value requires `kms:Decrypt` permission on the key that

encrypted it, regardless of which Parameter Store operation is used. Denying `kms:Decrypt` therefore prevents decryption through every retrieval path. See [Restricting decryption of `SecureString` parameter values].

6. **Verify the result.** Test each retrieval operation as the restricted principal. Include a test of `GetParametersByPath` against each ancestor path to confirm the policy behaves as you intend. You can also use the IAM policy simulator to evaluate a policy against specific actions and resources.

For more information about how IAM combines `Allow` and `Deny` statements, see Policy evaluation logic in the *IAM User Guide*.

Restricting decryption of `SecureString` parameter values

A `SecureString` parameter value is encrypted with an Amazon KMS key. Any principal that retrieves the decrypted value must have `kms:Decrypt` permission on that key, whichever Parameter Store operation they call. This makes Amazon KMS key permissions an effective control for `SecureString` parameters, because a single Amazon KMS policy statement applies to all retrieval paths at once.

To use this control effectively, encrypt sensitive parameters with a customer managed key rather than the Amazon managed key.

Important

The Amazon managed key for Parameter Store (`aws/ssm`) grants `Decrypt` permission to all IAM principals in the Amazon Web Services account. If you need different levels of access to `SecureString` parameters within an account, don't encrypt them with the default key.

For key policy examples, including how to deny access to the Amazon managed key and how to grant access to a customer managed key, see Encrypting and decrypting parameters using Amazon KMS keys.

Note

Restricting `kms:Decrypt` prevents a principal from reading an encrypted *value*. It doesn't hide the parameter's name, description, or other metadata, which aren't encrypted, and

it doesn't prevent the parameter from being listed. Use Parameter Store action denies as described in Restricting access to specific parameters and paths to control those.

Condition keys specific to Parameter Store

Systems Manager supports two condition keys that are specific to Parameter Store. Both apply to the `PutParameter` operation and control how parameters can be created and updated.

`ssm:Overwrite`

Controls whether a principal can update an existing parameter. See Preventing changes to existing parameters using `ssm:Overwrite`.

`ssm:Policies`

Controls whether a principal can create or update a parameter that includes a parameter policy. See Preventing creation or updates to parameters that use a parameter policy using `ssm:Policies`.

To restrict which parameters a principal can *read*, use resource-level and action-level controls as described in Restricting access to specific parameters and paths rather than condition keys.

Preventing changes to existing parameters using `ssm:Overwrite`

Use the `ssm:Overwrite` condition to control whether IAM Entities can update existing parameters.

In the following sample policy, the `"Allow"` statement grants permission to create parameters by running the `PutParameter` API operation in the Amazon Web Services account 123456789012 in the US East (Ohio) Region (us-east-2).

However, the `"Deny"` statement prevents Entities from changing values of *existing* parameters because the `Overwrite` option is explicitly denied for the `PutParameter` operation. Therefore, Entities that are assigned this policy can create parameters, but not make changes to existing parameters.

JSON

```
{
```

```
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:PutParameter"
            ],
            "Resource": "arn:aws-cn:ssm:us-east-1:111122223333:parameter/*"
        },
        {
            "Effect": "Deny",
            "Action": [
                "ssm:PutParameter"
            ],
            "Condition": {
                "StringEquals": {
                    "ssm:Overwrite": [
                        "true"
                    ]
                }
            },
            "Resource": "arn:aws-cn:ssm:us-east-1:111122223333:parameter/*"
        }
    ]
}
```

Preventing creation or updates to parameters that use a parameter policy using `ssm:Policies`

User the `ssm:Policies` condition to control whether Entities can create parameters that include a parameter policy and update existing parameters that include a parameter policy.

In the following policy example, the `"Allow"` statement grants general permission to create parameters, but the `"Deny"` statement prevents Entities from creating or updating parameters that include a parameter policy in the the Amazon Web Services account 123456789012 in the US East (Ohio) Region (us-east-2). Entities can still create or update parameters that aren't assigned a parameter policy.

                    ]
                }
            },
            "Resource": "arn:aws-cn:ssm:us-east-1:111122223333:parameter/*"
        }
    ]
}
```

Working with parameter labels in Parameter Store

A parameter label is a user-defined alias to help you manage different versions of a parameter. When you modify a parameter, Amazon Systems Manager automatically saves a new version and increments the version number by one. A label can help you remember the purpose of a parameter version when there are multiple versions.

For example, let's say you have a parameter called `/MyApp/Images/ApprovedAMI`. The value of the parameter is an approved AMI ID for a test environment. After you finish testing the image, you want the parameter to use the approved AMI ID for a production environment. You change the value of `/MyApp/Images/ApprovedAMI`. Systems Manager automatically creates version two with the new AMI ID. To help you remember the purpose of each version, you attach a label to each parameter. For version one, you attach the label *Test* and for version two you attach the label *Production*.

You can move labels from one version of a parameter to another version. For example, if you create version 3 of the `/MyApp/Images/ApprovedAMI` parameter with a new approved AMI ID, then you can move the *Production* label from version 2 of the parameter to version 3 of the parameter.

Parameter labels are a lightweight alternative to parameter tags. Your organization might have strict guidelines for tags that must be applied to different Amazon resources. In contrast, a label is simply a text association for a specific version of a parameter.

Similar to tags, you can query parameters by using labels. You can view a list of specific parameter versions that all use the same label if you query your parameter set by using the GetParametersByPath API operation, as described later in this section.

> **Note**
>
> If you run a command that specifies a version of a parameter that doesn't exist, the command fails. It doesn't fall back to the latest or default value of the parameter.

Label requirements and restrictions

Parameter labels have the following requirements and restrictions:

- A version of a parameter can have a maximum of 10 labels.
- You can't attach the same label to different versions of the same parameter. For example, if version 1 of the parameter has the label *Production*, then you can't attach *Production* to version 2.
- You can move a label from one version of a parameter to another.
- You can't create a label when you create a parameter. You must attach a label to a specific version of a parameter.
- If you no longer want to use a parameter label, then you can move it to a different version of a parameter or delete it.
- A label can have a maximum of 100 characters.
- Labels can contain letters (case sensitive), numbers, periods (.), hyphens (-), or underscores (_).
- Labels can't begin with a number, "aws", or "ssm" (not case sensitive). If a label doesn't meet these requirements, then the label isn't attached to the parameter version and the system displays it in the list of `InvalidLabels`.

Topics

- Working with parameter labels using the console
- Working with parameter labels using the Amazon CLI

Working with parameter labels using the console

This section describes how to perform the following tasks by using the Systems Manager console.

- Creating a parameter label using the console
- Viewing labels attached to a parameter using the console
- Moving a parameter label using the console
- Deleting parameter labels using the console

Creating a parameter label using the console

The following procedure describes how to attach a label to a specific version of an *existing* parameter by using the Systems Manager console. You can't attach a label when you create a parameter.

To attach a label to a parameter version

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the name of a parameter to open the details page for that parameter.
4. Choose the **History** tab.
5. Choose the parameter version for which you want to attach a label.
6. Choose **Manage labels**.
7. Choose **Add new label**.
8. In the text box, enter the label name. To add more labels, choose **Add new label**. You can attach a maximum of ten labels.
9. When you're finished, choose **Save changes**.

Viewing labels attached to a parameter using the console

A parameter version can have a maximum of ten labels. The following procedure describes how to view all labels attached to a parameter version by using the Systems Manager console.

To view labels attached to a parameter version

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the name of a parameter to open the details page for that parameter.
4. Choose the **History** tab.
5. Locate the parameter version for which you want to view all attached labels. The **Labels** column shows all labels attached to the parameter version.

Moving a parameter label using the console

The following procedure describes how to move a parameter label to a different version of the same parameter by using the Systems Manager console.

To move a label to a different parameter version

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the name of a parameter to open the details page for that parameter.
4. Choose the **History** tab.
5. Choose the parameter version for which you want to move the label.
6. Choose **Manage labels**.
7. Choose **Add new label**.
8. In the text box, enter the label name.
9. When you're finished, choose **Save changes**.

Deleting parameter labels using the console

The following procedure describes how to delete one or multiple parameter labels using the Systems Manager console.

To delete labels from a parameter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the name of a parameter to open the details page for that parameter.
4. Choose the **History** tab.
5. Choose the parameter version for which you want to delete labels.
6. Choose **Manage labels**.
7. Choose **Remove**. next to each label you want to delete.
8. When you're finished, choose **Save changes**.
9. Confirm that your changes are correct, enter `Confirm` in the text box, and choose **Confirm**.

Working with parameter labels using the Amazon CLI

This section describes how to perform the following tasks by using the Amazon Command Line Interface (Amazon CLI).

- Creating a new parameter label using the Amazon CLI
- Viewing labels for a parameter using the Amazon CLI
- Viewing a list of parameters that are assigned a label using the Amazon CLI
- Moving a parameter label using the Amazon CLI
- Deleting parameter labels using the Amazon CLI

Creating a new parameter label using the Amazon CLI

The following procedure describes how to attach a label to a specific version of an *existing* parameter by using the Amazon CLI. You can't attach a label when you create a parameter.

To create a parameter label

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.

2. Run the following command to view a list of parameters for which you have permission to attach a label.

   > **Note**
   >
   > Parameters are only available in the Amazon Web Services Region where they were created. If you don't see a parameter for which you want to attach a label, then verify your Region.

   ```
   aws ssm describe-parameters
   ```

   Note the name of a parameter for which you want to attach a label.

3. Run the following command to view all versions of the parameter.

   ```
   aws ssm get-parameter-history --name "parameter-name"
   ```

   Note the parameter version for which you want to attach a label.

4. Run the following command to retrieve information about a parameter by version number.

   ```
   aws ssm get-parameters --names "parameter-name:version-number"
   ```

   The following example shows the command.

   ```
   aws ssm get-parameters --names "/Production/ApprovedAMI:3"
   ```

5. Run one of the following commands to attach a label to a version of a parameter. If you attach multiple labels, separate label names with a space.

   Attach a label to the latest version of a parameter

```
aws ssm label-parameter-version --name parameter-name  --labels label-name
```

Attach a label to a specific version of a parameter

```
aws ssm label-parameter-version --name parameter-name --parameter-version version-
number --labels label-name
```

The following examples show the commands.

```
aws ssm label-parameter-version --name /config/approved-ami --labels production
 east-region finance
```

```
aws ssm label-parameter-version --name /config/approved-ami --parameter-version 3
 --labels image-test
```

> **Note**
>
> If the output shows the label you created in the `InvalidLabels` list, then the label doesn't meet the requirements described earlier in this topic. Review the requirements and try again. If the `InvalidLabels` list is empty, then your label was successfully applied to the version of the parameter.

6. You can view the details of the parameter by using either a version number or a label name. Run the following command and specify the label you created in the previous step.

```
aws ssm get-parameter --name parameter-name:label-name --with-decryption
```

The command returns information like the following.

```
{
    "Parameter": {
        "Version": version-number,
        "Type": "parameter-type",
        "Name": "parameter-name",
        "Value": "parameter-value",
        "Selector": ":label-name"
    }
```

```
}
```

> **Note**
>
> *Selector* in the output is either the version number or the label that you specified in the Name input field.

Viewing labels for a parameter using the Amazon CLI

You can use the GetParameterHistory API operation to view the full history and all labels attached to a specified parameter. Or, you can use the GetParametersByPath API operation to view a list of all parameters that are assigned a specific label.

To view labels for a parameter by using the GetParameterHistory API operation

1. Run the following command to view a list of parameters for which you can view labels.

   > **Note**
   >
   > Parameters are only available in the Region where they were created. If you don't see a parameter for which you want to move a label, then verify your Region.

   ```
   aws ssm describe-parameters
   ```

   Note the name of the parameter you want to view the labels of.

2. Run the following command to view all versions of the parameter.

   ```
   aws ssm get-parameter-history --name parameter-name --with-decryption
   ```

   The system returns information like the following.

   ```
   {
       "Parameters": [
           {
               "Name": "/Config/endpoint",
               "LastModifiedDate": 1528932105.382,
   ```

```
            "Labels": [
                "Deprecated"
            ],
            "Value": "MyTestService-June-Release.example.com",
            "Version": 1,
            "LastModifiedUser": "arn:aws:iam::123456789012:user/test",
            "Type": "String"
        },
        {
            "Name": "/Config/endpoint",
            "LastModifiedDate": 1528932111.222,
            "Labels": [
                "Current"
            ],
            "Value": "MyTestService-July-Release.example.com",
            "Version": 2,
            "LastModifiedUser": "arn:aws:iam::123456789012:user/test",
            "Type": "String"
        }
    ]
}
```

Viewing a list of parameters that are assigned a label using the Amazon CLI

You can use the GetParametersByPath API operation to view a list of all parameters in a path that are assigned a specific label.

Run the following command to view a list of parameters in a path that are assigned a specific label. Replace each *example resource placeholder* with your own information.

```
aws ssm get-parameters-by-path \
    --path parameter-path \
    --parameter-filters Key=Label,Values=label-name,Option=Equals \
    --max-results a-number \
    --with-decryption --recursive
```

The system returns information like the following. For this example, the user searched under the `/Config` path.

```
{
    "Parameters": [
        {
```

```
            "Version": 3,
            "Type": "SecureString",
            "Name": "/Config/DBpwd",
            "Value": "MyS@perGr&pass33"
        },
        {
            "Version": 2,
            "Type": "String",
            "Name": "/Config/DBusername",
            "Value": "TestUserDB"
        },
        {
            "Version": 2,
            "Type": "String",
            "Name": "/Config/endpoint",
            "Value": "MyTestService-July-Release.example.com"
        }
    ]
}
```

Moving a parameter label using the Amazon CLI

The following procedure describes how to move a parameter label to a different version of the same parameter.

To move a parameter label

1. Run the following command to view all versions of the parameter. Replace *parameter name* with your own information.

   ```
   aws ssm get-parameter-history \
       --name "parameter name"
   ```

   Note the parameter versions you want to move the label to and from.

2. Run the following command to assign an existing label to a different version of a parameter. Replace each *example resource placeholder* with your own information.

   ```
   aws ssm label-parameter-version \
       --name parameter name \
       --parameter-version version number \
       --labels name-of-existing-label
   ```

> **Note**
>
> If you want to move an existing label to the latest version of a parameter, then remove `--parameter-version` from the command.

Deleting parameter labels using the Amazon CLI

The following procedure describes how to delete parameter labels by using the Amazon CLI.

To delete a parameter label

1. Run the following command to view all versions of the parameter. Replace *parameter name* with your own information.

```
aws ssm get-parameter-history \
    --name "parameter name"
```

The system returns information like the following.

```
{
    "Parameters": [
        {
            "Name": "foo",
            "DataType": "text",
            "LastModifiedDate": 1607380761.11,
            "Labels": [
                "13",
                "12"
            ],
            "Value": "test",
            "Version": 1,
            "LastModifiedUser": "arn:aws:iam::123456789012:user/test",
            "Policies": [],
            "Tier": "Standard",
            "Type": "String"
        },
        {
            "Name": "foo",
            "DataType": "text",
            "LastModifiedDate": 1607380763.11,
```

```
            "Labels": [
                "l1"
            ],
            "Value": "test",
            "Version": 2,
            "LastModifiedUser": "arn:aws:iam::123456789012:user/test",
            "Policies": [],
            "Tier": "Standard",
            "Type": "String"
        }
    ]
}
```

Note the parameter version for which you want to delete a label or labels.

2. Run the following command to delete the labels you choose from that parameter. Replace each *example resource placeholder* with your own information.

```
aws ssm unlabel-parameter-version \
    --name parameter name \
    --parameter-version version \
    --labels label 1,label 2,label 3
```

The system returns information like the following.

```
{
    "InvalidLabels": ["invalid"],
    "DeletedLabels" : ["Prod"]
 }
```

Working with parameter versions in Parameter Store

Each time you edit the value of a parameter, Parameter Store, a tool in Amazon Systems Manager creates a new *version* of the parameter and retains the previous versions. When you initially create a parameter, Parameter Store assigns version 1 to that parameter. When you change the value of the parameter, Parameter Store automatically increments the version number by one. You can view the details, including the values, of all versions in a parameter's history.

You can also specify the version of a parameter to use in API commands and SSM documents; for example: `ssm:MyParameter:3`. You can specify a parameter name and a specific version number

in API calls and SSM documents. If you don't specify a version number, the system automatically uses the latest version. If you specify the number for a version that doesn't exist, the system returns an error rather than falling back to the latest or default version of the parameter.

You can use parameter versions to see the number of times a parameter changed over a period of time. Parameter versions also provide a layer of protection if a parameter value is accidentally changed.

You can create and maintain up to 100 versions of a parameter. After you have created 100 versions of a parameter, each time you create a new version, the oldest version of the parameter is removed from history to make room for the new version.

An exception to this is when there are already 100 parameter versions in history, and a parameter label is assigned to the oldest version of a parameter. In this case, that version isn't removed from history, and the request to create a new parameter version fails. This safeguard is to prevent parameter versions with mission critical labels assigned to them from being deleted. To continue creating new parameters, first move the label from the oldest version of the parameter to a newer one for use in your operations. For information about moving parameter labels, see Moving a parameter label using the console and Moving a parameter label using the Amazon CLI.

The following procedures show you how to edit a parameter and then verify that you created a new version. You can use the `get-parameter` and `get-parameters` commands to view parameter versions. For examples on using these commands, see GetParameter and GetParameters in the *Amazon Systems Manager API Reference*

Topics

- Creating a new version of a parameter using the console
- Referencing a parameter version

Creating a new version of a parameter using the console

You can use the Systems Manager console to create a new version of a parameter and view the version history of a parameter.

To create a new version of a parameter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.

3. Choose the name of a parameter that you created earlier. For information about creating a new parameter, see Creating Parameter Store parameters in Systems Manager.
4. Choose **Edit**.
5. In the **Value** box, enter a new value, and then choose **Save changes**.
6. Choose the name of the parameter you just updated. On the **Overview** tab, verify that the version number incremented by 1, and verify the new value.
7. To view the history of all versions of a parameter, choose the **History** tab.

Referencing a parameter version

You can reference specific parameter versions in commands, API calls, and SSM documents by using the following format: ssm:*parameter-name*:*version-number*.

In the following example, the Amazon Elastic Compute Cloud (Amazon EC2) `run-instances` command uses version 3 of the parameter `golden-ami`.

Linux & macOS

```
aws ec2 run-instances \
    --image-id resolve:ssm:/golden-ami:3 \
    --count 1 \
    --instance-type t2.micro \
    --key-name my-key-pair \
    --security-groups my-security-group
```

Windows

```
aws ec2 run-instances ^
    --image-id resolve:ssm:/golden-ami:3 ^
    --count 1 ^
    --instance-type t2.micro ^
    --key-name my-key-pair ^
    --security-groups my-security-group
```

Note

Using `resolve` and a parameter value only works with the `--image-id` option and a parameter that contains an Amazon Machine Image (AMI) as its value. For more

information, see Using native parameter support in Parameter Store for Amazon Machine Image IDs.

Here is an example for specifying version 2 of a parameter named `MyRunCommandParameter` in an SSM document.

YAML

```
---
schemaVersion: '2.2'
description: Run a shell script or specify the commands to run.
parameters:
  commands:
    type: String
    description: "(Required) Specify a shell script or a command to run."
    displayType: textarea
    default: "{{ssm:MyRunCommandParameter:2}}"
mainSteps:
- action: aws:runShellScript
  name: RunScript
  inputs:
    runCommand:
    - "{{commands}}"
```

JSON

```
{
    "schemaVersion": "2.2",
    "description": "Run a shell script or specify the commands to run.",
    "parameters": {
        "commands": {
            "type": "String",
            "description": "(Required) Specify a shell script or a command to run.",
            "displayType": "textarea",
            "default": "{{ssm:MyRunCommandParameter:2}}"
        }
    },
    "mainSteps": [
        {
            "action": "aws:runShellScript",
            "name": "RunScript",
```

```
            "inputs": {
                "runCommand": [
                    "{{commands}}"
                ]
            }
        }
    ]
}
```

Working with shared parameters in Parameter Store

Sharing advanced parameters simplifies configuration data management in a multi-account environment. You can centrally store and manage your parameters and share them with other Amazon Web Services accounts that need to reference them.

Parameter Store integrates with Amazon Resource Access Manager (Amazon RAM) to enable advanced parameter sharing. Amazon RAM is a service that lets you share resources with other Amazon Web Services accounts or through Amazon Organizations.

With Amazon RAM, you share resources that you own by creating a resource share. A resource share specifies the resources to share, permissions to grant, and the consumers with whom to share. Consumers can include:

- Specific Amazon Web Services accounts inside or outside of its organization in Amazon Organizations
- An organizational unit inside its organization in Amazon Organizations
- Its entire organization in Amazon Organizations

For more information about Amazon RAM, see the *Amazon RAM User Guide*.

This topic explains how to share parameters that you own, and how to use parameters that are shared with you.

Contents

- Prerequisites for sharing parameters
- Sharing a parameter
- Stop sharing a shared parameter
- Identifying shared parameters

- Accessing shared parameters
- Permissions sets for sharing parameters
- Maximum throughput for shared parameters
- Pricing for shared parameters
- Cross-account access for closed Amazon Web Services accounts

Prerequisites for sharing parameters

The following prerequisites must be met before you can share parameters from your account:

- To share a parameter, you must own it in your Amazon Web Services account. You can't share a parameter that has been shared with you.
- To share a parameter, it must be in the advanced parameter tier. For information about parameter tiers, see Choosing parameter tiers in Parameter Store. For information about changing an existing standard parameter to an advanced parameter, see Changing a standard parameter to an advanced parameter.
- To share a `SecureString` parameter, it must be encrypted with a customer managed key, and you must share the key separately through Amazon Key Management Service. Amazon managed keys cannot be shared. Parameters encrypted with the default Amazon managed key can be updated to use a customer managed key instead. For Amazon KMS key definitions, see Amazon KMS concepts in the *Amazon Key Management Service Developer Guide*.
- To share a parameter with your organization or an organizational unit in Amazon Organizations, you must enable sharing with Amazon Organizations. For more information, see Enable Sharing with Amazon Organizations in the *Amazon RAM User Guide*.

Sharing a parameter

To share a parameter, you must add it to a resource share. A resource share is an Amazon RAM resource that lets you share your resources across Amazon Web Services accounts. A resource share specifies the resources to share, and the consumers with whom they are shared.

When you share a parameter that you own with other Amazon Web Services accounts, you can choose from two Amazon managed permissions to grant the consumers. For more information, see Permissions sets for sharing parameters.

If you are part of an organization in Amazon Organizations and sharing within your organization is enabled, you can grant consumers in your organization access from the Amazon RAM console to

the shared parameter. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared parameter after accepting the invitation.

You can share a parameter that you own using the Amazon RAM console, or the Amazon CLI.

> **Note**
>
> While you can share a parameter using the Systems Manager PutResourcePolicy API operation, we recommend using Amazon Resource Access Manager (Amazon RAM) instead. This is because using `PutResourcePolicy` requires the extra step of promoting the parameter to a standard Resource Share using the Amazon RAM PromoteResourceShareCreatedFromPolicy API operation. Otherwise, the parameter won't be returned by the Systems Manager DescribeParameters API operation using the `--shared` option.

To share a parameter that you own using the Amazon RAM console

See Creating a resource share in Amazon RAM in the *Amazon RAM User Guide*.

Make the following selections as you complete the procedure:

- In the Step 1 page, for **Resources**, select `Parameter Store Advanced Parameter`, and then select the box of each parameter in the advanced parameter tier that you want to share.
- In the Step 2 page, for **Managed permissions**, choose the permission to grant consumers, as described in Permissions sets for sharing parameters later in this topic.

Choose other options based on your parameter sharing objectives.

To share a parameter that you own using the Amazon CLI

Use the create-resource-share command to add parameters to a new resource share.

Use the associate-resource-share command to add parameters to an existing resource share.

The following example creates a new resource share to share parameters with consumers in an organization and in an individual account.

```
aws ram create-resource-share \
    --name "MyParameter" \
```

```
    --resource-arns "arn:aws:ssm:us-east-2:123456789012:parameter/MyParameter" \
    --principals "arn:aws:organizations::123456789012:ou/o-63bEXAMPLE/ou-46xi-rEXAMPLE"
"987654321098"
```

Stop sharing a shared parameter

When you stop sharing a shared parameter, the consumer account can no longer access the parameter.

To stop sharing a parameter that you own, you must remove it from the resource share. You can do this using the Systems Manager console, Amazon RAM console, or the Amazon CLI.

To stop sharing a parameter that you own using the Amazon RAM console

See Update a resource share in Amazon RAM in the *Amazon RAM User Guide*.

To stop sharing a parameter that you own using the Amazon CLI

Use the disassociate-resource-share command.

Identifying shared parameters

Owners and consumers can identify shared parameters using the Amazon CLI.

To identify shared parameters using the Amazon CLI

To identify shared parameters using the Amazon CLI, you can choose from the Systems Manager `describe-parameters` command and the Amazon RAM `list-resources` command.

When you use the `--shared` option with `describe-parameters`, the command returns the parameters that are shared with you.

The following is an example:

```
aws ssm describe-parameters --shared
```

Accessing shared parameters

Consumers can access shared parameters using the Amazon command line tools, and Amazon SDKs. For consumer accounts, parameters shared with that account aren't included in the **My parameters** page.

CLI Example: Accessing shared parameter details using the Amazon CLI

To access shared parameter details using the Amazon CLI, you can use the get-parameter or get-parameters commands. You must specify the full parameter ARN as the `--name` in order to retrieve the parameter from another account.

The following is an example.

```
aws ssm get-parameter \
    --name arn:aws:ssm:us-east-2:123456789012:parameter/MySharedParameter
```

Supported and unsupported integrations for shared parameters

Currently, you can use shared parameters in the following integration scenarios:

- Amazon CloudFormation template parameters
- The Amazon Parameters and Secrets Lambda extension
- Amazon Elastic Compute Cloud (EC2) launch templates
- Values for `ImageID` with the EC2 RunInstances command to create instances from an Amazon Machine Image (AMI)
- Retrieving parameter values in runbooks for Automation, a tool in Systems Manager

The following scenarios and integrated services do not currently support the use of shared parameters:

- Parameters in commands in Run Command, a tool in Systems Manager
- Amazon CloudFormation dynamic references
- The values of environment variables in Amazon CodeBuild
- The values of environment variables in Amazon App Runner
- The value of a secret in Amazon Elastic Container Service

Permissions sets for sharing parameters

Consumer accounts receive read-only access to the parameters you share with them. The consumer can't update or delete the parameter. The consumer can't share the parameter with a third account.

When you create a resource share in Amazon Resource Access Manager for sharing your parameters, you can choose from two Amazon managed permission sets to grant this read-only access:

AWSRAMDefaultPermissionSSMParameterReadOnly

Allowed actions: `DescribeParameters`, `GetParameter`, `GetParameters`

AWSRAMPermissionSSMParameterReadOnlyWithHistory

Allowed actions: `DescribeParameters`, `GetParameter`, `GetParameters`, `GetParameterHistory`

When you follow the steps in Creating a resource share in Amazon RAM in the *Amazon RAM User Guide*, choose `Parameter Store Advanced Parameters` as the resource type. Select either of the managed permissions based on whether you want users to view parameter history.

> **Note**
>
> If you're retrieving shared parameters programmatically (for example, using Amazon Lambda) you might need to add the `ssm:GetResourcePolicies` and `ssm:PutResourcePolicy` permissions to any IAM roles calling Amazon Resource Access Manager API actions.

Maximum throughput for shared parameters

Systems Manager limits the maximum throughput (transactions per second) for the GetParameter and GetParameters. operations. Throughput is enforced at the individual account level. Therefore, each account that consumes a shared parameter can use its maximum allowed throughput without being affected by other accounts. For more information about maximum throughput for parameters, see the following topics:

- Increasing Parameter Store throughput
- Systems Manager Service quotas in the *Amazon Web Services General Reference*.

Pricing for shared parameters

Cross-account sharing is only available in the advanced parameter tier. For advanced parameters, charges are incurred at the current price for the *storage* and *API usage* for each advanced parameter. The owning account is charged for storage of the advanced parameter. Any consuming account that makes an API call to a shared advanced parameter is charged for the parameter usage.

For example, if Account A creates an advanced parameter, `MyAdvancedParameter`, that account is charged USD 0.05 per month to store the parameter.

Account A then shares `MyAdvancedParameter` with Account B and Account C. During a month, the three accounts make calls to `MyAdvancedParameter`. The following table illustrates the charges they would incur for the number of calls each makes.

> **Note**
>
> The charges in the following table are for illustration only. To verify current pricing, see Amazon Systems Manager Pricing for Parameter Store.

Account	Number of calls	Charges
Account A (owning account)	10,000 calls	• One month advanced parameter storage: USD 0.05 • 10,000 calls to `MyAdvancedParameter` : USD 0.05 • **Total: USD 0.10**
Account B (consuming account)	20,000 calls	• 20,000 calls to `MyAdvancedParameter` : USD 0.10 • **Total: USD 0.10**
Account C (consuming account)	30,000 calls	• 30,000 calls to `MyAdvancedParameter` : USD 0.15 • **Total: USD 0.15**

Cross-account access for closed Amazon Web Services accounts

If the Amazon Web Services account that owns a shared parameter is closed, all consuming accounts lose access to the shared parameter. If the owning account is reopened within 90 days after the account is closed, consuming accounts regain access to the previously shared parameters. For more information about reopening an account during the Post-Closure Period, see Accessing

your Amazon Web Services account after you close it in the *Amazon Account Management Reference Guide*.

Working with parameters in Parameter Store using Run Command commands

You can work with parameters in Run Command. For more information, see Amazon Systems Manager Run Command.

Running a String parameter using the console

The following procedure walks you through the process of running a command that uses a `String` parameter.

To run a String parameter using Parameter Store

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose `AWS-RunPowerShellScript` (Windows) or `AWS-RunShellScript` (Linux).
5. For **Command parameters**, enter **`echo {{ssm:parameter-name}}`**. For example: **`echo {{ssm:/Test/helloWorld}}`**.
6. In the **Targets** section, choose the managed nodes on which you want to run this operation by specifying tags, selecting instances or edge devices manually, or specifying a resource group.

   > **Tip**
   >
   > If a managed node you expect to see isn't listed, see Troubleshooting managed node availability for troubleshooting tips.

7. For **Other parameters**:
   - For **Comment**, enter information about this command.
   - For **Timeout (seconds)**, specify the number of seconds for the system to wait before failing the overall command execution.
8. For **Rate control**:

- For **Concurrency**, specify either a number or a percentage of managed nodes on which to run the command at the same time.

> **Note**
>
> If you selected targets by specifying tags applied to managed nodes or by specifying Amazon resource groups, and you aren't certain how many managed nodes are targeted, then restrict the number of targets that can run the document at the same time by specifying a percentage.

- For **Error threshold**, specify when to stop running the command on other managed nodes after it fails on either a number or a percentage of nodes. For example, if you specify three errors, then Systems Manager stops sending the command when the fourth error is received. Managed nodes still processing the command might also send errors.

9. (Optional) For **Output options**, to save the command output to a file, select the **Write command output to an S3 bucket** box. Enter the bucket and prefix (folder) names in the boxes.

> **Note**
>
> The S3 permissions that grant the ability to write the data to an S3 bucket are those of the instance profile (for EC2 instances) or IAM service role (hybrid-activated machines) assigned to the instance, not those of the IAM user performing this task. For more information, see Configure instance permissions required for Systems Manager or Create an IAM service role for a hybrid environment. In addition, if the specified S3 bucket is in a different Amazon Web Services account, make sure that the instance profile or IAM service role associated with the managed node has the necessary permissions to write to that bucket.

10. In the **SNS notifications** section, if you want notifications sent about the status of the command execution, select the **Enable SNS notifications** check box.

    For more information about configuring Amazon SNS notifications for Run Command, see Monitoring Systems Manager status changes using Amazon SNS notifications.

11. Choose **Run**.

12. In the **Command ID** page, in the **Targets and outputs** area, select the button next to the ID of a node where you ran the command, and then choose **View output**. Verify that the output of the command is the value you provided for the parameter, such as **`This is my first parameter`**.

Running a parameter using the Amazon CLI

Example 1: Simple command

The following example command includes a Systems Manager parameter named `DNS-IP`. The value of this parameter is simply the IP address of a node. This example uses an Amazon Command Line Interface (Amazon CLI) command to echo the parameter value.

Linux & macOS

```
aws ssm send-command \
    --document-name "AWS-RunShellScript" \
    --document-version "1" \
    --targets "Key=instanceids,Values=i-02573cafcfEXAMPLE" \
    --parameters "commands='echo {{ssm:DNS-IP}}'" \
    --timeout-seconds 600 \
    --max-concurrency "50" \
    --max-errors "0" \
    --region us-east-2
```

Windows

```
aws ssm send-command ^
    --document-name "AWS-RunPowerShellScript" ^
    --document-version "1" ^
    --targets "Key=instanceids,Values=i-02573cafcfEXAMPLE" ^
    --parameters "commands='echo {{ssm:DNS-IP}}'" ^
    --timeout-seconds 600 ^
    --max-concurrency "50" ^
    --max-errors "0" ^
    --region us-east-2
```

The command returns information like the following.

```
{
```

```
    "Command": {
        "CommandId": "c70a4671-8098-42da-b885-89716EXAMPLE",
        "DocumentName": "AWS-RunShellScript",
        "DocumentVersion": "1",
        "Comment": "",
        "ExpiresAfter": "2023-12-26T15:19:17.771000-05:00",
        "Parameters": {
            "commands": [
                "echo {{ssm:DNS-IP}}"
            ]
        },
        "InstanceIds": [],
        "Targets": [
            {
                "Key": "instanceids",
                "Values": [
                    "i-02573cafcfEXAMPLE"
                ]
            }
        ],
        "RequestedDateTime": "2023-12-26T14:09:17.771000-05:00",
        "Status": "Pending",
        "StatusDetails": "Pending",
        "OutputS3Region": "us-east-2",
        "OutputS3BucketName": "",
        "OutputS3KeyPrefix": "",
        "MaxConcurrency": "50",
        "MaxErrors": "0",
        "TargetCount": 0,
        "CompletedCount": 0,
        "ErrorCount": 0,
        "DeliveryTimedOutCount": 0,
        "ServiceRole": "",
        "NotificationConfig": {
            "NotificationArn": "",
            "NotificationEvents": [],
            "NotificationType": ""
        },
        "CloudWatchOutputConfig": {
            "CloudWatchLogGroupName": "",
            "CloudWatchOutputEnabled": false
        },
        "TimeoutSeconds": 600,
        "AlarmConfiguration": {
```

```
            "IgnorePollAlarmFailure": false,
            "Alarms": []
        },
        "TriggeredAlarms": []
    }
}
```

After a command execution completes, you can view more information about it using the following commands:

- get-command-invocation – View detailed information about the command execution.
- list-command-invocations – View the command execution status on a specific managed node.
- list-commands – View the command execution status across managed nodes.

Example 2: Decrypt a `SecureString` parameter value

The next example command uses a `SecureString` parameter named **SecureMerchantId**. The command used in the `parameters` field retrieves and decrypts the value of the `SecureString` parameter without including the plaintext value directly in the command.

Linux

```
aws ssm send-command \
        --document-name "AWS-RunShellScript" \
        --document-version "1" \
        --targets "Key=instanceids,Values=i-02573cafcfEXAMPLE" \
        --parameters '{"commands":["merchant_id=$(aws ssm get-parameters --names
 SecureMerchantId --with-decryption --query Parameters[0].Value --output text --
region us-east-2)","test -n "$merchant_id" && echo Retrieved SecureString parameter
 value"]}' \
        --timeout-seconds 600 \
        --max-concurrency "50" \
        --max-errors "0" \
        --region us-east-2
```

Windows

```
aws ssm send-command ^
        --document-name "AWS-RunPowerShellScript" ^
        --document-version "1" ^
```

```
        --targets "Key=instanceids,Values=i-02573cafcfEXAMPLE" ^
        --parameters "commands=['$merchantId = (Get-SSMParameterValue -Names
 SecureMerchantId -WithDecryption $True).Parameters[0].Value','if ($merchantId)
 { Write-Host ''Retrieved SecureString parameter value'' }']" ^
        --timeout-seconds 600 ^
        --max-concurrency "50" ^
        --max-errors "0" ^
        --region us-east-2
```

Example 3: Reference a parameter in an SSM document

You can also reference Systems Manager parameters in the *Parameters* section of an SSM document, as shown in the following example.

```
{
   "schemaVersion":"2.0",
   "description":"Sample version 2.0 document v2",
   "parameters":{
      "commands" : {
        "type": "StringList",
        "default": ["{{ssm:parameter-name}}"]
      }
    },
    "mainSteps":[
       {
          "action":"aws:runShellScript",
          "name":"runShellScript",
          "inputs":{
             "runCommand": "{{commands}}"
          }
       }
    ]
}
```

Don't confuse the similar syntax for *local parameters* used in the `runtimeConfig` section of SSM documents with Parameter Store parameters. A local parameter isn't the same as a Systems Manager parameter. You can distinguish local parameters from Systems Manager parameters by the absence of the `ssm:` prefix.

```
"runtimeConfig":{
        "aws:runShellScript":{
```

```
        "properties":[
            {
                "id":"0.aws:runShellScript",
                "runCommand":"{{ commands }}",
                "workingDirectory":"{{ workingDirectory }}",
                "timeoutSeconds":"{{ executionTimeout }}"
```

Note

SSM documents don't support references to `SecureString` parameters. This means that to use `SecureString` parameters with, for example, Run Command, you have to retrieve the parameter value before passing it to Run Command, as shown in the following examples.

Linux & macOS

```
merchant_id=$(aws ssm get-parameters --names parameter-name --with-decryption
 --query Parameters[0].Value --output text)
```

```
aws ssm send-command \
    --document-name AWS-RunShellScript \
    --parameters commands="test \"$merchant_id\" != \"\" && case
 \"$merchant_id\" in merchant-*) echo Merchant ID value retrieved ;; *) echo
 Unexpected merchant ID value; exit 1 ;; esac" \
    --instance-ids instance-id
```

Windows

```
aws ssm send-command ^
    --document-name AWS-RunPowerShellScript ^
    --parameters commands="$merchantId = (Get-SSMParameterValue -
Names parameter-name -WithDecryption $True).Parameters[0].Value; if
 ($merchantId -like 'merchant-*') { Write-Host 'Merchant ID value
 retrieved' } else { Write-Host 'Unexpected merchant ID value'; exit 1 }" ^
    --instance-ids instance-id
```

Powershell

```
$merchantId = (Get-SSMParameterValue -Names parameter-name -WithDecryption
 $True).Parameters[0].Value
```

```
if ($merchantId -like "merchant-*") { Write-Host "Merchant ID value
 retrieved" } else { Write-Host "Unexpected merchant ID value"; exit 1 }
```

Parameter data types in Parameter Store

When you create or update a parameter, you can specify a *data type* to tell Parameter Store how to validate the parameter value. For most data types, Parameter Store validates the value during the `PutParameter` operation and rejects values that don't conform. The exception is `aws:ec2:image`. For this data type, Parameter Store validates the value asynchronously. For more information, see Using native parameter support in Parameter Store for Amazon Machine Image IDs.

The default data type is `text`, which performs no validation. You can change an existing parameter from one data type to another, such as from `text` to `integer` or from `integer` to `float`. The exceptions are `aws:ec2:image` and `aws:ssm:integration`. You can't change a parameter to or from either of these data types.

Validation applies to every supported parameter type for a given data type. Most data types support `String` and `SecureString`. Some data types also support `StringList`. For a `StringList` parameter, Parameter Store validates each item in the list. If any item is invalid, the whole request fails. For the parameter types that each data type supports, see Supported data types.

Parameter Store API operations that retrieve parameters always return the value as a string, regardless of data type. These operations include `GetParameter`, `GetParameters`, and `GetParametersByPath`. For example, if a parameter has the data type `integer` and the value `443`, `GetParameter` returns the value as the string `"443"`. Convert the value to the type that your application needs after you retrieve it.

> **Note**
>
> You can use the `AllowedPattern` parameter constraint together with a predefined data type. If you specify both, the parameter value must pass the data type validation and match the allowed pattern.

Supported data types

Data types listed as *Advanced only* in the following table require the parameter to be an advanced parameter:

- If you create a standard parameter with one of these data types, the request fails.
- If you use Intelligent-Tiering, Parameter Store creates the parameter as an advanced parameter.
- If you change the data type of an existing standard parameter to one of these data types, you must also change the parameter to the advanced tier, or the request fails. If you use Intelligent-Tiering, Parameter Store upgrades the parameter to the advanced tier automatically. On the console, you must choose **Switch to advanced**. For more information, see Default tier and individual parameter tier settings.

The following table lists the data types that you can assign to parameters.

Parameter data types

Data type	Validation	Notes
`text` Parameter types: `String`, `StringList` , `SecureString` Tier: Standard or Advanced	None (default)	The default data type. Use it for values that don't need validation.
`aws:ec2:image` Parameter types: `String` Tier: Standard or Advanced	Valid Amazon Machine Image (AMI) ID format and AMI availability	Validated asynchronously. For more information, see Using native parameter support in Parameter Store for Amazon Machine Image IDs.
`aws:ssm:integration` Parameter types: `SecureString`	Valid Systems Manager integration definition	Used for Systems Manager Automation webhook integrations. For more information, see Creating webhook integrations for Automation.

Data type	Validation	Notes
Tier: Standard or Advanced		
`aws:region` Parameter types: `String`, `SecureString` Tier: Standard or Advanced	Name of a launched Amazon Web Services Region, including opt-in Regions	Example: `us-east-1`
`aws:account:id` Parameter types: `String`, `StringList` , `SecureString` Tier: Standard or Advanced	Amazon Web Services account ID format (12 digits)	Parameter Store checks only the format. It doesn't confirm that the account exists. The hyphenated form shown on the console (`1111-2222-3333`) isn't valid. Example: `111122223333`
`boolean` Parameter types: `String`, `SecureString` Tier: Standard or Advanced	Boolean value: `true`, `True`, `TRUE`, `false`, `False`, `FALSE`, `0`, or `1`	Valid values are `0`, `1`, and `true` or `false` in all lowercase, all uppercase, or with only an initial capital letter. Other capitalizations, such as `tRue`, aren't valid. Examples: `true`, `FALSE`, `1`
`integer` Parameter types: `String`, `SecureString` Tier: Standard or Advanced	Signed 32-bit integer (`-2147483648` to `2147483647`), with no leading zeros, plus sign, or decimal point	Values such as `007`, `+7`, `7.0`, and `5000000000` aren't valid. Examples: `443`, `-42`

Data type	Validation	Notes
`float` Parameter types: `String`, `SecureString` Tier: Standard or Advanced	Floating-point value (negative values and exponent notation allowed)	The value must be representable as a 64-bit IEEE 754 floating-point number. `NaN`, `Infinity`, and values that overflow or round to zero (such as `1e-999`) aren't valid. Examples: `3.14`, `-0.5`, `1e5`
`binary` Parameter types: `String`, `SecureString` Tier: Standard or Advanced	Binary value that contains only the digits `0` and `1`	The value can contain only the digits `0` and `1`. This data type doesn't accept base64-encoded data. There's no length limit beyond the parameter value size, and leading zeros are kept (`0011` is valid). Example: `101101`
`hostname` Parameter types: `String`, `SecureString` Tier: Standard or Advanced	Valid host name (single-label names such as `myhost` are allowed)	Underscores aren't allowed, so DNS names such as `_dmarc.example.com` aren't valid. IP addresses aren't valid host names. Internationalized names must use punycode (`xn--`). Examples: `www.example.com` , `myhost`
`email` Parameter types: `String`, `StringList` , `SecureString` Tier: Standard or Advanced	Valid email address	The value must be a bare address. Display names (`Mary <mary@example.com>`) and quoted local parts aren't accepted, and the domain must have at least two labels. Example: `mary_major@example.com`

Data type	Validation	Notes
`ipv4-address` Parameter types: `String`, `StringList` , `SecureString` Tier: Standard or Advanced	Valid IPv4 address	The value must be a single address. CIDR prefixes (`10.0.0.0/16`) and ports aren't accepted. Leading zeros (`192.168.001.1`) aren't valid. Example: `192.0.2.1`
`ipv6-address` Parameter types: `String`, `StringList` , `SecureString` Tier: Standard or Advanced	Valid IPv6 address (compressed form allowed)	The value must be a single address. CIDR prefixes and ports aren't accepted. Zone IDs and brackets aren't accepted, and the value isn't normalized. Examples: `2001:db8:0:0:0:0:0:1` , `2001:db8::1`
`url` Parameter types: `String`, `SecureString` Tier: Advanced only	Valid URL format, including the scheme (protocol) and host	Any scheme is accepted, but the URL must include a host, so `mailto:` and `file:///` URLs aren't valid. URLs that contain a password (`user:password@host`) aren't valid. Example: `https://example.com`
`json` Parameter types: `String`, `SecureString` Tier: Advanced only	Valid JSON. The top-level value must be an object or an array, and duplicate keys aren't allowed. The maximum nesting depth is 64.	Scalar values, such as `42` or `"abc"`, aren't valid. Example: `{"port": 443}`

Data type	Validation	Notes
`jsonc` Parameter types: `String`, `SecureString` Tier: Advanced only	Valid JSON. The top-level value must be an object or an array, and duplicate keys aren't allowed. Line (`//`) and block (`/* */`) comments are allowed. The maximum nesting depth is 64.	Scalar values, such as `42` or `"abc"`, aren't valid. Trailing commas aren't allowed. Comments are stored and returned as written, so use a JSONC-aware parser to read the value. Example: `{"port": 443 /* HTTPS */}`

Example: Creating a parameter with a data type

The following Amazon CLI example creates a `String` parameter with the data type `integer` and the value `443`.

Linux & macOS

```
aws ssm put-parameter \
    --name "/myapp/config/port" \
    --value "443" \
    --type String \
    --data-type "integer"
```

Windows

```
aws ssm put-parameter ^
    --name "/myapp/config/port" ^
    --value "443" ^
    --type String ^
    --data-type "integer"
```

If you specify a value that doesn't conform to the data type's rules, the command fails and returns an error. For example, the command fails if you specify `--data-type "integer"` with the value `"abc"`.

Using native parameter support in Parameter Store for Amazon Machine Image IDs

When you create a `String` parameter, you can specify the *data type* as `aws:ec2:image` to make sure that the parameter value you enter is a valid Amazon Machine Image (AMI) ID format.

Support for AMI ID formats lets you avoid updating all your scripts and templates with a new ID each time the AMI that you want to use in your processes changes. You can create a parameter with the data type `aws:ec2:image`, and for its value, enter the ID of an AMI. This is the AMI you want to create new instances from. You then reference this parameter in your templates, commands, and scripts.

For example, you can specify the parameter that contains your preferred AMI ID when you run the Amazon Elastic Compute Cloud (Amazon EC2) `run-instances` command.

> **Note**
>
> The user who runs this command must have Amazon Identity and Access Management (IAM) permissions that include the `ssm:GetParameters` API operation for the parameter value to be validated. Otherwise, the parameter creation process fails.

Linux & macOS

```
aws ec2 run-instances \
    --image-id resolve:ssm:/golden-ami \
    --count 1 \
    --instance-type t2.micro \
    --key-name my-key-pair \
    --security-groups my-security-group
```

Windows

```
aws ec2 run-instances ^
    --image-id resolve:ssm:/golden-ami ^
    --count 1 ^
    --instance-type t2.micro ^
    --key-name my-key-pair ^
    --security-groups my-security-group
```

You can also choose your preferred AMI when you create an instance using the Amazon EC2 console. For more information, see Using a Systems Manager parameter to find an AMI in the *Amazon EC2 User Guide*.

When it's time to use a different AMI in your instance creation workflow, you need only update the parameter with the new AMI value, and Parameter Store again validates that you have entered an ID in the proper format.

Granting permissions to create a parameter of `aws:ec2:image` data type

Using Amazon Identity and Access Management (IAM) policies, you can provide or restrict user access to Parameter Store API operations and content.

To create an `aws:ec2:image` data type parameter, the user must have both `ssm:PutParameter` and `ec2:DescribeImages` permissions.

The following example policy grants users permission to call the `PutParameter` API operation for `aws:ec2:image`. This means that the user can add a parameter of data type `aws:ec2:image` to the system.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ssm:PutParameter",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "ec2:DescribeImages",
            "Resource": "*"
        }
    ]
}
```

How AMI format validation works

When you specify `aws:ec2:image` as the data type for a parameter, Systems Manager doesn't create the parameter immediately. It instead performs an asynchronous validation operation to make sure that the parameter value meets the formatting requirements for an AMI ID, and that the specified AMI is available in your Amazon Web Services account.

A parameter version number might be generated before the validation operation is complete. The operation might not be complete even if a parameter version number is generated.

To monitor whether your parameters are created successfully, we recommend using Amazon EventBridge to send you notifications about your `create` and `update` parameter operations. These notifications report whether a parameter operation was successful or not. If an operation fails, the notification includes an error message that indicates the reason for the failure.

```
{
    "version": "0",
    "id": "eed4a719-0fa4-6a49-80d8-8ac65EXAMPLE",
    "detail-type": "Parameter Store Change",
    "source": "aws.ssm",
    "account": "111122223333",
    "time": "2020-05-26T22:04:42Z",
    "region": "us-east-2",
    "resources": [
        "arn:aws:ssm:us-east-2:111122223333:parameter/golden-ami"
    ],
    "detail": {
        "exception": "Unable to Describe Resource",
        "dataType": "aws:ec2:image",
        "name": "golden-ami",
        "type": "String",
        "operation": "Create"
    }
}
```

For information about subscribing to Parameter Store events in EventBridge, see Setting up notifications or triggering actions based on Parameter Store events.

Deleting parameters from Parameter Store

This topic describes how to delete parameters that you have created in Parameter Store, a tool in Amazon Systems Manager.

> **Warning**
>
> Deleting a parameter removes all versions of it. Once deleted, the parameter and its versions can't be restored.

To delete a parameter using the console

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. On the **My parameters** tab, select the check box next to each parameter to delete.
4. Choose **Delete**.
5. On the confirmation dialog, choose **Delete parameters**.

To delete a parameter using the Amazon CLI

- Run the following command:

  ```
  aws ssm delete-parameter --name "my-parameter"
  ```

  Replace *my-parameter* with the name of your parameter to be deleted.

  For information about all options available for use with the `delete-parameter` command, see delete-parameter in the *Amazon Systems Manager section of the Amazon CLI Command Reference*.

Working with public parameters in Parameter Store

Some Amazon Web Services services publish information about common artifacts as Amazon Systems Manager *public* parameters. For example, the Amazon Elastic Compute Cloud (Amazon EC2) service publishes information about Amazon Machine Images (AMIs) as public parameters.

Topics in this guide

- Discovering public parameters in Parameter Store
- Calling AMI public parameters in Parameter Store

- Calling the ECS optimized AMI public parameter in Parameter Store
- Calling the EKS optimized AMI public parameter in Parameter Store
- Calling public parameters for Amazon Web Services services, Regions, endpoints, Availability Zones, local zones, and Wavelength Zones in Parameter Store

Discovering public parameters in Parameter Store

You can search for public parameters using the Parameter Store console or the Amazon Command Line Interface.

A public parameter name begins with `aws/service/list`. The next part of the name corresponds to the service that owns that parameter.

The following is a partial list of Amazon Web Services services and other resources that provide public parameters:

- `ami-amazon-linux-latest`
- `ami-windows-latest`
- `ec2-macos`
- `appmesh`
- `aws-for-fluent-bit`
- `aws-sdk-pandas`
- `bottlerocket`
- `canonical`
- `cloud9`
- `datasync`
- `deeplearning`
- `ecs`
- `eks`
- `fis`
- `freebsd`
- `global-infrastructure`

- `marketplace`
- `neuron`
- `powertools`
- `sagemaker-distribution`
- `storagegateway`

Not all public parameters are published to every Amazon Web Services Region.

Finding public parameters using the Parameter Store console

You must have at least one parameter in your Amazon Web Services account and Amazon Web Services Region before you can search for public parameters using the console.

To find public parameters using the console

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Parameter Store**.
3. Choose the **Public parameters** tab.
4. Choose the **Select a service** dropdown. Choose the service whose parameters you want to use.
5. (Optional) Filter the parameters owned by the service you selected by entering more information into the search bar.
6. Choose the public parameter you want to use.

Finding public parameters using the Amazon CLI

Use `describe-parameters` for discovery of public parameters.

Use `get-parameters-by-path` to get the actual path for a service listed under `/aws/service/list`. To get the service's path, remove `/list` from the path. For example, `/aws/service/list/ecs` becomes `/aws/service/ecs`.

To retrieve a list of public parameters owned by different services in Parameter Store, run the following command.

```
aws ssm get-parameters-by-path --path /aws/service/list
```

The command returns information like the following. This example has been truncated for space.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/list/ami-al-latest",
            "Type": "String",
            "Value": "/aws/service/ami-al-latest/",
            "Version": 1,
            "LastModifiedDate": "2021-01-29T10:25:10.902000-08:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/list/ami-al-latest",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/list/ami-windows-latest",
            "Type": "String",
            "Value": "/aws/service/ami-windows-latest/",
            "Version": 1,
            "LastModifiedDate": "2021-01-29T10:25:12.567000-08:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/list/ami-windows-
latest",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/list/aws-storage-gateway-latest",
            "Type": "String",
            "Value": "/aws/service/aws-storage-gateway-latest/",
            "Version": 1,
            "LastModifiedDate": "2021-01-29T10:25:09.903000-08:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/list/aws-storage-
gateway-latest",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/list/global-infrastructure",
            "Type": "String",
            "Value": "/aws/service/global-infrastructure/",
            "Version": 1,
            "LastModifiedDate": "2021-01-29T10:25:11.901000-08:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/list/global-
infrastructure",
            "DataType": "text"
        }
    ]
```

```
}
```

If you want to view parameters owned by a specific service, choose the service from the list that was produced after running the earlier command. Then, make a `get-parameters-by-path` call using the name of your desired service.

For example, `/aws/service/global-infrastructure`. The path might be one-level (only calls parameters that match the exact values given) or recursive (contains elements in the path beyond what you have given).

> **Note**
>
> The `/aws/service/global-infrastructure` path is not supported for queries in all Regions. For information, see Calling public parameters for Amazon Web Services services, Regions, endpoints, Availability Zones, local zones, and Wavelength Zones in Parameter Store.

If no results are returned for the service you specify, add the `--recursive` flag and run the command again.

```
aws ssm get-parameters-by-path --path /aws/service/global-infrastructure
```

This returns all parameters owned by `global-infrastructure`. The following is an example.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/global-infrastructure/current-region",
            "Type": "String",
            "LastModifiedDate": "2019-06-21T05:15:34.252000-07:00",
            "Version": 1,
            "Tier": "Standard",
            "Policies": [],
            "DataType": "text"
        },
        {
            "Name": "/aws/service/global-infrastructure/version",
            "Type": "String",
            "LastModifiedDate": "2019-02-04T06:59:32.875000-08:00",
```

```
            "Version": 1,
            "Tier": "Standard",
            "Policies": [],
            "DataType": "text"
        }
    ]
}
```

You can also view parameters owned by a specific service by using the `Option:BeginsWith` filter.

```
aws ssm describe-parameters --parameter-filters "Key=Name, Option=BeginsWith, Values=/
aws/service/ami-amazon-linux-latest"
```

The command returns information like the following. This example output has been truncated for space.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-ebs",
            "Type": "String",
            "LastModifiedDate": "2021-01-26T13:39:40.686000-08:00",
            "Version": 25,
            "Tier": "Standard",
            "Policies": [],
            "DataType": "text"
        },
        {
            "Name": "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-gp2",
            "Type": "String",
            "LastModifiedDate": "2021-01-26T13:39:40.807000-08:00",
            "Version": 25,
            "Tier": "Standard",
            "Policies": [],
            "DataType": "text"
        },
        {
            "Name": "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-s3",
            "Type": "String",
            "LastModifiedDate": "2021-01-26T13:39:40.920000-08:00",
            "Version": 25,
            "Tier": "Standard",
            "Policies": [],
```

```
            "DataType": "text"
        }
    ]
}
```

> **Note**
>
> The returned parameters might be different when you use `Option=BeginsWith` because it uses a different search pattern.

Calling AMI public parameters in Parameter Store

Amazon Elastic Compute Cloud (Amazon EC2) Amazon Machine Image (AMI) public parameters are available for Amazon Linux 2, Amazon Linux 2023 (AL2023), macOS, and Windows Server from the following paths:

- Amazon Linux 2, and Amazon Linux 2023: `/aws/service/ami-amazon-linux-latest`
- macOS: `/aws/service/ec2-macos`
- Windows Server: `/aws/service/ami-windows-latest`

Calling AMI public parameters for Amazon Linux 2 and Amazon Linux 2023

You can view a list of all Amazon Linux 2 and Amazon Linux 2023 (AL2023) AMIs in the current Amazon Web Services Region by using the following command in the Amazon Command Line Interface (Amazon CLI).

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/ami-amazon-linux-latest \
    --query 'Parameters[].Name'
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/ami-amazon-linux-latest ^
```

```
    --query Parameters[].Name
```

The command returns information like the following.

```
[
    "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64",
    "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-x86_64",
    "/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-kernel-6.1-arm64",
    "/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-kernel-6.1-x86_64",
    "/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-kernel-default-arm64",
    "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-gp2",
    "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-s3",
    "/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-ebs",
    "/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-x86_64-gp2",
    "/aws/service/ami-amazon-linux-latest/amzn2-ami-kernel-5.10-hvm-x86_64-ebs",
    "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-default-arm64",
    "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-default-x86_64",
    "/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-kernel-default-x86_64",
    "/aws/service/ami-amazon-linux-latest/amzn-ami-hvm-x86_64-ebs",
    "/aws/service/ami-amazon-linux-latest/amzn-ami-minimal-hvm-x86_64-ebs",
    "/aws/service/ami-amazon-linux-latest/amzn-ami-minimal-hvm-x86_64-s3",
    "/aws/service/ami-amazon-linux-latest/amzn2-ami-hvm-arm64-gp2",
    "/aws/service/ami-amazon-linux-latest/amzn2-ami-kernel-5.10-hvm-arm64-gp2",
    "/aws/service/ami-amazon-linux-latest/amzn2-ami-kernel-5.10-hvm-x86_64-gp2",
    "/aws/service/ami-amazon-linux-latest/amzn2-ami-minimal-hvm-arm64-ebs",
    "/aws/service/ami-amazon-linux-latest/amzn2-ami-minimal-hvm-x86_64-ebs"
]
```

You can view details about these AMIs, including the AMI IDs and Amazon Resource Names (ARNs), by using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path "/aws/service/ami-amazon-linux-latest" \
    --region region
```

Windows

```
aws ssm get-parameters-by-path ^
    --path "/aws/service/ami-amazon-linux-latest" ^
```

```
    --region region
```

region represents the identifier for an Amazon Web Services Region supported by Amazon Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

The command returns information like the following. This example output has been truncated for space.

```
{
    "Parameters": [
         {
            "Name": "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64",
            "Type": "String",
            "Value": "ami-0b1b8b24a6c8e5d8b",
            "Version": 69,
            "LastModifiedDate": "2024-03-13T14:05:09.583000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-amazon-linux-
latest/al2023-ami-kernel-6.1-arm64",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-
x86_64",
            "Type": "String",
            "Value": "ami-0e0bf53f6def86294",
            "Version": 69,
            "LastModifiedDate": "2024-03-13T14:05:09.890000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-amazon-linux-
latest/al2023-ami-kernel-6.1-x86_64",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/ami-amazon-linux-latest/al2023-ami-minimal-
kernel-6.1-arm64",
            "Type": "String",
            "Value": "ami-09951bb66f9e5b5a5",
            "Version": 69,
            "LastModifiedDate": "2024-03-13T14:05:10.197000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-amazon-linux-
latest/al2023-ami-minimal-kernel-6.1-arm64",
```

```
            "DataType": "text"
        }
    ]
}
```

You can view details of a specific AMI by using the GetParameters API operation with the full AMI name, including the path. Here is an example command.

Linux & macOS

```
aws ssm get-parameters \
    --names /aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64 \
    --region us-east-2
```

Windows

```
aws ssm get-parameters ^
    --names /aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64 ^
    --region us-east-2
```

The command returns the following information.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/ami-amazon-linux-latest/al2023-ami-kernel-6.1-arm64",
            "Type": "String",
            "Value": "ami-0b1b8b24a6c8e5d8b",
            "Version": 69,
            "LastModifiedDate": "2024-03-13T14:05:09.583000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-amazon-linux-
latest/al2023-ami-kernel-6.1-arm64",
            "DataType": "text"
        }
    ],
    "InvalidParameters": []
}
```

Calling AMI public parameters for macOS

You can view a list of all macOS AMIs in the current Amazon Web Services Region by using the following command in the Amazon CLI.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/ec2-macos\
    --query 'Parameters[].Name'
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/ec2-macos ^
    --query Parameters[].Name
```

The command returns information like the following.

```
[
    "/aws/service/ec2-macos/sonoma/x86_64_mac/latest/image_id",
    "/aws/service/ec2-macos/ventura/x86_64_mac/latest/image_id",
    "/aws/service/ec2-macos/sonoma/arm64_mac/latest/image_id",
    "/aws/service/ec2-macos/ventura/arm64_mac/latest/image_id"
]
```

You can view details about these AMIs, including the AMI IDs and Amazon Resource Names (ARNs), by using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path "/aws/service/ec2-macos" \
    --region region
```

Windows

```
aws ssm get-parameters-by-path ^
    --path "/aws/service/ec2-macos" ^
```

```
    --region region
```

region represents the identifier for an Amazon Web Services Region supported by Amazon Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

The command returns information like the following. This example output has been truncated for space.

```
{
    "Parameters": [
        ...sample results pending...
    ]
}
```

You can view details of a specific AMI by using the GetParameters API operation with the full AMI name, including the path. Here is an example command.

Linux & macOS

```
aws ssm get-parameters \
    --names /aws/service/ec2-macos/...pending... \
    --region us-east-2
```

Windows

```
aws ssm get-parameters ^
     --names /aws/service/ec2-macos/...pending... ^
    --region us-east-2
```

The command returns the following information.

```
{
    "Parameters": [
         ...sample results pending...
    ],
    "InvalidParameters": []
```

```
}
```

Calling AMI public parameters for Windows Server

You can view a list of all Windows Server AMIs in the current Amazon Web Services Region by using the following command in the Amazon CLI.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/ami-windows-latest \
    --query 'Parameters[].Name'
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/ami-windows-latest ^
    --query Parameters[].Name
```

The command returns information like the following. This example output has been truncated for space.

```
[
    "/aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-English-Full-
Base",
    "/aws/service/ami-windows-latest/Windows_Server-2016-English-Full-
SQL_2014_SP3_Enterprise",

    "/aws/service/ami-windows-latest/Windows_Server-2016-Portuguese_Portugal-Full-
Base",
    "/aws/service/ami-windows-latest/Windows_Server-2019-English-Core-
EKS_Optimized-1.24",
    "/aws/service/ami-windows-latest/Windows_Server-2019-English-Deep-Learning",
    "/aws/service/ami-windows-latest/Windows_Server-2019-English-Full-SQL_2017_Web",
    "/aws/service/ami-windows-latest/Windows_Server-2019-Hungarian-Full-Base
]
```

You can view details about these AMIs, including the AMI IDs and Amazon Resource Names (ARNs), by using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path "/aws/service/ami-windows-latest" \
    --region region
```

Windows

```
aws ssm get-parameters-by-path ^
    --path "/aws/service/ami-windows-latest" ^
    --region region
```

region represents the identifier for an Amazon Web Services Region supported by Amazon Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported

region values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

The command returns information like the following. This example output has been truncated for space.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-
English-Full-Base",

            "DataType": "text"
        },
        {
            "Name": "/aws/service/ami-windows-latest/Windows_Server-2016-English-Full-
SQL_2014_SP3_Enterprise",
            "Type": "String",
            "Value": "ami-001f20c053dd120ce",
            "Version": 69,
            "LastModifiedDate": "2024-03-15T15:53:58.905000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-windows-latest/
Windows_Server-2016-English-Full-SQL_2014_SP3_Enterprise",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/ami-windows-latest/Windows_Server-2016-German-Full-
Base",
            "Type": "String",
            "Value": "ami-063be4935453e94e9",
            "Version": 102,
            "LastModifiedDate": "2024-03-15T15:51:12.003000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-windows-latest/
Windows_Server-2016-German-Full-Base",
            "DataType": "text"
        }
    ]
}
```

You can view details of a specific AMI by using the GetParameters API operation with the full AMI name, including the path. Here is an example command.

Linux & macOS

```
aws ssm get-parameters \
    --names /aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-English-
Full-Base \
    --region us-east-2
```

Windows

```
aws ssm get-parameters ^
    --names /aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-English-
Full-Base ^
    --region us-east-2
```

The command returns the following information.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/ami-windows-latest/EC2LaunchV2-Windows_Server-2016-
English-Full-Base",
            "Type": "String",
            "Value": "ami-0a30b2e65863e2d16",
            "Version": 36,
            "LastModifiedDate": "2024-03-15T15:58:37.976000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ami-windows-latest/
EC2LaunchV2-Windows_Server-2016-English-Full-Base",
            "DataType": "text"
        }
    ],
    "InvalidParameters": []
}
```

Calling the ECS optimized AMI public parameter in Parameter Store

The Amazon Elastic Container Service (Amazon ECS) service publishes the name of the latest Amazon ECS optimized Amazon Machine Images (AMIs) as public parameters. Users are encouraged

to use this AMI when creating a new Amazon Elastic Compute Cloud (Amazon EC2) cluster for Amazon ECS because the optimized AMIs include bug fixes and feature updates.

Use the following command to view the name of the latest Amazon ECS optimized AMI for Amazon Linux 2. To see commands for other operating systems, see Retrieving Amazon ECS-Optimized AMI metadata in the *Amazon Elastic Container Service Developer Guide*.

Linux & macOS

```
aws ssm get-parameters \
    --names /aws/service/ecs/optimized-ami/amazon-linux-2/recommended
```

Windows

```
aws ssm get-parameters ^
    --names /aws/service/ecs/optimized-ami/amazon-linux-2/recommended
```

The command returns information like the following.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/ecs/optimized-ami/amazon-linux-2/recommended",
            "Type": "String",
            "Value": "{\"schema_version\":1,\"image_name\":\"amzn2-ami-ecs-
hvm-2.0.20210929-x86_64-ebs\",\"image_id\":\"ami-0c38a2329ed4dae9a\",\"os\":\"Amazon
 Linux 2\",\"ecs_runtime_version\":\"Docker version 20.10.7\",\"ecs_agent_version\":
\"1.55.4\"}",
            "Version": 73,
            "LastModifiedDate": "2021-10-06T16:35:10.004000-07:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/ecs/optimized-ami/
amazon-linux-2/recommended",
            "DataType": "text"
        }
    ],
    "InvalidParameters": []
}
```

Calling the EKS optimized AMI public parameter in Parameter Store

The Amazon Elastic Kubernetes Service (Amazon EKS) service publishes the name of the latest Amazon EKS optimized Amazon Machine Image (AMI) as a public parameter. We encourage you to use this AMI when adding nodes to an Amazon EKS cluster, as new releases include Kubernetes patches and security updates. Previously, to guarantee you were using the latest AMI meant checking the Amazon EKS documentation and manually updating any deployment templates or resources with the new AMI ID.

Use the following command to view the name of the latest Amazon EKS optimized AMI for Amazon Linux 2.

Linux & macOS

```
aws ssm get-parameters \
    --names /aws/service/eks/optimized-ami/1.14/amazon-linux-2/recommended
```

Windows

```
aws ssm get-parameters ^
    --names /aws/service/eks/optimized-ami/1.14/amazon-linux-2/recommended
```

The command returns information like the following.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/eks/optimized-ami/1.14/amazon-linux-2/recommended",
            "Type": "String",
            "Value": "{\"schema_version\":\"2\",\"image_id\":\"ami-08984d8491de17ca0\",
\"image_name\":\"amazon-eks-node-1.14-v20201007\",\"release_version\":
\"1.14.9-20201007\"}",
            "Version": 24,
            "LastModifiedDate": "2020-11-17T10:16:09.971000-08:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/eks/optimized-
ami/1.14/amazon-linux-2/recommended",
            "DataType": "text"
        }
    ],
    "InvalidParameters": []
```

```
}
```

Calling public parameters for Amazon Web Services services, Regions, endpoints, Availability Zones, local zones, and Wavelength Zones in Parameter Store

You can call the Amazon Web Services Region, service, endpoint, Availability, and Wavelength Zones of public parameters by using the following path.

`/aws/service/global-infrastructure`

> **Note**
>
> Currently, the path `/aws/service/global-infrastructure` is supported for queries in the following Amazon Web Services Regions only:
>
> - US East (N. Virginia) (us-east-1)
> - US East (Ohio) (us-east-2)
> - US West (N. California) (us-west-1)
> - US West (Oregon) (us-west-2)
> - Asia Pacific (Hong Kong) (ap-east-1)
> - Asia Pacific (Mumbai) (ap-south-1)
> - Asia Pacific (Seoul) (ap-northeast-2)
> - Asia Pacific (Singapore) (ap-southeast-1)
> - Asia Pacific (Sydney) (ap-southeast-2)
> - Asia Pacific (Tokyo) (ap-northeast-1)
> - Canada (Central) (ca-central-1)
> - Europe (Frankfurt) (eu-central-1)
> - Europe (Ireland) (eu-west-1)
> - Europe (London) (eu-west-2)
> - Europe (Paris) (eu-west-3)
> - Europe (Stockholm) (eu-north-1)
> - South America (São Paulo) (sa-east-1)

If you are working in a different commercial Region, you can specify a supported Region in your query to view results. For example, if you are working in the Canada West (Calgary) (ca-west-1) Region, you could specify Canada (Central) (ca-central-1) in your query:

```
aws ssm get-parameters-by-path \
    --path /aws/service/global-infrastructure/regions \
    --region ca-central-1
```

View active Amazon Web Services Regions

You can view a list of all active Amazon Web Services Regions by using the following command in the Amazon Command Line Interface (Amazon CLI).

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/global-infrastructure/regions \
    --query 'Parameters[].Name'
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/global-infrastructure/regions ^
    --query Parameters[].Name
```

The command returns information like the following.

```
[
    "/aws/service/global-infrastructure/regions/af-south-1",
    "/aws/service/global-infrastructure/regions/ap-east-1",
    "/aws/service/global-infrastructure/regions/ap-northeast-3",
    "/aws/service/global-infrastructure/regions/ap-south-2",

]
```

View available Amazon Web Services services

You can view a complete list of all available Amazon Web Services services and sort them into alphabetical order by using the following command. This example output has been truncated for space.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/global-infrastructure/services \
    --query 'Parameters[].Name | sort(@)'
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/global-infrastructure/services ^
```

```
    --query "Parameters[].Name | sort(@)"
```

The command returns information like the following. This example has been truncated for space.

```
[
     "/aws/service/global-infrastructure/services/accessanalyzer",
    "/aws/service/global-infrastructure/services/account",
    "/aws/service/global-infrastructure/services/acm",
    "/aws/service/global-infrastructure/services/acm-pca",
    "/aws/service/global-infrastructure/services/ahl",
    "/aws/service/global-infrastructure/services/aiq",
    "/aws/service/global-infrastructure/services/amazonlocationservice",
    "/aws/service/global-infrastructure/services/amplify",
    "/aws/service/global-infrastructure/services/amplifybackend",
    "/aws/service/global-infrastructure/services/apigateway",
    "/aws/service/global-infrastructure/services/apigatewaymanagementapi",
    "/aws/service/global-infrastructure/services/apigatewayv2",
    "/aws/service/global-infrastructure/services/appconfig",
    "/aws/service/global-infrastructure/services/appconfigdata",
    "/aws/service/global-infrastructure/services/appflow",
    "/aws/service/global-infrastructure/services/appintegrations",
    "/aws/service/global-infrastructure/services/application-autoscaling",
    "/aws/service/global-infrastructure/services/application-insights",
    "/aws/service/global-infrastructure/services/applicationcostprofiler",
    "/aws/service/global-infrastructure/services/appmesh",
    "/aws/service/global-infrastructure/services/apprunner",
    "/aws/service/global-infrastructure/services/appstream",
    "/aws/service/global-infrastructure/services/appsync",
    "/aws/service/global-infrastructure/services/aps",
    "/aws/service/global-infrastructure/services/arc-zonal-shift",
    "/aws/service/global-infrastructure/services/artifact",
    "/aws/service/global-infrastructure/services/athena",
    "/aws/service/global-infrastructure/services/auditmanager",
    "/aws/service/global-infrastructure/services/augmentedairuntime",
    "/aws/service/global-infrastructure/services/aurora",
    "/aws/service/global-infrastructure/services/autoscaling",
    "/aws/service/global-infrastructure/services/aws-appfabric",
    "/aws/service/global-infrastructure/services/awshealthdashboard",
```

View supported Regions for an Amazon Web Services service

You can view a list of Amazon Web Services Regions where a service is available. This example uses Amazon Systems Manager (`ssm`).

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/global-infrastructure/services/ssm/regions \
    --query 'Parameters[].Value'
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/global-infrastructure/services/ssm/regions ^
    --query Parameters[].Value
```

The command returns information like the following.

```
[
    "ap-south-1",
    "eu-central-1",
    "eu-central-2",
    "eu-west-1",
    "eu-west-2",
    "eu-west-3",
    "il-central-1",
    "me-south-1",
    "us-east-2",
    "us-gov-west-1",
    "af-south-1",
    "ap-northeast-3",
    "ap-southeast-1",
    "ap-southeast-4",
    "ca-central-1",
    "ca-west-1",
    "cn-north-1",
    "eu-north-1",
    "eu-south-2",
    "us-west-1",
    "ap-east-1",
    "ap-northeast-1",
    "ap-northeast-2",
    "ap-southeast-2",
```

```
    "ap-southeast-3",
    "cn-northwest-1",
    "eu-south-1",
    "me-central-1",
    "us-gov-east-1",
    "us-west-2",
    "ap-south-2",
    "sa-east-1",
    "us-east-1"
]
```

View the Regional endpoint for a service

You can view a Regional endpoint for a service by using the following command. This command queries the US East (Ohio) (us-east-2) Region.

Linux & macOS

```
aws ssm get-parameter \
    --name /aws/service/global-infrastructure/regions/us-east-2/services/ssm/
endpoint \
    --query 'Parameter.Value'
```

Windows

```
aws ssm get-parameter ^
    --name /aws/service/global-infrastructure/regions/us-east-2/services/ssm/
endpoint ^
    --query Parameter.Value
```

The command returns information like the following.

```
"ssm.us-east-2.amazonaws.com"
```

View complete Availability Zone details

You can view Availability Zones by using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
```

```
    --path /aws/service/global-infrastructure/availability-zones/
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/global-infrastructure/availability-zones/
```

The command returns information like the following. This example has been truncated for space.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/global-infrastructure/availability-zones/afs1-az3",
            "Type": "String",
            "Value": "afs1-az3",
            "Version": 1,
            "LastModifiedDate": "2020-04-21T12:05:35.375000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
availability-zones/afs1-az3",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/global-infrastructure/availability-zones/aps1-az2",
            "Type": "String",
            "Value": "aps1-az2",
            "Version": 1,
            "LastModifiedDate": "2020-04-03T16:13:57.351000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
availability-zones/aps1-az2",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/global-infrastructure/availability-zones/apse3-az1",
            "Type": "String",
            "Value": "apse3-az1",
            "Version": 1,
            "LastModifiedDate": "2021-12-13T08:51:38.983000-05:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
availability-zones/apse3-az1",
            "DataType": "text"
        }
    ]
```

```
}
```

View Availability Zone names only

You can view the names of Availability Zones only by using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/global-infrastructure/availability-zones \
    --query 'Parameters[].Name | sort(@)'
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/global-infrastructure/availability-zones ^
    --query "Parameters[].Name | sort(@)"
```

The command returns information like the following. This example has been truncated for space.

```
[
    "/aws/service/global-infrastructure/availability-zones/afs1-az1",
    "/aws/service/global-infrastructure/availability-zones/afs1-az2",
    "/aws/service/global-infrastructure/availability-zones/afs1-az3",
    "/aws/service/global-infrastructure/availability-zones/ape1-az1",
    "/aws/service/global-infrastructure/availability-zones/ape1-az2",
    "/aws/service/global-infrastructure/availability-zones/ape1-az3",
    "/aws/service/global-infrastructure/availability-zones/apne1-az1",
    "/aws/service/global-infrastructure/availability-zones/apne1-az2",
    "/aws/service/global-infrastructure/availability-zones/apne1-az3",
    "/aws/service/global-infrastructure/availability-zones/apne1-az4"
```

View names of Availability Zones in a single Region

You can view the names of the Availability Zones in one Region (`us-east-2`, in this example) using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
```

```
    --path /aws/service/global-infrastructure/regions/us-east-2/availability-zones \
    --query 'Parameters[].Name | sort(@)'
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/global-infrastructure/regions/us-east-2/availability-zones ^
    --query "Parameters[].Name | sort(@)"
```

The command returns information like the following.

```
[
    "/aws/service/global-infrastructure/regions/us-east-2/availability-zones/use2-az1",
    "/aws/service/global-infrastructure/regions/us-east-2/availability-zones/use2-az2",
    "/aws/service/global-infrastructure/regions/us-east-2/availability-zones/use2-az3"
```

View Availability Zone ARNs only

You can view the Amazon Resource Names (ARNs) of Availability Zones only by using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/global-infrastructure/availability-zones \
    --query 'Parameters[].ARN | sort(@)'
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/global-infrastructure/availability-zones ^
    --query "Parameters[].ARN | sort(@)"
```

The command returns information like the following. This example has been truncated for space.

```
[
    "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-
zones/afs1-az1",
```

```
    "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-
zones/afs1-az2",
    "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-
zones/afs1-az3",
    "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-
zones/ape1-az1",
    "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-
zones/ape1-az2",
    "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-
zones/ape1-az3",
    "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/availability-
zones/apne1-az1",
```

View local zone details

You can view local zones by using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/global-infrastructure/local-zones
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/global-infrastructure/local-zones
```

The command returns information like the following. This example has been truncated for space.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/global-infrastructure/local-zones/afs1-los1-az1",
            "Type": "String",
            "Value": "afs1-los1-az1",
            "Version": 1,
            "LastModifiedDate": "2023-01-25T11:53:11.690000-05:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/afs1-los1-az1",
            "DataType": "text"
        },
```

```
        {
            "Name": "/aws/service/global-infrastructure/local-zones/apne1-tpe1-az1",
            "Type": "String",
            "Value": "apne1-tpe1-az1",
            "Version": 1,
            "LastModifiedDate": "2024-03-15T12:35:41.076000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/apne1-tpe1-az1",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/global-infrastructure/local-zones/aps1-ccu1-az1",
            "Type": "String",
            "Value": "aps1-ccu1-az1",
            "Version": 1,
            "LastModifiedDate": "2022-12-19T11:34:43.351000-05:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/aps1-ccu1-az1",
            "DataType": "text"
        }
    ]
}
```

View Wavelength Zone details

You can view Wavelength Zones by using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/global-infrastructure/wavelength-zones
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/global-infrastructure/wavelength-zones
```

The command returns information like the following. This example has been truncated for space.

```
{
    "Parameters": [
        {
```

```
            "Name": "/aws/service/global-infrastructure/wavelength-zones/apne1-wl1-nrt-
wlz1",
            "Type": "String",
            "Value": "apne1-wl1-nrt-wlz1",
            "Version": 3,
            "LastModifiedDate": "2020-12-15T17:16:04.715000-05:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
wavelength-zones/apne1-wl1-nrt-wlz1",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/global-infrastructure/wavelength-zones/apne2-wl1-sel-
wlz1",
            "Type": "String",
            "Value": "apne2-wl1-sel-wlz1",
            "Version": 1,
            "LastModifiedDate": "2022-05-25T12:29:13.862000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
wavelength-zones/apne2-wl1-sel-wlz1",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/global-infrastructure/wavelength-zones/cac1-wl1-yto-
wlz1",
            "Type": "String",
            "Value": "cac1-wl1-yto-wlz1",
            "Version": 1,
            "LastModifiedDate": "2022-04-26T09:57:44.495000-04:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
wavelength-zones/cac1-wl1-yto-wlz1",
            "DataType": "text"
        }
    ]
}
```

View all parameters and values under a local zone

You can view all parameter data for a local zone by using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path "/aws/service/global-infrastructure/local-zones/usw2-lax1-az1/"
```

Windows

```
aws ssm get-parameters-by-path ^
    --path "/aws/service/global-infrastructure/local-zones/use1-bos1-az1"
```

The command returns information like the following. This example has been truncated for space.

```
{
    "Parameters": [
        {
            "Name": "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/
geolocationCountry",
            "Type": "String",
            "Value": "US",
            "Version": 3,
            "LastModifiedDate": "2020-12-15T14:16:17.641000-08:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/use1-bos1-az1/geolocationCountry",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/
geolocationRegion",
            "Type": "String",
            "Value": "US-MA",
            "Version": 3,
            "LastModifiedDate": "2020-12-15T14:16:17.794000-08:00",
            "ARN": "arn:aws:ssm:us-east-2::parameter/aws/service/global-infrastructure/
local-zones/use1-bos1-az1/geolocationRegion",
            "DataType": "text"
        },
        {
            "Name": "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/
location",

local-zones/use1-bos1-az1/zone-group",
            "DataType": "text"
        }
```

```
    ]
}
```

View local zone parameter names only

You can view just the names of local zone parameters by using the following command.

Linux & macOS

```
aws ssm get-parameters-by-path \
    --path /aws/service/global-infrastructure/local-zones/usw2-lax1-az1 \
    --query 'Parameters[].Name | sort(@)'
```

Windows

```
aws ssm get-parameters-by-path ^
    --path /aws/service/global-infrastructure/local-zones/use1-bos1-az1 ^
    --query "Parameters[].Name | sort(@)"
```

The command returns information like the following.

```
[
    "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/geolocationCountry",
    "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/geolocationRegion",
    "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/location",
    "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/network-border-
group",
    "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/parent-availability-
zone",
    "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/parent-region",
    "/aws/service/global-infrastructure/local-zones/use1-bos1-az1/zone-group"
]
```

Parameter Store walkthroughs

The walkthrough in this section shows you how to create, store, and run parameters with Parameter Store in a test environment. This walkthrough shows you how to use Parameter Store with other Systems Manager tools. You can also use Parameter Store with other Amazon Web Services services. For more information, see Parameter Store reference.

Contents

- Creating a SecureString parameter in Parameter Store and joining a node to a Domain (PowerShell)

Creating a SecureString parameter in Parameter Store and joining a node to a Domain (PowerShell)

This walkthrough shows how to join a Windows Server node to a domain using Amazon Systems Manager `SecureString` parameters and Run Command. The walkthrough uses typical domain parameters, such as the domain name and a domain user name. These values are passed as unencrypted string values. The domain password is encrypted using an Amazon managed key and passed as an encrypted string.

Prerequisites

This walkthrough assumes that you already specified your domain name and DNS server IP address in the DHCP option set that is associated with your Amazon VPC. For information, see Working with DHCP Options Sets in the *Amazon VPC User Guide*.

To create a `SecureString` parameter and join a node to a domain

1. Enter parameters into the system using Amazon Tools for Windows PowerShell.

   In the following commands, replace each *`user input placeholder`* with your own information.

   ```
   Write-SSMParameter -Name "domainName" -Value "DOMAIN-NAME" -Type String
   Write-SSMParameter -Name "domainJoinUserName" -Value "DOMAIN\USERNAME" -Type String
   Write-SSMParameter -Name "domainJoinPassword" -Value "PASSWORD" -Type SecureString
   ```

   Only the *value* of a `SecureString` parameter is encrypted. Parameter names, descriptions, and other properties aren't encrypted.
2. Attach the following Amazon Identity and Access Management (IAM) policies to the IAM role permissions for your node:

   - **AmazonSSMManagedInstanceCore** – Required. This Amazon managed policy allows a managed node to use Systems Manager service core functionality.
   - **AmazonSSMDirectoryServiceAccess** – Required. This Amazon managed policy allows SSM Agent to access Amazon Directory Service on your behalf for requests to join the domain by the managed node.

- **A custom policy for S3 bucket access** – Required. SSM Agent, which is on your node and performs Systems Manager tasks, requires access to specific Amazon-owned Amazon Simple Storage Service (Amazon S3) buckets. In the custom S3 bucket policy that you create, you also provide access to S3 buckets of your own that are necessary for Systems Manager operations.

  Examples: You can write output for Run Command commands or Session Manager sessions to an S3 bucket, and then use this output later for auditing or troubleshooting. You store access scripts or custom patch baseline lists in an S3 bucket, and then reference the script or list when you run a command, or when a patch baseline is applied.

  For information about creating a custom policy for Amazon S3 bucket access, see Create a custom S3 bucket policy for an instance profile

  > **Note**
  >
  > Saving output log data in an S3 bucket is optional, but we recommend setting it up at the beginning of your Systems Manager configuration process if you have decided to use it. For more information, see Create a Bucket in the *Amazon Simple Storage Service User Guide*.

- **CloudWatchAgentServerPolicy** – Optional. This Amazon managed policy lets you run the CloudWatch agent on managed nodes. This policy makes it possible to read information on a node and write it to Amazon CloudWatch. Your instance profile needs this policy only if you use services such as Amazon EventBridge or CloudWatch Logs.

  > **Note**
  >
  > Using CloudWatch and EventBridge features is optional, but we recommend setting them up at the beginning of your Systems Manager configuration process if you have decided to use them. For more information, see the *Amazon EventBridge User Guide* and the *Amazon CloudWatch Logs User Guide*.

3. Edit the IAM role attached to the node and add the following policy. This policy gives the node permissions to call the `kms:Decrypt` and the `ssm:CreateDocument` API.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt",
                "ssm:CreateDocument"
            ],
            "Resource": [
                "arn:aws-cn:kms:us-east-1:111122223333:key/kms-key-id"
            ]
        }
    ]
}
```

4. Copy and paste the following json text into a text editor and save the file as `JoinInstanceToDomain.json` in the following location: `c:\temp\JoinInstanceToDomain.json`.

```
{
    "schemaVersion": "2.2",
    "description": "Run a PowerShell script to securely join a Windows Server
 instance to a domain",
    "mainSteps": [
        {
            "action": "aws:runPowerShellScript",
            "name": "runPowerShellWithSecureString",
            "precondition": {
                "StringEquals": [
                    "platformType",
                    "Windows"
                ]
            },
            "inputs": {
                "runCommand": [
                    "$domain = (Get-SSMParameterValue -Name
 domainName).Parameters[0].Value",
```

```
                    "if ((gwmi Win32_ComputerSystem).domain -eq $domain){write-host
 \"Computer is part of $domain, exiting\"; exit 0}",
                    "$username = (Get-SSMParameterValue -Name
 domainJoinUserName).Parameters[0].Value",
                    "$password = (Get-SSMParameterValue -Name domainJoinPassword -
WithDecryption $True).Parameters[0].Value | ConvertTo-SecureString -asPlainText -
Force",
                    "$credential = New-Object
 System.Management.Automation.PSCredential($username,$password)",
                    "Add-Computer -DomainName $domain -Credential $credential -
ErrorAction SilentlyContinue -ErrorVariable domainjoinerror",
                    "if($?){Write-Host \"Instance joined to domain successfully.
 Restarting\"; exit 3010}else{Write-Host \"Instance failed to join domain with
 error:\" $domainjoinerror; exit 1 }"
                ]
            }
        }
    ]
}
```

5. Run the following command in Tools for Windows PowerShell to create a new SSM document.

```
$json = Get-Content C:\temp\JoinInstanceToDomain | Out-String
New-SSMDocument -Name JoinInstanceToDomain -Content $json -DocumentType Command
```

6. Run the following command in Tools for Windows PowerShell to join the node to the domain.

```
Send-SSMCommand -InstanceId instance-id -DocumentName JoinInstanceToDomain
```

If the command succeeds, the system returns information similar to the following.

```
WARNING: The changes will take effect after you restart the computer EC2ABCD-
EXAMPLE.
Domain join succeeded, restarting
Computer is part of example.local, exiting
```

If the command fails, the system returns information similar to the following.

```
Failed to join domain with error:
Computer 'EC2ABCD-EXAMPLE' failed to join domain 'example.local'
from its current workgroup 'WORKGROUP' with following error message:
```

```
The specified domain either does not exist or could not be contacted.
```

Auditing and logging Parameter Store activity

Amazon CloudTrail captures API calls made in the Amazon Systems Manager console, the Amazon Command Line Interface (Amazon CLI), and the Systems Manager SDK. You can view the information in the CloudTrail console or in an Amazon Simple Storage Service (Amazon S3) bucket. All CloudTrail logs for your account use one bucket. For more information about viewing and using CloudTrail logs of Systems Manager activity, see Logging Amazon Systems Manager API calls with Amazon CloudTrail. For more information about auditing and logging options for Systems Manager, see Logging and monitoring in Amazon Systems Manager.

Troubleshooting Parameter Store

Use the following information to help you troubleshoot problems with Parameter Store.

Troubleshooting throughput issues

Use the following information to troubleshoot throughput issues in Parameter Store. For information about throughput quotas and why throttling occurs, see Optimizing throughput in Parameter Store.

Application receives `ThrottlingException` or `RateExceeded` errors

Problem: Your application logs or CloudWatch Logs show an error such as the following when calling `GetParameter`, `GetParameters`, or `GetParametersByPath`:

```
An error occurred (ThrottlingException) when calling the GetParameters operation
 (reached max retries: 4): Rate exceeded
```

- **Solution**: This error means your combined call rate for these API actions exceeded your account throughput quota for the current Amazon Web Services Region. Take one or more of the following actions:
  - Reduce how often your application calls Parameter Store. Cache parameter values in your application instead of retrieving them on every invocation or request.

    For more information, see Parameters and Secrets Lambda Extension and Using the Amazon Parameter and Secrets Lambda extension to cache parameters and secrets.

- Use `GetParameters` to retrieve multiple known parameter names in a single call, rather than issuing separate `GetParameter` calls or a `GetParametersByPath` call.
- Stagger reads when many instances, containers, or functions start at the same time, such as during a deployment or a scaling event.
- If your application uses efficient request patterns and continues to generate throttling errors, enable higher throughput for your account and Amazon Web Services Region. You can enable and disable higher throughput at any time. The cost is determined by usage. For more information, see Amazon Systems Manager Pricing for Parameter Store.

Throttling occurs only on `DescribeParameters` calls

Problem: Your application receives a `ThrottlingException` error on `DescribeParameters` calls, even though your `GetParameter`, `GetParameters`, and `GetParametersByPath` calls don't exceed the quota.

- **Solution**: `DescribeParameters` has a separate throughput limit from the other parameter retrieval actions: 3 TPS by default, or 10 TPS with higher throughput enabled. Making fewer `GetParameter`, `GetParameters`, or `GetParametersByPath` calls doesn't affect this limit.

  A common cause is calling `DescribeParameters` with a filter on an account that has a large number of parameters. The API paginates over all parameters in the account before applying the filter. Accounts with many parameters can exceed the `DescribeParameters` quota even when the filtered result set is small.

  Where possible, use `GetParametersByPath` against a specific hierarchy instead of `DescribeParameters` with a filter. You can also reduce the frequency of `DescribeParameters` calls in scripts and automation that run on a schedule.

No throttling error, but latency increases during deployments

Problem: You don't see a `ThrottlingException` error in your logs, but your application experiences elevated latency or intermittent failures during deployments, restarts, or scaling events.

- **Solution**: If your application or SDK retries throttled requests automatically, a retry can succeed without ever surfacing a throttling error. If your latency increases, check the retry count in the logs or metrics of your SDK. A nonzero retry count on Parameter Store calls during these events

indicates you're approaching your throughput quota, even without a failure. Apply the same optimization techniques described in Optimizing throughput in Parameter Store to reduce retries before they become failures.

Troubleshooting `aws:ec2:image` parameter creation

Use the following information to help troubleshoot problems with creating `aws:ec2:image` data type parameters.

No permission to create an instance

Problem: You try to create an instance using an `aws:ec2:image` parameter but receive an error message such as "You are not authorized to perform this operation."

- **Solution**: You do not have all the permissions needed to create an EC2 instance using a parameter value, such as permissions for `ec2:RunInstances`, `ec2:DescribeImages`, and `ssm:GetParameter`, among others. Contact a user with administrator permissions in your organization to request the necessary permissions.

EventBridge reports the failure message "Unable to Describe Resource"

Problem: You ran a command to create an `aws:ec2:image` parameter, but parameter creation failed. You receive a notification from Amazon EventBridge that reports the exception "Unable to Describe Resource".

Solution: This message can indicate the following:

- You do not have all the permissions needed for the `ec2:DescribeImages` API operation, or you lack permission to access the specific image referenced in the parameter. Contact a user with administrator permissions in your organization to request the necessary permissions.
- The Amazon Machine Image (AMI) ID you entered as a parameter value isn't valid. Make sure you're entering the ID of an AMI that is available in the current Amazon Web Services Region and account you're working in.

New `aws:ec2:image` parameter isn't available

Problem: You just ran a command to create an `aws:ec2:image` parameter and a version number was reported, but the parameter isn't available.

- **Solution**: When you run the command to create a parameter that uses the `aws:ec2:image` data type, a version number is generated for the parameter right away, but the parameter format must be validated before the parameter is available. This process can take up to a few minutes. To monitor the parameter creation and validation process, you can do the following:
  - Use EventBridge to send you notifications about your `create` and `update` parameter operations. These notifications report whether a parameter operation was successful or not. For information about subscribing to Parameter Store events in EventBridge, see Setting up notifications or triggering actions based on Parameter Store events.
  - In the Parameter Store section of the Systems Manager console, refresh the list of parameters periodically to search for the new or updated parameter details.
  - Use the **GetParameter** command to check for the new or updated parameter. For example, using the Amazon Command Line Interface (Amazon CLI):

    ```
    aws ssm get-parameter name MyParameter
    ```

    For a new parameter, a `ParameterNotFound` message is returned until the parameter is validated. For an existing parameter that you're updating, information about the new version isn't included until the parameter is validated.

  If you attempt to create or update the parameter again before the validation process is complete, the system reports that validation is still in process. If the parameter isn't created or updated, you can try again after 5 minutes have passed from the original attempt.

Parameter Store reference

A *parameter* is any piece of data stored in Parameter Store, such as a block of text, a list of names, an AMI ID, a merchant ID, or another configuration value. You can centrally reference this data in your scripts, commands, and SSM documents.

When you reference a parameter, you specify the parameter name using the following convention.

{{ssm:*parameter-name*}}

> **Note**
>
> Parameters can't be referenced or nested in the values of other parameters. You can't include {{}} or {{ssm:*parameter-name*}} in a parameter value.

Parameter Store provides support for three types of parameters: `String`, `StringList`, and `SecureString`.

By default, when you create or update a parameter, Parameter Store performs no validation on the value you enter. However, you can specify a *data type* to enable value validation. For example, set the data type to `aws:ec2:image` to validate that the value is a valid AMI ID, or `integer` to validate that the value is an integer. For the full list of supported data types, see Parameter data types in Parameter Store.

Parameter type: String

By default, the value of a `String` parameter consists of any block of text you enter. For example:

- `abc123`
- `Example Corp`
- `<img src="images/bannerImage1.png"/>`

Parameter type: StringList

The values of `StringList` parameters contain a comma-separated list of values, as shown in the following examples.

`Monday,Wednesday,Friday`

`CSV,TSV,CLF,ELF,JSON`

Parameter type: SecureString

Use `SecureString` for configuration values that require encryption, such as service endpoints and account identifiers. For secrets such as database credentials, API keys, or tokens, we recommend Amazon Secrets Manager, which provides purpose built security controls including automatic rotation and cross-region replication.

Only the parameter value is encrypted. The parameter name, description, and other metadata aren't encrypted.

Parameter Store encrypts and decrypts `SecureString` parameter values using an Amazon KMS key. You can use the default Amazon managed key for Parameter Store or a customer managed key. Use a customer managed key when you need to restrict which principals can decrypt particular

parameters. For more information, see Encrypting and decrypting parameters using Amazon KMS keys.

Important

Note the following important information.

- If you manage credentials that require automatic rotation, cross-account access, or fine-grained audit logging, we recommend using Amazon Secrets Manager. Secrets Manager is purpose-built for managing secrets such as database credentials, API keys, and supported third-party software-vended secrets. For more information, see What is Amazon Secrets Manager? in the *Amazon Secrets Manager User Guide*.
- Don't store sensitive data in a `String` or `StringList` parameter. For all sensitive data that must remain encrypted, use only the `SecureString` parameter type.
- Only the *value* of a `SecureString` parameter is encrypted. Parameter names, descriptions, and other properties aren't encrypted.

You can use `SecureString` parameters with other Amazon Web Services services. The following Lambda function retrieves an encrypted merchant ID from the `/myapp/dev/vendor/merchant-id` parameter. The function uses the value without writing it to the function logs or returning it in the response.

```
import json
import boto3

ssm = boto3.client("ssm", region_name="us-east-1")

def lambda_handler(event, context):
    response = ssm.get_parameter(
        Name="/myapp/dev/vendor/merchant-id",
        WithDecryption=True
    )

    merchant_id = response["Parameter"]["Value"]

    # Use merchant_id when communicating with the vendor system.
    # Don't write the value to logs or include it in the response.

    return {
```

```
        "statusCode": 200,
        "body": json.dumps("Vendor configuration retrieved.")
    }
```

Amazon KMS encryption and pricing

When you create a `SecureString` parameter, Systems Manager uses Amazon KMS to encrypt the parameter value.

> **Important**
>
> Parameter Store only supports symmetric encryption KMS keys. You can't use an asymmetric encryption KMS key to encrypt your parameters. For help determining whether a KMS key is symmetric or asymmetric, see Identifying symmetric and asymmetric KMS keys in the *Amazon Key Management Service Developer Guide*

There is no charge from Parameter Store to create a `SecureString` parameter, but charges for using Amazon KMS can apply. For more information, see Amazon Key Management Service pricing.

For more information about Amazon managed keys and customer managed keys, see Amazon Key Management Service Concepts in the *Amazon Key Management Service Developer Guide*. For more information about how Parameter Store uses Amazon KMS, see How Amazon Systems Manager Parameter Store uses Amazon KMS.

> **Note**
>
> To view the default Amazon managed key for Parameter Store, run the following command.
>
> ```
> aws kms describe-key \
>     --region us-east-1 \
>     --key-id alias/aws/ssm
> ```

Parameter name constraints

Use the information in this topic to help you specify valid values for parameter names when you create a parameter.

This information supplements the details in the topic PutParameter in the *Amazon Systems Manager API Reference*, which also provides information about the values **AllowedPattern**, **Description**, **KeyId**, **Overwrite**, **Type**, and **Value**.

The requirements and constraints for parameter names include the following:

- **Case sensitivity**: Parameter names are case sensitive.
- **Spaces**: Parameter names can't include spaces.
- **Valid characters**: Parameter names can consist of the following symbols and letters only: `a-zA-Z0-9_.-`

  In addition, the slash character (/) is used to delineate hierarchies in parameter names. For example: `/Dev/Production/East/Project-ABC/MyParameter`
- **Data type validation**: When you specify a data type other than `text`, the parameter value must conform to the rules for that data type. For example, a parameter with data type `aws:ec2:image` must be a valid AMI ID such as `ami-12345abcdeEXAMPLE`. For more information, see Parameter data types in Parameter Store.
- **Fully qualified**: When you create or reference a parameter in a hierarchy, include a leading forward slash character (/) . When you reference a parameter that is part of a hierarchy, specify the entire hierarchy path including the initial slash (/).
  - Fully qualified parameter names: `MyParameter1`, `/MyParameter2`, `/Dev/Production/East/Project-ABC/MyParameter`
  - Not fully qualified parameter name: `MyParameter3/L1`
- **Length**: The maximum length for a parameter name that you specify is 1011 characters. This count of 1011 characters includes the characters in the ARN that precede the name you specify, such as the 45 characters in `arn:aws:ssm:us-east-2:111122223333:parameter/`.
- **Prefixes**: A parameter name can't be prefixed with "`aws`" or "`ssm`" (case-insensitive). For example, attempts to create parameters with the following names fail with an exception:
  - `awsTestParameter`
  - `SSM-testparameter`
  - `/aws/testparam1`

> **Note**
>
> When you specify a parameter in an SSM document, command, or script, include `ssm` as part of the syntax. For example, {{ssm:*parameter-name*}} and {{ ssm:*parameter-name* }}, such as `{{ssm:MyParameter}}`, and `{{ ssm:MyParameter }}`.

- **Uniqueness**: A parameter name must be unique within an Amazon Web Services Region. For example, Systems Manager treats the following as separate parameters, if they exist in the same Region:
  - `/Test/TestParam1`
  - `/TestParam1`

  The following examples are also unique:
  - `/Test/TestParam1/Logpath1`
  - `/Test/TestParam1`

  The following examples, however, if in the same Region, aren't unique:
  - `/TestParam1`
  - `TestParam1`
- **Hierarchy depth**: If you specify a parameter hierarchy, the hierarchy can have a maximum depth of fifteen levels. You can define a parameter at any level of the hierarchy. Both of the following examples are structurally valid:
  - `/Level-1/L2/L3/L4/L5/L6/L7/L8/L9/L10/L11/L12/L13/L14/parameter-name`
  - `parameter-name`

  Attempting to create the following parameter would fail with a `HierarchyLevelLimitExceededException` exception:
  - `/Level-1/L2/L3/L4/L5/L6/L7/L8/L9/L10/L11/L12/L13/L14/L15/L16/parameter-name`

> **Important**
>
> Parameter Store authorizes the `GetParametersByPath` operation against the path that you specify in the request, not against each parameter that the operation returns. A

principal who is allowed to call `GetParametersByPath` for the path `/a` receives every parameter under that path, including `/a/b`. This is true even if the same policy explicitly denies access to `/a/b` for other actions.
To prevent a parameter from being returned by `GetParametersByPath`, deny the `ssm:GetParametersByPath` action on every ancestor path that could include the parameter in its results. For example, to prevent `/a/b` from being returned, deny `ssm:GetParametersByPath` for both `/a` and `/`.

For guidance on writing IAM policies that account for this behavior, see Restricting access to specific parameters and paths.

Amazon Systems Manager operations tools

Operations tools are a suite of capabilities that help you manage your Amazon resources.

- Explorer is a customizable operations dashboard that reports information about your Amazon resources. Explorer displays an aggregated view of operations data (OpsData) for your Amazon Web Services accounts and across Amazon Web Services Regions.
- Incident Manager helps you mitigate and recover from incidents affecting your applications hosted on Amazon.
- OpsCenter provides a central location where operations engineers and IT professionals can view, investigate, and resolve operational work items (OpsItems) related to Amazon resources.

Topics

- Amazon Systems Manager Incident Manager
- Amazon Systems Manager Explorer
- Amazon Systems Manager OpsCenter

Amazon Systems Manager Incident Manager

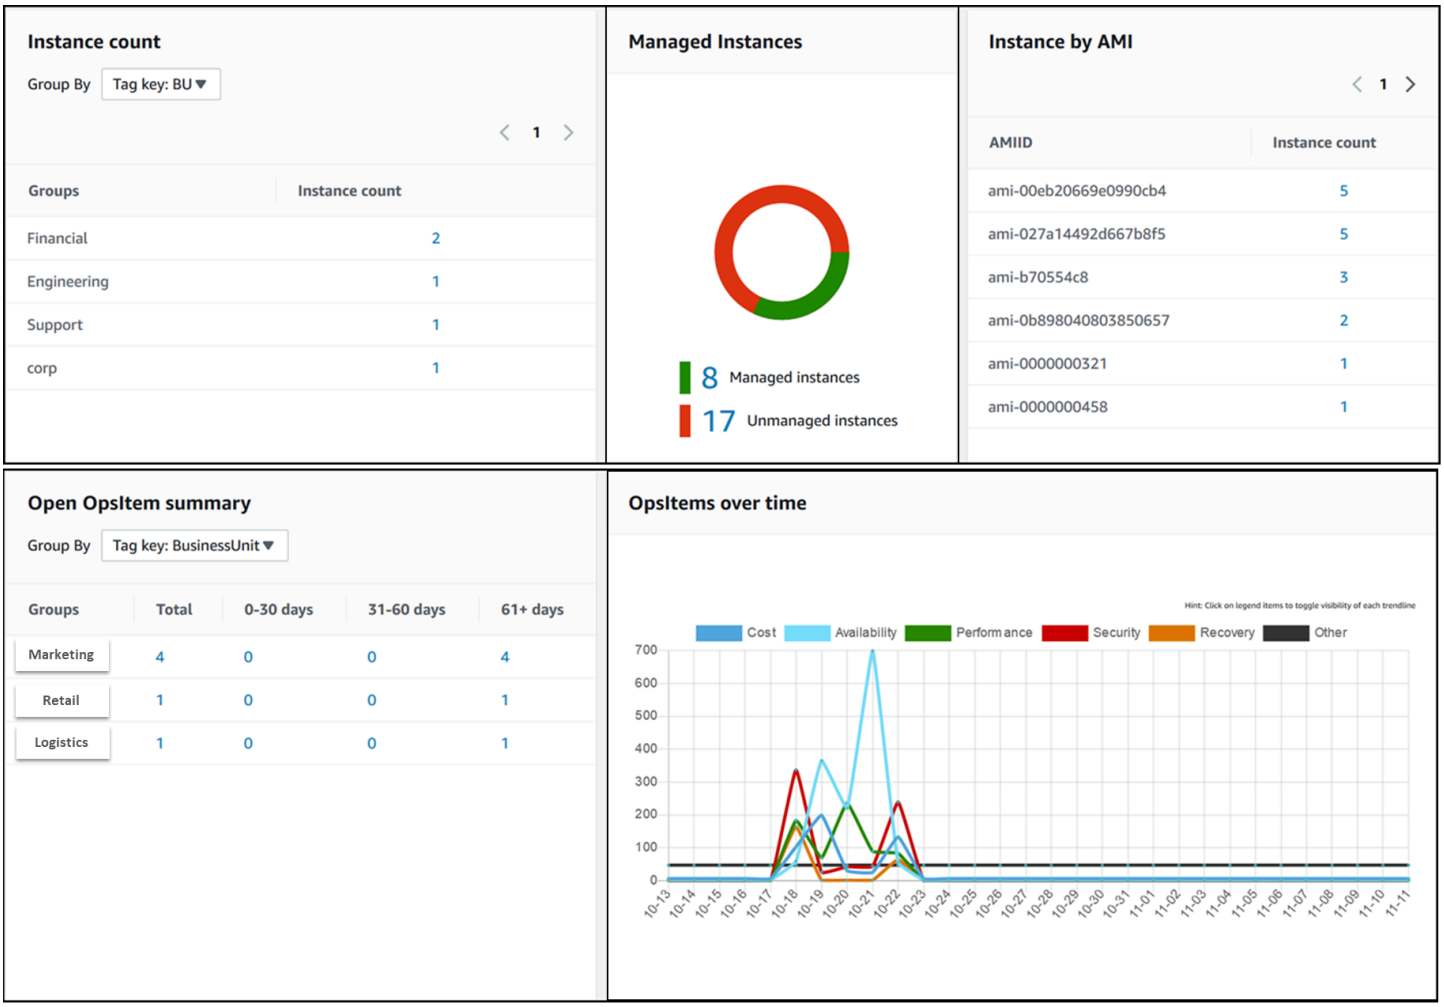
Incident Manager availability change

Amazon Systems Manager Incident Manager will no longer be open to new customers starting November 7, 2025. If you want to use Incident Manager, sign up before that date.

Existing customers can continue to use the service as normal. For more information, see Amazon Systems Manager Incident Manager availability change.

Use Incident Manager to manage incidents occurring in your Amazon hosted applications. Incident Manager combines user engagements, escalation, runbooks, response plans, chat channels, and post-incident analysis. These features help your team triage incidents faster and return your applications to normal. To learn more about Incident Manager, see the Incident Manager User Guide.

Amazon Systems Manager Explorer



The Explorer page will be deprecated on December 31, 2026.

As we simplify the Systems Manager console experience, Resource Data Sync will move to OpsCenter. All your operational data stays available via API and viewable in the relevant Amazon service consoles. Learn more

Amazon Systems Manager Explorer is a customizable operations dashboard that reports information about your Amazon resources. Explorer displays an aggregated view of operations data (OpsData) for your Amazon Web Services accounts and across Amazon Web Services Regions. In Explorer, OpsData includes metadata about the managed nodes in your hybrid and multicloud environment. OpsData also includes information provided by other Systems Manager tools, including Patch Manager patch compliance and State Manager association compliance details. To further simplify how you access OpsData, Explorer displays information from supporting Amazon services like Amazon Config, Amazon Trusted Advisor, Amazon Compute Optimizer, and Amazon Web Services Support (support cases).

To raise operational awareness, Explorer also displays operational work items (OpsItems). Explorer provides context about how OpsItems are distributed across your business units or applications, how they trend over time, and how they vary by category. You can group and filter information in Explorer to focus on items that are relevant to you and that require action. When you identify high priority issues, you can use Systems Manager OpsCenter to run Automation runbooks and quickly resolve those issues. To get started with Explorer, open the Systems Manager console. In the navigation pane, choose **Explorer**.

The following image shows some of the individual report boxes, called *widgets*, which are available in Explorer.

What are the features of Explorer?

Explorer includes the following features:

- **Customizable display of actionable information**: Explorer includes drag-and-drop widgets that automatically display actionable information about your Amazon resources. Explorer displays information in two types of widgets.
  - **Informational widgets**: These widgets summarize data from Amazon EC2, Patch Manager, State Manager, and supporting Amazon Web Services services like Amazon Trusted Advisor, Amazon Compute Optimizer, and Amazon Web Services Support. These widgets provide important context to help you understand the state and operational risks of your Amazon resources. Examples of informational widgets include **Instance count**, **Instance by AMI**, **Total noncompliant nodes** (patching), **Noncompliant associations**, and **Support Center cases**.

  - **OpsItem widgets**: A Systems Manager *OpsItem* is an operational work item that is related to one or more Amazon resources. OpsItems are a feature of Systems Manager OpsCenter. OpsItems might require DevOps engineers to investigate and potentially remediate an issue. Examples of possible OpsItems include high EC2 instance CPU utilization, detached Amazon Elastic Block Store (Amazon EBS) volumes, Amazon CodeDeploy deployment failure, or Systems Manager Automation execution failure. Examples of OpsItem widgets include **Open OpsItem summary**, **OpsItem by status**, and **OpsItems over time**.
- **Filters**: Each widget offers the ability to filter information based on Amazon Web Services account, Amazon Web Services Region, and tag. Filters help you quickly refine the information displayed in Explorer.
- **Direct links to service screens**: To help you investigate issues with Amazon resources, Explorer widgets contain direct links to related service screens. Filters applied to a widget remain in effect if you navigate to a related service screen.
- **Groups**: To help you understand the types of operational issues across your organization, some widgets allow you to group data based on account, Region, and tag.
- **Reporting tag keys**: When you set up Explorer, you can specify up to five tag keys. These keys help you group and filter data in Explorer. If a specified key matches a key on a resource that generates an OpsItem, then the key and value are included in the OpsItems.
- **Three modes of Amazon Web Services account and Amazon Web Services Region display**: Explorer includes the following display modes for OpsData and OpsItems in Amazon Web Services accounts and Amazon Web Services Regions:
  - *Single-account/single-Region*: This is the default view. This mode allows users to view data and OpsItems from their own account and the current Region.
  - *Single-account/multiple-Region*: This mode requires you to create one or more resource data syncs by using the Explorer **Settings** page. A resource data sync aggregates OpsData from one or more Regions. After you create a resource data sync, you can toggle which sync to use on the Explorer dashboard. You can then filter and group data based on Region.
  - *Multiple-account/multiple-Region*: This mode requires that your organization or company use Amazon Organizations with **All features** turned on. After you configure Amazon Organizations in your computing environment, you can aggregate all account data in a management account. You can then create resource data syncs so that you can filter and group data based on Region. For more information about Organizations **All features** mode, see Enabling All Features in Your Organization.

- **Reporting**: You can export Explorer reports as comma separated value (.csv) files to an Amazon Simple Storage Service (Amazon S3) bucket. You receive an alert from Amazon Simple Notification Service (Amazon SNS) when an export is complete.

How does Explorer relate to OpsCenter?

Systems Manager OpsCenter provides a central location where operations engineers and IT professionals view, investigate, and resolve OpsItems related to Amazon resources. Explorer is a report hub where DevOps managers view aggregated summaries of their operations data, including OpsItems, across Amazon Web Services Regions and accounts. Explorer helps users discover trends and patterns and, if necessary, quickly resolve issues using Systems Manager Automation runbooks.

OpsCenter setup is now integrated with Explorer Setup. If you already set up OpsCenter, then Explorer automatically displays operations data, including aggregated information about OpsItems. If you haven't set up OpsCenter, then you can use Explorer Setup to get started with both tool. For more information, see Getting started with Systems Manager Explorer and OpsCenter.

What is OpsData?

OpsData is any operations data that is displayed in the Systems Manager Explorer dashboard. Explorer retrieves OpsData from the following sources:

- **Amazon Elastic Compute Cloud (Amazon EC2)**

  Data displayed in Explorer includes: total number of nodes, total number of managed and unmanaged nodes, and a count of nodes using a specific Amazon Machine Image (AMI).

- **Systems Manager OpsCenter**

  Data displayed in Explorer includes: a count of OpsItems by status, a count of OpsItems by severity, a count of open OpsItems across groups and across 30-day time periods, and historical data of OpsItems over time.

- **Systems Manager Patch Manager**

  Data displayed in Explorer includes a count of noncompliant and critical noncompliant nodes.

- **Amazon Trusted Advisor**

Data displayed in Explorer includes: status of best practice checks for EC2 Reserved Instances in the areas of cost optimization, security, fault tolerance, performance, and service limits.

- **Amazon Compute Optimizer**

  Data displayed in Explorer includes: a count of **Under provisioned** and **Over provisioned** EC2 instances, optimization findings, on-demand pricing details, and recommendations for instance type and price.

- **Amazon Web Services Support Center cases**

  Data displayed in Explorer includes: case ID, severity, status, created time, subject, service, and category.

- **Amazon Config**

  Data displayed in Explorer includes: overall summary of compliant and non-compliant Amazon Config rules, the number of compliant and non-compliant resources, and specific details about each (when you drill down into a non-compliant rule or resource).

- **Amazon Security Hub CSPM**

  Data displayed in Explorer includes: overall summary of Security Hub CSPM findings, the number of each finding grouped by severity, and specific details about finding.

> **Note**
>
> To view Amazon Trusted Advisor and Amazon Web Services Support Center cases in Explorer, you must have either an Enterprise or Business account set up with Amazon Web Services Support.

You can view and manage OpsData sources from the Explorer **Settings** page. For information about setting up and configuring services that populate Explorer widgets with OpsData, see Setting up related services for Explorer.

Is there a charge to use Explorer?

Yes. When you turn on the default rules for creating OpsItems during Integrated Setup, you initiate a process that automatically creates OpsItems. Your account is charged based on the number of OpsItems created per month. Your account is also charged based on the number of

`GetOpsItem`, `DescribeOpsItem`, `UpdateOpsItem`, and `GetOpsSummary` API calls made per month. Additionally, you can be charged for public API calls to other services that expose relevant diagnostic information. For more information, see Amazon Systems Manager Pricing.

Changes to Amazon Systems Manager Explorer

Where you view operational data (OpsData) in Amazon Systems Manager is changing. Starting December 31, 2026, the Explorer dashboard is no longer part of the Systems Manager console. You continue to view the same OpsData in the console of the Amazon Web Services service or Systems Manager tool that produces it.

Only the dashboard changes. None of your OpsData is deleted, and how Systems Manager collects it stays the same. Explorer displays data that Systems Manager tools and other Amazon Web Services services collect and store, so that data remains where it is today. Your resource data syncs continue to aggregate OpsData across your Amazon Web Services accounts and Amazon Web Services Regions, and every Systems Manager API operation that Explorer uses, including `GetOpsSummary`, continues to be supported in the Amazon CLI and the Amazon SDKs.

Use the following sections to find where each of your Explorer views is available, and to review answers to common questions about this change.

Where to find each of your Explorer views

Explorer has multiple widgets that provide operational data. The following table shows where the data in each widget is available. Some alternatives require setup before they display data for multiple Amazon Web Services accounts and Amazon Web Services Regions.

Explorer widget or view	Where to find this data	What you need to know
Managed instances, **Instance count**, **Instances by AMI**	Systems Manager console, **Review node insights** and **Explore nodes** pages	These pages aggregate node details for your organization or account. For more information, see Reviewing node insights and Exploring nodes. These pages require the Systems Manager unified console. To learn more about the Amazon Web Services Regions where the unified console is available, see Supported Amazon

Explorer widget or view	Where to find this data	What you need to know
		Web Services Regions. In other Regions, use Fleet Manager or the Systems Manager API to list your managed nodes.
Total noncompliant nodes (patching)	Patch Manager console, **Dashboard** tab	Patch Manager presents this data differently than Explorer does. Instead of the timeline that the Explorer widget displays, the **Dashboard** tab shows counts of compliant and noncompliant managed nodes, and a patch compliance report for the past 7 days. For more information, see Viewing patch Dashboard summaries.
Noncompliant associations (desired state compliance)	Systems Manager console, **Compliance** page, and State Manager console	For more information, see Amazon Systems Manager Compliance and Amazon Systems Manager State Manager. If you use Quick Setup to create associations, you can also review status for each configuration in the Quick Setup console. For more information, see Amazon Systems Manager Quick Setup.
Amazon Trusted Advisor	Amazon Trusted Advisor console	You must have a Business or Enterprise Support plan. The Amazon Trusted Advisor console shows checks for the current account. To review checks across an organization, turn on the organizational view and generate a report. For more information, see Organizational view for Trusted Advisor.

Explorer widget or view	Where to find this data	What you need to know
Amazon Config compliance	Amazon Config console	To review compliance for multiple accounts and Regions, create an aggregator in Amazon Config. For more information, see Creating an aggregator.
Amazon Security Hub CSPM findings	Amazon Security Hub CSPM console	To review findings for multiple accounts and Regions, turn on central configuration in Security Hub CSPM. For more information, see Starting central configuration.
Amazon Compute Optimizer	Amazon Compute Optimizer console	Opt in for your account or your organization. Compute Optimizer aggregates findings for under-pro visioned resources, and lists over-provisioned resources per resource type rather than as a single aggregate d view. For more information, see Opting in your account.
Support Center cases	Amazon Support Center Console	Support Center Console shows active cases and case history for the current account. It doesn't provide a view of cases across multiple accounts. To build one, see Create a comprehen sive view of Amazon support cases with Amazon QuickSight.
Open OpsItem summary, **OpsItems by status**, **OpsItems by severity**, **OpsItems over time**	OpsCenter console	The OpsCenter console provides information about your OpsItems. For more information, see Amazon Systems Manager OpsCenter.

Explorer widget or view	Where to find this data	What you need to know
Export OpsData to Amazon S3 bucket	Systems Manager Automation console, or the Amazon CLI	Explorer uses the AWS-Expor tOpsDataToS3 runbook to export OpsData. You can continue to run this runbook directly from the Automatio n console or the Amazon CLI. For more information, see AWS-Expor tOpsDataToS3.

The aggregated counts that Explorer widgets display are returned by the GetOpsSummary API operation. You can call `GetOpsSummary` with the Amazon CLI, an Amazon SDK, or the Systems Manager API to build your own reports, including for the accounts and Regions covered by a resource data sync.

You can also build your own visualization of this data. For an example that combines an Explorer resource data sync, the AWS-ExportOpsDataToS3 runbook, and Amazon Quick Sight to chart Amazon Web Services Support cases across the accounts in an organization, see Create a comprehensive view of Amazon support cases with Amazon QuickSight.

Resource data syncs that you already created continue to aggregate OpsData for your accounts and Regions. Resource data sync management in the console will move to OpsCenter. You can manage them with the Systems Manager API by using the CreateResourceDataSync, ListResourceDataSync, UpdateResourceDataSync, and DeleteResourceDataSync API operations.

Frequently asked questions

Is my OpsData deleted when Explorer is discontinued?

No. Explorer displays data that other Amazon Web Services services and Systems Manager tools collect and store. That data remains in those services, and remains available through their consoles and APIs.

Are any API operations being removed?

No. This change affects the console experience only. The API operations that Explorer uses, including `GetOpsSummary` and the resource data sync operations, continue to be available.

Do I need to delete or re-create my resource data syncs?

No. Your existing resource data syncs continue to work, and you can manage them with the Systems Manager API.

Can I still view data for multiple accounts and Regions?

In most cases, yes, but the setup and the level of aggregation depend on the service. Review the **What you need to know** column in Where to find each of your Explorer views for the data sources you use.

If you have additional questions, contact us through the Amazon Support Center.

- Using Explorer
- Exporting OpsData from Systems Manager Explorer
- Troubleshooting Systems Manager Explorer

Getting started with Systems Manager Explorer and OpsCenter

Amazon Systems Manager uses an integrated setup experience to help you get started with Systems Manager Explorer and Systems Manager OpsCenter. In this documentation, Explorer and OpsCenter Setup is called *Integrated Setup*. If you already set up OpsCenter, you still need to complete Integrated Setup to verify settings and options. If you haven't set up OpsCenter, then you can use Integrated Setup to get started with both tools.

> **Note**
>
> Integrated Setup is only available in the Systems Manager console. You can't set up Explorer or OpsCenter programmatically.

Integrated Setup performs the following tasks:

- Configures roles and permissions: Integrated Setup creates an Amazon Identity and Access Management (IAM) role that allows Amazon EventBridge to automatically create OpsItems

based on default rules. After setting up, you must configure user, group, or role permissions for OpsCenter, as described in this section.

- Allows default rules for OpsItem creation: Integrated Setup creates default rules in EventBridge. These rules automatically create OpsItems in response to events. Examples of these events are: state change for an Amazon resource, a change in security settings, or a service becoming unavailable.
- Activates OpsData sources: Integrated Setup activates the following data sources that populate Explorer widgets.
  - Amazon Web Services Support Center (You must have either a Business or Enterprise Support plan to activate this source.)
  - Amazon Compute Optimizer (You must have either a Business or Enterprise Support plan to activate this source.)
  - Systems Manager State Manager association compliance
  - Amazon Config Compliance
  - Systems Manager OpsCenter
  - Systems Manager Patch Manager patch compliance
  - Amazon Elastic Compute Cloud (Amazon EC2)
  - Systems Manager Inventory
  - Amazon Trusted Advisor (You must have either a Business or Enterprise Support plan to activate this source.)
  - Amazon Security Hub CSPM

> **Note**
>
> You can change setup configurations at any time on the **Settings** page.

After you complete Integrated Setup, we recommend that you Set up Explorer to display data from multiple Regions and accounts. Explorer and OpsCenter automatically synchronize OpsData and OpsItems for the Amazon Web Services account and Amazon Web Services Region you used when you completed Integrated Setup. You can aggregate OpsData and OpsItems from other accounts and Regions by creating a resource data sync.

Setting up related services for Explorer

Amazon Systems Manager Explorer and Amazon Systems Manager OpsCenter collect information from, or interact with, other Amazon Web Services services and Systems Manager tools. We recommend that you set up and configure these other services or tools before you use Integrated Setup.

The following table includes tasks that allow Explorer and OpsCenter to collect information from, or interact with, other Amazon Web Services services and Systems Manager tools.

Task	Information
Verify permissions in Systems Manager Automation	Explorer and OpsCenter allow you to remediate issues with Amazon resources by using Systems Manager Automation runbooks. To use this remediation tool, you must have permission to run Systems Manager Automation runbooks. For more information, see Setting up Automation.
Set up and configure Systems Manager Patch Manager	Explorer includes a widget that provides information about patch compliance. To view this data in Explorer, you must configure patching. For more information, see Amazon Systems Manager Patch Manager.
Set up and configure Systems Manager State Manager	Explorer includes a widget that provides information about Systems Manager State Manager association compliance. To view this data in Explorer, you must configure State Manager. For more information, see Amazon Systems Manager State Manager.
Turn on Amazon Config Configuration Recorder	Explorer uses data provided by Amazon Config configuration recorder to populate widgets with information about your EC2 instances. To view this data in Explorer, turn on Amazon Config configuration recorder. For more

Task	Information
	information, see Managing the Configuration Recorder. **Note** After you allow configuration recorder, Systems Manager can take up to six hours to display data in Explorer widgets that display information about your EC2 instances.
Turn on Amazon Trusted Advisor	Explorer uses data provided by Trusted Advisor to display a status of best practice checks for Amazon EC2 Reserved Instances in the areas of cost optimization, security, fault tolerance , performance, and service limits. To view this data in Explorer, you must have a business or enterprise support plan. For more information, see Amazon Web Services Support.
Turn on Amazon Compute Optimizer	Explorer uses data provided by Compute Optimizer to display details a count of **Under provisioned** and **Over provisioned** EC2 instances, optimization findings, on-demand pricing details, and recommendations for instance type and price. To view this data in Explorer, turn on Compute Optimizer. For more information, see Getting started with Amazon Compute Optimizer.

Task	Information
Turn on Amazon Security Hub CSPM	Explorer uses data provided by Security Hub CSPM to populate widgets with informati on about your security findings. To view this data in Explorer, turn on Security Hub CSPM integration. For more information, see What is Amazon Security Hub CSPM.

Configuring roles and permissions for Systems Manager Explorer

Integrated Setup automatically creates and configures Amazon Identity and Access Management (IAM) roles for Amazon Systems Manager Explorer and Amazon Systems Manager OpsCenter. If you completed Integrated Setup, then you don't need to perform any additional tasks to configure roles and permissions for Explorer. However, you must configure permission for OpsCenter, as described later in this topic.

Integrated Setup creates and configures the following roles for working with Explorer and OpsCenter.

- `AWSServiceRoleForAmazonSSM`: Provides access to Amazon resources managed or used by Systems Manager.
- `OpsItem-CWE-Role`: Allows CloudWatch Events and EventBridge to create OpsItems in response to common events.
- `AWSServiceRoleForAmazonSSM_AccountDiscovery`: Allows Systems Manager to call other Amazon Web Services services to discover Amazon Web Services account information when synchronizing data. For more information about this role, see Using roles to collect Amazon Web Services account information for OpsCenter and Explorer.
- `AmazonSSMExplorerExport`: Allows Explorer to export OpsData to a comma-separated value (CSV) file.

If you configure Explorer to display data from multiple accounts and Regions by using Amazon Organizations and a resource data sync, then Systems Manager creates the `AWSServiceRoleForAmazonSSM_AccountDiscovery` service-linked role. Systems Manager uses this role to get information about your Amazon Web Services accounts in Amazon Organizations. The role uses the following permissions policy.

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "organizations:DescribeAccount",
            "organizations:DescribeOrganization",
            "organizations:ListAccounts",
            "organizations:ListAWSServiceAccessForOrganization",
            "organizations:ListChildren",
            "organizations:ListParents"
         ],
         "Resource":"*"
      }
   ]
}
```

For more information about the `AWSServiceRoleForAmazonSSM_AccountDiscovery` role, see Using roles to collect Amazon Web Services account information for OpsCenter and Explorer.

Configuring permissions for Systems Manager OpsCenter

After you complete Integrated Setup, you must configure user, group, or role permissions so that users can perform actions in OpsCenter.

Before you begin

You can configure OpsCenter to create and manage OpsItems for a single account or across multiple accounts. If you configure OpsCenter to create and manage OpsItems across multiple accounts, you can use either the Systems Manager delegated administrator account or the Amazon Organizations management account to manually create, view, or edit OpsItems in other accounts. For more information about the Systems Manager delegated administrator account, see Configuring a delegated administrator for Explorer.

If you configure OpsCenter for a single account, you can only view or edit OpsItems in the account where OpsItems were created. You can't share or transfer OpsItems across Amazon Web Services accounts. For this reason, we recommend that you configure permissions for OpsCenter in the

Amazon Web Services account that is used to run your Amazon workloads. You can then create users or groups in that account. In this way, multiple operations engineers or IT professionals can create, view, and edit OpsItems in the same Amazon Web Services account.

Explorer and OpsCenter use the following API operations. You can use all features of Explorer and OpsCenter if your user, group, or role has access to these actions. You can also create more restrictive access, as described later in this section.

- CreateOpsItem
- CreateResourceDataSync
- DescribeOpsItems
- DeleteResourceDataSync
- GetOpsItem
- GetOpsSummary
- ListResourceDataSync
- UpdateOpsItem
- UpdateResourceDataSync

If you prefer, you can specify read-only permission by adding the following inline policy to your account, group, or role.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetOpsItem",
        "ssm:GetOpsSummary",
        "ssm:DescribeOpsItems",
        "ssm:GetServiceSetting",
        "ssm:ListResourceDataSync"
      ],
      "Resource": "*"
    }
  ]
```

```
}
```

For more information about creating and editing IAM policies, see Creating IAM Policies in the *IAM User Guide*. For information about how to assign this policy to an IAM group, see Attaching a Policy to an IAM Group.

Create a permission using the following and add it to your users, groups, or roles:

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetOpsItem",
        "ssm:UpdateOpsItem",
        "ssm:DescribeOpsItems",
        "ssm:CreateOpsItem",
        "ssm:CreateResourceDataSync",
        "ssm:DeleteResourceDataSync",
        "ssm:ListResourceDataSync",
        "ssm:UpdateResourceDataSync"

      ],
      "Resource": "*"
    }
  ]
}
```

Depending on the identity application that you are using in your organization, you can select any of the following options to configure user access.

To provide access, add permissions to your users, groups, or roles:

- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Create a role for a third-party identity provider (federation) in the *IAM User Guide*.

- IAM users:
  - Create a role that your user can assume. Follow the instructions in Create a role for an IAM user in the *IAM User Guide*.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the *IAM User Guide*.

Restricting access to OpsItems by using tags

You can also restrict access to OpsItems by using an inline IAM policy that specifies tags. Here is an example that specifies a tag key of *Department* and a tag value of *Finance*. With this policy, the user can only call the *GetOpsItem* API operation to view OpsItems that were previously tagged with Key=Department and Value=Finance. Users can't view any other OpsItems.

JSON

```
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetOpsItem"
             ],
      "Resource": "*"
      ,
      "Condition": { "StringEquals": { "ssm:resourceTag/Department":
 "Finance" } }
    }
  ]
}
```

Here is an example that specifies API operations for viewing and updating OpsItems. This policy also specifies two sets of tag key-value pairs: Department-Finance and Project-Unity.

JSON

```
{
   "Version":"2012-10-17",
```

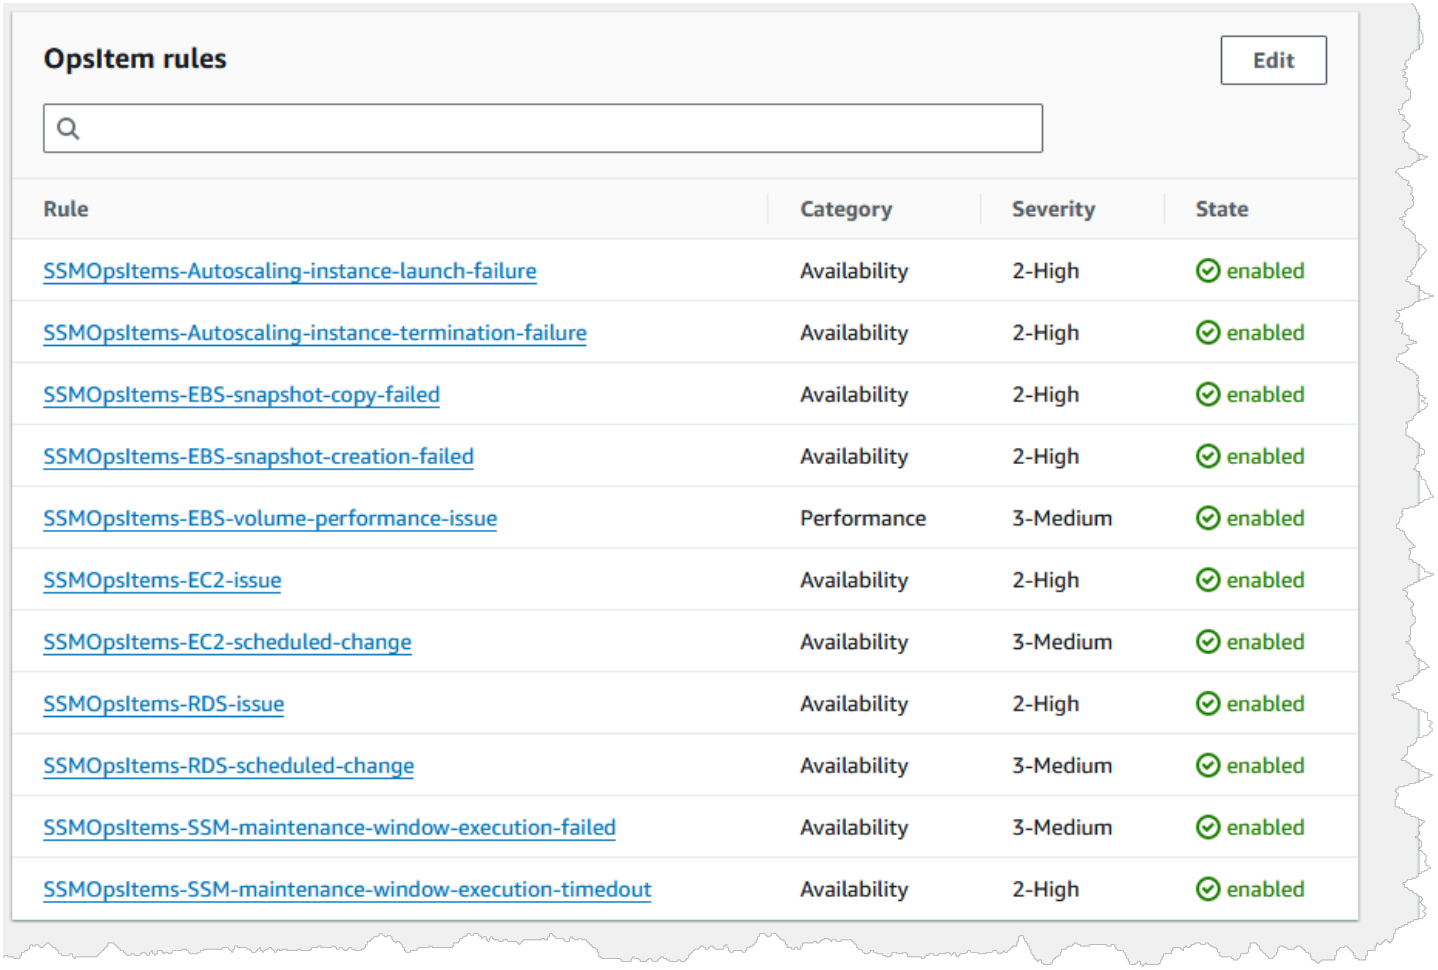
```
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "ssm:GetOpsItem",
            "ssm:UpdateOpsItem"
         ],
         "Resource":"*",
         "Condition":{
            "StringEquals":{
               "ssm:resourceTag/Department":"Finance",
               "ssm:resourceTag/Project":"Unity"
            }
         }
      }
   ]
}
```

For information about adding tags to an OpsItem, see Create OpsItems manually.

Understanding default EventBridge rules created by Integrated Setup

During the integrated setup process for Explorer and OpsCenter, you can choose to enable several default rules that are based on events detected by Amazon EventBridge. When these events are detected, the system automatically creates OpsItems in Amazon Systems Manager OpsCenter.

For example, the rule `SSMOpsItems-Autoscaling-instance-termination-failure` results in an OpsItem being created when the termination of an EC2 auto scaling instance fails.



The rule `SSMOpsItems-SSM-maintenance-window-execution-failed` results in an OpsItem being created when a Systems Manager maintenace window fails to complete successfully.

For setup instructions and descriptions of all the EventBridge rules you can enable during the setup process, see Set up OpsCenter.

If you don't want EventBridge to create OpsItems for these events, you can choose not to enable this option in Integrated Setup. If you prefer, you can specify OpsCenter as the target of specific EventBridge events. For more information, see Configure EventBridge rules to create OpsItems.

You can disable a default rule or change its category and severity level in the OpsCenter **Settings** page by choosing **OpsCenter, Settings**, and then choosing **Edit** in the **OpsItem rules** area.

You can also edit the category or severity assigned to an individual OpsItem created from these rules in the Systems Manager console. For information, see Editing an OpsItem.

Configuring a delegated administrator for Explorer

If you aggregate Amazon Systems Manager Explorer data from multiple Amazon Web Services Regions and accounts by using resource data sync with Amazon Organizations, then we recommend that you configure a delegated administrator for Explorer. A delegated administrator improves Explorer security in the following ways.

- You limit the number of Explorer administrators who can create or delete multi-account and Region resource data syncs to an individual Amazon Web Services account.
- You no longer need to be logged into the Amazon Organizations management account to administer resource data syncs in Explorer.

A delegated administrator can use the following Explorer resource data sync APIs using the console, SDK, Amazon Command Line Interface (Amazon CLI), or Amazon Tools for Windows PowerShell:

- CreateResourceDataSync
- DeleteResourceDataSync
- ListResourceDataSync
- UpdateResourceDataSync

A delegated administrator can search, filter, and aggregate Explorer data from the console or by using programmatic tools such as the SDK, the Amazon CLI, or Amazon Tools for Windows PowerShell. Search, filter, and data aggregation use the GetOpsSummary API operation.

A delegated administrator can create a maximum of five resource data syncs for either an entire organization or a subset of organizational units. Resource data syncs created by a delegated administrator are only available in the delegated administrator account. You can't view the syncs or the aggregated data in the Amazon Organizations management account.

> **Note**
>
> You can't use a delegated administrator account to create a resource data sync in opt-in Amazon Web Services Regions. You must use an Amazon Organizations management account.

For more information about resource data sync, see Setting up Systems Manager Explorer to display data from multiple accounts and Regions. For more information about Amazon Organizations, see What is Amazon Organizations? in the *Amazon Organizations User Guide*.

Topics

- Before you begin
- Configure an Explorer delegated administrator
- Deregister an Explorer delegated administrator

Before you begin

The following list includes important information about Explorer delegated administration.

- You can delegate only one account for Explorer administration.
- The account ID that you specify as an Explorer delegated administrator must be listed as a member account in Amazon Organizations. For more information, see Creating an Amazon Web Services account in your organization in the *Amazon Organizations User Guide*.
- A delegated administrator can use all Explorer resource data sync API operations in the console or by using programmatic tools such as the SDK, the Amazon Command Line Interface (Amazon CLI), or Amazon Tools for Windows PowerShell. Resource data sync API operations include the following: CreateResourceDataSync, DeleteResourceDataSync, ListResourceDataSync, and UpdateResourceDataSync.
- A delegated administrator can search, filter, and aggregate Explorer data in the console or by using programmatic tools such as the SDK, the Amazon CLI, or Amazon Tools for Windows PowerShell. Search, filter, and data aggregation use the GetOpsSummary API operation.
- Resource data syncs created by a delegated administrator are only available in the delegated administrator account. You can't view the syncs or the aggregated data in the Amazon Organizations management account.
- A delegated administrator can create a maximum of five resource data syncs.
- A delegated administrator can create a resource data sync for either an entire organization in Amazon Organizations or a subset of organizational units.

Configure an Explorer delegated administrator

Use the following procedure to register an Explorer delegated administrator.

To register an Explorer delegated administrator

1. Log into your Amazon Organizations management account.
2. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
3. In the navigation pane, choose **Explorer**.
4. Choose **Settings**.
5. In the **Delegated administrator for Explorer** section, verify that you have configured the required service-linked role and service access options. If necessary, choose the **Create role** and **Enable access** buttons to configure these options.
6. For **Account ID**, enter the Amazon Web Services account ID. This account must be a member account in Amazon Organizations.

7. Choose **Register delegated administrator**.

The delegated administrator now has access to the **Include all accounts from my Amazon Organizations configuration** and **Select organization units in Amazon Organizations** options on the **Create resource data sync** page.

Deregister an Explorer delegated administrator

Use the following procedure to deregister an Explorer delegated administrator. A delegated administrator account can only be deregistered by the Amazon Organizations management account. When a delegated administrator account is deregistered, the system deletes all Amazon Organizations resource data syncs created by the delegated administrator.

To deregister an Explorer delegated administrator

1. Log into your Amazon Organizations management account.
2. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
3. In the navigation pane, choose **Explorer**.
4. Choose **Settings**.
5. In the **Delegated administrator for Explorer** section, choose **Deregister**. The system displays a warning.
6. Enter the account ID and choose **Remove**.

The account no longer has access to the Amazon Organizations resource data sync API operations. The system deletes all Amazon Organizations resource data syncs created by the account.

Setting up Systems Manager Explorer to display data from multiple accounts and Regions

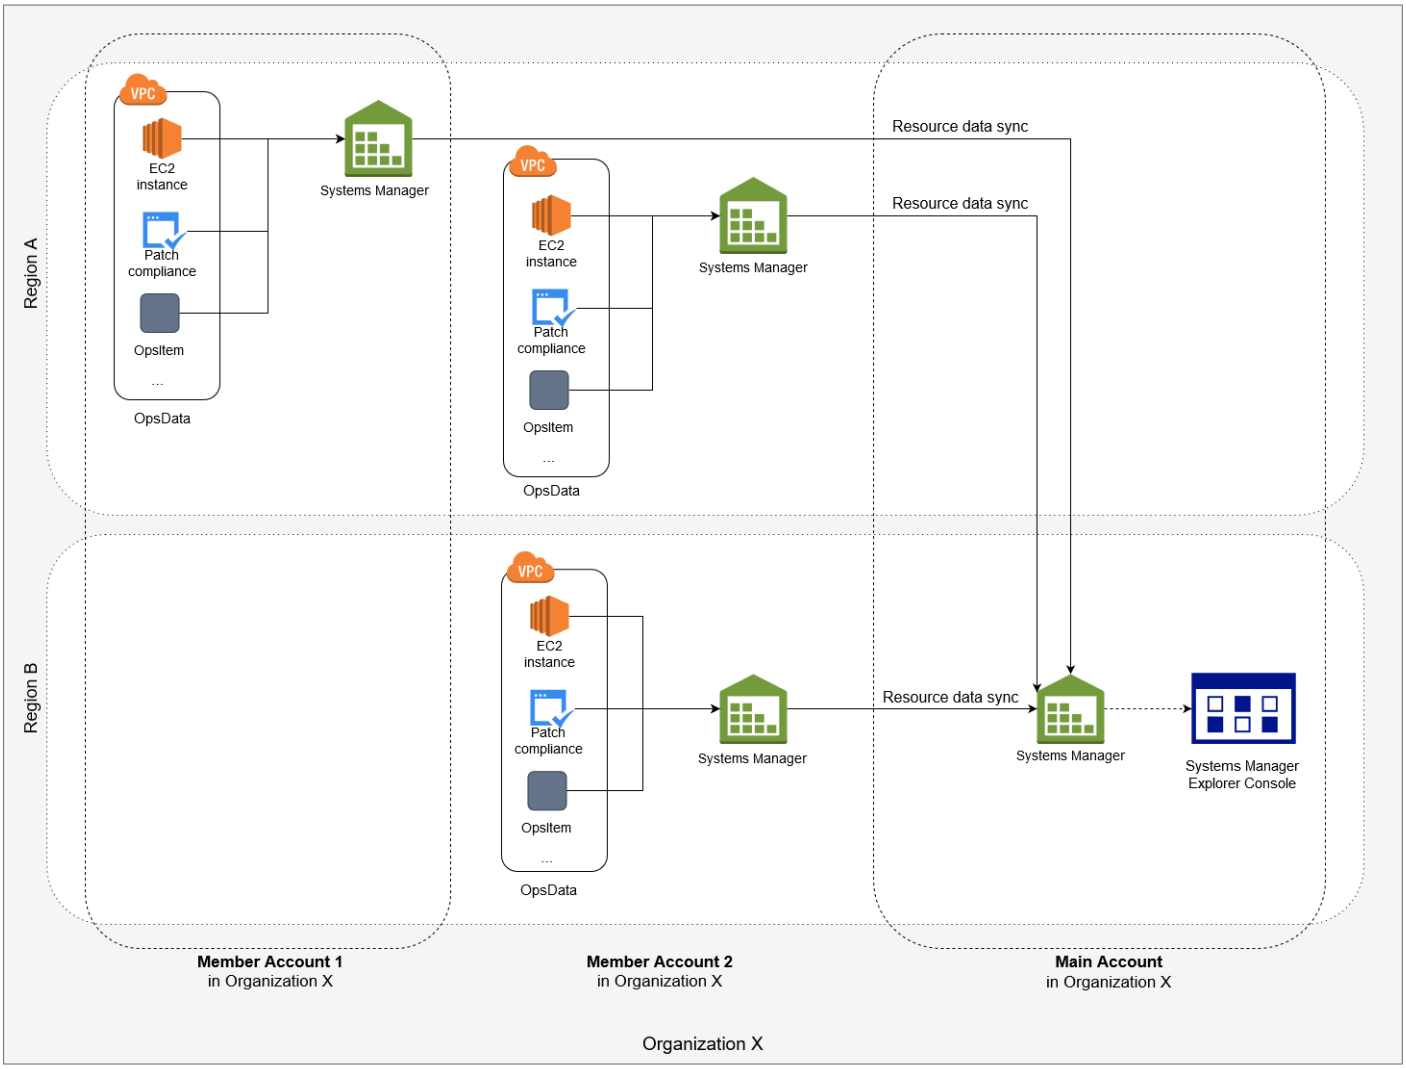
Amazon Systems Manager uses an integrated setup experience to help you get started with Amazon Systems Manager Explorer *and* Amazon Systems Manager OpsCenter. After completing Integrated Setup, Explorer and OpsCenter automatically synchronize data. More specifically, these tools synchronize OpsData and OpsItems for the Amazon Web Services account and Amazon Web Services Region you used when you completed Integrated Setup. If you want to aggregate OpsData and OpsItems from other accounts and Regions, you must create a resource data sync, as described in this topic.

> **Note**
>
> For more information about Integrated Setup, see Getting started with Systems Manager Explorer and OpsCenter.

Topics

- Understanding resource data syncs for Explorer
- Understanding multiple account and Region resource data syncs
- Creating a resource data sync

Understanding resource data syncs for Explorer



Resource data sync for Explorer offers two aggregation options:

- **Single-account/Multiple-regions:** You can configure Explorer to aggregate OpsItems and OpsData data from multiple Amazon Web Services Regions, but the data set is limited to the current Amazon Web Services account.
- **Multiple-accounts/Multiple-regions:** You can configure Explorer to aggregate data from multiple Amazon Web Services Regions and accounts. This option requires that you set up and configure Amazon Organizations. After you set up and configure Amazon Organizations, you can aggregate data in Explorer by organizational unit (OU) or for an entire organization. Systems Manager aggregates the data into the Amazon Organizations management account before displaying it in Explorer. For more information, see What is Amazon Organizations? in the *Amazon Organizations User Guide*.

> **Warning**
>
> If you configure Explorer to aggregate data from an organization in Amazon Organizations, the system enables OpsData in all member accounts in the organization. Enabling OpsData sources in all member accounts increases the number of calls to OpsCenter APIs like CreateOpsItem and GetOpsSummary. You are charged for calls to these API actions.

The following diagram shows a resource data sync configured to work with Amazon Organizations. In this scenario, the user has two accounts defined in Amazon Organizations. Resource data sync

aggregates data from both accounts and multiple Amazon Web Services Regions into the Amazon Organizations management account where it's then displayed in Explorer.

Understanding multiple account and Region resource data syncs

This section describes important details about multiple account and multiple Region resource data syncs that use Amazon Organizations. Specifically, the information in this section applies if you choose one of the following options in the **Create resource data sync** page:

- Include all accounts from my Amazon Organizations configuration
- Select organization units in Amazon Organizations

If you don't plan to use one of these options, you can skip this section.

When you create a resource data sync in the SSM console and choose one of the Amazon Organizations options, Systems Manager automatically allows all OpsData sources in the selected Regions for all Amazon Web Services accounts in your organization or selected organizational units. For example, even if you haven't turned Explorer on in a Region, selecting an Amazon Organizations option causes Systems Manager to automatically collect OpsData from that Region. To create a resource data sync without allowing OpsData sources, specify **EnableAllOpsDataSources** as false when creating the data sync. For more information, see the `EnableAllOpsDataSources` parameter details for the ResourceDataSyncSource data type in the *Amazon EC2 Systems Manager API Reference*.

If you don't choose one of the Amazon Organizations options for a resource data sync, then you must complete Integrated Setup in each account and Region where you want Explorer to access data. If you don't, Explorer won't display OpsData and OpsItems for those accounts and Regions in which you didn't complete Integrated Setup.

If you add a child account to your organization, Explorer automatically allows all OpsData sources for the account. If, at a later time, you remove the child account from your organization, Explorer continues to collect OpsData from the account.

If you update an existing resource data sync that uses one of the Amazon Organizations options, the system prompts you to approve collection of all OpsData sources for all accounts and Regions affected by the change.

If you add a new service to your Amazon Web Services account, and if Explorer collects OpsData for that service, Systems Manager automatically configures Explorer to collect that OpsData. For example, if your organization didn't use Amazon Trusted Advisor when you previously created a resource data sync, but your organization signs up for this service, Explorer automatically updates your resource data syncs to collect this OpsData.

Important

Note the following important information about multiple account and Region resource data syncs:

- Deleting a resource data sync doesn't turn off an OpsData source in Explorer.
- To view OpsData and OpsItems from multiple accounts, you must have the Amazon Organizations **All features** mode turned on and you must be signed into the Amazon Organizations management account.

- Most Amazon Web Services Regions are active by default for your Amazon Web Services account, but certain Regions are activated only when you manually select them. These Regions are known as opt-in Regions. By default, Explorer cross-account/cross-Region resource data syncs don't support data aggregation in opt-in Regions. Support was added for the following opt-in Regions on June 30, 2025.
  - Europe (Milan)
  - Africa (Cape Town)
  - Middle East (Bahrain)
  - Asia Pacific (Hong Kong)

  Note that you can't use a delegated administrator account to create a resource data sync in opt-in Regions. You must use an Amazon Organizations management account.

Creating a resource data sync

Before you configure a resource data sync for Explorer, note the following details.

- Explorer supports a maximum of five resource data syncs.
- After you create a resource data sync for a Region, you can't change the *account options* for that sync. For example, if you create a sync in the us-east-2 (Ohio) Region and you choose the **Include only the current account** option, you can't edit that sync later and choose the **Include all accounts from my Amazon Organizations configuration** option. Instead, you must delete the first resource data sync, and create a new one.
- OpsData viewed in Explorer is read-only.

Use the following procedure to create a resource data sync for Explorer.

To create a resource data sync

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Explorer**.
3. Choose **Settings**.
4. In the **Configure resource data sync** section, choose **Create resource data sync**.
5. For **Resource data sync name**, enter a name.

6. In the **Add accounts** section, choose an option.

> **Note**
>
> To use either of the Amazon Organizations options, you must be logged into the Amazon Organizations management account or you must be logged into an Explorer delegated administrator account. For more information about the delegated administrator account, see Configuring a delegated administrator for Explorer.

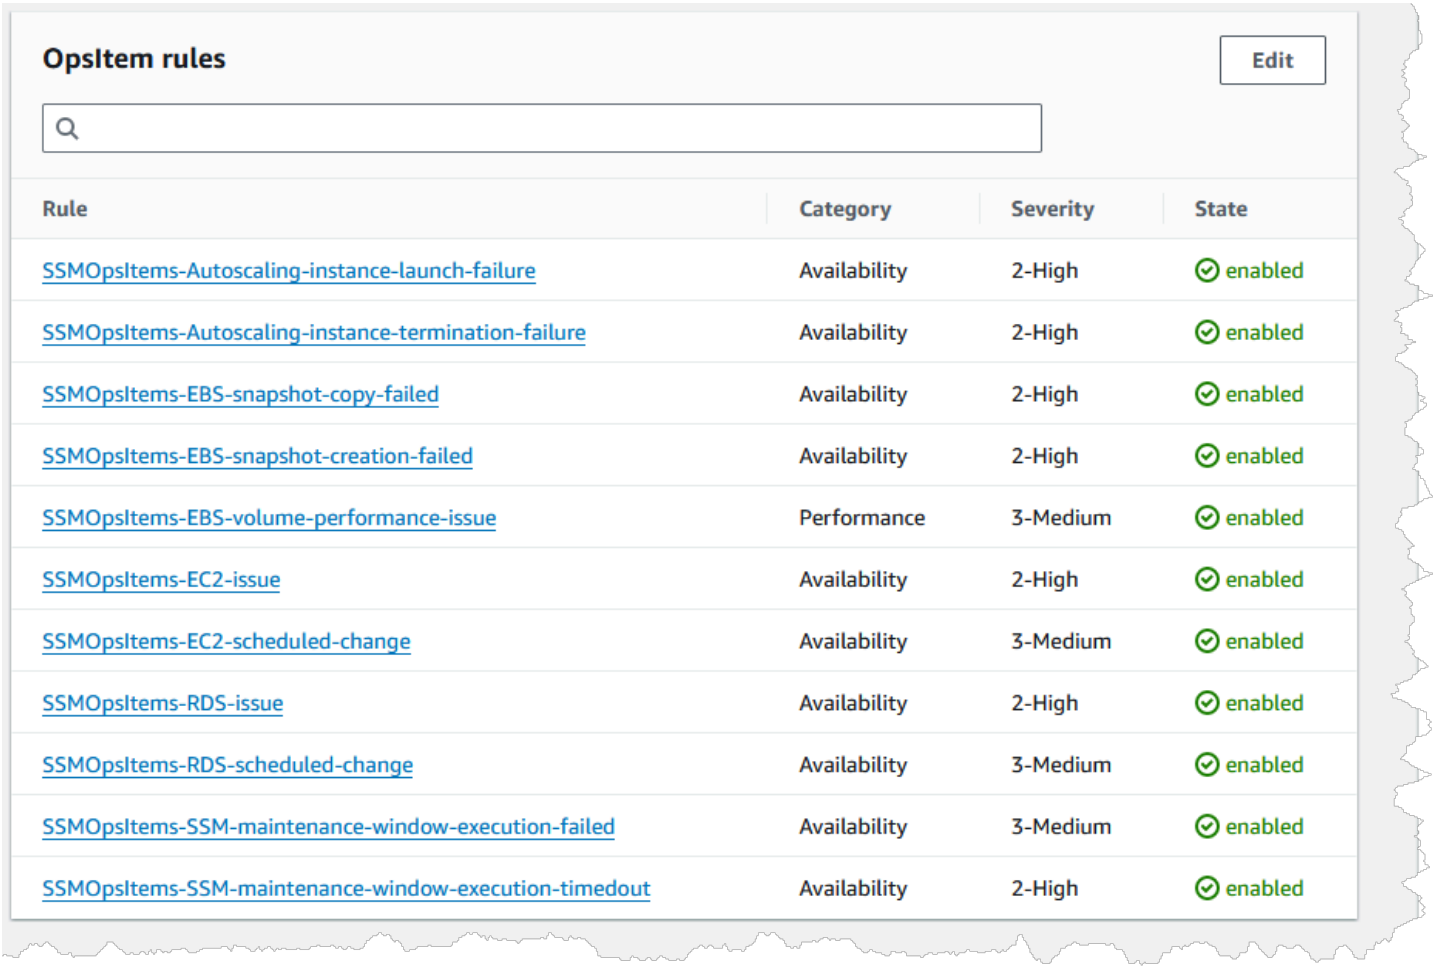
7. In the **Regions to include** section, choose one of the following options.
   - Choose **All current and future regions** to automatically sync data from all current Amazon Web Services Regions and any new Regions that come online in the future.
   - Choose **All regions** to automatically sync data from all current Amazon Web Services Regions.
   - Individually choose Regions that you want to include.
8. Choose **Create resource data sync**.

The system can take several minutes to populate Explorer with data after you create a resource data sync. You can view the sync by choosing it from the **Select a resource data sync** list in Explorer.

Using Explorer

This section includes information about how to customize Amazon Systems Manager Explorer by changing the widget layout and by changing the data that displays in the dashboard.

Contents



- Editing EventBridge rules created for Explorer
- Editing Systems Manager Explorer data sources
- Customizing the Explorer display
- Receiving findings from Amazon Security Hub CSPM in Explorer
- Deleting a Systems Manager Explorer resource data sync

Editing EventBridge rules created for Explorer

When you complete Integrated Setup, the system allows more than a dozen rules in Amazon EventBridge. These rules automatically create OpsItems in Amazon Systems Manager OpsCenter. Amazon Systems Manager Explorer then displays aggregated information about the OpsItems.

Each rule includes a preset **Category** and **Severity** value. When the system creates OpsItems from an event, it automatically assigns the preset **Category** and **Severity**.

> **Important**
>
> You can't edit the **Category** and **Severity** values for default rules but you can edit these values on OpsItems created from the default rules.

To edit default rules for creating OpsItems

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Explorer**.
3. Choose **Settings**.
4. In the **OpsItems rules** section, choose **Edit**.
5. Expand **CWE rules**.
6. Clear the check box beside those rules that you don't want to use.
7. Use the **Category** and **Severity** lists to change this information for a rule.
8. Choose **Save**.

Your changes take effect the next time the system creates an OpsItem.

Editing Systems Manager Explorer data sources

For Amazon Web Services Regions that are available by default, Amazon Systems Manager Explorer displays data from the following sources. You can edit Explorer settings to add or remove data sources:

- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Systems Manager Inventory
- Amazon Systems Manager OpsCenter OpsItems
- Amazon Systems Manager Patch Manager patch compliance
- Amazon Systems Manager State Manager association compliance
- Amazon Trusted Advisor
- Amazon Compute Optimizer
- Amazon Web Services Support Center cases
- Amazon Config rule and resource compliance
- Amazon Security Hub CSPM findings

> **Note**
>
> For the Asia Pacific (Osaka) Region, Explorer doesn't display data from Amazon Compute Optimizer and Amazon Security Hub CSPM findings.

For the Amazon opt-in Regions, Explorer displays data from the following sources:

- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Systems Manager Inventory
- Amazon Systems Manager OpsCenter OpsItems
- Amazon Systems Manager Patch Manager patch compliance
- Amazon Systems Manager State Manager association compliance
- Amazon Trusted Advisor
- Amazon Web Services Support Center cases
- Amazon Config rule and resource compliance

> **Note**
>
> - To view Amazon Web Services Support Center cases in Explorer, you must have either an Enterprise or Business account set up with Amazon Web Services Support.
> - You can't configure Explorer to stop displaying OpsCenter OpsItem data.

Before you begin

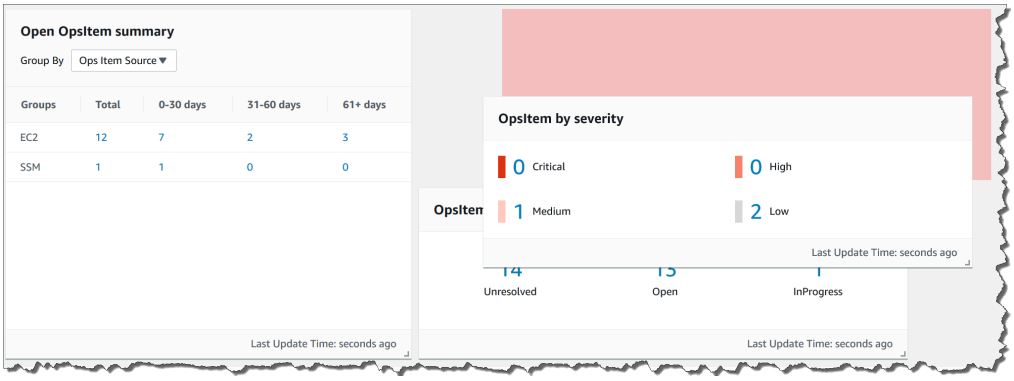
Verify that you set up and configured services that populate Explorer widgets with data. For more information, see Setting up related services for Explorer.

To edit data sources

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Explorer**.
3. Choose **Settings**, and then choose the **Configure Dashboard** tab.

4. In the **OpsData sources** section, in the **Status** column, turn on or turn off sources according to the data you want to view.

Customizing the Explorer display



You can customize widget layout in Amazon Systems Manager Explorer by using a drag-and-drop capability. You can also customize the OpsData and OpsItems displayed in Explorer by using filters, as described in this topic.

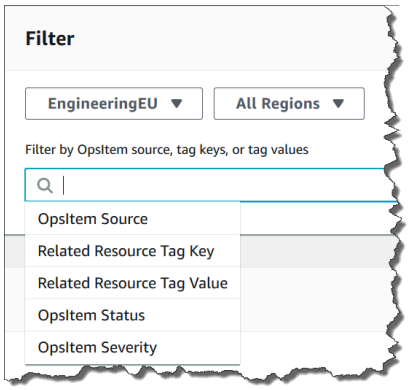
Before you customize widget layout, verify that the widgets you want to view are currently displayed in Explorer. To view some widgets in Explorer (such as the Amazon Config compliance widget), you must enable them on the **Configure dashboard** page.

To enable widgets to display in Explorer

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Explorer**.
3. Choose **Dashboard actions**, **Configure dashboard**.
4. Choose the **Configure Dashboard** tab.
5. Either choose **Enable all** or turn on an individual widget or data source.
6. Choose **Explorer** to view your changes.

To customize widget layout in Explorer, choose a widget that you want to move. Press and hold the name of the widget and then drag it to its new location.

Repeat this process for each widget that you want to reposition.



If you decide that you don't like the new layout, choose **Reset layout** to move all widgets back to their original location.

Using filters to the change the data displayed in Explorer

By default, Explorer displays data for the current Amazon Web Services account and the current Region. If you create one or more resource data syncs, you can use filters to change which sync is active. You can then choose to display data for a specific Region or all Regions. You can also use the Search bar to filter on different OpsItem and key-tag criteria.

To change the data displayed in Explorer by using filters

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Explorer**.
3. In the **Filter** section, use the **Select a resource data sync** list to choose a sync.
4. Use the **Regions** list to choose either a specific Amazon Web Services Region or choose **All Regions**.
5. Choose the Search bar, and then choose the criteria on which to filter the data.

6. Press Enter.

Explorer retains the filter options you selected if you close and reopen the page.

Receiving findings from Amazon Security Hub CSPM in Explorer

Amazon Security Hub CSPM provides a comprehensive view of your security state in Amazon. The service collects security data, called *findings*, from across Amazon Web Services accounts, services, and supported third-party products. Security Hub CSPM findings can help you check your

environment against security industry standards and best practices, analyze your security trends, and identify the highest priority security issues.

Security Hub CSPM sends findings to Amazon EventBridge, which uses an event rule to send the findings to Explorer. After you enable integration, as described here, you can view Security Hub CSPM findings in an Explorer widget and view finding details in OpsCenter OpsItems. The widget provides a summary of all Security Hub CSPM findings based on severity. New findings in Security Hub CSPM are usually visible in Explorer within seconds of being created.

Warning

Note the following important information:

- Explorer is integrated with OpsCenter. After you enable Explorer integration with Security Hub CSPM, OpsCenter automatically creates OpsItems for Security Hub CSPM findings. Depending on your Amazon environment, enabling integration can result in large numbers of OpsItems, at a cost.

  Before you continue, read about OpsCenter integration with Security Hub CSPM. The topic includes specific details about how changes and updates to findings and OpsItems are charged to your account. For more information, see Understanding OpsCenter integration with Amazon Security Hub CSPM. For OpsCenter pricing information, see Amazon Systems Manager Pricing.
- If you create a resource data sync in Explorer while logged into the administrator account, Security Hub CSPM integration is automatically enabled for the administrator and all member accounts in the sync. Once enabled, OpsCenter automatically creates OpsItems for Security Hub CSPM findings, at a cost. For more information about creating a resource data sync, see Setting up Systems Manager Explorer to display data from multiple accounts and Regions.

Types of findings that Explorer receives

Explorer receives all findings from Security Hub CSPM. You can see all findings based on severity in the Explorer widget when you turn on the Security Hub CSPM default settings. By default, Explorer creates OpsItems for Critical severity findings. You can manually configure Explorer to create OpsItems for other severity levels (High, Medium, and Low).

Though Explorer doesn't create OpsItems for informational findings, you can view informational operations data (OpsData) in the Security Hub CSPM findings summary widget. Explorer creates OpsData for all findings regardless of severity. For more information about Security Hub CSPM severity levels, see Severity in the *Amazon Security Hub API Reference*.

Enabling integration

This section describes how to enable and configure Explorer to start receiving Security Hub CSPM findings.

Before you begin

Complete the following tasks before you configure Explorer to start receiving Security Hub CSPM findings.

- Enable and configure Security Hub CSPM. For more information, see Setting up Security Hub CSPM in the *Amazon Security Hub User Guide*.
- Log in to the Amazon Organizations management account. Systems Manager requires access to Amazon Organizations to create OpsItems from Security Hub CSPM findings. After you log in to the management account, you can enable this access from the Explorer **Configure dashboard** tab, as described in the following procedure. If the **Enable access** button is not shown, trusted access is already enabled. If you don't log in to the Amazon Organizations management account, you can't allow access and Explorer can't create OpsItems from Security Hub CSPM findings.

> **Note**
>
> If your account isn't part of an organization in Amazon Organizations, you don't need to enable OpsData Sync trusted access. The management account requirement described in this section doesn't apply. Enable Amazon Security Hub CSPM in each Amazon Web Services Region where you want to receive findings, and then, on the Explorer **Configure dashboard** tab, turn on the **OpsItems created by Security Hub CSPM findings** toggle.

To start receiving Security Hub CSPM findings

1. (management account) Enable Amazon Security Hub CSPM in each Amazon Web Services Region where you want to receive findings. For more information, see Setting up Security Hub CSPM in the *Amazon Security Hub User Guide*.

2. (management account) Enable OpsData Sync trusted access for Amazon Organizations. You must enable trusted access before you can turn on the management account's own OpsData source in step 3. Steps 4 and 5, for member and delegated administrator accounts, don't depend on trusted access. Choose one of the following options:

   - In Explorer, on the **Configure dashboard** tab, under the **OpsItems created by Security Hub CSPM findings** section, choose the **Enable access** button.
   - Run the following command by using the Amazon CLI.

   ```
   aws organizations enable-aws-service-access --service-principal
    opsdatasync.ssm.amazonaws.com
   ```

   Note

   If you are signed in to the management account and the **Enable access** button is not shown, trusted access is already enabled. To confirm, run the following command.

   ```
   aws organizations list-aws-service-access-for-organization
   ```

   Note

   The **Enable access** alert also appears in the **Create resource data sync** wizard, a common entry point from the management account.

3. (management account, optional) Complete this step only if you also want findings from the management account itself. Turn on the **OpsItems created by Security Hub CSPM findings** toggle. By default, Explorer creates OpsItems for Critical severity findings, and you can configure it to create OpsItems for additional severity levels.
4. (Each member or delegated administrator account) Enable Amazon Security Hub CSPM in the relevant Amazon Web Services Region.
5. (Each member or delegated administrator account) Turn on the **OpsItems created by Security Hub CSPM findings** toggle. These accounts can complete this step at any time, with no dependency on step 2. If you create an organization-scoped resource data sync in Explorer from the management account (that is, a sync whose source is the entire organization or

specific organizational units), this OpsData source is enabled automatically for all member accounts in the sync.

How to view findings from Security Hub CSPM

The following procedure describes how to view Security Hub CSPM findings.

To view Security Hub CSPM findings

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Explorer**.
3. Find the **Amazon Security Hub CSPM findings summary** widget. This displays your Security Hub CSPM findings. You can select a severity level to view a detailed description of the corresponding OpsItem.

How to stop receiving findings

The following procedure describes how to stop receiving Security Hub CSPM findings.

To stop receiving Security Hub CSPM findings

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Explorer**.
3. Select **Settings**.
4. Select the **Configure dashboard** tab.
5. Select the **Enabled** slider to turn off **Amazon Security Hub CSPM**.

Important

If the option to disable Security Hub CSPM findings is grayed out in the console, you can disable this setting by running the following command in the Amazon CLI. You must run the command while logged into either the Amazon Organizations management account or the Systems Manager delegated administrator account. For the `region` parameter, specify the Amazon Web Services Region where you want to stop receiving Security Hub CSPM findings in Explorer.

```
aws ssm update-service-setting --setting-id /ssm/opsdata/SecurityHub --setting-
value Disabled --region Amazon Web Services Region
```

Here's an example.

```
aws ssm update-service-setting --setting-id /ssm/opsdata/SecurityHub --setting-
value Disabled --region us-east-1
```

Deleting a Systems Manager Explorer resource data sync

In Amazon Systems Manager Explorer, you can aggregate OpsData and OpsItems from other accounts and Regions by creating a resource data sync.

You can't change the account options for a resource data sync. For example, if you created a sync in the us-east-2 (Ohio) Region and you chose the **Include only the current account** option, you can't edit that sync later and choose the **Include all accounts from my Amazon Organizations configuration** option. Instead, you must delete the resource data sync, and create a new one, as described in the following procedure.

To delete a resource data sync

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Explorer**.
3. Choose **Settings**.
4. In the **Configure resource data sync** section, choose the resource data sync that you want to delete.
5. Choose **Delete**.

Exporting OpsData from Systems Manager Explorer

You can export 5,000 OpsData items as a comma separated value (.csv) file to an Amazon Simple Storage Service (Amazon S3) bucket from Amazon Systems Manager Explorer. Explorer uses the

AWS-ExportOpsDataToS3 automation runbook to export OpsData. When you export OpsData, the system displays the automation runbook page where you can specify details, such as assumeRole, Amazon S3 bucket name, SNS topic ARN, and fields to be exported.

To export OpsData:

- Step 1: Specifying an SNS topic
- Step 2: (Optional) Configuring data export
- Step 3: Exporting OpsData

Step 1: Specifying an SNS topic

When you configure data export, you must specify an Amazon Simple Notification Service (Amazon SNS) topic that exists in the same Amazon Web Services Region where you want to export the data. Systems Manager sends a notification to the Amazon SNS topic when an export is complete. For information about creating an Amazon SNS topic, see Creating an Amazon SNS topic.

Step 2: (Optional) Configuring data export

You can configure data export settings from the **Settings** or **Export Ops Data to S3 Bucket** page.

To configure data export from Explorer

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Explorer**.
3. Choose **Settings**.
4. In the **Configure data export** section, choose **Edit**.
5. To upload the data export file to an existing Amazon S3 bucket, choose **Select an existing S3 bucket** and choose the bucket from the list.

   To upload the data export file to a new Amazon S3 bucket, choose **Create a new S3 bucket** and enter the name that you want to use for the new bucket.

   > **Note**
   >
   > You can only edit the Amazon S3 bucket name and Amazon SNS topic ARN from the page where you configured those settings for the first time in Explorer. If you set up

the Amazon S3 bucket and the Amazon SNS topic ARN from the **Settings** page, then you can only modify those settings from the **Settings** page.

6. For **Select an Amazon SNS topic ARN**, choose the topic that you want to notify when the export is complete.
7. Choose **Create**.

Step 3: Exporting OpsData

When you export Explorer data, Systems Manager creates an Amazon Identity and Access Management (IAM) role named `AmazonSSMExplorerExportRole`. This role uses the following IAM policy.

JSON

```
{
      "Version":"2012-10-17",
      "Statement": [
          {
              "Sid": "OpsSummaryExportAutomationServiceRoleStatement1",
              "Effect": "Allow",
              "Action": [
                  "s3:PutObject"
              ],
              "Resource": [
                 "arn:aws-cn:s3:::amzn-s3-demo-bucket/*"
              ]
          },
          {
              "Sid": "OpsSummaryExportAutomationServiceRoleStatement2",
              "Effect": "Allow",
              "Action": [
                  "s3:GetBucketAcl",
                  "s3:GetBucketLocation"
              ],
              "Resource": [
                 "arn:aws-cn:s3:::amzn-s3-demo-bucket"
              ]
          },
          {
              "Sid": "OpsSummaryExportAutomationServiceRoleStatement3",
```

```
            "Effect": "Allow",
            "Action": [
                "sns:Publish"
            ],
            "Resource": [
                "arn:aws-cn:sns:us-east-1:111122223333:SNSTopicName"
            ]
        },
        {
            "Sid": "OpsSummaryExportAutomationServiceRoleStatement4",
            "Effect": "Allow",
            "Action": [
                "logs:DescribeLogGroups",
                "logs:DescribeLogStreams"
            ],
            "Resource": [
                "arn:aws-cn:logs:us-east-1:111122223333:log-group:MyLogGroup"
            ]
        },
        {
            "Sid": "OpsSummaryExportAutomationServiceRoleStatement5",
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogGroup",
                "logs:PutLogEvents",
                "logs:CreateLogStream"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Sid": "OpsSummaryExportAutomationServiceRoleStatement6",
            "Effect": "Allow",
            "Action": [
                "ssm:GetOpsSummary"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

The role includes the following trust entity.

JSON

```
{
      "Version":"2012-10-17",
      "Statement": [
        {
          "Sid": "OpsSummaryExportAutomationServiceRoleTrustPolicy",
          "Effect": "Allow",
          "Principal": {
            "Service": "ssm.amazonaws.com.cn"
          },
          "Action": "sts:AssumeRole"
        }
      ]
    }
```

To export OpsData from Explorer

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Explorer**.
3. Choose a data link in an Explorer widget. For example, choose **Unresolved** or **Open issues** in the **OpsItems by status** widget. Or choose the **Critical** or **High** data link in the **OpsItem by severity** widget. Explorer opens the **OpsData** page for the selected data set.
4. Choose **Export Table**.

> **Note**
>
> When you export OpsData for the first time, the system creates an assume role for the export. You can't modify the default assume role.

5. For **S3 Bucket Name**, choose an existing bucket. You can choose **Create** to create an Amazon S3 bucket if needed.

   If you can't change the S3 bucket name, it means that you configured the bucket name from the **Settings** page. You can only change the bucket name from the **Settings** page.

> **Note**
>
> You can only edit the Amazon S3 bucket name and Amazon SNS topic ARN from the page where you configured those settings for the first time in Explorer.

6. For **SNS Topic Arn**, choose an existing Amazon SNS topic ARN to notify when the download completes.

   If you can't change the Amazon SNS topic ARN, it means that you configured the Amazon SNS topic ARN from the **Settings** page. You can only change the topic ARN from the **Settings** page.

7. (Optional) For **SNS Success Message**, specify a success message that you want to display when the export is successfully completed.

8. Choose **Submit**. The system navigates to the previous page and displays the message **Click to view status of export process. View details**.

   You can choose **View details** to view the status of the runbook and progress in Systems Manager Automation.

You can now export OpsData from Explorer to the specified Amazon S3 bucket.

If you can't export data by using this procedure, verify that your user, group, or role includes the `iam:CreatePolicyVersion` and `iam:DeletePolicyVersion` actions. For information about adding these actions to your user, group, or role, see Editing IAM policies in the *IAM User Guide*.

Troubleshooting Systems Manager Explorer

This topic includes information about how to troubleshoot common problems with Amazon Systems Manager Explorer.

Resource data sync stopped working

If your resource data sync has stopped working for an *opt-in Amazon Web Services Region*, verify that the Region was opted into for both the Amazon Organizations management account and the member account for which the sync is configured.

Most Amazon Web Services Regions are active by default for your Amazon Web Services account, but certain Regions are activated only when you manually select them. These Regions are known as

opt-in Regions. By default, Explorer cross-account/cross-Region resource data syncs don't support data aggregation in opt-in Regions. Support was added for the following opt-in Regions on June 30, 2025.

- Europe (Milan)
- Africa (Cape Town)
- Middle East (Bahrain)
- Asia Pacific (Hong Kong)

Note that you can't use a delegated administrator account to create a resource data sync in opt-in Regions. You must use an Amazon Organizations management account.

Not able to filter Amazon resources in Explorer after updating tags on the Settings page

If you update tags keys or other data settings in Explorer, the system can take up to six hours to synchronize data based on your changes.

The Amazon Organizations options on the *Create resource data sync* page are greyed out

The **Include all accounts from my Amazon Organizations configuration** and **Select organization units in Amazon Organizations** options on the **Create resource data sync** page are only available if you set up and configured Amazon Organizations. If you set up and configured Amazon Organizations, then either the Amazon Organizations management account or an Explorer delegated administrator can create resource data syncs that use these options.

For more information, see Setting up Systems Manager Explorer to display data from multiple accounts and Regions and Configuring a delegated administrator for Explorer.

Explorer doesn't display any data at all

- Verify that you completed Integrated Setup in each account and Region where you want Explorer to access and display data. If you don't, Explorer won't display OpsData and OpsItems for those accounts and Regions in which you didn't complete Integrated Setup. For more information, see Getting started with Systems Manager Explorer and OpsCenter.
- When using Explorer to view data from multiple accounts and Regions, verify that you're logged into the Amazon Organizations management account or the Explorer delegated administrator account. To view OpsData and OpsItems from multiple accounts and Regions, you must be signed in to this account.

Widgets about Amazon EC2 instances don't display data

If widgets about Amazon Elastic Compute Cloud (Amazon EC2) instances, such as the **Instance count**, **Managed instances**, and **Instance by AMI** widgets don't display data, then verify the following:

- Verify that you waited several minutes. OpsData can take several minutes to display in Explorer after you completed Integrated Setup.
- Verify that you configured Amazon Config configuration recorder. Explorer uses data provided by Amazon Config configuration recorder to populate widgets with information about your EC2 instances. For more information, see Managing the Configuration Recorder.
- Verify that the **Amazon EC2** OpsData source is active on the **Settings** page. Also, verify that more than 6 hours have passed since you activated configuration recorder or since you made changes to your instances. Systems Manager can take up to six hours to display data from Amazon Config in Explorer EC2 widgets after you initially activated configuration recorder or make changes to your instances.
- Be aware that if an instance is either stopped or terminated, then Explorer stops showing those instances after 24 hours.
- Verify that you're in the correct Amazon Web Services Region where you configured your Amazon EC2 instances. Explorer doesn't display data about on-premises instances.
- If you configured a resource data sync for multiple accounts and Regions, verify that you're signed in to the Organizations management account or the Explorer delegated administator account.

Patch widget doesn't display data

The **Non-compliant instances for patching** widget only displays data about patch instances that aren't compliant. This widget displays no data if your instances are compliant. If you suspect that you have non-compliant instances, then verify that you set up and configured Systems Manager patching and use Amazon Systems Manager Patch Manager to check your patch compliance. For more information, see Amazon Systems Manager Patch Manager.

Miscellaneous issues

Explorer doesn't let you edit or remediate OpsItems: OpsItems viewed across accounts or Regions are read-only. They can only be updated and remediated from their home account or Region.

Amazon Systems Manager OpsCenter

OpsCenter provides a central location where operations engineers and IT professionals can view, investigate, and resolve operational work items (OpsItems) related to Amazon resources. OpsCenter is designed to reduce mean time to resolution for issues impacting Amazon resources. OpsCenter aggregates and standardizes OpsItems across services while providing contextual investigation data about each OpsItem, related OpsItems, and related resources. OpsCenter also provides Systems Manager Automation runbooks that you can use to quickly resolve issues. You can specify searchable, custom data for each OpsItem. You can also view automatically-generated summary reports about OpsItems by status and source. To get started with OpsCenter, open the Systems Manager console. In the navigation pane, choose **OpsCenter**.

OpsCenter is integrated with Amazon EventBridge and Amazon CloudWatch. This means you can configure these services to automatically create an OpsItem in OpsCenter when a CloudWatch alarm enters the `ALARM` state or when EventBridge processes an event from any Amazon service that publishes events. Configuring CloudWatch alarms and EventBridge events to automatically create OpsItems lets you quickly diagnose and remediate issues with Amazon resources from a single console.

To help you diagnose issues, each OpsItem includes contextually relevant information such as the name and ID of the Amazon resource that generated the OpsItem, alarm or event details, alarm history, and an alarm timeline graph.

For the Amazon resource, OpsCenter aggregates information from Amazon Config, Amazon CloudTrail logs, and Amazon CloudWatch Events, so you don't have to navigate across multiple console pages during your investigation.

The following list includes types of Amazon resources and metrics for which customers configure CloudWatch alarms that create OpsItems.

- Amazon DynamoDB: database read and write actions reach a threshold
- Amazon EC2: CPU utilization reaches a threshold
- Amazon billing: estimated charges reach a threshold
- Amazon EC2: an instance fails a status check
- Amazon Elastic Block Store (EBS): disk space utilization reaches a threshold

The following list includes types of EventBridge rules customer configure to create OpsItems.

- Amazon Security Hub CSPM: security alert issued
- DynamoDB: a throttling event
- Amazon EC2 Auto Scaling: failure to launch an instance
- Systems Manager: failure to run an automation
- Amazon Health: an alert for scheduled maintenance
- EC2: instance state change from `Running` to `Stopped`

OpsCenter is also integrated with Amazon CloudWatch Application Insights for .NET and SQL Server. This means you can automatically create OpsItems for problems detected in your applications. You can also integrate OpsCenter with Amazon Security Hub CSPM to aggregate and take action on your security, performance, and operational issues in Systems Manager.

Operations engineers and IT professionals can create, view, and edit OpsItems by using the OpsCenter page in the Amazon Systems Manager console, public API operations, the Amazon Command Line Interface (Amazon CLI), Amazon Tools for Windows PowerShell, or the Amazon SDKs. OpsCenter public API operations also lets you integrate OpsCenter with your case management systems and health dashboards.

How can OpsCenter benefit my organization?

OpsCenter provides a standard and unified experience for viewing, working on, and remediating issues related to Amazon resources. A standard and unified experience improves the time it takes to remedy issues, investigate related issues, and train new operations engineers and IT professionals. A standard and unified experience also reduces the number of manual errors entered into the system of managing and remediating issues.

More specifically, OpsCenter offers the following benefits for operations engineers and organizations:

- You no longer need to navigate across multiple console pages to view, investigate, and resolve OpsItems related to Amazon resources. OpsItems are aggregated, across services, in a central location.
- You can view service-specific and contextually relevant data for OpsItems that are automatically generated by CloudWatch alarms, EventBridge events, and CloudWatch Application Insights for .NET and SQL Server.

- You can specify the Amazon Resource Name (ARN) of a resource related to an OpsItem. By specifying related resources, OpsCenter uses built-in logic to help you avoid creating duplicate OpsItems.
- You can view details and resolution information about similar OpsItems.
- You can quickly view information about and run Systems Manager Automation runbooks to resolve issues.

What are the features of OpsCenter?

- **Automated and manual OpsItem creation**

  OpsCenter is integrated with Amazon CloudWatch. This means you can configure CloudWatch to automatically create an OpsItem in OpsCenter when an alarm enters the ALARM state or when Amazon EventBridge processes an event from any Amazon service that publishes events. You can also manually create OpsItems.

  OpsCenter is also integrated with Amazon CloudWatch Application Insights for .NET and SQL Server. This means you can automatically create OpsItems for problems detected in your applications.

- **Detailed and searchable OpsItems**

  Each OpsItem includes multiple fields of information, including a title, ID, priority, description, the source of the OpsItem, and the date/time it was last updated. Each OpsItem also includes the following configurable features:

  - **Status**: Open, In progress, Resolved, or Open and In progress.
  - **Related resources**: A related resource is the impacted resource or the resource that initiated the EventBridge event that created the OpsItem. Each OpsItem includes a **Related resources** section where OpsCenter automatically lists the Amazon Resource Name (ARN) of the related resource. You can also manually specify ARNs of related resources. For some ARN types, OpsCenter automatically creates a deep link that displays details about the resource without having to visit other console pages to view that information. For example, if you specify the ARN of an EC2 instance, you can view all of the EC2-provided details about that instance in OpsCenter. You can manually add the ARNs of additional related resources. Each OpsItem can list a maximum of 100 related resource ARNs. For more information, see Adding related resources to an OpsItem.

- **Related and Similar OpsItems**: With the **Related OpsItems** feature, you can specify the IDs of OpsItems that are in some way related to the current OpsItem. The **Similar OpsItem** feature automatically reviews OpsItem titles and descriptions and then lists other OpsItems that might be related or of interest to you.
- **Searchable and private operational data**: Operational data is custom data that provides useful reference details about the OpsItem. For example, you can specify log files, error strings, license keys, troubleshooting tips, or other relevant data. You enter operational data as key-value pairs. The key has a maximum length of 128 characters. The value has a maximum size of 20 KB.

  This custom data is searchable, but with restrictions. For the **Searchable operational data** feature, all users with access to the OpsItem Overview page (as provided by the DescribeOpsItems API operation) can view and search on the specified data. For the **Private operational data** feature, the data is only viewable by users who have access to the OpsItem (as provided by the GetOpsItem API operation).
- **Deduplication**: By specifying related resources, OpsCenter uses built-in logic to help you avoid creating duplicate OpsItems. OpsCenter also includes a feature called **Operational insights**, which displays information about duplicate OpsItems. To further limit the number of duplicate OpsItems in your account, you can manually specify a deduplication string for an EventBridge event rule. For more information, see Managing duplicate OpsItems.

- **Bulk edit OpsItems**: You can select multiple OpsItems in OpsCenter and edit one of the following fields: **Status**, **Priority**, **Severity**, **Category**.
- **Easy remediation using runbooks**

  Each OpsItem includes a **Runbooks** section with a list of Systems Manager Automation runbooks that you can use to automatically remediate common issues with Amazon resources. If you open an OpsItem, choose an Amazon resource for that OpsItem, and then choose the **Run automation** button in the console, then OpsCenter provides a list of Automation runbooks that you can run on the Amazon resource that generated the OpsItem. After you run an Automation runbook from an OpsItem, the runbook is automatically associated with the related resource of the OpsItem for future reference. Additionally, if you automatically set up OpsItem rules in EventBridge by using OpsCenter, then EventBridge automatically associates runbooks for common events. OpsCenter keeps a 30-day record of Automation runbooks run for a specific OpsItem. For more information, see Remediate OpsItem issues.

- **Change notification**: You can specify the ARN of an Amazon Simple Notification Service (SNS) topic and publish notifications anytime an OpsItem is changed or edited. The SNS topic must exist in the same Amazon Web Services Region as the OpsItem.
- **Comprehensive OpsItem search capabilities**: OpsCenter provides multiple search options to help you quickly locate OpsItems. Here are several examples of how you can search: OpsItem ID, Title, Last modified time, Operational data value, Source, and Automation ID of a runbook execution, to name a few. You can further limit search results by using status filters.
- **OpsItem summary reports**

  OpsCenter includes a summary report page that automatically displays the following sections:

  - **Status summary**: a summary of OpsItems by status (Open, In progress, Resolved, Open and In progress).
  - **Sources with most open OpsItems**: a breakdown of the top Amazon services with open OpsItems.
  - **OpsItems by source and age**: a count of OpsItems grouped by source and days since creation.

  For more information about viewing OpsCenter summary reports, see Viewing OpsCenter summary reports.
- **Logging and auditing capability support**

  You can audit and log OpsCenter user actions in your Amazon Web Services account through integration with other Amazon services. For more information, see Viewing OpsCenter logs and reports.
- **Console, CLI, PowerShell, and SDK access to OpsCenter tool**

  You can work with OpsCenter by using the Amazon Systems Manager console, Amazon Command Line Interface (Amazon CLI), Amazon Tools for PowerShell, or the Amazon SDK of your choice.

Does OpsCenter integrate with my existing case management system?

OpsCenter is designed to complement your existing case management systems. You can integrate OpsItems into your existing case management system by using public API operations. You can also maintain manual lifecycle workflows in your current systems and use OpsCenter as an investigation and remediation hub.

For information about OpsCenter public API operations, see the following API operations in the *Amazon Systems Manager API Reference*.

- CreateOpsItem
- DescribeOpsItems
- GetOpsItem
- GetOpsSummary
- UpdateOpsItem

Is there a charge to use OpsCenter?

Yes. For more information, see Amazon Systems Manager Pricing.

Does OpsCenter work with my on-premises and hybrid managed nodes?

Yes. You can use OpsCenter to investigate and remediate issues with your on-premises managed nodes that are configured for Systems Manager. For more information about setting up and configuring on-premises servers and virtual machines for Systems Manager, see Managing nodes in hybrid and multicloud environments with Systems Manager.

What are the quotas for OpsCenter?

You can view quotas for all Systems Manager tools in the Systems Manager service quotas in the *Amazon Web Services General Reference*. Unless otherwise noted, each quota is Region-specific.

Set up OpsCenter

Amazon Systems Manager uses an integrated setup experience to help you get started with OpsCenter and Explorer, which are tools in Systems Manager. Explorer is a customizable operations dashboard that reports information about your Amazon resources. In this documentation, Explorer and OpsCenter setup is called *Integrated Setup*.

You must use Integrated Setup to set up OpsCenter with Explorer. Integrated Setup is only available in the Amazon Systems Manager console. You can't set up Explorer and OpsCenter programmatically. For more information, see Getting started with Systems Manager Explorer and OpsCenter.

Before you begin

When you set up OpsCenter, you enable default rules in Amazon EventBridge that automatically create OpsItems. The following table describes the default EventBridge rules that automatically create OpsItems. You can disable EventBridge rules in the OpsCenter **Settings** page under **OpsItem rules**.

> **Important**
>
> Your account is charged for OpsItems created by default rules. For more information, see Amazon Systems Manager Pricing.

Rule name	Description
SSMOpsItems-Autoscaling-instance-launch-failure	This rule creates OpsItems when the launch of an EC2 auto scaling instance failed.
SSMOpsItems-Autoscaling-instance-termination-failure	This rule creates OpsItems when the termination of an EC2 auto scaling instance failed.
SSMOpsItems-EBS-snapshot-copy-failed	This rule creates OpsItems when the system failed to copy an Amazon Elastic Block Store (Amazon EBS) snapshot.
SSMOpsItems-EBS-snapshot-creation-failed	This rule creates OpsItems when the system failed to create an Amazon EBS snapshot.
SSMOpsItems-EBS-volume-performance-issue	This rule corresponds to an Amazon Health tracking rule. The rule creates OpsItems whenever there is a performance issue with an Amazon EBS volume (health event = `AWS_EBS_DEGRADED_EBS_VOLUME_PERFORMANCE`).
SSMOpsItems-EC2-issue	This rule corresponds to an Amazon Health tracking rule for unexpected events that affect Amazon services or resources. The rule creates OpsItems when, for example, a service sends communications about operational issues that

Rule name	Description
	are causing service degradation or to raise awarness about localized resource-level issues. For example, this rule creates an OpsItem for the following event: `AWS_EC2_OPERATIONAL_ISSUE` .
SSMOpsItems-EC2-scheduled-change	This rule corresponds to an Amazon Health tracking rule. Amazon can schedule events for your instances, such as rebooting, stopping, or starting instances. The rule creates OpsItems for EC2 scheduled events. For more informati on about scheduled events, see Scheduled events for your instances in the *Amazon EC2 User Guide*.
SSMOpsItems-RDS-issue	This rule corresponds to an Amazon Health tracking rule for unexpected events that affect Amazon services or resources. The rule creates OpsItems when, for example, a service sends communications about operational issues that are causing service degradation or to raise awarness about localized resource-level issues. For example, this rule creates an OpsItem for the following events: `AWS_RDS_MYSQL_DATABASE_CRASHING_REPEATEDLY` , `AWS_RDS_EXPORT_TASK_FAILED` , and `AWS_RDS_CONNECTIVITY_ISSUE` .

Rule name	Description
SSMOpsItems-RDS-scheduled-change	This rule corresponds to an Amazon Health tracking rule. The rule creates OpsItems for Amazon RDS scheduled events. Scheduled events provide information about upcoming changes to your Amazon RDS resources. Some events might recommend that you take action to avoid service disruptions. Other events occur automatically without any action on your part. Your resource might be temporarily unavailable during the scheduled change activity. For example, this rule creates an OpsItem for the following events: `AWS_RDS_SYSTEM_UPGRADE_SCHEDULED` and `AWS_RDS_MAINTENANCE_SCHEDULED`. For more information about scheduled events, see Event type categories in the *Amazon Health User Guide*.
SSMOpsItems-SSM-maintenance-window-execution-failed	This rule creates OpsItems when the processing of the Systems Manager maintenance window failed.
SSMOpsItems-SSM-maintenance-window-execution-timedout	This rule creates OpsItems when the launch of the Systems Manager maintenance window timed out.

Use the following procedure to set up OpsCenter.

To set up OpsCenter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. On the OpsCenter home page, choose **Get started**.

4. On the OpsCenter setup page, choose **Enable this option to have Explorer configure Amazon Config and Amazon CloudWatch events to automatically create OpsItems based on commonly-used rules and events**. If you don't choose this option, OpsCenter remains disabled.

   > **Note**
   >
   > Amazon EventBridge (formerly Amazon CloudWatch Events) provides all functionality of CloudWatch Events and some new features, such as custom event buses, third-party event sources and schema registry.

5. Choose **Enable OpsCenter**.

After you enable OpsCenter, you can do the following from **Settings**:

- Create CloudWatch alarms using the **Open CloudWatch console** button. For more information, see Configure CloudWatch alarms to create OpsItems.
- Enable operational insights. For more information, see Analyzing operational insights to reduce OpsItems.
- Enable Amazon Security Hub CSPM findings alarms. For more information, see Understanding OpsCenter integration with Amazon Security Hub CSPM.

Contents

- (Optional) Setting up OpsCenter to centrally manage OpsItems across accounts
- (Optional) Set up Amazon SNS to receive notifications about OpsItems

(Optional) Setting up OpsCenter to centrally manage OpsItems across accounts

You can use Systems Manager OpsCenter to centrally manage OpsItems across multiple Amazon Web Services accounts in a selected Amazon Web Services Region. This feature is available after you set up your organization in Amazon Organizations. Amazon Organizations is an account management service that lets you consolidate multiple Amazon accounts into an organization that you create and centrally manage. Amazon Organizations includes account management and consolidated billing capabilities that enable you to better meet the budgetary, security, and compliance needs of your business. For more information, see What is Amazon Organizations? in the *Amazon Organizations User Guide*

Users who belong to the Amazon Organizations management account can set up a delegated administrator account for Systems Manager. In the context of OpsCenter, delegated administrators can create, edit, and view OpsItems in member accounts. The delegated administrator can also use Systems Manager Automation runbooks to bulk resolve OpsItems or remediate issues with Amazon resources that are generating OpsItems.

> **Note**
>
> You can assign only one account as the delegated administrator for Systems Manager. For more information, see Creating an Amazon Organizations delegated administrator for Systems Manager.

Systems Manager offers the following methods for setting up OpsCenter to centrally manage OpsItems across multiple Amazon Web Services accounts.

- **Quick Setup**: Quick Setup, a tool in Systems Manager, simplifies set up and configuration tasks for Systems Manager tools. For more information, see Amazon Systems Manager Quick Setup.

  Quick Setup for OpsCenter helps you complete the following tasks for managing OpsItems across accounts:

  - Registering an account as the delegated administrator (if the delegated administrator hasn't already been designated)
  - Creating required Amazon Identity and Access Management (IAM) policies and roles
  - Specifying an Amazon Organizations organization or organizational units (OUs) where a delegated administrator can manage OpsItems across accounts

  For more information, see (Optional) Configure OpsCenter to manage OpsItems across accounts by using Quick Setup.

  > **Note**
  >
  > Quick Setup isn't available in all Amazon Web Services Regions where Systems Manager is currently available. If Quick Setup isn't available in a Region where you want to use it to configure OpsCenter to centrally manage OpsItems across multiple accounts, then you must use the manual method. To view a list of Amazon Web Services Regions where Quick Setup is available, see Availability of Quick Setup in Amazon Web Services Regions.

- **Manual set up**: If Quick Setup isn't available in the Region where you want to configure OpsCenter to centrally manage OpsItems across accounts, then you can use the manual procedure to do so. For more information, see [(Optional) Manually set up OpsCenter to centrally manage OpsItems across accounts].

(Optional) Configure OpsCenter to manage OpsItems across accounts by using Quick Setup

Quick Setup simplifies setup and configuration tasks for Systems Manager tools. Quick Setup for OpsCenter helps you complete the following tasks for managing OpsItems across accounts:

- Specifying the delegated administrator account
- Creating required Amazon Identity and Access Management (IAM) policies and roles
- Specifying an Amazon Organizations organization, or a subset of member accounts, where a delegated administrator can manage OpsItems across accounts

When you configure OpsCenter to manage OpsItems across accounts by using Quick Setup, Quick Setup creates the following resources in the specified accounts. These resources give the specified accounts permission to work with OpsItems and use Automation runbooks to fix issues with Amazon resources generating OpsItems.

Resources	Accounts
`AWSServiceRoleForAmazonSSM_AccountDiscovery` Amazon Identity and Access Management (IAM) service-linked role For more information about this role, see [Using roles to collect Amazon Web Services account information for OpsCenter and Explorer].	Amazon Organizations management account and delegated administrator account
`OpsItem-CrossAccountManagementRole` IAM role `AWS-SystemsManager-AutomationAdministrationRole` IAM role	Delegated administrator account

Resources	Accounts
`OpsItem-CrossAccountExecutionRole` IAM role `AWS-SystemsManager-AutomationExecutionRole` IAM role `AWS::SSM::ResourcePolicy` Systems Manager resource policy for the default OpsItem group (`OpsItemGroup`)	All Amazon Organizations member accounts

> **Note**
>
> If you previously configured OpsCenter to manage OpsItems across accounts using the manual method, you must delete the Amazon CloudFormation stacks or stack sets created during Steps 4 and 5 of that process. If those resources exist in your account when you complete the following procedure, Quick Setup fails to configure cross-account OpsItem management properly.

To configure OpsCenter to manage OpsItems across accounts by using Quick Setup

1. Sign in to the Amazon Web Services Management Console using the Amazon Organizations management account.
2. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
3. In the navigation pane, choose **Quick Setup**.
4. Choose the **Library** tab.
5. Scroll to the bottom and locate the **OpsCenter** configuration tile. Choose **Create**.
6. On the Quick Setup OpsCenter page, in the **Delegated administrator** section, enter an account ID. If you are unable to edit this field, then a delegated administrator account has already been specified for Systems Manager.
7. In the **Targets** section, choose an option. If you choose **Custom**, then select the organizational units (OU) where you want to manage OpsItems across accounts.

8. Choose **Create**.

Quick Setup creates the OpsCenter configuration and deploys the required Amazon resources to the designated OUs.

> **Note**
>
> If you don't want to manage OpsItems across multiple accounts, you can delete the configuration from Quick Setup. When you delete the configuration, Quick Setup deletes the following IAM policies and roles created when the configuration was originally deployed:
>
> - `OpsItem-CrossAccountManagementRole` from the delegated administrator account
> - `OpsItem-CrossAccountExecutionRole` and `SSM::ResourcePolicy` from all Organizations member accounts
>
> Quick Setup removes the configuration from all organizational units and Amazon Web Services Regions where the configuration was originally deployed.

Troubleshooting issues with a Quick Setup configuration for OpsCenter

This section includes information to help you troubleshoot issues when configuring cross-account OpsItem management using Quick Setup.

Topics

- Deployment to these StackSets failed: delegatedAdmin
- Quick Setup configuration status shows Failed

Deployment to these StackSets failed: delegatedAdmin

When creating an OpsCenter configuration, Quick Setup deploys two Amazon CloudFormation stack sets in the Organizations management account. The stack sets use the following prefix: `AWS-QuickSetup-SSMOpsCenter`. If Quick Setup displays the following error: `Deployment to these StackSets failed: delegatedAdmin` use the following procedure to fix this issue.

To troubleshoot a StackSets failed:delegatedAdmin error

1. If you received the `Deployment to these StackSets failed: delegatedAdmin` error in a red banner in the Quick Setup console, sign in to the delegated administrator account and the Amazon Web Services Region designated as the Quick Setup home Region.
2. Open the Amazon CloudFormation console at https://console.amazonaws.cn/cloudformation.
3. Choose the stack created by your Quick Setup configuration. The stack name includes the following: **AWS-QuickSetup-SSMOpsCenter**.

   > **Note**
   >
   > Sometimes CloudFormation deletes failed stack deployments. If the stack isn't available in the **Stacks** table, choose **Deleted** from the filter list.

4. View the **Status** and **Status reason**. For more information about stack statuses, see Stack status codes in the *Amazon CloudFormation User Guide*.
5. To understand the exact step that failed, view the **Events** tab and review each event's **Status**. For more information, see Troubleshooting in the *Amazon CloudFormation User Guide*.

> **Note**
>
> If you are unable to resolve the deployment failure using the CloudFormation troubleshooting steps, delete the configuration and try again.

Quick Setup configuration status shows Failed

If the **Configuration details** table on the **Configuration details** page shows a configuration status of `Failed`, sign in to the Amazon Web Services account and Region where it failed.

To troubleshoot a Quick Setup failure to create an OpsCenter configuration

1. Sign in to the Amazon Web Services account and the Amazon Web Services Region where the failure occurred.
2. Open the Amazon CloudFormation console at https://console.amazonaws.cn/cloudformation.
3. Choose the stack created by your Quick Setup configuration. The stack name includes the following: **AWS-QuickSetup-SSMOpsCenter**.

> **Note**
>
> Sometimes CloudFormation deletes failed stack deployments. If the stack isn't available in the **Stacks** table, choose **Deleted** from the filter list.

4. View the **Status** and **Status reason**. For more information about stack statuses, see Stack status codes in the *Amazon CloudFormation User Guide*.
5. To understand the exact step that failed, view the **Events** tab and review each event's **Status**. For more information, see Troubleshooting in the *Amazon CloudFormation User Guide*.

Member account configuration shows ResourcePolicyLimitExceededException

If a stack status shows `ResourcePolicyLimitExceededException`, the account has previously onboarded to OpsCenter cross-account management by using the manual method. To resolve this issue, you must delete the Amazon CloudFormation stacks or stack sets created during Steps 4 and 5 of the manual onboarding process. For more information, see Delete a stack set and Deleting a stack on the Amazon CloudFormation console in the *Amazon CloudFormation User Guide*.

(Optional) Manually set up OpsCenter to centrally manage OpsItems across accounts

This section describes how to manually configure OpsCenter for cross-account OpsItem management. While this process is still supported, it has been replaced by a newer process that uses Systems Manager Quick Setup. For more information, see (Optional) Configure OpsCenter to manage OpsItems across accounts by using Quick Setup.

You can set up a central account to create manual OpsItems for member accounts, and manage and remediate those OpsItems. The central account can be the Amazon Organizations management account, or both the Amazon Organizations management account and Systems Manager delegated administrator account. We recommend that you use the Systems Manager delegated administrator account as a central account. You can only use this feature after you configure Amazon Organizations.

With Amazon Organizations, you can consolidate multiple Amazon Web Services accounts into an organization that you create and manage centrally. The central account user can create OpsItems for all selected member accounts simultaneously, and manage those OpsItems.

Use the process in this section to enable the Systems Manager service principal in Organizations and configure Amazon Identity and Access Management (IAM) permissions for working with OpsItems across accounts.

Topics

- Before you begin
- Step 1: Creating a resource data sync
- Step 2: Enabling the Systems Manager service principal in Amazon Organizations
- Step 3: Creating the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role
- Step 4: Configuring permissions to work with OpsItems across accounts
- Step 5: Configuring permissions to work with related resources across accounts

> **Note**
>
> Only OpsItems of type `/aws/issue` are supported when working in OpsCenter across accounts.

Before you begin

Before you set up OpsCenter to work with OpsItems across accounts, make sure that you have set up the following:

- A Systems Manager delegated administrator account. For more information, see Configuring a delegated administrator for Explorer.
- One organization set up and configured in Organizations. For more information, see Creating and managing an organization in the *Amazon Organizations User Guide*.
- You configured Systems Manager Automation to run automation runbooks across multiple Amazon Web Services Regions and Amazon accounts. For more information, see Running automations in multiple Amazon Web Services Regions and accounts.

Step 1: Creating a resource data sync

After you set up and configure Amazon Organizations, you can aggregate OpsItems in OpsCenter for an entire organization by creating a resource data sync. For more information, see Creating a

resource data sync. When you create the sync, in the **Add accounts** section, be sure to choose the **Include all accounts from my Amazon Organizations configuration** option.

Step 2: Enabling the Systems Manager service principal in Amazon Organizations

To enable a user to work with OpsItems across accounts, the Systems Manager service principal must be enabled in Amazon Organizations. If you previously configured Systems Manager for multi-account scenarios using other tools, the Systems Manager service principal might already be configured in Organizations. Run the following commands from the Amazon Command Line Interface (Amazon CLI) to verify. If you *haven't* configured Systems Manager for other multi-account scenarios, skip to the next procedure, *To enable the Systems Manager service principal in Amazon Organizations*.

To verify the Systems Manager service principal is enabled in Amazon Organizations

1. Download the latest version of the Amazon CLI to your local machine.
2. Open the Amazon CLI, and run the following command to specify your credentials and an Amazon Web Services Region.

   ```
   aws configure
   ```

   The system prompts you to specify the following. In the following example, replace each *`user input placeholder`* with your own information.

   ```
   AWS Access Key ID [None]: key_name
   AWS Secret Access Key [None]: key_name
   Default region name [None]: region
   Default output format [None]: ENTER
   ```

3. Run the following command to verify that the Systems Manager service principal is enabled for Amazon Organizations.

   ```
   aws organizations list-aws-service-access-for-organization
   ```

   The command returns information similar to that shown in the following example.

   ```
   {
       "EnabledServicePrincipals": [
           {
   ```

```
            "ServicePrincipal":
 "member.org.stacksets.cloudformation.amazonaws.com",
            "DateEnabled": "2020-12-11T16:32:27.732000-08:00"
        },
        {
            "ServicePrincipal": "opsdatasync.ssm.amazonaws.com",
            "DateEnabled": "2022-01-19T12:30:48.352000-08:00"
        },
        {
            "ServicePrincipal": "ssm.amazonaws.com",
            "DateEnabled": "2020-12-11T16:32:26.599000-08:00"
        }
    ]
}
```

To enable the Systems Manager service principal in Amazon Organizations

If you haven't previously configured the Systems Manager service principal for Organizations, use the following procedure to do so. For more information about this command, see enable-aws-service-access in the *Amazon CLI Command Reference*.

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already. For information, see Installing CLI and Configuring CLI.
2. Download the latest version of the Amazon CLI to your local machine.
3. Open the Amazon CLI, and run the following command to specify your credentials and an Amazon Web Services Region.

   ```
   aws configure
   ```

   The system prompts you to specify the following. In the following example, replace each *user input placeholder* with your own information.

   ```
   AWS Access Key ID [None]: key_name
   AWS Secret Access Key [None]: key_name
   Default region name [None]: region
   Default output format [None]: ENTER
   ```

4. Run the following command to enable the Systems Manager service principal for Amazon Organizations.

```
aws organizations enable-aws-service-access --service-principal
 "ssm.amazonaws.com.cn"
```

Step 3: Creating the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role

A service-linked role such as the AWSServiceRoleForAmazonSSM_AccountDiscovery role is a unique type of IAM role that is linked directly to an Amazon Web Services service, such as Systems Manager. Service-linked roles are predefined by the service and include all the permissions that the service requires to call other Amazon Web Services services on your behalf. For more information about the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role, see Service-linked role permissions for Systems Manager account discovery.

Use the following procedure to create the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role by using the Amazon CLI. For more information about the command used in this procedure, see create-service-linked-role in the *Amazon CLI Command Reference.*

To create the AWSServiceRoleForAmazonSSM_AccountDiscovery service-linked role

1. Sign in to the Amazon Organizations management account.
2. While signed in to the Organizations management account, run the following command.

```
aws iam create-service-linked-role \
    --aws-service-name accountdiscovery.ssm.amazonaws.com.cn \
    --description "Systems Manager account discovery for Amazon Organizations
 service-linked role"
```

Step 4: Configuring permissions to work with OpsItems across accounts

Use Amazon CloudFormation stacksets to create an OpsItemGroup resource policy and an IAM execution role that give users permission to work with OpsItems across accounts. To get started, download and unzip the OpsCenterCrossAccountMembers.zip file. This file contains the OpsCenterCrossAccountMembers.yaml Amazon CloudFormation template file. When you create a stack set by using this template, CloudFormation automatically creates the OpsItemCrossAccountResourcePolicy resource policy and the OpsItemCrossAccountExecutionRole execution role in the account. For more information about creating a stack set, see Create a stack set in the *Amazon CloudFormation User Guide*.

Important

Note the following important information about this task:

- You must deploy the stackset while signed in to the Amazon Organizations management account.
- You must repeat this procedure while signed in to *every* account that you want to *target* for working with OpsItems across accounts, including the delegated administrator account.
- If you want to enable cross-account OpsItems administration in different Amazon Web Services Regions, choose **Add all regions** in the **Specify regions** section of the template. Cross-account OpsItem administration isn't supported for opt-in Regions.

Step 5: Configuring permissions to work with related resources across accounts

An OpsItem can include detailed information about impacted resources such as Amazon Elastic Compute Cloud (Amazon EC2) instances or Amazon Simple Storage Service (Amazon S3) buckets. The `OpsItemCrossAccountExecutionRole` execution role, which you created in the previous Step 4, provides OpsCenter with read-only permissions for member accounts to view related resources. You must also create an IAM role to provide management accounts with permission to view and interact with related resources, which you complete in this task.

To get started, download and unzip the `OpsCenterCrossAccountManagementRole.zip` file. This file contains the `OpsCenterCrossAccountManagementRole.yaml` Amazon CloudFormation template file. When you create a stack by using this template, CloudFormation automatically creates the `OpsCenterCrossAccountManagementRole` IAM role in the account. For more information about creating a stack, see Creating a stack on the Amazon CloudFormation console in the *Amazon CloudFormation User Guide*.

Important

Note the following important information about this task:

- If you plan to specify an account as a delegated administrator for OpsCenter, be sure to specify that Amazon Web Services account when you create the stack.

- You must perform this procedure while signed in to the Amazon Organizations management account and again while signed in to the delegated administrator account.

(Optional) Set up Amazon SNS to receive notifications about OpsItems

You can configure OpsCenter to send notifications to an Amazon Simple Notification Service (Amazon SNS) topic when the system creates an OpsItem or updates an existing OpsItem.

Complete the following steps to receive notifications for OpsItems.

- Step 1: Creating and subscribing to an Amazon SNS topic
- Step 2: Updating the Amazon SNS access policy
- Step 3: Updating the Amazon KMS access policy

> **Note**
>
> If you turn on Amazon Key Management Service (Amazon KMS) server-side encryption in Step 2, then you must complete Step 3. Otherwise, you can skip Step 3.

- Step 4: Turning on default OpsItems rules to send notifications for new OpsItems

Step 1: Creating and subscribing to an Amazon SNS topic

To receive notifications, you must create and subscribe to an Amazon SNS topic. For more information, see Creating an Amazon SNS topic and Subscribing to an Amazon SNS topic in the *Amazon Simple Notification Service Developer Guide*.

> **Note**
>
> If you're using OpsCenter in multiple Amazon Web Services Regions or accounts, you must create and subscribe to an Amazon SNS topic in *each* Region or account where you want to receive OpsItem notifications.

Step 2: Updating the Amazon SNS access policy

You have to associate an Amazon SNS topic with OpsItems. Use the following procedure to set up an Amazon SNS access policy so that Systems Manager can publish OpsItems notifications to the Amazon SNS topic that you created in Step 1.

1. Sign in to the Amazon Web Services Management Console and open the Amazon SNS console at https://console.amazonaws.cn/sns/v3/home.
2. In the navigation pane, choose **Topics**.
3. Choose the topic that you created in Step 1, and then choose **Edit**.
4. Expand **Access policy**.
5. Add the following `Sid` block to the existing policy. Replace each *`example resource placeholder`* with your own information.

```
{
      "Sid": "Allow OpsCenter to publish to this topic",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com.cn"
      },
      "Action": "SNS:Publish",
      "Resource": "arn:aws-cn:sns:region:account ID:topic name", // Account ID of
 the SNS topic owner
      "Condition": {
      "StringEquals": {
        "AWS:SourceAccount": "account ID" //  Account ID of the OpsItem owner
      }
   }
}
```

> **Note**
>
> The `aws:SourceAccount` global condition key protects against the confused deputy scenario. To use this condition key, set the value to the account ID of the OpsItem owner. For more information, see Confused Deputy in the *IAM User Guide*.

6. Choose **Save changes**.

The system now sends notifications to the Amazon SNS topic when OpsItems are created or updated.

> **Important**
>
> If you configure the Amazon SNS topic with an Amazon Key Management Service (Amazon KMS) server-side encryption key in the Step 2, then complete Step 3. Otherwise, you can skip Step 3.

Step 3: Updating the Amazon KMS access policy

If you turned on Amazon KMS server-side encryption for your Amazon SNS topic, you must also update the access policy of the Amazon KMS key that you chose when you configured the topic. Use the following procedure to update the access policy so that Systems Manager can publish OpsItem notifications to the Amazon SNS topic you created in Step 1.

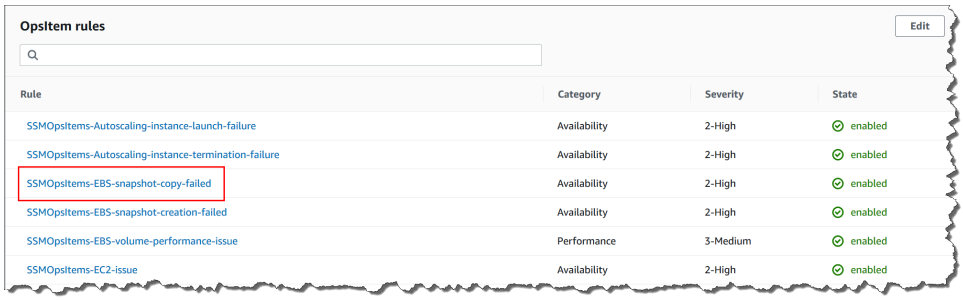
> **Note**
>
> OpsCenter doesn't support publishing OpsItems to an Amazon SNS topic that is configured with an Amazon managed key.

1. Open the Amazon KMS console at https://console.amazonaws.cn/kms.
2. To change the Amazon Web Services Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Choose the ID of the KMS key that you chose when you created the topic.
5. In the **Key policy** section, choose **Switch to policy view**.
6. Choose **Edit**.
7. Add the following `Sid` block to the existing policy. Replace each *`example resource placeholder`* with your own information.

```
{
      "Sid": "Allow OpsItems to decrypt the key",
      "Effect": "Allow",
      "Principal": {
        "Service": "ssm.amazonaws.com.cn"
```

```
      },
      "Action": ["kms:Decrypt", "kms:GenerateDataKey*"],
       "Resource": "arn:aws-cn:kms:region:account ID:key/key ID"
    }
```

In the following example, the new block is entered at line 14.



8. Choose **Save changes**.

Step 4: Turning on default OpsItems rules to send notifications for new OpsItems

Default OpsItems rules in Amazon EventBridge aren't configured with an Amazon Resource Name (ARN) for Amazon SNS notifications. Use the following procedure to edit a rule in EventBridge and enter a `notifications` block.

To add a notifications block to a default OpsItem rule

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose the **OpsItems** tab, and then choose **Configure sources**.
4. Choose the name of the source rule that you want to configure with a `notifications` block, as shown in the following example.

The rule opens in Amazon EventBridge.

5. On the rule details page, on the **Targets** tab, choose **Edit**.
6. In the **Additional settings** section, choose **Configure input transformer**.
7. In the **Template** box, add a `notifications` block in the following format.

```
"notifications":[{"arn":"arn:aws-cn:sns:region:account ID:topic name"}],
```

Here's an example.

```
"notifications":[{"arn":"arn:aws:sns:us-west-2:1234567890:MySNSTopic"}],
```

Enter the notifications block before the `resources` block, as shown in the following example for the US West (Oregon) (us-west-2) Region.

```
{
    "title": "EBS snapshot copy failed",
    "description": "CloudWatch Event Rule SSMOpsItems-EBS-snapshot-copy-failed was
 triggered. Your EBS snapshot copy has failed. See below for more details.",
    "category": "Availability",
    "severity": "2",
    "source": "EC2",
    "notifications": [{
        "arn": "arn:aws:sns:us-west-2:1234567890:MySNSTopic"
    }],
    "resources": <resources>,
    "operationalData": {
        "/aws/dedup": {
            "type": "SearchableString",
            "value": "{\"dedupString\":\"SSMOpsItems-EBS-snapshot-copy-failed\"}"
        },
        "/aws/automations": {
            "value": "[ { \"automationType\": \"AWS:SSM:Automation\",
 \"automationId\": \"AWS-CopySnapshot\" } ]"
        },
        "failure-cause": {
            "value": <failure - cause>
        },
        "source": {
            "value": <source>
        },
```

```
        "start-time": {
            "value": <start - time>
        },
        "end-time": {
            "value": <end - time>
        }
    }
}
```

8. Choose **Confirm**.
9. Choose **Next**.
10. Choose **Next**.
11. Choose **Update rule**.

The next time that the system creates an OpsItem for the default rule, it publishes a notification to the Amazon SNS topic.

Integrate OpsCenter with other Amazon Web Services services

OpsCenter integrates with multiple Amazon Web Services services to diagnose and remediate issues with Amazon resources. You must set up the Amazon Web Services service before you integrate it with OpsCenter.

By default, the following Amazon Web Services services are integrated with OpsCenter and can create OpsItems automatically:

- Amazon CloudWatch
- Amazon CloudWatch Application Insights
- Amazon EventBridge
- Amazon Config
- Amazon Systems Manager Incident Manager

You have to integrate the following services with OpsCenter to create OpsItems automatically:

- Amazon DevOps Guru
- Amazon Security Hub CSPM

When any of these services create an OpsItem, you can manage and remediate the OpsItem from OpsCenter. For more information, see Manage OpsItems and Remediate OpsItem issues.

For more information about each Amazon Web Services service and how it integrates with OpsCenter, see the following topics.

Topics

- Understanding OpsCenter integration with Amazon CloudWatch
- Understanding OpsCenter integration with Amazon CloudWatch Application Insights
- Understanding OpsCenter integration with Amazon DevOps Guru
- Understanding OpsCenter integration with Amazon EventBridge
- Understanding OpsCenter integration with Amazon Config
- Understanding OpsCenter integration with Amazon Security Hub CSPM
- Understanding OpsCenter integration with Incident Manager

Understanding OpsCenter integration with Amazon CloudWatch

Amazon CloudWatch monitors your Amazon resources and services, and displays metrics on every Amazon Web Services service that you use. CloudWatch creates an OpsItem when an alarm enters the alarm state. For example, you can configure an alarm to automatically create an OpsItem if there is a spike in HTTP errors generated by your Application Load Balancer.

Some alarms that you can configure in CloudWatch to create OpsItems are shown in the following list:

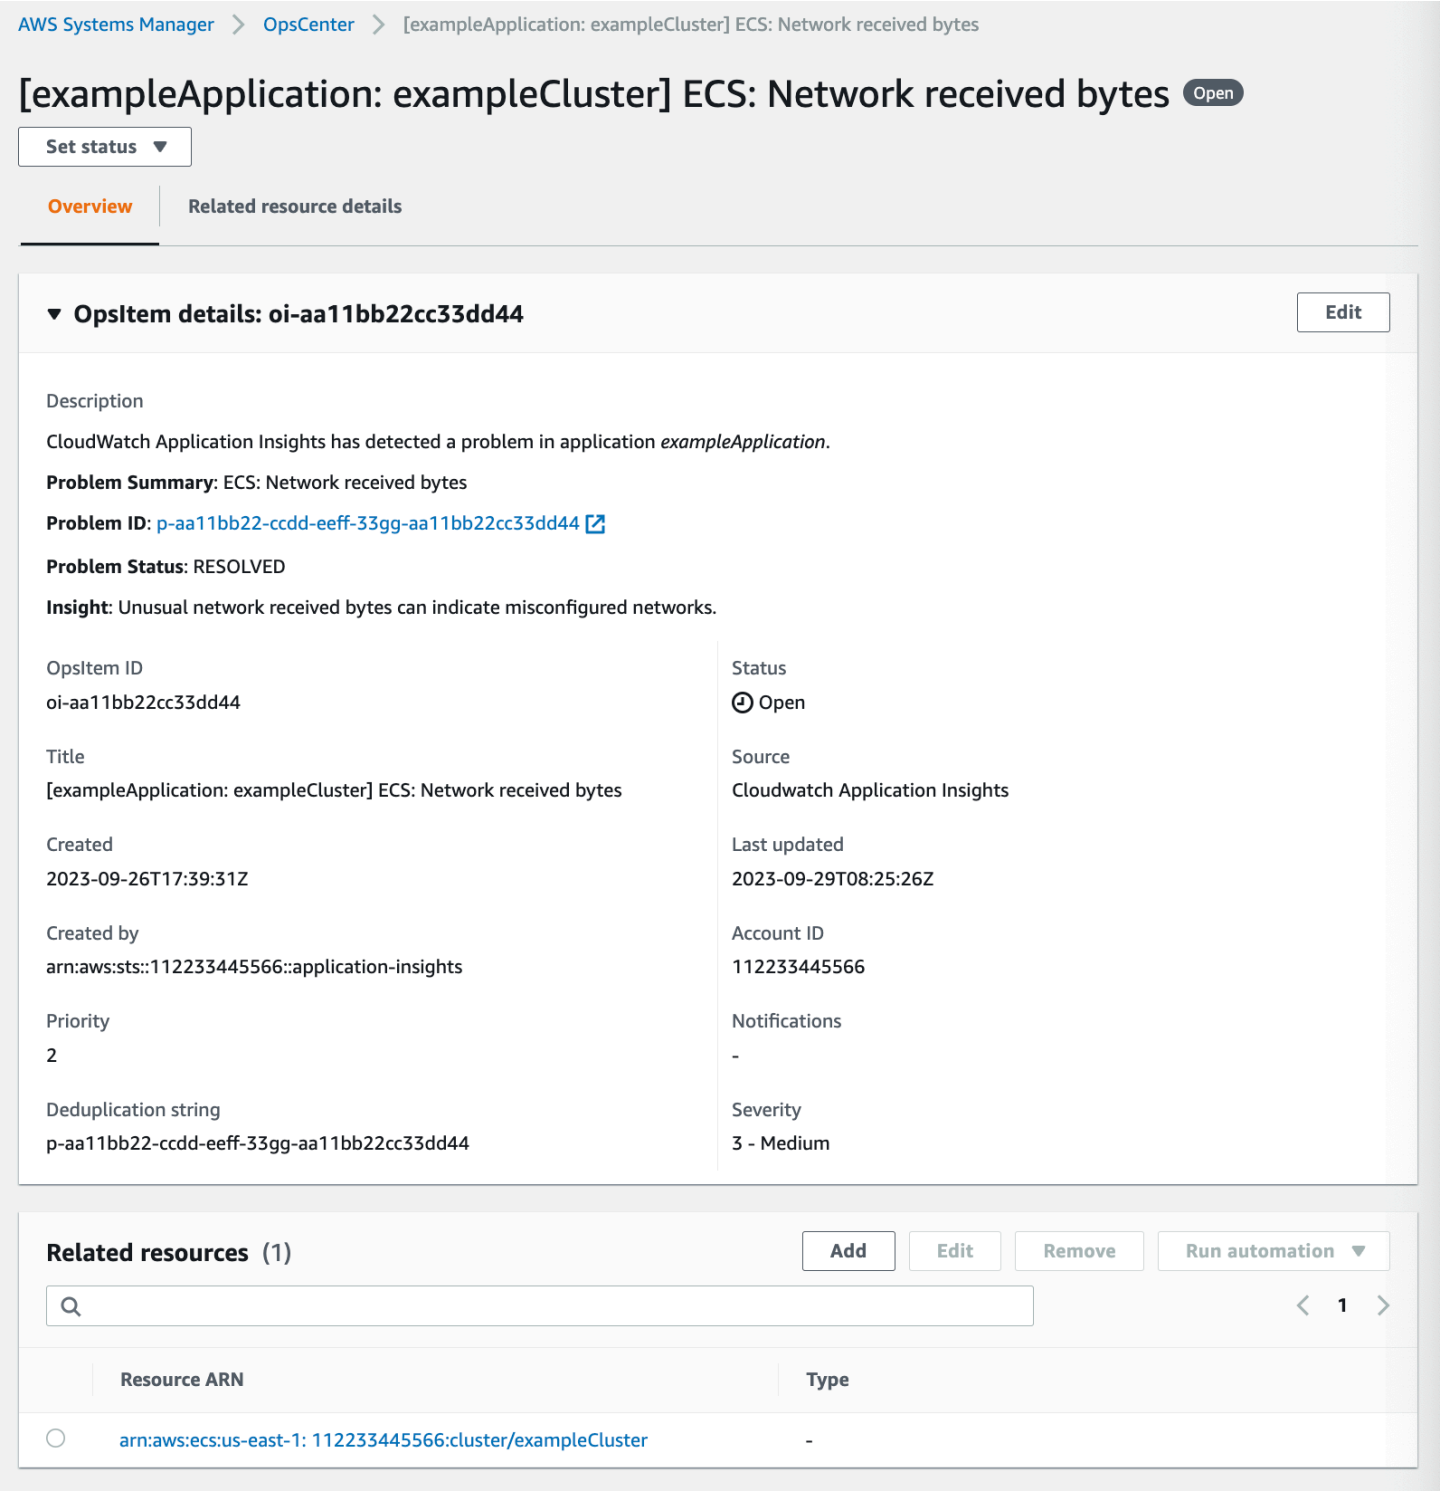
- Amazon DynamoDB: database read and write actions reach a threshold
- Amazon EC2: CPU utilization reaches a threshold
- Amazon billing: estimated charges reach a threshold
- Amazon EC2: an instance fails a status check
- Amazon Elastic Block Store (EBS): disk space utilization reaches a threshold

You can either create an alarm or edit an existing alarm to create an OpsItem. For more information, see Configure CloudWatch alarms to create OpsItems.

When you enable OpsCenter using Integrated Setup, it integrates CloudWatch with OpsCenter.

Understanding OpsCenter integration with Amazon CloudWatch Application Insights

Using Amazon CloudWatch Application Insights, you can set up the most appropriate monitors for your application resources to continuously analyze data for signs of problems with your applications. When you configure application resources in CloudWatch Application Insights, you can choose to have the system create OpsItems in OpsCenter. An OpsItem is created on the OpsCenter console for every problem detected with the application. For information, see Set up, configure, and manage your application for monitoring in the *Amazon CloudWatch User Guide*.



> **Note**
>
> Starting October 16, 2023, the title and description for OpsItems created by CloudWatch Application Insights now use the following improved format:

```
OpsItem title: [<APPLICATION NAME>: <RESOURCE ID>] <PROBLEM SUMMARY>

OpsItem description:

CloudWatch Application Insights has detected a problem in application <APPLICATION
 NAME>.
Problem summary: <PROBLEM SUMMARY>
Problem ID: <PROBLEM ID> (hyperlinks to the Application Insights problem summary page)
Problem Status: <PROBLEM STATUS>
Insight: <INSIGHT>
```

Here is an example:

Understanding OpsCenter integration with Amazon DevOps Guru

Amazon DevOps Guru applies machine learning to analyze your operational data, application metrics, and application events to identify behaviors that deviate from normal operating patterns.

If you enable DevOps Guru to generate an OpsItem in OpsCenter, each insight generates a new OpsItem. You can use OpsCenter to manage your OpsItems.

DevOps Guru automatically creates OpsItems. You can enable Amazon DevOps Guru to create OpsItems by using Quick Setup, which is a tool in Systems Manager. The system creates OpsItems by using the AWSServiceRoleForDevOpsGuru Amazon Identity and Access Management (IAM) service-linked role.

To integrate OpsCenter with DevOps Guru

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Quick Setup**.
3. On the **Customize DevOps Guru configuration options** page, choose the **Library** tab.
4. In the **DevOps Guru** pane, choose **Create**.
5. For **Configuration options**, select **Enable Amazon Systems Manager OpsItems.**
6. Select **Create** after you complete the setup.

Understanding OpsCenter integration with Amazon EventBridge

Amazon EventBridge delivers a stream of events that describe changes in Amazon resources. When you enable OpsCenter using Integrated Setup, it integrates EventBridge with OpsCenter, and enables default EventBridge rules. Based on these rules, EventBridge creates OpsItems. Using rules, you can filter and route events to OpsCenter for investigation and remediation.

> **Note**
>
> Amazon EventBridge (formerly Amazon CloudWatch Events) provides all functionality of CloudWatch Events and some new features, such as custom event buses, third-party event sources and schema registry.

Following are some rules that you can configure in EventBridge to create an OpsItem:

- Security Hub CSPM: security alert issued
- Amazon DynamoDB a throttling event
- Amazon Elastic Compute Cloud Auto Scaling: failure to launch an instance

- Systems Manager: failure to run an automation
- Amazon Health: an alert for scheduled maintenance
- Amazon EC2: instance state changed from running to stop

Based on your requirements, you can either create a rule or edit an existing rule to create an OpsItems. For instructions on how to edit a rule to create an OpsItem, see Configure EventBridge rules to create OpsItems.

Understanding OpsCenter integration with Amazon Config

Amazon Config provides a detailed view of the configuration of Amazon resources in your Amazon Web Services account.

Amazon Config does not integrate *directly* with OpsCenter. Instead, you create an Amazon Config rule that sends an event to Amazon EventBridge, such as when Amazon Config detects a noncompliant instance. Then EventBridge evaluates that event against an EventBridge rule you've created. If the rule matches, EventBridge transforms the event to an OpsItem and transmits it to OpsCenter as the destination target.

Using this OpsItem, you can track details of the noncompliant resource, record investigative actions, and provide access to consistent remediation actions.

Configure EventBridge rules to create OpsItems

Using Amazon Systems Manager OpsCenter and Amazon Config for compliance monitoring

Understanding OpsCenter integration with Amazon Security Hub CSPM

Amazon Security Hub CSPM collects security data, called *findings*, from across Amazon Web Services accounts and services. Using a set of rules to detect and generate findings, Security Hub CSPM helps you identify, prioritize, and remediate security issues for the resources you manage. After you configure integration, as described in this topic, Systems Manager creates OpsItems for Security Hub CSPM findings in OpsCenter.

> **Note**
>
> OpsCenter has bidirectional integration with Security Hub CSPM. This means that if you update the **Status** or **Severity** field for an OpsItem related to a security finding, the system

synchronizes the changes with Security Hub CSPM. Likewise, any changes to a finding are automatically updated in the corresponding OpsItems in OpsCenter.
When an OpsItem is created from a Security Hub CSPM finding, Security Hub CSPM metadata is automatically added to the operational data field of the OpsItem. If this metadata is deleted, the bidirectional updates no longer function.

By default, Systems Manager creates OpsItems for critical and high severity findings. You can manually configure OpsCenter to create OpsItems for medium and low severity findings. OpsCenter doesn't create OpsItems for informational findings as they don't require remediation. For more information about Security Hub CSPM severity levels, see Severity in the *Amazon Security Hub API Reference*.

Before you begin

Before you configure OpsCenter to create OpsItems based on Security Hub CSPM findings, verify that you completed the Security Hub CSPM set up tasks. For more information, see Setting up Security Hub CSPM in the *Amazon Security Hub User Guide*.

When you integrate Security Hub CSPM with OpsCenter, the system creates OpsItems by using the `AWSServiceRoleForSystemsManagerOpsDataSync` IAM service-linked role. For more information about this role, see Using roles to create OpsData and OpsItems for Explorer.

Warning

Note the following important information about pricing for OpsCenter integration with Security Hub CSPM:

- If you are logged into the Security Hub CSPM administrator account when you configure OpsCenter and Security Hub CSPM integration, the system creates OpsItems for findings in the administrator *and* all member accounts. The OpsItems are all created *in the administrator account*. Depending on a variety of factors, this can lead to an unexpectedly large bill from Amazon.

  If you are logged into a member account when you configure integration, the system only creates OpsItems for findings in that individual account. For more information about the Security Hub CSPM administrator account, member accounts, and their relation to the EventBridge event feed for findings, see Types of Security Hub CSPM integration with EventBridge in the *Amazon Security Hub User Guide*.

- For each finding that creates an OpsItem, you are charged the regular price for creating the OpsItem. You are also charged if you edit the OpsItem or if the corresponding finding is updated in Security Hub CSPM (which triggers an OpsItem update).
- OpsItems that are created by an integration with Amazon Security Hub CSPM count toward the OpsItem quotas of 500,000 total OpsItems and 10,000 OpsItems per month for each account in a Region. If your account reaches either quota, you can't create new OpsItems from any source, including Security Hub CSPM findings, until your account is below the quota. For more information, see You receive the OpsItemLimitExceededException.

  For high-production environments, we recommend limiting the scope of Security Hub CSPM findings to high severity issues only.

To configure OpsCenter to create OpsItems for Security Hub CSPM findings

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose **Settings**.
4. In the **Security Hub CSPM findings** section, choose **Edit.**
5. Choose the slider to change **Disabled** to **Enabled**.
6. If you want the system to create OpsItems for medium or low severity findings, toggle these options.
7. Choose **Save** to save your configuration.

Use the following procedure if you no longer want the system to create OpsItems for Security Hub CSPM findings.

To stop receiving OpsItems for Security Hub CSPM findings

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose **Settings**.

4. In the **Security Hub CSPM findings** section, choose **Edit.**
5. Choose the slider to change **Enabled** to **Disabled**. If you can't toggle the slider, Security Hub CSPM hasn't been enabled for your Amazon Web Services account.
6. Choose **Save** to save your configuration. OpsCenter no longer creates OpsItems based on Security Hub CSPM findings.

> **Important**
>
> A Systems Manager delegated administrator or the Amazon Organizations management account can enable Security Hub CSPM findings in OpsCenter for multiple accounts and Amazon Web Services Regions by creating a resource data sync in Explorer. If the **Security Hub CSPM** source is enabled in Explorer and a resource data sync exists that targets the member account where you disabled Security Hub CSPM integration, then the settings selected by your administrator take precedence. OpsCenter continues to create OpsItems for Security Hub CSPM findings. To stop creating OpsItems for Security Hub CSPM findings in a member account targeted by a resource data sync, contact your administrator and ask them to remove your account from the resource data sync or turn off the **Security Hub CSPM** source in Explorer. For information about changing settings in Explorer, see Editing Systems Manager Explorer data sources.

Understanding OpsCenter integration with Incident Manager

Incident Manager provides an incident management console that helps you mitigate and recover from incidents affecting your Amazon hosted applications. An *incident* is any unplanned interruption or reduction in quality of services. After you set up and configure Incident Manager, the system automatically creates OpsItems in OpsCenter.

When the system creates an incident in Incident Manager, it also creates an OpsItem in OpsCenter, and displays the incident as a related item. If the OpsItem already exists, Incident Manager doesn't create an OpsItem. The first OpsItem is known as the parent OpsItem. If an incident grows in scale and scope, you can add incidents to an existing OpsItem. If required, you can manually create an incident for an OpsItem. After an incident is closed, you can create an analysis in Incident Manager to review and improve the remediation process for similar issues.

By default, OpsCenter integrates with Incident Manager. If Incident Manager is not set up, the OpsCenter page displays a message to set up Incident Manager. When Incident Manager creates an

OpsItem, you can manage and remediate the OpsItem from OpsCenter. For instructions on creating an incident for an OpsItem, see Creating an incident for an OpsItem.

Create OpsItems

After you set up OpsCenter, and integrate it with your Amazon Web Services services, your Amazon Web Services services automatically create OpsItems based on default rules, events, or alarms.

You can view the statuses and severity levels of default Amazon EventBridge rules. If required, you can create or edit these rules from Amazon EventBridge. You can also view alarms from Amazon CloudWatch, and create or edit alarms. Using rules and alarms, you can configure events for which you want to generate OpsItems automatically.

When the system creates an OpsItem, it's in the **Open** status. You can change the status to **In progress** when you start investigation of the OpsItem and to **Resolved** after you remediate the OpsItem. For more information about how to configure alarms and rules in Amazon Web Services services to create OpsItems and how to create OpsItems manually, see the following topics.

Topics

- Configure EventBridge rules to create OpsItems
- Configure CloudWatch alarms to create OpsItems
- Create OpsItems manually

Configure EventBridge rules to create OpsItems

When Amazon EventBridge receives an event, it creates a new OpsItem based on default rules. You can create a rule or edit an existing rule to set OpsCenter as the target of an EventBridge event. For information about how to create an event rule, see Creating a rule for an Amazon Web Services service in the *Amazon EventBridge User Guide*.

To configure an EventBridge rule to create OpsItems in OpsCenter

1. Open the Amazon EventBridge console at https://console.amazonaws.cn/events/.
2. In the navigation pane, choose **Rules**.
3. On the **Rules** page, for **Event bus**, choose **default**.
4. For **Rules**, choose a rule by selecting the check box next to its name.
5. Select the name of the rule to open its details page. In **Rule details**, verify that **Status** is set to **Enabled**.

> **Note**
>
> If required, you can update the status using **Edit** in the upper-right corner of the page.

6. Choose the **Targets** tab.
7. On the **Targets** tab, choose **Edit**.
8. For **Target types**, select **Amazon Web Services service**.
9. For **Select a target**, choose **Systems Manager OpsItem**.
10. For many target types, EventBridge needs permission to send events to the target. In these cases, EventBridge can create the Amazon Identity and Access Management (IAM) role needed for your rule to run:

    - To create an IAM role automatically, choose **Create a new role for this specific resource**.
    - To use an IAM role that you created to give EventBridge permission to create OpsItems in OpsCenter, choose **Use existing role**.
11. In **Additional settings**, for **Configure target input**, choose **Input Transformer**.

    You can use the **Input transformer** option to specify a deduplication string and other important information for OpsItems, such as title and severity.
12. Choose **Configure input transformer**.
13. In **Target input transformer**, for **Input path**, specify the values to parse from the triggering event. For example, to parse the start time, end time, and other details from the event that triggers the rule, use the following JSON.

```
{
    "end-time": "$.detail.EndTime",
    "failure-cause": "$.detail.cause",
    "resources": "$.resources[0]",
    "source": "$.detail.source",
    "start-time": "$.detail.StartTime"
}
```

14. For **Template**, specify the information to send to the target. For example, use the following JSON to pass information to OpsCenter. The information is used to create an OpsItem.

Note

If the input template is in the JSON format, then the object value in the template can't include quotes. For example, the values for resources, failure-cause, source, start time, and end time can't be in quotes.

```
{
    "title": "EBS snapshot copy failed",
    "description": "CloudWatch Event Rule SSMOpsItems-EBS-snapshot-copy-failed was
 triggered. Your EBS snapshot copy has failed. See below for more details.",
    "category": "Availability",
    "severity": "2",
    "source": "EC2",
    "operationalData": {
        "/aws/dedup": {
            "type": "SearchableString",
            "value": "{\"dedupString\":\"SSMOpsItems-EBS-snapshot-copy-failed\"}"
        },
        "/aws/automations": {
            "value": "[ { \"automationType\": \"AWS:SSM:Automation\",
 \"automationId\": \"AWS-CopySnapshot\" } ]"
        },
        "failure-cause": {
            "value": <failure-cause>
        },
        "source": {
            "value": <source>
        },
        "start-time": {
            "value": <start-time>
        },
        "end-time": {
            "value": <end-time>
        },
         },
        "resources": {
            "value": <resources>
        }
    }
}
```

For more information about these fields, see Transforming target input in the *Amazon EventBridge User Guide*.

15. Choose **Confirm**.
16. Choose **Next**.
17. Choose **Next**.
18. Choose **Update rule**.

After an OpsItem is created from an event, you can view the event details by opening the OpsItem and scrolling down to the **Private operational data** section. For information about how to configure the options in an OpsItem, see Manage OpsItems.

Configure CloudWatch alarms to create OpsItems

During the integrated setup of OpsCenter, you enable Amazon CloudWatch to automatically create OpsItems based on common alarms. You can create an alarm or edit an existing alarm to create OpsItems in OpsCenter.

CloudWatch creates a new service-linked role in Amazon Identity and Access Management (IAM) when you configure an alarm to create OpsItems. The new role is named `AWSServiceRoleForCloudWatchAlarms_ActionSSM`. For more information about CloudWatch service-linked roles, see Using service-linked roles for CloudWatch in the *Amazon CloudWatch User Guide*.

When a CloudWatch alarm generates an OpsItem, the OpsItem displays **CloudWatch alarm - '*`alarm_name`*' is in ALARM state**.

To view details about a specific OpsItem, choose the OpsItem and then choose the **Related resource details** tab. You can manually edit OpsItems to change details, such as the severity or category. However, when you edit the severity or the category of an alarm, Systems Manager can't update the severity or category of OpsItems that are already created from the alarm. If an alarm created an OpsItem and if you specified a deduplication string, the alarm won't create additional OpsItems even if you edit the alarm in CloudWatch. If the OpsItem is resolved in OpsCenter, CloudWatch will create a new OpsItem.

For more information about configuring CloudWatch alarms, see the following topics.

Topics

- Configuring a CloudWatch alarm to create OpsItems (console)
- Configuring an existing CloudWatch alarm to create OpsItems (programmatically)

Configuring a CloudWatch alarm to create OpsItems (console)

You can manually create an alarm or update an existing alarm to create OpsItems from Amazon CloudWatch.

To create a CloudWatch alarm and configure Systems Manager as a target of that alarm

1. Complete steps 1–9 as specified in Create a CloudWatch alarm based on a static threshold in the *Amazon CloudWatch User Guide*.
2. In the **Systems Manager action** section, choose **Add Systems Manager OpsCenter action**.
3. Choose **OpsItems**.
4. For **Severity**, choose from 1 to 4.
5. (Optional) For **Category**, choose a category for the OpsItem.
6. Complete steps 11–13 as specified in Create a CloudWatch alarm based on a static threshold in the *Amazon CloudWatch User Guide*.
7. Choose **Next** and complete the wizard.

To edit an existing alarm and configure Systems Manager as a target of that alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**.
3. Select the alarm, and then choose **Actions**, **Edit**.
4. (Optional) Change settings in the **Metrics** and **Conditions** sections, and then choose **Next**.
5. In the **Systems Manager** section, choose **Add Systems Manager OpsCenter action**.
6. For **Severity**, choose a number.

> **Note**
>
> Severity is a user-defined value. You or your organization determine what each severity value means and any service-level agreement associated with each severity.

7. (Optional) For **Category**, choose an option.

8. Choose **Next** and complete the wizard.

Configuring an existing CloudWatch alarm to create OpsItems (programmatically)

You can configure Amazon CloudWatch alarms to create OpsItems programmatically by using the Amazon Command Line Interface (Amazon CLI), Amazon CloudFormation templates, or Java code snippets.

Topics

- Before you begin
- Configuring CloudWatch alarms to create OpsItems (Amazon CLI)
- Configuring CloudWatch alarms to create or update OpsItems (CloudFormation)
- Configuring CloudWatch alarms to create or update OpsItems (Java)

Before you begin

If you edit an existing alarm programmatically or create an alarm that creates OpsItems, you must specify an Amazon Resource Name (ARN). This ARN identifies Systems Manager OpsCenter as the target for OpsItems created from the alarm. You can customize the ARN so that OpsItems created from the alarm include specific information such as severity or category. Each ARN includes the information described in the following table.

Parameter	Details
`Region` (required)	The Amazon Web Services Region where the alarm exists. For example: `us-west-2` . For information about Amazon Web Services Regions where you can use OpsCenter, see Amazon Systems Manager endpoints and quotas.
`account_ID` (required)	The same Amazon Web Services account ID used to create the alarm. For example: `123456789012` . The account ID must be followed by a colon (`:`) and the parameter `opsitem` as shown in the following examples.

Parameter	Details
`severity` (required)	A user-defined severity level for OpsItems created from the alarm. Valid values: 1, 2, 3, 4
`Category`(optional)	A category for OpsItems created from the alarm. Valid values: `Availability` , `Cost`, `Performance` , `Recovery`, and `Security`.

Create the ARN by using the following syntax. This ARN doesn't include the optional `Category` parameter.

```
arn:aws-cn:ssm:Region:account_ID:opsitem:severity
```

Following is an example.

```
arn:aws-cn:ssm:us-west-2:123456789012:opsitem:3
```

To create an ARN that uses the optional `Category` parameter, use the following syntax.

```
arn:aws-cn:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name
```

Following is an example.

```
arn:aws-cn:ssm:us-west-2:123456789012:opsitem:3#CATEGORY=Security
```

Configuring CloudWatch alarms to create OpsItems (Amazon CLI)

This command requires that you specify an ARN for the `alarm-actions` parameter. For information about how to create the ARN, see Before you begin.

To configure a CloudWatch alarm to create OpsItems (Amazon CLI)

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.

2. Run the following command to collect information about the alarm that you want to configure.

```
aws cloudwatch describe-alarms --alarm-names "alarm name"
```

3. Run the following command to update an alarm. Replace each *example resource placeholder* with your own information.

```
aws cloudwatch put-metric-alarm --alarm-name name \
--alarm-description "description" \
--metric-name name --namespace namespace \
--statistic statistic --period value --threshold value \
--comparison-operator value \
--dimensions "dimensions" --evaluation-periods value \
    --alarm-actions arn:aws-
cn:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name \
--unit unit
```

Here's an example.

Linux & macOS

```
aws cloudwatch put-metric-alarm --alarm-name cpu-mon \
--alarm-description "Alarm when CPU exceeds 70 percent" \
--metric-name CPUUtilization --namespace AWS/EC2 \
--statistic Average --period 300 --threshold 70 \

```

Configuring CloudWatch alarms to create or update OpsItems (CloudFormation)

This section includes Amazon CloudFormation templates that you can use to configure CloudWatch alarms to automatically create or update OpsItems. Each template requires that you specify an ARN for the `AlarmActions` parameter. For information about how to create the ARN, see Before you begin.

Metric alarm – Use the following CloudFormation template to create or update a CloudWatch metric alarm. The alarm specified in this template monitors Amazon Elastic Compute Cloud (Amazon EC2) instance status checks. If the alarm enters the `ALARM` state, it creates an OpsItem in OpsCenter.

```
   {
     "AWSTemplateFormatVersion": "2010-09-09",
     "Parameters" : {
       "RecoveryInstance" : {
         "Description" : "The EC2 instance ID to associate this alarm with.",
         "Type" : "AWS::EC2::Instance::Id"
       }
     },
     "Resources": {
       "RecoveryTestAlarm": {
         "Type": "AWS::CloudWatch::Alarm",
         "Properties": {
           "AlarmDescription": "Run a recovery action when instance status check fails
 for 15 consecutive minutes.",
           "Namespace": "AWS/EC2" ,
           "MetricName": "StatusCheckFailed_System",
           "Statistic": "Minimum",
           "Period": "60",
           "EvaluationPeriods": "15",
           "ComparisonOperator": "GreaterThanThreshold",
           "Threshold": "0",
           "AlarmActions": [ {"Fn::Join" : ["", ["arn:arn:aws-
cn:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name", { "Ref" :
```

```
 "AWS::Partition" }, ":ssm:", { "Ref" : "AWS::Region" }, { "Ref" : "AWS:: AccountId" },
 ":opsitem:3" ]]} ],
            "Dimensions": [{"Name": "InstanceId","Value": {"Ref": "RecoveryInstance"}}]
          }
        }
      }
    }
```

Composite alarm – Use the following CloudFormation template to create or update a composite alarm. A composite alarm consists of multiple metric alarms. If the alarm enters the ALARM state, it creates an OpsItem in OpsCenter.

```
"Resources":{
       "HighResourceUsage":{
          "Type":"AWS::CloudWatch::CompositeAlarm",
          "Properties":{
             "AlarmName":"HighResourceUsage",
             "AlarmRule":"(ALARM(HighCPUUsage) OR ALARM(HighMemoryUsage)) AND NOT
 ALARM(DeploymentInProgress)",
             "AlarmActions":"arn:aws-
cn:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name",
             "AlarmDescription":"Indicates that the system resource usage is high while
 no known deployment is in progress"
          },
          "DependsOn":[
             "DeploymentInProgress",
             "HighCPUUsage",
             "HighMemoryUsage"
          ]
       },
       "DeploymentInProgress":{
          "Type":"AWS::CloudWatch::CompositeAlarm",
          "Properties":{
             "AlarmName":"DeploymentInProgress",
             "AlarmRule":"FALSE",
             "AlarmDescription":"Manually updated to TRUE/FALSE to disable other
 alarms"
          }
       },
       "HighCPUUsage":{
          "Type":"AWS::CloudWatch::Alarm",
          "Properties":{
             "AlarmDescription":"CPUusageishigh",
```

```
            "AlarmName":"HighCPUUsage",
            "ComparisonOperator":"GreaterThanThreshold",
            "EvaluationPeriods":1,
            "MetricName":"CPUUsage",
            "Namespace":"CustomNamespace",
            "Period":60,
            "Statistic":"Average",
            "Threshold":70,
            "TreatMissingData":"notBreaching"
         }
      },
      "HighMemoryUsage":{
         "Type":"AWS::CloudWatch::Alarm",
         "Properties":{
            "AlarmDescription":"Memoryusageishigh",
            "AlarmName":"HighMemoryUsage",
            "ComparisonOperator":"GreaterThanThreshold",
            "EvaluationPeriods":1,
            "MetricName":"MemoryUsage",
            "Namespace":"CustomNamespace",
            "Period":60,
            "Statistic":"Average",
            "Threshold":65,
            "TreatMissingData":"breaching"
         }
      }
   }
```

Configuring CloudWatch alarms to create or update OpsItems (Java)

This section includes Java code snippets that you can use to configure CloudWatch alarms to automatically create or update OpsItems. Each snippet requires that you specify an ARN for the `validSsmActionStr` parameter. For information about how to create the ARN, see Before you begin.

A specific alarm – Use the following Java code snippet to create or update a CloudWatch alarm. The alarm specified in this template monitors Amazon EC2 instance status checks. If the alarm enters the `ALARM` state, it creates an OpsItem in OpsCenter.

```
import com.amazonaws.services.cloudwatch.AmazonCloudWatch;
    import com.amazonaws.services.cloudwatch.AmazonCloudWatchClientBuilder;
    import com.amazonaws.services.cloudwatch.model.ComparisonOperator;
    import com.amazonaws.services.cloudwatch.model.Dimension;
```

```
    import com.amazonaws.services.cloudwatch.model.PutMetricAlarmRequest;
    import com.amazonaws.services.cloudwatch.model.PutMetricAlarmResult;
    import com.amazonaws.services.cloudwatch.model.StandardUnit;
    import com.amazonaws.services.cloudwatch.model.Statistic;

    private void putMetricAlarmWithSsmAction() {
        final AmazonCloudWatch cw =
                AmazonCloudWatchClientBuilder.defaultClient();

        Dimension dimension = new Dimension()
                .withName("InstanceId")
                .withValue(instanceId);

        String validSsmActionStr = "arn:aws-
cn:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name";

        PutMetricAlarmRequest request = new PutMetricAlarmRequest()
                .withAlarmName(alarmName)
                .withComparisonOperator(
                        ComparisonOperator.GreaterThanThreshold)
                .withEvaluationPeriods(1)
                .withMetricName("CPUUtilization")
                .withNamespace("AWS/EC2")
                .withPeriod(60)
                .withStatistic(Statistic.Average)
                .withThreshold(70.0)
                .withActionsEnabled(false)
                .withAlarmDescription(
                        "Alarm when server CPU utilization exceeds 70%")
                .withUnit(StandardUnit.Seconds)
                .withDimensions(dimension)
                .withAlarmActions(validSsmActionStr);

        PutMetricAlarmResult response = cw.putMetricAlarm(request);
    }
```

Update all alarms – Use the following Java code snippet to update all CloudWatch alarms in your Amazon Web Services account to create OpsItems when an alarm enters the ALARM state.

```
import com.amazonaws.services.cloudwatch.AmazonCloudWatch;
    import com.amazonaws.services.cloudwatch.AmazonCloudWatchClientBuilder;
    import com.amazonaws.services.cloudwatch.model.DescribeAlarmsRequest;
    import com.amazonaws.services.cloudwatch.model.DescribeAlarmsResult;
```

```
    import com.amazonaws.services.cloudwatch.model.MetricAlarm;

    private void listMetricAlarmsAndAddSsmAction() {
        final AmazonCloudWatch cw = AmazonCloudWatchClientBuilder.defaultClient();

        boolean done = false;
        DescribeAlarmsRequest request = new DescribeAlarmsRequest();

        String validSsmActionStr = "arn:aws-
cn:ssm:Region:account_ID:opsitem:severity#CATEGORY=category_name";

        while(!done) {

            DescribeAlarmsResult response = cw.describeAlarms(request);

            for(MetricAlarm alarm : response.getMetricAlarms()) {
                // assuming there are no alarm actions added for the metric alarm
                alarm.setAlarmActions(ImmutableList.of(validSsmActionStr));
            }

            request.setNextToken(response.getNextToken());

            if(response.getNextToken() == null) {
                done = true;
            }
        }
    }
```

Create OpsItems manually

When you find an operational issue, you can manually create an OpsItem from OpsCenter to manage and resolve the issue.

If you set up OpsCenter for cross-account administration, a Systems Manager delegated administrator or Amazon Organizations management account can create OpsItems for member accounts. For more information, see (Optional) Manually set up OpsCenter to centrally manage OpsItems across accounts.

You can create OpsItems by using the Amazon Systems Manager console, the Amazon Command Line Interface (Amazon CLI), or Amazon Tools for Windows PowerShell.

Topics

- Creating OpsItems manually (console)
- Creating OpsItems manually (Amazon CLI)
- Creating OpsItems manually (PowerShell)

Creating OpsItems manually (console)

You can manually create OpsItems using the Amazon Systems Manager console. When you create an OpsItem, it's displayed in your OpsCenter account. If you set up OpsCenter for cross-account administration, OpsCenter provides the delegated administrator or management account with the option to create OpsItems for selected member accounts. For more information, see (Optional) Manually set up OpsCenter to centrally manage OpsItems across accounts.

To create an OpsItem using the Amazon Systems Manager console

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose **Create OpsItem**. If you don't see this button, choose the **OpsItems** tab, and then choose **Create OpsItem**.
4. (Optional) Choose **Other account**, and then choose the account where you want to create the OpsItem.

   > **Note**
   >
   > This step is required if you're creating OpsItems for a member account.

5. For **Title**, enter a descriptive name to help you understand the purpose of the OpsItem.
6. For **Source**, enter the type of impacted Amazon resource or other source information to help users understand the origin of the OpsItem.

   > **Note**
   >
   > You can't edit the **Source** field after you create the OpsItem.

7. (Optional) For **Priority**, choose the priority level.
8. (Optional) For **Severity**, choose the severity level.
9. (Optional) For **Category**, choose a category.

10. For **Description**, enter information about this OpsItem including (if applicable) steps for reproducing the issue.

    > **Note**
    >
    > The console supports most markdown formatting in the OpsItem description field. For more information, see Using Markdown in the Console in the *Getting Started with the Amazon Web Services Management Console Getting Started Guide.*

11. For **Deduplication string**, enter words that the system can use to check for duplicate OpsItems. For more information about deduplication strings, see Managing duplicate OpsItems.
12. (Optional) For **Notifications**, specify the Amazon Resource Name (ARN) of the Amazon SNS topic where you want notifications sent when this OpsItem is updated. You must specify an Amazon SNS ARN that is in the same Amazon Web Services Region as the OpsItem.
13. (Optional) For **Related resources**, choose **Add** to specify the ID or ARN of the impacted resource and any related resources.
14. Choose **Create OpsItem**.

If successful, the page displays the OpsItem. When a delegated administrator or management account creates an OpsItem for selected member accounts, the new OpsItems are displayed in the OpsCenter of the administrator and members accounts. For information about how to configure the options in an OpsItem, see Manage OpsItems.

Creating OpsItems manually (Amazon CLI)

The following procedure describes how to create an OpsItem by using the Amazon Command Line Interface (Amazon CLI).

To create an OpsItem using the Amazon CLI

1. Install and configure the Amazon Command Line Interface (Amazon CLI), if you haven't already.

   For information, see Installing or updating the latest version of the Amazon CLI.
2. Open the Amazon CLI and run the following command to create an OpsItem. Replace each *`example resource placeholder`* with your own information.

```
aws ssm create-ops-item \
    --title "Descriptive_title" \
    --description "Information_about_the_issue" \
    --priority Number_between_1_and_5 \
    --source Source_of_the_issue \
    --operational-data Up_to_20_KB_of_data_or_path_to_JSON_file \
    --notifications Arn="SNS_ARN_in_same_Region" \
    --tags "Key=key_name,Value=a_value"
```

Specify operational data from a file

When you create an OpsItem, you can specify operational data from a file. The file must be a JSON file, and the contents of the file must use the following format.

```
{
  "key_name": {
    "Type": "SearchableString",
    "Value": "Up to 20 KB of data"
  }
}
```

Here is an example.

```
aws ssm create-ops-item ^
    --title "EC2 instance disk full" ^
    --description "Log clean up may have failed which caused the disk to be full" ^
    --priority 2 ^
    --source ec2 ^
    --operational-data file:///Users/TestUser1/Desktop/OpsItems/opsData.json ^
    --notifications Arn="arn:aws-cn:sns:us-west-1:12345678:TestUser1" ^
    --tags "Key=EC2,Value=Production"
```

> **Note**
>
> For information about how to enter JSON-formatted parameters on the command line on different local operating systems, see Using quotation marks with strings in the Amazon CLI in the *Amazon Command Line Interface User Guide*.

The system returns information like the following.

```
{
    "OpsItemId": "oi-1a2b3c4d5e6f"
}
```

3. Run the following command to view details about the OpsItem that you created.

```
aws ssm get-ops-item --ops-item-id ID
```

The system returns information like the following.

```
{
    "OpsItem": {
        "CreatedBy": "arn:aws-cn:iam::12345678:user/TestUser",
        "CreatedTime": 1558386334.995,
        "Description": "Log clean up may have failed which caused the disk to be
 full",
        "LastModifiedBy": "arn:aws-cn:iam::12345678:user/TestUser",
        "LastModifiedTime": 1558386334.995,
        "Notifications": [
            {
                "Arn": "arn:aws-cn:sns:us-west-1:12345678:TestUser"
            }
        ],
        "Priority": 2,
        "RelatedOpsItems": [],
        "Status": "Open",
        "OpsItemId": "oi-1a2b3c4d5e6f",
        "Title": "EC2 instance disk full",
        "Source": "ec2",
        "OperationalData": {
            "EC2": {
                "Value": "12345",
                "Type": "SearchableString"
            }
        }
    }
}
```

4. Run the following command to update the OpsItem. This command changes the status from Open (the default) to `InProgress`.

```
aws ssm update-ops-item --ops-item-id ID --status InProgress
```

   The command has no output.

5. Run the following command again to verify that the status changed to `InProgress`.

```
aws ssm get-ops-item --ops-item-id ID
```

Examples of creating an OpsItem

The following code examples show you how to create an OpsItem by using the Linux management portal, macOS, or Windows Server.

Linux management portal or macOS

The following command creates an OpsItem when an Amazon Elastic Compute Cloud (Amazon EC2) instance disk is full.

```
aws ssm create-ops-item \
    --title "EC2 instance disk full" \
    --description "Log clean up may have failed which caused the disk to be full" \
    --priority 2 \
    --source ec2 \
    --operational-data '{"EC2":{"Value":"12345","Type":"SearchableString"}}' \
    --notifications Arn="arn:aws-cn:sns:us-west-1:12345678:TestUser1" \
    --tags "Key=EC2,Value=ProductionServers"
```

The following command uses the `/aws/resources` key in `OperationalData` to create an OpsItem with an Amazon DynamoDB related resource.

```
aws ssm create-ops-item \
    --title "EC2 instance disk full" \
    --description "Log clean up may have failed which caused the disk to be full" \
    --priority 2 \
    --source ec2 \
    --operational-data '{"/aws/resources":{"Value":"[{\"arn\": \"arn:aws-
cn:dynamodb:us-west-2:12345678:table/OpsItems\"}]","Type":"SearchableString"}}' \
```

```
    --notifications Arn="arn:aws-cn:sns:us-west-2:12345678:TestUser"
```

The following command uses the `/aws/automations` key in `OperationalData` to create an OpsItem that specifies the `AWS-ASGEnterStandby` document as an associated Automation runbook.

```
aws ssm create-ops-item \
    --title "EC2 instance disk full" \
    --description "Log clean up may have failed which caused the disk to be full" \
    --priority 2 \
    --source ec2 \
    --operational-data '{"/aws/automations":{"Value":"[{\"automationId
\": \"AWS-ASGEnterStandby\", \"automationType\": \"AWS::SSM::Automation
\"}]","Type":"SearchableString"}}' \
    --notifications Arn="arn:aws-cn:sns:us-west-2:12345678:TestUser"
```

Windows

The following command creates an OpsItem when an Amazon Relational Database Service (Amazon RDS) instance is not responding.

```
aws ssm create-ops-item ^
    --title "RDS instance not responding" ^
    --description "RDS instance not responding to ping" ^
    --priority 1 ^
    --source RDS ^
    --operational-data={\"RDS\":{\"Value\":\"abcd\",\"Type\":\"SearchableString\"}} ^
    --notifications Arn="arn:aws-cn:sns:us-west-1:12345678:TestUser1" ^
    --tags "Key=RDS,Value=ProductionServers"
```

The following command uses the `/aws/resources` key in `OperationalData` to create an OpsItem with an Amazon EC2 instance related resource.

```
aws ssm create-ops-item ^
    --title "EC2 instance disk full" ^
    --description "Log clean up may have failed which caused the disk to be full" ^
    --priority 2 ^
    --source ec2 ^
    --operational-data={\"/aws/resources\":{\"Value\":\"[{\\\"""arn\\\""":\\\"""arn:aws-
cn:ec2:us-east-1:123456789012:instance/i-1234567890abcdef0\\\"""}]\",\"Type\":
\"SearchableString\"}}
```

The following command uses the `/aws/automations` key in `OperationalData` to create an OpsItem that specifies the `Amazon-RestartEC2Instance` runbook as an associated Automation runbook.

```
aws ssm create-ops-item ^
    --title "EC2 instance disk full" ^
    --description "Log clean up may have failed which caused the disk to be full" ^
    --priority 2 ^
    --source ec2 ^
    --operational-data={\"/aws/automations\":{\"Value\":\"[{\\"""automationId\\""":
\\"""AWS-RestartEC2Instance\\""",\\"""automationType\\""":\\"""AWS::SSM::Automation\
\"""}]\",\"Type\":\"SearchableString\"}}
```

Creating OpsItems manually (PowerShell)

The following procedure describes how to create an OpsItem by using Amazon Tools for Windows PowerShell.

To create an OpsItem using Amazon Tools for Windows PowerShell

1. Open Amazon Tools for Windows PowerShell and run the following command to specify your credentials.

   ```
   Set-AWSCredentials –AccessKey key-name –SecretKey key-name
   ```

2. Run the following command to set the Amazon Web Services Region for your PowerShell session.

   ```
   Set-DefaultAWSRegion -Region Region
   ```

3. Run the following command to create a new OpsItem. Replace each *example resource placeholder* with your own information. This command specifies a Systems Manager Automation runbook for remediating this OpsItem.

   ```
   $opsItem = New-Object Amazon.SimpleSystemsManagement.Model.OpsItemDataValue
   $opsItem.Type = [Amazon.SimpleSystemsManagement.OpsItemDataType]::SearchableString
   $opsItem.Value = '[{\"automationId\":\"runbook_name\",\"automationType\":
   \"AWS::SSM::Automation\"}]'
   $newHash = @{" /aws/
   automations"=[Amazon.SimpleSystemsManagement.Model.OpsItemDataValue]$opsItem}
   ```

```
New-SSMOpsItem `
    -Title "title" `
    -Description "description" `
    -Priority priority_number `
    -Source Amazon_service `
    -OperationalData $newHash
```

If successful, the command outputs the ID of the new OpsItem.

The following example specifies the Amazon Resource Name (ARN) of an impaired Amazon Elastic Compute Cloud (Amazon EC2) instance.

```
$opsItem = New-Object Amazon.SimpleSystemsManagement.Model.OpsItemDataValue
$opsItem.Type = [Amazon.SimpleSystemsManagement.OpsItemDataType]::SearchableString
$opsItem.Value = '[{\"arn\":\"arn:aws-cn:ec2:us-east-1:123456789012:instance/
i-1234567890abcdef0\"}]'
$newHash = @{" /aws/
resources"=[Amazon.SimpleSystemsManagement.Model.OpsItemDataValue]$opsItem}
New-SSMOpsItem -Title "EC2 instance disk full still" -Description "Log clean up may
 have failed which caused the disk to be full" -Priority 2 -Source ec2 -OperationalData
 $newHash
```

Manage OpsItems

OpsCenter tracks OpsItems from their creation to resolution. If you set up OpsCenter for cross-account administration, a delegated administrator or management account can manage OpsItems from their account. For more information, see (Optional) Manually set up OpsCenter to centrally manage OpsItems across accounts.

You can view and manage OpsItems by using the following pages in the Systems Manager console:

- **Summary** – Displays a count of open and in-progress OpsItems, count of OpsItems by source and age, and operational insights. You can filter OpsItems by source and OpsItems status.

- **OpsItems** – Displays a list of OpsItems with multiple fields of information, such as title, ID, priority, description, the source of the OpsItem, and the date and time of last update. Using this page, you can manually create OpsItems, configure sources, change the status of an OpsItem, and filter OpsItems by new incidents. You can choose an OpsItem to display its **OpsItems details** page.

- **OpsItem details** – Provides detailed insights and tools that you can use to manage an OpsItem. The OpsItems details page has the following tabs:
  - **Overview** – Displays related resources, runbooks that ran in the last 30 days, and a list of available runbooks that you can run. You can also view similar OpsItems, add operational data, and add related OpsItems.
  - **Related resource details** – Displays information about the resource from several Amazon services. Expand the **Resource details** section to view information about this resource as provided by the Amazon service that hosts it. You can also toggle through other related resources associated with this OpsItem by using the **Related resources** list.

For more information about how to manage OpsItems, see the following topics.

Topics

- Viewing details of an OpsItem
- Editing an OpsItem
- Adding related resources to an OpsItem
- Adding related OpsItems to an OpsItem
- Adding operational data to an OpsItem
- Creating an incident for an OpsItem
- Managing duplicate OpsItems
- Analyzing operational insights to reduce OpsItems
- Viewing OpsCenter logs and reports

Viewing details of an OpsItem

To get a comprehensive view of an OpsItem, use the **OpsItem details** page in the OpsCenter console. The **Overview** page displays the following information:

- **OpsItems details**– Displays general information for the selected OpsItem.
- **Related Resources** – A related resource is the impacted resource or the resource that initiated the event that created the OpsItem.
- **Automation executions in the last 30 days** – A list of runbooks that ran in last 30 days.
- **Runbooks** – You can choose a runbook from a list of available runbooks.

- **Similar OpsItems** – This is a system-generated list of OpsItems that might be related or of interest to you. To generate the list, the system scans the titles and descriptions of all OpsItems and returns OpsItems that use similar words.
- **Operational data** – Operational data is custom data that provides useful reference details about the OpsItem. For example, you can specify log files, error strings, license keys, troubleshooting tips, or other relevant data.
- **Related OpsItems** – You can specify the IDs of OpsItems that are in some way related to the current OpsItem.
- **Related Resource Details** – Displays data providers, including Amazon CloudWatch metrics and alarms, Amazon CloudTrail logs, and details from Amazon Config.

To view details of an OpsItem

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose an OpsItem to view its details.

Editing an OpsItem

The **OpsItem details** section includes information about an OpsItem, including the description, title, source, OpsItem ID, and the status. You can edit a single OpsItem or you can select multiple OpsItems and edit the following fields: **Status**, **Priority**, **Severity**, **Category**.

When Amazon EventBridge creates an OpsItem, it populates the **Title**, **Source**, and **Description** fields. You can edit the **Title** and **Description** fields, but you can't edit the **Source** field.

> **Note**
>
> The console supports most markdown formatting in the OpsItem description field. For more information, see Using Markdown in the Console in the *Getting Started with the Amazon Web Services Management Console Getting Started Guide.*

Generally, you can edit the following configurable data for an OpsItem:

- **Title** – Name of the OpsItem. The source creates the title of the OpsItem.
- **Description** – Information about this OpsItem including (if applicable) steps for reproducing the issue.
- **Status** – Status of an OpsItem. For a list of valid status values, see OpsItem Status in the *Amazon Systems Manager API Reference*.
- **Priority** – Priority of an OpsItem can be between 1 and 5. We recommend that your organization determine what each priority level means and a corresponding service level agreement for each level.
- **Severity** – Severity of an OpsItem can be between 1 to 4, where 1 is critical, 2 is high, 3 is medium, and 4 is low.
- **Category** – Category of an OpsItem can be availability, cost, performance, recovery, or security.
- **Notifications** – When you edit an OpsItem, you can specify the Amazon Resource Name (ARN) of an Amazon Simple Notification Service topic in the **Notifications** field. By specifying an ARN, you make sure that all stakeholders receive a notification when the OpsItem is edited, including a status change. For more information, see the *Amazon Simple Notification Service Developer Guide*.

> **Important**
>
> The Amazon SNS topic must exist in the same Amazon Web Services Region as the OpsItem. If the topic and the OpsItem are in different Regions, the system returns an error.

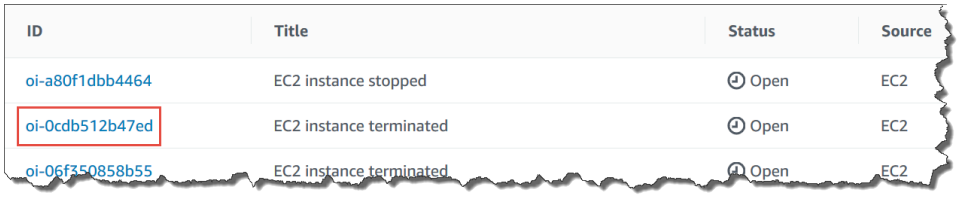
OpsCenter has bidirectional integration with Amazon Security Hub CSPM. When you update an OpsItem status and severity related to a security finding, those changes are automatically sent to Security Hub CSPM to make sure you always see the latest and correct information.

When an OpsItem is created from a Security Hub CSPM finding, Security Hub CSPM metadata is automatically added to the operational data field of the OpsItem. If this metadata is deleted, the bidirectional updates no longer function.

To edit OpsItem details

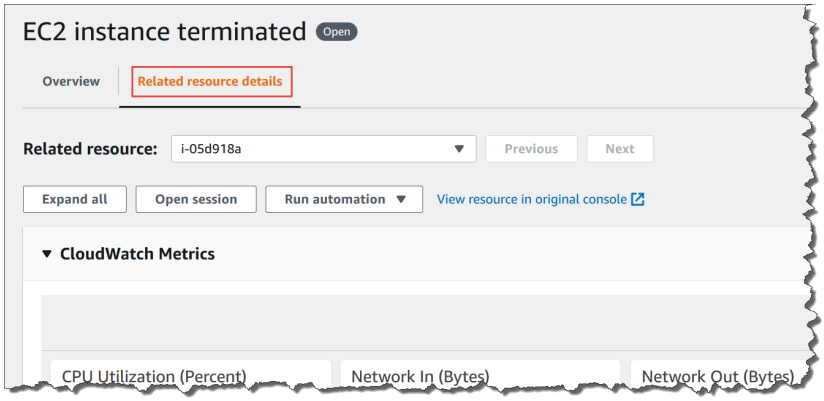
1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.

3. Choose an OpsItem ID to open the details page or choose multiple OpsItems. If you choose multiple OpsItems, you can only edit the status, priority, severity, or category. If you edit multiple OpsItems, OpsCenter updates and saves your changes as soon as you choose the new status, priority, severity, or category.
4. In the **OpsItem details** section, choose **Edit**.
5. Edit the details of the OpsItem according to the requirements and guidelines specified by your organization.
6. When you're finished, choose **Save**.



Adding related resources to an OpsItem

Each OpsItem includes a **Related resources** section that lists the Amazon Resource Name (ARN) of the related resource. A *related resource* is the impacted Amazon resource that needs to be investigated.



If Amazon EventBridge creates the OpsItem, the system automatically populates the OpsItem with the ARN of the resource. You can manually specify ARNs of related resources. For certain ARN types, OpsCenter automatically creates a deep link that displays details about the resource directly in the OpsCenter console. For example, if you specify the ARN of an Amazon Elastic Compute Cloud (Amazon EC2) instance as a related resource, then OpsCenter pulls in details about that EC2 instance. This lets you view detailed information about your impacted Amazon resources without having to leave OpsCenter.

To view and add related resources to an OpsItem

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose the **OpsItems** tab.
4. Choose an OpsItem ID.

5. To view information about the impacted resource, choose the **Related resources details** tab.

This tab displays information about the resource from several Amazon Web Services services. Expand the **Resource details** section to view information about this resource as provided by the Amazon Web Services service that hosts it. You can also toggle through other related resources associated with this OpsItem by using the **Related resources** list.

6. To add additional related resources, choose the **Overview** tab.
7. In the **Related resources** section, choose **Add**.
8. For **Resource type**, choose a resource from the list.
9. For **Resource ID**, enter either the ID or the Amazon Resource Name (ARN). The type of information you choose depends on the resource that you chose in the previous step.

> **Note**
>
> You can manually add the ARNs of additional related resources. Each OpsItem can list a maximum of 100 related resource ARNs.

The following table lists the resource types that automatically create deep links to related resources.

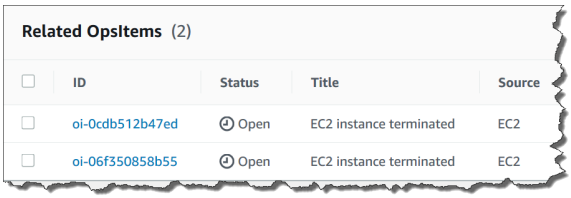
Supported resource types

Resource name	ARN format
Amazon Certificate Manager certificate	`arn:aws-cn:acm: region:account-id :certificate/ certificate-id`

Resource name	ARN format
Amazon EC2 Auto Scaling group	`arn:aws-cn:autosca ling: region:account-id :autoScal ingGroup: groupid:autoScalingGroupN ame/ groupfriendlyname`
Amazon CloudFront distribution	`arn:aws-cn:cloudfront:: account-id :*`
Amazon CloudFormation stack	`arn:aws-cn:cloudfo rmation: region:account-i d :stack/stackname /additionalidentifi er`
Amazon CloudWatch alarm	`arn:aws-cn:cloudwatch: region:account- id :alarm:alarm-name`
Amazon CloudTrail trail	`arn:aws-cn:cloudtrail: region:account- id :trail/trailname`
Amazon CodeBuild project	`arn:aws-cn:codebuild: region:account-i d :resourcetype /resource`
Amazon CodePipeline	`arn:aws-cn:codepip eline: region:account-id :resource- specifier`
Amazon DevOps Guru insight	`arn:aws-cn:devops- guru: region:account-id :insight/ proactive or reactive/resource-id`
Amazon DynamoDB table	`arn:aws-cn:dynamodb: region:account-i d :table/tablename`

Resource name	ARN format
Amazon Elastic Compute Cloud (Amazon EC2) customer gateway	`arn:aws-cn:ec2:region:account-id:customer-gateway/cgw-id`
Amazon EC2 elastic IP	`arn:aws-cn:ec2:region:account-id:eip/eipalloc-id`
Amazon EC2 Dedicated Host	`arn:aws-cn:ec2:region:account-id:dedicated-host/host-id`
Amazon EC2 instance	`arn:aws-cn:ec2:region:account-id:instance/instance-id`
Amazon EC2 internet gateway	`arn:aws-cn:ec2:region:account-id:internet-gateway/igw-id`
Amazon EC2 network access control list (network ACL)	`arn:aws-cn:ec2:region:account-id:network-acl/nacl-id`
Amazon EC2 network interface	`arn:aws-cn:ec2:region:account-id:network-interface/eni-id`
Amazon EC2 route table	`arn:aws-cn:ec2:region:account-id:route-table/route-table-id`
Amazon EC2 security group	`arn:aws-cn:ec2:region:account-id:security-group/security-group-id`
Amazon EC2 subnet	`arn:aws-cn:ec2:region:account-id:subnet/subnet-id`

Resource name	ARN format
Amazon EC2 volume	`arn:aws-cn:ec2: region:account-id :volume/volume-id`
Amazon EC2 VPC	`arn:aws-cn:ec2: region:account-id :vpc/vpc-id`
Amazon EC2 VPN connection	`arn:aws-cn:ec2: region:account-id :vpn-connection/ vpn-id`
Amazon EC2 VPN gateway	`arn:aws-cn:ec2: region:account-id :vpn-gateway/ vgw-id`
Amazon Elastic Beanstalk application	`arn:aws-cn:elasticbeanstalk : region:account-id :application/ applicationname`
Elastic Load Balancing (Classic Load Balancer)	`arn:aws-cn:elasticloadbalancing: region:account-id :loadbalancer/ name`
Elastic Load Balancing (Application Load Balancer)	`arn:aws-cn:elasticloadbalancing: region:account-id :loadbalancer/app/ load-balancer-name /load-balancer-id`
Elastic Load Balancing (Network Load Balancer)	`arn:aws-cn:elasticloadbalancing: region:account-id :loadbalancer/net/ load-balancer-name /load-balancer-id`
Amazon Identity and Access Management (IAM) group	`arn:aws-cn:iam:: account-id :group/group-name`



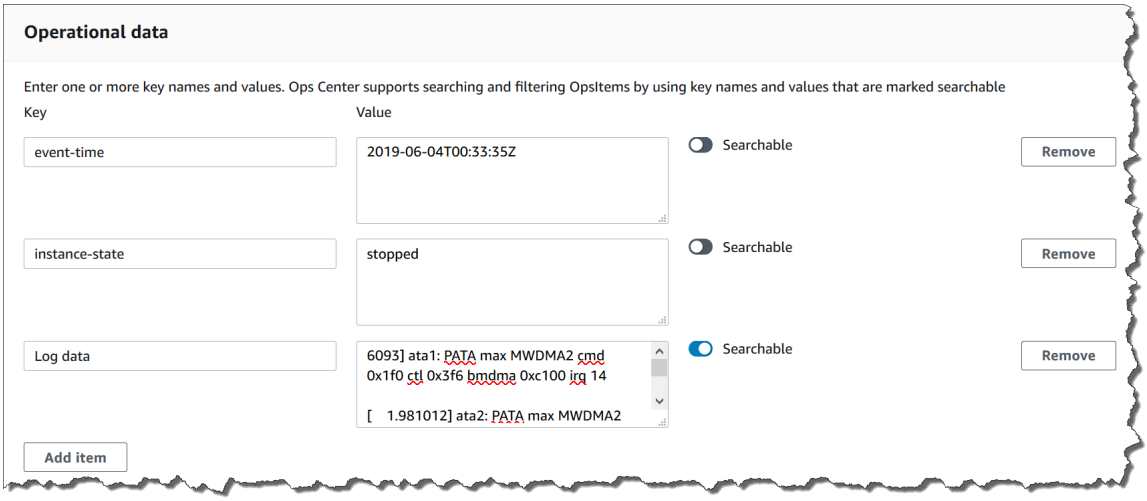
Resource name	ARN format
IAM policy	`arn:aws-cn:iam:: account-id :policy/policy-name`
IAM role	`arn:aws-cn:iam:: account-id :role/role-name`
IAM user	`arn:aws-cn:iam:: account-id :user/user-name`
Amazon Lambda function	`arn:aws-cn:lambda: region:account-id :function: function-name`
Amazon Relational Database Service (Amazon RDS) cluster	`arn:aws-cn:rds: region:account-id :cluster: db-cluster-name`
Amazon RDS database instance	`arn:aws-cn:rds: region:account-id :db:db-instance-name`
Amazon RDS subscription	`arn:aws-cn:rds: region:account-id :es:subscription-name`
Amazon RDS security group	`arn:aws-cn:rds: region:account-id :secgrp:security-group-name`
Amazon RDS cluster snapshot	`arn:aws-cn:rds: region:account-id :cluster-snapshot: cluster-snapshot-name`
Amazon RDS subnet group	`arn:aws-cn:rds: region:account-id :subgrp:subnet-group-name`

Resource name	ARN format
Amazon Redshift cluster	`arn:aws-cn:redshift: region:account-id :cluster: cluster-name`
Amazon Redshift parameter group	`arn:aws-cn:redshift: region:account-id :parametergroup: parameter-group-name`
Amazon Redshift security group	`arn:aws-cn:redshift: region:account-id :securitygroup: security-group-name`
Amazon Redshift cluster snapshot	`arn:aws-cn:redshift: region:account-id :snapshot: cluster-name /snapshot-name`
Amazon Redshift subnet group	`arn:aws-cn:redshift: region:account-id :subnetgroup: subnet-group-name`
Amazon Simple Storage Service (Amazon S3) bucket	`arn:aws-cn:s3::: bucket_name`
Amazon Config recording of Amazon Systems Manager managed node inventory	`arn:aws-cn:ssm: region:account-id :managed-instance-inventory / node_id`
Systems Manager State Manager association	`arn:aws-cn:ssm: region:account-id :association/ association_ID`

Adding related OpsItems to an OpsItem

By using **Related OpsItems** of the **OpsItems Details** page, you can investigate operations issues and provide context for an issue. OpsItems can be related in different ways, including a parent-child relationship between OpsItems, a root cause, or a duplicate. You can associate one OpsItem

with another to display it in the **Related OpsItem** section.You can specify a maximum of 10 IDs for other OpsItems that are related to the current OpsItem.



To add a related OpsItem

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose an OpsItem ID to open the details page.
4. In the **Related OpsItem** section, choose **Add**.
5. For **OpsItem ID**, specify an ID.
6. Choose **Add**.

Adding operational data to an OpsItem

Operational data is custom data that provides useful reference details about an OpsItem. You can enter multiple key-value pairs of operational data. For example, you can specify log files, error strings, license keys, troubleshooting tips, or other relevant data. The maximum length of the key can be 128 characters, and the maximum size of the value can be 20 KB.

You can make the data searchable by other users in the account, or you can restrict search access. Searchable data means that all users with access to the OpsItem **Overview** page (as provided by the DescribeOpsItems API operation) can view and search on the specified data. Operational data that isn't searchable is only viewable by users who have access to the OpsItem (as provided by the GetOpsItem API operation).

To add operational data to an OpsItem

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose an OpsItem ID to open its details page.
4. Expand **Operational data**.
5. If no operational data exists for the OpsItem, choose **Add**. If operational data already exists for the OpsItem, choose **Manage**.

   After you create operational data, you can edit the key and the value, remove the operational data, or add additional key-value pairs by choosing **Manage**.
6. For **Key**, specify a word or words to help users understand the purpose of the data.

   > **Important**
   >
   > Operational data keys *can't* begin with the following: `amazon`, `aws`, `amzn`, `ssm`, `/amazon`, `/aws`, `/amzn`, `/ssm`.
7. For **Value**, specify the data.
8. Choose **Save**.

> **Note**
>
> You can filter OpsItems by using the **Operational data** operator on the **OpsItems** page. In the **Search** box, choose **Operational data**, and then enter a key-value pair in JSON. You must enter the key-value pair by using the following format: `{"key":"key_name","value":"a_value"}`

Creating an incident for an OpsItem

Use the following procedure to manually create an incident for an OpsItem to track and manage it in Amazon Systems Manager Incident Manager, which is a tool in Amazon Systems Manager. An *incident* is any unplanned interruption or reduction in quality of services. For more information about Incident Manager, see the section called “Integrate OpsCenter with other Amazon Web Services services”.

To manually create an incident for an OpsItem

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. If Incident Manager created an OpsItem for you, choose it and go to step 5. If not, choose **Create OpsItem** and complete the form. If you don't see this button, choose the **OpsItems** tab, and then choose **Create OpsItem**.
4. If you created an OpsItem, open it.
5. Choose **Start Incident**.
6. For **Response plan**, choose the Incident Manager response plan that you want to assign to this incident.
7. (Optional) For **Title**, enter a descriptive name to help other team members understand the nature of the incident. If you don't enter a new title, OpsCenter creates the OpsItem and the corresponding incident in Incident Manager using the title in the response plan.
8. (Optional) For **Incident impact**, choose an impact level for this incident. If you don't choose an impact level, OpsCenter creates the OpsItem and the corresponding incident in Incident Manager using the impact level in the response plan.
9. Choose **Start**.

Managing duplicate OpsItems

OpsCenter can receive multiple duplicate OpsItems for a single source from multiple Amazon Web Services services. OpsCenter uses a combination of built-in logic and configurable deduplication strings to avoid creating duplicate OpsItems. Amazon Systems Manager applies deduplication built-in logic when the CreateOpsItem API operation is called.

Amazon Systems Manager uses the following deduplication logic:

1. When creating the OpsItem, Systems Manager creates and stores a hash based on the deduplication string and the resource that initiated the OpsItem.
2. When another request is made to create an OpsItem, the system checks the deduplication string of the new request.
3. If a matching hash exists for this deduplication string, Systems Manager checks the status of the existing OpsItem. If the status of an existing OpsItem is open or in progress, the OpsItem is not created. If the existing OpsItem is resolved, Systems Manager creates a new OpsItem.

After you create an OpsItem, you *can't* edit or change the deduplication strings in that OpsItem.

To manage duplicate OpsItems, you can do the following:

- Edit the deduplication string for an Amazon EventBridge rule that targets OpsCenter. For more information, see Editing a deduplication string in a default EventBridge rule.
- Specify a deduplication string when you manually create an OpsItem. For more information, see Specifying a deduplication string using Amazon CLI.
- Review and resolve duplicate OpsItems using operational insights. You can use runbooks to resolve duplicate OpsItems.

  To help you resolve duplicate OpsItems and reduce the number of OpsItems created by a source, Systems Manager provides automation runbooks. For information, see Resolving duplicate OpsItems based on insights.

Editing a deduplication string in a default EventBridge rule

Use the following procedure to specify a deduplication string for an EventBridge rule that targets OpsCenter.

To edit a deduplication string for an EventBridge rule

1. Sign in to the Amazon Web Services Management Console and open the Amazon EventBridge console at https://console.amazonaws.cn/events/.
2. In the navigation pane, choose **Rules**.
3. Choose a rule, and then choose **Edit**.
4. Go to the **Select target(s)** page.
5. In the **Additional settings** section, choose **Configure input transformer**.

6. In the **Template** box, locate the `"operationalData": { "/aws/dedup"` JSON entry and the deduplication strings that you want to edit.

   The deduplication string entry in EventBridge rules uses the following JSON format.

   ```
   "operationalData": { "/aws/dedup": {"type": "SearchableString","value":
    "{\"dedupString\":\"Words the system should use to check for duplicate
    OpsItems\"}"}}
   ```

   Here is an example.

   ```
   "operationalData": { "/aws/dedup": {"type": "SearchableString","value":
    "{\"dedupString\":\"SSMOpsCenter-EBS-volume-performance-issue\"}"}}
   ```

7. Edit the deduplication strings, and then choose **Confirm**.
8. Choose **Next**.
9. Choose **Next**.
10. Choose **Update rule**.

Specifying a deduplication string using Amazon CLI

You can specify a deduplication string when you manually create a new OpsItem by using either the Amazon Systems Manager console or the Amazon CLI. For information about entering deduplication strings when you manually create an OpsItem in the console, see Create OpsItems manually. If you're using the Amazon CLI, you can enter the deduplication string for the `OperationalData` parameter. The parameter syntax uses JSON, as shown in the following example.

```
--operational-data '{"/aws/dedup":{"Value":"{\"dedupString\": \"Words the system should
 use to check for duplicate OpsItems\"}","Type":"SearchableString"}}'
```

Here is an example command that specifies a deduplication string of `disk full`.

Linux & macOS

```
aws ssm create-ops-item \
    --title "EC2 instance disk full" \
    --description "Log clean up may have failed which caused the disk to be full" \
    --priority 1 \
```

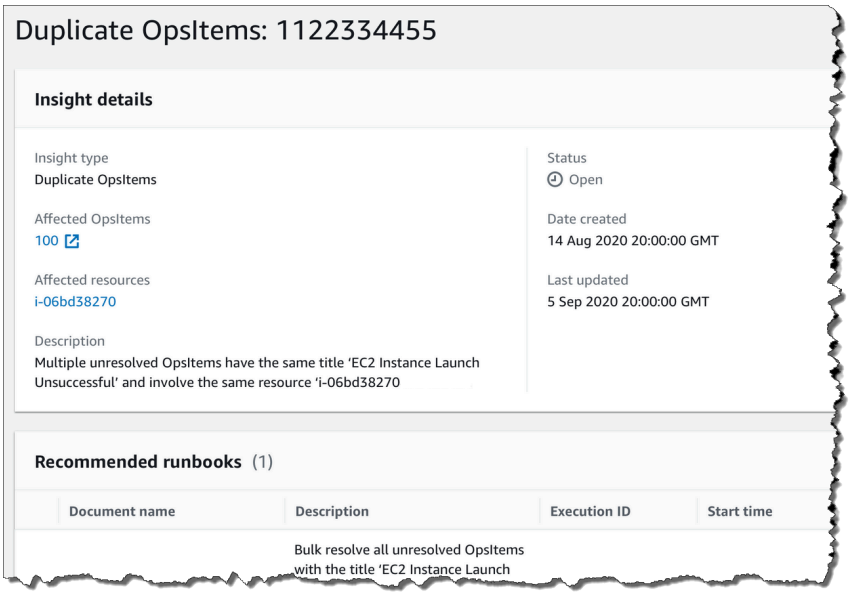
```
    --source ec2 \
    --operational-data '{"/aws/dedup":{"Value":"{\"dedupString\": \"disk full
\"}","Type":"SearchableString"}}' \
    --tags "Key=EC2,Value=ProductionServers" \
    --notifications Arn="arn:aws-cn:sns:us-west-1:12345678:TestUser"
```

Windows

```
aws ssm create-ops-item ^
    --title "EC2 instance disk full" ^
    --description "Log clean up may have failed which caused the disk to be full" ^
    --priority 1 ^
    --source EC2 ^
    --operational-data={\"/aws/dedup\":{\"Value\":\"{\\\"""dedupString\\""":\\"""disk
 full\\"""}\",\"Type\":\"SearchableString\"}} ^
    --tags "Key=EC2,Value=ProductionServers" --notifications Arn="arn:aws-cn:sns:us-
west-1:12345678:TestUser"
```

Analyzing operational insights to reduce OpsItems

OpsCenter *operational insights* display information about duplicate OpsItems. OpsCenter automatically analyzes OpsItems in your account and generates three types of *insights*. You can view this information in the **Operational insights** section of the OpsCenter **Summary** tab.



- **Duplicate OpsItems** – An insight is generated when eight or more OpsItems have the same title for the same resource.
- **Most common titles** – An insight is generated when more than 50 OpsItems have the same title.
- **Resources generating the most OpsItems** – An insight is generated when an Amazon resource has more than 10 open OpsItems. These insights and their corresponding resources are displayed in the **Resources generating the most OpsItems** table on the OpsCenter **Summary** tab. Resources are listed in decreasing order of OpsItem count.

> **Note**
>
> OpsCenter creates **Resources generating the most OpsItems** insights for the following resource types:
>
> - Amazon Elastic Compute Cloud (Amazon EC2) instances

- Amazon EC2 security groups
- Amazon EC2 Auto Scaling group
- Amazon Relational Database Service (Amazon RDS) database
- Amazon RDS cluster
- Amazon Lambda function
- Amazon DynamoDB table
- Elastic Load Balancing load balancer
- Amazon Redshift cluster
- Amazon Certificate Manager certificate
- Amazon Elastic Block Store volume

OpsCenter enforces a limit of 15 insights per type. If a type reaches this limit, OpsCenter stops displaying more insights for that type. To view additional insights, you must resolve all OpsItems associated with an OpsInsight of that type. If a pending insight is prevented from being displayed in the console because of the 15-insight limit, that insight becomes visible after another insight is closed.

When you choose an insight, OpsCenter displays information about the affected OpsItems and resources. The following screenshot shows an example with the details of a duplicate OpsItem insight.

Operational insights are turned off by default. For more information about working with operational insights, see the following topics.

Topics

- Enabling operational insights
- Resolving duplicate OpsItems based on insights
- Disabling operational insights

Enabling operational insights

You can enable operational insights on the **OpsCenter** page in the Systems Manager console. When you enable operational insights, Systems Manager creates an Amazon Identity and Access Management (IAM) service-linked role called `AWSServiceRoleForAmazonSSM_OpsInsights`. A service-linked role is a unique type of IAM role that is linked directly to Systems Manager. Service-linked roles are predefined and include all the permissions that the service requires to call other Amazon Web Services services on your behalf. For more information about the `AWSServiceRoleForAmazonSSM_OpsInsights` service-linked role, see Using roles to create operational insight OpsItems in Systems Manager OpsCenter.

> **Note**
>
> Note the following important information:
>
> - Your Amazon Web Services account is charged for operational insights. For more information, see Amazon Systems Manager Pricing.
> - OpsCenter periodically refreshes insights using a batch process. This means the list of insights displayed in OpsCenter might be out of sync.

Use the following procedure to enable and view operational insights in OpsCenter.

To enable and view operational insights

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.

3. In the **Operational insight is available** message box, choose **Enable**. If you don't see this message, scroll down to the **Operational insights** section and choose **Enable**.
4. After you enable this feature, on the **Summary** tab, scroll down to the **Operational insights** section.
5. To view a filtered list of insights, choose the link beside **Duplicate OpsItems**, **Most common titles**, or **Resources generating the most OpsItems**. To view all insights, choose **View all operational insights**.
6. Choose an insight ID to view more information.

Resolving duplicate OpsItems based on insights

To resolve insights, you must first resolve all OpsItems associated with an insight. You can use the `AWS-BulkResolveOpsItemsForInsight` runbook to resolve OpsItems associated with an insight.

To help you resolve duplicate OpsItems and reduce the number of OpsItems created by a source, Systems Manager provides the following automation runbooks:

- The `AWS-BulkResolveOpsItems` runbook resolves OpsItems that match a specified filter.
- The `AWS-AddOpsItemDedupStringToEventBridgeRule` runbook adds a deduplication string for all OpsItem targets that are associated with a specific Amazon EventBridge rule. This runbook doesn't add a deduplication string if a rule already has one.
- The `AWS-DisableEventBridgeRule` turns off a rule in EventBridge if the rule is generating dozens or hundreds of OpsItems.

To resolve an operational insight

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. On the **Overview** tab, scroll down to **Operational insights**.
4. Choose **View all operational insights**.
5. Choose an insight ID to view more information.
6. Choose a runbook and choose **Execute**.

Disabling operational insights

When you turn off operational insights, the system stops creating new insights and stops displaying insights in the console. Any active insights remain unchanged in the system, although you won't see them displayed in the console. If you enable this feature again, the system displays previously unresolved insights and starts creating new insights. Use the following procedure to turn off operational insights.

To turn off operational insights

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose **Settings**.
4. In the **Operational insights** section, choose **Edit** and then toggle the **Disable** option.
5. Choose **Save**.

Viewing OpsCenter logs and reports

Amazon CloudTrail logs Amazon Systems Manager OpsCenter API calls to the console, the Amazon Command Line Interface (Amazon CLI), and the SDK. You can view the information in the CloudTrail console or in an Amazon Simple Storage Service (Amazon S3) bucket. Amazon S3 uses one bucket to store all CloudTrail logs for your account.

Logs of OpsCenter actions show create, update, get, and describe OpsItem activities. For more information about viewing and using CloudTrail logs of Systems Manager activity, see Logging Amazon Systems Manager API calls with Amazon CloudTrail.

Amazon Systems Manager OpsCenter provides you with the following information about OpsItems:

- **OpsItem status summary** – Provides a summary of OpsItems by status (Open and In progress, Open, or In Progress).
- **Sources with most open OpsItems** – Provides a breakdown of the top Amazon Web Services services with open OpsItems.
- **OpsItems by source and age** – Provides a count of OpsItems, grouped by source and days since creation.

To view the OpsCenter summary report

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. On the OpsItems **Overview** page, choose **Summary**.
4. Under **OpsItems by source and age**, choose the Search bar to filter OpsItems according to **Source**. Use the list to filter according to **Status**.

Delete OpsItems

You can delete an individual OpsItem by calling the DeleteOpsItem API operation using the Amazon Command Line Interface or the Amazon SDK. You can't delete an OpsItem in the Amazon Web Services Management Console. To delete an OpsItem, your Amazon Identity and Access Management (IAM) user, group, or role must have administrator permission or permission to call the `DeleteOpsItem` API operation.

Important

Note the following important information about this operation.

- Deleting an OpsItem is irreversible. You can't restore a deleted OpsItem.
- This operation uses an *eventual consistency model*, which means the system can take a few minutes to complete this operation. If you delete an OpsItem and immediately call, for example, GetOpsItem, the deleted OpsItem might still appear in the response.
- This operation is idempotent. The system doesn't throw an exception if you repeatedly call this operation for the same OpsItem. If the first call is successful, all additional calls return the same successful response as the first call.
- This operation doesn't support cross-account calls. A delegated administrator or management account can't delete OpsItems in other accounts, even if OpsCenter has been set up for cross-account administration. For more information about cross-account administration, see (Optional) Setting up OpsCenter to centrally manage OpsItems across accounts.

- If you receive the `OpsItemLimitExceededException`, you can delete one or more OpsItems to reduce your total number of OpsItems below the quota limits. For more information about this exception, see Troubleshooting issues with OpsCenter.

Deleting an OpsItem

Use the following procedure to delete an OpsItem.

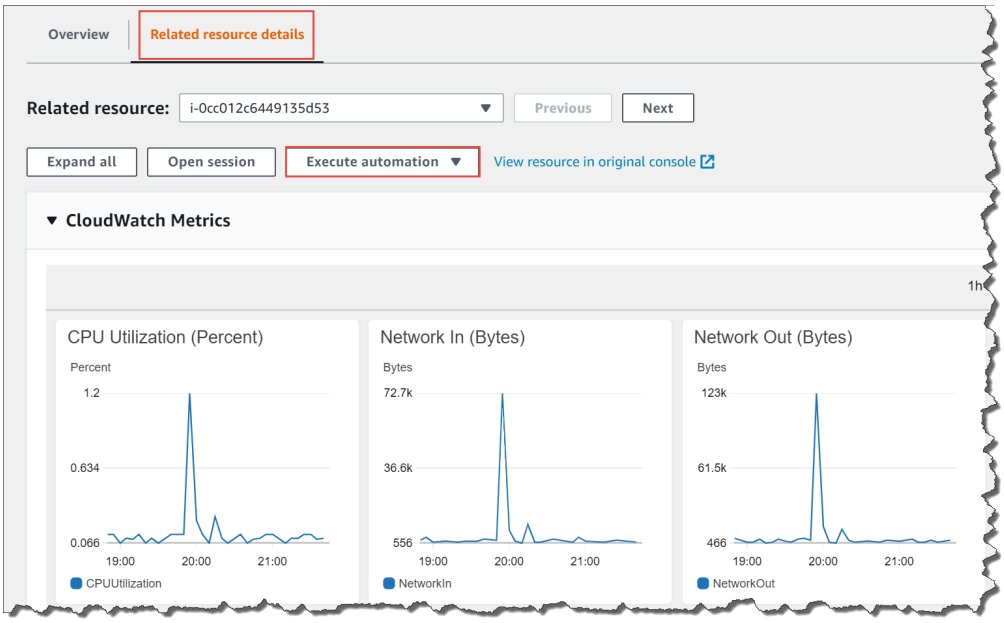
To delete an OpsItem

1. Install and configure the Amazon CLI if you haven't already. For more information, see Installing or updating the latest version of the Amazon CLI.
2. Run the following command. Replace *ID* with the ID of the OpsItem you want to delete.

```
aws ssm delete-ops-item --ops-item-id ID
```

If successful, the command returns no data.

Remediate OpsItem issues



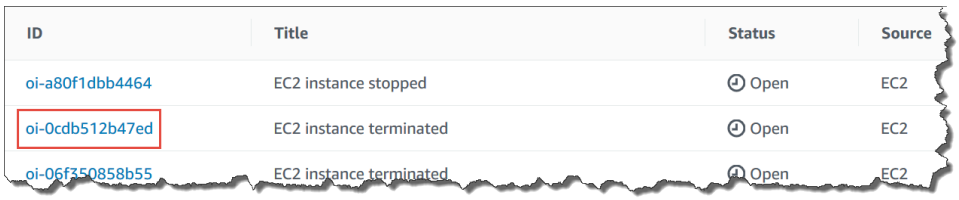
Using Amazon Systems Manager Automation runbooks, you can remediate issues with Amazon resources that are identified in an OpsItem. Automation uses predefined runbooks to remediate common issues with Amazon resources.

Each OpsItem includes the **Runbooks** section that provides a list of runbooks that you can use for remediation. When you choose an Automation runbook from the list, OpsCenter automatically displays some of the fields required to run the document. When you run an Automation runbook, the system associates the runbook with the related resource of the OpsItem. If Amazon EventBridge creates an OpsItem, it associates a runbook with the OpsItem. OpsCenter keeps a 30-day record of Automation runbooks for an OpsItem.

You can choose a status to view important details about the runbook, such as the reason why an automation failed and which step of the Automation runbook was running when the failure occurred, as shown in the following example.

The **Related resource details** page for a selected OpsItem includes the **Run automation** list. You can choose recent or resource-specific Automation runbooks and run them to remediate issues. This page also includes data providers, including Amazon CloudWatch metrics and alarms, Amazon CloudTrail logs, and details from Amazon Config.

You can view information about an Automation runbook by either choosing its name in the console or by using the Systems Manager Automation Runbook Reference.



Remediating an OpsItem using a runbook

Before you use an Automation runbook to remediate an OpsItem issue, do the following:

- Verify that you have permission to run Systems Manager Automation runbooks. For more information, see Setting up Automation.
- Collect resource-specific ID information for the automation that you want to run. For example, if you want to run an automation that restarts an EC2 instance, then you must specify the ID of the EC2 instance to restart.

To run an Automation runbook to remediate an OpsItem issue

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose the OpsItem ID to open the details page.

4. Scroll to the **Runbooks** section.
5. Use the search bar or the numbers in the upper right to find the Automation runbook that you want to run.
6. Choose a runbook, and then choose **Execute**.
7. Enter the required information for the runbook, and then choose **Submit**.

   Once you start the runbook, the system returns to the previous screen and displays the status.
8. In the **Automation executions in the last 30 days** section, choose the **Execution ID** link to view steps and the status of the execution.

Remediating an OpsItem using an associated runbook

After you run an Automation runbook from an OpsItem, OpsCenter associates the runbook with the OpsItem. An *associated* runbook is ranked higher than other runbooks in the **Runbooks** list.

Use the following procedure to run an Automation runbook that has already been associated with a related resource in an OpsItem. For information about adding related resources, see Manage OpsItems.

To run a resource-associated runbook to remediate an OpsItem issue

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Open the OpsItem.
4. In the **Related resources** section, choose the resource on which you want to run the Automation runbook.
5. Choose **Run automation**, and then choose the associated Automation runbook that you want to run.
6. Enter the required information for the runbook, and then choose **Execute**.

   Once you start the runbook, the system returns to the previous screen and displays the status.
7. In the **Automation executions in the last 30 days** section, choose the **Execution ID** link to view steps and the status of the execution.

Viewing OpsCenter summary reports

Amazon Systems Manager OpsCenter includes a summary page that automatically displays the following information:

- **OpsItem status summary** – A summary of OpsItems by status, such as `Open` and `In progress`.
- **Sources with most open OpsItems** – A breakdown of the top Amazon Web Services services that have open OpsItems.
- **OpsItems by source and age** – A count of OpsItems, grouped by source and number of days since creation.

To view OpsCenter summary reports

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**, and then choose the **Summary** tab.
3. In the **OpsItems by source and age** section, do the following:
    1. (Optional) In the filter field, choose **Source**, select `Equal`, `Begin With`, or `Not Equal`, and then enter a search parameter.
    2. In the adjacent list, select one of the following status values:
        - `Open`
        - `In progress`
        - `Resolved`
        - `Open and in progress`
        - `All`

Troubleshooting issues with OpsCenter

This topic includes information to help you troubleshoot common errors and issues with OpsCenter.

You receive the OpsItemLimitExceededException

If your Amazon Web Services account has reached the maximum number of OpsItems allowed when you call the CreateOpsItem API operation, you receive an `OpsItemLimitExceededException`. OpsCenter returns the exception if your call would exceed the maximum number of OpsItems for either of the following quotas:

- Total number of OpsItems per Amazon Web Services account per Region (including `Open` and `Resolved` OpsItems): 500,000
- Maximum number of OpsItems per Amazon Web Services account per month: 10,000

These quotas apply to OpsItems created from any source, including OpsItems created by Amazon Security Hub CSPM findings. If your account reaches either quota, you can't create new OpsItems from any source, including Security Hub CSPM findings, until your account is below the quota.

OpsItems that are auto-generated when an Incident Manager incident is opened don't count against your OpsItem quotas, but you are charged for each OpsItem.

If you receive an `OpsItemLimitExceededException`, you can manually delete OpsItems until you are below the quota preventing you from creating a new OpsItem. Deleting OpsItems created for Incident Manager incidents won't reduce your total number of OpsItems enforced by the quotas. You must delete OpsItems from other sources. For information about how to delete an OpsItem, see Delete OpsItems.

If you need higher quotas, you can request an increase for the **Total OpsItems** and **OpsItems per month** quotas in the Service Quotas console. For more information, see Requesting a quota increase in the *Service Quotas User Guide*.

You receive a large bill from Amazon for large numbers of auto-generated OpsItems

If you configured integration with Amazon Security Hub CSPM, OpsCenter creates OpsItems for Security Hub CSPM findings. Depending on the number of finding Security Hub CSPM generates and the account you were logged into when you configured integration, OpsCenter can generate large numbers of OpsItems, at a cost. Here are more specific details related to OpsItems generated by Security Hub CSPM findings:

- If you are logged into the Security Hub CSPM administrator account when you configure OpsCenter and Security Hub CSPM integration, the system creates OpsItems for findings in the administrator *and* all member accounts. The OpsItems are all created *in the administrator account*. Depending on a variety of factors, this can lead to an unexpectedly large bill from Amazon.

  If you are logged into a member account when you configure integration, the system only creates OpsItems for findings in that individual account. For more information about the Security Hub CSPM administrator account, member accounts, and their relation to the EventBridge event feed for findings, see Types of Security Hub CSPM integration with EventBridge in the *Amazon Security Hub User Guide*.
- For each finding that creates an OpsItem, you are charged the regular price for creating the OpsItem. You are also charged if you edit the OpsItem or if the corresponding finding is updated in Security Hub CSPM (which triggers an OpsItem update).
- OpsItems that are created by an integration with Amazon Security Hub CSPM count toward the OpsItem quotas of 500,000 total OpsItems and 10,000 OpsItems per month for each account in a Region. If your account reaches either quota, you can't create new OpsItems from any

source, including Security Hub CSPM findings, until your account is below the quota. For more information, see You receive the OpsItemLimitExceededException.

For high-production environments, we recommend limiting the scope of Security Hub CSPM findings to high severity issues only.

> **Important**
>
> If you believe a large number of OpsItems were created in error and your Amazon bill is unwarranted, contact Amazon Web Services Support.

Use the following procedure if you no longer want the system to create OpsItems for Security Hub CSPM findings.

To stop receiving OpsItems for Security Hub CSPM findings

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **OpsCenter**.
3. Choose **Settings**.
4. In the **Security Hub CSPM findings** section, choose **Edit.**
5. Choose the slider to change **Enabled** to **Disabled**. If you can't toggle the slider, Security Hub CSPM hasn't been enabled for your Amazon Web Services account.
6. Choose **Save** to save your configuration. OpsCenter no longer creates OpsItems based on Security Hub CSPM findings.

> **Important**
>
> If OpsCenter toggles the setting back to **Enabled** and continues to create OpsItems for findings, log into the Systems Manager delegated administrator account or the Amazon Organizations management account and repeat this procedure. If you don't have permission to log into either of those accounts, contact your administrator and ask them to repeat this procedure to disable integration for your account.

Working with SSM Agent

Amazon Systems Manager Agent (SSM Agent) is Amazon software that runs on Amazon Elastic Compute Cloud (Amazon EC2) instances, edge devices, on-premises servers, and virtual machines (VMs). SSM Agent makes it possible for Systems Manager to update, manage, and configure these resources. The agent processes requests from the Systems Manager service in the Amazon Web Services Cloud, and then runs them as specified in the request. SSM Agent then sends status and execution information back to the Systems Manager service by using the Amazon Message Gateway Service (`ssmmessages`). (In Amazon Web Services Regions launched before 2024, status and execution information might also be sent back by the Amazon Message Delivery Service (service prefix: `ec2messages`).)

If you monitor traffic, you see that your managed nodes communicate with `ssmmessages.*` endpoints and possibly `ec2messages.*` endpoints. For more information, see Reference: ec2messages, ssmmessages, and other API operations. For information about porting SSM Agent logs to Amazon CloudWatch Logs, see Logging and monitoring in Amazon Systems Manager.

- Understanding SSM Agent hibernation

SSM Agent version 3.2.x.x credential behavior

SSM Agent stores a set of temporary credentials at `/var/lib/amazon/ssm/credentials` (for Linux and macOS) or `%PROGRAMFILES%\Amazon\SSM\credentials` (for Windows Server) when an instance is onboarded using the Default Host Management Configuration in Quick Setup. The temporary credentials have the permissions you specify for the IAM role you chose for Default Host Management Configuration. On Linux, only the root account can access these credentials. On Windows Server, only the SYSTEM account and local Administrators can access these credentials.

SSM Agent credentials precedence

This topic describes important information about how SSM Agent is granted permission to perform actions on your resources.

> **Note**
>
> Support for edge devices differs slightly. You must configure your edge devices to use Amazon IoT Greengrass Core software, configure an Amazon Identity and Access Management (IAM) service role, and deploy SSM Agent to your devices by using Amazon IoT Greengrass. For more information, see Managing edge devices with Systems Manager.

When SSM Agent is installed on a machine, it requires permissions in order to communicate with the Systems Manager service. On Amazon Elastic Compute Cloud (Amazon EC2) instances, these permissions are provided in an instance profile that is attached to the instance. On a non-EC2 machine, SSM Agent normally gets the needed permissions from the shared credentials file, located at `/root/.aws/credentials` (Linux and macOS) or `%USERPROFILE%\.aws\credentials` (Windows Server). The needed permissions are added to this file during the hybrid activation process. If a hybrid-activated node is deregistered, the agent may enter hibernation mode. For more information, see Understanding SSM Agent hibernation.

In rare cases, however, a machine might end up with permissions added to more than one of the locations where SSM Agent checks for permissions to run its tasks.

For example, say that you have configured an EC2 instance to be managed by Systems Manager. That configuration includes attaching an instance profile. But then you decide to also use that instance for developer or end-user tasks and install the Amazon Command Line Interface (Amazon CLI) on it. This installation results in additional permissions being added to a credentials file on the instance.

When you run a Systems Manager command on the instance, SSM Agent might try to use credentials different from the ones you expect it to use, such as from a credentials file instead of an instance profile. This is because SSM Agent looks for credentials in the order prescribed for the *default credential provider chain*.

> **Note**
>
> On Linux and macOS, SSM Agent runs as the root user. Therefore, the environment variables and credentials file that SSM Agent looks for in this process are those of the root user only (`/root/.aws/credentials`). SSM Agent doesn't look at the environment variables or credentials file of any other users on the instance during the search for credentials.

The default provider chain looks for credentials in the following order:

1. Environment variables, if configured (`AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`).
2. Shared credentials file (`$HOME/.aws/credentials` for Linux and macOS or `%USERPROFILE%\.aws\credentials` for Windows Server) with permissions provided by, for example, a hybrid activation or an Amazon CLI installation.
3. An Amazon Identity and Access Management (IAM) role for tasks if an application is present that uses an Amazon Elastic Container Service (Amazon ECS) task definition or **RunTask** API operation.
4. An instance profile attached to an Amazon EC2 instance.
5. The IAM role chosen for Default Host Management Configuration.

For related information, see the following topics:

- Instance profiles for EC2 instances – Configure instance permissions required for Systems Manager
- Hybrid activations – Create a hybrid activation to register nodes with Systems Manager
- Amazon CLI credentials – Configuration and credential file settings in the *Amazon Command Line Interface User Guide*
- Default credential provider chain – Specifying Credentials in the *Amazon SDK for Go Developer Guide*

> **Note**
>
> This topic in the *Amazon SDK for Go Developer Guide* describes the default provider chain in terms of the SDK for Go; however, the same principles apply to evaluating credentials for SSM Agent.

Configuring SSM Agent for use with the Federal Information Processing Standard (FIPS)

If you need to use Systems Manager with Federal Information Processing Standard (FIPS) 140-3 validated cryptographic modules, you can configure Amazon Systems Manager Agent (SSM Agent) to use the FIPS endpoints in supported Regions.

To configure SSM Agent to connect to FIPS 140-3 endpoints

1. Connect to your managed node.
2. Navigate to the directory that contains the `amazon-ssm-agent.json` file:
   - Linux: `/etc/amazon/ssm/`
   - macOS: `/opt/aws/ssm/`
   - Windows Server: `C:\Program Files\Amazon\SSM\`
3. Open the file named `amazon-ssm-agent.json` for editing.

> **Tip**
>
> If no `amazon-ssm-agent.json` file exists yet, copy the contents of `amazon-ssm-agent.json.template` to a new file named `amazon-ssm-agent.json`. Save `amazon-ssm-agent.json` in the same directory where `amazon-ssm-agent.json.template` is located.

4. Add the following content to the file. Replace the *region* placeholder values with the appropriate Region code for your partition:

```
{
    ---Existing file content, if any---
    "Mds": {
        "Endpoint": "ec2messages-fips.region.amazonaws.com",
    },
    "Ssm": {
        "Endpoint": "ssm-fips.region.amazonaws.com",
    },
    "Mgs": {
        "Endpoint": "ssmmessages-fips.region.amazonaws.com",
        "Region": "region"
    },
    "S3": {
        "Endpoint": "s3-fips.dualstack.region.amazonaws.com",
        "Region": region"
    },
    "Kms": {
        "Endpoint": "kms-fips.region.amazonaws.com"
    }
}
```

Supported Regions include the following:

- `us-east-1` for the US East (N. Virginia) Region
- `us-east-2` for the US East (Ohio) Region
- `us-west-1` for the US West (N. California) Region
- `us-west-2` for the US West (Oregon) Region
- `ca-west-1` for the Canada West (Calgary) Region

5. Save the file and restart SSM Agent.

Every time you change the configuration, restart SSM Agent.

You can customize other features of SSM Agent using the same procedure. For an up-to-date list of the available configuration properties and their default values, see Config Property Definitions in the `amazon-ssm-agent` repository in GitHub.

For more information about Amazon support for FIPS, see Federal Information Processing Standard (FIPS) 140-3.

About the local ssm-user account

Starting with version 2.3.50.0 of SSM Agent, the agent creates a local user account called `ssm-user` and adds it to the `/etc/sudoers.d` directory (Linux and macOS) or to the Administrators group (Windows Server). On agent versions before 2.3.612.0, the account is created the first time SSM Agent starts or restarts after installation. On version 2.3.612.0 and later, the `ssm-user` account is created the first time a session is started on an instance. This `ssm-user` is the default OS user when a session starts in Session Manager. You can change the permissions by moving `ssm-user` to a less-privileged group or by changing the `sudoers` file. The `ssm-user` account isn't removed from the system when SSM Agent is uninstalled.

On Windows Server, SSM Agent handles setting a new password for the `ssm-user` account when the SSM Agent starts and when each session starts. No passwords are set for `ssm-user` on Linux managed instances.

Starting with SSM Agent version 2.3.612.0, the `ssm-user` account isn't created automatically on Windows Server machines that are being used as domain controllers. To use Session Manager on a Windows Server domain controller, create the `ssm-user` account manually if it isn't already present, and assign Domain Administrator permissions to the user.

Important

For the `ssm-user` account to be created, the instance profile attached to the instance must provide the necessary permissions. For information, see Step 2: Verify or add instance permissions for Session Manager.

SSM Agent and the Instance Metadata Service (IMDS)

Systems Manager relies on EC2 instance metadata to function correctly. Systems Manager can access instance metadata using either version 1 or version 2 of the Instance Metadata Service (IMDSv1 and IMDSv2). Your instance must be able to access IPv4 address of the instance metadata service: 169.254.169.254. For more information, see Instance metadata and user data in the *Amazon EC2 User Guide*.

Keeping SSM Agent up-to-date

An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Note

An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Amazon Machine Images (AMIs) that include SSM Agent by default can take up to two weeks to be updated with the newest version of SSM Agent. We recommend that you configure even more frequent automated updates to SSM Agent.

Ensuring that the SSM Agent installation directory is not modified, moved, or deleted

SSM Agent is installed at `/var/lib/amazon/ssm/` (Linux and macOS) and `%PROGRAMFILES%\Amazon\SSM\` (Windows Server). These installation directories contain critical files and folders used by SSM Agent, such as a credentials file, resources for inter-process communication (IPC), and orchestration folders. Nothing within the installation directory should be modified, moved, or deleted. Otherwise, SSM Agent might cease to function properly.

SSM Agent rolling updates by Amazon Web Services Regions

After an SSM Agent update is made available in its GitHub repository, it can take up to two weeks until the updated version is rolled out to all Amazon Web Services Regions at different times. For this reason, you might receive the "Unsupported on current platform" or "updating amazon-ssm-agent to an older version, please turn on allow downgrade to proceed" error when trying to deploy a new version of SSM Agent in a Region.

To determine the version of SSM Agent available to you, you can run a `curl` command.

To view the version of the agent available in the global download bucket, run the following command.

```
curl https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/VERSION
```

To view the version of the agent available in a specific Region, run the following command, substituting *`region`* with the Region you're working in, such as `us-east-2` for the US East (Ohio) Region.

```
curl https://s3.region.amazonaws.com/amazon-ssm-region/latest/VERSION
```

You can also open the `VERSION` file directly in your browser without a `curl` command.

SSM Agent communications with Amazon managed S3 buckets

In the course of performing various Systems Manager operations, Amazon Systems Manager Agent (SSM Agent) accesses several Amazon Simple Storage Service (Amazon S3) buckets. These S3 buckets are publicly accessible, and by default, SSM Agent connects to them using `HTTP` calls.

However, if you're using a virtual private cloud (VPC) endpoint in your Systems Manager operations, you must provide explicit permission in an Amazon Elastic Compute Cloud (Amazon EC2) instance profile for Systems Manager, or in a service role for non-EC2 machines in a hybrid and multicloud environment. Otherwise, your resources can't access these public buckets.

To grant your managed nodes access to these buckets when you are using a VPC endpoint, you create a custom Amazon S3 permissions policy, and then attach it to your instance profile (for EC2 instances) or your service role (for non-EC2 managed nodes).

For information about using a virtual private cloud (VPC) endpoint in your Systems Manager operations, see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

> **Note**
>
> These permissions only provide access to the Amazon managed buckets required by SSM Agent. They don't provide the permissions that are necessary for other Amazon S3 operations. They also don't provide permission to your own S3 buckets.

For more information, see the following topics:

- Configure instance permissions required for Systems Manager
- Create the IAM service role required for Systems Manager in hybrid and multicloud environments
- Reference: Amazon S3 buckets for patching operations

Contents

- Required bucket permissions
- Example
- Validating hybrid-activated machines using a hardware fingerprint

Required bucket permissions

The following table describes each of the S3 buckets that SSM Agent might need to access for Systems Manager operations.

Note

region represents the identifier for an Amazon Web Services Region supported by Amazon Systems Manager, such as us-east-2 for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

Amazon S3 permissions required by SSM Agent

S3 bucket ARN	Description
arn:aws-cn:s3:::aws-windows-downloads- *region*/*	Required for some SSM documents that support only Windows Server operating systems, plus some for cross-platform support, such as AWSEC2-ConfigureSTIG .
arn:aws-cn:s3:::amazon-ssm- *region*/*	Required for updating SSM Agent installations. These buckets contain the SSM Agent installation packages, and the installation manifests that are referenced by the AWS-UpdateSSMAgent document and plugin. If these permissions aren't provided, the SSM Agent makes an HTTP call to download the update.
arn:aws-cn:s3:::aws-ssm- *region*/*	Provides access to the S3 bucket containing modules required for use with Systems Manager documents (SSM Command documents), including both non-patching and patching operations. For example: arn:aws-cn:s3:::aws-ssm-us-east-2/* . The following are some commonly used SSM documents that use modules from these buckets. • AWS-RunPatchBaseline

S3 bucket ARN	Description
	• AWS-RunPatchBaselineAssociation • AWS-RunPatchBaselineWithHooks • AWS-ApplyPatchBaseline (a legacy SSM document) • AWS-ConfigureWindowsUpdate • AWS-FindWindowsUpdates • AWS-UpdateSSMAgent

S3 bucket ARN	Description

`arn:aws-cn:s3:::patch-baseline-snapshot-` *region*`/*`
 	
-or-
 	
`arn:aws-cn:s3:::patch-baseline-snapshot-` *region*`-`*unique-suffix*` /*`
	Provides access to the S3 bucket containing patch baseline snapshots. This is required if you use any of the following SSM Command documents:
	
	• `AWS-RunPatchBaseline`
	• `AWS-RunPatchBaselineAssociation`
	• `AWS-RunPatchBaselineWithHooks`
	• `AWS-ApplyPatchBaseline` (a legacy SSM document)
	
	The buckets for most supported Amazon Web Services Regions use the following format:
	
	`arn:aws-cn:s3:::patch-baseline-snapshot-` *region*
	
	For some Regions, an additional unique suffix is included in the bucket name. For example, the bucket name for the Middle East (Bahrain) Region (me-south-1) is as follows:
	
	• `patch-baseline-snapshot-me-south-1-uduvl7q8`
	
	For a complete list of patch baseline snapshot bucket names, see Buckets containing Amazon managed patch baseline snapshots.
	
	Note
	If you use an on-premises firewall and plan to use Patch Manager, that

S3 bucket ARN	Description
	firewall must also allow access to the appropriate patch baseline endpoint.

S3 bucket ARN	Description
For Linux and Windows Server managed nodes: `arn:aws-cn:s3:::aws-patch-manager-` *region-unique-suffix* `/*` For Amazon EC2 instances for macOS: `arn:aws-cn:s3:::aws-patchmanager-macos-` *region-unique-suffix* `/*`	Provides access to the S3 bucket containing modules used by SSM Command documents for patching operations in Patch Manager. Each bucket name includes a unique suffix, such as `552881074` for buckets in the US East (Ohio) (us-east-2) Region: • `arn:aws-cn:s3:::aws-patch-manager-us-east-2-552881074/*` • `arn:aws-cn:s3::: aws-patch-manager-macos-us-east-2-552881074/*` **SSM documents** The following are some commonly used SSM documents that use modules from these buckets. • `AWS-RunPatchBaseline` • `AWS-RunPatchBaselineAssociation` • `AWS-RunPatchBaselineWithHooks` • `AWS-InstanceRebootWithHooks` • `AWS-PatchAsgInstance` • `AWS-PatchInstanceWithRollback` For complete lists of Amazon managed S3 buckets for patching operations, see the following topics:

S3 bucket ARN	Description
	• Buckets containing SSM Command documents for patching operations (Linux and Windows Server) • Buckets containing SSM Command documents for patching operations (macOS)
`arn:aws-cn:s3::: region-birdwatcher-prod/*`	Required for Distributor operations. This bucket contains package manifests used by the `aws:configurePackage` plugin when installing or updating Distributor packages using documents such as `AWS-ConfigureAWSPackage`. If you are using a VPC endpoint, your S3 VPC endpoint policy must include access to this bucket.

Example

The following example illustrates how to provide access to the S3 buckets required for Systems Manager operations in the US East (Ohio) Region (us-east-2). In most cases, you need to provide these permissions explicitly in an instance profile or service role only when using a VPC endpoint.

> **Important**
>
> We recommend that you avoid using wildcard characters (*) in place of specific Regions in this policy. For example, use `arn:aws:s3:::aws-ssm-us-east-2/*` and don't use `arn:aws:s3:::aws-ssm-*/*`. Using wildcards could provide access to S3 buckets that you don't intend to grant access to. If you want to use the instance profile for more than one Region, we recommend repeating the first `Statement` block for each Region.

JSON

```
{
        "Version":"2012-10-17",
        "Statement": [
```

*"
                ]
            }
        ]
    }
```

Validating hybrid-activated machines using a hardware fingerprint

When non-EC2 machines in a hybrid and multicloud environment, SSM Agent gathers a number of system attributes (referred to as the *hardware hash*) and uses these attributes to compute a *fingerprint*. The fingerprint is an opaque string that the agent passes to certain Systems Manager APIs. This unique fingerprint associates the caller with a particular hybrid-activated managed node. The agent stores the fingerprint and hardware hash on the local disk in a location called the *Vault*.

The agent computes the hardware hash and fingerprint when the machine is registered for use with Systems Manager. Then, the fingerprint is passed back to the Systems Manager service when the agent sends a `RegisterManagedInstance` command.

Later, when sending a `RequestManagedInstanceRoleToken` command, the agent checks the fingerprint and hardware hash in the Vault to make sure that the current machine attributes match with the stored hardware hash. If the current machine attributes do match the hardware hash stored in the Vault, the agent passes in the fingerprint from the Vault to `RegisterManagedInstance`, resulting in a successful call.

If the current machine attributes don't match the stored hardware hash, SSM Agent computes a new fingerprint, stores the new hardware hash and fingerprint in the Vault, and passes the new fingerprint to `RequestManagedInstanceRoleToken`. *This causes `RequestManagedInstanceRoleToken` to fail, and the agent won't be able to obtain a role token to connect to the Systems Manager service.*

This failure is by design and is used as a verification step to prevent multiple managed nodes from communicating with the Systems Manager service as the same managed node.

When comparing the current machine attributes to the hardware hash stored in the Vault, the agent uses the following logic to determine whether the old and new hashes match:

- If the SID (system/machine ID) is different, then no match.
- Otherwise, if the IP address is the same, then match.
- Otherwise, the percentage of machine attributes that match is computed and compared with the user-configured similarity threshold to determine whether there is a match.

The similarity threshold is stored in the Vault, as part of the hardware hash.

The similarity threshold can be set after an instance is registered using a command like the following.

On Linux machines:

```
sudo amazon-ssm-agent -fingerprint -similarityThreshold 1
```

On Windows Server machines using PowerShell:

```
cd "C:\Program Files\Amazon\SSM\" `
    .\amazon-ssm-agent.exe -fingerprint -similarityThreshold 1
```

Important

If one of the components used to calculate the fingerprint changes, this can cause the agent to hibernate. To help avoid this hibernation, set the similarity threshold to a low value, such as **1**. For more information about hibernation, see Understanding SSM Agent hibernation.

SSM Agent on GitHub

The source code for SSM Agent is available on GitHub so that you can adapt the agent to meet your needs. We encourage you to submit pull requests for changes that you would like to have

included. However, Amazon Web Services doesn't provide support for running modified copies of this software.

Understanding SSM Agent hibernation

Amazon Systems Manager Agent (SSM Agent) hibernation is an operational mode that occurs when the agent can't maintain proper communication with the Systems Manager service. During hibernation, the agent reduces its communication frequency and enters a standby state.

When SSM Agent hibernation occurs

SSM Agent hibernation can occur in the following scenarios:

Deregistered hybrid nodes

When you deregister a hybrid-activated node from Systems Manager, the SSM Agent on that node can't refresh its authorization token. This causes the agent to enter hibernation mode because it can't authenticate with the service.

Hardware fingerprint changes

SSM Agent uses a hardware fingerprint to validate hybrid-activated machines. If one of the components used to calculate this fingerprint changes significantly, the agent might hibernate as a security measure. This is by design to prevent multiple managed nodes from communicating with Systems Manager as the same node. For more information, see Validating hybrid-activated machines using a hardware fingerprint.

SSM Agent hibernation on Amazon EC2 instances

Hibernation can also occur on Amazon EC2 instances under certain conditions, such as when there are connectivity issues or authentication problems with the Systems Manager service.

Hibernation communication behavior

When SSM Agent enters hibernation mode, its communication pattern with the Systems Manager service changes:

- **Normal operation**: The agent regularly communicates with Systems Manager (typically every few minutes) to check for new commands and report status.
- **Hibernation mode**: The ping frequency starts at 5 minutes and gradually increases to once per hour by default (configurable up to 24 hours). This reduced communication frequency helps

minimize unnecessary network traffic while still allowing the agent to potentially recover if conditions change.

During hibernation, the agent continues to retry authentication and connection attempts at the reduced frequency, but it can't process new commands or report detailed status information until hibernation is resolved.

Configuration options to prevent hibernation in hybrid instances

The primary configuration option to help prevent hibernation caused by hardware fingerprint changes is adjusting the similarity threshold:

On Linux machines:

```
sudo amazon-ssm-agent -fingerprint -similarityThreshold 1
```

On Windows Server machines using PowerShell:

```
cd "C:\Program Files\Amazon\SSM\" `
.\amazon-ssm-agent.exe -fingerprint -similarityThreshold 1
```

The similarity threshold determines how strictly the agent compares current machine attributes with the stored hardware hash:

- Higher values require more matching attributes
- Lower values (such as **1**) are more lenient and can help avoid hibernation caused by minor hardware changes

Hibernation logging and monitoring

When SSM Agent enters hibernation mode, it creates log entries that can help you identify and troubleshoot the hibernation state:

- **Agent log files**: Hibernation events are logged in the standard SSM Agent log files. For more information about log file locations, see Troubleshoot issues using SSM Agent log files.
- **Amazon EC2 console logging**: For EC2 instances, hibernation messages are now logged to the Amazon EC2 console system logs, providing additional visibility into agent status. To

access the logs, select the instance in the EC2 console, and then choose **Actions**, **Monitor and troubleshoot**, **Get system log**.

- **Specific log files**: When hibernation starts, particular log files are created that contain detailed information about the hibernation trigger and status.

Monitor these log sources to detect hibernation events early and take corrective action to restore normal agent operation.

Recovering from hibernation

To recover from hibernation, address the underlying cause:

- **For deregistered hybrid nodes**: Reregister the node with Systems Manager using a new activation code and ID, as described in the section called “Deregister and reregister a managed node (Linux)” and the section called “Deregister and reregister a managed node (Windows Server)”.
- **For hardware fingerprint issues**: Adjust the similarity threshold as described above under **Configuration options to prevent hibernation in hybrid instances**, or re-register the node if hardware changes are significant.
- **For connectivity issues**: Verify network connectivity and make sure the required endpoints are accessible. For more information, see Troubleshooting managed node availability using `ssm-cli`.

After you resolve the underlying issue, the agent should automatically exit hibernation mode and resume normal operation at the next communication attempt.

Find AMIs with the SSM Agent preinstalled

Amazon Systems Manager Agent (SSM Agent) is preinstalled on some Amazon Machine Images (AMIs) provided by Amazon and trusted third-parties.

For example, when you launch an Amazon Elastic Compute Cloud (Amazon EC2) instance created from an AMI with one of the following operating systems, you'll likely find that the SSM Agent is already installed:

- AlmaLinux
- Amazon Linux 2

- Amazon Linux 2 ECS-Optimized Base AMIs
- Amazon Linux 2023 (AL2023)
- Amazon EKS-Optimized Amazon Linux AMIs
- macOS 13.x (Ventura), 14.x (Sonoma), and 15.x (Sequoia)
- SUSE Linux Enterprise Server (SLES) 15.3 and later
- Ubuntu Server 18.04, 20.04, 22.04 LTS, 24.04 LTS, 24.0, and 25.04
- Windows Server 2012 R2 AMIs published in November 2016 or later
- Windows Server 2016, 2019, 2022 (excluding Nano versions), and 2025

> **Note**
>
> The version of SSM Agent preinstalled on an AMI might not be the latest available version. As a best practice, we recommend always using the latest available version of SSM Agent on your managed nodes. For more information about automating SSM Agent updates, see Automating updates to SSM Agent.
>
> SSM Agent might be preinstalled on Amazon managed AMIs that aren't on this list. This typically indicates that the operating system (OS) is not fully supported by all Systems Manager tools.
>
> SSM Agent might also be preinstalled on AMIs found in Amazon Web Services Marketplace or in the Community AMIs repository, but Amazon doesn't support these AMIs.

Verify the status of SSM Agent

Depending on when it was initialized, an instance created from an AMI on the preceding list might not have SSM Agent preinstalled. It's also possible that an instance has the agent preinstalled, but the agent isn't running. Therefore, we recommend that you check the status of SSM Agent before you try to use Systems Manager on an instance for the first time.

Use the following procedure to verify that SSM Agent is installed and running on an instance. If you find that the agent is not installed, you can manually install it on Linux, macOS, and Windows Server instances.

To verify installation of SSM Agent on an instance

1. After launching a new instance, wait a few minutes for it to initialize.

2. Connect to the instance using your preferred method. For example, you can use SSH to connect to Linux instances or use Remote Desktop to connect to Windows Server instances.
3. Check the status of SSM Agent by running the command for your instance's operating system type.

Operating system	Command
Amazon Linux 2 and Amazon Linux 2023	`sudo systemctl status amazon-ssm-agent`
macOS	There is no command to check SSM Agent status on macOS. You can check the status by locating and evaluating the agent log file `/var/log/amazon/ssm/amazon-ssm-agent.log` .
SUSE Linux Enterprise Server	`sudo systemctl status amazon-ssm-agent`
Ubuntu Server (64-bit - Deb)	`sudo systemctl status amazon-ssm-agent`
Ubuntu Server (64-bit - Snap)	`sudo systemctl status snap.amazon-ssm-agent.amazon-ssm-agent.service`
Windows Server	`Get-Service AmazonSSMAgent`

> **Tip**
>
> To view the commands for checking SSM Agent status on all operating system types supported by Systems Manager, see Checking SSM Agent status and starting the agent.

4. Evaluate the command output to learn the status of the SSM Agent.

   Status: *Installed and running*

   In most cases, the command output indicates that the agent is installed and running.

The following example shows that SSM Agent is installed and running on an Amazon Linux 2 instance.

```
amazon-ssm-agent.service - amazon-ssm-agent
Loaded: loaded (/usr/lib/systemd/system/amazon-ssm-agent.service; enabled; vendor
 preset: enabled)
Active: active (running) since Wed 2021-10-20 19:09:29 UTC; 4min 6s ago
--truncated--
```

The following example shows that SSM Agent is installed and running on a Windows Server instance.

```
Status   Name               DisplayName
------   ----               -----------
Running  AmazonSSMAgent     Amazon SSM Agent
```

Status: *Installed but not running*

In some cases, the command output indicates that the agent is installed but not running.

The following example shows that SSM Agent is installed but not running on an Amazon Linux 2 instance.

```
amazon-ssm-agent.service - amazon-ssm-agent
Loaded: loaded (/usr/lib/systemd/system/amazon-ssm-agent.service; enabled; vendor
 preset: enabled)
Active: inactive (dead) since Wed 2021-10-20 22:16:41 UTC; 18s ago
--truncated--
```

The following example shows that SSM Agent is installed but not running on a Windows Server instance.

```
Status   Name               DisplayName
------   ----               -----------
Stopped  AmazonSSMAgent     Amazon SSM Agent
```

If the agent is installed but not running, you can activate it manually using the commands for your instance's operating system type.

Operating system	Command

Amazon Linux 2 and Amazon Linux 2023	`sudo systemctl enable amazon-ssm-agent`
	
	`sudo systemctl start amazon-ssm-agent`

macOS	`sudo launchctl load -w /Library/LaunchDaemons/com.amazon.aws.ssm.plist`
	
	`sudo launchctl start com.amazon.aws.ssm`

SUSE Linux Enterprise Server	`sudo systemctl enable amazon-ssm-agent`
	
	`sudo systemctl start amazon-ssm-agent`

Ubuntu Server (64-bit - Deb)	`sudo systemctl enable amazon-ssm-agent`
	
	`sudo systemctl start amazon-ssm-agent`

Ubuntu Server (64-bit - Snap)	`sudo snap start amazon-ssm-agent`
Windows Server	Run the following command in PowerShell. `Start-Service AmazonSSMAgent`

Status: *Not installed*

In some cases, the command output indicates that the agent is not installed.

The following example shows that SSM Agent is not installed on an Amazon Linux 2 instance.

```
Unit amazon-ssm-agent.service could not be found.
```

The following example shows that SSM Agent is not installed on a Windows Server instance.

```
Get-Service : Cannot find any service with service name 'AmazonSSMAgent'.
--truncated--
```

If the agent isn't installed, you can install it manually using the procedure for your operating system type:

- Manually installing and uninstalling SSM Agent on EC2 instances for Linux
- Manually installing and uninstalling SSM Agent on EC2 instances for macOS
- Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Working with SSM Agent on EC2 instances for Linux

Amazon Systems Manager Agent (SSM Agent) processes Systems Manager requests and configures your machine as specified in the request. Use the procedures in following topics to install, configure, or uninstall SSM Agent on Linux operating systems.

Topics

- Verifying the signature of SSM Agent
- Manually installing and uninstalling SSM Agent on EC2 instances for Linux
- Configuring SSM Agent to use a proxy on Linux nodes

Verifying the signature of SSM Agent

The Amazon Systems Manager Agent (SSM Agent) deb and rpm installer packages for Linux instances are cryptographically signed. You can use a public key to verify that the agent package is original and unmodified. If the files are damaged or have been altered, the verification fails.

You can verify the signature of the installer package using either RPM or GPG. The following information is for SSM Agent versions 3.1.1141.0 or later.

To find the correct signature file for your instance's architecture and operating system, see the following table.

region represents the identifier for an Amazon Web Services Region supported by Amazon Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

Architecture	Operating system	Signature file URL	Agent download file name

x86_64	AlmaLinux, Amazon Linux 2, Amazon Linux 2023, RHEL, Oracle Linux, Rocky Linux	`https://s3.region.amazonaws.com/amazon-ssm-region/latest/linux_amd64/amazon-ssm-agent.rpm.sig`
		
		`https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/linux_amd64/amazon-ssm-agent.rpm.sig`
			`amazon-ssm-agent.rpm`

x86_64	Debian Server, Ubuntu Server	`https://s3.region.amazonaws.com/amazon-ssm-region/latest/d`	`amazon-ssm-agent.deb`

Architecture	Operating system	Signature file URL	Agent download file name
		ebian_amd64/amazon-ssm-agent.deb.sig https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/debian_amd64/amazon-ssm-agent.deb.sig	
ARM64	Amazon Linux 2, Amazon Linux 2023, RHEL	https://s3. *region*.amazonaws.com/amazon-ssm-*region*/latest/linux_arm64/amazon-ssm-agent.rpm.sig https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/linux_arm64/amazon-ssm-agent.rpm.sig	amazon-ssm-agent.rpm

Verifying the SSM Agent package on a Linux server (v3.3.4851.0 and later)

Before you begin

The procedures for **GPG** and **RPM** in this section apply to SSM Agent version 3.3.4851.0 and later. Before you verify the signature of SSM Agent, make sure that you have downloaded the latest agent package for your operating system. For example, `https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/linux_arm64/amazon-ssm-agent.rpm`. For more information about downloading SSM Agent packages, see Manually installing and uninstalling SSM Agent on EC2 instances for Linux.

If you use agent version 3.3.1802.0 through 3.3.4793.0, follow the instructions in Verifying the SSM Agent package on a Linux server (v3.3.1802.0 and later). For agent version 3.3.1611.0 or earlier, follow the instructions in Verifying the SSM Agent package on a Linux server (v3.3.1611.0 and earlier).

GPG

To verify the SSM Agent package on a Linux server (v3.3.4851.0 and later)

1. Copy the following public key and save it to a file named `amazon-ssm-agent.gpg`.

> **Important**
>
> The following public key expires on November 25, 2027. We will publish a new public key in this topic before the old one expires. To get a notification when the new key is available, subscribe to the RSS feed for this topic.

```

M98H0Sl+MxUsAg==
=TpOv
-----END PGP PUBLIC KEY BLOCK-----
```

2. Import the public key into your keyring, and note the returned key value.

```
gpg --import amazon-ssm-agent.gpg
```

3. Verify the fingerprint. Be sure to replace *key-value* with the value from the preceding step. Use GPG to verify the fingerprint even if you use RPM to verify the installer package.

```
gpg --fingerprint key-value
```

This command returns output similar to the following:

```
pub   rsa4096 2026-06-04 [SCEA] [expires: 2027-11-25]
```

```
      Key fingerprint = 1C5B 395C BE5E 74E2 F1CA  2159 2784 DBF3 88D1 9D46
uid                  SSM Agent <ssm-agent-signer@amazon.com>
```

The fingerprint should match the following.

```
1C5B 395C BE5E 74E2 F1CA 2159 2784 DBF3 88D1 9D46
```

If the fingerprint doesn't match, don't install the agent. Contact Amazon Web Services Support.

4. Download the signature file according to your instance's architecture and operating system if you haven't already done so.
5. Verify the installer package signature. Be sure to replace the *signature-filename* and *agent-download-filename* with the values you specified when downloading the signature file and agent, as listed in the table earlier in this topic.

```
gpg --verify signature-filename agent-download-filename
```

For example, for the x86_64 architecture on Amazon Linux 2:

```
gpg --verify amazon-ssm-agent.rpm.sig amazon-ssm-agent.rpm
```

This command returns output similar to the following:

```
gpg: Signature made Mon 14 Jul 2026 12:00:00 AM UTC using RSA key ID 88D19D46
gpg: Good signature from "SSM Agent <ssm-agent-signer@amazon.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 1C5B 395C BE5E 74E2 F1CA  2159 2784 DBF3 88D1 9D46
```

If the output includes the phrase `BAD signature`, check whether you performed the procedure correctly. If the issue persists, contact Amazon Web Services Support and don't install the agent.

The warning about trust doesn't mean the signature is invalid. It means you haven't verified the public key. You can trust a key only if you or someone you trust has signed it.

If the output includes the phrase `Can't check signature: No public key`, verify that you downloaded SSM Agent version 3.3.4851.0 or later.

RPM

To verify the SSM Agent package on a Linux server (v3.3.4851.0 and later)

1. Copy the following public key and save it to a file named `amazon-ssm-agent.gpg`.

> **Important**
>
> The following public key expires on November 25, 2027. We will publish a new public key in this topic before the old one expires. To get a notification when the new key is available, subscribe to the RSS feed for this topic.

-----END PGP PUBLIC KEY BLOCK-----
```

2. Import the public key into your keyring, and note the returned key value.

```
rpm --import amazon-ssm-agent.gpg
```

3. Verify the fingerprint. Use GPG to verify the fingerprint even if you use RPM to verify the installer package.

```
rpm -qa gpg-pubkey --qf '%{Description}' | gpg --with-fingerprint | grep -A 1
 "ssm-agent-signer@amazon.com"
```

This command returns output similar to the following:

```
pub  4096R/88D19D46 2026-06-04 SSM Agent <ssm-agent-signer@amazon.com>
      Key fingerprint = 1C5B 395C BE5E 74E2 F1CA  2159 2784 DBF3 88D1 9D46
```

The fingerprint should match the following.

```
1C5B 395C BE5E 74E2 F1CA 2159 2784 DBF3 88D1 9D46
```

If the fingerprint doesn't match, don't install the agent. Contact Amazon Web Services Support.

4. Verify the installer package signature. Be sure to replace the *agent-download-filename* with the values you specified when downloading the agent, as listed in the table earlier in this topic.

```
rpm --checksig agent-download-filename
```

For example, for the x86_64 architecture on Amazon Linux 2:

```
rpm --checksig amazon-ssm-agent.rpm
```

This command returns output similar to the following.

```
amazon-ssm-agent.rpm: digests signatures OK
```

If the output contains `SIGNATURES NOT OK` or `NOT OK (MISSING KEYS: (MD5) key-id`), check whether you performed the procedure correctly and verify you downloaded SSM Agent version 3.3.4851.0 or later. If you continue to get this response, contact Amazon Web Services Support and don't install the agent.

Verifying the SSM Agent package on a Linux server (v3.3.1802.0 and later)

Before you begin

The procedures for **GPG** and **RPM** in this section apply to SSM Agent version 3.3.1802.0 through 3.3.4793.0. We recommend always using the latest version of the agent. For information, see Verifying the SSM Agent package on a Linux server (v3.3.4851.0 and later). However, if you have a specific reason to continue using agent version 3.3.1802.0 through 3.3.4793.0, follow the instructions in one of the following procedures.

GPG

To verify the SSM Agent package on a Linux server (v3.3.1802.0 and later)

1. Copy one the following public key and save it to a file named `amazon-ssm-agent.gpg`.

> **Important**
>
> The following public key expires on 2026-07-15 (July 15, 2026). Systems Manager will publish a new public key in this topic before the old one expires. We encourage you to subscribe to the RSS feed for this topic to get a notification when the new key is available.

```

-----END PGP PUBLIC KEY BLOCK-----
```

2. Import the public key into your keyring, and note the returned key value.

```
gpg --import amazon-ssm-agent.gpg
```

3. Verify the fingerprint. Be sure to replace *key-value* with the value from the preceding step. We recommend that you use GPG to verify the fingerprint even if you use RPM to verify the installer package.

```
gpg --fingerprint key-value
```

This command returns output similar to the following:

```
pub   4096R/D0052E5D 2025-01-22 [expires: 2026-07-15]
      Key fingerprint = 4855 A9E6 8332 16D6 A77D  8FE4 51A8 E050 D005 2E5D
uid                  SSM Agent <ssm-agent-signer@amazon.com>
```

The fingerprint should match the following.

```
4855 A9E6 8332 16D6 A77D 8FE4 51A8 E050 D005 2E5D
```

If the fingerprint doesn't match, don't install the agent. Contact Amazon Web Services Support.

4. Download the signature file according to your instance's architecture and operating system if you haven't already done so.

5. Verify the installer package signature. Be sure to replace the *signature-filename* and *agent-download-filename* with the values you specified when downloading the signature file and agent, as listed in the table earlier in this topic.

```
gpg --verify signature-filename agent-download-filename
```

For example, for the x86_64 architecture on Amazon Linux 2:

```
gpg --verify amazon-ssm-agent.rpm.sig amazon-ssm-agent.rpm
```

This command returns output similar to the following:

```
gpg: Signature made Sat 08 Feb 2025 12:05:08 AM UTC using RSA key ID D0052E5D
gpg: Good signature from "SSM Agent <ssm-agent-signer@amazon.com>"
```

```
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 4855 A9E6 8332 16D6 A77D  8FE4 51A8 E050 D005 2E5D
```

If the output includes the phrase `BAD signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services Support and don't install the agent. The warning message about the trust doesn't mean that the signature isn't valid, only that you haven't verified the public key. A key is trusted only if you or someone who you trust has signed it. If the output includes the phrase `Can't check signature: No public key`, verify you downloaded SSM Agent version 3.1.1141.0 or later.

RPM

To verify the SSM Agent package on a Linux server (v3.3.1802.0 and later)

1. Copy the following public key and save it to a file named `amazon-ssm-agent.gpg`.

> **Important**
>
> The following public key expires on 2026-07-15 (July 15, 2026). Systems Manager will publish a new public key in this topic before the old one expires. We encourage you to subscribe to the RSS feed for this topic to get a notification when the new key is available.

-----END PGP PUBLIC KEY BLOCK-----
```

2. Import the public key into your keyring, and note the returned key value.

```
rpm --import amazon-ssm-agent.gpg
```

3. Verify the fingerprint. We recommend that you use GPG to verify the fingerprint even if you use RPM to verify the installer package.

```
rpm -qa gpg-pubkey --qf '%{Description}' | gpg --with-fingerprint | grep -A 1
 "ssm-agent-signer@amazon.com"
```

This command returns output similar to the following:

```
pub  4096R/D0052E5D 2025-01-22 SSM Agent <ssm-agent-signer@amazon.com>
```

```
      Key fingerprint = 4855 A9E6 8332 16D6 A77D  8FE4 51A8 E050 D005 2E5D
```

The fingerprint should match the following.

```
4855 A9E6 8332 16D6 A77D 8FE4 51A8 E050 D005 2E5D
```

If the fingerprint doesn't match, don't install the agent. Contact Amazon Web Services Support.

4. Verify the installer package signature. Be sure to replace the *agent-download-filename* with the values you specified when downloading the agent, as listed in the table earlier in this topic.

```
rpm --checksig agent-download-filename
```

For example, for the x86_64 architecture on Amazon Linux 2:

```
rpm --checksig amazon-ssm-agent.rpm
```

This command returns output similar to the following.

```
amazon-ssm-agent.rpm: rsa sha1 md5 OK
```

If pgp is missing from the output and you have imported the public key, then the agent isn't signed. If the output contains the phrase `NOT OK (MISSING KEYS: (MD5) key-id)`, check whether you performed the procedure correctly and verify you downloaded SSM Agent version 3.1.1141.0 or later. If you continue to get this response, contact Amazon Web Services Support and don't install the agent.

Verifying the SSM Agent package on a Linux server (v3.3.1611.0 and earlier)

Before you begin

The procedures for **GPG** and **RPM** in this section apply to SSM Agent version 3.3.1611.0 and earlier versions. We recommend always using the latest version of the agent. For information, see Verifying the SSM Agent package on a Linux server (v3.3.4851.0 and later). However, if you have a specific reason to continue using agent version 3.3.1611.0 or earlier, follow the instructions in one of the following procedures.

GPG

To verify the SSM Agent package on a Linux server (v3.3.1611.0 and earlier)

1. Copy the following public keys and save it to a file named `amazon-ssm-agent.gpg`.

> **Important**
>
> The public key shown below expired on 2025-02-17 (February 17, 2025) and works for Version 3.3.1611.0 and earlier versions up to 3.2.1542.0, and only if it was used previously to verify the agent's signature. Systems Manager will publish a new public key in this topic before the old one expires. We encourage you to subscribe to the RSS feed for this topic to get a notification when the new key is available.

```

-----END PGP PUBLIC KEY BLOCK-----
```

2. Import the public key into your keyring, and note the returned key value.

```
gpg --import amazon-ssm-agent.gpg
```

3. Verify the fingerprint. Be sure to replace *key-value* with the value from the preceding step. We recommend that you use GPG to verify the fingerprint even if you use RPM to verify the installer package.

```
gpg --fingerprint key-value
```

This command returns output similar to the following.

```
pub   2048R/97DD04ED 2023-08-28 [expired: 2025-02-17]
      Key fingerprint = DE92 C7DA 3E56 E923 31D6 2A36 BC1F 495C 97DD 04ED
uid                  SSM Agent <ssm-agent-signer@amazon.com>
```

The fingerprint should match the following.

```
DE92 C7DA 3E56 E923 31D6 2A36 BC1F 495C 97DD 04ED
```

If the fingerprint doesn't match, don't install the agent. Contact Amazon Web Services Support.

4. Download the signature file according to your instance's architecture and operating system if you haven't already done so.
5. Verify the installer package signature. Be sure to replace the *signature-filename* and *agent-download-filename* with the values you specified when downloading the signature file and agent, as listed in the table earlier in this topic.

```
gpg --verify signature-filename agent-download-filename
```

For example, for the x86_64 architecture on Amazon Linux 2:

```
gpg --verify amazon-ssm-agent.rpm.sig amazon-ssm-agent.rpm
```

This command returns output similar to the following:

```
gpg: Signature made Fri 10 Jan 2025 01:54:18 AM UTC using RSA key ID 97DD04ED
gpg: Good signature from "SSM Agent <ssm-agent-signer@amazon.com>"
gpg: Note: This key has expired!
Primary key fingerprint: DE92 C7DA 3E56 E923 31D6  2A36 BC1F 495C 97DD 04ED
```

If the output includes the phrase `BAD signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services Support and don't install the agent. The warning message about the trust doesn't mean that the signature isn't valid, only that you haven't verified the public key. A key is trusted only if you or someone who you trust has signed it. If the output includes the phrase `Can't check signature: No public key`, verify you downloaded SSM Agent version 3.1.1141.0 or later.

RPM

To verify the SSM Agent package on a Linux server (v3.3.1611.0 and earlier)

1. Copy the following public key and save it to a file named `amazon-ssm-agent.gpg`.

> **Important**
>
> The public key shown below expired on 2025-02-17 (February 17, 2025) and works for Version 3.3.1611.0 and earlier versions up to 3.2.1542.0, and only if it was used previously to verify the agent's signature. Systems Manager will publish a new public key in this topic before the old one expires. We encourage you to subscribe to the RSS feed for this topic to get a notification when the new key is available.

=zr5w
-----END PGP PUBLIC KEY BLOCK-----
```

2. Import the public key into your keyring, and note the returned key value.

```
rpm --import amazon-ssm-agent.gpg
```

3. Verify the fingerprint. We recommend that you use GPG to verify the fingerprint even if you use RPM to verify the installer package.

```
rpm -qa gpg-pubkey --qf '%{Description}' | gpg --with-fingerprint | grep -A 1
 "ssm-agent-signer@amazon.com"
```

This command returns output similar to the following:

```
pub  2048R/97DD04ED 2023-08-28 SSM Agent <ssm-agent-signer@amazon.com>
      Key fingerprint = DE92 C7DA 3E56 E923 31D6 2A36 BC1F 495C 97DD 04ED
```

The fingerprint should match the following.

```
DE92 C7DA 3E56 E923 31D6 2A36 BC1F 495C 97DD 04ED
```

If the fingerprint doesn't match, don't install the agent. Contact Amazon Web Services Support.

4. Verify the installer package signature. Be sure to replace the *agent-download-filename* with the values you specified when downloading the agent, as listed in the table earlier in this topic.

```
rpm --checksig agent-download-filename
```

For example, for the x86_64 architecture on Amazon Linux 2:

```
rpm --checksig amazon-ssm-agent.rpm
```

This command returns output similar to the following.

```
amazon-ssm-agent.rpm: rsa sha1 md5 OK
```

If pgp is missing from the output and you have imported the public key, then the agent isn't signed. If the output contains the phrase `NOT OK (MISSING KEYS: (MD5)` *key-id*), check whether you performed the procedure correctly and verify you downloaded SSM Agent version 3.1.1141.0 or later. If you continue to get this response, contact Amazon Web Services Support and don't install the agent.

Manually installing and uninstalling SSM Agent on EC2 instances for Linux

Before you manually install Amazon Systems Manager Agent (SSM Agent) on an Amazon Elastic Compute Cloud (Amazon EC2) Linux operating system, review the following information.

> **⚠ Installation on other machine types**
>
> The procedures in this section are designed specifically for Amazon EC2 instances. For on-premises servers, virtual machines, or other non-EC2 environments, use the `ssm-setup-cli` tool as described in How to install the SSM Agent on hybrid Linux nodes.
> Using EC2 installation procedures on non-EC2 systems can potentially result in security vulnerabilities. The `ssm-setup-cli` tool provides additional security protections for non-EC2 machines.

We strongly recommend that you avoid using OS versions that have reached End-of-Life (EOL). OS vendors including Amazon typically don't provide security patches or other updates for versions that have reached EOL. Continuing to use an EOL system greatly increases the risk of not being able to apply upgrades, including security fixes, and other operational problems. Amazon does not test Systems Manager functionality on OS versions that have reached EOL.

SSM Agent installation file URLs

You can access the installation files for SSM Agent that are stored in any commercial Amazon Web Services Region. We also provide installation files in a globally available Amazon Simple Storage Service (Amazon S3) bucket that you can use as an alternative or backup source of files.

If you're manually installing the agent on a instance or two, you can use the commands in the **Quick installation** procedures we provide to save time. The commands provided in these procedures can also be passed to Amazon EC2 instances as scripts through user data.

If you're creating a script or template to use for installing the agent on multiple instances, we recommend that you use the installation files in or near an Amazon Web Services Region where you're geographically located. For bulk installations, this can increase the speed of your downloads and reduce latency. In these cases, we recommend using the **Create custom installation commands** procedures in the installation topics.

Amazon Machine Images with the agent preinstalled

SSM Agent is preinstalled on some Amazon Machine Images (AMIs) provided by Amazon. For information, see Find AMIs with the SSM Agent preinstalled.

Keeping the agent up to date

An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Choose your operating system

To view the procedure for manually installing SSM Agent on the specified operating system, choose a link from the following list:

> **Note**
>
> For a list of supported versions of each of the following operating systems, see Supported operating systems for Systems Manager.

- AlmaLinux
- Amazon Linux 2 and Amazon Linux 2023
- Debian Server
- Oracle Linux
- Red Hat Enterprise Linux
- Rocky Linux
- Ubuntu Server

Uninstalling SSM Agent from Linux instances

Use the package manager for your operating system to uninstall SSM Agent from Linux instances. Depending on the operating system, the uninstall command will be similar to the following example command:

```
sudo dpkg -r amazon-ssm-agent
```

Manually install SSM Agent on AlmaLinux instances

Use the information in this section to help you manually install or reinstall SSM Agent on an AlmaLinux instance.

Before you begin

Before you install SSM Agent on an AlmaLinux instance, note the following:

- Make sure that Python 3 is installed on your AlmaLinux instance. This is required for SSM Agent to work properly.

- For important information that applies to installation of SSM Agent on all Linux-based operating systems, see Manually installing and uninstalling SSM Agent on EC2 instances for Linux.

Topics

- Quick installation commands for SSM Agent on AlmaLinux
- Create custom agent installation commands for AlmaLinux in your Region

Quick installation commands for SSM Agent on AlmaLinux

Use the following steps to manually install SSM Agent on a single instance. This procedure uses globally available installation files.

Before you begin

Before you install SSM Agent on a AlmaLinux instance, note the following:

- Make sure that Python 3 is installed on your AlmaLinux instance. This is required for SSM Agent to work properly.

To install SSM Agent on AlmaLinux

1. Connect to your AlmaLinux instance using your preferred method, such as SSH.
2. Copy the command for your instance's architecture and run it on the instance.

> **Note**
>
> Even though URLs in the following commands include an `ec2-downloads-windows` directory, these are the correct global installation files for AlmaLinux.

x86_64 instances

```
sudo dnf install -y https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/
latest/linux_amd64/amazon-ssm-agent.rpm
```

ARM64 instances

```
sudo dnf install -y https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/
latest/linux_arm64/amazon-ssm-agent.rpm
```

3. (Recommended) Run the following command to verify that the agent is running.

```
sudo systemctl status amazon-ssm-agent
```

In most cases, the command reports that the agent is running, as shown in the following example.

```
# amazon-ssm-agent.service - amazon-ssm-agent
   Loaded: loaded (/etc/systemd/system/amazon-ssm-agent.service; enabled; vendo>
   Active: active (running) since Tue 2025-04-19 16:40:41 UTC; 9s ago
 Main PID: 4898 (amazon-ssm-agen)
    Tasks: 14 (limit: 4821)
   Memory: 34.6M
   CGroup: /system.slice/amazon-ssm-agent.service
           ##4898 /usr/bin/amazon-ssm-agent
           ##4954 /usr/bin/ssm-agent-worker
            --truncated--
```

In rare cases, the command reports that the agent is installed but not running, as shown in the following example.

```
# amazon-ssm-agent.service - amazon-ssm-agent
   Loaded: loaded (/etc/systemd/system/amazon-ssm-agent.service; enabled; vendo>
   Active: inactive (dead) since Tue 2025-04-19 16:42:05 UTC; 2s ago
            --truncated--
```

To activate the agent in these cases, run the following commands.

```
sudo systemctl enable amazon-ssm-agent
```

```
sudo systemctl start amazon-ssm-agent
```

Create custom agent installation commands for AlmaLinux in your Region

When you install SSM Agent on multiple instances using a script or template, we recommend using installation files that are stored in the Amazon Web Services Region you're working in.

For the following commands, we provide examples that use a publicly accessible S3 bucket in the US East (Ohio) Region (`us-east-2`).

> **Tip**
>
> You can also replace a global URL in the procedure Quick installation commands for SSM Agent on AlmaLinux earlier in this topic with a custom Regional URL you construct.

In the following command, replace *`region`* with your own information. For a list of supported *`region`* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

x86_64

```
sudo dnf install -y https://s3.region.amazonaws.com/amazon-ssm-region/latest/
linux_amd64/amazon-ssm-agent.rpm
```

See the following example.

```
sudo dnf install -y https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/
linux_amd64/amazon-ssm-agent.rpm
```

ARM64

```
sudo dnf install -y https://s3.region.amazonaws.com/amazon-ssm-region/latest/
linux_arm64/amazon-ssm-agent.rpm
```

See the following example.

```
sudo dnf install -y https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/
linux_arm64/amazon-ssm-agent.rpm
```

Manually installing SSM Agent on Amazon Linux 2 and Amazon Linux 2023 instances

In most cases, the Amazon Machine Images (AMIs) for Amazon Linux 2 and Amazon Linux 2023 that are provided by Amazon come with Amazon Systems Manager Agent (SSM Agent) preinstalled by default. For more information, see Find AMIs with the SSM Agent preinstalled.

In the event that SSM Agent isn't preinstalled on a new Amazon Linux 2 or Amazon Linux 2023 instance, or if you need to manually reinstall the agent, use the information on this page to help you.

Before you begin

Before you install SSM Agent on an Amazon Linux 2 or Amazon Linux 2023 instance, note the following:

- For important information that applies to installation of SSM Agent on all Linux-based operating systems, see Manually installing and uninstalling SSM Agent on EC2 instances for Linux.
- If you use a `yum` command to update SSM Agent on a managed node after the agent has been installed or updated using the SSM document `AWS-UpdateSSMAgent`, you might see the following message: `"Warning: RPMDB altered outside of yum."` This message is expected and can be safely ignored.

linux_amd64/amazon-ssm-agent.rpm
```

See the following example.

```
sudo dnf install -y https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/
linux_amd64/amazon-ssm-agent.rpm
```

ARM64

```
sudo dnf install -y https://s3.region.amazonaws.com/amazon-ssm-region/latest/
linux_arm64/amazon-ssm-agent.rpm
```

See the following example.

```
sudo dnf install -y https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/
linux_arm64/amazon-ssm-agent.rpm
```

Manually installing SSM Agent on Debian Server instances

The Amazon Machine Images (AMIs) for Debian Server that are provided by Amazon do not come with Amazon Systems Manager Agent (SSM Agent) preinstalled by default. For a list of Amazon managed AMIs on which the agent might be preinstalled, see Find AMIs with the SSM Agent preinstalled.

Use the information in this section to help you manually install or reinstall SSM Agent on a Debian Server instance.

Before you begin

Before you install SSM Agent on a Debian Server instance, note the following:

- For important information that applies to installation of SSM Agent on all Linux-based operating systems, see Manually installing and uninstalling SSM Agent on EC2 instances for Linux.

Topics

- Quick installation commands for SSM Agent on Debian Server
- Create custom agent installation commands for Debian Server in your Region

Quick installation commands for SSM Agent on Debian Server

Use the following steps to manually install SSM Agent on a single instance. This procedure uses globally available installation files.

To install SSM Agent on Debian Server

1. Connect to your Debian Server instance using your preferred method, such as SSH.
2. Run the following command to create a temporary directory on the instance.

```
mkdir /tmp/ssm
```

3. Run the following command to change to the temporary directory.

```
cd /tmp/ssm
```

4. Copy the command for your instance's architecture and run it on the instance.

> **Note**
>
> Even though URLs in the following commands include an `ec2-downloads-windows` directory, these are the correct global installation files for Debian Server.
> For Debian Server 8, only the x86_64 architecture is supported.

x86_64 instances

```
wget https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/
debian_amd64/amazon-ssm-agent.deb
```

ARM64 instances

```
wget https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/
debian_arm64/amazon-ssm-agent.deb
```

5. Run the following command.

```
sudo dpkg -i amazon-ssm-agent.deb
```

6. (Recommended) Run the following command to verify that the agent is running.

```
sudo systemctl status amazon-ssm-agent
```

In most cases, the command reports that the agent is running, as shown in the following example.

```
# amazon-ssm-agent.service - amazon-ssm-agent
   Loaded: loaded (/lib/systemd/system/amazon-ssm-agent.service; enabled; vendor
   Active: active (running) since Tue 2025-04-19 16:25:03 UTC; 4s ago
 Main PID: 628 (amazon-ssm-agen)
   CGroup: /system.slice/amazon-ssm-agent.service
           ##628 /usr/bin/amazon-ssm-agent
           ##650 /usr/bin/ssm-agent-worker
            --truncated--
```

In rare cases, the command reports that the agent is installed but not running, as shown in the following example.

```
# amazon-ssm-agent.service - amazon-ssm-agent
   Loaded: loaded (/lib/systemd/system/amazon-ssm-agent.service; enabled; vendor
   Active: inactive (dead) since Tue 2025-04-19 16:26:30 UTC; 5s ago
 Main PID: 628 (code=exited, status=0/SUCCESS)
            --truncated--
```

To activate the agent in these cases, run the following commands.

```
sudo systemctl enable amazon-ssm-agent
```

```
sudo systemctl start amazon-ssm-agent
```

Create custom agent installation commands for Debian Server in your Region

When you install SSM Agent on multiple instances using a script or template, we recommend using installation files that are stored in the Amazon Web Services Region you're working in.

For the following commands, we provide examples that use a publicly accessible S3 bucket in the US East (Ohio) Region (`us-east-2`).

Tip

You can also replace a global URL in the procedure Quick installation commands for SSM Agent on Debian Server earlier in this topic with a custom Regional URL you construct.

In the following command, replace *region* with your own information. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

x86_64

```
wget https://s3.region.amazonaws.com/amazon-ssm-region/latest/debian_amd64/amazon-ssm-agent.deb
```

```
sudo dpkg -i amazon-ssm-agent.deb
```

See the following example.

```
wget https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/debian_amd64/amazon-ssm-agent.deb
```

```
sudo dpkg -i amazon-ssm-agent.deb
```

ARM64

```
wget https://s3.region.amazonaws.com/amazon-ssm-region/latest/debian_arm64/amazon-ssm-agent.deb
```

```
sudo dpkg -i amazon-ssm-agent.deb
```

See the following example.

```
wget https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/debian_arm64/amazon-ssm-agent.deb
```

```
sudo dpkg -i amazon-ssm-agent.deb
```

Manually installing SSM Agent on Oracle Linux instances

The Amazon Machine Images (AMIs) for Oracle Linux that are provided by Amazon do not come with Amazon Systems Manager Agent (SSM Agent) preinstalled by default. For a list of Amazon managed AMIs on which the agent might be preinstalled, see Find AMIs with the SSM Agent preinstalled.

Use the information in this section to help you manually install or reinstall SSM Agent on an Oracle Linux instance.

Before you begin

Before you install SSM Agent on an Oracle Linux instance, note the following:

- For important information that applies to installation of SSM Agent on all Linux-based operating systems, see Manually installing and uninstalling SSM Agent on EC2 instances for Linux.
- If you use a `yum` command to update SSM Agent on a managed node after the agent has been installed or updated using the SSM document `AWS-UpdateSSMAgent`, you might see the following message: `"Warning: RPMDB altered outside of yum."` This message is expected and can be safely ignored.

Quick installation commands for SSM Agent on Oracle Linux

Use the following steps to manually install SSM Agent on a single instance. This procedure uses globally available installation files.

To install SSM Agent on Oracle Linux using quick copy and paste commands

1. Connect to your Oracle Linux instance using your preferred method, such as SSH.
2. Copy the following command and run it on the instance.

> **Note**
>
> Even though URL in the following command includes an `ec2-downloads-windows` directory, these are the correct global installation files for Oracle Linux.

x86_64

```
sudo yum install -y https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/
latest/linux_amd64/amazon-ssm-agent.rpm
```

3. (Recommended) Run the following command to verify that the agent is running.

```
sudo systemctl status amazon-ssm-agent
```

In most cases, the command reports that the agent is running, as shown in the following example.

```
amazon-ssm-agent.service - amazon-ssm-agent
Loaded: loaded (/usr/lib/systemd/system/amazon-ssm-agent.service; enabled; vendor
 preset: enabled)
Active: active (running) since Wed 2021-10-20 19:09:29 UTC; 4min 6s ago
            --truncated--
```

In rare cases, the command reports that the agent is installed but not running, as shown in the following example.

```
amazon-ssm-agent.service - amazon-ssm-agent
Loaded: loaded (/usr/lib/systemd/system/amazon-ssm-agent.service; enabled; vendor
 preset: enabled)
Active: inactive (dead) since Wed 2021-10-20 22:16:41 UTC; 18s ago
            --truncated--
```

To activate the agent in these cases, run the following commands.

```
sudo systemctl enable amazon-ssm-agent
```

```
sudo systemctl start amazon-ssm-agent
```

Create custom agent installation commands for Oracle Linux in your Region

When you install SSM Agent on multiple instances using a script or template, we recommend using installation files that are stored in the Amazon Web Services Region you're working in.

For the following commands, we provide examples that use a publicly accessible S3 bucket in the US East (Ohio) Region (`us-east-2`).

> **Tip**
>
> You can also replace a global URL in the procedure Quick installation commands for SSM Agent on Oracle Linux earlier in this topic with a custom Regional URL you construct.

In the following command, replace *`region`* with your own information. For a list of supported *`region`* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

x86_64

```
sudo yum install -y https://s3.region.amazonaws.com/amazon-ssm-region/latest/
linux_amd64/amazon-ssm-agent.rpm
```

See the following example.

```
sudo yum install -y https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/
linux_amd64/amazon-ssm-agent.rpm
```

Manually installing SSM Agent on Red Hat Enterprise Linux instances

The Amazon Machine Images (AMIs) for Red Hat Enterprise Linux (RHEL) that are provided by Amazon do not come with Amazon Systems Manager Agent (SSM Agent) preinstalled by default. For a list of Amazon managed AMIs on which the agent might be preinstalled, see Find AMIs with the SSM Agent preinstalled.

Use the information in this section to help you manually install or reinstall SSM Agent on a RHEL instance.

Before you begin

Before you install SSM Agent on a RHEL instance, note the following:

- For important information that applies to installation of SSM Agent on all Linux-based operating systems, see Manually installing and uninstalling SSM Agent on EC2 instances for Linux.
- If you use a `yum` command to update SSM Agent on a managed node after the agent has been installed or updated using the SSM document `AWS-UpdateSSMAgent`, you might see the following message: `"Warning: RPMDB altered outside of yum."` This message is expected and can be safely ignored.

Quick installation commands for SSM Agent on RHEL 8, 9, and 10

Use the following steps to manually install SSM Agent on a single instance. This procedure uses globally available installation files.

To install SSM Agent on RHEL 8.x, 9.x, or 10.x

1. Connect to your RHEL 8, 9, or 10 instance using your preferred method, such as SSH.
2. Copy the command for your instance's architecture and run it on the instance.

   > **Note**
   >
   > Even though URLs in the following commands include an `ec2-downloads-windows` directory, these are the correct global installation files for RHEL 8, 9, and 10.

   x86_64 instances

   ```
   sudo dnf install -y https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/
   latest/linux_amd64/amazon-ssm-agent.rpm
   ```

   ARM64 instances

   ```
   sudo dnf install -y https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/
   latest/linux_arm64/amazon-ssm-agent.rpm
   ```

3. (Recommended) Run the following command to verify that the agent is running.

   ```
   sudo systemctl status amazon-ssm-agent
   ```

   In most cases, the command reports that the agent is running, as shown in the following example.

   ```
   # amazon-ssm-agent.service - amazon-ssm-agent
      Loaded: loaded (/etc/systemd/system/amazon-ssm-agent.service; enabled; vendo>
      Active: active (running) since Tue 2025-04-19 16:40:41 UTC; 9s ago
    Main PID: 4898 (amazon-ssm-agen)
       Tasks: 14 (limit: 4821)
      Memory: 34.6M
      CGroup: /system.slice/amazon-ssm-agent.service
   ```

```
           ##4898 /usr/bin/amazon-ssm-agent
           ##4954 /usr/bin/ssm-agent-worker
            --truncated--
```

In rare cases, the command reports that the agent is installed but not running, as shown in the following example.

```
# amazon-ssm-agent.service - amazon-ssm-agent
   Loaded: loaded (/etc/systemd/system/amazon-ssm-agent.service; enabled; vendo>
   Active: inactive (dead) since Tue 2025-04-19 16:42:05 UTC; 2s ago
            --truncated--
```

To activate the agent in these cases, run the following commands.

```
sudo systemctl enable amazon-ssm-agent
```

```
sudo systemctl start amazon-ssm-agent
```

Create custom agent installation commands for RHEL 8, 9, and 10 in your Region

When you install SSM Agent on multiple instances using a script or template, we recommend using installation files that are stored in the Amazon Web Services Region you're working in.

Quick installation commands for SSM Agent on Rocky Linux

Use the following steps to manually install SSM Agent on a single instance. This procedure uses globally available installation files.

Before you begin

Before you install SSM Agent on a Rocky Linux instance, note the following:

- Make sure that either Python 2 or Python 3 is installed on your Rocky Linux instance. This is required for SSM Agent to work properly.

To install SSM Agent on Rocky Linux

1. Connect to your Rocky Linux instance using your preferred method, such as SSH.
2. Copy the command for your instance's architecture and run it on the instance.

> **Note**
>
> Even though URLs in the following commands include an `ec2-downloads-windows` directory, these are the correct global installation files for Rocky Linux.

x86_64 instances

```
sudo dnf install -y https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/
latest/linux_amd64/amazon-ssm-agent.rpm
```

ARM64 instances

```
sudo dnf install -y https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/
latest/linux_arm64/amazon-ssm-agent.rpm
```

3. (Recommended) Run the following command to verify that the agent is running.

```
sudo systemctl status amazon-ssm-agent
```

In most cases, the command reports that the agent is running, as shown in the following example.

```
# amazon-ssm-agent.service - amazon-ssm-agent
   Loaded: loaded (/etc/systemd/system/amazon-ssm-agent.service; enabled; vendo>
   Active: active (running) since Tue 2025-04-19 16:40:41 UTC; 9s ago
 Main PID: 4898 (amazon-ssm-agen)
    Tasks: 14 (limit: 4821)
   Memory: 34.6M
```

```
   CGroup: /system.slice/amazon-ssm-agent.service
           ##4898 /usr/bin/amazon-ssm-agent
           ##4954 /usr/bin/ssm-agent-worker
            --truncated--
```

In rare cases, the command reports that the agent is installed but not running, as shown in the following example.

```
# amazon-ssm-agent.service - amazon-ssm-agent
   Loaded: loaded (/etc/systemd/system/amazon-ssm-agent.service; enabled; vendo>
   Active: inactive (dead) since Tue 2025-04-19 16:42:05 UTC; 2s ago
            --truncated--
```

To activate the agent in these cases, run the following commands.

```
sudo systemctl enable amazon-ssm-agent
```

```
sudo systemctl start amazon-ssm-agent
```

Create custom agent installation commands for Rocky Linux in your Region

When you install SSM Agent on multiple instances using a script or template, we recommend using installation files that are stored in the Amazon Web Services Region you're working in.

For the following commands, we provide examples that use a publicly accessible S3 bucket in the US East (Ohio) Region (`us-east-2`).

> **Tip**

In the following command, replace *`region`* with your own information. For a list of supported *`region`* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

x86_64

```
sudo dnf install -y https://s3.region.amazonaws.com/amazon-ssm-region/latest/
linux_amd64/amazon-ssm-agent.rpm
```

See the following example.

```
sudo dnf install -y https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/
linux_amd64/amazon-ssm-agent.rpm
```

ARM64

```
sudo dnf install -y https://s3.region.amazonaws.com/amazon-ssm-region/latest/
linux_arm64/amazon-ssm-agent.rpm
```

See the following example.

```
sudo dnf install -y https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/
linux_arm64/amazon-ssm-agent.rpm
```

Manually install SSM Agent on SUSE Linux Enterprise Server instances

In most cases, the Amazon Machine Images (AMIs) for SUSE Linux Enterprise Server (SLES) that are provided by Amazon come with Amazon Systems Manager Agent (SSM Agent) preinstalled by default. For more information, see Find AMIs with the SSM Agent preinstalled.

In the event that SSM Agent isn't preinstalled on a new SLES instance, or if you need to manually reinstall the agent, use the information on this page to help you.

Before you begin

Before you install SSM Agent on a SLES instance, note the following:

- For important information that applies to installation of SSM Agent on all Linux-based operating systems, see Manually installing and uninstalling SSM Agent on EC2 instances for Linux.

Topics

- Quick installation commands for SSM Agent on SLES
- Create custom agent installation commands for SLES in your Region

Quick installation commands for SSM Agent on SLES

Use the following steps to manually install SSM Agent on a single instance. This procedure uses globally available installation files.

To install SSM Agent on SLES using quick copy and paste commands

1. Connect to your SLES instance using your preferred method, such as SSH.
2. **Option 1**: Use a `zypper` command:

   - Run the following command:

     ```
     sudo zypper install amazon-ssm-agent
     ```

   - Enter `y` in response to any prompts.

   Option 2: Use an `rpm` command.

   - Create a temporary directory on the instance.

     ```
     mkdir /tmp/ssm
     ```

   - Change to the temporary directory.

     ```
     cd /tmp/ssm
     ```

   - Run the following commands one at a time to download and run the SSM Agent installer.

     > **Note**
     >
     > Even though URLs in the following commands include an `ec2-downloads-windows` directory, these are the correct global installation files for SLES.

     x86_64 instances:

     ```
     wget https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/linux_amd64/
     amazon-ssm-agent.rpm
     ```

     ARM64 instances:

```
wget https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/linux_arm64/
amazon-ssm-agent.rpm
```

- Run the following command.

```
sudo rpm --install amazon-ssm-agent.rpm
```

- (Recommended) Run the following command to verify that the agent is running.

```
sudo systemctl status amazon-ssm-agent
```

In most cases, the command reports that the agent is running, as shown in the following example.

```
# amazon-ssm-agent.service - amazon-ssm-agent
 Loaded: loaded (/usr/lib/systemd/system/amazon-ssm-agent.service; enabled;
 vendor preset: disabled)
 Active: active (running) since Mon 2025-02-21 23:13:28 UTC; 7s ago
 Main PID: 2102 (amazon-ssm-agen)
 Tasks: 15 (limit: 512)
 CGroup: /system.slice/amazon-ssm-agent.service
 ##2102 /usr/sbin/amazon-ssm-agent
 ##2107 /usr/sbin/ssm-agent-worker
           --truncated--
```

In rare cases, the command reports that the agent is installed but not running, as shown in the following example.

```
# amazon-ssm-agent.service - amazon-ssm-agent
   Loaded: loaded (/usr/lib/systemd/system/amazon-ssm-agent.service; disabled;
 vendor preset: disabled)
   Active: inactive (dead)
           --truncated--
```

To activate the agent in these cases, run the following commands.

```
sudo systemctl enable amazon-ssm-agent
```

```
sudo systemctl start amazon-ssm-agent
```

Create custom agent installation commands for SLES in your Region

When you install SSM Agent on multiple instances using a script or template, we recommend using installation files that are stored in the Amazon Web Services Region you're working in.

For the following commands, we provide examples that use a publicly accessible S3 bucket in the US East (Ohio) Region (`us-east-2`).

> **Tip**

> You can also replace a global URL in the procedure Quick installation commands for SSM Agent on SLES earlier in this topic with a custom Regional URL you construct.

In the following command, replace *`region`* with your own information. For a list of supported *`region`* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

x86_64

```
wget https://s3.region.amazonaws.com/amazon-ssm-region/latest/linux_amd64/amazon-ssm-agent.rpm
```

```
sudo rpm --install amazon-ssm-agent.rpm
```

See the following example.

```
wget https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/linux_amd64/amazon-ssm-agent.rpm
```

```
sudo rpm --install amazon-ssm-agent.rpm
```

ARM64

```
wget https://s3.region.amazonaws.com/amazon-ssm-region/latest/linux_arm64/amazon-ssm-agent.rpm
```

```
sudo rpm --install amazon-ssm-agent.rpm
```

See the following example.

```
wget https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/linux_arm64/amazon-ssm-agent.rpm
```

```
sudo rpm --install amazon-ssm-agent.rpm
```

Manually installing SSM Agent on Ubuntu Server instances

In most cases, the Amazon Machine Images (AMIs) for Ubuntu Server that are provided by Amazon come with Amazon Systems Manager Agent (SSM Agent) preinstalled by default. For more information, see Find AMIs with the SSM Agent preinstalled.

In the event that SSM Agent isn't preinstalled on a new Ubuntu Server instance, or if you need to manually reinstall the agent, use the information in this section to help you.

Before you begin

Before you install SSM Agent on an Ubuntu Server instance, note the following:

- For important information that applies to installation of SSM Agent on all Linux-based operating systems, see Manually installing and uninstalling SSM Agent on EC2 instances for Linux.

Topics

- Install SSM Agent on Ubuntu Server 18.04, 20.04, 22.04 LTS, 23.10, 24.04 LTS, 24.0, and 25.04

Install SSM Agent on Ubuntu Server 18.04, 20.04, 22.04 LTS, 23.10, 24.04 LTS, 24.0, and 25.04

Before you begin

Before you install SSM Agent on an Ubuntu Server 18.04, 20.04, 22.04 LTS, 23.10, 24.04 LTS, 24.0, and 25.04, note the following:

SSM Agent installer files locations

On Ubuntu Server 18.04, 20.04, 22.04 LTS, 23.10, 24.04 LTS, 24.0, and 25.04, SSM Agent installer files, including agent binaries and config files, are stored in the following directory: `/snap/amazon-ssm-agent/current/`. If you make changes to any configuration files in this directory, then you must copy these files from the `/snap` directory to the `/etc/amazon/ssm/` directory. Log and library files haven't changed (`/var/lib/amazon/ssm`, `/var/log/amazon/ssm`).

Using the Snap `candidate` channel

The *candidate* channel in the Snap store contains the latest version of SSM Agent (including all of the latest bug fixes); not the stable channel. To learn more about the differences between the candidate and stable channels, see **Risk-levels** at https://snapcraft.io/docs/channels.

If you want to track SSM Agent version information on the candidate channel, run the following command on your Ubuntu Server 20.04 and 18.04 LTS 64-bit instances.

```
sudo snap switch --channel=candidate amazon-ssm-agent
```

Snaps recommended on versions 18.04 and later

On Ubuntu Server 18.04, 20.04, 22.04 LTS, 23.10, 24.04 LTS, 24.0, and 25.04, we recommend you only use Snaps. Also verify that only one instance of the agent is installed and running on your instances.

`Maximum timeout exceeded` error message

Because of a known issue with Snap, you might see a `Maximum timeout exceeded` error with `snap` commands. If you get this error, run the following commands one at a time to start the agent, stop it, and check its status:

```
sudo systemctl start snap.amazon-ssm-agent.amazon-ssm-agent.service
```

```
sudo systemctl stop snap.amazon-ssm-agent.amazon-ssm-agent.service
```

```
sudo systemctl status snap.amazon-ssm-agent.amazon-ssm-agent.service
```

To install SSM Agent on Ubuntu Server 18.04, 20.04, 22.04 LTS, 23.10, 24.04 LTS, 24.0, and 25.04 (with Snap package)

1. SSM Agent is installed, by default, on Ubuntu Server 18.04, 20.04, 22.04 LTS, 23.10, 24.04 LTS, 24.0, and 25.04 AMIs with an identifier of `20180627` or later.

   You can use the following script if you need to install SSM Agent on an on-premises server or if you need to reinstall the agent. You don't need to specify a URL for the download, because the `snap` command automatically downloads the agent from the Snap app store at https://snapcraft.io.

   ```
   sudo snap install amazon-ssm-agent --classic
   ```

2. Run the following command to determine if SSM Agent is running.

   ```
   sudo snap list amazon-ssm-agent
   ```

3. Run the following command to start the service if the previous command returned `amazon-ssm-agent is stopped`, `inactive`, or `disabled`.

   ```
   sudo snap start amazon-ssm-agent
   ```

4. Check the status of the agent.

   ```
   sudo snap services amazon-ssm-agent
   ```

Configuring SSM Agent to use a proxy on Linux nodes

You can configure Amazon Systems Manager Agent (SSM Agent) to communicate through an HTTP proxy by creating an override configuration file and adding `http_proxy`, `https_proxy`, and `no_proxy` settings to the file. An override file also preserves the proxy settings if you install newer or older versions of SSM Agent. This section includes procedures for creating an override file in both *upstart* and *systemd* environments. If you intend to use Session Manager, note that HTTPS proxy servers aren't supported.

Topics

- Configure SSM Agent to use a proxy (upstart)
- Configure SSM Agent to use a proxy (systemd)

Configure SSM Agent to use a proxy (upstart)

Use the following procedure to create an override configuration file for an `upstart` environment.

To configure SSM Agent to use a proxy (upstart)

1. Connect to the managed instance where you installed SSM Agent.
2. Open a simple editor like VIM, and depending on whether you're using an HTTP proxy server or HTTPS proxy server, add one of the following configurations.

   For an HTTP proxy server:

   ```
   env http_proxy=http://hostname:port
   env https_proxy=http://hostname:port
   env no_proxy=IP address for instance metadata services (IMDS)
   ```

   For an HTTPS proxy server:

   ```
   env http_proxy=http://hostname:port
   env https_proxy=https://hostname:port
   env no_proxy=IP address for instance metadata services (IMDS)
   ```

   Important

   Add the `no_proxy` setting to the file and specify the IP address. The IP address for `no_proxy` is the instance metadata services (IMDS) endpoint for Systems Manager. If you don't specify `no_proxy`, calls to Systems Manager take on the identity from the proxy service (if IMDSv1 fallback is enabled) or calls to Systems Manager fail (if IMDSv2 is enforced).

   - For IPv4, specify `no_proxy=169.254.169.254`.
   - For IPv6, specify `no_proxy=[fd00:ec2::254]`. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on instances built on the Amazon Nitro System. For more information, see How Instance Metadata Service Version 2 works in the *Amazon EC2 User Guide*.

3. Save the file with the name `amazon-ssm-agent.override` in the following location: `/etc/init/`

4. Stop and restart SSM Agent using the following commands.

```
sudo service stop amazon-ssm-agent
sudo service start amazon-ssm-agent
```

> **Note**
>
> For more information about working with `.override` files in Upstart environments, see init: Upstart init daemon job configuration.

Configure SSM Agent to use a proxy (systemd)

Use the following procedure to configure SSM Agent to use a proxy in a `systemd` environment.

> **Note**
>
> Some of the steps in this procedure contain explicit instructions for Ubuntu Server instances where SSM Agent was installed using Snap.

1. Connect to the instance where you installed SSM Agent.
2. Run one of the follow commands, depending on the operating system type.

   - On Ubuntu Server instances where SSM Agent is installed by using a snap:

     ```
     sudo systemctl edit snap.amazon-ssm-agent.amazon-ssm-agent
     ```

     On other operating systems:

     ```
     sudo systemctl edit amazon-ssm-agent
     ```

3. Open a simple editor like VIM, and depending on whether you're using an HTTP proxy server or HTTPS proxy server, add one of the following configurations.

For an HTTP proxy server:

```
[Service]
Environment="http_proxy=http://hostname:port"
Environment="https_proxy=http://hostname:port"
Environment="no_proxy=IP address for instance metadata services (IMDS)"
```

For an HTTPS proxy server:

```
[Service]
Environment="http_proxy=http://hostname:port"
Environment="https_proxy=https://hostname:port"
Environment="no_proxy=IP address for instance metadata services (IMDS)"
```

Important

Add the `no_proxy` setting to the file and specify the IP address. The IP address for `no_proxy` is the instance metadata services (IMDS) endpoint for Systems Manager. If you don't specify `no_proxy`, calls to Systems Manager take on the identity from the proxy service (if IMDSv1 fallback is enabled) or calls to Systems Manager fail (if IMDSv2 is enforced).

- For IPv4, specify `no_proxy=169.254.169.254`.
- For IPv6, specify `no_proxy=[fd00:ec2::254]`. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only

accessible on instances built on the Amazon Nitro System. For more information, see How Instance Metadata Service Version 2 works in the *Amazon EC2 User Guide*.

4. Save your changes. The system automatically creates one of the following files, depending on the operating system type.

   - On Ubuntu Server instances where SSM Agent is installed by using a snap:

     `/etc/systemd/system/snap.amazon-ssm-agent.amazon-ssm-agent.service.d/`**`override.conf`**

   - On Amazon Linux 2, Amazon Linux 2023, and RHEL instances:

     `/etc/systemd/system/amazon-ssm-agent.service.d/`**`override.conf`**

   - On other operating systems:

     `/etc/systemd/system/amazon-ssm-agent.service.d/`**`amazon-ssm-agent.override`**

5. Restart SSM Agent by using one of the following commands, depending on the operating system type.

   - On Ubuntu Server instances installed by using a snap:

     ```
     sudo systemctl daemon-reload && sudo systemctl restart snap.amazon-ssm-agent.amazon-ssm-agent
     ```

   - On other operating systems:

     ```
     sudo systemctl daemon-reload && sudo systemctl restart amazon-ssm-agent
     ```

Note

For more information about working with `.override` files in systemd environments, see Modifying Existing Unit Files in the *Red Hat Enterprise Linux 7 System Administrator's Guide*.

Working with SSM Agent on EC2 instances for macOS

Amazon Systems Manager (SSM Agent) processes Systems Manager requests and configures your machine as specified in the request. Use the following procedures to install, configure, or uninstall SSM Agent for macOS.

> **Note**
>
> SSM Agent is preinstalled, by default, on Amazon Machine Images (AMIs) for macOS. You don't need to install SSM Agent on an Amazon Elastic Compute Cloud (Amazon EC2) instance for macOS unless you have uninstalled it.

The source code for SSM Agent is available on GitHub so that you can adapt the agent to meet your needs. We encourage you to submit pull requests for changes that you would like to have included. However, Amazon doesn't provide support for running modified copies of this software.

> **Note**
>
> To view details about the different versions of SSM Agent, see the release notes.

Before you manually install SSM Agent on a macOS operating system, review the following information.

- SSM Agent is installed by default on the EC2 instances and Amazon Machine Images supported by Systems Manager. For more information, see the list of supported operating systems for macOS.

  SSM Agent doesn't need to be manually installed on macOS EC2 instances unless it has been uninstalled.
- EC2 instances for macOS are not supported in all Amazon Web Services Regions. For lists of Regions where x86-based and M1 EC2 instances for macOS are supported, see macOS workloads in the Amazon EC2 FAQs.
- An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we

recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Topics

- Manually installing and uninstalling SSM Agent on EC2 instances for macOS

Manually installing and uninstalling SSM Agent on EC2 instances for macOS

Connect to your macOS instance and perform the following steps to install Amazon Systems Manager Agent (SSM Agent). Perform these steps on each instance that will run commands using Systems Manager. The commands provided in this procedure can also be passed to Amazon EC2 instances as scripts through user data.

> **Important**
>
> We strongly recommend that you avoid using OS versions that have reached End-of-Life (EOL). OS vendors including Amazon typically don't provide security patches or other updates for versions that have reached EOL. Continuing to use an EOL system greatly increases the risk of not being able to apply upgrades, including security fixes, and other operational problems. Amazon does not test Systems Manager functionality on OS versions that have reached EOL.

Before you begin

Install `wget` using Homebrew.

To install SSM Agent on macOS

1. Download the agent installer file for x86_64 instances using the following command.

   In the following command, replace *`region`* with your own information. For a list of supported *`region`* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

```
sudo wget https://s3.region.amazonaws.com/amazon-ssm-region/latest/darwin_amd64/
amazon-ssm-agent.pkg
```

For Apple silicon instances use the following command.

```
sudo wget https://s3.region.amazonaws.com/amazon-ssm-region/latest/darwin_arm64/
amazon-ssm-agent.pkg
```

Here is an example.

```
sudo wget https://s3.us-east-2.amazonaws.com/amazon-ssm-us-east-2/latest/
darwin_amd64/amazon-ssm-agent.pkg
```

2. Use the following command to run the SSM Agent installer.

   x86_64:

   ```
   sudo installer -pkg amazon-ssm-agent.pkg -target /
   ```

3. Check the status of the agent.

   To determine if SSM Agent is running, check the agent log at `/var/log/amazon/ssm/amazon-ssm-agent.log` .

4. Run the following command to start the service if the the agent log indicates that "amazon-ssm-agent is stopped."

   ```
   sudo launchctl load -w /Library/LaunchDaemons/com.amazon.aws.ssm.plist && sudo
    launchctl start com.amazon.aws.ssm
   ```

Important

An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM

Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Uninstall SSM Agent from macOS instances

macOS doesn't natively support uninstallation of PKG files. To uninstall SSM Agent from an Amazon EC2 instance for macOS, use the Amazon managed script from the following location.

https://github.com/aws/amazon-ssm-agent/blob/mainline/Tools/src/update/darwin/uninstall.sh

Working with SSM Agent on EC2 instances for Windows Server

Amazon Systems Manager Agent (SSM Agent) is preinstalled, by default, on the Amazon Machine Images (AMIs) for Windows Server that are provided by Amazon. Support is provided for the following operating system (OS) versions.

- Windows Server 2012 R2 AMIs published in November 2016 or later
- Windows Server 2016, 2019, 2022 (excluding Nano versions), and 2025

Support notes for previous versions

Windows Server AMIs published *before* November 2016 use the EC2Config service to process requests and configure instances.

Unless you have a specific reason for using the EC2Config service, or an earlier version of SSM Agent to process Systems Manager requests, we recommend that you download and install the latest version of SSM Agent to each of your Amazon Elastic Compute Cloud (Amazon EC2) instances or non-EC2 machines that are configured for Systems Manager in a hybrid and multicloud environment.

Keeping SSM Agent up to date

An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

To view details about the different versions of SSM Agent, see the release notes.

Topics

- Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server
- Configure SSM Agent to use a proxy for Windows Server instances

Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Amazon Systems Manager Agent (SSM Agent) is preinstalled, by default, on the following Amazon Machine Images (AMIs) for Windows Server provided by Amazon:

- Windows Server 2012 R2 AMIs published in November 2016 or later
- Windows Server 2016, 2019, 2022 (excluding Nano versions), and 2025

> **Important**
>
> We strongly recommend that you avoid using OS versions that have reached End-of-Life (EOL). OS vendors including Amazon typically don't provide security patches or other updates for versions that have reached EOL. Continuing to use an EOL system greatly increases the risk of not being able to apply upgrades, including security fixes, and other operational problems. Amazon does not test Systems Manager functionality on OS versions that have reached EOL.

Install SSM Agent on EC2 instances for Windows Server

If necessary, you can manually download and install the latest version of SSM Agent on your Amazon Elastic Compute Cloud (Amazon EC2) instance for Windows Server by using the following procedure. The commands provided in this procedure can also be passed to Amazon EC2 instances as scripts through user data.

SSM Agent requires Windows PowerShell 3.0 or later to run certain Amazon Systems Manager documents (SSM documents) on Windows Server instances (for example, the legacy `AWS-ApplyPatchBaseline` document). Verify that your Windows Server instances are running Windows Management Framework 3.0 or later. This framework includes Windows PowerShell. For more information, see Windows Management Framework 3.0.

Installation on other machine types

This procedure in this topic applies specifically to installing or reinstalling SSM Agent on an EC2 instance for Windows Server. For on-premises servers, virtual machines, or other non-EC2 environments, use the `ssm-setup-cli` tool as described in the section called "Install SSM Agent on hybrid Windows Server nodes".

Using EC2 installation procedures on non-EC2 systems can potentially result in security vulnerabilities. The `ssm-setup-cli` tool provides additional security protections for non-EC2 machines.

To manually install the latest version of SSM Agent on EC2 instances for Windows Server

1. Connect to your instance by using Remote Desktop or Windows PowerShell. For more information, see Connect to your instance in the *Amazon EC2 User Guide*.
2. Download the latest version of SSM Agent to your instance. You can download using either PowerShell commands or a direct download link.

   PowerShell

   Run the following three PowerShell commands in order. These commands allow you to download SSM Agent without adjusting Internet Explorer (IE) Enhanced Security settings, and then install the agent and remove the installation file.

   64-bit

   ```
   [System.Net.ServicePointManager]::SecurityProtocol = 'TLS12'
   $progressPreference = 'silentlyContinue'
   Invoke-WebRequest `
       https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/
   windows_amd64/AmazonSSMAgentSetup.exe `
       -OutFile $env:USERPROFILE\Desktop\SSMAgent_latest.exe
   ```

   32-bit

   ```
   [System.Net.ServicePointManager]::SecurityProtocol = 'TLS12'
   $progressPreference = 'silentlyContinue'
   Invoke-WebRequest `
       https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/
   windows_386/AmazonSSMAgentSetup.exe `
   ```

```
    -OutFile $env:USERPROFILE\Desktop\SSMAgent_latest.exe
```

```
Start-Process `
    -FilePath $env:USERPROFILE\Desktop\SSMAgent_latest.exe `
    -ArgumentList "/S" `
    -Wait
```

```
rm -Force $env:USERPROFILE\Desktop\SSMAgent_latest.exe
```

Direct download

https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/windows_amd64/AmazonSSMAgentSetup.exe

Run the downloaded `AmazonSSMAgentSetup.exe` file to install SSM Agent.

3. Start or restart SSM Agent by sending the following command in PowerShell:

```
Restart-Service AmazonSSMAgent
```

> **Note**
>
> To uninstall the SSM Agent from a Windows Server instance, open **Control Panel**, **Programs**. Choose the **Uninstall a program** option. Open the context menu for **Amazon SSM Agent** and choose **Uninstall**.

Configure SSM Agent to use a proxy for Windows Server instances

The information in this topic applies to Windows Server instances created on or after November 2016 that do *not* use the Nano installation option. If you intend to use Session Manager, note that HTTPS proxy servers aren't supported.

Before you begin

Before you configure SSM Agent to use a proxy, note the following important information.

In the following procedure, you run a command to configure SSM Agent to use a proxy. The command includes a `no_proxy` setting with an IP address. The IP address is the instance metadata

services (IMDS) endpoint for Systems Manager. If you don't specify `no_proxy`, calls to Systems Manager take on the identity from the proxy service (if IMDSv1 fallback is enabled) or calls to Systems Manager fail (if IMDSv2 is enforced).

- For IPv4, specify `no_proxy=169.254.169.254`.
- For IPv6, specify `no_proxy=[fd00:ec2::254]`. The IPv6 address of the instance metadata service is compatible with IMDSv2 commands. The IPv6 address is only accessible on instances built on the Amazon Nitro System. For more information, see How Instance Metadata Service Version 2 works in the *Amazon EC2 User Guide*.

To configure SSM Agent to use a proxy

1. Using Remote Desktop or Windows PowerShell, connect to the instance that you would like to configure to use a proxy.
2. Run the following command block in PowerShell. Replace *`hostname`* and *`port`* with the information about your proxy.

```
$serviceKey = "HKLM:\SYSTEM\CurrentControlSet\Services\AmazonSSMAgent"
$keyInfo = (Get-Item -Path $serviceKey).GetValue("Environment")
$proxyVariables = @("http_proxy=hostname:port", "https_proxy=hostname:port",
 "no_proxy=IP address for instance metadata services (IMDS)")

if ($keyInfo -eq $null) {
    New-ItemProperty -Path $serviceKey -Name Environment -Value $proxyVariables -
PropertyType MultiString -Force
} else {
    Set-ItemProperty -Path $serviceKey -Name Environment -Value $proxyVariables
}

Restart-Service AmazonSSMAgent
```

After running the preceding command, you can review the SSM Agent logs to confirm the proxy settings were applied. Entries in the logs look similar to the following. For more information about SSM Agent logs, see Viewing SSM Agent logs.

```
2020-02-24 15:31:54 INFO Getting IE proxy configuration for current user: The operation
 completed successfully.
```

```
2020-02-24 15:31:54 INFO Getting WinHTTP proxy default configuration: The operation
 completed successfully.
2020-02-24 15:31:54 INFO Proxy environment variables:
2020-02-24 15:31:54 INFO http_proxy: hostname:port
2020-02-24 15:31:54 INFO https_proxy: hostname:port
2020-02-24 15:31:54 INFO no_proxy: IP address for instance metadata services (IMDS)
2020-02-24 15:31:54 INFO Starting Agent: amazon-ssm-agent - v2.3.871.0
2020-02-24 15:31:54 INFO OS: windows, Arch: amd64
```

To reset SSM Agent proxy configuration

1. Using Remote Desktop or Windows PowerShell, connect to the instance to configure.
2. If you connected using Remote Desktop, launch PowerShell as an administrator.
3. Run the following command block in PowerShell.

```
Remove-ItemProperty -Path HKLM:\SYSTEM\CurrentControlSet\Services\AmazonSSMAgent -
Name Environment
Restart-Service AmazonSSMAgent
```

SSM Agent proxy setting precedence

When configuring proxy settings for the SSM Agent on Windows Server instances, it's important to understand these settings are evaluated and applied to the agent configuration when the SSM Agent is started. How you configure your proxy settings for a Windows Server instance can determine whether other settings might supersede your intended settings. The agent uses the first proxy settings it finds.

> **Important**
>
> SSM Agent communicates using the HTTPS protocol. For this reason, you must configure the `HTTPS_PROXY` parameter by using one of the following settings options.

SSM Agent proxy settings are evaluated in the following order.

1. `AmazonSSMAgent` Registry settings (`HKLM:\SYSTEM\CurrentControlSet\Services\AmazonSSMAgent`)
2. `System` environment variables (`http_proxy`, `https_proxy`, `no_proxy`)

3. `LocalSystem` user account environment variables `http_proxy`, `https_proxy`, `no_proxy`)
4. Browser settings (`HTTP`, `secure`, `exceptions`)
5. `WinHTTP` proxy settings (`http=`, `https=`, `bypass-list=`)

SSM Agent proxy settings and Systems Manager services

If you configured the SSM Agent to use a proxy and are using Amazon Systems Manager tools, such as Run Command and Patch Manager, that use PowerShell or the Windows Update client during their execution on Windows Server instances, configure additional proxy settings. Otherwise, the operation might fail because proxy settings used by PowerShell and the Windows Update client aren't inherited from the SSM Agent proxy configuration.

For Run Command, configure `WinINet` proxy settings on your Windows Server instances. The `[System.Net.WebRequest]` commands provided are per-session. To apply these configurations to subsequent network commands that are run in Run Command, these commands must precede other PowerShell commands in the same `aws:runPowershellScript` plugin input.

The following PowerShell commands return the current `WinINet` proxy settings, and apply your proxy settings to `WinINet`.

```
[System.Net.WebRequest]::DefaultWebProxy

$proxyServer = "http://hostname:port"
$proxyBypass = "169.254.169.254"
$WebProxy = New-Object System.Net.WebProxy($proxyServer,$true,$proxyBypass)

[System.Net.WebRequest]::DefaultWebProxy = $WebProxy
```

For Patch Manager, configure system-wide proxy settings so the Windows Update client can scan for and download updates. We recommend that you use Run Command to run the following commands because they run on the SYSTEM account, and the settings apply system-wide. The following `netsh` commands return the current proxy settings, and apply your proxy settings to the local system.

```
netsh winhttp show proxy

netsh winhttp set proxy proxy-server="hostname:port" bypass-list="169.254.169.254"
```

For more information about using Run Command, see Amazon Systems Manager Run Command.

Checking SSM Agent status and starting the agent

This topic lists the commands to check whether Amazon Systems Manager Agent (SSM Agent) is running on each supported operating system. It also provides the commands to start the agent if it isn't running.

> **Note**
>
> These commands require that SSM Agent is already installed on the managed node. You must have administrator privileges on Windows, or root/sudo access on Linux and macOS, to run these commands.

Operating system	Command to check SSM Agent status	Command to start SSM Agent

Amazon Linux 2and Amazon Linux 2023	`sudo systemctl status amazon-ssm-agent`	`sudo systemctl enable amazon-ssm-agent`
		
		`sudo systemctl start amazon-ssm-agent`

Debian Server11 and 12	`sudo systemctl status amazon-ssm-agent`	`sudo systemctl enable amazon-ssm-agent`
		
		`sudo systemctl start amazon-ssm-agent`

macOS	Check the agent log file at `/var/log/amazon/ssm/amazon-ssm-agent.log`	`sudo launchctl load -w /Library/LaunchDaemons/com.amazon.aws.ssm.plist`
		
		`sudo launchctl start com.amazon.aws.ssm`

Oracle Linux	`sudo systemctl status amazon-ssm-agent`	`sudo systemctl enable amazon-ssm-agent`

Operating system	Command to check SSM Agent status	Command to start SSM Agent
		`sudo systemctl start amazon-ssm-agent`

Red Hat Enterprise Linux (RHEL) 7.x, 8.x, 9.x, and 10.x	`sudo systemctl status amazon-ssm-agent`	`sudo systemctl enable amazon-ssm-agent`
		
		`sudo systemctl start amazon-ssm-agent`

SUSE Linux Enterprise Server (SLES)	`sudo systemctl status amazon-ssm-agent`	`sudo systemctl enable amazon-ssm-agent`
		
		`sudo systemctl start amazon-ssm-agent`

Ubuntu Server 18.04, 20.04, 22.04 LTS, 23.10, 24.04 LTS, 24.0, and 25.04	`sudo systemctl status snap.amazon-ssm-agent.amazon-ssm-agent.service`	`sudo snap start amazon-ssm-agent`
Windows Server	*Run in PowerShell:* `Get-Service AmazonSSMAgent`	*Run in PowerShell Administrator mode:* `Start-Service AmazonSSMAgent`

More info

- Working with SSM Agent on EC2 instances for Linux
- Working with SSM Agent on EC2 instances for Windows Server
- Checking the SSM Agent version number

Checking the SSM Agent version number

Certain Amazon Systems Manager functionalities have prerequisites that include a minimum Systems Manager Agent (SSM Agent) version be installed on your managed nodes. You can get the currently installed SSM Agent version on your managed nodes using the Systems Manager console, or by logging in to your managed nodes.

> **Note**
>
> To view details about earlier versions, see the SSM Agent release notes on GitHub.

The following procedures describe how to get the currently installed SSM Agent version on your managed nodes.

To check the version number of SSM Agent installed on a managed node

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. In the **SSM Agent version** column, note the **Agent version** number.

To get the currently installed SSM Agent version from within the operating system

Choose from the following tabs to get the currently installed SSM Agent version from within an operating system.

Amazon Linux 2 and Amazon Linux 2023

> **Note**
>
> This command varies depending on the package manager for your operating system.

1. Log in to your managed node.
2. Run the following command.

```
yum info amazon-ssm-agent
```

This command returns output similar to the following.

```
Loaded plugins: extras_suggestions, langpacks, priorities, update-motd
Installed Packages
Name        : amazon-ssm-agent
Arch        : x86_64
Version     : 3.0.655.0
```

Debian Server

1. Log in to your managed node.
2. Run the following command.

```
apt list amazon-ssm-agent
```

This command returns output similar to the following.

```
apt list amazon-ssm-agent
Listing... Done
amazon-ssm-agent/now 3.0.655.0-1 amd64 [installed,local]

3.0.655.0 is the version of SSM agent
```

macOS

1. Log in to your managed node.
2. Run the following command.

```
pkgutil --pkg-info com.amazon.aws.ssm
```

RHEL

1. Log in to your managed node.
2. Run the following command for RHEL 7, 8, 9, and 10.

```
yum info amazon-ssm-agent
```

This command returns output similar to the following.

```
Loaded plugins: extras_suggestions, langpacks, priorities, update-motd
Installed Packages
Name        : amazon-ssm-agent
Arch        : x86_64
Version     : 3.0.655.0
```

Run the following command for the DNF package utility.

```
dnf info amazon-ssm-agent
```

SLES

1. Log in to your managed node.
2. Run the following command for SLES 15.*x*.

```
zypper info amazon-ssm-agent
```

This command returns output similar to the following.

```
Loading repository data...
Reading installed packages...
Information for package amazon-ssm-agent:
----------------------------------------
Repository : @System
Name : amazon-ssm-agent
Version : 3.0.655.0-1
```

Ubuntu Server

1. Log in to your managed node.
2. Run the following command for Ubuntu Server 18.04, 20.04, 22.04 LTS, 23.10, 24.04 LTS, 24.0, and 25.04.

```
sudo snap list amazon-ssm-agent
```

This command returns output similar to the following.

```
snap list amazon-ssm-agent
Name Version Rev Tracking Publisher Notes
amazon-ssm-agent 3.0.529.0 3552 latest/stable/… aws# classic-

3.0.529.0 is the version of SSM agent
```

Windows

1. Log in to your managed node.
2. Run the following PowerShell command.

```
& "C:\Program Files\Amazon\SSM\amazon-ssm-agent.exe" -version
```

This command returns output similar to the following.

```
SSM Agent version: 3.1.804.0
```

We recommend using the latest version of the SSM Agent so you can benefit from new or updated capabilities. To make sure your managed instances are always running the most up-to-date version of the SSM Agent, you can automate the process of updating the SSM Agent. For more information, see Automating updates to SSM Agent.

Viewing SSM Agent logs

Amazon Systems Manager Agent (SSM Agent) writes information about executions, commands, scheduled actions, errors, and health statuses to log files on each managed node. You can view log files by manually connecting to a managed node, or you can automatically send logs to Amazon CloudWatch Logs. For more information about sending logs to CloudWatch Logs, see Logging and monitoring in Amazon Systems Manager.

You can view SSM Agent logs on managed nodes in the following locations.

Linux and macOS

```
/var/log/amazon/ssm/
```

Windows

```
%PROGRAMDATA%\Amazon\SSM\Logs\
```

For Linux managed nodes, the SSM Agent `stderr` and `stdout` files are written to the following directory: `/var/lib/amazon/ssm/`.

For Windows managed nodes, the SSM Agent `stderr` and `stdout` files are written to the following directory: `%PROGRAMDATA%\Amazon\SSM\InstanceData\`.

For information about allowing SSM Agent debug logging, see Allowing SSM Agent debug logging.

For more information about `cihub/seelog` configuration, see the Seelog Wiki on GitHub. For examples of `cihub/seelog` configurations, see the cihub/seelog examples repository on GitHub.

Allowing SSM Agent debug logging

Use the following procedure to allow SSM Agent debug logging on your managed nodes.

Linux and macOS

To allow SSM Agent debug logging on Linux and macOS managed nodes

1. Either use Session Manager to connect to the managed node where you want to allow debug logging, or log on to the managed node. For more information, see Working with Session Manager.
2. Locate the **seelog.xml.template** file.

   Linux:

   On most Linux managed node types, the file is located in the directory `/etc/amazon/ssm/seelog.xml.template`.

   On Ubuntu Server 20.04 and 18.04 LTS, the file is located in the directory `/snap/amazon-ssm-agent/current/seelog.xml.template`. Copy this file from the `/snap/amazon-ssm-agent/current/` directory to the `/etc/amazon/ssm/` directory before making any changes.

macOS:

On macOS instance types, the file is located in the directory `/opt/aws/ssm/seelog.xml.template`.

3. Change the file name from `seelog.xml.template` to `seelog.xml`.

> **Note**
>
> On Ubuntu Server 20.04 and 18.04 LTS, the file `seelog.xml` must be created in the directory `/etc/amazon/ssm/`. You can create this directory and file by running the following commands.
>
> ```
> sudo mkdir -p /etc/amazon/ssm
> ```
>
> ```
> sudo cp -p /snap/amazon-ssm-agent/current/seelog.xml.template /etc/amazon/ssm/seelog.xml
> ```

4. Edit the `seelog.xml` file to change the default logging behavior. Change the value of **minlevel** from **info** to **debug**, as shown in the following example.

   `<seelog type="adaptive" mininterval="2000000" maxinterval="100000000" critmsgcount="500" minlevel="`**`debug`**`">`

5. (Optional) Restart SSM Agent using the following command.

   Linux:

   ```
   sudo service amazon-ssm-agent restart
   ```

   macOS:

   ```
   sudo /opt/aws/ssm/bin/amazon-ssm-agent restart
   ```

Windows

To allow SSM Agent debug logging on Windows Server managed nodes

1. Either use Session Manager to connect to the managed node where you want to allow debug logging, or log on to the managed nodes. For more information, see Working with Session Manager.
2. Make a copy of the **seelog.xml.template** file. Change the name of the copy to **seelog.xml**. The file is located in the following directory.

   ```
   %PROGRAMFILES%\Amazon\SSM\seelog.xml.template
   ```
3. Edit the `seelog.xml` file to change the default logging behavior. Change the value of **minlevel** from **info** to **debug**, as shown in the following example.

   ```
   <seelog type="adaptive" mininterval="2000000" maxinterval="100000000"
   critmsgcount="500" minlevel="debug">
   ```
4. Locate the following entry.

   ```
   filename="{{LOCALAPPDATA}}\Amazon\SSM\Logs\{{EXECUTABLENAME}}.log"
   ```

   Change this entry to use the following path.

   ```
   filename="C:\ProgramData\Amazon\SSM\Logs\{{EXECUTABLENAME}}.log"
   ```
5. Locate the following entry.

   ```
   filename="{{LOCALAPPDATA}}\Amazon\SSM\Logs\errors.log"
   ```

   Change this entry to use the following path.

   ```
   filename="C:\ProgramData\Amazon\SSM\Logs\errors.log"
   ```
6. Restart SSM Agent using the following PowerShell command in Administrator mode.

   ```
   Restart-Service AmazonSSMAgent
   ```

Restricting access to root-level commands through SSM Agent

Amazon Systems Manager Agent (SSM Agent) runs on Amazon Elastic Compute Cloud (Amazon EC2) instances and other machine types in hybrid and multicloud environments using root

permissions (Linux) or SYSTEM permissions (Windows Server). Because these are the highest level of system access permissions, any trusted entity that has been granted permission to send commands to SSM Agent has root or SYSTEM permissions. (In Amazon, a trusted entity that can perform actions and access resources in Amazon is called a *principal*. A principal can be an Amazon Web Services account root user, user, or a role.)

This level of access is required for a principal to send authorized Systems Manager commands to SSM Agent, but also makes it possible for a principal to run malicious code by exploiting any potential vulnerabilities in SSM Agent.

In particular, permissions to run the commands SendCommand and StartSession should be carefully restricted. A good first step is to grant permissions for each command only to select principals in your organization. However, we recommend tightening your security posture even further by restricting which managed nodes a principal can run these commands on. This can be done in the IAM policy assigned to the principal. In the IAM policy, you can include a condition that limits the user to running commands only on managed nodes that are tagged with specific tags or a combination of tags.

For example, say you have two fleets of servers, one for testing, one for production. In the IAM policy applied to junior engineers, you specify that they can run commands only on instances tagged with `ssm:resourceTag/testServer`. But, for a smaller group of lead engineers, who should have access to all instances, you grant access to instances tagged with both `ssm:resourceTag/testServer` and `ssm:resourceTag/productionServer`.

Using this approach, if junior engineers attempt to run a command on a production instance, they will be denied access because their assigned IAM policy doesn't provide explicit access to instances tagged with `ssm:resourceTag/productionServer`.

For more information and examples, see the following topics:

- Restricting Run Command access based on tags
- Restrict session access based on instance tags

Automating updates to SSM Agent

Amazon releases a new version of Amazon Systems Manager Agent (SSM Agent) when we add or update Systems Manager tools. If your managed nodes use an older version of the agent, then you can't use the new tools or benefit from the updated tools. For these reasons, we recommend

that you automate the process of updating SSM Agent on your managed nodes using any of the following methods.

Agent updates on the Bottlerocket operating system

SSM Agent on the Bottlerocket operating system can't be updated using the Systems Manager Command document `AWS-UpdateSSMAgent`. Updates are managed within the Bottlerocket control container. For more information, see Bottlerocket Control Container and Bottlerocket update operator on GitHub.

macOS version requirement

If an instance is running macOS version 11.0 (Big Sur) or later, the instance must have the SSM Agent version 3.1.941.0 or higher to run the AWS-UpdateSSMAgent document. If the instance is running a version of SSM Agent released before 3.1.941.0, update your SSM Agent to run the AWS-UpdateSSMAgent by running `brew update` and `brew upgrade amazon-ssm-agent` commands.

Method	Details
Automated update on all managed nodes (Recommended)	You can configure all managed nodes in your Amazon Web Services account to automatic ally check for and download new versions of SSM Agent. To do this, choose **Auto update SSM Agent** on the **Settings** tab in Fleet Manager, as described later in this topic.
Global or selective update	You can use State Manager to create an association that automatically downloads and installs SSM Agent on your managed nodes. If you want to limit the disruption to your workloads, you can create a Systems Manager maintenance window to perform the installat ion during designated time periods. Both methods allow you to create either a global update configuration for all of your managed nodes or selectively choose which instances get updated. For information about creating

Method	Details
	a State Manager association, see Walkthrough: Automatically update SSM Agent with the Amazon CLI. For information about creating a maintenance window, see Tutorial: Create a maintenance window for patching using the console.
Global or selective update for new environments	If you're getting started with Systems Manager, we recommend that you use the **Update Systems Manager (SSM) Agent every two weeks** option in Quick Setup. With Quick Setup, you can create either a global update configuration for all of your managed nodes or selectively choose which managed nodes get updated. For more information, see Set up Amazon EC2 host management using Quick Setup.

If you prefer to update SSM Agent on your managed nodes manually, you can subscribe to notifications that Amazon publishes when a new version of the agent is released. For information, see Subscribing to SSM Agent notifications. After you subscribe to notifications, you can use Run Command to manually update one or more managed nodes with the latest version. For more information, see Updating the SSM Agent using Run Command.

Automatically updating SSM Agent

You can configure Systems Manager to automatically update SSM Agent on all Linux-based and Windows-based managed nodes in your Amazon Web Services account. If you turn on this option, then Systems Manager automatically checks every two weeks for a new version of the agent. If there is a new version, then Systems Manager automatically updates the agent to the latest released version using the SSM document `AWS-UpdateSSMAgent`. We encourage you to choose this option to make sure that your managed nodes are always running the most up-to-date version of SSM Agent.

> **Note**
>
> If you use a `yum` command to update SSM Agent on a managed node after the agent has been installed or updated using the SSM document `AWS-UpdateSSMAgent`, you might see the following message: `"Warning: RPMDB altered outside of yum."` This message is expected and can be safely ignored.

To automatically update SSM Agent

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Fleet Manager**.
3. Choose the **Settings** tab.
4. In the **Agent auto update** area, choose **Auto update SSM Agent**.

To change the version of SSM Agent your fleet updates to, choose **Edit** under **Agent auto update** on the **Settings** tab. Then enter the version number of SSM Agent you want to update to in **Version** under **Parameters**. If not specified, the agent updates to the latest version.

To stop automatically deploying updated versions of SSM Agent to all managed nodes in your account, choose **Delete** under **Agent auto update** on the **Settings** tab. This action deletes the State Manager association that automatically updates SSM Agent on your managed nodes.

Subscribing to SSM Agent notifications

Amazon Simple Notification Service (Amazon SNS) can notify you when new versions of Amazon Systems Manager Agent (SSM Agent) are released. Use the following procedure to subscribe to these notifications.

> **Tip**
>
> You can also subscribe to notifications by watching the SSM Agent Release Notes page on GitHub.

To subscribe to SSM Agent notifications

1. Open the Amazon SNS console at https://console.amazonaws.cn/sns/v3/home.
2. From the Region selector in the navigation bar, choose **US East (N. Virginia)**, if it isn't selected already. You must select this Amazon Web Services Region because the Amazon SNS notifications for SSM Agent that you're subscribing to are generated from this Region only.
3. In the navigation pane, choose **Subscriptions**.
4. Choose **Create subscription**.
5. For **Create subscription**, do the following:
   a. For **Topic ARN**, use the following Amazon Resource Name (ARN):

      ```
      arn:aws-cn:sns:us-east-1:720620558202:SSM-Agent-Update
      ```

   b. For **Protocol**, choose `Email` or `SMS`.
   c. For **Endpoint**, depending on whether you chose `Email` or `SMS` in the previous step, enter an email address or an area code and number to receive notifications.
   d. Choose **Create subscription**.
6. If you chose `Email`, you receive an email message asking you to confirm your subscription. Open the message, and follow the directions to complete your subscription.

Whenever a new version of SSM Agent is released, we send notifications to subscribers. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

To unsubscribe from SSM Agent notifications

1. Open the Amazon SNS console.
2. In the navigation pane, choose **Subscriptions**.
3. Select the subscription, and then choose **Delete**. When prompted for confirmation, choose **Delete**.

Troubleshooting SSM Agent

If you experience problems running operations on your managed nodes, there might be a problem with Amazon Systems Manager Agent (SSM Agent). Use the following information to help you view

SSM Agent log files and troubleshoot the agent. If your agent appears to be unresponsive or has reduced communication frequency, see Understanding SSM Agent hibernation.

Topics

- SSM Agent is out of date
- Troubleshoot issues using SSM Agent log files
- File watcher fails with too many open files (Linux)
- Agent log files don't rotate (Windows)
- Unable to connect to SSM endpoints
- Verify your VPC configuration
- Verify your VPC DNS-related attributes
- Verify ingress rules on endpoint security groups
- Use ssm-cli to troubleshoot managed node availability

SSM Agent is out of date

An updated version of SSM Agent is released whenever new tools are added to Systems Manager or updates are made to existing tools. Failing to use the latest version of the agent can prevent your managed node from using various Systems Manager tools and features. For that reason, we recommend that you automate the process of keeping SSM Agent up to date on your machines. For information, see Automating updates to SSM Agent. Subscribe to the SSM Agent Release Notes page on GitHub to get notifications about SSM Agent updates.

Troubleshoot issues using SSM Agent log files

SSM Agent logs information in the following files. The information in these files can also help you troubleshoot problems. For more information about SSM Agent log files, including how to turn on debug logging, see Viewing SSM Agent logs.

> **Note**
>
> If you choose to view these logs by using Windows File Explorer, be sure to allow the viewing of hidden files and system files in Folder Options.

On Windows

- `%PROGRAMDATA%\Amazon\SSM\Logs\amazon-ssm-agent.log`
- `%PROGRAMDATA%\Amazon\SSM\Logs\errors.log`

On Linux and macOS

- `/var/log/amazon/ssm/amazon-ssm-agent.log`
- `/var/log/amazon/ssm/errors.log`

For Linux managed nodes, you might find more information in the `messages` file written to the following directory: `/var/log`.

For additional information about troubleshooting using agent logs, see How do I use SSM Agent logs to troubleshoot issues with SSM Agent in my managed instance? in the *Amazon re:Post Knowledge Center*.

File watcher fails with `too many open files` (Linux)

SSM Agent uses file watchers for inter-process communication with worker processes. This mechanism can be used by multiple Systems Manager operations, including associations and Session Manager sessions. If the agent can't create a new file watcher, the agent log can contain an entry similar to the following:

```
ERROR [NewFileWatcherChannel @ filewatcherchannel.go.104] ... filewatcher listener
 encountered error when start watcher: too many open files
```

Depending on the operating system, the final text can be `too many open file` or `too many open files`. For this specific signature, the strongest cause is exhaustion of the Linux per-user ID (UID) inotify instance limit. The failure occurs when the agent creates the watcher, before it adds a path to the watcher.

Use the following command on the managed node to inspect the current inotify instance limit:

```
sudo sysctl fs.inotify.max_user_instances
```

The supported recommendation for this condition is to set `fs.inotify.max_user_instances` to 8192. To apply the value to the running system, use the following command:

```
sudo sysctl -w fs.inotify.max_user_instances=8192
```

To persist the value, create a sysctl configuration file and load it:

```
printf '%s\n' 'fs.inotify.max_user_instances=8192' | sudo tee /etc/sysctl.d/99-amazon-ssm-agent.conf
sudo sysctl -p /etc/sysctl.d/99-amazon-ssm-agent.conf
```

Important

Size operating system limits according to the workload on the managed node and your organization's operating system policies. Don't apply unrelated limit values without evaluating other processes that run under the same UID.

The `fs.inotify.max_user_watches` setting limits the number of paths that inotify instances can watch. It is different from `fs.inotify.max_user_instances` and doesn't normally need to change for this watcher-creation failure. Change it only when your operating system diagnostics show that the watch-count limit is exhausted.

Note

Process open-file limits, including shell `nofile` limits and the `systemd` `LimitNOFILE` setting, and system settings `fs.nr_open` and `fs.file-max` apply to other file-descriptor exhaustion conditions. They don't increase the per-UID inotify instance limit and don't resolve this specific `NewFileWatcherChannel` signature.

Agent log files don't rotate (Windows)

If you specify date-based log file rotation in the seelog.xml file (on Windows Server managed nodes) and the logs don't rotate, specify the `fullname=true` parameter. Here is an example of a seelog.xml configuration file with the `fullname=true` parameter specified.

```
<seelog type="adaptive" mininterval="2000000" maxinterval="100000000"
 critmsgcount="500" minlevel="debug">
   <exceptions>
```

```
      <exception filepattern="test*" minlevel="error" />
   </exceptions>
   <outputs formatid="fmtinfo">
      <console formatid="fmtinfo" />
      <rollingfile type="date" datepattern="200601021504" maxrolls="4" filename="C:
\ProgramData\Amazon\SSM\Logs\amazon-ssm-agent.log" fullname="true" />
      <filter levels="error,critical" formatid="fmterror">
         <rollingfile type="date" datepattern="200601021504" maxrolls="4" filename="C:
\ProgramData\Amazon\SSM\Logs\errors.log" fullname="true" />
      </filter>
   </outputs>
   <formats>
      <format id="fmterror" format="%Date %Time %LEVEL [%FuncShort @ %File.%Line] %Msg
%n" />
      <format id="fmtdebug" format="%Date %Time %LEVEL [%FuncShort @ %File.%Line] %Msg
%n" />
      <format id="fmtinfo" format="%Date %Time %LEVEL %Msg%n" />
   </formats>
</seelog>
```

Unable to connect to SSM endpoints

SSM Agent must allow HTTPS (port 443) outbound traffic to the following endpoints:

- `ssm.region.amazonaws.com.cn`
- `ssmmessages.region.amazonaws.com.cn`

region represents the identifier for an Amazon Web Services Region supported by Amazon Systems Manager, such as `us-east-2` for the US East (Ohio) Region. For a list of supported *region* values, see the **Region** column in Systems Manager service endpoints in the *Amazon Web Services General Reference*.

> **Note**
>
> Prior to 2024, `ec2messages.region.amazonaws.com.cn` was also required.
> For Amazon Web Services Regions launched before 2024, allowing traffic to `ssmmessages.region.amazonaws.com.cn` is still required but optional to `ec2messages.region.amazonaws.com.cn`.
> For Regions launched in 2024 and later, allowing traffic to `ssmmessages.region.amazonaws.com.cn` is required, but

`ec2messages.region.amazonaws.com.cn` endpoints are not supported for these Regions.

SSM Agent won't work if it can't communicate with the preceding endpoints, as described, even if you use Amazon provided Amazon Machine Images (AMIs) such as Amazon Linux 2 or Amazon Linux 2023. Your network configuration must have open internet access or you must have custom virtual private cloud (VPC) endpoints configured. If you don't plan on creating a custom VPC endpoint, check your internet gateways or NAT gateways. For more information about how to manage VPC endpoints, see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

Verify your VPC configuration

If you are using a virtual private cloud (VPC), to manage EC2 instances with Systems Manager, your VPC endpoints must be configured properly for `ssm.region.amazonaws.com.cn`, `ssmmessages.region.amazonaws.com.cn`, and in some cases explained earlier in this topic in Unable to connect to SSM endpoints, `ec2messages.region.amazonaws.com.cn`.

Note

The alternative to using a VPC endpoint is to allow outbound internet access on your managed instances. In this case, the managed instances must also allow HTTPS (port 443) outbound traffic to the following endpoints:

- `ssm.region.amazonaws.com.cn`
- `ssmmessages.region.amazonaws.com.cn`
- `ec2messages.region.amazonaws.com.cn`

SSM Agent initiates all connections to the Systems Manager service in the cloud. For this reason, you don't need to configure your firewall to allow inbound traffic to your instances for Systems Manager.
For more information about calls to these endpoints, see Reference: ec2messages, ssmmessages, and other API operations.

To troubleshoot issues with your VPC endpoints, do the following:

- Make sure that VPC endpoints are included at the VPC level. If the VPC endpoint with a specific service name is not found on the VPC, first verify that DNS support is enabled at the VPC level. Next, create a new VPC endpoint and associate it with one subnet in each Availability Zone.
- Make sure that a private DNS name is enabled at the VPC endpoint level. Private DNS names are enabled by default but might have been manually disabled at some point.
- Make sure that existing VPC endpoints are associated with the proper subnet. In addition, make sure that the VPCE is already associated with a subnet in that Availability Zone.

For more information, see the following topics:

- Access an Amazon Web Services service using an interface VPC endpoint in the *Amazon PrivateLink Guide*
- Associate a private DNS name in the *Amazon PrivateLink Guide*
- Improve the security of EC2 instances by using VPC endpoints for Systems Manager

Verify your VPC DNS-related attributes

If you are using a virtual private cloud (VPC), as part of verifying your VPC configuration, make sure that the attributes `enableDnsSupport` and `enableDnsHostnames` are enabled.

You can enable these attributes using the Amazon EC2 ModifyVPCAttribute API action or the Amazon CLI command modify-vpc-attribute.

For information about enabling these attributes in the Amazon VPC Console, see View and update DNS attributes for your VPC in the *Amazon VPC User Guide*.

> **Note**
>
> The alternative to using a VPC endpoint is to allow outbound internet access on your managed instances. In this case, the managed instances must also allow HTTPS (port 443) outbound traffic to the following endpoints:
>
> - `ssm.region.amazonaws.com.cn`
> - `ssmmessages.region.amazonaws.com.cn`
> - `ec2messages.region.amazonaws.com.cn`

SSM Agent initiates all connections to the Systems Manager service in the cloud. For this reason, you don't need to configure your firewall to allow inbound traffic to your instances for Systems Manager.
For more information about calls to these endpoints, see Reference: ec2messages, ssmmessages, and other API operations.

Verify ingress rules on endpoint security groups

Make sure that any VPC endpoints you have configured (`ssm`, `ssmmessages`, and `ec2messages`) include an ingress rule on their security groups to allow traffic in on port 443. If necessary, you can create a new security group in the VPC with an ingress rule to allow traffic on port 443 for the Classless Inter-Domain Routing (CIDR) block for the VPC. After you create the security group, attach it to each VPC endpoint.

For more information, see the following topics:

- How do I create VPC endpoints so that I can use Systems Manager to manage private EC2 instances without internet access? on Amazon re:Post
- VPC CIDR blocks in the *Amazon VPC User Guide*

Use `ssm-cli` to troubleshoot managed node availability

Starting with SSM Agent version 3.1.501.0, you can use `ssm-cli` to determine whether a managed node meets the primary requirements to be managed by Systems Manager, and to appear in lists of managed nodes in Fleet Manager. The `ssm-cli` is a standalone command line tool included in the SSM Agent installation. Preconfigured commands are included that gather the required information to help you diagnose why an Amazon EC2 instance or non-EC2 machine that you have confirmed is running isn't included in your lists of managed nodes in Systems Manager. These commands are run when you specify the `get-diagnostics` option.

For more information, see Troubleshooting managed node availability using `ssm-cli`.

Security in Amazon Systems Manager

Cloud security at Amazon Web Services is the highest priority. As an Amazon customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between Amazon and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – Amazon is responsible for protecting the infrastructure that runs Amazon Web Services services in the Amazon Web Services Cloud. Amazon also gives you services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the Amazon Compliance Programs. To learn about the compliance programs that apply to Amazon Systems Manager, see Amazon Web Services services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the Amazon Web Services service that you use. You're also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon Systems Manager. The following topics show you how to configure Systems Manager to meet your security and compliance objectives. You also learn how to use other Amazon Web Services services that help you to monitor and secure your Systems Manager resources.

Topics

- Data protection in Amazon Systems Manager
- Data perimeters in Amazon Systems Manager
- Identity and access management for Amazon Systems Manager
- Using service-linked roles for Systems Manager
- Logging and monitoring in Amazon Systems Manager
- Compliance validation for Amazon Systems Manager
- Resilience in Amazon Systems Manager
- Infrastructure security in Amazon Systems Manager
- Configuration and vulnerability analysis in Amazon Systems Manager

- Security best practices for Systems Manager

Data protection in Amazon Systems Manager

Data protection refers to protecting data while *in transit* (as it travels to and from Systems Manager) and *at rest* (while it's stored in Amazon data centers).

The Amazon shared responsibility model applies to data protection in Amazon Systems Manager. As described in this model, Amazon is responsible for protecting the global infrastructure that runs all of the Amazon Web Services Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the Amazon Web Services services that you use. For more information about data privacy, see Amazon China Region Legal Terms.

For data protection purposes, we recommend that you protect Amazon Web Services account credentials and set up individual users with Amazon IAM Identity Center or Amazon Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with Amazon resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with Amazon CloudTrail. For information about using CloudTrail trails to capture Amazon activities, see Working with CloudTrail trails in the *Amazon CloudTrail User Guide*.
- Use Amazon encryption solutions, along with all default security controls within Amazon Web Services services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing Amazon through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Systems Manager or other Amazon Web Services services using the console,

API, Amazon CLI, or Amazon SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Data encryption

Encryption at rest

Parameter Store parameters

The types of parameters you can create in Parameter Store, include `String`, `StringList`, and `SecureString`.

All parameters, regardless of their type, are encrypted both in transit and at rest. In transit, parameters are encrypted using transport layer security (TLS) to create a secure HTTPS connection for API requests. At rest, they are encrypted with an Amazon owned key in Amazon Key Management Service (Amazon KMS). For more information about Amazon owned key encryption, see Amazon owned keys in the *Amazon Key Management Service Developer Guide* .

The `SecureString` type offers additional encryption options and is recommended for all sensitive data. You can choose from the following types of Amazon KMS keys to encrypt and decrypt the value of a `SecureString` parameter:

- The Amazon managed key for your account
- A customer managed key (CMK) that you have created in your account
- A CMK in another Amazon Web Services account that has been shared with you

For more information about Amazon KMS encryption, see the Amazon Key Management Service Developer Guide.

Content in S3 buckets

As part of your Systems Manager operations, you might choose to upload or store data in one or more Amazon Simple Storage Service (Amazon S3) buckets.

For information about S3 bucket encryption, see Protecting data using encryption and Data protection in Amazon S3 in the *Amazon Simple Storage Service User Guide*.

The following are types of data you can upload or have stored in S3 buckets as part of your Systems Manager activities:

- The output of commands in Run Command, a tool in Amazon Systems Manager
- Packages in Distributor, a tool in Amazon Systems Manager
- Patching operation logs in Patch Manager, a tool in Amazon Systems Manager
- Patch Manager patch override lists
- Scripts or Ansible Playbooks to run in a runbook workflow in Automation, a tool in Amazon Systems Manager
- Chef InSpec profiles for use with scans in Compliance, a tool in Amazon Systems Manager
- Amazon CloudTrail logs
- Session history logs in Session Manager, a tool in Amazon Systems Manager
- Reports from Explorer, a tool in Amazon Systems Manager
- OpsData from OpsCenter, a tool in Amazon Systems Manager
- Amazon CloudFormation templates for use with Automation workflows
- Compliance data from a resource data sync scan
- Output of requests to create or edit association in State Manager, a tool in Amazon Systems Manager, on managed nodes
- Custom Systems Manager documents (SSM documents) that you can run using the Amazon managed SSM document `AWS-RunDocument`

CloudWatch Logs log groups

As part of your Systems Manager operations, you might choose to stream data to one or more Amazon CloudWatch Logs log groups.

For information about CloudWatch Logs log group encryption, see Encrypt log data in CloudWatch Logs using Amazon Key Management Service in the *Amazon CloudWatch Logs User Guide*.

The following are types of data you might have streamed to a CloudWatch Logs log group as part of your Systems Manager activities:

- The output of Run Command commands
- The output of scripts run using the `aws:executeScript` action in an Automation runbook
- Session Manager session history logs

- Logs from SSM Agent on your managed nodes

Encryption in transit

We recommend that you use an encryption protocol such as Transport Layer Security (TLS) to encrypt sensitive data in transit between clients and your nodes.

Systems Manager provides the following support for encryption of your data in transit.

Connections to Systems Manager API endpoints

Systems Manager API endpoints only support secure connections over HTTPS. When you manage Systems Manager resources with the Amazon Web Services Management Console, Amazon SDK, or the Systems Manager API, all communication is encrypted with Transport Layer Security (TLS). For a full list of API endpoints, see Amazon Web Services service endpoints in the *Amazon Web Services General Reference*.

Managed instances

Amazon provides secure and private connectivity between Amazon Elastic Compute Cloud (Amazon EC2) instances. In addition, we automatically encrypt in-transit traffic between supported instances in the same virtual private cloud (VPC) or in peered VPCs, using AEAD algorithms with 256-bit encryption. This encryption feature uses the offload capabilities of the underlying hardware, and there is no impact on network performance. The supported instances are: C5n, G4, I3en, M5dn, M5n, P3dn, R5dn, and R5n.

Session Manager sessions

By default, Session Manager uses TLS 1.3 to encrypt session data transmitted between the local machines of users in your account and your EC2 instances. You can also choose to further encrypt the data in transit using an Amazon KMS key that has been created in Amazon KMS. Amazon KMS encryption is available for `Standard_Stream`, `InteractiveCommands`, and `NonInteractiveCommands` session types.

Run Command access

By default, remote access to your nodes using Run Command is encrypted using TLS 1.3, and requests to create a connection are signed using SigV4.

Internetwork traffic privacy

You can use Amazon Virtual Private Cloud (Amazon VPC) to create boundaries between resources in your managed nodes and control traffic between them, your on-premises network, and the internet. For details, see Improve the security of EC2 instances by using VPC endpoints for Systems Manager.

For more information about Amazon Virtual Private Cloud security, see Internetwork traffic privacy in Amazon VPC in the *Amazon VPC User Guide*.

Data perimeters in Amazon Systems Manager

A data perimeter is a set of preventive guardrails in your Amazon environment that help make sure your data can only be accessed by trusted identities from expected networks and resources. When you implement data perimeter controls, you might need to include exceptions for Amazon service-owned resources that Systems Manager accesses on your behalf.

Example scenario: SSM document categories S3 bucket

Systems Manager accesses an Amazon managed S3 bucket to retrieve document category information for Amazon Systems Manager Documents. This bucket contains metadata about document categories that help organize and classify SSM Documents in the console.

Resource ARN pattern

`arn:aws-cn:s3:::ssm-document-categories-`*`region`*

Regional examples:

- `arn:aws:s3:::ssm-document-categories-us-east-1`
- `arn:aws:s3:::ssm-document-categories-us-west-2`
- `arn:aws:s3:::ssm-document-categories-eu-west-1`
- `arn:aws:s3:::ssm-document-categories-ap-northeast-1`

When accessed

This resource is accessed when you view SSM Documents in the Systems Manager console or when using APIs that retrieve document metadata and categories.

Data stored

The bucket contains JSON files with document category definitions and metadata. This data is read-only and does not contain customer-specific information.

Identity used

Systems Manager accesses this resource using Amazon service credentials on behalf of your requests.

Required permissions

`s3:GetObject` on the bucket contents.

Data perimeter policy considerations

When implementing data perimeter controls using Service Control Policies (SCPs) or VPC endpoint policies with conditions like `aws:ResourceOrgID`, you need to create exceptions for the Amazon service-owned resources that Systems Manager requires.

For example, if you're using an SCP with `aws:ResourceOrgID` to restrict access to resources outside your organization, you would need to add an exception for the SSM Document categories bucket.

The policy would need to access to resources outside your organization but include an exception for the appropriate S3 buckets, allowing Systems Manager to continue functioning properly.

Similarly, if you're using VPC endpoint policies to restrict S3 access, you would need to make sure that the SSM document categories buckets are accessible through your VPC endpoints.

Example scenario: Hybrid node registration APIs

Hybrid nodes don't natively belong to an Amazon Web Services account – they are registered to one. Because of this, the `ssm:RegisterManagedInstance`, `ssm:RequestManagedInstanceRoleToken`, and `ssm:UpdateManagedInstancePublicKey` APIs don't use Amazon Signature Version 4 (SigV4) when authenticating hybrid nodes.

As a result, policy evaluation can't access an Amazon principal identity or global context keys such as `aws:PrincipalOrgId`, `aws:PrincipalAccount`, and `aws:SourceAccount`. Service control policies (SCPs) and VPC endpoint policies that rely on these global keys or on Amazon principal

identity might block these three APIs when hybrid nodes attempt to register. This can prevent hybrid nodes from completing registration.

To restrict access to these APIs based on account or organization membership, use the following Systems Manager condition keys, which resolve consistently for both Amazon EC2 instances and hybrid nodes:

- `ssm:NodeAccountId` – Resolves to the account in which an Amazon EC2 instance exists, or the account to which a hybrid node is registered.
- `ssm:NodeOrgId` – Resolves to the organization that owns the Amazon EC2 instance's account, or the organization of the account to which a hybrid node is registered.

More information

For more information about data perimeters in Amazon, see the following topics:

- Data perimeters on Amazon.
- Establish permissions guardrails using data perimeters in the *IAM User Guide*
- Service-specific guidance: Amazon Systems Manager and Service-owned resources in the *Amazon Samples* repository on GitHub

Identity and access management for Amazon Systems Manager

Amazon Identity and Access Management (IAM) is an Amazon Web Services service that helps an administrator securely control access to Amazon resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Systems Manager resources. IAM is an Amazon Web Services service that you can use with no additional charge.

Topics

- Audience
- Authenticating with identities
- Managing access using policies
- How Amazon Systems Manager works with IAM
- Amazon Systems Manager identity-based policy examples
- Amazon managed policies for Amazon Systems Manager
- Troubleshooting Amazon Systems Manager identity and access

Audience

How you use Amazon Identity and Access Management (IAM) differs based on your role:

- **Service user** - request permissions from your administrator if you cannot access features (see Troubleshooting Amazon Systems Manager identity and access)
- **Service administrator** - determine user access and submit permission requests (see How Amazon Systems Manager works with IAM)
- **IAM administrator** - write policies to manage access (see Amazon Systems Manager identity-based policy examples)

Authenticating with identities

Authentication is how you sign in to Amazon using your identity credentials. You must be authenticated as the Amazon Web Services account root user, an IAM user, or by assuming an IAM role.

For programmatic access, Amazon provides an SDK and CLI to cryptographically sign requests. For more information, see Amazon Signature Version 4 for API requests in the *IAM User Guide*.

Amazon Web Services account root user

When you create an Amazon Web Services account, you begin with one sign-in identity called the Amazon Web Services account *root user* that has complete access to all Amazon Web Services services and resources. We strongly recommend that you don't use the root user for everyday tasks. For tasks that require root user credentials, see Tasks that require root user credentials in the *IAM User Guide*.

IAM users and groups

An *IAM user* is an identity with specific permissions for a single person or application. We recommend using temporary credentials instead of IAM users with long-term credentials. For more information, see Require human users to use federation with an identity provider to access Amazon using temporary credentials in the *IAM User Guide*.

An *IAM group* specifies a collection of IAM users and makes permissions easier to manage for large sets of users. For more information, see Use cases for IAM users in the *IAM User Guide*.

IAM roles

An *IAM role* is an identity with specific permissions that provides temporary credentials. You can assume a role by switching from a user to an IAM role (console) or by calling an Amazon CLI or Amazon API operation. For more information, see Methods to assume a role in the *IAM User Guide*.

IAM roles are useful for federated user access, temporary IAM user permissions, cross-account access, cross-service access, and applications running on Amazon EC2. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Managing access using policies

You control access in Amazon by creating policies and attaching them to Amazon identities or resources. A policy defines permissions when associated with an identity or resource. Amazon evaluates these policies when a principal makes a request. Most policies are stored in Amazon as JSON documents. For more information about JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

Using policies, administrators specify who has access to what by defining which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. An IAM administrator creates IAM policies and adds them to roles, which users can then assume. IAM policies define permissions regardless of the method used to perform the operation.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you attach to an identity (user, group, or role). These policies control what actions identities can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

Identity-based policies can be *inline policies* (embedded directly into a single identity) or *managed policies* (standalone policies attached to multiple identities). To learn how to choose between managed and inline policies, see Choose between managed policies and inline policies in the *IAM User Guide*.

For information about Amazon managed policies for Systems Manager, see Amazon Systems Manager managed policies.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples include IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. You must specify a principal in a resource-based policy.

Resource-based policies are inline policies that are located in that service. You can't use Amazon managed policies from IAM in a resource-based policy.

Policy condition keys

The actions that users and roles can perform and the resources on which they can take those actions can be further restricted by specific *conditions*.

In JSON policy documents, the `Condition` element (or `Condition` block) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use condition operators, such as `StringEquals` or `StringNotLike`, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, Amazon evaluates them using a logical `AND` operation. If you specify multiple values for a single condition key, Amazon evaluates the condition using a logical `OR` operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the *IAM User Guide*.

Amazon supports global condition keys and service-specific condition keys. For more information, see Amazon global condition context keys in the *IAM User Guide*.

> **Important**
>
> If you use Systems Manager Automation, we recommend you don't use the aws:SourceIp condition key in your policies. The behavior of this condition key is dependent on multiple factors, including whether an IAM role for Automation runbook execution is supplied and the Automation actions used in the runbook. As a result, the condition key can produce unexpected behavior. For this reason, we recommend you don't use it.

Systems Manager supports several of its own condition keys. For more information, see Condition Keys for Amazon Systems Manager in the *Service Authorization Reference*. The actions and resources you can use a Systems Manager-specific condition key with are listed in Resource types defined by Amazon Systems Manager in the *Service Authorization Reference*.

If your policy must depend on a service principal name owned by the Systems Manager service, we recommend you check for its existence or non-existence using the `aws:PrincipalServiceNamesList` multivalued condition key, rather than the `aws:PrincipalServiceName` condition key. The `aws:PrincipalServiceName` condition key contains only one entry from the list of service principal names and it may not always be the service principal name you expect. The following `Condition` block demonstrates checking for the existence of `ssm.amazonaws.com`.

```
{
    "Condition": {
        "ForAnyValue:StringEquals": {
            "aws:PrincipalServiceNamesList": "ssm.amazonaws.com"
        }
    }
}
```

To view examples of Systems Manager identity-based policies, see Amazon Systems Manager identity-based policy examples.

Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, Amazon WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the *Amazon Simple Storage Service Developer Guide*.

Other policy types

Amazon supports additional policy types that can set the maximum permissions granted by more common policy types:

- **Permissions boundaries** – Set the maximum permissions that an identity-based policy can grant to an IAM entity. For more information, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs)** – Specify the maximum permissions for an organization or organizational unit in Amazon Organizations. For more information, see Service control policies in the *Amazon Organizations User Guide*.
- **Resource control policies (RCPs)** – Set the maximum available permissions for resources in your accounts. For more information, see Resource control policies (RCPs) in the *Amazon Organizations User Guide*.
- **Session policies** – Advanced policies passed as a parameter when creating a temporary session for a role or federated user. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how Amazon determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon Systems Manager works with IAM

Before you use Amazon Identity and Access Management (IAM) to manage access to Amazon Systems Manager, you should understand what IAM features are available to use with Systems Manager. To get a high-level view of how Systems Manager and other Amazon Web Services services work with IAM, see Amazon Web Services services that work with IAM in the *IAM User Guide*.

Topics

- Systems Manager identity-based policies
- Systems Manager resource-based policies
- Authorization based on Systems Manager tags
- Systems Manager IAM roles

Systems Manager identity-based policies

With IAM identity-based policies, you can specify allowed or denied actions and resources and the conditions under which actions are allowed or denied. Systems Manager supports specific actions,

resources, and condition keys. To learn about all of the elements that you use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Actions

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Include actions in a policy to grant permissions to perform the associated operation.

Policy actions in Systems Manager use the following prefix before the action: `ssm:`. For example, to grant someone permission to create a Systems Manager parameter (SSM parameter) with the Systems Manager `PutParameter` API operation, you include the `ssm:PutParameter` action in their policy. Policy statements must include either an `Action` or `NotAction` element. Systems Manager defines its own set of actions that describe tasks that you can perform with this service.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": [
      "ssm:action1",
      "ssm:action2"
]
```

Note

The following tools in Amazon Systems Manager use different prefixes before actions.

- Amazon AppConfig uses the prefix `appconfig:` before actions.
- Incident Manager uses the prefix `ssm-incidents:` or `ssm-contacts:` before actions.
- Systems Manager GUI Connect uses the prefix `ssm-guiconnect:` before actions.
- Quick Setup uses the prefix `ssm-quicksetup:` before actions.

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Describe`, include the following action:

```
"Action": "ssm:Describe*"
```

To see a list of Systems Manager actions, see Actions Defined by Amazon Systems Manager in the *Service Authorization Reference*.

Resources

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. As a best practice, specify a resource using its Amazon Resource Name (ARN). For actions that don't support resource-level permissions, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

For example, the Systems Manager maintenance window resource has the following ARN format.

```
arn:aws-cn:ssm:region:account-id:maintenancewindow/window-id
```

To specify the mw-0c50858d01EXAMPLE maintenance windows in your statement in the Region, you would use an ARN similar to the following.

```
"Resource": "arn:aws-cn:ssm:us-west-2:123456789012:maintenancewindow/
mw-0c50858d01EXAMPLE"
```

To specify all maintenance windows that belong to a specific account, use the wildcard (*).

```
"Resource": "arn:aws-cn:ssm:region:123456789012:maintenancewindow/*"
```

For `Parameter Store` API operations, you can provide or restrict access to all parameters in one level of a hierarchy by using hierarchical names and Amazon Identity and Access Management (IAM) policies as follows.

```
"Resource": "arn:aws-cn:ssm:region:123456789012:parameter/Dev/ERP/Oracle/*"
```

Some Systems Manager actions, such as those for creating resources, can't be performed on a specific resource. In those cases, you must use the wildcard (*).

```
"Resource": "*"
```

Some Systems Manager API operations accept multiple resources. To specify multiple resources in a single statement, separate their ARNs with commas as follows.

```
"Resource": [
      "resource1",
      "resource2"
```

Note

Most Amazon Web Services services treat a colon (:) or a forward slash (/) as the same character in ARNs. However, Systems Manager requires an exact match in resource patterns and rules. When creating event patterns, be sure to use the correct ARN characters so that they match the resource's ARN.

The table below describes the ARN formats for the resource types supported by Systems Manager.

Note

Note the following exceptions to ARN formats.

- The following tools in Amazon Systems Manager use different prefixes before actions.
  - Amazon AppConfig uses the prefix `appconfig:` before actions.
  - Incident Manager uses the prefix `ssm-incidents:` or `ssm-contacts:` before actions.
  - Systems Manager GUI Connect uses the prefix `ssm-guiconnect` before actions.
- Documents and automation definition resources that are owned by Amazon, and public parameters that are provided by both Amazon and third-party sources, do not include account IDs in their ARN formats. For example:
  - The SSM document `AWS-RunPatchBaseline`:

    `arn:aws:ssm:us-east-2::document/AWS-RunPatchBaseline`
  - The automation runbook `AWS-ConfigureMaintenanceWindows`:

`arn:aws:ssm:us-east-2::automation-definition/AWS-ConfigureMaintenanceWindows`

- The public parameter `/aws/service/bottlerocket/aws-ecs-1-nvidia/x86_64/1.13.4/image_version`:

  `arn:aws:ssm:us-east-2::parameter/aws/service/bottlerocket/aws-ecs-1-nvidia/x86_64/1.13.4/image_version`

For more information about these three resource types, see the following topics:

- Working with documents
- Run an automated operation powered by Systems Manager Automation
- Working with public parameters in Parameter Store

- Quick Setup uses the prefix `ssm-quicksetup:` before actions.

Resource type	ARN format
Application (Amazon AppConfig)	arn:aws-cn:appconfig:*region*:*account-id* :application/*application-id*
Association	arn:aws-cn:ssm:*region*:*account-id* :association/*association-id*
Automation execution	arn:aws-cn:ssm:*region*:*account-id* :automation-execution/*automation-execution-id*
Automation definition (with version subresource)	arn:aws-cn:ssm:*region*:*account-id* :automation-definition/*automation-definition-id* :*version-id* [1]
Configuration profile (Amazon AppConfig)	arn:aws-cn:appconfig:*region*:*account-id* :application/*application-id* /configurationprofile/*configurationprofile-id*
Contact (Incident Manager)	arn:aws-cn:ssm-contacts:*region*:*account-id* :contact/*contact-alias*

Resource type	ARN format
Deployment strategy (Amazon AppConfig)	arn:aws-cn:appconfig:*region*:*account-id* :deploymentstrategy/*deploymentstrategy-id*
Document	arn:aws-cn:ssm:*region*:*account-id* :document/*document-name*
Environment (Amazon AppConfig)	arn:aws-cn:appconfig:*region*:*account-id* :application/*application-id* /environment/*environment-id*
Incident	arn:aws-cn:ssm-incidents:*region*:*account-id* :incident-record/*response-plan-name* /*incident-id*
Maintenance window	arn:aws-cn:ssm:*region*:*account-id* :maintenancewindow/*window-id*
Managed node	arn:aws-cn:ssm:*region*:*account-id* :managed-instance/*managed-node-id*
Managed node inventory	arn:aws-cn:ssm:*region*:*account-id* :managed-instance-inventory/*managed-node-id*
OpsItem	arn:aws-cn:ssm:*region*:*account-id* :opsitem/*OpsItem-id*
Parameter	A one-level parameter: • arn:aws-cn:ssm:*region*:*account-id* :parameter/*parameter-name*/ A parameter named with a hierarchical construction: • arn:aws-cn:ssm:*region*:*account-id* :parameter/*parameter-name-root* /*level-2*/*level-3*/*level-4*/*level-5* [2]
Patch baseline	arn:aws-cn:ssm:*region*:*account-id* :patchbaseline/*patch-baseline-id*
Response plan	arn:aws-cn:ssm-incidents:*region*:*account-id* :response-plan/*response-plan-name*

Resource type	ARN format
Session	arn:aws-cn:ssm:*region*:*account-id* :session/*session-id* [3]
All Systems Manager resources	arn:aws-cn:ssm:*
All Systems Manager resources owned by the specified Amazon Web Services account in the specified Amazon Web Services Region	arn:aws-cn:ssm:*region*:*account-id* :*

> **Note**
>
> Automation definition resources are being deprecated. Update your IAM policies to include an allow for `ssm:StartAutomationExecution` or `ssm:StartChangeRequestExecution` on `document` and `automation-execution` resources. To view best practices and examples for setting up IAM permissions, refer to our Setting up identity based policies example user guide.

[1] For automation definitions, Systems Manager supports a second-level resource, *version ID*. In Amazon, these second-level resources are known as *subresources*. Specifying a version subresource for an automation definition resource lets you provide access to certain versions of an automation definition. For example, you might want to make sure that only the latest version of an automation definition is used in your node management.

[2] To organize and manage parameters, you can create names for parameters with a hierarchical construction. With hierarchical construction, a parameter name can include a path that you define by using forward slashes. You can name a parameter resource with a maximum of fifteen levels. We recommend that you create hierarchies that reflect an existing hierarchical structure in your environment. For more information, see Creating Parameter Store parameters in Systems Manager.

[3] In most cases, the session ID is constructed using the ID of the account user who started the session, plus an alphanumeric suffix. For example:

```
arn:aws:us-east-2:111122223333:session/JohnDoe-1a2b3c4sEXAMPLE
```

However, if the user ID isn't available, the ARN is constructed this way instead:

```
arn:aws:us-east-2:111122223333:session/session-1a2b3c4sEXAMPLE
```

For more information about the format of ARNs, see Amazon Resource Names (ARNs) in the *Amazon Web Services General Reference*.

For a list of Systems Manager resource types and their ARNs, see Resources Defined by Amazon Systems Manager in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions Defined by Amazon Systems Manager.

Condition keys for Systems Manager

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element specifies when statements execute based on defined criteria. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. To see all Amazon global condition keys, see Amazon global condition context keys in the *IAM User Guide*.

To see a list of Systems Manager condition keys, see Condition Keys for Amazon Systems Manager in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions Defined by Amazon Systems Manager.

For information about using the `ssm:resourceTag/*` condition key, see the following topics:

- Restricting access to root-level commands through SSM Agent
- Restricting Run Command access based on tags
- Restrict session access based on instance tags

For information about using the `ssm:Policies` and `ssm:Overwrite` condition keys, and for guidance on restricting access to individual parameters and parameter paths, see Preventing access to Parameter Store API operations.

Examples

To view examples of Systems Manager identity-based policies, see Amazon Systems Manager identity-based policy examples.

Systems Manager resource-based policies

Other Amazon Web Services services, such as Amazon Simple Storage Service (Amazon S3), support resource-based permissions policies. For example, you can attach a permissions policy to an S3 bucket to manage access permissions to that bucket.

Systems Manager doesn't support resource-based policies.

Authorization based on Systems Manager tags

You can attach tags to Systems Manager resources or pass tags in a request to Systems Manager. To control access based on tags, you provide tag information in the condition element of a policy using the `ssm:resourceTag/key-name`, `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys. You can add tags to the following resource types when you create or update them:

- Document
- Managed node
- Maintenance window
- Parameter
- Patch baseline
- OpsItem

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Viewing Systems Manager documents based on tags.

Systems Manager IAM roles

An IAM role is an entity within your Amazon Web Services account that has specific permissions.

Using temporary credentials with Systems Manager

You can use temporary credentials to sign in with federation, assume an IAM role, or to assume a cross-account role. You obtain temporary security credentials by calling Amazon Security Token Service (Amazon STS) API operations such as AssumeRole or GetFederationToken.

Systems Manager supports using temporary credentials.

Service-linked roles

Service-linked roles allow Amazon Web Services services to access resources in other services to complete an action on your behalf. Service-linked roles are listed in your IAM account and are owned by the service. An administrator can view but not edit the permissions for service-linked roles.

Systems Manager supports service-linked roles. For details about creating or managing Systems Manager service-linked roles, see Using service-linked roles for Systems Manager.

Service roles

This feature allows a service to assume a service role on your behalf. This role allows the service to access resources in other services to complete an action on your behalf. Service roles are displayed in your IAM account and are owned by the account. This means that an administrator can change the permissions for this role. However, doing so might break the functionality of the service.

Systems Manager supports service roles.

Choosing an IAM role in Systems Manager

For Systems Manager to interact with your managed nodes, you must choose a role to allow Systems Manager to access nodes on your behalf. If you have previously created a service role or service-linked role, then Systems Manager gives you a list of roles to choose from. It's important to choose a role that allows access to start and stop managed nodes.

To access EC2 instances, you must configure instance permissions. For information, see Configure instance permissions required for Systems Manager.

To access non-EC2 nodes in a hybrid and multicloud, the role your Amazon Web Services account needs is an IAM service role. For information, see Create the IAM service role required for Systems Manager in hybrid and multicloud environments.

An Automation workflow can be initiated under the context of a service role (or assume role). This allows the service to perform actions on your behalf. If you don't specify an assume role, Automation uses the context of the user who invoked the execution. However, certain situations require that you specify a service role for Automation. For more information, see Configuring a service role (assume role) access for automations.

Amazon Systems Manager managed policies

Amazon addresses many common use cases by providing standalone IAM policies that are created and administered by Amazon. These Amazon *managed policies* grant necessary permissions for common use cases so you can avoid having to investigate which permissions are needed. (You can also create your own custom IAM policies to allow permissions for Systems Manager actions and resources.)

For more information about managed policies for Systems Manager, see Amazon managed policies for Amazon Systems Manager

For general information about managed policies, see Amazon managed policies in the *IAM User Guide*.

Amazon Systems Manager identity-based policy examples

By default, Amazon Identity and Access Management (IAM) entities (users and roles) don't have permission to create or modify Amazon Systems Manager resources. They also can't perform tasks using the Systems Manager console, Amazon Command Line Interface (Amazon CLI), or Amazon API. An administrator is needed to create IAM policies that grant users and roles permission to perform specific API operations on the specified resources they need. The administrator must then attach those policies to the users or groups that require those permissions.

The following is an example of a permissions policy that allows a user to delete documents with names that begin with **`MyDocument-`** in the (us-west-2) Amazon Web Services Region.

JSON

```
{
  "Version":"2012-10-17",
  "Statement" : [
    {
      "Effect" : "Allow",
      "Action" : [
        "ssm:DeleteDocument"
      ],
      "Resource" : [
        "arn:aws-cn:ssm:us-east-1:111122223333:document/MyDocument-*"
      ]
    }
  ]
```

```
}
```

To learn how to create an IAM identity-based policy using these example JSON Policy documents, see Creating IAM policies in the *IAM User Guide*.

Topics

- Policy best practices
- Example: Permission to using the Systems Manager console
- Example: Permission to allow users to view their own permissions
- Example: Permission to read and describe individual parameters
- Cross-service confused deputy prevention
- Customer managed policy examples
- Viewing Systems Manager documents based on tags

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Systems Manager resources in your account. These actions can incur costs for your Amazon Web Services account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with Amazon managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *Amazon managed policies* that grant permissions for many common use cases. They are available in your Amazon Web Services account. We recommend that you reduce permissions further by defining Amazon customer managed policies that are specific to your use cases. For more information, see Amazon managed policies or Amazon managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific Amazon Web Services service, such as Amazon

CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.

- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your Amazon Web Services account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Example: Permission to using the Systems Manager console

To access the Systems Manager console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Systems Manager resources and other resources in your Amazon Web Services account.

If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for IAM entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the Amazon CLI or the Amazon API. Instead, allow access to only the actions that match the API operation that you're trying to perform.

To make sure that users and roles can still use the Systems Manager console, also attach the AmazonSSMFullAccess or AmazonSSMReadOnlyAccess Amazon managed policy to the entities. For more information, see Adding permissions to a user in the *IAM User Guide*.

Example: Permission to allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the Amazon CLI or Amazon API.

```
{

    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws-cn:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
        }
    ]
}
```

Example: Permission to read and describe individual parameters

Example Read and describe one parameter

You can grant access to a parameter by attaching the following policy to an identity.

JSON

```
{
```

```
"Version":"2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": [
      "ssm:GetParameter",
      "ssm:DescribeParameters"
      ],
    "Resource": "arn:aws-cn:ssm:us-east-1:111122223333:parameter/parameter-name"
  }
]
}
```

Cross-service confused deputy prevention

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. In Amazon, cross-service impersonation can result in the confused deputy problem. Cross-service impersonation can occur when one service (the *calling service*) calls another service (the *called service*). The calling service can be manipulated to use its permissions to act on another customer's resources in a way it should not otherwise have permission to access. To prevent this, Amazon provides tools that help you protect your data for all services with service principals that have been given access to resources in your account.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource policies to limit the permissions that Amazon Systems Manager gives another service to the resource. If the `aws:SourceArn` value does not contain the account ID, such as an Amazon Resource Name (ARN) for an S3 bucket, you must use both global condition context keys to limit permissions. If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement. Use `aws:SourceArn` if you want only one resource to be associated with the cross-service access. Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

The following sections provide example policies for Amazon Systems Manager tools.

Hybrid activation policy example

For service roles used in a hybrid activation, the value of `aws:SourceArn` must be the ARN of the Amazon Web Services account. Be sure to specify the Amazon Web Services Region in the ARN where you created your hybrid activation. If you don't know the full ARN of the resource or if you're specifying multiple resources, use the `aws:SourceArn` global context condition key with wildcards (*) for the unknown portions of the ARN. For example, `arn:aws-cn:ssm:*:region:123456789012:*`.

The following example demonstrates using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys for Automation to prevent the confused deputy problem in the Region (us-west-2).

JSON

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Sid":"",
         "Effect":"Allow",
         "Principal":{
            "Service":"ssm.amazonaws.com.cn"
         },
         "Action":"sts:AssumeRole",
         "Condition":{
            "StringEquals":{
               "aws:SourceAccount":"123456789012"
            },
            "ArnEquals":{
               "aws:SourceArn":"arn:aws-cn:ssm:us-east-1:123456789012:*"
            }
         }
      }
   ]
}
```

Resource data sync policy example

Systems Manager Inventory, Explorer, and Compliance enable you to create a resource data sync to centralize storage of your operations data (OpsData) in a central Amazon Simple Storage Service bucket. To encrypt a resource data sync with Amazon Key Management Service (Amazon KMS), create a new key that includes the following policy, or update an existing key to add this policy. The `aws:SourceArn` and `aws:SourceAccount` condition keys in this policy prevent the confused deputy problem.

JSON

```
{
    "Version":"2012-10-17",
    "Id": "ssm-access-policy",
    "Statement": [
        {
            "Sid": "ssm-access-policy-statement",
            "Action": [
                "kms:GenerateDataKey"
            ],
            "Effect": "Allow",
            "Principal": {
                "Service": "ssm.amazonaws.com.cn"
            },
            "Resource": "arn:aws-cn:kms:us-east-1:123456789012:key/KMS_key_id",
            "Condition": {
                "StringLike": {
                    "aws:SourceAccount": "123456789012"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws-cn:ssm:*:123456789012:role/aws-
service-role/ssm.amazonaws.com.cn/AWSServiceRoleForAmazonSSM"
                }
            }
        }
    ]
}
```

Note

The ARN in the policy example enables the system to encrypt OpsData from all sources except Amazon Security Hub CSPM. If you need to encrypt Security Hub CSPM data, for example if you use Explorer to collect Security Hub CSPM data, then you must attach an additional policy that specifies the following ARN: `"aws:SourceArn": "arn:aws-cn:ssm:*:account-id:role/aws-service-role/opsdatasync.ssm.amazonaws.com.cn/AWSServiceRoleForSystemsManagerOpsDataSync"`

Customer managed policy examples

You can create standalone policies that you administer in your own Amazon Web Services account. We refer to these as *customer managed policies*. You can attach these policies to multiple principal entities in your Amazon Web Services account. When you attach a policy to a principal entity, you give the entity the permissions that are defined in the policy. For more information, see Customer managed policy examples in the *IAM User Guide*.

The following examples of user policies grant permissions for various Systems Manager actions. Use them to limit the Systems Manager access for your IAM entities (users and roles). These policies work when performing actions in the Systems Manager API, Amazon SDKs, or the Amazon CLI. For users who use the console, you need to grant additional permissions specific to the console. For more information, see Example: Permission to using the Systems Manager console.

Note

All examples use the US West (Oregon) Region (us-west-2) and contain fictitious account IDs. The account ID shouldn't be specified in the Amazon Resource Name (ARN) for Amazon public documents (documents that begin with `AWS-*`).

Examples

- Example 1: Allow a user to perform Systems Manager operations in a single Region
- Example 2: Allow a user to list documents for a single Region

Example 1: Allow a user to perform Systems Manager operations in a single Region

The following example grants permissions to perform Systems Manager operations only in the Region (us-west-2).

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:*"
            ],
            "Resource": [
                "arn:aws-cn:ssm:us-east-1:111122223333:*"
            ]
        }
    ]
}
```

Example 2: Allow a user to list documents for a single Region

The following example grants permissions to list all document names that begin with **`Update`** in the Region (us-west-2).

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:ListDocuments"
            ],
            "Resource": [
                "arn:aws-cn:ssm:us-east-1:111122223333:document/Update*"
            ]
```

```
        }
    ]
}
```

Example 3: Allow a user to use a specific SSM document to run commands on specific nodes

The following example IAM policy allows a user to do the following in the Region (us-west-2):

- List Systems Manager documents (SSM documents) and document versions.
- View details about documents.
- Send a command using the document specified in the policy. The name of the document is determined by the following entry.

```
arn:aws-cn:ssm:us-west-2:aws-account-ID:document/Systems-Manager-document-name
```

- Send a command to three nodes. The nodes are determined by the following entries in the second `Resource` section.

```
"arn:aws-cn:ec2:us-west-2:aws-account-ID:instance/i-02573cafcfEXAMPLE",
"arn:aws-cn:ec2:us-west-2:aws-account-ID:instance/i-0471e04240EXAMPLE",
"arn:aws-cn:ec2:us-west-2:aws-account-ID:instance/i-07782c72faEXAMPLE"
```

- View details about a command after it has been sent.
- Start and stop workflows in Automation, a tool in Amazon Systems Manager.
- Get information about Automation workflows.

To give a user permission to use this document to send commands on any node they have access to, specify an entry similar to the following in the `Resource` section. Remove the other node entries. This example uses the Region (us-west-2).

```
"arn:aws-cn:ec2:us-west-2:*:instance/*"
```

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
```

```
        {
            "Action": [
                "ssm:ListDocuments",
                "ssm:ListDocumentVersions",
                "ssm:DescribeDocument",
                "ssm:GetDocument",
                "ssm:DescribeInstanceInformation",
                "ssm:DescribeDocumentParameters",
                "ssm:DescribeInstanceProperties"
            ],
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "ssm:SendCommand",
            "Effect": "Allow",
            "Resource": [
                "arn:aws-cn:ec2:us-east-1:111122223333:instance/
i-02573cafcfEXAMPLE",
                "arn:aws-cn:ec2:us-east-1:111122223333:instance/
i-0471e04240EXAMPLE",
                "arn:aws-cn:ec2:us-east-1:111122223333:instance/
i-07782c72faEXAMPLE",

                "arn:aws-cn:ssm:us-east-1:111122223333:document/Systems-Manager-
document-name"
            ]
        },
        {
            "Action": [
                "ssm:CancelCommand",
                "ssm:ListCommands",
                "ssm:ListCommandInvocations"
            ],
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "ec2:DescribeInstanceStatus",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "ssm:StartAutomationExecution",
```

```
            "Effect": "Allow",
            "Resource": [
                "arn:aws-cn:ssm:us-east-1:111122223333:document/*",
                "arn:aws-cn:ssm:us-east-1:111122223333:automation-execution/*"
            ]
        },
        {
            "Action": "ssm:DescribeAutomationExecutions",
            "Effect": "Allow",
            "Resource": [
                "*"
            ]
        },
        {
            "Action": [
                "ssm:StopAutomationExecution",
                "ssm:GetAutomationExecution"
            ],
            "Effect": "Allow",
            "Resource": [
                "*"
            ]
        }
    ]
}
```

Viewing Systems Manager documents based on tags

You can use conditions in your identity-based policy to control access to Systems Manager resources based on tags. This example shows how you might create a policy that allows viewing an SSM document. However, permission is granted only if the document tag `Owner` has the value of that user's user name. This policy also grants the permissions necessary to complete this action on the console.

JSON

```
{
    "Version":"2012-10-17",
    "Statement": [
        {
```

```
            "Sid": "ListDocumentsInConsole",
            "Effect": "Allow",
            "Action": "ssm:ListDocuments",
            "Resource": "*"
        },
        {
            "Sid": "ViewDocumentIfOwner",
            "Effect": "Allow",
            "Action": "ssm:GetDocument",
            "Resource": "arn:aws-cn:ssm:*:*:document/*",
            "Condition": {
                "StringEquals": {"ssm:ResourceTag/Owner": "${aws:username}"}
            }
        }
    ]
}
```

You can attach this policy to the users in your account. If a user named `richard-roe` attempts to view an Systems Manager document, the document must be tagged `Owner=richard-roe` or `owner=richard-roe`. Otherwise they're denied access. The condition tag key `Owner` matches both `Owner` and `owner` because condition key names aren't case-sensitive. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.

Amazon managed policies for Amazon Systems Manager

An Amazon managed policy is a standalone policy that is created and administered by Amazon. Amazon managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that Amazon managed policies might not grant least-privilege permissions for your specific use cases because they're available for all Amazon customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in Amazon managed policies. If Amazon updates the permissions defined in an Amazon managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. Amazon is most likely to update an Amazon managed policy when a new Amazon Web Services service is launched or new API operations become available for existing services.

For more information, see Amazon managed policies in the *IAM User Guide*.

Amazon managed policy: AmazonSSMServiceRolePolicy

This policy provides access to several Amazon resources that are managed by Amazon Systems Manager or used in Systems Manager operations.

You can't attach `AmazonSSMServiceRolePolicy` to your Amazon Identity and Access Management (IAM) entities. This policy is attached to a service-linked role that allows Amazon Systems Manager to perform actions on your behalf. For more information, see Using roles to collect inventory and view OpsData.

Permissions details

This policy includes the following permissions.

- `ssm` – Allows principals to start and step executions for both Run Command and Automation; and to retrieve information about Run Command and Automation operations; to retrieve information about Parameter Store parameters Change Calendar calendars; to update and retrieve information about Systems Manager service settings for OpsCenterresources; and to read information about tags that have have applied to resources.
- `cloudformation` – Allows principals to retrieve information about stackset operations and stackset instances, and to delete stacksets on the resource `arn:aws-cn:cloudformation:*:*:stackset/AWS-QuickSetup-SSM*:*`. Allows principals to delete stack instances that are associated with the following resources:

```
arn:aws-cn:cloudformation:*:*:stackset/AWS-QuickSetup-SSM*:*
arn:aws-cn:cloudformation:*:*:stackset-target/AWS-QuickSetup-SSM*:*
arn:aws-cn:cloudformation:*:*:type/resource/*
```

- `cloudwatch` – Allows principals to retrieve information about Amazon CloudWatch alarms.

> **Note**
>
> The `AmazonSSMServiceRolePolicy` includes `cloudwatch:DescribeAlarms` permission. However, Automation no longer uses the service-linked role for CloudWatch alarm monitoring. This operation now uses your runbook execution identity.

- `compute-optimizer` – Allows principals to retrieve the enrollment (opt in) status of an account to the Amazon Compute Optimizer service, and to retrieve recommendations for Amazon EC2 instances that meet a specific set of stated requirements.
- `config` – Allows principals to retrieve information remediation configurations and configuration recorders in Amazon Config, and to determine whether specified Amazon Config rules and Amazon resources are compliant.
- `events` – Allows principals retrieve information about EventBridge rules; to create EventBridge rules and targets exclusively for the the Systems Manager service (`ssm.amazonaws.com.cn`); and to delete rules and targets for the resource `arn:aws-cn:events:*:*:rule/SSMExplorerManagedRule`.
- `ec2` – Allows principals to retrieve information about Amazon EC2 instances..
- `iam` – Allows principals to pass roles permissions for the Systems Manager service (`ssm.amazonaws.com.cn`).

- `lambda` – Allows principals to invoke Lambda functions that are configured specifically for use by Systems Manager.
- `resource-explorer-2` – Allows principals to retrieve data about EC2 instances to determine whether each instance is currently managed by Systems Manager.

  The action `resource-explorer-2:CreateManagedView` is allowed for the `arn:aws:resource-explorer-2:*:*:managed-view/AWSManagedViewForSSM*` resource.
- `resource-groups` – Allows principals to retrieve list resource groups and their members from Amazon Resource Groups of resources that belong to a resource group.
