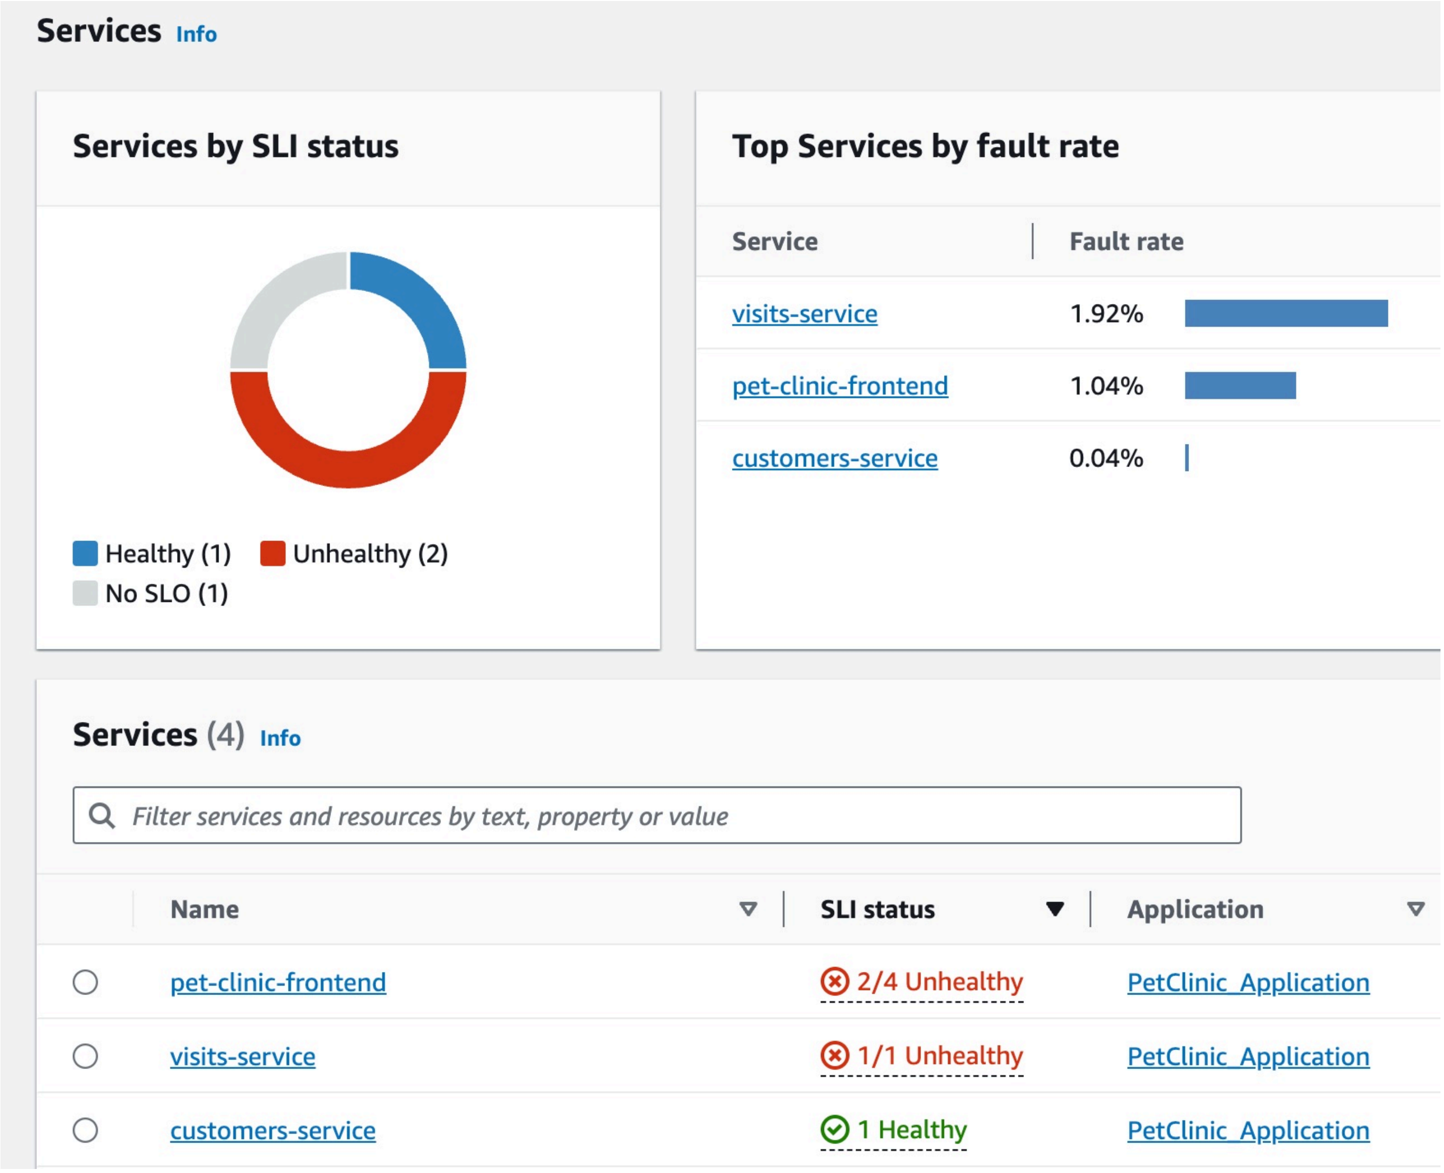
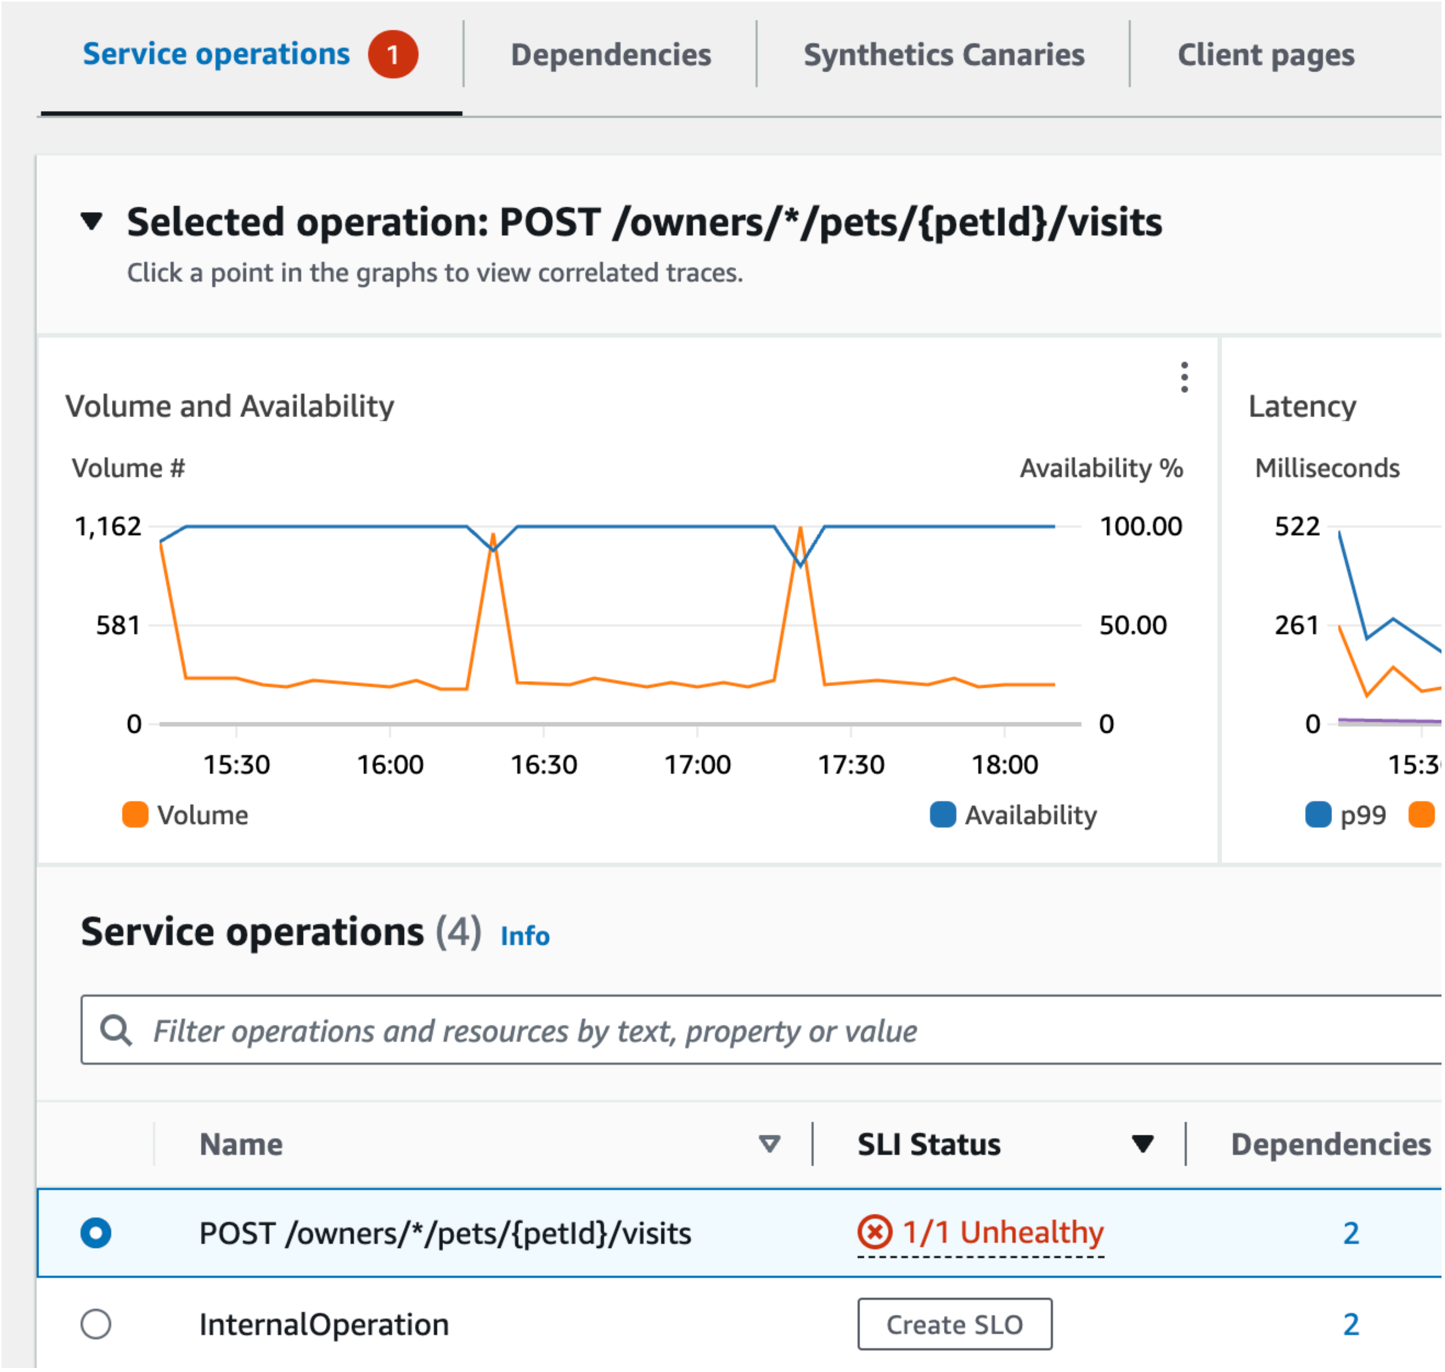
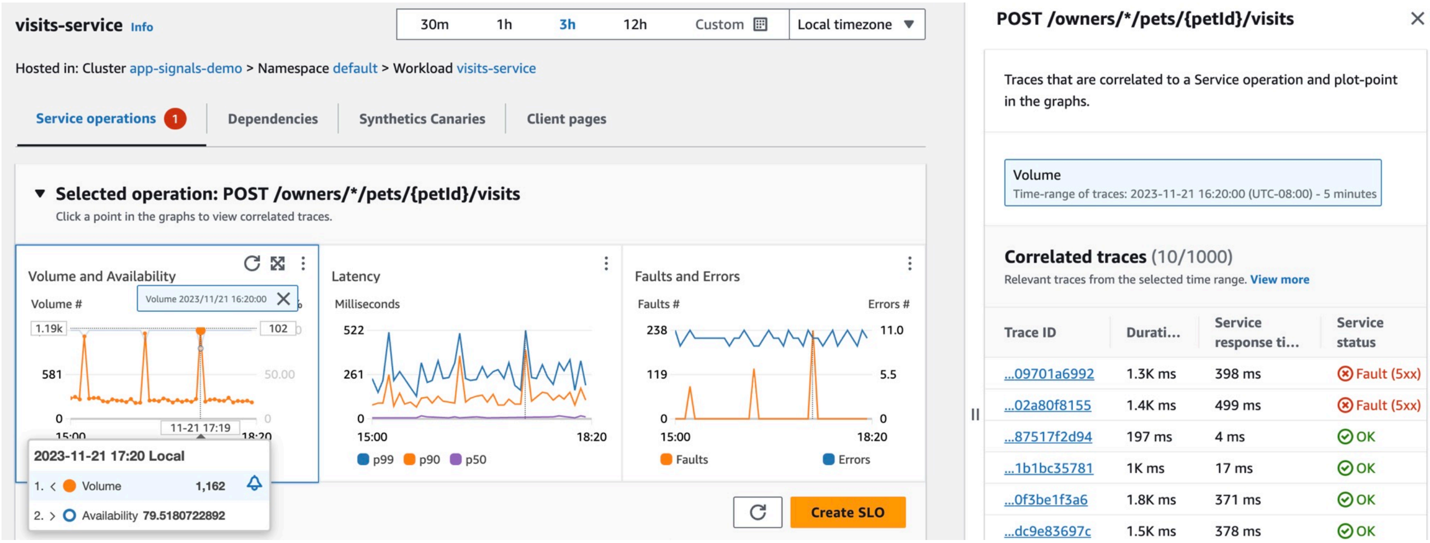
Jane is part of a DevOps team that oversees the operational health of a pet clinic application. Jane's team is committed to ensuring that the application is highly available and responsive. They use service level objectives (SLOs) to measure application performance against these business commitments. She receives an alert about several unhealthy service level indicators (SLIs). She opens the CloudWatch console and navigates to the Services page, where she sees several services in an unhealthy state.



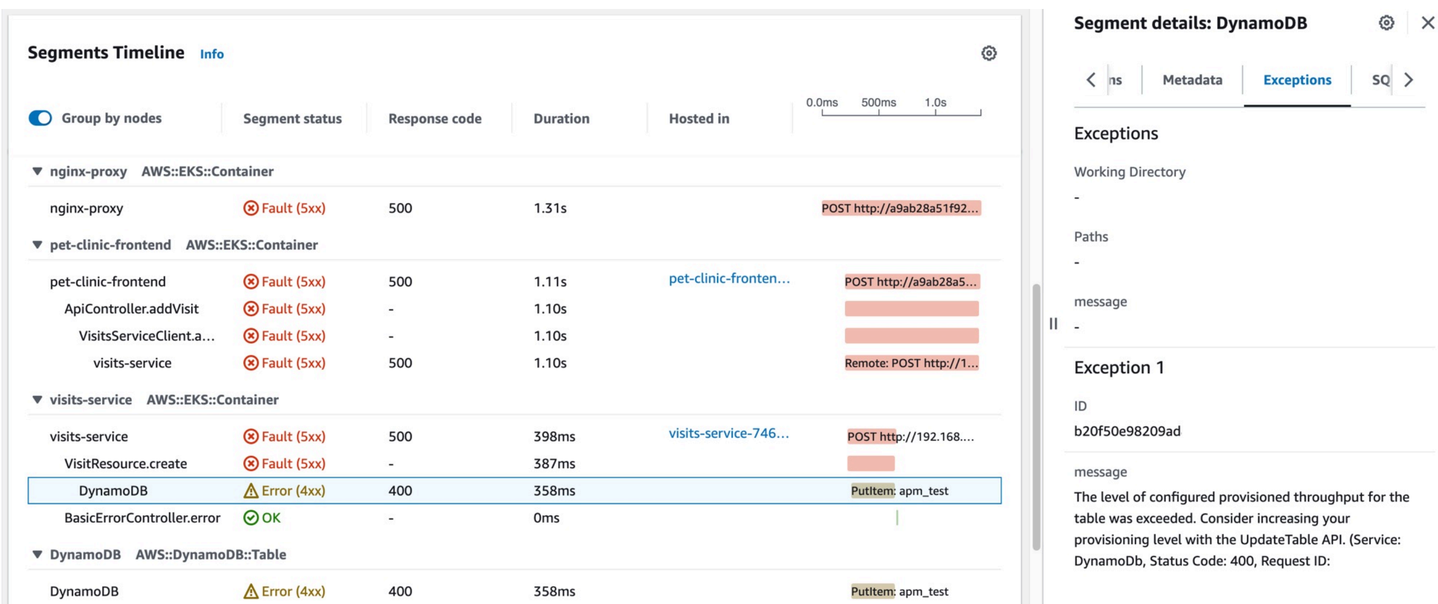
At the top of the page, Jane sees that the `visits-service` is the top service by fault rate. She selects the link in the graph, which opens the Service detail page for the service. She sees that there is an unhealthy operation in the Service operations table. She selects this operation and sees in the Volume and Availability graph that there are periodic call volume spikes that seem to correlate to dips in availability.



In order to look closer at the dips in service availability, Jane selects one of the availability data points in the graph. A drawer opens showing X-Ray traces that are correlated to the selected data point. She sees that there are multiple traces containing faults.



Jane selects one of the correlated traces with a fault status, which opens the X-Ray Trace detail page for the selected trace. Jane scrolls down to the Segments Timeline section and follows the call path until she sees that calls to a DynamoDB table are returning errors. She selects the DynamoDB segment and navigates to the Exceptions tab of the right-side drawer.



Jane sees that a DynamoDB resource is misconfigured, resulting in errors during spikes in customer requests. The DynamoDB table's level of provisioned throughput is periodically exceeded, resulting in service availability issues and unhealthy SLIs. Based on this information, her team is able to configure a higher level of provisioned throughput and ensure high availability of the application.

Example: Use Application Signals to troubleshoot generative AI applications interacting with Amazon Bedrock models

You can use Application Signals to troubleshoot your generative AI applications that interact with Amazon Bedrock models. Application Signals streamlines this process by providing out-of-the-box telemetry data, offering deeper insights into your application's interactions with LLM models. It helps address key use cases such as:

- Model configuration issues
- Model usage costs
- Model latency
- Model response generation stopped reasons

Enabling Application Signals with LLM/GenAI Observability provides real-time visibility into your application's interactions with Amazon Bedrock services. Application Signals automatically generates and correlates performance metrics and traces for Amazon Bedrock API calls.

Application Signals currently support the following LLM Models from Amazon Bedrock.

- AI21 Jamba
- Amazon Titan
- Anthropic Claude
- Cohere Command
- Meta Llama
- Mistral AI
- Nova

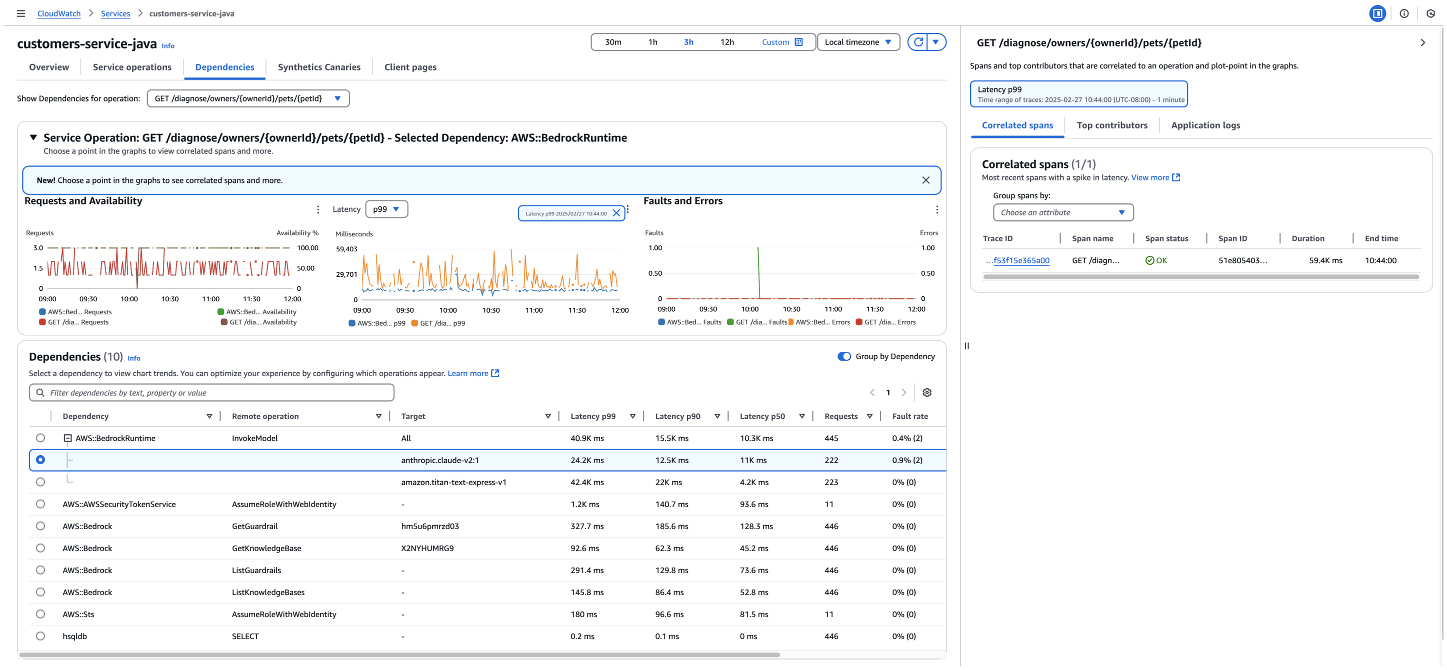
Fine-grained metrics and traces

For each Amazon Bedrock API call, Application Signals generates detailed performance metrics at the resource level, including:

- Model ID
- Guardrails ID
- Knowledge Base ID

- Bedrock Agent ID

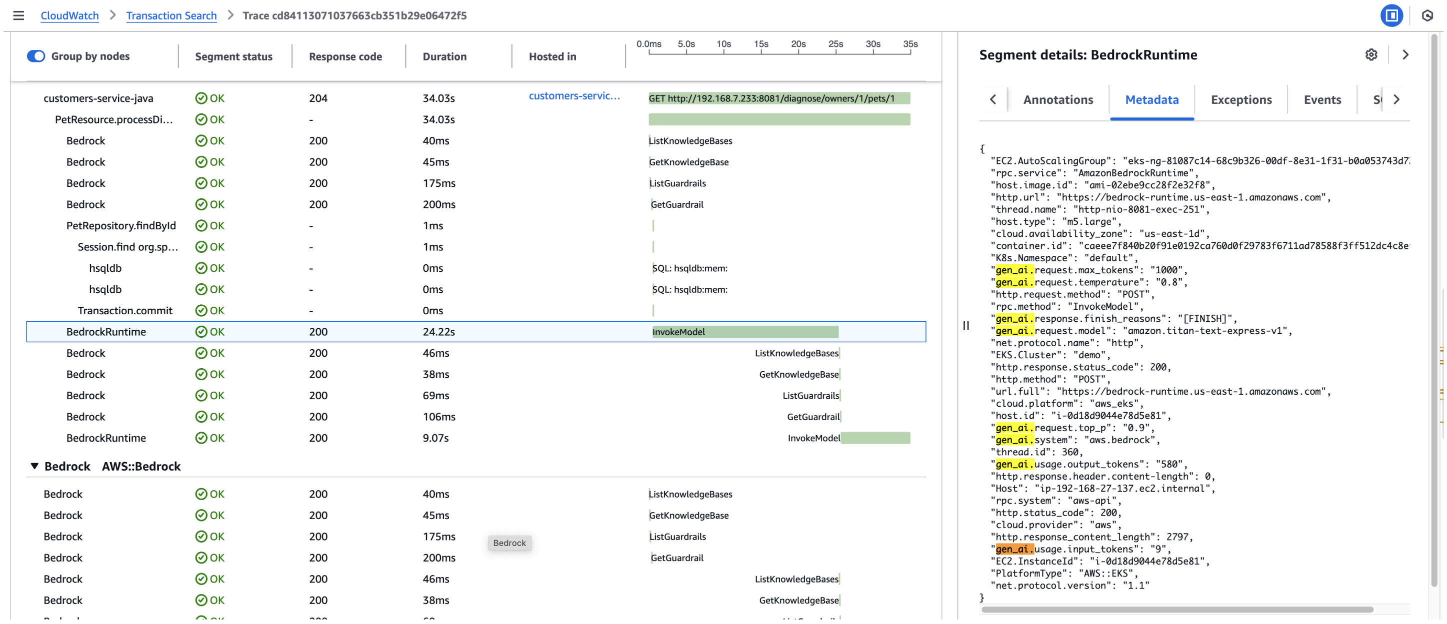
Additionally, correlated trace spans at the same level help provide a comprehensive view of request execution and dependencies.



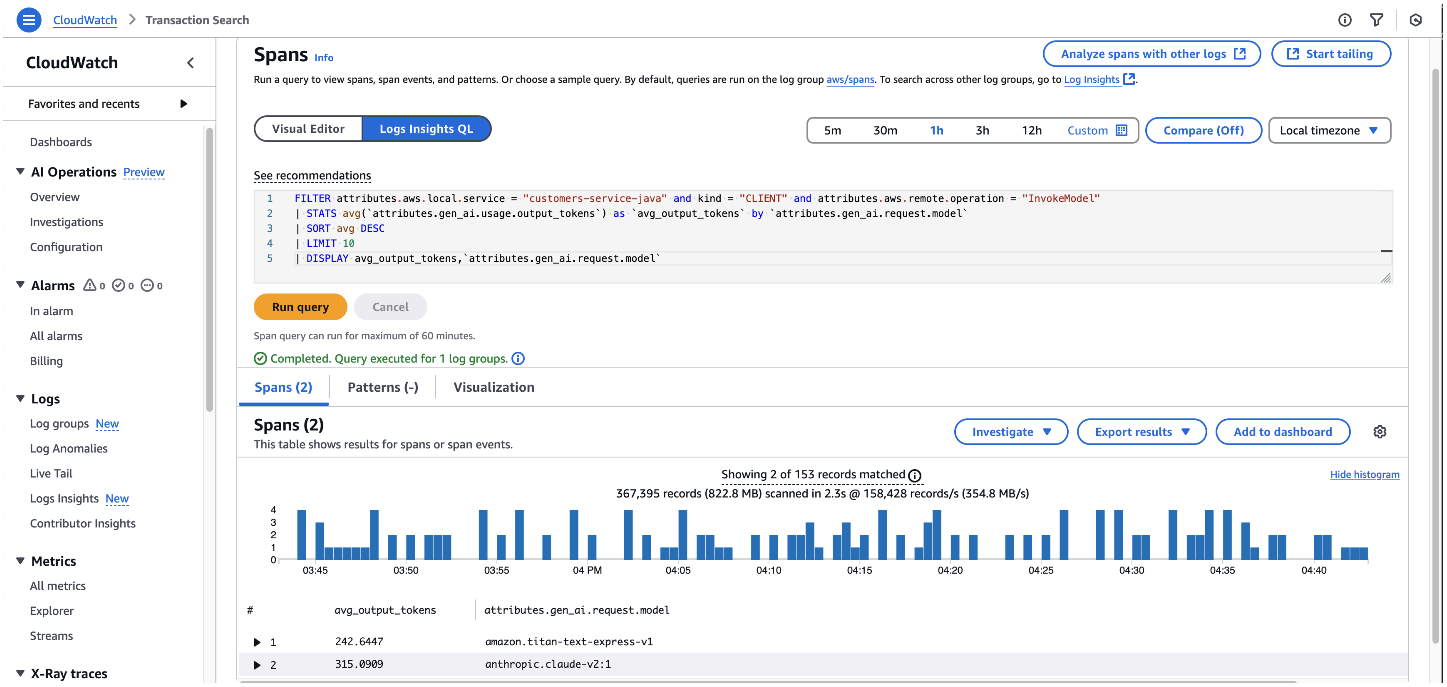
OpenTelemetry GenAI attributes support

Application Signals generates the following GenAI attributes for Amazon Bedrock API calls with OpenTelemetry semantic convention. These attributes help analyze model usage, cost, and response quality, and can be leveraged through Transaction Search for deeper insights.

- gen_ai.system
- gen_ai.request.model
- gen_ai.request.max_tokens
- gen_ai.request.temperature
- gen_ai.request.top_p
- gen_ai.usage.input_tokens
- gen_ai.usage.output_tokens
- gen_ai.response.finish_reasons



For example, your can leverage the analytic capability from Transaction Search to compare the token usage and cost across different LLM models for the same prompt, enabling cost-efficient model selection.



For more information, see [Improve Amazon Bedrock Observability with CloudWatch Application Signals](#).

Metrics collected by Application Signals

Application Signals collects both standard application metrics and runtime metrics from the applications that you enable it for.

Standard application metrics relate to the most critical parts of service performance, latency and availability.

Runtime metrics track application metrics over time, including memory usage, CPU usage, and garbage collection. Application Signals displays the runtime metrics in the context of the services that you have enabled for Application Signals. When you have an operational issue, observing the runtime metrics can be useful to help you find the root cause of the issue. For example, you can see if spikes in latency in your service relate to spikes in a runtime metric.

Topics

Standard application metrics collected

Application Signals collects *standard application metrics* from the services that it discovers. These metrics relate to the most critical aspects of a service's performance: latency, faults, and errors. They can help you identify issues, monitor performance trends, and optimize resources to improve the overall user experience.

The following table lists the metrics collected by Application Signals. These metrics are sent to CloudWatch in the `ApplicationSignals` namespace.

Metric	Description
`Latency`	The delay before data transfer begins after the request is made. Units: Milliseconds
`Fault`	A count of both HTTP 5XX server-side faults and OpenTelemetry span status errors.

Metric	Description
	Units: None
`Error`	A count of HTTP 4XX client-side errors. These are considered to be request errors that are not caused by service problems. Therefore, the `Availability` metric displayed on Application Signals dashboards does not regard these errors as service faults. Units: None

The `Availability` metric displayed on Application Signals dashboards is computed as **(1 - `Faults/Total`)*100**. Total responses includes all responses and is derived from `SampleCount(Latency)`. Successful responses are all responses without a `5XX` error. `4XX` responses are treated as successful when Application Signals calculates `Availability`.

Dimensions collected and dimension combinations

The following dimensions are defined for each of the standard application metrics. For more information about dimensions, see Dimensions.

Different dimensions are collected for *service metrics* and *dependency metrics*. Within the services discovered by Application Signals, when microservice A calls microservice B, microservice B is serving the request. In this case, microservice A emits dependency metrics and microservice B emits service metrics. When a client calls microservice A, microservice A is serving the request and emits service metrics.

Dimensions for service metrics

The following dimensions are collected for service metrics.

Dimension	Description
`Service`	The name of the service. The maximum value is 255 characters.
`Operation`	The name of the API operation or other activity.

Dimension	Description
	The maxiumum value is 1024 characters. Currently, you can set service level objectives on operations only if the operation name is 194 characters or fewer.
`Environment`	The name of the environment where services are running. If services are not running on Amazon EKS, you can specify an optional custom value for `deployment.environment` in the `OTEL_ATTRIBUTE_RESOURCES` parameter. The maxiumum value is 259 characters.

When you view these metrics in the CloudWatch console, you can view them using the following dimension combinations:

- `[Environment, Service, Operation, [Latency, Error, Fault]]`
- `[Environment, Service, [Latency, Error, Fault]]`

Dimensions for dependency metrics

The following dimensions are collected for dependency metrics:

Dimension	Description
`Service`	The name of the service. The maximum value is 255 characters.
`Operation`	The name of the API operation or other operation. The maximum value is 1024 characters.
`RemoteService`	The name of the remote service being invoked. The maximum value is 255 characters.
`RemoteOperation`	The name of the API operation being invoked.

Dimension	Description
	The maximum value is 1024 characters.
`Environment`	The name of the environment where services are running. If services are not running on Amazon EKS, you can specify an optional custom value for `deployment.environment` in the `OTEL_ATTRIBUTE_RESOURCES` parameter. The maxiumum value is 259 characters.
`RemoteEnvironment`	The name of the environment where dependency services are running. The `RemoteEnvironment` parameter is automatically generated when a service calls a dependency and they are both running in the same cluster. Otherwise, `RemoteEnvironment` is neither generated nor reported in the service dependency's metrics. Currently only available on Amazon EKS and K8S platforms. The maximum value is 259 characters.
`RemoteResourceIdentifier`	The name of the resource invoked by a remote call. The `RemoteResourceIdentifier` parameter is automatically generated if service calls a remote Amazon service. Otherwise, `RemoteResourceIdentifier` is neither generated nor reported in the service dependency's metrics. The maximum value is 1024 characters.
`RemoteResourceType`	The type of the resource that is invoked by a remote call. Required only if `RemoteResourceIdentifier` is defined. The maximum value is 1024 characters.

When you view these metrics in the CloudWatch console, you can view them using the following dimension combinations:

Running on Amazon EKS clusters

- `[Environment, Service, Operation, RemoteService, RemoteOperation, RemoteEnvironment, RemoteResourceIdentifier, RemoteResourceType, [Latency, Error, Fault]]`
- `[Environment, Service, Operation, RemoteService, RemoteOperation, RemoteEnvironment, [Latency, Error, Fault]]`
- `[Environment, Service, Operation, RemoteService, RemoteOperation, RemoteResourceIdentifier, RemoteResourceType, [Latency, Error, Fault]]`
- `[Environment, Service, Operation, RemoteService, RemoteOperation, [Latency, Error, Fault]]`
- `[Environment, Service, RemoteService, RemoteEnvironment, [Latency, Error, Fault]]`
- `[Environment, Service, RemoteService, [Latency, Error, Fault]]`
- `[Environment, Service, RemoteService, RemoteOperation, RemoteEnvironment, RemoteResourceIdentifier, RemoteResourceType, [Latency, Error, Fault]]`
- `[Environment, Service, RemoteService, RemoteOperation, RemoteEnvironment, [Latency, Error, Fault]]`
- `[Environment, Service, RemoteService, RemoteOperation, RemoteResourceIdentifier, RemoteResourceType, [Latency, Error, Fault]]`
- `[Environment, Service, RemoteService, RemoteOperation, [Latency, Error, Fault]]`
- `[RemoteService [Latency, Error, Fault]]`
- `[RemoteService, RemoteResourceIdentifier, RemoteResourceType [Latency, Error, Fault]]`

Runtime metrics

Application Signals uses the Amazon Distro for OpenTelemetry SDK to automatically collect OpenTelemetry-compatible metrics from your Java and Python applications. To have runtime metrics collected, you must meet the following pre-requisites:

- Your CloudWatch agent must be version `1.300049.1` or later.
- If you use the Amazon CloudWatch Observability EKS add-on, it must be version `2.30-eksbuild.1` or later. If you update the add-on, you must restart your applications.

- For Java applications, you must be running `1.32.5` or later of the Amazon Distro for OpenTelemetry SDK for Java.
- For Python applications, you must be running `0.7.0` or later of the Amazon Distro for OpenTelemetry SDK for Python.
- For .Net applications, you must be running `1.6.0` or later of the Amazon Distro for OpenTelemetry SDK for .Net.

Runtime metrics are not collected for Node.js applications.

Runtime metric are charged as part of Application Signals costs. For more information about CloudWatch pricing, see [Amazon CloudWatch Pricing](#).

> **Note**
>
> **Known issues**
> The runtime metrics collection in the Java SDK release v1.32.5 is known to not work with applications using JBoss Wildfly. This issue extends to the Amazon CloudWatch Observability EKS add-on, affecting versions `2.3.0-eksbuild.1` through `2.6.0-eksbuild.1`. The issue is fixed in Java SDK release `v1.32.6` and the Amazon CloudWatch Observability EKS add-on version `v3.0.0-eksbuild.1`.
> If you are impacted, either upgrade the Java SDK version or disable your runtime metrics collection by adding the environment variable `OTEL_AWS_APPLICATION_SIGNALS_RUNTIME_ENABLED=false` to your application.

Java runtime metrics

Application Signals collects the following JVM metrics from Java applications that you enable for Application Signals. All runtime metrics are sent to CloudWatch in the `ApplicationSignals` namespace, and are collected with the `Service` and `Environment` dimension set.

Metric name	Description	Meaningful statistics
`JVMGCDuration`	Aggregated metric for the duration of JVM garbage collection actions.	Sum, Average, Minimum, Maximum

Metric name	Description	Meaningful statistics
	Unit: Milliseconds	
`JVMGCOldGenDuration`	Aggregated metric for the duration of JVM garbage collection actions of the old generation. Available only in G1. Unit: Milliseconds	Sum, Average, Minimum, Maximum
`JVMGCYoungGenDuration`	Aggregated metric for the duration of JVM garbage collection actions of the young generation. Available only in G1. Unit: Milliseconds	Sum, Average, Minimum, Maximum
`JVMGCCount`	Aggregated metric for the number of JVM garbage collection actions. Unit: None	Sum, Average, Minimum, Maximum
`JVMGCOldGenCount`	Aggregated metric for the number of JVM garbage collection actions of the old generation. Available only in G1. Unit: None	Sum, Average, Minimum, Maximum
`JVMGCYoungGenCount`	Aggregated metric for the number of JVM garbage collection actions of the young generation. Available only in G1. Unit: None	Sum, Average, Minimum, Maximum
`JVMMemoryHeapUsed`	The amount of memory heap used. Unit: Bytes	Average, Minimum, Maximum

Metric name	Description	Meaningful statistics
JVMMemoryUsedAfter LastGC	Amount of memory used, as measured after the most recent garbage collection event on this pool. Unit: Bytes	Average, Minimum, Maximum
JVMMemoryOldGenUsed	The amount of memory used by the old generation. Unit: Bytes	Average, Minimum, Maximum
JVMMemorySurvivorS paceUsed	The amount of memory heap used by the survivor space. Unit: Bytes	Average, Minimum, Maximum
JVMMemoryEdenSpaceUsed	The amount of memory used by the eden space. Unit: Bytes	Average, Minimum, Maximum
JVMMemoryNonHeapUsed	The amount of non-heap memory used. Unit: Bytes	Average, Minimum, Maximum
JVMThreadCount	The number of executing threads, including both daemon and non-daemon threads. Unit: None	Sum, Average, Minimum, Maximum
JVMClassLoaded	The number of classes loaded. Unit: None	Sum, Average, Minimum, Maximum

Metric name	Description	Meaningful statistics
JVMCpuTime	The CPU time used by the process, as reported by the JVM. Unit: None (Nanoseconds)	Sum, Average, Minimum, Maximum
JVMCpuRecentUtilization	The recent CPU utilized by the process, as reported by the JVM. Unit: None	Average, Minimum, Maximum

Python runtime metrics

Application Signals collects the following metrics from Python applications that you enable for Application Signals. All runtime metrics are sent to CloudWatch in the `ApplicationSignals` namespace, and are collected with the `Service` and `Environment` dimension set.

Metric name	Description	Meaningful statistics
PythonProcessGCCount	The total number of objects currently being tracked. Unit: None	Sum, Average, Minimum, Maximum
PythonProcessGCGen0Count	The number of objects currently being tracked in Generation 0. Unit: None	Sum, Average, Minimum, Maximum
PythonProcessGCGen1Count	The number of objects currently being tracked in Generation 1. Unit: None	Sum, Average, Minimum, Maximum

Metric name	Description	Meaningful statistics
PythonProcessGCGen2Count	The number of objects currently being tracked in Generation 2. Unit: None	Sum, Average, Minimum, Maximum
PythonProcessVMSMemoryUsed	The total amount of virtual memory used by the process. Unit: Bytes	Average, Minimum, Maximum
PythonProcessRSSMemoryUsed	The total amount of non-swapped physical memory used by the process. Unit: Bytes	Average, Minimum, Maximum
PythonProcessThreadCount	The number of threads currently used by the process. Unit: None	Sum, Average, Minimum, Maximum
PythonProcessCpuTime	The CPU time used by the process. Unit: Seconds	Sum, Average, Minimum, Maximum
PythonProcessCpuUtilization	The CPU utilization of the process. Unit: None	Average, Minimum, Maximum

.Net runtime metrics

Application Signals collects the following metrics from .Net applications that you enable for Application Signals. All runtime metrics are sent to CloudWatch in the `ApplicationSignals` namespace, and are collected with the `Service` and `Environment` dimension set.

Metric name	Description	Meaningful statistics
`DotNetGCGen0Count`	The total number of garbage collection metrics tracked in Generation 0 since the process started. Unit: None	Sum, Average, Minimum, Maximum
`DotNetGCGen1Count`	The total number of garbage collection metrics tracked in Generation 1 since the process started. Unit: None	Sum, Average, Minimum, Maximum
`DotNetGCGen2Count`	The total number of garbage collection metrics tracked in Generation 2 since the process started. Unit: None	Sum, Average, Minimum, Maximum
`DotNetGCDuration`	The total amount of time paused in garbage collection since the process started. Unit: None	Sum, Average, Minimum, Maximum
`DotNetGCGen0HeapSize`	The heap size (including fragmentation) of Generation 0 observed during the latest garbage collection. **Note** This metric is only available after the first Garbage Collection is complete. Unit: Bytes	Average, Minimum, Maximum

Metric name	Description	Meaningful statistics
`DotNetGCGen1HeapSize`	The heap size (including fragmentation) of Generation 1 observed during the latest garbage collection. **Note** This metric is only available after the first Garbage Collection is complete. Unit: Bytes	Average, Minimum, Maximum
`DotNetGCGen2HeapSize`	The heap size (including fragmentation) of Generation 2 observed during the latest garbage collection. **Note** This metric is only available after the first Garbage Collection is complete. Unit: Bytes	Average, Minimum, Maximum

Metric name	Description	Meaningful statistics
`DotNetGCLOHHeapSize`	The large object heap size (including fragmentation) observed during the latest garbage collection. **Note** This metric is only available after the first Garbage Collection is complete. Unit: Bytes	Average, Minimum, Maximum
`DotNetGCPOHHeapSize`	The pinned object heap size (including fragmentation) observed during the latest garbage collection. **Note** This metric is only available after the first Garbage Collection is complete. Unit: Bytes	Average, Minimum, Maximum
`DotNetThreadCount`	The number of thread pool threads that currently exist. Unit: None	Average, Minimum, Maximum

Metric name	Description	Meaningful statistics
`DotNetThreadQueueLength`	The number of work items that are currently queued to be processed by the thread pool. Unit: None	Average, Minimum, Maximum

Disabling the collection of runtime metrics

Runtime metrics are collected by default for Java and Python applications that are enabled for Application Signals. If you want to disable the collection of these metrics, follow the instructions in this section for your environment.

Amazon EKS

To disable runtime metrics in Amazon EKS applications at the application level, add the following environment variable to your workload specification.

```
env:
    - name: OTEL_AWS_APPLICATION_SIGNALS_RUNTIME_ENABLED
      value: "false"
```

To disable runtime metrics in Amazon EKS applications at the cluster level, apply the configuration to the advanced configuration of your Amazon CloudWatch Observability EKS add-on.

```
{
  "agent": {
    "config": {
      "traces": {
        "traces_collected": {
          "application_signals": {

          }
        }
      },
      "logs": {
        "metrics_collected": {
          "application_signals": {
```

```
          }
        }
      }
    },
    "manager": {
      "autoInstrumentationConfiguration": {
        "java": {
          "runtime_metrics": {
            "enabled": false
          }
        },
        "python": {
          "runtime_metrics": {
            "enabled": false
          }
        },
        "dotnet": {
          "runtime_metrics": {
            "enabled": false
          }
        }
      }
    }
  }
}
```

Amazon ECS

To disable runtime metrics in Amazon ECS applications, add the environment variable `OTEL_AWS_APPLICATION_SIGNALS_RUNTIME_ENABLED=false` in the new task definition revision and redeploy the application.

EC2

To disable runtime metrics in Amazon EC2 applications, add the environment variable `OTEL_AWS_APPLICATION_SIGNALS_RUNTIME_ENABLED=false` before the application starts.

Kubernetes

To disable runtime metrics in Kubernetes applications at the application level, add the following environment variable to your workload specification.

```
env:
    - name: OTEL_AWS_APPLICATION_SIGNALS_RUNTIME_ENABLED
      value: "false"
```

To disable runtime metrics in Kubernetes applications at the cluster level, use the following:

```
helm upgrade ... \
--set-string
 manager.autoInstrumentationConfiguration.java.runtime_metrics.enabled=false \
--set-string
 manager.autoInstrumentationConfiguration.python.runtime_metrics.enabled=false \
-\-set-string
 manager.autoInstrumentationConfiguration.dotnet.runtime_metrics.enabled=false
```

Service level objectives (SLOs)

You can use Application Signals to create *service level objectives* for the services for your critical business operations or dependencies. By creating SLOs on these services, you will be able to track them on the SLO dashboard, giving you an at-a-glance view of your most important operations.

In addition to creating a quick view your operators can use to see the current status of critical operations, you can use SLOs to track the longer-term performance of your services, to ensure that they are meeting your expectations. If you have service level agreements with customers, SLOs are a great tool to ensure that they are met.

Assessing your services' health with SLOs starts with setting clear, measurable objectives based on key performance metrics— *service level indicators (SLIs)*. An SLO tracks the SLI performance against the threshold and goal that you set, and reports how far or how close your application performance is to the threshold.

Application Signals helps you set SLOs on your key performance metrics. Application Signals automatically collects `Latency` and `Availability` metrics for every service and operation that it discovers, and these metrics are often ideal to use as SLIs. With the SLO creation wizard, you can use these metrics for your SLOs. You can then track the status of all of your SLOs with the Application Signals dashboards.

You can set SLOs on specific operations or dependencies that your service calls or uses. You can use any CloudWatch metric or metric expression as an SLI, in addition to using the `Latency` and `Availability` metrics.

Creating SLOs is very important for getting the most benefit from CloudWatch Application Signals. After you create SLOs, you can view their status in the Application Signals console to quickly see which of your these critical services and operations are performing well and which are unhealthy. Having SLOs to track provides the following major benefits:

- It is easier for your service operators to see the current operational health of critical services as measured against the SLI. Then they can quickly triage and identify unhealthy services and operations.
- You can track your service performance against measurable business goals over longer periods of time.

By choosing what to set SLOs on, you are prioritizing what is important to you. The Application Signals dashboards automatically present information about what you have prioritized.

When you create an SLO, you can also choose to create CloudWatch alarms at the same time to monitor the SLOs. You can set alarms that monitor for breaches of the threshold, and also for warning levels. These alarms can automatically notify you if the SLO metrics are breaching the threshold that you set, or if they are nearing a warning threshold. For example, an SLO nearing its warning threshold can let you know that your team might need to slow down churn in the application to make sure that long-term performance goals are met.

Topics

SLO concepts

An SLO includes the following components:

- A *service level indicator (SLI)*, which is a key performance metric that you specify. It represents the desired level of performance for your application. Application Signals automatically collects the key metrics `Latency` and `Availability` for the services and operations that it discovers, and these can often be ideal metrics to set SLOs for.

  You choose the threshold to use for your SLI. For example, 200ms for latency.
- A *goal* or *attainment goal*, which is the percentage of time or requests that the SLI is expected to meet the threshold over each time *interval*. The time intervals can be as short as hours or as long as a year.

  Intervals can be either calendar intervals or rolling intervals.
  - *Calendar intervals* are aligned with the calendar, such as an SLO that is tracked per month. CloudWatch automatically adjusts health, budget, and attainment numbers based on the number of days in a month. Calendar intervals are better suited for business goals that are measured on a calendar-aligned basis.
  - *Rolling intervals* are calculated on a rolling basis. Rolling intervals are better suited for tracking recent user experience of your application.
- The *period* is a shorter length of time, and many periods make up an interval. The application's performance is compared to the SLI during each period within the interval. For each period, the application is determined to have either achieved or not achieved the necessary performance.

For example, a goal of 99% with a calendar interval of one day and a period of 1 minute means that the application must meet or achieve the success threshold during 99% of the 1-minute periods during the day. If it does, then the SLO is met for that day. The next day is a new evaluation interval, and the application must meet or achieve the success threshold during 99% of the 1-minute periods during the second day to meet the SLO for that second day.

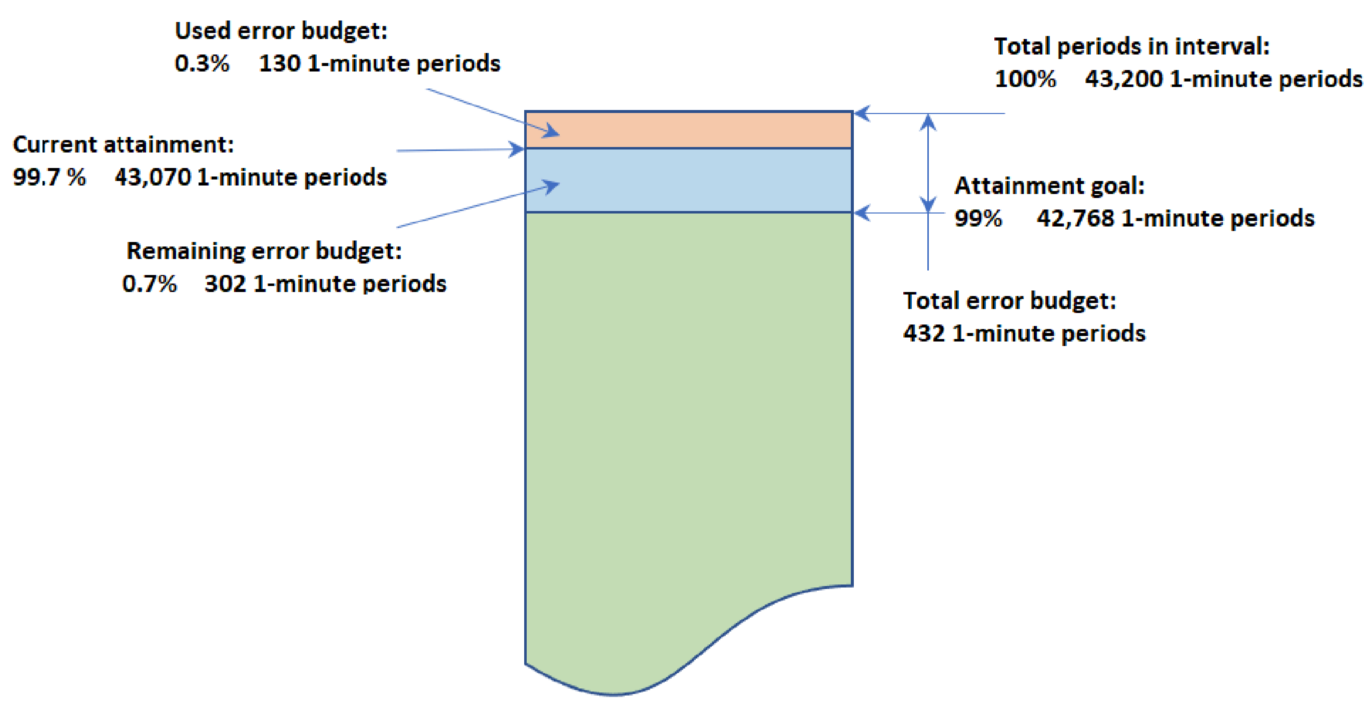
An SLI can be based on one of the new standard application metrics collected by Application Signals. Alternatively, it can be any CloudWatch metric or metric expression. The standard application metrics that you can use for an SLI are `Latency` and `Availability`. `Availability` represents the successful responses divided by the total requests. It is calculated as **(1 - Fault Rate)*100**, where Fault responses are `5xx` errors. Success responses are responses without a 5XX error. 4XX responses are treated as successful.

Calculate error budget and attainment for period-based SLOs

When you view information about an SLO, you see its current health status and its *error budget*. The error budget is the amount of time within the interval that can breach the threshold but still let the SLO be met. The *total error budget* is the total amount of breaching time that can be tolerated through the entire interval. The *remaining error budget* is the remaining amount of breaching time that can be tolerated during the current interval. This is after the amount of breaching time that has already happened has been subtracted from the total error budget.

The following figure illustrates the attainment and error budget concepts for a goal with a 30-day interval, 1-minute periods, and a 99% attainment goal. 30 days includes 43,200 1-minute periods. 99% of 43,200 is 42,768, so 42,768 minutes during the month must be healthy for the SLO to be met. So far in the current interval, 130 of the 1-minute periods were unhealthy.

SLO with an interval of 30 days and 1-minute periods



Determine success within each period

Within each period, the SLI data is aggregated into a single data point based on the statistic used for the SLI. This data point represents the entire length of the period. That single data point is compared to the SLI threshold to determine if the period is healthy. Seeing unhealthy periods during the current time range on the dashboard can alert your service operators that the service needs to be triaged.

If the period is determined to be unhealthy, the entire length of the period is counted as failed against the error budget. Tracking the error budget lets you know whether the service is achieving the performance that you want over a longer period of time.

Time window exclusions

Time window exclusions is a block of time with a defined start and end date. This time period is excluded from the SLO's performance metrics and you can schedule one-time or recurring time exclusions windows. For example, scheduled maintenance.

Note

- For period-based SLOs, SLI data in the exclusion window is considered as non-breaching.
- For request-based SLOs, all good and bad requests in the exclusion window are excluded.
- When an interval for a request-based SLO is completely excluded, a default attainment rate metric of 100% is published.
- You can only specify time windows with a start date in the future.

Calculate error budget and attainment for request-based SLOs

After you have created an SLO, you can retrieve error budget reports for it. An *error budget* is the amount of requests that your application can be non-compliant with the SLO's goal, and still have your application meet the goal. For a request-based SLO, the remaining error budget is dynamic and can increase or decrease, depending on the ratio of good requests to total requests

The following table illustrates the calculation for a request-based SLO with an interval of 5 days and 85% attainment goal. In this example, we assume there is no traffic before Day 1. The SLO did not meet the goal on Day 10.

Time	Total requests	Bad requests	Accumulative total requests in last 5 days	Accumulative total good requests in last 5 days	Request-based attainment	Total budget requests
Day 1	10	1	10	9	9/10 = 90%	1.5
Day 2	5	1	15	13	13/15=86%	2.3
Day 3	1	1	16	13	13/16=81%	2.4
Day 4	24	0	40	37	37/40=92%	6.0
Day 5	20	5	60	52	52/60=87%	9.0
Day 6	6	2	56	47	47/56=84%	8.4
Day 7	10	3	61	50	50/61=82%	9.2
Day 8	15	6	75	59	59/75=79%	11.3
Day 9	12	1	63	46	46/63=73%	9.5
Day 10		5	57	40	40/57=70%	8.5
Final attainment for last 5 days					**70%**	

Calculate burn rates and optionally set burn rate alarms

You can use Application Signals to calculate the *burn rates* for your service level objectives. A burn rate is a metric that indicates how fast the service is consuming the error budget, relative to the attainment goal of the SLO. It's expressed as a mutliple factor of the baseline error rate.

The burn rate is calculated according to the *baseline error rate*, which depends on the attainment goal. The attainment goal is the percentage of either healthy time periods or successful requests that must be achieved to meet the SLO goal. The baseline error rate is (100% - attainment goal percentage), and this number would use up the exact complete error budget at the end of the SLO's time interval. So an SLO with an attainment goal of 99% would have a baseline error rate of 1%.

Monitoring the burn rate tells us how far off we are from the baseline error rate. Again taking the example of an attainment goal of 99%, the following is true:

- **Burn rate = 1**: If the burn rate remains exactly at the baseline error rate all the time, we meet exactly the SLO goal.
- **Burn rate < 1**: If the burn rate is lower than the baseline error rate, we are on track to exceed the SLO goal.
- **Burn rate > 1**: If the burn rate is higher than baseline error rate, we have chance to fail the SLO goal.

When you create burn rates for your SLOs, you can also choose to create CloudWatch alarms at the same time to monitor the burn rates. You can set a threshold for the burn rates and the alarms can automatically notify you if the burn rate metrics are breaching the threshold that you set. For example, a burn rate nearing its threshold can let you know that the SLO is burning through the error budget faster than your team can tolerate and your team might need to slow down churn in the application to make sure that long-term performance goals are met.

Creating alarms incurs charges. For more information about CloudWatch pricing, see [Amazon CloudWatch Pricing](https://aws.amazon.com/cloudwatch/pricing/).

Calculate the burn rate

To calculate the burn rate, you must specify a *look-back window*. The look-back window is the time duration over which to measure the error rate.

```
burn rate = error rate over the look-back window / (100% - attainment goal)
```

> **Note**
>
> When there is no data for the burn rate period, Application Signals calculates the burn rate based on attainment.

The error rate is calculated as the ratio of the number of bad events over the total number of events during the burn rate window:

- For period-based SLOs, error rate is calculated as bad periods divided by total periods. The total periods represents the entirety of periods during the look-back window.
- For request-based SLOs, this is a measure of bad requests divided by total requests. The total number of requests is the number of requests during the look-back window.

The look-back window must be a multiple of the SLO period time, and must be less than the SLO interval.

Determine the appropriate threshold for a burn rate alarm

When you configure a burn rate alarm, you need to choose a value for the burn rate as the alarm threshold. The value for this threshold depends on the SLO interval length and look-back window, and depends on the which method or mental model that your team wants to adopt. There are two main methods available for determining the threshold.

Method 1: Determine the percentage of estimated total error budget your team is willing to burn in the look-back window.

If you want to get alarmed when X% of the estimated error budget is spent within the last burn rate look-back hours, the burn rate threshold is the following:

```
burn rate threshold = X% * SLO interval length / look-back window size
```

For example, 5% of a 30-day (720-hour) error budget spent over one hour requires a burn rate of `5% * 720 / 1 = 36`. Therefore, if the burn rate look-back window is1 hour, we set the burn rate threshold to be 36.

You can use the CloudWatch console to create burn rate alarms using this method. You can specify the number X, and the threshold is determined using the above formula.

The SLO interval length is determined based on the SLO interval type:

- For SLOs with a rolling interval, it’s the length of the interval in hours.
- For SLOs with a calendar-based interval:
  - If the unit is days or weeks, it’s the length of the interval in hours.

- If the unit is a month, we take 30 days as the estimated length and convert it to hours.

Method 2: Determine the time unitl budget exhaustion for the next interval

To have the alarm notify you when the current error rate in the most recent look-back window indicates that the time until budget exhaustion is less than X hours away (assuming the budget remaining is currently 100%), you can use the following formula to determine the burn rate threshold.

```
burn rate threshold = SLO interval length / X
```

We emphasize that the time until budget exhaustion (X) in the above formula assumes that the total budget remaining is currently 100%, and therefore it does not take into account the amount of budget that has already been burnt in this interval. We can also think of it as the time till budget exhaustion for the next interval.

Walkthroughs for burn rate alarms

As an example, let's take an SLO with a 28-day rolling interval. Setting a burn rate alarm for this SLO involves two steps:

1. Set the burn rate and the look-back window.
2. Crete a CloudWatch alarm that monitors the burn rate.

To get started, determine how much of the total error budget the service is willing to burn through within a specific time frame. In other words, statie your objective by using this sentence: "I want to get alerted when X% of my total error budget is consumed within M minutes."

For example, you might want to set the objective to be alerted when 2% of the total error budget is consumed within 60 minutes.

To set the burn rate, you first define the look-back window. The look-back windows is M, which in this example is 60 minutes.

Next, you create the CloudWatch alarm. When you do so, you must specify a threshold for the burn rate. If burn rate exceeds this threshold, the alarm will notify you. To find the threshold,use the following formula:

```
burn rate threshold = X% * SLO interval length/ look-back window size
```

In this example, X is 2 because we want to be alerted if 2% of the error budget is consumed within 60 minutes. The interval length is 40,320 minutes (28 days), and 60 minutes is the look-back window, so the answer is:

```
burn rate threshold = 2% * 40,320 / 60 = 13.44.
```

In this example, you would set 13.44 as the alarm threshold.

Multiple alarms with different windows

By setting up alarms on multiple look-back windows, you can quickly detect sharp error rate increases with the short window and at the same time detect smaller error rate increases that eventually deplete the error budget if they remain unnoticed.

Additionally, you could set a *composite alarm* on a burn rate with long window and on a burn rate with a short window (1/12th of the long window), and be informed only when both of the burn rates breach a threshold. This way, you can ensure that you get alerted only for situations that are still happening. For more information about composite alarms in CloudWatch, see [Combining alarms](#).

> **Note**
>
> You can set a metric alarm on a burn rate when you create the burn rate. To set a compoaite alarm on multiple burn rate alarms, you must use the instructions in [Create a composite alarm](#).

One composite alarm strategy recommended in the [Google Site Reliability Engineering workbook](#) includes three composite alarms:

- One composite alarm that watches a pair of alarms, one with a one-hour window and one with a five-minute window.
- A second composite alarm that watches a pair of alarms, one with a six-hour window and one with a 30-minute window.
- A third composite alarm that watches a pair of alarms, one with a three-day window and one with a six-hour window.

The steps to do this set up are the following:

1. Create five burn rates, with windows of five minutes, 30 minutes, one hour, six hours, and three days.
2. Create the following three pairs of CloudWatch alarms. Each pair includes one long window and one short window that is 1/12th of the long window, and the thresholds are determined by using the steps in Determine the appropriate threshold for a burn rate alarm. When you calculate the threshold for each alarm in the pair, use the longer look-back window of the pair in your calculation.
   - Alarms on the 1-hour and 5-minute burn rates (the threshold is determined by 2% of the total budget)
   - Alarms on the 6-hour and 30-minute burn rates (the threshold is determined by 5% of the total budget)
   - Alarms on the 3-day and 6-hour burn rates (the threshold is determined by 10% of the total budget)
3. For each of these pairs, create a composite alarm to get alerted when both of the individual alarms go into ALARM state. For more information about creating composite alarms, see Create a composite alarm.

   For example, if your alarms for the first pair (one-hour window and five-minute window) are named `OneHourBurnRate` and `FiveMinuteBurnRate`, the CloudWatch composite alarm rule would be `ALARM(OneHourBurnRate) AND ALARM(FiveMinuteBurnRate)`

The previous strategy is possible only for SLOs with interval length of at least three hours. For SLOs with shorter interval lengths, we recommend that you start with one pair of burn rate alarms where one alarm has a look-back window that is 1/12th of the look-back window of the other alarm. Then set a composite alarm on this pair.

Create an SLO

We recommend that you set both latency and availability SLOs on your critical applications. These metrics collected by Application Signals align with common business goals.

You can also set SLOs on any CloudWatch metric or any metric math expression that results in a single time series.

The first time that you create an SLO in your account, CloudWatch automatically creates the **AWSServiceRoleForCloudWatchApplicationSignals** service-linked role in your account, if it doesn't already exist. This service-linked role allows CloudWatch to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data from applications in your account. For more information about CloudWatch service-linked roles, see Using service-linked roles for CloudWatch.

When you create an SLO, you specify whether it is a *period-based SLO* or a *request-based SLO*. Each type of SLO has a different way of evaluating your application's performance against its attainment goal.

- A *period-based SLO* uses defined *periods* of time within a specified total time interval. For each period of time, Application Signals determines whether the application met its goal. The attainment rate is calculated as the `number of good periods/number of total periods`.

  For example, for a period-based SLO, meeting an attainment goal of 99.9% means that within your interval, your application must meet its performance goal during at least 99.9% of the time periods.
- A *request-based SLO* doesn't use pre-defined periods of time. Instead, the SLO measures `number of good requests/number of total requests` during the interval. At any time, you can find the ratio of good requests to total requests for the interval up to the time stamp that you specify, and measure that ratio against the goal set in your SLO.

Topics

Create a period-based SLO

Use the following procedure to create a period-based SLO.

To create a period-based SLO

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Service Level Objectives (SLO)**.
3. Choose **Create SLO**.
4. Enter a name for the SLO. Including the name of a service or operation, along with appropriate keywords such as latency or availability, will help you quickly identify what the SLO status indicates during triage.

5. For **Set Service Level Indicator (SLI)**, do one of the following:

   - To set the SLO on either of the standard application metrics `Latency` or `Availability`:

     a. Choose **Service Operation**.
     b. Select an account that this SLO will monitor.
     c. Select the service that this SLO will monitor.
     d. Select the operation that this SLO will monitor.
     e. For **Select a calculation method**, choose **Periods**.

        The **Select service** and **Select operation** drop-downs are populated by services and operations that have been active within the past 24 hours.
     f. Choose either **Availability** or **Latency** and then set the threshold.

   - To set the SLO on any CloudWatch metric or a CloudWatch metric math expression:

     a. Choose **CloudWatch Metric**.
     b. Choose **Select CloudWatch metric**.

        The **Select metric** screen appears. Use the **Browse** or **Query** tabs to find the metric you want, or create a metric math expression.

        After you select the metric that you want, choose the **Graphed metrics** tab and select the **Statistic** and **Period** to use for the SLO. Then choose **Select metric**.

        For more information about these screens, see Graph a metric and Add a math expression to a CloudWatch graph.
     c. For **Select a calculation method**, choose **Periods**.
     d. For **Set condition**, select a comparison operator and threshold for the SLO to use as the indicator of success.

   - To set the SLO on the dependency of a service on either of the standard application metrics `Latency` or `Availability`:

     a. Choose **Service Dependency**.
     b. Under **Select a service**, select the service that this SLO will monitor.
     c. Based on the selected service, under **Select an operation**, you can select one specific operation or select **All operations** to use the metrics from all operations of this service that calls a dependency.

   d. Under **Select a dependency**, you can search and select the required dependency for which you want to measure the reliability.

      After you select the dependency, you can view the updated graph and historical data based on the dependency.

6. If you selected **Service Operation** or **Service Dependency** in step 5, set the period length for this SLO.
7. Set the **interval** and **attainment goal** for the SLO. For more information about intervals and attainment goals and how they work together, see SLO concepts.
8. (Optional) For **Set SLO burn rates** do the following:
   - Set the length (in minutes) of the look-back window for the burn rate. For information about how to choose this length, see Walkthroughs for burn rate alarms.
   - To create more burn rates for this SLO, choose **Add more burn rates** and set the look-back window for the additional burn rates.
9. (Optional) Create burn rate alarms by doing the following:
   - Under **Set burn rate alarms** select the check box for each burn rate that you want to create an alarm for. For each of these alarms, do the following:
     - Specify the Amazon SNS topic to use for notifications when the alarm goes into ALARM state.
     - Either set a burn rate threshold or specify the percentage of the estimated total budget burnt in the last look-back window you want to stay below. If you set the percentage of estimated total budget burned, the burn rate threshold is calculated for you and used in the alarm. To either decide what threshold to set or to understand how this option is used to compute the burn rate threshold, see Determine the appropriate threshold for a burn rate alarm.
10. (Optional) Set one or more CloudWatch alarms or a warning threshold for the SLO.
    a. CloudWatch alarms can use Amazon SNS to proactively notify you if an application is unhealthy based on its SLI performance.

       To create an alarm, select one of the alarm check boxes and enter or create the Amazon SNS topic to use for notifications when the alarm goes into `ALARM` state. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms. Creating alarms incurs charges. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

b. If you set a warning threshold, it appears in Application Signals screens to help you identify SLOs that are in danger of being unmet, even if they're currently healthy.

   To set a warning threshold, enter the threshold value in **Warning threshold**. When the SLO's error budget is lower than the warning threshold, the SLO is marked with **Warning** in several Application Signals screens. Warning thresholds also appear on error budget graphs. You can also create an **SLO warning alarm** that's based on the warning threshold.

11. (Optional) For **Set SLO time window exclusion**, do the following:

   - Under **Exclude time window**, set the time window to be excluded from the SLO performance metrics.

     You can choose **Set time window** and enter the **Start window** for every hour or month or you can choose **Set time window with CRON** and enter the CRON expression.
   - Under **Repeat**, set if this time window exclusion is recurring or not.
   - (Optional) Under **Add reason**, you can choose to enter a reason for the time window exclusion. For example, scheduled maintenance.
   - Select **Add time window** to add upto 10 time exclusion windows.

12. To add tags to this SLO, choose the **Tags** tab and then choose **Add new tag**. Tags can help you manage, identify, organize, search for, and filter resources. For more information about tagging, see Tagging your Amazon resources.

   > **Note**
   >
   > If the application this SLO is related to is registered in Amazon Service Catalog AppRegistry, you can use the `awsApplication` tag to associate this SLO with that application in AppRegistry. For more information, see What is AppRegistry?

13. Choose **Create SLO**. If you also chose to create one or more alarms, the button name changes to reflect this.

Create a request-based SLO

Use the following procedure to create a request-based SLO.

To create a request-based SLO

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Service Level Objectives (SLO)**.
3. Choose **Create SLO**.
4. Enter a name for the SLO. Including the name of a service or operation, along with appropriate keywords such as latency or availability, will help you quickly identify what the SLO status indicates during triage.
5. For **Set Service Level Indicator (SLI)**, do one of the following:
   - To set the SLO on either of the standard application metrics `Latency` or `Availability`:
     a. Choose **Service Operation**.
     b. Select the service that this SLO will monitor.
     c. Select the operation that this SLO will monitor.
     d. For **Select a calculation method**, choose **Requests**.
     e. The **Select service** and **Select operation** drop-downs are populated by services and operations that have been active within the past 24 hours.
     f. Choose either **Availability** or **Latency**. If you choose **Latency**, set the threshold.
   - To set the SLO on any CloudWatch metric or a CloudWatch metric math expression:
     a. Choose **CloudWatch Metric**.
     b. For **Define target requests**, do the following:
        i. Choose whether you want to measure **Good Requests** or **Bad Requests**.
        ii. Choose **Select CloudWatch metric**. This metric will be the numerator of the ratio of target requests to total requests. If you use a latency metric, use the **Trimmed count (TC)** statistics. If the threshold is 9 ms and you're using the less than (<) comparison operator, then use threshold TC (:threshold - 1). For more information about TC, see Syntax.

            The **Select metric** screen appears. Use the **Browse** or **Query** tabs to find the metric you want, or create a metric math expression.
     c. For **Define total requests**, choose the CloudWatch metric that you want to use for the source. This metric will be the denominator of the ratio of target requests to total requests.

The **Select metric** screen appears. Use the **Browse** or **Query** tabs to find the metric you want, or create a metric math expression.

After you select the metric that you want, choose the **Graphed metrics** tab and select the **Statistic** and **Period** to use for the SLO. Then choose **Select metric**.

If you use a latency metric which emits one data point per request, use the **Sample count statistics** to count the number of total requests.

For more information about these screens, see Graph a metric and Add a math expression to a CloudWatch graph.

- To set the SLO on the dependency of a service on either of the standard application metrics `Latency` or `Availability`:

    a. Choose **Service Dependency**.

    b. Under **Select a service**, select the service that this SLO will monitor.

    c. Based on the selected service, under **Select an operation**, you can select one specific operation or select **All operations** to use the metrics from all operations of this service that calls a dependency.

    d. Under **Select a dependency**, you can search and select the required dependency for which you want to measure the reliability.

    After you select the dependency, you can view the updated graph and historical data based on the dependency.

6. Set the **interval** and **attainment goal** for the SLO. For more information about intervals and attainment goals and how they work together, see SLO concepts.

7. (Optional) For **Set SLO burn rates** do the following:

    - Set the length (in minutes) of the look-back window for the burn rate. For information about how to choose this length, see Walkthroughs for burn rate alarms.
    - To create more burn rates for this SLO, choose **Add more burn rates** and set the look-back window for the additional burn rates.

8. (Optional) Create burn rate alarms by doing the following:

    - Under **Set burn rate alarms** select the check box for each burn rate that you want to create an alarm for. For each of these alarms, do the following:

- Specify the Amazon SNS topic to use for notifications when the alarm goes into ALARM state.
- Either set a burn rate threshold or specify the percentage of the estimated total budget burnt in the last look-back window you want to stay below. If you set the percentage of estimated total budget burned, the burn rate threshold is calculated for you and used in the alarm. To either decide what threshold to set or to understand how this option is used to compute the burn rate threshold, see Determine the appropriate threshold for a burn rate alarm.

9. (Optional) Set one or more CloudWatch alarms or a warning threshold for the SLO.

   a. CloudWatch alarms can use Amazon SNS to proactively notify you if an application is unhealthy based on its SLI performance.

      To create an alarm, select one of the alarm check boxes and enter or create the Amazon SNS topic to use for notifications when the alarm goes into `ALARM` state. For more information about CloudWatch alarms, see Using Amazon CloudWatch alarms. Creating alarms incurs charges. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

   b. If you set a warning threshold, it appears in Application Signals screens to help you identify SLOs that are in danger of being unmet, even if they're currently healthy.

      To set a warning threshold, enter the threshold value in **Warning threshold**. When the SLO's error budget is lower than the warning threshold, the SLO is marked with **Warning** in several Application Signals screens. Warning thresholds also appear on error budget graphs. You can also create an **SLO warning alarm** that's based on the warning threshold.

10. (Optional) For **Set SLO time window exclusion**, do the following:

    - Under **Exclude time window**, set the time window to be excluded from the SLO performance metrics.

      You can choose **Set time window** and enter the **Start window** for every hour or month or you can choose **Set time window with CRON** and enter the CRON expression.
    - Under **Repeat**, set if this time window exclusion is recurring or not.
    - (Optional) Under **Add reason**, you can choose to enter a reason for the time window exclusion. For example, scheduled maintenance.
    - Select **Add time window** to add upto 10 time exclusion windows.

11. To add tags to this SLO, choose the **Tags** tab and then choose **Add new tag**. Tags can help you manage, identify, organize, search for, and filter resources. For more information about tagging, see [Tagging your Amazon resources](#).

> **Note**
>
> If the application this SLO is related to is registered in Amazon Service Catalog AppRegistry, you can use the `awsApplication` tag to associate this SLO with that application in AppRegistry. For more information, see [What is AppRegistry?](#)

12. Choose **Create SLO**. If you also chose to create one or more alarms, the button name changes to reflect this.

View and triage SLO status

You can quickly see the health of your SLOs using either the **Service Level Objectives** or the **Services** options in the CloudWatch console. The **Services** view provides an at-a-glance view of the ratio of unhealthy services, calculated based on SLOs that you have set. For more information about using the **Services** option, see [Monitor the operational health of your applications with Application Signals](#).

The **Service Level Objectives** view provides a macro view of your organization. You can see the met and unmet SLOs as a whole. This gives you a view of how many of your services and operations are performing to your expectations over longer periods of time, according to the SLIs that you chose.

To view all of your SLOs using the Service Level Objectives view

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Service Level Objectives (SLO)**.

   The **Service Level Objectives (SLO)** list appears.

   You can quickly see the current status of your SLOs in the **SLI status** column. To sort the SLOs so that all the unhealthy ones are at the top of the list, choose the **SLI status** column until the unhealthy SLOs are all at the top.

The SLO table has the following default columns. You can adjust which columns are displayed by choosing the gear icon above the list. For more information about goals, SLIs, attainment, and intervals, see SLO concepts.

- The name of the SLO.
- The **Goal** column displays the percentage of periods during each interval that must successfully meet the SLI threshold for the SLO goal to be met. It also displays the interval length for the SLO.
- The **SLI status** displays whether the current operational state of the application is healthy or not. If any period during the currently selected time range was unhealthy for the SLO, then the **SLI status** displays **Unhealthy**.
- If this SLO is configured to monitor a dependency, the **Dependency** and **Remote Operation** columns will show the details about that dependency relationship.
- The **Ending attainment** is the attainment level achieved as of the end of the selected time range. Sort by this column to see the SLOs that are most in danger of not being met.
- The **Attainment delta** is the difference in attainment level between the start and end of the selected time range. A negative delta means that the metric is trending in a downward direction. Sort by this column to see the latest trends of the SLOs.
- The **Ending error budget (%)** is the percentage of total time in the period that can have unhealthy periods and still have the SLO be achieved successfully. If you set this to 5%, and the SLI is unhealthy in 5% or fewer of the remaining periods in the interval, the SLO is still achieved successfully.
- The **Error budget delta** is the difference in error budget between the start and end of the selected time range. A negative delta means that the metric is trending in a failing direction.
- The **Ending error budget (time)** is the amount of actual time in the interval that can be unhealthy and still have the SLO be achieved successfully. For example, if this is 14 minutes, then if the SLI is unhealthy for fewer than 14 minutes during the remaining interval, the SLO will still be achieved successfully.
- The **Ending error budget (requests)** is the amount of requests in the interval that can be unhealthy and still have the SLO be achieved successfully. For request-based SLOs, this value is dynamic and can fluctuate as the cumulative total number of requests changes over time.
- The **Service**, **Operation**, and **Type** columns display information about what service and operation this SLO is set for.

3. To see the attainment and error budget graphs for an SLO, choose the radio button next to the SLO name.

   The graphs at the top of the page display the **SLO attainment** and **Error budget** status. A graph about the SLI metric associated with this SLO is also displayed.

4. To further triage an SLO that is not meeting its goal, choose the service name, operation name, or dependency name associated with that SLO. You are taken to the details page where you can triage further. For more information, see View detailed service activity and operational health with the service detail page.

5. To change the time range of the charts and tables on the page, choose a new time range near the top of the screen.

Edit an existing SLO

Follow these steps to edit an existing SLO. When you edit an SLO, you can change only the threshold, interval, attainment goal, and tags. To change other aspects such as service, operation, or metric, create a new SLO instead of editing an existing one.

Changing part of an SLO core configuration, such as period or threshold, invalidates all the previous data points and assessments about attainment and health. It effectively deletes and re-creates the SLO.

> **Note**
>
> If you edit an SLO, alarms associated with that SLO are not automatically updated. You might need to update the alarms to keep them in sync with the SLO.

To edit an existing SLO

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Service Level Objectives (SLO)**.
3. Choose the radio button next to the SLO that you want to edit, and choose **Actions**, **Edit SLO**.
4. Make your changes, then choose **Save changes**.

Delete an SLO

Follow these steps to delete an existing SLO.

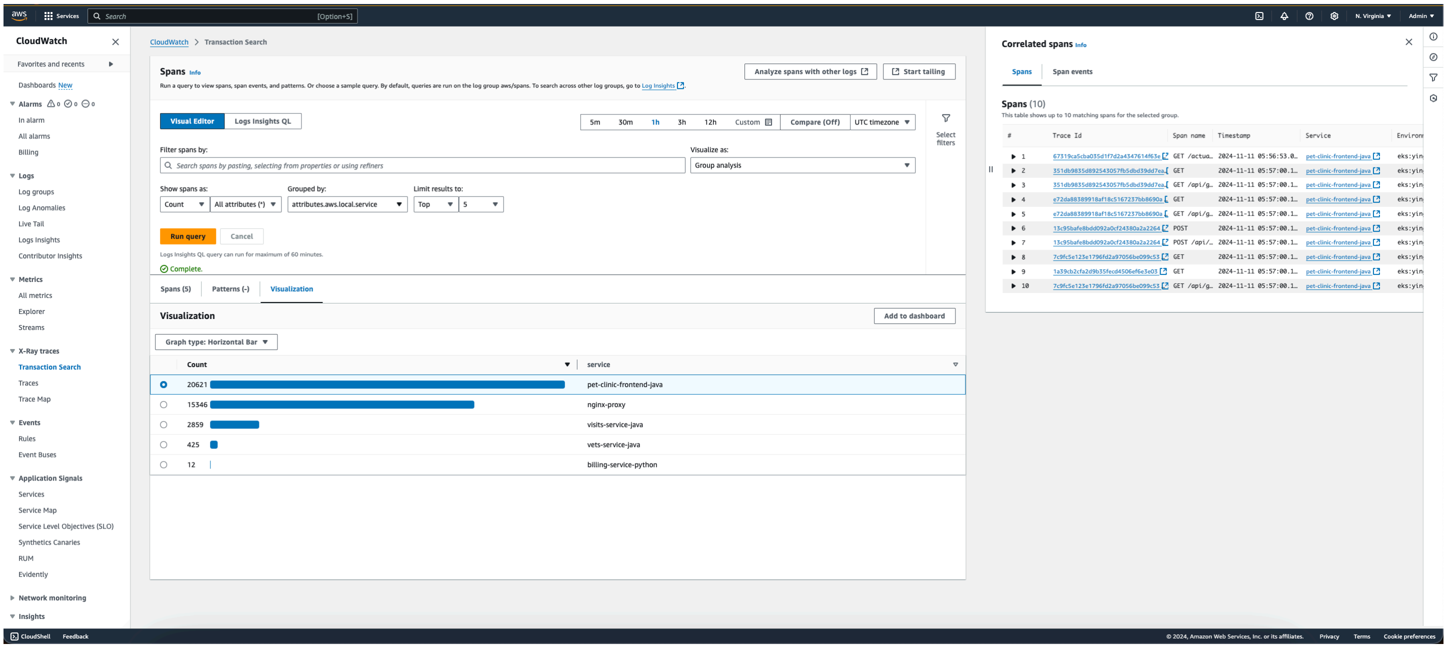
> **Note**
>
> When you delete an SLO, alarms associated with that SLO are not automatically deleted. You'll need to delete them yourself. For more information, see Managing alarms.

To delete an SLO

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Service Level Objectives (SLO)**.
3. Choose the radio button next to the SLO that you want to edit, and choose **Actions**, **Delete SLO**.
4. Choose **Confirm**.

Transaction Search

Transaction Search is an interactive analytics experience you can use to get complete visibility of your application transaction spans. Spans are the fundamental units of operation in a distributed trace and represent specific actions or tasks in an application or system. Every span records details about a particular segment of the transaction. These details include start and end times, duration, and associated metadata, which can include business attributes like customer IDs and order IDs. Spans are arranged in a parent-child hierarchy. This hierarchy forms a complete trace, mapping the flow of a transaction across different components or services.



Topics

- [Benefits]
- [How it works]
- [Pricing]
- [Getting started with Transaction Search]
- [Spans]
- [Adding custom attributes]
- [Troubleshooting application issues]

Benefits

The following are benefits of using Transaction Search:

Capture all spans

Ingest 100 percent of spans as structured logs in CloudWatch to get complete visibility. This prevents broken traces and provides you the ability to view large traces containing up to 10,000 spans for detailed insights.

Index spans as trace summaries

Index a percentage of spans as trace summaries in X-Ray to unlock end to end trace search and analytics.

Investigate transaction issues with free form analytics

Search all span attributes in the visual editor to identify the cause of issues in application transactions. This helps you answer questions about application performance and the impact end-users make based on their application transactions.

Send spans to the OpenTelemetry endpoint

Send spans to the OpenTelemetry endpoint for X-Ray traces. These spans are stored in the semantic convention format with W3C trace IDs.

> **Note**
>
> X-Ray traces automatically convert to the semantic convention format before they're stored in a log group called `aws/spans`. For more information, see The span log group.

Use CloudWatch Logs with spans

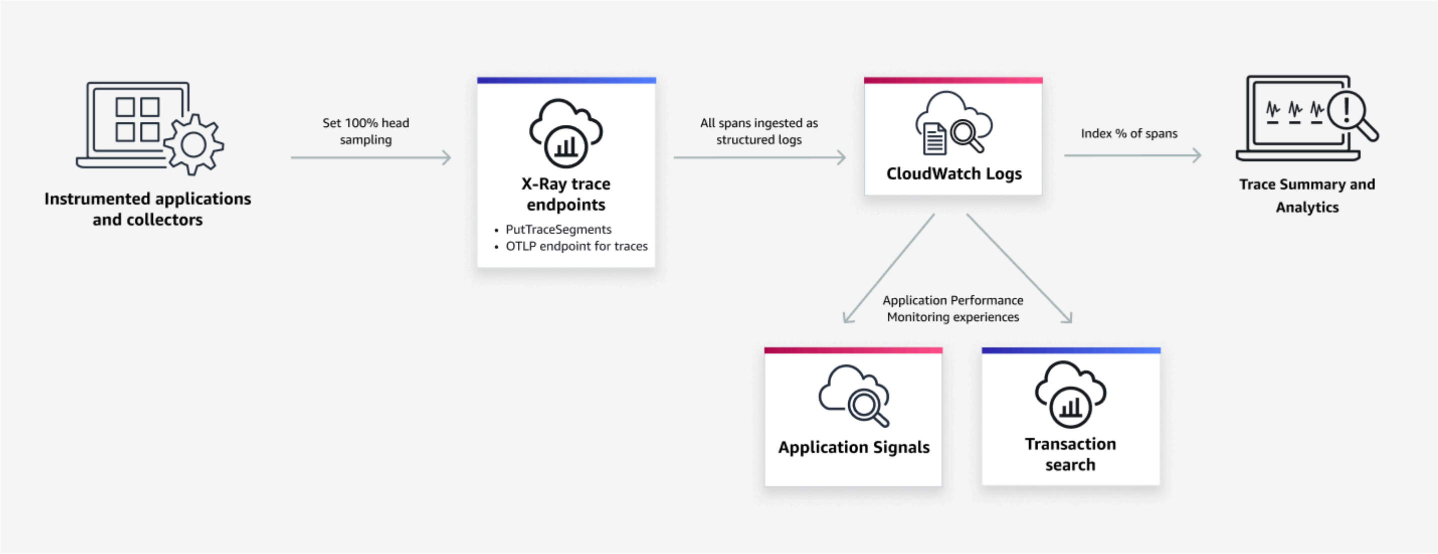
Use metric filters to extract custom metrics, subscription filters to forward data, and data masking to protect personally identifiable information.

Troubleshoot application issues

Access application dashboards, metrics, and topology when you enable Application Signals for all spans sent to CloudWatch.

How it works

When you enable Transaction Search, you unlock multiple capabilities, including features in Application Signals and CloudWatch Logs.



If you send traces to X-Ray, you can get started by enabling Transaction Search in the console or with the API. If you don't send traces to X-Ray, you can use the CloudWatch Application Signals that provides pre-packaged OpenTelemetry setup with Amazon Distro fro OpenTelemetry (ADOT), CloudWatch Agent, or use OpenTelemetry directly.

When you enable Transaction Search, spans sent to X-Ray are ingested in a log group called `aws/spans`. CloudWatch uses these spans to generate a curated application performance monitoring (APM) experience in CloudWatch Application Signals. This provides you the ability to search and analyze spans, as well as use CloudWatch Logs capabilities like anomaly and pattern detection. You can even use custom metric extraction . CloudWatch Application Signals provides you with a unified, application-centric view of your applications, services, and dependencies. It also helps you monitor and triage application health.

You can also explore spans using the interactive search and analytics experience in CloudWatch to answer any questions related to application performance or end-user impact with Transaction Search. Detect the impact on end users, find transactions in context of those issues using relevant attributes, such as customer name or order number. You can correlate transactions to business events, such as failed payments, and dive into interactions between application components to establish a root cause. With CloudWatch, you get complete application transaction coverage with correlated insights, helping you to accelerate mean time to resolution.

Pricing

For information about pricing, see Amazon CloudWatch Pricing.

Getting started with Transaction Search

If you send traces to X-Ray, you can enable Transaction Search in the CloudWatch console or with the CloudWatch API.

Topics

- Prerequisites
- Enable transaction search
- Using Transaction Search with Amazon CloudFormation

Prerequisites

Before you can enable Transaction Search, you must create a role with the following permissions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "TransactionSearchXRayPermissions",
      "Effect": "Allow",
      "Action": [
        "xray:GetTraceSegmentDestination",
        "xray:UpdateTraceSegmentDestination",
        "xray:GetIndexingRules",
        "xray:UpdateIndexingRule"
      ],
      "Resource": "*"
    },
    {
      "Sid": "TransactionSearchLogGroupPermissions",
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutRetentionPolicy"
      ],
      "Resource": [
        "arn:aws:logs:*:*:log-group:/aws/application-signals/data:*",
        "arn:aws:logs:*:*:log-group:aws/spans:*"
      ]
    },
```

```
    {
      "Sid": "TransactionSearchLogsPermissions",
      "Effect": "Allow",
      "Action": [
        "logs:PutResourcePolicy",
        "logs:DescribeResourcePolicies"
      ],
      "Resource": [
        "*"
      ]
    },
    {
      "Sid": "TransactionSearchApplicationSignalsPermissions",
      "Effect": "Allow",
      "Action": [
        "application-signals:StartDiscovery"
      ],
      "Resource": "*"
    },
    {
      "Sid": "CloudWatchApplicationSignalsCreateServiceLinkedRolePermissions",
      "Effect": "Allow",
      "Action": "iam:CreateServiceLinkedRole",
      "Resource": "arn:aws:iam::*:role/aws-service-role/application-
signals.cloudwatch.amazonaws.com/AWSServiceRoleForCloudWatchApplicationSignals",
      "Condition": {
        "StringLike": {
          "iam:AWSServiceName": "application-signals.cloudwatch.amazonaws.com"
        }
      }
    },
    {
      "Sid": "CloudWatchApplicationSignalsGetRolePermissions",
      "Effect": "Allow",
      "Action": "iam:GetRole",
      "Resource": "arn:aws:iam::*:role/aws-service-role/application-
signals.cloudwatch.amazonaws.com/AWSServiceRoleForCloudWatchApplicationSignals"
    }
  ]
}
```

> **Note**
>
> To use Transaction Search and other CloudWatch features, add the CloudWatchReadOnlyAccess policy to your role. For information about how to create a role, see IAM role creation.

Enable transaction search

You can enhance Lambda observability by using *transaction search*, which enables the capture of all trace spans for Lambda function invocation without sampling. This feature allows you to collect 100% of the spans for your functions, unaffected by the `sampled` flag in trace context propagation. This ensures that there is no additional impact to downstream dependent services. By enabling transaction search on Lambda, you gain complete visibility into your function performance and you can troubleshoot rarely occurring issues. To get started, see Transaction Search.

Enabling Transaction Search in the console

The following procedure describes how to enable Transaction Search in the console.

To enable Transaction Search in the CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. From the navigation pane, under **Application Signals**, choose **Transaction Search**.
3. Choose **Enable Transaction Search**.
4. Select the box to ingest spans as structured logs, and enter a percentage of spans to be indexed. You can index spans at 1% for free and change the percentage later based on your requirements.

Enabling Transaction Search using an API

The following procedure describes how to enable Transaction Search using an API.

Step 1. Create a policy that grants access to ingest spans in CloudWatch Logs

When using the Amazon CLI or SDK to enable Transaction Search, you must configure permissions using a resource-based policy with `PutResourcePolicy`.

Example policy

The following example policy allows X-Ray to send traces to CloudWatch Logs

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "TransactionSearchXRayAccess",
            "Effect": "Allow",
            "Principal": {
                "Service": "xray.amazonaws.com"
            },
            "Action": "logs:PutLogEvents",
            "Resource": [
                "arn:partition:logs:region:account-id:log-group:aws/spans:*",
                "arn:partition:logs:region:account-id:log-group:/aws/application-
signals/data:*"
            ],
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:partition:xray:region:account-id:*"
                },
                "StringEquals": {
                    "aws:SourceAccount": "account-id"
                }
            }
        }
    ]
}
```

Example command

The following example shows how to format your Amazon CLI command with `PutResourcePolicy`.

```
aws logs put-resource-policy --policy-name MyResourcePolicy --policy-document
 '{ "Version": "2012-10-17", "Statement": [ { "Sid": "TransactionSearchXRayAccess",
 "Effect": "Allow", "Principal": { "Service": "xray.amazonaws.com" }, "Action":
 "logs:PutLogEvents", "Resource": [ "arn:partition:logs:region:account-id:log-
group:aws/spans:*", "arn:partition:logs:region:account-id:log-group:/aws/
application-signals/data:*" ], "Condition": { "ArnLike": { "aws:SourceArn":
```

```
"arn:partition:logs:region:account-id:*" }, "StringEquals": { "aws:SourceAccount":
"account-id" } } } ]}'
```

Step 2. Configure the destination of trace segments

Configure the ingestion of spans with `UpdateTraceSegmentDestination`.

Example command

The following example shows how to format your Amazon CLI command with `UpdateTraceSegmentDestination`.

```
aws xray update-trace-segment-destination --destination CloudWatchLogs
```

Step 3. Configure the amount of spans to index

Configure your desired sampling percentage with `UpdateIndexingRule`

Example command

The following example shows how to format your Amazon CLI command with `UpdateIndexingRule`.

```
aws xray update-indexing-rule --name "Default" --rule '{"Probabilistic":
 {"DesiredSamplingPercentage": number}}'
```

> **Note**
>
> After you enable Transaction Search, it can take ten minutes for spans to become available for search and analysis.

Step 4. Verify spans are available for search and analysis

To verify spans are available for search and analysis, use `GetTraceSegmentDestination`.

Example commands

The following example shows how to format your Amazon CLI command with `GetTraceSegmentDestination`.

```
aws xray get-trace-segment-destination
```

Example response

The following example shows the response you can expect when Transaction Search is active.

```
{
    "Destination": "CloudWatchLogs",
    "Status": "ACTIVE"
}
```

Using Transaction Search with Amazon CloudFormation

You can use Amazon CloudFormation to enable and configure X-Ray Transaction Search.

> **Note**
>
> To create a Amazon CloudFormation stack, see Creating your first stack .

Prerequisites

- You must have access to an Amazon account with an IAM user or role that has permissions to use Amazon EC2, Amazon S3, Amazon CloudFormation, or have administrative user access.
- You must have a Virtual Private Cloud (VPC) that has access to the internet. To keep things simple, you can use the default VPC that comes with your account. The default VPC and default subnets are sufficient for this configuration.
- Make sure Transaction Search is disabled before you enable using Amazon CDK or Amazon CloudFormation.

Enabling Transaction Search

To enable Transaction Search using CloudFormation, you need to create the following two resources.

- `AWS::Logs::ResourcePolicy`
- `AWS::XRay::TransactionSearchConfig`

1. **Create AWS::Logs::ResourcePolicy** – Create a resource policy that allows X-Ray to send traces to CloudWatch Logs

YAML

```
Resources:
  LogsResourcePolicy:
    Type: AWS::Logs::ResourcePolicy
    Properties:
      PolicyName: TransactionSearchAccess
      PolicyDocument: !Sub >
        {
          "Version": "2012-10-17",
          "Statement": [
            {
              "Sid": "TransactionSearchXRayAccess",
              "Effect": "Allow",
              "Principal": {
                "Service": "xray.amazonaws.com"
              },
              "Action": "logs:PutLogEvents",
              "Resource": [
                "arn:${AWS::Partition}:logs:${AWS::Region}:${AWS::AccountId}:log-
group:aws/spans:*",
                "arn:${AWS::Partition}:logs:${AWS::Region}:${AWS::AccountId}:log-
group:/aws/application-signals/data:*"
              ],
              "Condition": {
                "ArnLike": {
                  "aws:SourceArn": "arn:${AWS::Partition}:xray:${AWS::Region}:
${AWS::AccountId}:*"
                },
                "StringEquals": {
                  "aws:SourceAccount": "${AWS::AccountId}"
                }
              }
            }
          ]
        }
```

JSON

```
{
    "Resources": {
        "LogsResourcePolicy": {
```

```
            "Type": "AWS::Logs::ResourcePolicy",
            "Properties": {
                "PolicyName": "TransactionSearchAccess",
                "PolicyDocument": {
                    "Fn::Sub": "{\n  \"Version\": \"2012-10-17\",\n  \"Statement
\": [\n    {\n      \"Sid\": \"TransactionSearchXRayAccess\",\n      \"Effect\":
 \"Allow\",\n      \"Principal\": {\n        \"Service\": \"xray.amazonaws.com
\"\n      },\n      \"Action\": \"logs:PutLogEvents\",\n      \"Resource\":
 [\n        \"arn:${AWS::Partition}:logs:${AWS::Region}:${AWS::AccountId}:log-
group:aws/spans:*\",\n        \"arn:${AWS::Partition}:logs:${AWS::Region}:
${AWS::AccountId}:log-group:/aws/application-signals/data:*\"\n      ],\n
 \"Condition\": {\n        \"ArnLike\": {\n          \"aws:SourceArn\": \"arn:
${AWS::Partition}:xray:${AWS::Region}:${AWS::AccountId}:*\"\n        },\n
 \"StringEquals\": {\n          \"aws:SourceAccount\": \"${AWS::AccountId}\"\n
   }\n      }\n    }\n  ]\n}"
                }
            }
        }
    }
}
```

2. **Create and Configure AWS::XRay::TransactionSearchConfig** – Create the `TransactionSearchConfig` resource to enable Transaction Search.

   YAML

```
Resources:
  XRayTransactionSearchConfig:
    Type: AWS::XRay::TransactionSearchConfig
```

   JSON

```
{
  "Resources": {
    "XRayTransactionSearchConfig": {
      "Type": "AWS::XRay::TransactionSearchConfig"
    }
  }
}
```

3. (Optional) You can set the `IndexingPercentage` property to control the percentage of spans that will be indexed.

YAML

```
Resources:
  XRayTransactionSearchConfig:
    Type: AWS::XRay::TransactionSearchConfig
    Properties:
      IndexingPercentage: 50
```

JSON

```
{
  "Resources": {
    "XRayTransactionSearchConfig": {
      "Type": "AWS::XRay::TransactionSearchConfig",
      "Properties": {
        "IndexingPercentage": 20
      }
    }
  }
}
```

The IndexingPercentage value can be set between 0 and 100.

Template examples

The following example includes both the resource policy and the TransactionSearchConfig.

YAML

```
Resources:
  LogsResourcePolicy:
    Type: AWS::Logs::ResourcePolicy
    Properties:
      PolicyName: TransactionSearchAccess
      PolicyDocument: !Sub >
        {
          "Version": "2012-10-17",
          "Statement": [
            {
              "Sid": "TransactionSearchXRayAccess",
              "Effect": "Allow",
```

```
              "Principal": {
                "Service": "xray.amazonaws.com"
              },
              "Action": "logs:PutLogEvents",
              "Resource": [
                "arn:${AWS::Partition}:logs:${AWS::Region}:${AWS::AccountId}:log-
group:aws/spans:*",
                "arn:${AWS::Partition}:logs:${AWS::Region}:${AWS::AccountId}:log-
group:/aws/application-signals/data:*"
              ],
              "Condition": {
                "ArnLike": {
                  "aws:SourceArn": "arn:${AWS::Partition}:xray:${AWS::Region}:
${AWS::AccountId}:*"
                },
                "StringEquals": {
                  "aws:SourceAccount": "${AWS::AccountId}"
                }
              }
            }
          ]
        }

  XRayTransactionSearchConfig:
    Type: AWS::XRay::TransactionSearchConfig
    Properties:
      IndexingPercentage: 10
```

JSON

```
{
    "Resources": {
        "LogsResourcePolicy": {
            "Type": "AWS::Logs::ResourcePolicy",
            "Properties": {
                "PolicyName": "TransactionSearchAccess",
                "PolicyDocument": {
                    "Fn::Sub": "{\n  \"Version\": \"2012-10-17\",\n  \"Statement
\": [\n    {\n      \"Sid\": \"TransactionSearchXRayAccess\",\n      \"Effect\":
 \"Allow\",\n      \"Principal\": {\n        \"Service\": \"xray.amazonaws.com\"\n
      },\n      \"Action\": \"logs:PutLogEvents\",\n      \"Resource\": [\n
 \"arn:${AWS::Partition}:logs:${AWS::Region}:${AWS::AccountId}:log-group:aws/spans:*
\",\n        \"arn:${AWS::Partition}:logs:${AWS::Region}:${AWS::AccountId}:log-
```

```
group:/aws/application-signals/data:*\"\n      ],\n      \"Condition\": {\n
     \"ArnLike\": {\n          \"aws:SourceArn\": \"arn:${AWS::Partition}:xray:
${AWS::Region}:${AWS::AccountId}:*\"\n        },\n        \"StringEquals\": {\n
  \"aws:SourceAccount\": \"${AWS::AccountId}\"\n        }\n      }\n    }\n  ]\n}"
                }
            }
        },
        "XRayTransactionSearchConfig": {
            "Type": "AWS::XRay::TransactionSearchConfig",
            "Properties": {
                "IndexingPercentage": 20
            }
        }
    }
}
```

Here is an example using Amazon CDK in TypeScript.

CDK

```
import * as cdk from '@aws-cdk/core';
import * as logs from '@aws-cdk/aws-logs';
import * as xray from '@aws-cdk/aws-xray';

export class XRayTransactionSearchStack extends cdk.Stack {
  constructor(scope: cdk.Construct, id: string, props?: cdk.StackProps) {
    super(scope, id, props);

    // Create the resource policy
    const transactionSearchAccess = new logs.CfnResourcePolicy(this,
 'XRayLogResourcePolicy', {
      policyName: 'TransactionSearchAccess',
      policyDocument: JSON.stringify({
        Version: '2012-10-17',
        Statement: [
          {
            Sid: 'TransactionSearchXRayAccess',
            Effect: 'Allow',
            Principal: {
              Service: 'xray.amazonaws.com',
            },
            Action: 'logs:PutLogEvents',
            Resource: [
```

```
              `arn:${this.partition}:logs:${this.region}:${this.account}:log-group:aws/
spans:*`,
              `arn:${this.partition}:logs:${this.region}:${this.account}:log-group:/
aws/application-signals/data:*`,
            ],
            Condition: {
              ArnLike: {
                'aws:SourceArn': `arn:${this.partition}:xray:${this.region}:
${this.account}:*`,
              },
              StringEquals: {
                'aws:SourceAccount': this.account,
              },
            },
          },
        ],
      }),
    });

    // Create the TransactionSearchConfig with dependency
    const transactionSearchConfig = new xray.CfnTransactionSearchConfig(this,
 'XRayTransactionSearchConfig', {
      indexingPercentage: 10,
    });

    // Add the dependency to ensure Resource Policy is created first
    transactionSearchConfig.addDependsOn(transactionSearchAccess);
  }
}
```

Verifying the configuration

After deploying your Amazon CloudFormation stack, you can verify the configuration using the Amazon CLI.

aws xray get-trace-segment-destination

A successful configuration will return the following.

```
{
    "Destination": "CloudWatchLogs",
```

```
    "Status": "ACTIVE"
}
```

Spans

Spans sent to X-Ray are ingested and managed in a log group called `aws/spans`. This topic describes which CloudWatch Logs features are available for transaction spans.

Available features

The following CloudWatch Logs features are available for transaction spans.

- Metric filters – Use metric filters to extract custom metrics from spans.
- Subscriptions – Use subscriptions to access a real-time feed of span events from CloudWatch Logs.
- Log anomaly detection – Use log anomaly detection to establish a baseline for spans sent to the `aws/spans` log group.
- Contributor Insights – Use Contributor Insights to analyze span data and create a time series displaying contributor data.

Unsupported features

The following are features not supported for transaction spans.

- Spans cannot be sent to CloudWatch Logs with the `PutLogEvents` API.
- Span data cannot be enriched or transformed.

> **Note**
>
> Span ingestion is charged separately from log ingestion. For information about pricing, see Amazon CloudWatch Pricing.

Searching and analyzing spans

Transaction Search provides you with a visual editor to search and analyze all ingested spans using attributes. You can use the visual editor to narrow down transaction spans and create interactive visualizations to troubleshoot issues in your distributed applications. You can also use the CloudWatch Logs Insights query language to analyze your spans. This topic describes how to access and use the visual editor.

The visual editor

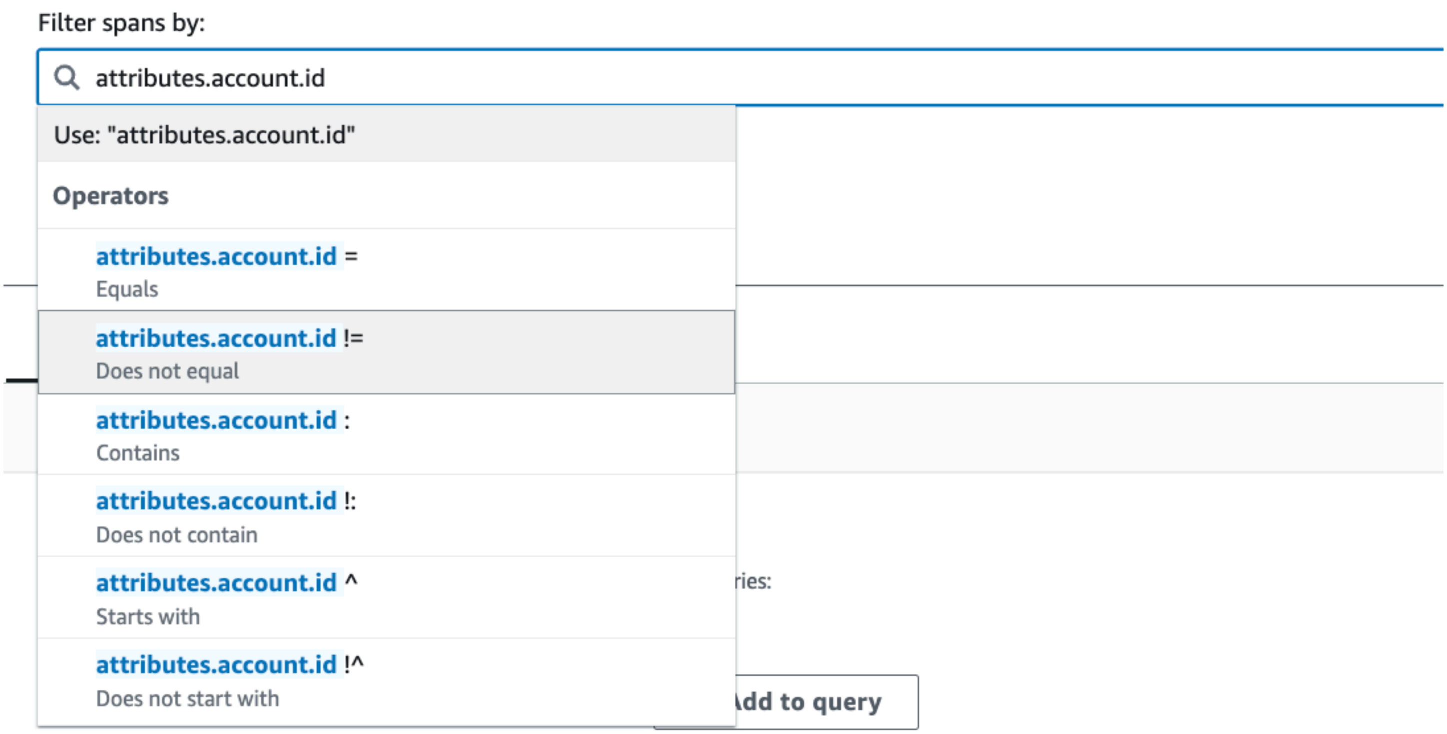
The following procedure describes how to access the visual editor.

To access the visual editor

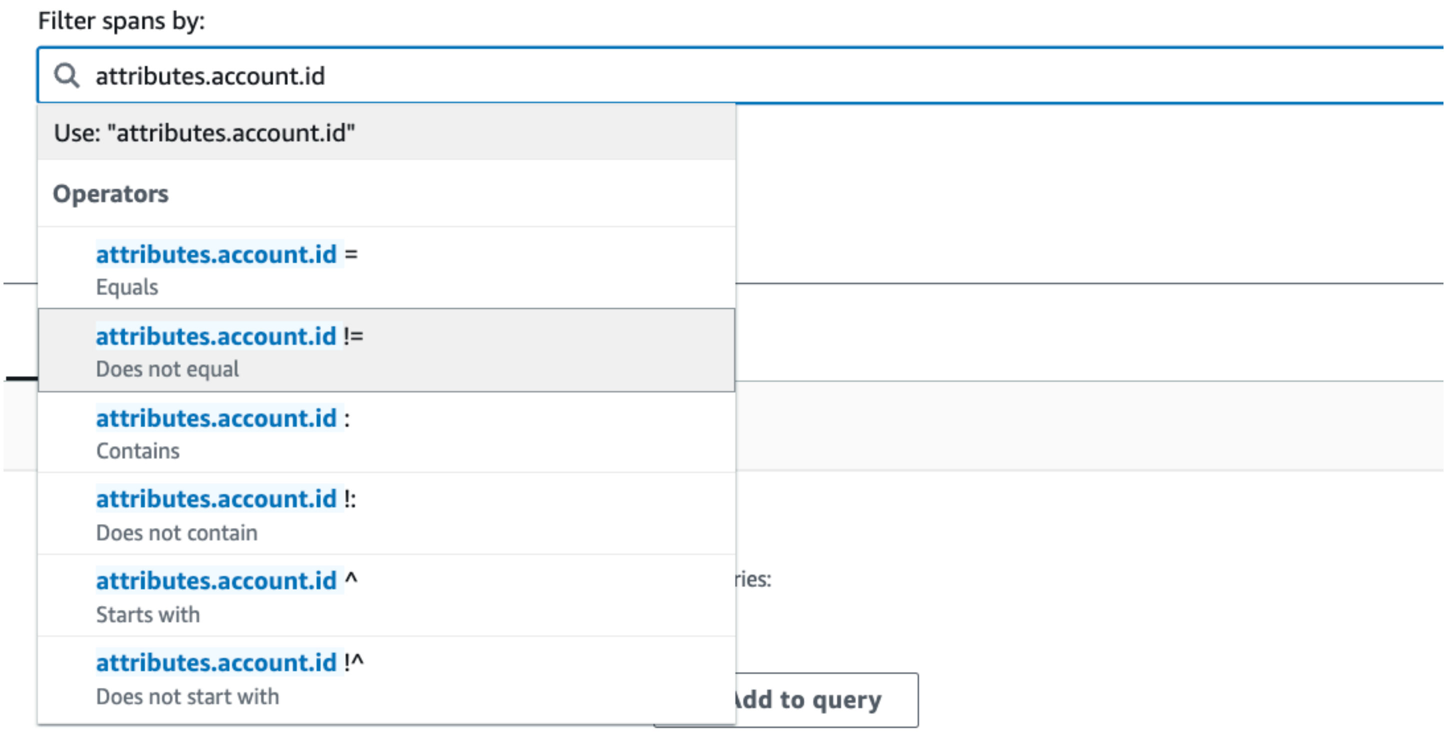
1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. From the navigation pane, choose **Application Signals**, and then choose **Transaction Search**.

Use span attributes, such as service name, span duration, and span status to narrow down transaction spans quickly. You can access these filters and more on the right side of the visual editor under **Select filters**.

This visual editor suggests a list of attributes in the span. These attributes include attributes added through auto-instrumentation and custom attributes added through custom instrumentation.



Select a span key, and enter a value to refine span results. You can filter spans using various operations, such as "Equals," "Does Not Equal," and more.



Query formats

You can run queries in the visual editor using different formats. This section describes each of these formats.

List

View spans or span events in a list format, which displays information about each span. Use this type of analysis to analyze individual spans, understand specific transactions, or identify unique patterns in transaction events. Other use cases include the following:

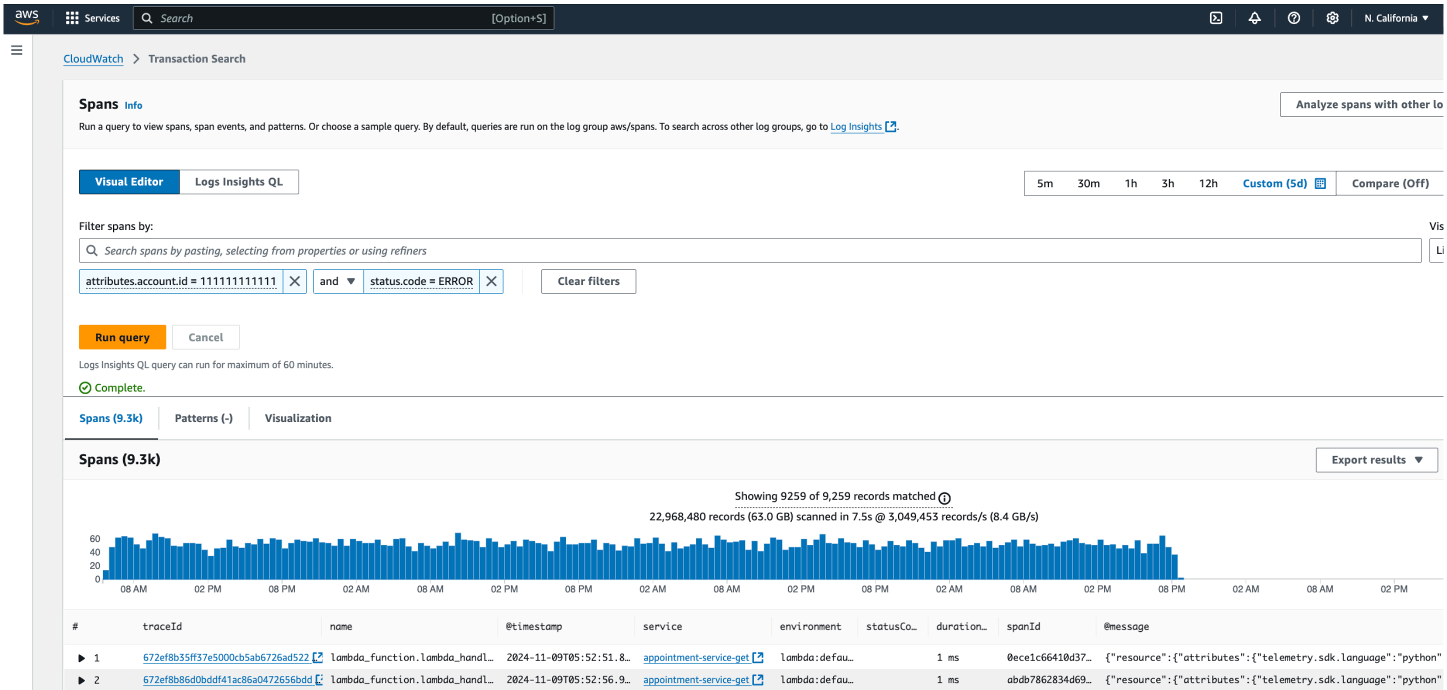
Use cases

- Troubleshoot customer support tickets
- Locate APIs or dependencies, such as database queries taking longer than 1000 milliseconds to execute
- Locate spans with errors

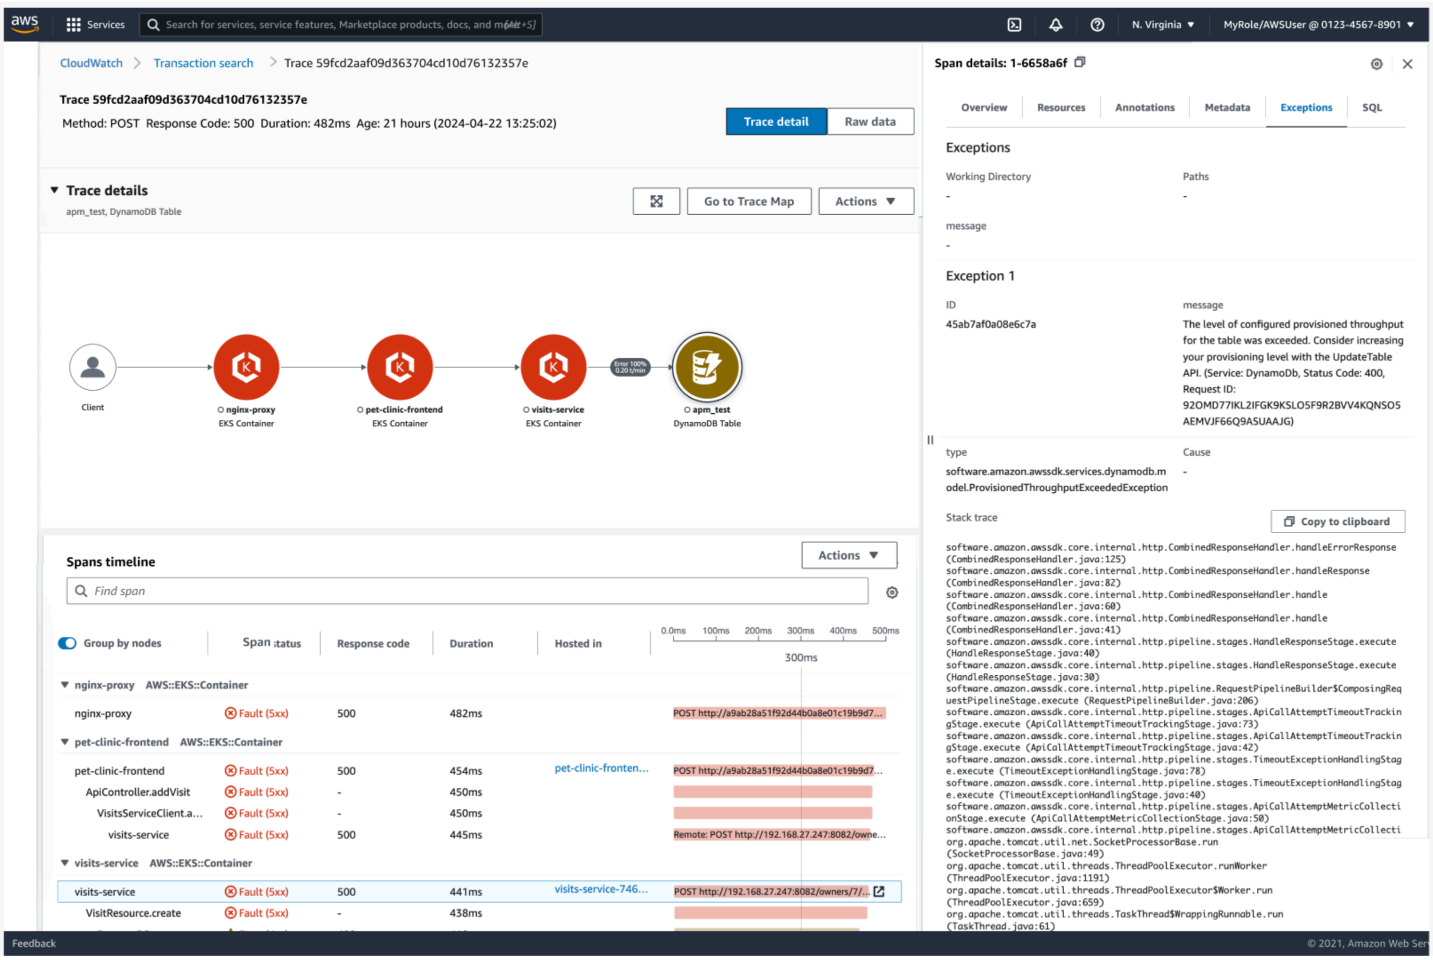
The following screenshots show how to troubleshoot a customer support ticket with this type of analysis.

Example scenario

In the visual editor, filter on all transaction spans with a particular customer issue. Before you run your query, choose **List** from the **Visualize as** dropdown.



The results show a list of spans where you can choose a trace ID to get the end-to-end journey for the transaction and determine the root cause of the issue.



Timeseries

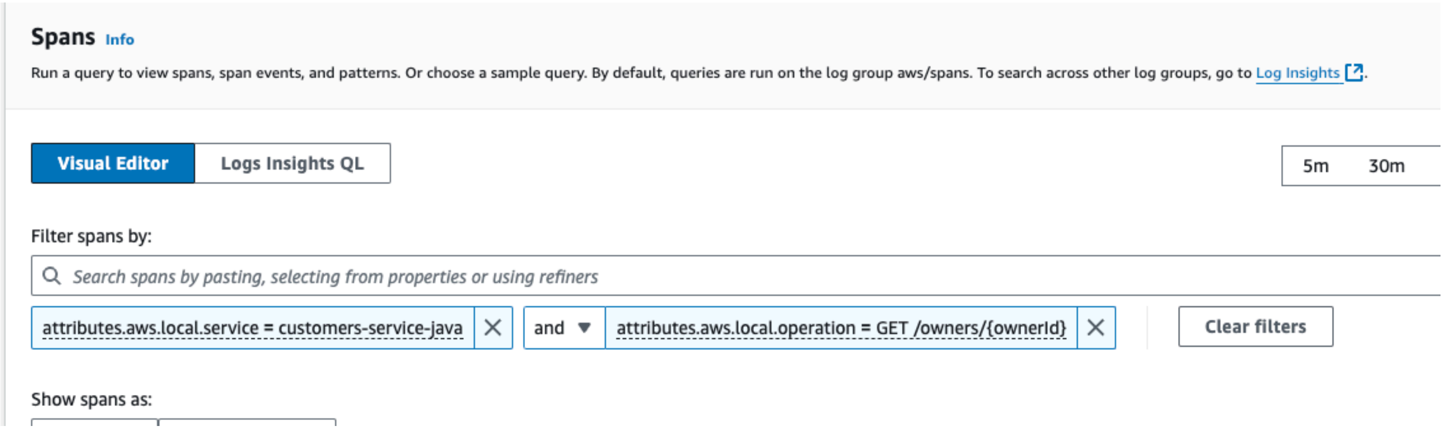
View spans or span events over time. Use this type of analysis to look at trends and spikes in transaction activity. Other use cases include the following:

- Visualize latency
- Visualize frequency of spans
- Visualize performance

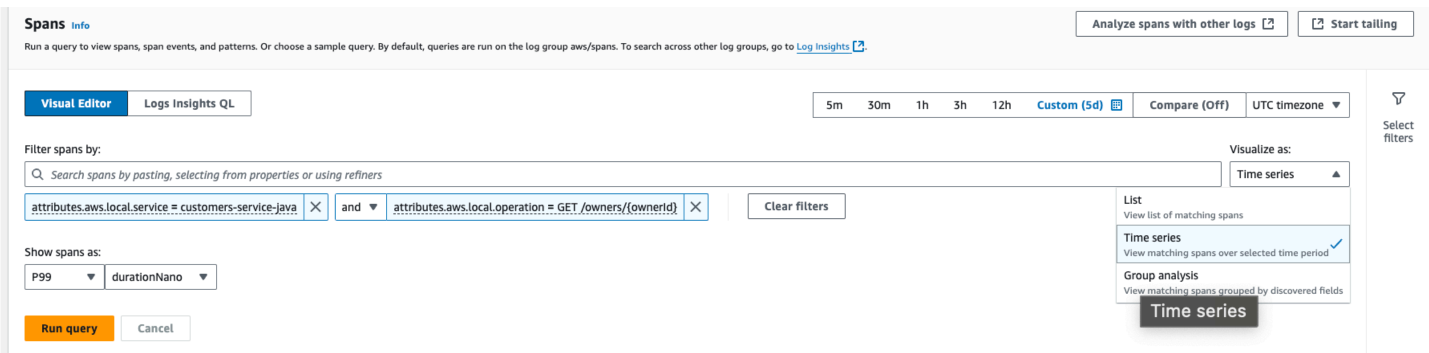
The following screenshots show how you can view p99 latency trends for an API with this type of analysis.

Example scenario

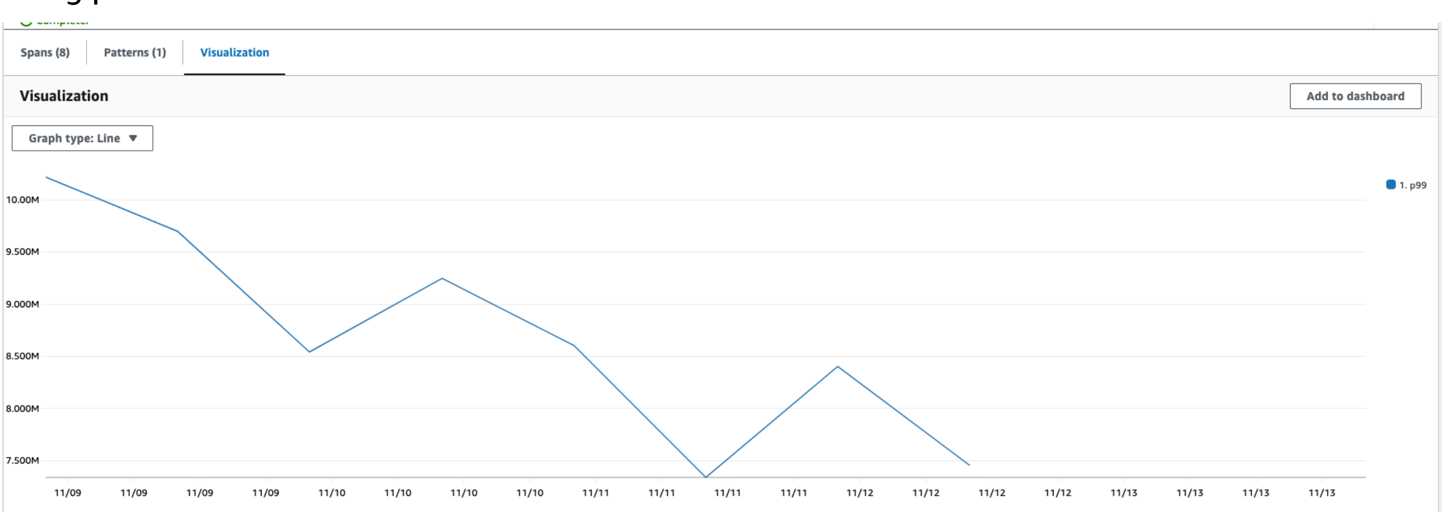
In the visual editor, filter on the service and API you want to analyze.



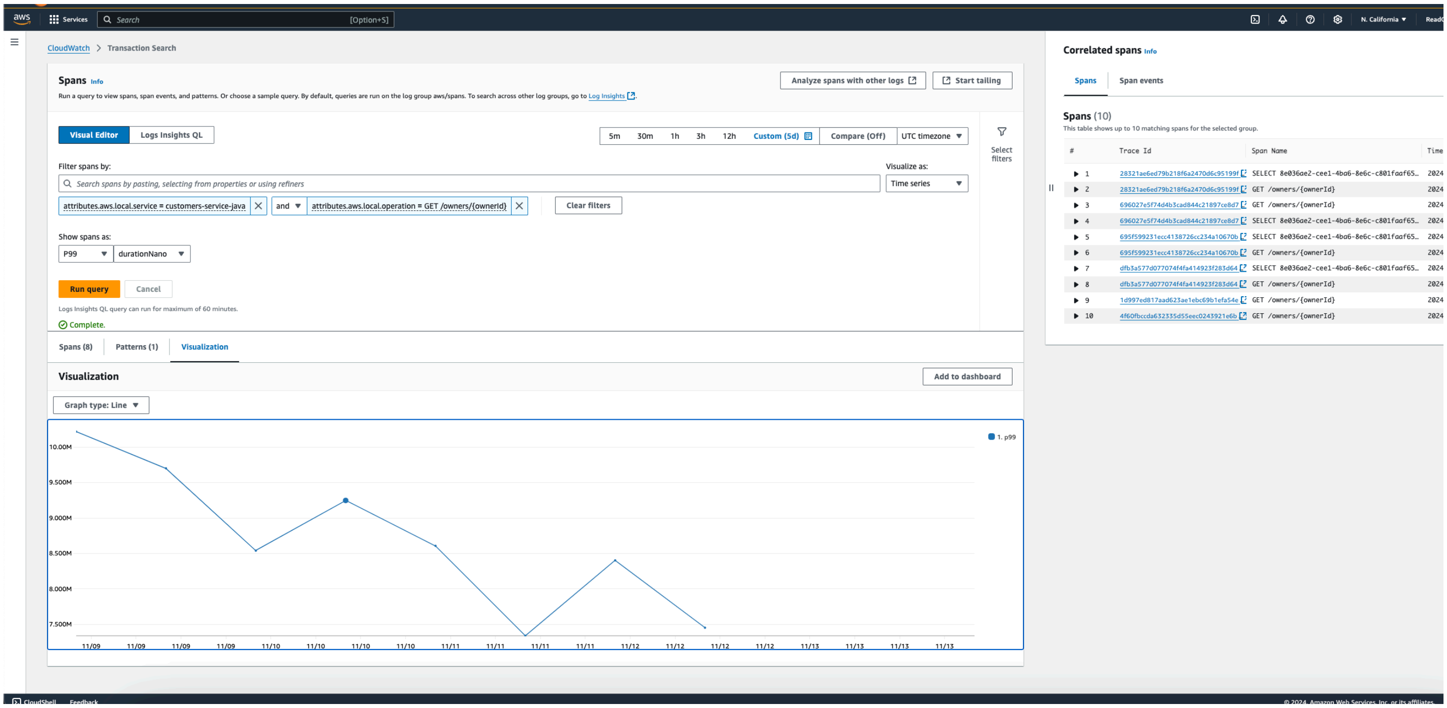
Before you run your query, choose **Time series** from the **Visualize as** dropdown. Choose **P99** for the duration statistic from the **Show span as** dropdown.



The results show a latency trend for the service, with the x-axis of the graph being time and y-axis being p99 duration.



You can choose a point on the chart to view correlated spans and span events.



Group analysis

Aggregate spans or span events based on specific attributes, such as account IDs and status codes, to display statistical metrics. Use this type of analysis to analyze spans in clusters, compare different groups, and uncover trends at the macro level. Other use cases include the following:

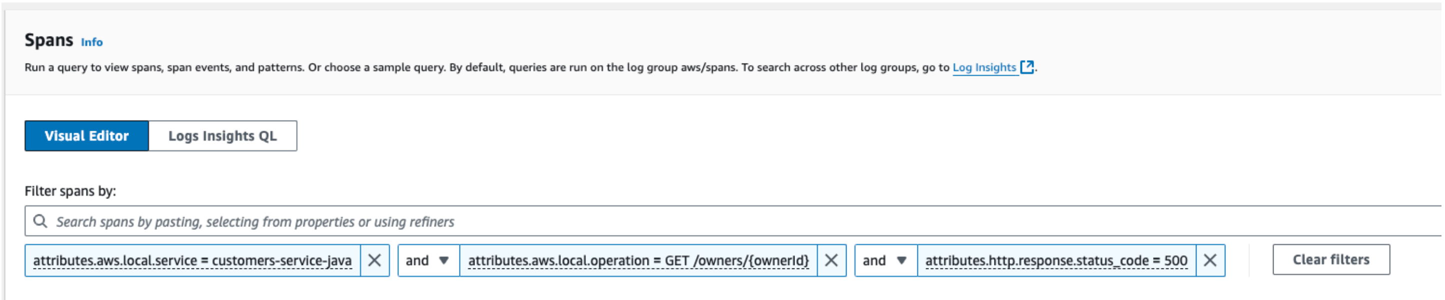
Use cases

- Identify top customers impacted by a service outage
- Identify availability zones with the most errors
- Identify the top slowest database queries

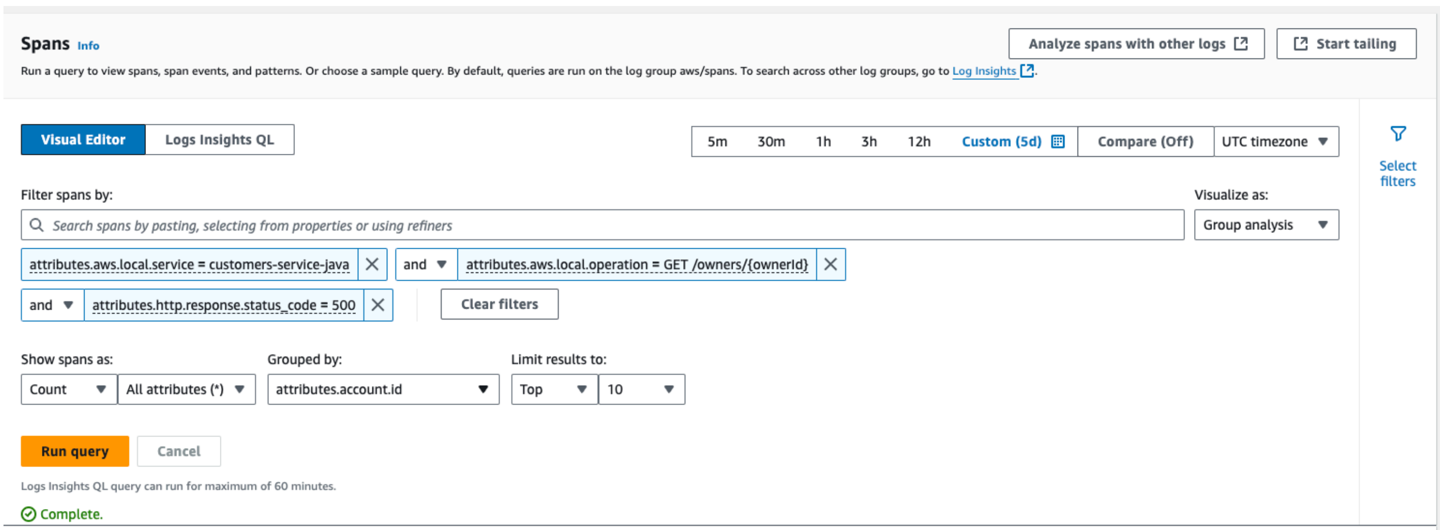
The following screenshots show how you can view the top customers impacted by a service outage with this type of analysis.

Example scenario

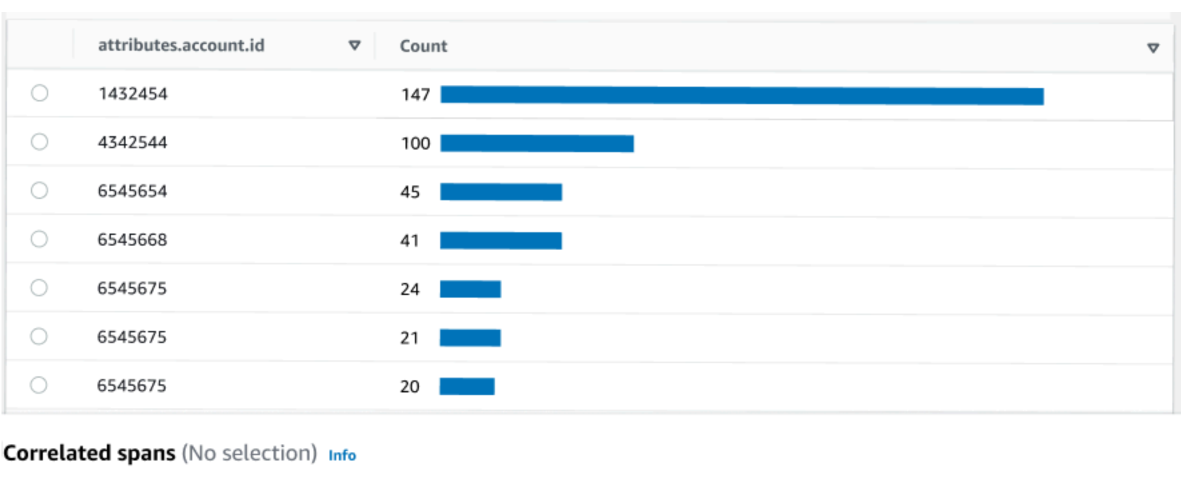
In the visual editor, you filter on the service experiencing issues.



Before you run your query, choose **Group Analysis** from the **Visualize as** dropdown. Group your query results by `account.id`, and limit the number of results to 10..



The results show the top 10 customers who experienced the most number of errors.



CloudWatch Logs Insights

You can use CloudWatch Logs Insights to analyze your spans.

Example query

The following query shows the top five slowest database queries.

```
STATS pct(durationNano, 99) as `p99` by attributes.db.statement
| SORT p99 ASC
| LIMIT 5
| DISPLAY p99,attributes.db.statement
```

Example query

The following query shows which top five services are throwing errors.

```
FILTER `attributes.http.response.status_code` >= 500
| STATS count(*) as `count` by attributes.aws.local.service as service
| SORT count ASC
| LIMIT 5
| DISPLAY count,service
```

Ingesting spans for complete visibility

Recording all transaction spans provides comprehensive visibility into application issues. It enables you to debug customer support tickets or troubleshoot rarely occurring p99 API latency spikes, which is crucial when identifying the root cause of issues in customer-facing and mission-critical applications. You can create a cost-effective strategy to start capturing 100% of trace spans in CloudWatch by configuring the head sampling rate and then adjusting a lower span indexing rate.

Setting up head sampling

Head sampling is a tracing technique capturing requests at the beginning of a trace, which is based on a set rate or condition.

When the head sampling rate is set to 100%, it captures the beginning of every trace without skips, guaranteeing complete visibility into all incoming requests, and that no transaction data is missed.

You can configure head sampling if you're using X-Ray or Amazon Distro for OpenTelemetry SDKs or the OpenTelemetry SDK.

If you're using X-Ray or Amazon Distro for OpenTelemetry SDKs

Navigate to your sampling rules in the console, and set the fixed sampling rate to 100%. This guarantees all trace spans are captured and ingested into CloudWatch logs. For more information, see Configuring sampling rules

If you're using the OpenTelemetry SDK

To record 100% of spans and get complete visibility, set your sampling configuration to `always_on`. For more information, see Language APIs & SDKs on the OpenTelemetry website.

Features unlocked with head sampling

When you enable Transaction Search, all spans collected from your application through head sampling are ingested as structured logs in CloudWatch. This provides you with the following features:

- The ability to search span attributes and analyze span events in a visual editor.
- The ability to visualize traces containing up to 10,000 spans.
- Total support for OpenTelemetry, which includes the ability to embed business events into spans for analysis and use span links to define connections between traces for end-to-end viewing.
- Access to application dashboards, metrics, and topology with CloudWatch Application Signals enabled for all spans sent to CloudWatch.

> **Note**
>
> Because spans are available in a log group called `aws/spans`, you can use CloudWatch Logs features with transaction spans. For more information, see The span log group.

Setting up span indexing with trace summaries

Trace summaries can help you debug transactions and are beneficial for asynchronous processes. You only need to index a small percentage of spans as trace summaries.

You configure span indexing when you enable Transaction Search in the console or with the API. To enable Transaction Search, see Getting started with Transaction Search.

Features unlocked with trace summaries

The key features of X-Ray trace summaries include the following:

- Trace summary search – Search and find traces from trace summaries.
- Trace summary analytics – Interpret trace data.
- Trace insights – Analyze trace data to identify application issues.

Monitoring spans across accounts

Spans sent to X-Ray are ingested and managed in a log group called `aws/spans`. To monitor spans across multiple accounts, you must enable Transaction Search across all source and monitoring accounts and enable cross-account observability for logs and traces. When you enable cross-account observability, you can search up to 10,000 accounts and get visibility into traces across accounts. This feature is provided at no extra cost for the `aws/spans` log group. If you enable cross-account observability for trace summaries, the first trace summary copy is free. For more information about pricing, see Amazon CloudWatch Pricing.

Adding custom attributes

CloudWatch Application Signals utilizes OpenTelemetry to auto-instrument your applications and collect spans from popular libraries in different languages, such as Java, Python, and more.

Auto-instrumentation captures information, such as database queries, HTTP requests, cache accesses, and external service calls, which allows you to troubleshoot application performance issues.

You can add custom instrumentation to enrich spans with business-specific data or other information you wish to capture. This data can be recorded as a custom attribute or a span event, providing insights tailored to your troubleshooting needs.

> **Note**
>
> For information about adding custom attributes or span events in a different language, see Language APIs and SDKS in the *OpenTelemetry website*.

Custom attributes

You can add business related attributes or any other attributes to your spans in all languages OpenTelemetry supports. The following is a Java code snippet that adds an order id and customer details to a span.

```
import io.opentelemetry.api.trace.Span;

public class OrderProcessor {

    public void processOrder() {
        Span span = Span.current();
        span.setAttribute("order.id", "123456");
        span.setAttribute("customer.name", "John Doe");
        span.setAttribute("customer.id", "4343dfdd");

        // Your order processing logic here
        System.out.println("Order processed with custom attributes");
    }
}
```

After these attributes have been added to the span, they become available to search and analyze in the Transaction Search visual editor.

Span events

A span event is typically used to denote a meaningful, singular point in time during a span duration. Exceptions are auto-captured as span events through auto-instrumentation, but you can also add custom business events, such as payment-status or cart-abandonment. For more information, see Span events on the OpenTelemetry website.

You can embed span events to your spans in all the languages CloudWatch Application Signals and OpenTelemetry support. The following is a Java code snippet of adding a custom event to a span.

```
import io.opentelemetry.api.trace.Span;

public class OrderProcessor {

    public void bookOrder() {
        Span span = Span.current();
```

```
        // Add a booking started event
        span.addEvent("booking started");

        // Add a payment succeeded event or failed event
        span.addEvent("booking failed");
    }
}
```

Prerequisites for the CloudWatch agent

When using the CloudWatch agent to emit span events to X-Ray, you must turn on the `` `transit_spans_in_otlp_format` `` flag in your configuration.

```
{
  "traces": {
    ...
    "transit_spans_in_otlp_format": true
    ...
  }
}
```

After you add these events, they become available in the Transaction Search visual editor.

CloudWatch Logs queries

You can query span events in CloudWatch Logs to view advanced insights. The following example query commands show how to analyze exceptions thrown by your application:

```
fields jsonparse(@message) as js
| unnest js.events into event
| filter event.name = "exception"
| display event.attributes.`exception.stacktrace`
```

```
fields jsonparse(@message) as js
| unnest js.events into event
| filter event.name = "exception"
| stats count() by event.attributes.`exception.type`
```

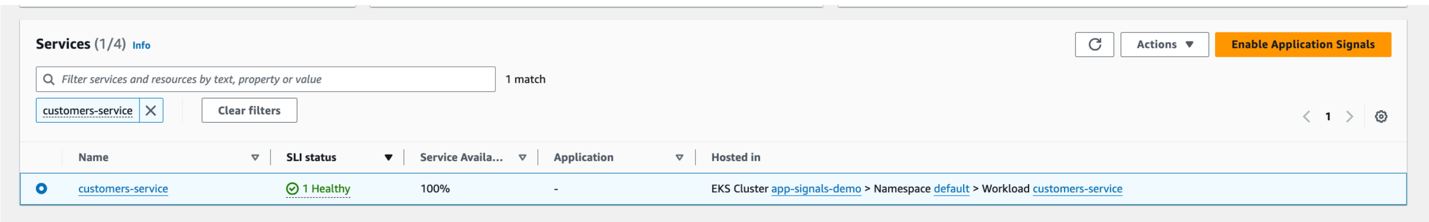
Troubleshooting application issues

With Application Signals, you can troubleshoot rarely occurring latency spikes in your applications. After you enable Transaction Search and configure a head sampling rate capturing 100% of spans, you get complete visibility into any application issue. The following scenario describes how Application Signals can be used with transaction spans to monitor your services and identify service quality issues.

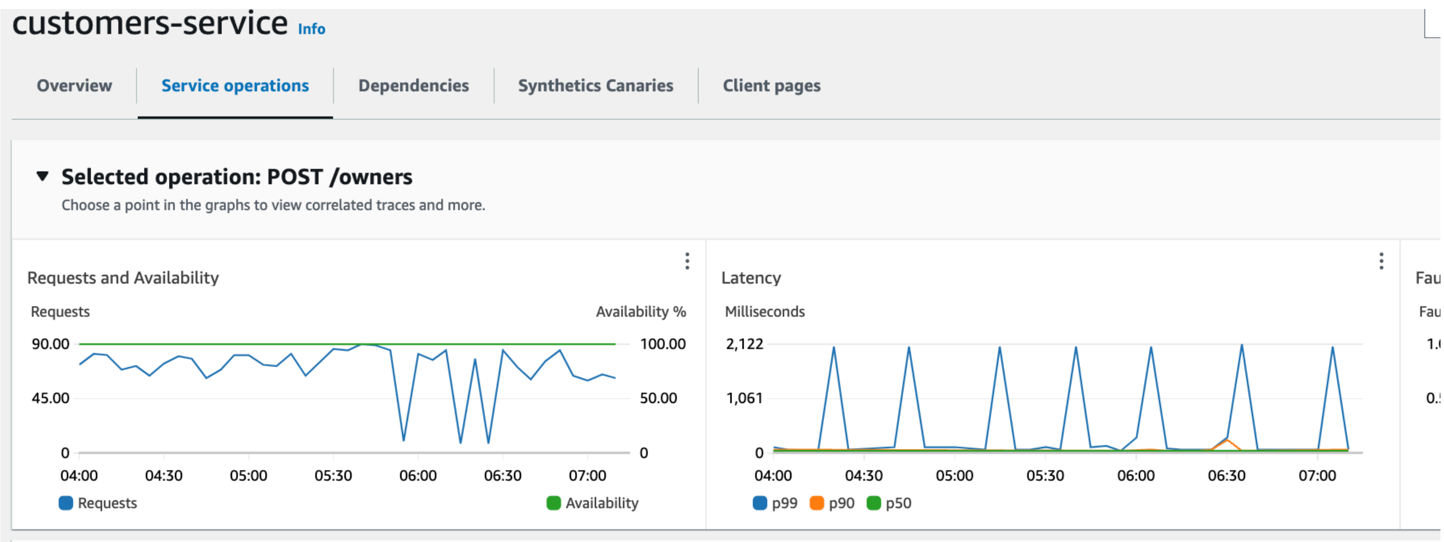
Example troubleshooting scenario

This scenario focuses on a pet clinic application composed of several micro-services calling third-party payment APIs. These calls have been intermittently slow, thus impacting revenue.

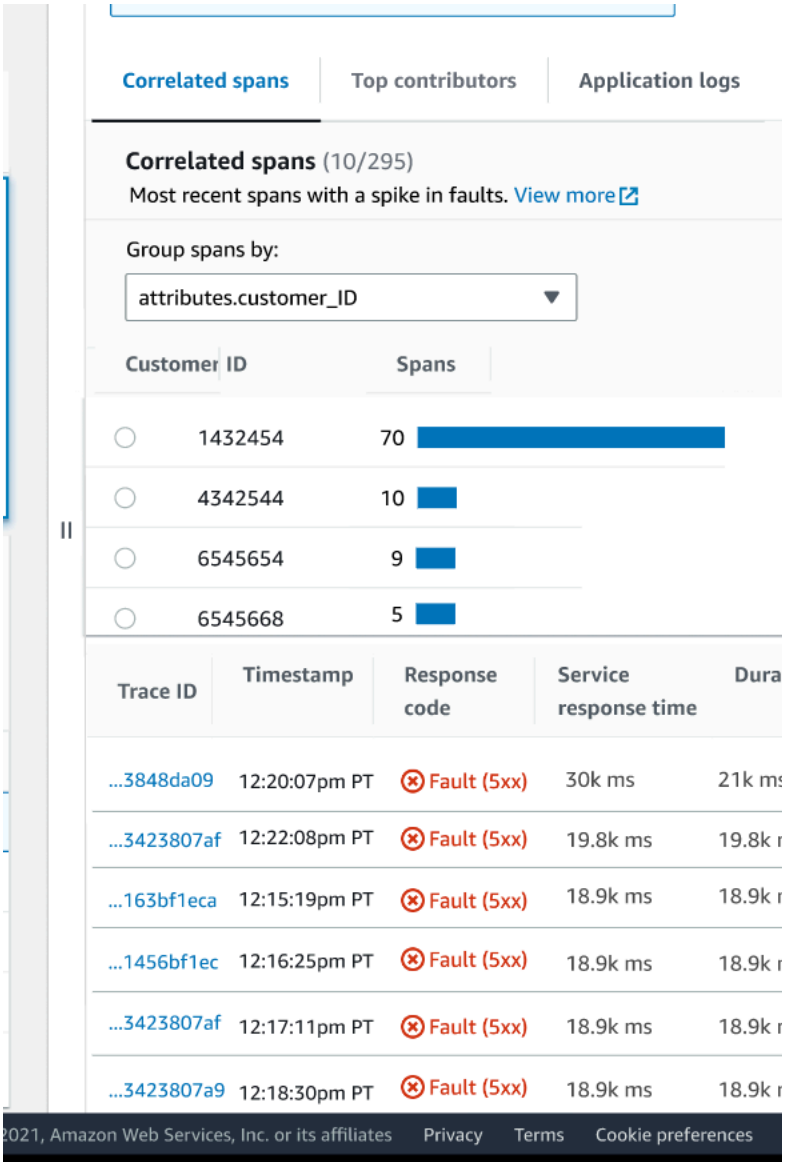
Jane opens the CloudWatch Application Signals console and notices a customer-service application responsible for registering customers is healthy and not breaching any SLOs.



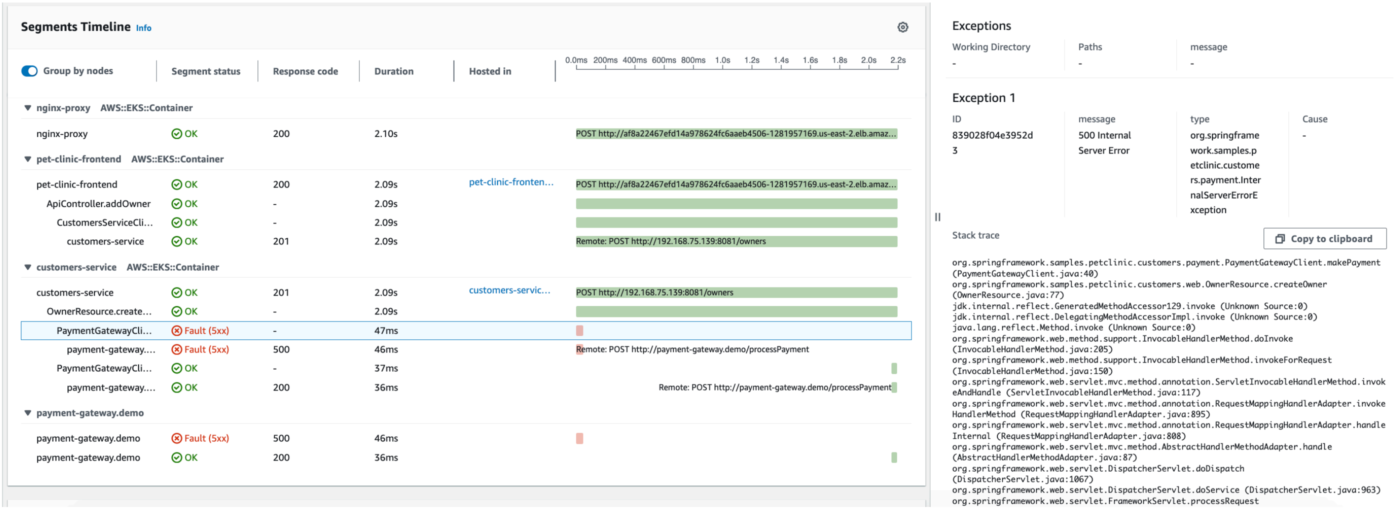
She opens the service to investigate any patterns of rarely occurring failures and notices the registration API experienced intermittent p99 latency spikes.



Jane chooses a datapoint in the latency chart to view correlated spans. She groups the spans by customer ID to view all the customers who are impacted by the latency spikes.



Jane selects one of the correlated spans with a fault status, which opens the trace detail page for the selected trace. She scrolls to the segments timeline section to follow the call path, where she notices that calls to the payment gateway have been failing and preventing customers from registering.



Synthetic monitoring (canaries)

You can use Amazon CloudWatch Synthetics to create *canaries*, configurable scripts that run on a schedule, to monitor your endpoints and APIs. Canaries follow the same routes and perform the same actions as a customer, which makes it possible for you to continually verify your customer experience even when you don't have any customer traffic on your applications. By using canaries, you can discover issues before your customers do.

Canaries are scripts written in Node.js or Python. They create Lambda functions in your account that use Node.js or Python as a framework. Canaries work over both HTTP and HTTPS protocols. Canaries use Lambda layers that contain the CloudWatch Synthetics library. The library contains the NodeJS version of CloudWatch Synthetics for NodeJS canaries and the Python version of CloudWatch Synthetics for Python canaries. The layers belong to the CloudWatch Synthetics service account. Libraries never transmit or store customer information. All customer data is stored in the customer account only.

Canaries offer programmatic access to a headless Google Chrome Browser via Puppeteer or Selenium Webdriver. For more information about Puppeteer, see [Puppeteer](). For more information about Selenium, see [www.selenium.dev/]().

Canaries check the availability and latency of your endpoints and can store load time data and screenshots of the UI. They monitor your REST APIs, URLs, and website content, and they can check for unauthorized changes from phishing, code injection and cross-site scripting.

CloudWatch Synthetics is integrated with [Application Signals](), which can discover and monitor your application services, clients, Synthetics canaries, and service dependencies. Use Application

Signals to see a list or visual map of your services, view health metrics based on your service level objectives (SLOs), and drill down to see correlated X-Ray traces for more detailed troubleshooting. To see your canaries in Application Signals, turn on X-Ray active tracing. Your canaries are displayed on the Service Map connected to your services, and in the Service detail page of the services they call.

You can run a canary once or on a regular schedule. Canaries can run as often as once per minute. You can use both cron and rate expressions to schedule canaries.

For information about security issues to consider before you create and run canaries, see Security considerations for Synthetics canaries.

By default, canaries create several CloudWatch metrics in the `CloudWatchSynthetics` namespace. These metrics have `CanaryName` as a dimension. Canaries that use the `executeStep()` or `executeHttpStep()` function from the function library also have `StepName` as a dimension. For more information about the canary function library, see Library functions available for canary scripts.

CloudWatch Synthetics integrates well with the X-Ray Trace Map, which uses CloudWatch with Amazon X-Ray to provide an end-to-end view of your services to help you more efficiently pinpoint performance bottlenecks and identify impacted users. Canaries that you create with CloudWatch Synthetics appear on the trace map. For more information, see X-Ray Trace Map.

CloudWatch Synthetics is currently available in all commercial Amazon Regions and the GovCloud Regions.

> **Note**
>
> In Asia Pacific (Osaka), Amazon PrivateLink is not supported. In Asia Pacific (Jakarta), Amazon PrivateLink and X-Ray are not supported.

Topics

Required roles and permissions for CloudWatch canaries

Both the users who create and manage canaries, and the canaries themselves, must have certain permissions.

Required roles and permissions for users who manage CloudWatch canaries

To view canary details and the results of canary runs, you must be signed in as a user with either the `CloudWatchSyntheticsFullAccess` or the `CloudWatchSyntheticsReadOnlyAccess` policies attached. To read all Synthetics data in the console, you also need the `AmazonS3ReadOnlyAccess` and `CloudWatchReadOnlyAccess` policies. To view the source code used by canaries, you also need the `AWSLambda_ReadOnlyAccess` policy.

To create canaries, you must be signed in as an user who has the `CloudWatchSyntheticsFullAccess` policy or a similar set of permissions. To create IAM roles for the canaries, you also need the following inline policy statement:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:CreateRole",
```

```
                "iam:CreatePolicy",
                "iam:AttachRolePolicy"
            ],
            "Resource": [
                "arn:aws:iam::*:role/service-role/CloudWatchSyntheticsRole*",
                "arn:aws:iam::*:policy/service-role/CloudWatchSyntheticsPolicy*"
            ]
        }
    ]
}
```

> **Important**
>
> Granting a user the `iam:CreateRole`, `iam:CreatePolicy`, and `iam:AttachRolePolicy` permissions gives that user full administrative access to your Amazon account. For example, a user with these permissions can create a policy that has full permissions for all resources and can attach that policy to any role. Be very careful about who you grant these permissions to.

For information about attaching policies and granting permissions to users, see Changing Permissions for an IAM User and To embed an inline policy for a user or role.

Required roles and permissions for canaries

Each canary must be associated with an IAM role that has certain permissions attached. When you create a canary using the CloudWatch console, you can choose for CloudWatch Synthetics to create an IAM role for the canary. If you do, the role will have the permissions needed.

If you want to create the IAM role yourself, or create an IAM role that you can use when using the Amazon CLI or APIs to create a canary, the role must contain the permissions listed in this section.

All IAM roles for canaries must include the following trust policy statement.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "lambda.amazonaws.com"
```

```
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Additionally, the canary's IAM role needs one of the following statements.

Basic canary that doesn't use Amazon KMS or need Amazon VPC access

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::path/to/your/s3/bucket/canary/results/folder"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::name/of/the/s3/bucket/that/contains/canary/results"

            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:CreateLogGroup"
            ],
            "Resource": [
                "arn:aws:logs:canary_region_name:canary_account_id:log-group:/aws/
lambda/cwsyn-canary_name-*"
            ]
```

```
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListAllMyBuckets",
                "xray:PutTraceSegments"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Resource": "*",
            "Action": "cloudwatch:PutMetricData",
            "Condition": {
               "StringEquals": {
                "cloudwatch:namespace": "CloudWatchSynthetics"
               }
            }
        }
    ]
}
```

Canary that uses Amazon KMS to encrypt canary artifacts but does not need Amazon VPC access

```
{
    "Version": "2012-10-17",
    "Statement": [{
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::path/to/your/S3/bucket/canary/results/folder"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [

lambda/cwsyn-canary_name-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListAllMyBuckets",
                "xray:PutTraceSegments"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Resource": "*",
            "Action": "cloudwatch:PutMetricData",
            "Condition": {
                "StringEquals": {
                    "cloudwatch:namespace": "CloudWatchSynthetics"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateNetworkInterface",
                "ec2:DescribeNetworkInterfaces",
                "ec2:DeleteNetworkInterface"
            ],
            "Resource": [
                "*"
            ]
       }
    ]
}
```

Canary that uses Amazon KMS to encrypt canary artifacts and also needs Amazon VPC access

If you update a non-VPC canary to start using a VPC, you'll need to update the canary's role to include the network interface permissions listed in the following policy.

```
{
    "Version": "2012-10-17",
    "Statement": [{
            "Effect": "Allow",
            "Action": [
                "s3:PutObject",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::path/to/your/S3/bucket/canary/results/folder"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::name/of/the/S3/bucket/that/contains/canary/results"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogStream",
                "logs:PutLogEvents",
                "logs:CreateLogGroup"
            ],
            "Resource": [
                "arn:aws:logs:canary_region_name:canary_account_id:log-group:/aws/
lambda/cwsyn-canary_name-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListAllMyBuckets",
                "xray:PutTraceSegments"
            ],
            "Resource": [
                "*"
            ]
        },
```

```
        {
            "Effect": "Allow",
            "Resource": "*",
            "Action": "cloudwatch:PutMetricData",
            "Condition": {
                "StringEquals": {
                    "cloudwatch:namespace": "CloudWatchSynthetics"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateNetworkInterface",
                "ec2:DescribeNetworkInterfaces",
                "ec2:DeleteNetworkInterface"
            ],
            "Resource": [
                "*"
            ]
       },
       {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt",
                "kms:GenerateDataKey"
            ],
            "Resource":
 "arn:aws:kms:KMS_key_region_name:KMS_key_account_id:key/KMS_key_id",
            "Condition": {
                "StringEquals": {
                    "kms:ViaService": [
                        "s3.region_name_of_the_canary_results_S3_bucket.amazonaws.com"
                    ]
                }
            }
        }
    ]
}
```

Amazon managed policies for CloudWatch Synthetics

To add permissions to users, groups, and roles, it is easier to use Amazon managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our Amazon managed policies. These policies cover common use cases and are available in your Amazon account. For more information about Amazon managed policies, see Amazon managed policies Amazon managed policies in the IAM User Guide.

Amazon services maintain and update Amazon managed policies. You can't change the permissions in Amazon managed policies. Services occasionally change the permissions in an Amazon managed policy. This type of update affects all identities (users, groups, and roles) where the policy is attached.

CloudWatch Synthetics updates to Amazon managed policies

View details about updates to Amazon managed policies for CloudWatch Synthetics since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the CloudWatch Document history page.

Change	Description	Date
Redundant actions removed from **CloudWatchSyntheticsFullAccess**	CloudWatch Synthetics removed the `s3:PutBucketEncryption` and `lambda:GetLayerVersionByArn` actions from **CloudWatchSyntheticsFullAccess** policy because those actions were redundant with other permissions in the policy. The removed actions did not provide any permissions, and there's no net change to the permissions granted by the policy.	March 12, 2021

Change	Description	Date
CloudWatch Synthetics started tracking changes	CloudWatch Synthetics started tracking changes for its Amazon managed policies.	March 10, 2021

CloudWatchSyntheticsFullAccess

Here are the contents of the `CloudWatchSyntheticsFullAccess` policy:

```
{
    "Version": "2012-10-17",
    "Statement": [{
            "Effect": "Allow",
            "Action": [
                "synthetics:*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:CreateBucket",
                "s3:PutEncryptionConfiguration"
            ],
            "Resource": [
                "arn:aws:s3:::cw-syn-results-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:ListRoles",
                "s3:ListAllMyBuckets",
                "xray:GetTraceSummaries",
                "xray:BatchGetTraces",
                "apigateway:GET"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
```

```
            "Action": [
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:::cw-syn-*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetObjectVersion"
            ],
            "Resource": "arn:aws:s3:::aws-synthetics-library-*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:PassRole"
            ],
            "Resource": [
                "arn:aws:iam::*:role/service-role/CloudWatchSyntheticsRole*"
            ],
            "Condition": {
                "StringEquals": {
                    "iam:PassedToService": [
                        "lambda.amazonaws.com",
                        "synthetics.amazonaws.com"
                    ]
                }
            }
        },

                "arn:aws:lambda:*:*:layer:Synthetics_Selenium:*",
                "arn:aws:lambda:*:*:layer:AWS-CW-Synthetics*:*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeVpcs",
                "ec2:DescribeSubnets",
                "ec2:DescribeSecurityGroups"
```

```
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "sns:ListTopics"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "sns:CreateTopic",
                "sns:Subscribe",
                "sns:ListSubscriptionsByTopic"
            ],
            "Resource": [
                "arn:*:sns:*:*:Synthetics-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:ListAliases"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:DescribeKey"
            ],
            "Resource": "arn:aws:kms:*:*:key/*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Decrypt"
            ],
```

```
            "Resource": "arn:aws:kms:*:*:key/*",
            "Condition": {
                "StringLike": {
                    "kms:ViaService": [
                        "s3.*.amazonaws.com"
                    ]
                }
            }
        }
    ]
}
```

CloudWatchSyntheticsReadOnlyAccess

Here are the contents of the `CloudWatchSyntheticsReadOnlyAccess` policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "synthetics:Describe*",
                "synthetics:Get*",
                "synthetics:List*"
            ],
            "Resource": "*"
        }
    ]
}
```

Limiting a user to viewing specific canaries

You can limit a user's ability to view information about canaries, so that they can only see information about the canaries you specify. To do this, use an IAM policy with a `Condition` statement similar to the following, and attach this policy to a user or an IAM role.

The following example limits the user to only viewing information about `name-of-allowed-canary-1` and `name-of-allowed-canary-2`.

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "synthetics:DescribeCanaries",
            "Resource": "*",
            "Condition": {
                "ForAnyValue:StringEquals": {
                    "synthetics:Names": [
                        "name-of-allowed-canary-1",
                        "name-of-allowed-canary-2"
                    ]
                }
            }
        }
    ]
}
```

CloudWatch Synthetics supports listing as many as five items in the `synthetics:Names` array.

You can also create a policy that uses a * as a wildcard in canary names that are to be allowed, as in the following example:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "synthetics:DescribeCanaries",
            "Resource": "*",
            "Condition": {
                "ForAnyValue:StringLike": {
                    "synthetics:Names": [
                        "my-team-canary-*"
                    ]
                }
            }
        }
    ]
}
```

Any user signed in with one of these policies attached can't use the CloudWatch console to view any canary information. They can view canary information only for the canaries authorized by the policy and only by using the DescribeCanaries API or the describe-canaries Amazon CLI command.

Creating a canary

> **Important**
>
> Ensure that you use Synthetics canaries to monitor only endpoints and APIs where you have ownership or permissions. Depending on the canary frequency settings, these endpoints might experience increased traffic.

When you use the CloudWatch console to create a canary, you can use a blueprint provided by CloudWatch to create your canary or you can write your own script. For more information, see Using canary blueprints.

You can also create a canary using Amazon CloudFormation if you are using your own script for the canary. For more information, see AWS::Synthetics::Canary in the *Amazon CloudFormation User Guide*.

If you are writing your own script, you can use several functions that CloudWatch Synthetics has built into a library. For more information, see Synthetics runtime versions.

> **Note**
>
> When you create a canary, one of the layers created is a Synthetics layer prepended with `Synthetics`. This layer is owned by the Synthetics service account and contains the runtime code.

To create a canary

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Synthetics Canaries**.
3. Choose **Create Canary**.
4. Choose one of the following:

- To base your canary on a blueprint script, choose **Use a blueprint**, and then choose the type of canary you want to create. For more information about what each type of blueprint does, see Using canary blueprints.
- To upload your own Node.js script to create a custom canary, choose **Upload a script**.

  You can then drag your script into the **Script** area or choose **Browse files** to navigate to the script in your file system.
- To import your script from an S3 bucket, choose **Import from S3**. Under **Source location**, enter the complete path to your canary or choose **Browse S3**.

  You must have `s3:GetObject` and `s3:GetObjectVersion` permissions for the S3 bucket that you use. The bucket must be in the same Amazon Region where you are creating the canary.

5. Under **Name**, enter a name for your canary. The name is used on many pages, so we recommend that you give it a descriptive name that distinguishes it from other canaries.
6. Under **Application or endpoint URL**, enter the URL that you want the canary to test. This URL must include the protocol (such as https://).

   If you want the canary to test an endpoint on a VPC, you must also enter information about your VPC later in this procedure.
7. If you are using your own script for the canary, under **Lambda handler**, enter the entry point where you want the canary to start. If you use a runtime earlier than `syn-nodejs-puppeteer-3.4` or `syn-python-selenium-1.1`, the string that you enter must end with `.handler`. If you use `syn-nodejs-puppeteer-3.4` or `syn-python-selenium-1.1` or a later runtime, this restriction does not apply.
8. If you are using environment variables in your script, choose **Environment variables** and then specify a value for each environment variable defined in your script. For more information, see Environment variables.
9. Under **Schedule**, choose whether to run this canary just once, run it continuously using a rate expression, or schedule it using a cron expression.

   - When you use the CloudWatch console to create a canary that runs continuously, you can choose a rate anywhere between once a minute and once an hour.

- For more information about writing a cron expression for canary scheduling, see Scheduling canary runs using cron.

10. (Optional) To set a timeout value for the canary, choose **Additional configuration** and then specify the timeout value. Make it no shorter than 15 seconds to allow for Lambda cold starts and the time it takes to boot up the canary instrumentation.
11. Under **Data retention**, specify how long to retain information about both failed and successful canary runs. The range is 1-455 days.

    This setting affects the range of information returned by GetCanaryRuns operations, as well as the range of information displayed in the Synthetics console.

    It does not affect the data stored in your Amazon S3 buckets, or logs or metrics that are published by the canary.

    Regardless of the canary's data retention period, the range of information displayed in console has certain limits. In the Synthetics console home view, the relative and absolute time range are limited to seven days. In the Synthetics console view for a specific canary, the relative time range is limited to seven days and the absolute time range is limited to 30 days.
12. Under **Data Storage**, select the S3 bucket to use to store the data from the canary runs. The bucket name can't contain a period (.). If you leave this blank, a default S3 bucket is used or created.

    If you are using the `syn-nodejs-puppeteer-3.0` or later runtime, when you enter the URL for the bucket in the text box, you can specify a bucket in the current Region or in a different Region. If you are using an earlier runtime version, the bucket must be in the current Region.
13. (Optional) By default, canaries store their artifacts on Amazon S3, and the artifacts are encrypted at rest using an Amazon-managed Amazon KMS key. You can use a different encryption option by choosing **Additional configuration** in the **Data Storage** section. You can then choose the type of key to use for encryption. For more information, see Encrypting canary artifacts.
14. Under **Access permissions**, choose whether to create an IAM role to run the canary or use an existing one.

    If you have CloudWatch Synthetics create the role, it automatically includes all the necessary permissions. If you want to create the role yourself, see Required roles and permissions for canaries for information about the necessary permissions.

If you use the CloudWatch console to create a role for a canary when you create the canary, you can't re-use the role for other canaries, because these roles are specific to just one canary. If you have manually created a role that works for multiple canaries, you can use that existing role.

To use an existing role, you must have the `iam:PassRole` permission to pass that role to Synthetics and Lambda. You must also have the `iam:GetRole` permission.

15. (Optional) Under **Alarms**, choose whether you want default CloudWatch alarms to be created for this canary. If you choose to create alarms, they are created with the following name convention:`Synthetics-Alarm-canaryName-index`

    `index` is a number representing each different alarm created for this canary. The first alarm has an index of 1, the second alarm has an index of 2, and so on.
16. (Optional) To have this canary test an endpoint that is on a VPC, choose **VPC settings**, and then do the following:

    a. Select the VPC that hosts the endpoint.

    b. Select one or more subnets on your VPC. You must select a private subnet because a Lambda instance can't be configured to run in a public subnet when an IP address can't be assigned to the Lambda instance during execution. For more information, see Configuring a Lambda Function to Access Resources in a VPC.

    c. Select one or more security groups on your VPC.

    d. To allow outbound IPv6 traffic for this canary, select **Allow IPv6 Traffic for dual-stack subnets**. This enables the canary to monitor IPv6-only and dual stack enabled endpoints over IPv6.

       You can monitor endpoints external to your VPC by giving the canary internet access and configuring the VPC subnets appropriately. For more information, see Running a canary on a VPC.

    If the endpoint is on a VPC, you must enable your canary to send information to CloudWatch and Amazon S3. For more information, see Running a canary on a VPC.
17. (Optional) Under **Tags**, add one or more key-value pairs as tags for this canary. Tags can help you identify and organize your Amazon resources and track your Amazon costs. For more information, see Tagging your Amazon CloudWatch resources.

If you want the tags that you apply to the canary to also be applied to the Lambda function that the canary uses, choose **Lambda function** under **Tag Replication**. If you choose this option, CloudWatch Synthetics will keep the tags on the canary and the Lambda function synchronized:

- Synthetics will apply the same tags that you specify here to both your canary and your Lambda function.
- If you later update the canary's tags and keep this option selected, Synthetics modifies the tags on your Lambda function to remain in sync with the canary.

18. (Optional) Under **Active tracing**, choose whether to enable active X-Ray tracing for this canary. This option is available only if the canary uses runtime version **syn-nodejs-2.0** or later. **Active tracing** is only available for Puppeteer runtimes. For more information, see [Canaries and X-Ray tracing](#).

Resources that are created for canaries

When you create a canary, the following resources are created:

- An IAM role with the name `CloudWatchSyntheticsRole-canary-name-uuid` (if you use CloudWatch console to create the canary and specify for a new role to be created for the canary)
- An IAM policy with the name `CloudWatchSyntheticsPolicy-canary-name-uuid`.
- An S3 bucket with the name `cw-syn-results-accountID-region`.
- Alarms with the name `Synthetics-Alarm-MyCanaryName`, if you want alarms to be created for the canary.
- Lambda functions and layers, if you use a blueprint to create the canary. These resources have the prefix `cwsyn-MyCanaryName`.
- CloudWatch Logs log groups with the name `/aws/lambda/cwsyn-MyCanaryName-randomId`.

Using canary blueprints

This section provides details about each of the canary blueprints and the tasks each blueprint is best suited for. Blueprints are provided for the following canary types:

- Heartbeat Monitor
- API Canary

- Broken Link Checker
- Visual Monitoring
- Canary Recorder
- GUI Workflow

When you use a blueprint to create a canary, as you fill out the fields in the CloudWatch console, the **Script editor** area of the page displays the canary you are creating as a Node.js script. You can also edit your canary in this area to customize it further.

Heartbeat monitoring

Heartbeat scripts load the specified URL and store a screenshot of the page and an HTTP archive file (HAR file). They also store logs of accessed URLs.

You can use the HAR files to view detailed performance data about the web pages. You can analyze the list of web requests and catch performance issues such as time to load for an item.

If your canary uses the `syn-nodejs-puppeteer-3.1` or later runtime version, you can use the heartbeat monitoring blueprint to monitor multiple URLs and see the status, duration, associated screenshots, and failure reason for each URL in the step summary of the canary run report.

API canary

API canaries can test the basic Read and Write functions of a REST API. REST stands for *representational state transfer* and is a set of rules that developers follow when creating an API. One of these rules states that a link to a specific URL should return a piece of data.

Canaries can work with any APIs and test all types of functionality. Each canary can make multiple API calls.

In canaries that use runtime version `syn-nodejs-2.2` or later, the API canary blueprint supports multi-step canaries that monitor your APIs as HTTP steps. You can test multiple APIs in a single canary. Each step is a separate request that can access a different URL, use different headers, and use different rules for whether headers and response bodies are captured. By not capturing headers and response body, you can prevent sensitive data from being recorded.

Each request in an API canary consists of the following information:

- The *endpoint*, which is the URL that you request.

- The *method*, which is the type of request that is sent to the server. REST APIs support GET (read), POST (write), PUT (update), PATCH (update), and DELETE (delete) operations.
- The *headers*, which provide information to both the client and the server. They are used for authentication and providing information about the body content. For a list of valid headers, see [HTTP Headers](#).
- The *data* (or *body*), which contains information to be sent to the server. This is used only for POST, PUT, PATCH, or DELETE requests.

> **Note**
>
> API canary blueprints are not supported by Playwright runtimes.

The API canary blueprint supports GET and POST methods. When you use this blueprint, you must specify headers. For example, you can specify **`Authorization`** as a **Key** and specify the necessary authorization data as the **Value** for that key.

If you are testing a POST request, you also specify the content to post in the **Data** field.

Integration with API Gateway

The API blueprint is integrated with Amazon API Gateway. This enables you to select an API Gateway API and stage from the same Amazon account and Region as the canary, or to upload a Swagger template from API Gateway for cross-account and cross-Region API monitoring. You can then choose the rest of the details in the console to create the canary, instead of entering them from scratch. For more information about API Gateway, see [What is Amazon API Gateway?](#)

Using a private API

You can create a canary that uses a private API in Amazon API Gateway. For more information, see [Creating a private API in Amazon API Gateway?](#)

Broken link checker

The broken link checker collects all the links inside the URL that you are testing by using `document.getElementsByTagName('a')`. It tests only up to the number of links that you specify, and the URL itself is counted as the first link. For example, if you want to check all the links on a page that contains five links, you must specify for the canary to follow six links.

Broken link checker canaries created using the `syn-nodejs-2.0-beta` runtime or later support the following additional features:

- Provides a report that includes the links that were checked, status code, failure reason (if any), and source and destination page screenshots.
- When viewing canary results, you can filter to see only the broken links and then fix the link based on the reason for failure.
- This version captures annotated source page screenshots for each link and highlights the anchor where the link was found. Hidden components are not annotated.
- You can configure this version to capture screenshots of both source and destination pages, just source pages, or just destination pages.
- This version fixes an issue in the earlier version where the canary script stops after the first broken link even when more links are scraped from the first page.

> **Note**
>
> Broken link checker blueprints are not supported by Playwright runtimes.

To update an existing canary using `syn-1.0` to use the new runtime, you must delete and re-create the canary. Updating an existing canary to the new runtime does not make these features available.

A broken link checker canary detects the following types of link errors:

- 404 Page Not Found
- Invalid Host Name
- Bad URL. For example, the URL is missing a bracket, has extra slashes, or uses the wrong protocol.
- Invalid HTTP response code.
- The host server returns empty responses with no content and no response code.
- The HTTP requests constantly time out during the canary's run.
- The host consistently drops connections because it is misconfigured or is too busy.

Visual monitoring blueprint

The visual monitoring blueprint includes code to compare screenshots taken during a canary run with screenshots taken during a baseline canary run. If the discrepancy between the two screenshots is beyond a threshold percentage, the canary fails. Visual monitoring is supported in canaries running **syn-puppeteer-node-3.2** and later. It is not currently supported in canaries running Python and Selenium, or using Playwright runtimes.

The visual monitoring blueprint includes the following line of code in the default blueprint canary script, which enables visual monitoring.

```
syntheticsConfiguration.withVisualCompareWithBaseRun(true);
```

The first time that the canary runs successfully after this line is added to the script, it uses the screenshots taken during that run as the baseline for comparison. After that first canary run, you can use the CloudWatch console to edit the canary to do any of the following:

- Set the next run of the canary as the new baseline.
- Draw boundaries on the current baseline screenshot to designate areas of the screenshot to ignore during visual comparisons.
- Remove a screenshot from being used for visual monitoring.

For more information about using the CloudWatch console to edit a canary, see Edit or delete a canary.

You can also change the canary run that is used as the baseline by using the `nextrun` or `lastrun` parameters or specifing a canary run ID in the UpdateCanary API.

When you use the visual monitoring blueprint, you enter the URL where you want the screenshot to be taken, and specify a difference threshold as a percentage. After the baseline run, future runs of the canary that detect a visual difference greater than that threshold trigger a canary failure. After the baseline run, you can also edit the canary to "draw" boundaries on the baseline screenshot that you want to ignore during the visual monitoring.

The visual monitoring feature is powered by the the ImageMagick open source software toolkit. For more information, see ImageMagick .

Canary recorder

With the canary recorder blueprint, you can use the CloudWatch Synthetics Recorder to record your click and type actions on a website and automatically generate a Node.js script that can be used to create a canary that follows the same steps. The CloudWatch Synthetics Recorder is a Google Chrome extension provided by Amazon. The canary recorder is not supported for canaries that use the Playwright runtime.

Credits: The CloudWatch Synthetics Recorder is based on the [Headless recorder](#).

For more information, see [Using the CloudWatch Synthetics Recorder for Google Chrome](#).

GUI workflow builder

The GUI Workflow Builder blueprint verifies that actions can be taken on your webpage. For example, if you have a webpage with a login form, the canary can populate the user and password fields and submit the form to verify that the webpage is working correctly.

When you use a blueprint to create this type of canary, you specify the actions that you want the canary to take on the webpage. The actions that you can use are the following:

- **Click**— Selects the element that you specify and simulates a user clicking or choosing the element.

  To specify the element in a Node.js script, use `[id=]` or `a[class=]`.

  To specify the element in a Python script, use `xpath //*[@id=]` or `//*[@class=]`.
- **Verify selector**— Verifies that the specified element exists on the webpage. This test is useful for verifying that a previous action has causes the correct elements to populate the page.

  To specify the element to verify in a Node.js script, use `[id=]` or `a[class=]`.

  To specify the element to verify in a Python script, use `xpath //*[@id=]` or `//*[class=]`.
- **Verify text**— Verifies that the specified string is contained within the target element. This test is useful for verifying that a previous action has caused the correct text to be displayed.

  To specify the element in a Node.js script, use a format such as `div[@id=]//h1` because this action uses the `waitForXPath` function in Puppeteer.

  To specify the element in a Python script, use xpath format such as `//*[@id=]` or //*[@class=] because this action uses the `implicitly_wait` function in Selenium.

- **Input text**— Writes the specified text in the target element.

  To specify the element to verify in a Node.js script, use `[id=]` or `a[class=]`.

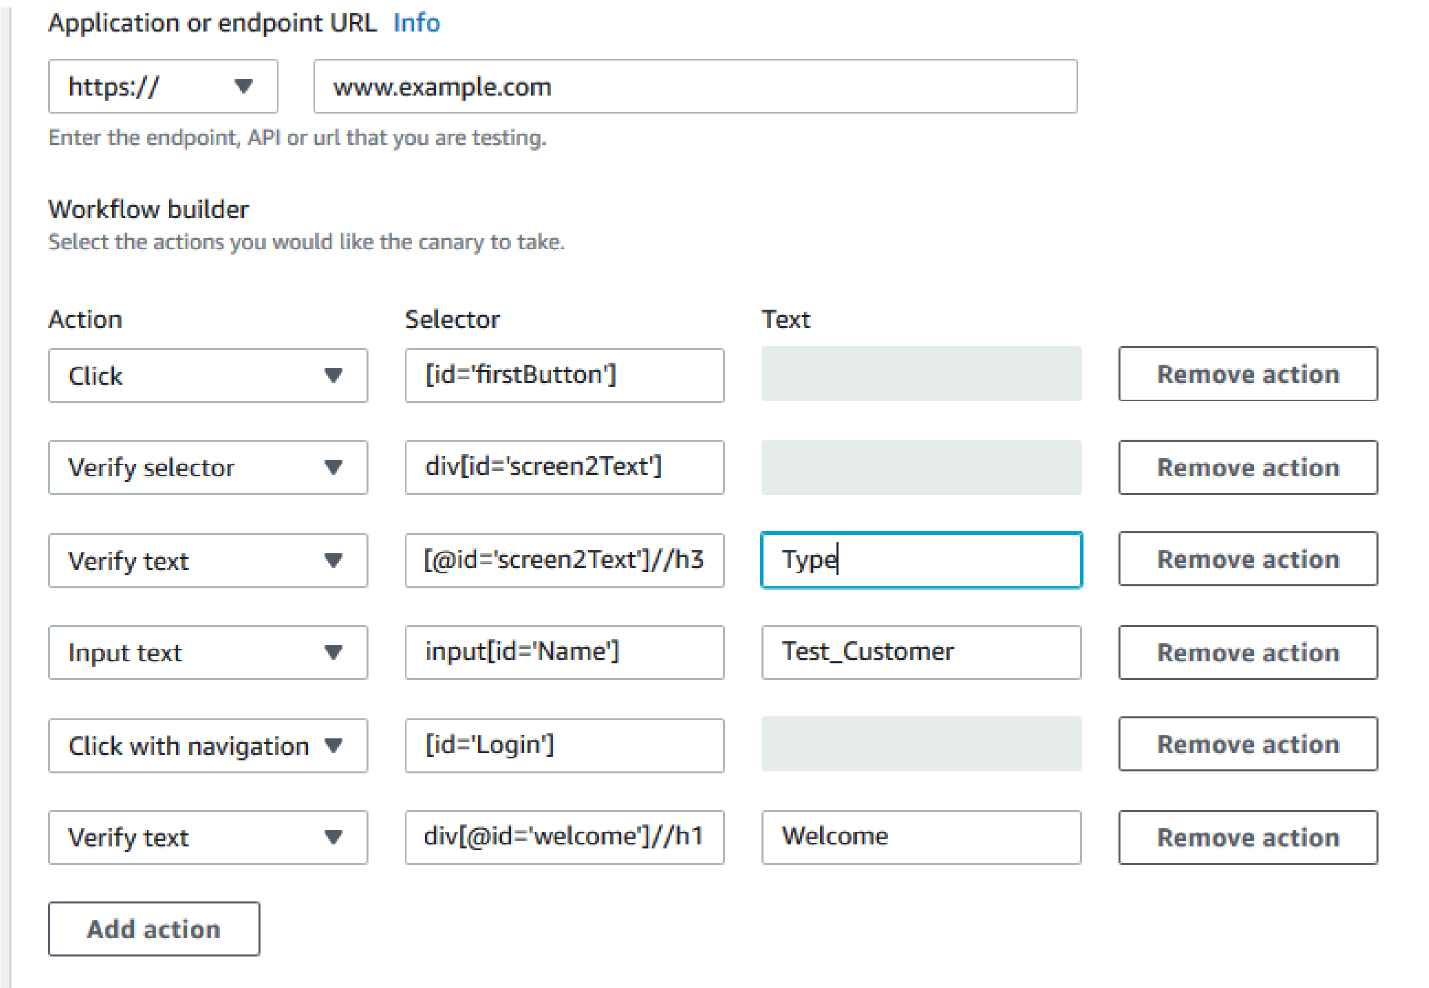
  To specify the element to verify in a Python script, use `xpath //*[@id=]` or `//*[@class=]`.

- **Click with navigation**— Waits for the whole page to load after choosing the specified element. This is most useful when you need to reload the page.

  To specify the element in a Node.js script, use `[id=]` or `a[class=]`.

  To specify the element in a Python script, use `xpath //*[@id=]` or `//*[@class=]`.

For example, the following blueprint uses Node.js. It clicks the **firstButton** on the specified URL, verifies that the expected selector with the expected text appears, inputs the name `Test_Customer` into the **Name** field, clicks the **Login** button, and then verifies that the login is successful by checking for the **Welcome** text on the next page.



GUI workflow canaries that use the following runtimes also provide a summary of the steps executed for each canary run. You can use the screenshots and error message associated with each step to find the root cause of failure.

- `syn-nodejs-2.0` or later
- `syn-python-selenium-1.0` or later

Using the CloudWatch Synthetics Recorder for Google Chrome

Amazon provides a CloudWatch Synthetics Recorder to help you create canaries more easily. The recorder is a Google Chrome extension.

The recorder records your click and type actions on a website and automatically generates a Node.js script that can be used to create a canary that follows the same steps.

After you start recording, the CloudWatch Synthetics Recorder detects your actions in the browser and converts them to a script. You can pause and resume the recording as needed. When you stop recording, the recorder produces a Node.js script of your actions, which you can easily copy with the **Copy to Clipboard** button. You can then use this script to create a canary in CloudWatch Synthetics.

Credits: The CloudWatch Synthetics Recorder is based on the Headless recorder.

Installing the CloudWatch Synthetics Recorder extension for Google Chrome

To use the CloudWatch Synthetics Recorder, you can start creating a canary and choose the **Canary Recorder** blueprint. If you do this when you haven't already downloaded the recorder, the CloudWatch Synthetics console provides a link to download it.

Alternatively, you can follow these steps to download and install the recorder directly.

To install the CloudWatch Synthetics Recorder

1. Using Google Chrome, go to this website: https://chrome.google.com/webstore/detail/cloudwatch-synthetics-rec/bhdnlmmgiplmbcdmkkdfplenecpegfno
2. Choose **Add to Chrome**, then choose **Add extension**.

Using the CloudWatch Synthetics Recorder for Google Chrome

To use the CloudWatch Synthetics Recorder to help you create a canary, you can choose **Create canary** in the CloudWatch console, and then choose **Use a blueprint**, **Canary Recorder**. For more information, see Creating a canary.

Alternatively, you can use the recorder to record steps without immediately using them to create a canary.

To use the CloudWatch Synthetics Recorder to record your actions on a website

1. Navigate to the page that you want to monitor.
2. Choose the Chrome extensions icon, and then choose **CloudWatch Synthetics Recorder**.
3. Choose **Start Recording**.
4. Perform the steps that you want to record. To pause recording, choose **Pause**.
5. When you are finished recording the workflow, choose **Stop recording**.
6. Choose **Copy to clipboard** to copy the generated script to your clipboard. Or, if you want to start over, choose **New recording**.
7. To create a canary with the copied script, you can paste your copied script into the recorder blueprint inline editor, or save it to an Amazon S3 bucket and import it from there.
8. If you're not immediately creating a canary, you can save your recorded script to a file.

Known limitations of the CloudWatch Synthetics Recorder

The CloudWatch Synthetics Recorder for Google Chrome currently has the following limitations.

- HTML elements that don’t have IDs will use CSS selectors. This can break canaries if the webpage structure changes later. We plan to provide some configuration options (such as using data-id) around this in a future version of the recorder.
- The recorder doesn't support actions such as double-click or copy/paste, and doesn't support key combinations such as CMD+0.
- To verify the presence of an element or text on the page, users must add assertions after the script is generated. The recorder doesn't support verifying an element without performing any action on that element. This is similar to the “Verify text” or “Verify element” options in the canary workflow builder. We plan to add some assertions support in a future version of the recorder.

- The recorder records all actions in the tab where the recording is initiated. It doesn't record pop-ups (for instance, to allow location tracking) or navigation to different pages from pop-ups.

Synthetics runtime versions

When you create or update a canary, you choose a Synthetics runtime version for the canary. A Synthetics runtime is a combination of the Synthetics code that calls your script handler, and the Lambda layers of bundled dependencies.

CloudWatch Synthetics currently supports runtimes that use Node.js for scripts and the Puppeteer framework, and runtimes that use Python for scripting and Selenium Webdriver for the framework.

We recommend that you always use the most recent runtime version for your canaries, to be able to use the latest features and updates made to the Synthetics library.

When you create a canary, one of the layers created is a Synthetics layer prefixed with `Synthetics`. This layer is owned by the Synthetics service account and contains the runtime code.

> **Note**
>
> Whenever you a canary to use a new version of the Synthetics runtime, all Synthetics library functions that your canary uses are also automatically u to the same version of NodeJS that the Synthetics runtime supports.

Topics

- CloudWatch Synthetics runtime support policy
- Runtime versions using Node.js and Playwright
- Runtime versions using Node.js and Puppeteer
- Runtime versions using Python and Selenium Webdriver

CloudWatch Synthetics runtime support policy

Synthetics runtime versions are subject to maintenance and security updates. When any component of a runtime version is no longer supported, that Synthetics runtime version is deprecated.

You can't create canaries using deprecated runtime versions. Canaries that use deprecated runtimes continue to run. You can stop, start, and delete these canaries. You can update an existing canary that uses a deprecated runtime version by updating the canary to use a supported runtime version.

CloudWatch Synthetics notifies you by email if you have canaries that use runtimes that are scheduled to be deprecated in the next 60 days. We recommend that you migrate your canaries to a supported runtime version to benefit from the new functionality, security, and performance enhancements that are included in more recent releases.

How do I update a canary to a new runtime version?

You can update a canary's runtime version by using the CloudWatch console, Amazon CloudFormation, the Amazon CLI or the Amazon SDK. When you use the CloudWatch console, you can update up to five canaries at once by selecting them in the canary list page and then choosing **Actions**, **Update Runtime**.

You can verify the update by first testing your update before committing the runtime update. When updating the runtime versions, choose the **Start Dry Run** or **Validate and save later** options in the CloudWatch console to create a dry run of the original canary along with any changes you made to the configuration. The dry run will update and execute the canary to validate whether the runtime update is safe for the canary. Once you have verified your canary with the new runtime version, you can update the runtime version of your canary. For more information, see Performing safe canary updates.

Alternatively, you can verify the update by first cloning the canary using the CloudWatch console and updating the runtime version. This creates another canary which is a clone of your original canary. Once you have verified your canary with the new runtime version, you can update the runtime version of your original canary and delete the clone canary.

You can also update multiple canaries using an upgrade script. For more information, see Canary runtime upgrade script.

If you upgrade a canary and it fails, see Troubleshooting a failed canary.

CloudWatch Synthetics runtime deprecation dates

The following table lists the date of deprecation of each deprecated CloudWatch Synthetics runtime.

Runtime Version	Deprecation date
`syn-nodejs-puppeteer-7.0`	October 1, 2025
`syn-nodejs-puppeteer-6.2`	October 1, 2025
`syn-nodejs-puppeteer-5.2`	October 1, 2025
`syn-python-selenium-3.0`	October 1, 2025
`syn-python-selenium-2.1`	October 1, 2025
`syn-nodejs-puppeteer-6.1`	March 8, 2024
`syn-nodejs-puppeteer-6.0`	March 8, 2024
`syn-nodejs-puppeteer-5.1`	March 8, 2024
`syn-nodejs-puppeteer-5.0`	March 8, 2024
`syn-nodejs-puppeteer-4.0`	March 8, 2024
`syn-nodejs-puppeteer-3.9`	January 8, 2024
`syn-nodejs-puppeteer-3.8`	January 8, 2024

Runtime Version	Deprecation date
syn-python-selenium-2.0	March 8, 2024
syn-python-selenium-1.3	March 8, 2024
syn-python-selenium-1.2	March 8, 2024
syn-python-selenium-1.1	March 8, 2024
syn-python-selenium-1.0	March 8, 2024
syn-nodejs-puppeteer-3.7	January 8, 2024
syn-nodejs-puppeteer-3.6	January 8, 2024
syn-nodejs-puppeteer-3.5	January 8, 2024
syn-nodejs-puppeteer-3.4	November 13, 2022
syn-nodejs-puppeteer-3.3	November 13, 2022
syn-nodejs-puppeteer-3.2	November 13, 2022
syn-nodejs-puppeteer-3.1	November 13, 2022

Runtime Version	Deprecation date
syn-nodejs-puppeteer-3.0	November 13, 2022
syn-nodejs-2.2	May 28, 2021
syn-nodejs-2.1	May 28, 2021
syn-nodejs-2.0	May 28, 2021
syn-nodejs-2.0-beta	February 8, 2021
syn-1.0	May 28, 2021

Canary runtime upgrade script

To upgrade a canary script to a supported runtime version, use the following script.

```
const AWS = require('aws-sdk');

// You need to configure your Amazon credentials and Region.
//   https://docs.aws.amazon.com/sdk-for-javascript/v3/developer-guide/setting-credentials-node.html
//   https://docs.aws.amazon.com/sdk-for-javascript/v3/developer-guide/setting-region.html

const synthetics = new AWS.Synthetics();

const DEFAULT_OPTIONS = {
  /**
   * The number of canaries to upgrade during a single run of this script.
   */
  count: 10,
  /**
   * No canaries are upgraded unless force is specified.
   */
  force: false
};
```

```
/**
 * The number of milliseconds to sleep between GetCanary calls when
 * verifying that an update succeeded.
 */
const SLEEP_TIME = 5000;

(async () => {
  try {
    const options = getOptions();

    const versions = await getRuntimeVersions();
    const canaries = await getAllCanaries();
    const upgrades = canaries
      .filter(canary => !versions.isLatestVersion(canary.RuntimeVersion))
      .map(canary => {
        return {
          Name: canary.Name,
          FromVersion: canary.RuntimeVersion,
          ToVersion: versions.getLatestVersion(canary.RuntimeVersion)
        };
      });

    if (options.force) {
      const promises = [];

      for (const upgrade of upgrades.slice(0, options.count)) {
        const promise = upgradeCanary(upgrade);
        promises.push(promise);
        // Sleep for 100 milliseconds to avoid throttling.
        await usleep(100);
      }

      const succeeded = [];
      const failed = [];
      for (let i = 0; i < upgrades.slice(0, options.count).length; i++) {
        const upgrade = upgrades[i];
        const promise = promises[i];
        try {
          await promise;
          console.log(`The update of ${upgrade.Name} succeeded.`);
          succeeded.push(upgrade.Name);
        } catch (e) {
          console.log(`The update of ${upgrade.Name} failed with error: ${e}`);
          failed.push({
```

```
            Name: upgrade.Name,
            Reason: e
          });
        }
      }

      if (succeeded.length) {
        console.group('The following canaries were upgraded successfully.');
        for (const name of succeeded) {
          console.log(name);
        }
        console.groupEnd()
      } else {
        console.log('No canaries were upgraded successfully.');
      }

      if (failed.length) {
        console.group('The following canaries were not upgraded successfully.');
        for (const failure of failed) {
          console.log('\x1b[31m', `${failure.Name}: ${failure.Reason}`, '\x1b[0m');
        }
        console.groupEnd();
      }
    } else {
      console.log('Run with --force [--count <count>] to perform the first <count>
 upgrades shown. The default value of <count> is 10.')
      console.table(upgrades);
    }
  } catch (e) {
    console.error(e);
  }
})();

function getOptions() {
  const force = getFlag('--force', DEFAULT_OPTIONS.force);
  const count = getOption('--count', DEFAULT_OPTIONS.count);
  return { force, count };

  function getFlag(key, defaultValue) {
    return process.argv.includes(key) || defaultValue;
  }
  function getOption(key, defaultValue) {
    const index = process.argv.indexOf(key);
    if (index < 0) {
```

```
      return defaultValue;
    }
    const value = process.argv[index + 1];
    if (typeof value === 'undefined' || value.startsWith('-')) {
      throw `The ${key} option requires a value.`;
    }
    return value;
  }
}

function getAllCanaries() {
  return new Promise((resolve, reject) => {
    const canaries = [];

    synthetics.describeCanaries().eachPage((err, data) => {
      if (err) {
        reject(err);
      } else {
        if (data === null) {
          resolve(canaries);
        } else {
          canaries.push(...data.Canaries);
        }
      }
    });
  });
}

function getRuntimeVersions() {
  return new Promise((resolve, reject) => {
    const jsVersions = [];
    const pythonVersions = [];
    synthetics.describeRuntimeVersions().eachPage((err, data) => {
      if (err) {
        reject(err);
      } else {
        if (data === null) {
          jsVersions.sort((a, b) => a.ReleaseDate - b.ReleaseDate);
          pythonVersions.sort((a, b) => a.ReleaseDate - b.ReleaseDate);
          resolve({
            isLatestVersion(version) {
              const latest = this.getLatestVersion(version);
              return latest === version;
            },
```

```
            getLatestVersion(version) {
              if (jsVersions.some(v => v.VersionName === version)) {
                return jsVersions[jsVersions.length - 1].VersionName;
              } else if (pythonVersions.some(v => v.VersionName === version)) {
                return pythonVersions[pythonVersions.length - 1].VersionName;
              } else {
                throw Error(`Unknown version ${version}`);
              }
            }
          });
        } else {
          for (const version of data.RuntimeVersions) {
            if (version.VersionName === 'syn-1.0') {
              jsVersions.push(version);
            } else if (version.VersionName.startsWith('syn-nodejs-2.')) {
              jsVersions.push(version);
            } else if (version.VersionName.startsWith('syn-nodejs-puppeteer-')) {

    console.log(`The state of canary ${upgrade.Name} is ${state}`);
    if (state === 'ERROR' || response.Canary.Status.StateReason) {
      throw response.Canary.Status.StateReason;
    }
```

```
    if (state !== 'UPDATING') {
      return;
    }
  }
}

function usleep(ms) {
  return new Promise(resolve => setTimeout(resolve, ms));
}
```

Runtime versions using Node.js and Playwright

The following sections contain information about the CloudWatch Synthetics runtime versions for Node.js and Playwright. Playwright is an open-source automation library for browser testing. For more information about Playwright, see https://playwright.dev/

The naming convention for these runtime versions is `syn-*language*-*framework*-*majorversion*.*minorversion*`.

syn-nodejs-playwright-2.0

Major dependencies:

- Amazon Lambda runtime Node.js 20.x
- Playwright version 1.49.1
- Playwright/test version 1.49.1
- Chromium version 131.0.6778.264

Changes in syn-nodejs-playwright-2.0

- The mismatch between total duration and sum of timings for a given request in HAR file is fixed.
- Supports dry runs for the canary which allows for adhoc executions or performing a safe canary update.

Previous runtime versions for Node.js and Playwright

The following earlier runtime versions for Node.js and Playwright are still supported.

syn-nodejs-playwright-1.0

Major dependencies:

- Amazon Lambda runtime Node.js 20.x
- Playwright version 1.44.1
- Playwright/test version 1.44.1
- Chromium version 126.0.6478.126

Features:

- **PlayWright support –** You can write canary scripts by using the Playwright automation framework. You can bring your existing Playwright scripts to run as canaries, and enhance them with Amazon monitoring capabilities.
- **CloudWatch Logs integration –** You can query and filter for logs through the CloudWatch Synthetics console. Each log message contains unique `canaryRunId`, making it easy to search for logs for a particular canary run.
- **Metrics and canary artifacts –** You can monitor canary run pass rate through CloudWatch metrics, and configure alarms to alert you when canaries detect issues.
- **Screenshots and steps association –** You can capture screenshots using native Playwright functionality to visualize the stages of a canary script on each run. Screenshots are automatically associated with canary steps, and are uploaded to Amazon S3 buckets.
- **Multiple tabs–** You can create canaries that open multiple browser tabs, and access screenshots from each tab. You can create multi-tab and multi-step user workflows in Synthetics.

Runtime versions using Node.js and Puppeteer

The first runtime version for Node.js and Puppeteer was named `syn-1.0`. Later runtime versions have the naming convention `syn-`*`language`*`-`*`majorversion`*`.`*`minorversion`*. Starting with `syn-nodejs-puppeteer-3.0`, the naming convention is `syn-`*`language`*`-`*`framework`*`-`*`majorversion`*`.`*`minorversion`*

An additional `-beta` suffix shows that the runtime version is currently in a beta preview release.

Runtime versions with the same major version number are backward compatible.

> **Important**
>
> IMPORTANT: The included Amazon SDK for JavaScript v2 dependency will be removed and updated to use Amazon SDK for JavaScript v3 in a future runtime release. When that happens, you can update your canary code references. Alternatively, you can continue referencing and using the included Amazon SDK for JavaScript v2 dependency by adding it as a dependency to your source code zip file.

The Lambda code in a canary is configured to have a maximum memory of 1 GB. Each run of a canary times out after a configured timeout value. If no timeout value is specified for a canary, CloudWatch chooses a timeout value based on the canary's frequency. If you configure a timeout value, make it no shorter than 15 seconds to allow for Lambda cold starts and the time it takes to boot up the canary instrumentation.

Notes for all runtime versions

When using `syn-nodejs-puppeteer-3.0` runtime version, make sure that your canary script is compatible with Node.js 12.x. If you use an earlier version of a `syn-nodejs` runtime version, make sure that that your script is compatible with Node.js 10.x.

syn-nodejs-puppeteer-10.0

`syn-nodejs-puppeteer-10.0` is the most recent Synthetics runtime for Node.js and Puppeteer.

> **Important**
>
> Lambda Node.js 18 and later runtimes use Amazon SDK for JavaScript V3. If you need to migrate a function from an earlier runtime, follow the aws-sdk-js-v3 Migration Workshop on GitHub. For more information about Amazon SDK for JavaScript version 3, see this blog post.

Major dependencies:

- Lambda runtime Node.js 20.x
- Puppeteer-core version 24.2.0
- Chromium version 131.0.6778.264

Changes in syn-nodejs-puppeteer-10.0

- The bug related to closing the browser that took excessively long is fixed.
- Supports dry runs for the canary which allows for adhoc executions or performing a safe canary update.

Previous runtime versions for Node.js and Puppeteer

The following earlier runtime versions for Node.js and Puppeteer are still supported.

syn-nodejs-puppeteer-9.1

`syn-nodejs-puppeteer-9.1` is the most recent Synthetics runtime for Node.js and Puppeteer.

> **Important**
>
> Lambda Node.js 18 and later runtimes use Amazon SDK for JavaScript V3. If you need to migrate a function from an earlier runtime, follow the aws-sdk-js-v3 Migration Workshop on GitHub. For more information about Amazon SDK for JavaScript version 3, see this blog post.

Major dependencies:

- Lambda runtime Node.js 20.x
- Puppeteer-core version 22.12.1
- Chromium version 126.0.6478.126

Changes in syn-nodejs-puppeteer-9.1 – Bug fixes related to date ranges and pending requests in HAR files are fixed.

syn-nodejs-puppeteer-9.0

> **Important**
>
> Lambda Node.js 18 and later runtimes use Amazon SDK for JavaScript V3. If you need to migrate a function from an earlier runtime, follow the aws-sdk-js-v3 Migration Workshop

on GitHub. For more information about Amazon SDK for JavaScript version 3, see this blog post.

Major dependencies:

- Lambda runtime Node.js 20.x
- Puppeteer-core version 22.12.1
- Chromium version 126.0.6478.126

Changes in syn-nodejs-puppeteer-9.0 – The bug fix to enable visual monitoring capabilities is fixed.

syn-nodejs-puppeteer-8.0

> **Warning**
>
> Because of a bug, the `syn-nodejs-puppeteer-8.0` runtime doesn't support visual monitoring in canaries. Upgrade to syn-nodejs-puppeteer-9.0 for the bug fix for visual monitoring.

> **Important**
>
> Lambda Node.js 18 and later runtimes use Amazon SDK for JavaScript V3. If you need to migrate a function from an earlier runtime, follow the aws-sdk-js-v3 Migration Workshop on GitHub. For more information about Amazon SDK for JavaScript version 3, see this blog post.

Major dependencies:

- Lambda runtime Node.js 20.x
- Puppeteer-core version 22.10.0
- Chromium version 125.0.6422.112

Updates in syn-nodejs-puppeteer-8.0:

- **Support for two-factor authentication**
- **Bug fixes** related to some service clients losing data in Node.js SDK V3 responses is fixed.

syn-nodejs-puppeteer-7.0

Major dependencies:

- Lambda runtime Node.js 18.x
- Puppeteer-core version 21.9.0
- Chromium version 121.0.6167.139

Code size:

The size of code and dependencies that you can package into this runtime is 80 MB.

Updates in syn-nodejs-puppeteer-7.0:

- **Updated versions of the bundled libraries in Puppeteer and Chromium**— The Puppeteer and Chromium dependencies are updated to new versions.

> **Important**
>
> Moving from Puppeteer 19.7.0 to Puppeteer 21.9.0 introduces breaking changes regarding testing and filters. For more information, see the **BREAKING CHANGES** sections in puppeteer: v20.0.0 and puppeteer-core: v21.0.0.

Recommended upgrade to Amazon SDK v3

The Lambda nodejs18.x runtime doesn't support Amazon SDK v2. We strongly recommend that you migrate to Amazon SDK v3.

syn-nodejs-puppeteer-6.2

Major dependencies:

- Lambda runtime Node.js 18.x
- Puppeteer-core version 19.7.0

- Chromium version 111.0.5563.146

Changes in syn-nodejs-puppeteer-6.2:

- **Updated versions of the bundled libraries in Chromium**
- **Ephemeral storage monitoring**— This runtime adds ephemeral storage monitoring in customer accounts.
- **Bug fixes**

syn-nodejs-puppeteer-5.2

Major dependencies:

- Lambda runtime Node.js 16.x
- Puppeteer-core version 19.7.0
- Chromium version 111.0.5563.146

Updates in syn-nodejs-puppeteer-5.2:

- **Updated versions of the bundled libraries in Chromium**
- **Bug fixes**

Deprecated runtime versions for Node.js and Puppeteer

The following runtimes for Node.js and Puppeteer have been deprecated. For information about runtime deprecation dates, see CloudWatch Synthetics runtime deprecation dates.

syn-nodejs-puppeteer-6.1

Major dependencies:

- Lambda runtime Node.js 18.x
- Puppeteer-core version 19.7.0
- Chromium version 111.0.5563.146

Updates in syn-nodejs-puppeteer-6.1:

- **Stability improvements**— Added auto-retry logic for handling intermittent Puppeteer launch errors.
- **Dependency upgrades**— Upgrades for some third-party dependency packages.
- **Canaries without Amazon S3 permissions**— Bug fixes, such that canaries that don't have any Amazon S3 permissions can still run. These canaries with no Amazon S3 permissions won't be able to upload screenshots or other artifacts to Amazon S3. For more information about permissions for canaries, see [Required roles and permissions for canaries](#).

> **Important**
>
> IMPORTANT: The included Amazon SDK for JavaScript v2 dependency will be removed and updated to use Amazon SDK for JavaScript v3 in a future runtime release. When that happens, you can update your canary code references. Alternatively, you can continue referencing and using the included Amazon SDK for JavaScript v2 dependency by adding it as a dependency to your source code zip file.

syn-nodejs-puppeteer-6.0

Major dependencies:

- Lambda runtime Node.js 18.x
- Puppeteer-core version 19.7.0
- Chromium version 111.0.5563.146

Updates in syn-nodejs-puppeteer-6.0:

- **Dependency upgrade**— The Node.js dependency is upgraded to 18.x.
- **Intercept mode support**— Puppeteer cooperative intercept mode support was added to the Synthetics canary runtime library.
- **Tracing behavior change**— Changed default tracing behavior to trace only fetch and xhr requests, and not trace resource requests. You can enable the tracing of resource requests by configuring the `traceResourceRequests` option.
- **Duration metric refined**— The `Duration` metric now excludes the operation time the canary uses to upload artifacts, take screenshots, and generate CloudWatch metrics. `Duration` metric values are reported to CloudWatch, and you can also see them in the Synthetics console.

- **Bug fix**— Clean up core dump generated when Chromium crashes during a canary run.

> **Important**
>
> IMPORTANT: The included Amazon SDK for JavaScript v2 dependency will be removed and updated to use Amazon SDK for JavaScript v3 in a future runtime release. When that happens, you can update your canary code references. Alternatively, you can continue referencing and using the included Amazon SDK for JavaScript v2 dependency by adding it as a dependency to your source code zip file.

syn-nodejs-puppeteer-5.1

Major dependencies:

- Lambda runtime Node.js 16.x
- Puppeteer-core version 19.7.0
- Chromium version 111.0.5563.146

Bug fixes in syn-nodejs-puppeteer-5.1:

- **Bug fix**— This runtime fixes a bug in `syn-nodejs-puppeteer-5.0` where the HAR files created by the canaries were missing request headers.

syn-nodejs-puppeteer-5.0

Major dependencies:

- Lambda runtime Node.js 16.x
- Puppeteer-core version 19.7.0
- Chromium version 111.0.5563.146

Updates in syn-nodejs-puppeteer-5.0:

- **Dependency upgrade**— The Puppeteer-core version is updated to 19.7.0. The Chromium version is upgraded to 111.0.5563.146.

> **Important**
>
> The new Puppeteer-core version is not completely backward-compatible with previous versions of Puppeteer. Some of the changes in this version can cause existing canaries that use deprecated Puppeteer functions to fail. For more information, see the breaking changes in the change logs for Puppeteer-core versions 19.7.0 through 6.0, in Puppeteer change logs.

syn-nodejs-puppeteer-4.0

Major dependencies:

- Lambda runtime Node.js 16.x
- Puppeteer-core version 5.5.0
- Chromium version 92.0.4512

Updates in syn-nodejs-puppeteer-4.0:

- **Dependency upgrade**— The Node.js dependency is updated to 16.x.

syn-nodejs-puppeteer-3.9

> **Important**
>
> This runtime version was deprecated on January 8, 2024. For more information, see CloudWatch Synthetics runtime support policy.

Major dependencies:

- Lambda runtime Node.js 14.x
- Puppeteer-core version 5.5.0
- Chromium version 92.0.4512

Updates in syn-nodejs-puppeteer-3.9:

- **Dependency upgrades**— Upgrades some third-party dependency packages.

syn-nodejs-puppeteer-3.8

> **Important**
>
> This runtime version was deprecated on January 8, 2024. For more information, see [CloudWatch Synthetics runtime support policy](#).

Major dependencies:

- Lambda runtime Node.js 14.x
- Puppeteer-core version 5.5.0
- Chromium version 92.0.4512

Updates in syn-nodejs-puppeteer-3.8:

- **Profile cleanup**— Chromium profiles are now cleaned up after each canary run.

Bug fixes in syn-nodejs-puppeteer-3.8:

- **Bug fixes**— Previously, visual monitoring canaries would sometimes stop working properly after a run with no screenshots. This is now fixed.

syn-nodejs-puppeteer-3.7

> **Important**
>
> This runtime version was deprecated on January 8, 2024. For more information, see [CloudWatch Synthetics runtime support policy](#).

Major dependencies:

- Lambda runtime Node.js 14.x
- Puppeteer-core version 5.5.0

- Chromium version 92.0.4512

Updates in syn-nodejs-puppeteer-3.7:

- **Logging enhancement**— The canary will upload logs to Amazon S3 even if it times out or crashes.
- **Lambda layer size reduced**— The size of the Lambda layer used for canaries is reduced by 34%.

Bug fixes in syn-nodejs-puppeteer-3.7:

- **Bug fixes**— Japanese, Simplified Chinese, and Traditional Chinese fonts will render properly.

syn-nodejs-puppeteer-3.6

> **Important**
>
> This runtime version was deprecated on January 8, 2024. For more information, see CloudWatch Synthetics runtime support policy.

Major dependencies:

- Lambda runtime Node.js 14.x
- Puppeteer-core version 5.5.0
- Chromium version 92.0.4512

Updates in syn-nodejs-puppeteer-3.6:

- **More precise timestamps**— The start time and stop time of canary runs are now precise to the millisecond.

syn-nodejs-puppeteer-3.5

> **Important**
>
> This runtime version was deprecated on January 8, 2024. For more information, see CloudWatch Synthetics runtime support policy.

Major dependencies:

- Lambda runtime Node.js 14.x
- Puppeteer-core version 5.5.0
- Chromium version 92.0.4512

Updates in syn-nodejs-puppeteer-3.5:

- **Updated dependencies**— The only new features in this runtime are the updated dependencies.

syn-nodejs-puppeteer-3.4

> **Important**
>
> This runtime version was deprecated on November 13, 2022. For more information, see CloudWatch Synthetics runtime support policy.

Major dependencies:

- Lambda runtime Node.js 12.x
- Puppeteer-core version 5.5.0
- Chromium version 88.0.4298.0

Updates in syn-nodejs-puppeteer-3.4:

- **Custom handler function**— You can now use a custom handler function for your canary scripts. Previous runtimes required the script entry point to include `.handler`.

You can also put canary scripts in any folder and pass the folder name as part of the handler. For example, `MyFolder/MyScriptFile.functionname` can be used as an entry point.

- **Expanded HAR file information**— You can now see bad, pending, and incomplete requests in the HAR files produced by canaries.

syn-nodejs-puppeteer-3.3

> **Important**
>
> This runtime version was deprecated on November 13, 2022. For more information, see [CloudWatch Synthetics runtime support policy](#).

Major dependencies:

- Lambda runtime Node.js 12.x
- Puppeteer-core version 5.5.0
- Chromium version 88.0.4298.0

Updates in syn-nodejs-puppeteer-3.3:

- **More options for artifact encryption**— For canaries using this runtime or later, instead of using an Amazon managed key to encrypt artifacts that the canary stores in Amazon S3, you can choose to use an Amazon KMS customer managed key or an Amazon S3-managed key. For more information, see [Encrypting canary artifacts](#).

syn-nodejs-puppeteer-3.2

> **Important**
>
> This runtime version was deprecated on November 13, 2022. For more information, see [CloudWatch Synthetics runtime support policy](#).

Major dependencies:

- Lambda runtime Node.js 12.x
- Puppeteer-core version 5.5.0
- Chromium version 88.0.4298.0

Updates in syn-nodejs-puppeteer-3.2:

- **visual monitoring with screenshots**— Canaries using this runtime or later can compare a screenshot taken during a run with a baseline version of the same screenshot. If the screenshots are more different than a specified percentage threshold, the canary fails. For more information, see Visual monitoring or Visual monitoring blueprint.
- **New functions regarding sensitive data** You can prevent sensitive data from appearing in canary logs and reports. For more information, see SyntheticsLogHelper class.
- **Deprecated function** The `RequestResponseLogHelper` class is deprecated in favor of other new configuration options. For more information, see RequestResponseLogHelper class.

syn-nodejs-puppeteer-3.1

> **Important**
>
> This runtime version was deprecated on November 13, 2022. For more information, see CloudWatch Synthetics runtime support policy.

Major dependencies:

- Lambda runtime Node.js 12.x
- Puppeteer-core version 5.5.0
- Chromium version 88.0.4298.0

Updates in syn-nodejs-puppeteer-3.1:

- **Ability to configure CloudWatch metrics**— With this runtime, you can disable the metrics that you do not require. Otherwise, canaries publish various CloudWatch metrics for each canary run.
- **Screenshot linking**— You can link a screenshot to a canary step after the step has completed. To do this, you take the screenshot by using the **takeScreenshot** method, using the name of the

step that you want to associate the screenshot with. For example, you might want to perform a step, add a wait time, and then take the screenshot.

- **Heartbeat monitor blueprint can monitor multiple URLs**— You can use the heartbeat monitoring blueprint in the CloudWatch console to monitor multiple URLs and see the status, duration, associated screenshots, and failure reason for each URL in the step summary of the canary run report.

syn-nodejs-puppeteer-3.0

> **Important**
>
> This runtime version was deprecated on November 13, 2022. For more information, see CloudWatch Synthetics runtime support policy.

Major dependencies:

- Lambda runtime Node.js 12.x
- Puppeteer-core version 5.5.0
- Chromium version 88.0.4298.0

Updates in syn-nodejs-puppeteer-3.0:

- **Upgraded dependencies**— This version uses Puppeteer version 5.5.0, Node.js 12.x, and Chromium 88.0.4298.0.
- **Cross-Region bucket access**— You can now specify an S3 bucket in another Region as the bucket where your canary stores its log files, screenshots, and HAR files.
- **New functions available**— This version adds library functions to retrieve the canary name and the Synthetics runtime version.

  For more information, see Synthetics class.

syn-nodejs-2.2

This section contains information about the `syn-nodejs-2.2` runtime version.

> **Important**
>
> This runtime version was deprecated on May 28, 2021. For more information, see CloudWatch Synthetics runtime support policy.

Major dependencies:

- Lambda runtime Node.js 10.x
- Puppeteer-core version 3.3.0
- Chromium version 83.0.4103.0

Changes in syn-nodejs-2.2:

- **Monitor your canaries as HTTP steps**— You can now test multiple APIs in a single canary. Each API is tested as a separate HTTP step, and CloudWatch Synthetics monitors the status of each step using step metrics and the CloudWatch Synthetics step report. CloudWatch Synthetics creates `SuccessPercent` and `Duration` metrics for each HTTP step.

  This functionality is implemented by the **executeHttpStep(stepName, requestOptions, callback, stepConfig)** function. For more information, see executeHttpStep(stepName, requestOptions, [callback], [stepConfig]).

  The API canary blueprint is updated to use this new feature.
- **HTTP request reporting**— You can now view detailed HTTP requests reports which capture details such as request/response headers, response body, status code, error and performance timings, TCP connection time, TLS handshake time, first byte time, and content transfer time. All HTTP requests which use the HTTP/HTTPS module under the hood are captured here. Headers and response body are not captured by default but can be enabled by setting configuration options.
- **Global and step-level configuration**— You can set CloudWatch Synthetics configurations at the global level, which are applied to all steps of canaries. You can also override these configurations at the step level by passing configuration key/value pairs to enable or disable certain options.

  For more information, see SyntheticsConfiguration class.

- **Continue on step failure configuration**— You can choose to continue canary execution when a step fails. For the `executeHttpStep` function, this is turned on by default. You can set this option once at global level or set it differently per-step.

syn-nodejs-2.1

> **Important**
>
> This runtime version was deprecated on May 28, 2021. For more information, see CloudWatch Synthetics runtime support policy.

Major dependencies:

- Lambda runtime Node.js 10.x
- Puppeteer-core version 3.3.0
- Chromium version 83.0.4103.0

Updates in syn-nodejs-2.1:

- **Configurable screenshot behavior**— Provides the ability to turn off the capturing of screenshots by UI canaries. In canaries that use previous versions of the runtimes, UI canaries always capture screenshots before and after each step. With `syn-nodejs-2.1`, this is configurable. Turning off screenshots can reduce your Amazon S3 storage costs, and can help you comply with HIPAA regulations. For more information, see SyntheticsConfiguration class.
- **Customize the Google Chrome launch parameters** You can now configure the arguments used when a canary launches a Google Chrome browser window. For more information, see launch(options).

There can be a small increase in canary duration when using syn-nodejs-2.0 or later, compared to earlier versions of the canary runtimes.

syn-nodejs-2.0

Important

This runtime version was deprecated on May 28, 2021. For more information, see CloudWatch Synthetics runtime support policy.

Major dependencies:

- Lambda runtime Node.js 10.x
- Puppeteer-core version 3.3.0
- Chromium version 83.0.4103.0

Updates in syn-nodejs-2.0:

- **Upgraded dependencies**— This runtime version uses Puppeteer-core version 3.3.0 and Chromium version 83.0.4103.0
- **Support for X-Ray active tracing.** When a canary has tracing enabled, X-Ray traces are sent for all calls made by the canary that use the browser, the Amazon SDK, or HTTP or HTTPS modules. Canaries with tracing enabled appear on the X-Ray Trace Map, even when they don't send requests to other services or applications that have tracing enabled. For more information, see Canaries and X-Ray tracing.
- **Synthetics reporting**— For each canary run, CloudWatch Synthetics creates a report named `SyntheticsReport-PASSED.json` or `SyntheticsReport-FAILED.json` which records data such as start time, end time, status, and failures. It also records the PASSED/FAILED status of each step of the canary script, and failures and screenshots captured for each step.
- **Broken link checker report**— The new version of the broken link checker included in this runtime creates a report that includes the links that were checked, status code, failure reason (if any), and source and destination page screenshots.
- **New CloudWatch metrics**— Synthetics publishes metrics named `2xx`, `4xx`, `5xx`, and `RequestFailed` in the `CloudWatchSynthetics` namespace. These metrics show the number of 200s, 400s, 500s, and request failures in the canary runs. With this runtime version, these metrics are reported only for UI canaries, and are not reported for API canaries. They are also reported for API canaries starting with runtime version `syn-nodejs-puppeteeer-2.2`.
- **Sortable HAR files**— You can now sort your HAR files by status code, request size, and duration.

- **Metrics timestamp**— CloudWatch metrics are now reported based on the Lambda invocation time instead of the canary run end time.

Bug fixes in syn-nodejs-2.0:

- Fixed the issue of canary artifact upload errors not being reported. Such errors are now surfaced as execution errors.
- Fixed the issue of redirected requests (3xx) being incorrectly logged as errors.
- Fixed the issue of screenshots being numbered starting from 0. They should now start with 1.
- Fixed the issue of screenshots being garbled for Chinese and Japanese fonts.

There can be a small increase in canary duration when using syn-nodejs-2.0 or later, compared to earlier versions of the canary runtimes.

syn-nodejs-2.0-beta

> **Important**
>
> This runtime version was deprecated on February 8, 2021. For more information, see [CloudWatch Synthetics runtime support policy](#).

Major dependencies:

- Lambda runtime Node.js 10.x
- Puppeteer-core version 3.3.0
- Chromium version 83.0.4103.0

Changes in syn-nodejs-2.0-beta:

- **Upgraded dependencies**— This runtime version uses Puppeteer-core version 3.3.0 and Chromium version 83.0.4103.0
- **Synthetics reporting**— For each canary run, CloudWatch Synthetics creates a report named `SyntheticsReport-PASSED.json` or `SyntheticsReport-FAILED.json` which records data such as start time, end time, status, and failures. It also records the PASSED/FAILED status of each step of the canary script, and failures and screenshots captured for each step.

- **Broken link checker report**— The new version of the broken link checker included in this runtime creates a report that includes the links that were checked, status code, failure reason (if any), and source and destination page screenshots.
- **New CloudWatch metrics**— Synthetics publishes metrics named `2xx`, `4xx`, `5xx`, and `RequestFailed` in the `CloudWatchSynthetics` namespace. These metrics show the number of 200s, 400s, 500s, and request failures in the canary runs. These metrics are reported only for UI canaries, and are not reported for API canaries.
- **Sortable HAR files**— You can now sort your HAR files by status code, request size, and duration.
- **Metrics timestamp**— CloudWatch metrics are now reported based on the Lambda invocation time instead of the canary run end time.

Bug fixes in syn-nodejs-2.0-beta:

- Fixed the issue of canary artifact upload errors not being reported. Such errors are now surfaced as execution errors.
- Fixed the issue of redirected requests (3xx) being incorrectly logged as errors.
- Fixed the issue of screenshots being numbered starting from 0. They should now start with 1.
- Fixed the issue of screenshots being garbled for Chinese and Japanese fonts.

syn-1.0

The first Synthetics runtime version is `syn-1.0`.

Major dependencies:

- Lambda runtime Node.js 10.x
- Puppeteer-core version 1.14.0
- The Chromium version that matches Puppeteer-core 1.14.0

Runtime versions using Python and Selenium Webdriver

The following sections contain information about the CloudWatch Synthetics runtime versions for Python and Selenium Webdriver. Selenium is an open-source browser automation tool. For more information about Selenium, see www.selenium.dev/

The naming convention for these runtime versions is `syn-language-framework-majorversion.minorversion`.

syn-python-selenium-5.1

Version 5.1 is the newest CloudWatch Synthetics runtime for Python and Selenium.

Major dependencies:

- Python 3.9
- Selenium 4.21.0
- Chromium version 131.0.6778.264

Changes in syn-python-selenium-5.1

- Minor updates on metric emission.
- Supports dry runs for the canary which allows for adhoc executions or performing a safe canary update.

Previous runtime versions for Python and Selenium

The following earlier runtime versions for Python and Selenium are still supported.

syn-python-selenium-5.0

Version 5.0 is the newest CloudWatch Synthetics runtime for Python and Selenium.

Major dependencies:

- Python 3.9
- Selenium 4.21.0
- Chromium version 131.0.6778.264

Changes in syn-python-selenium-5.0:

- Automatic retry if the browser fails to launch.

syn-python-selenium-4.1

Version 4.1 is the newest CloudWatch Synthetics runtime for Python and Selenium.

Major dependencies:

- Python 3.9
- Selenium 4.15.1
- Chromium version 126.0.6478.126

Changes in syn-python-selenium-4.1:

- **Addresses security vulnerability**– This runtime has an update to address the CVE-2024-39689 vulnerability.

syn-python-selenium-4.0

Major dependencies:

- Python 3.9
- Selenium 4.15.1
- Chromium version 126.0.6478.126

Changes in syn-python-selenium-4.0:

- **Bug fixes** for errors in HAR parser logging.

syn-python-selenium-3.0

Major dependencies:

- Python 3.8
- Selenium 4.15.1
- Chromium version 121.0.6167.139

Changes in syn-python-selenium-3.0:

- **Updated versions of the bundled libraries in Chromium**— The Chromium dependency is updated to a new version.

syn-python-selenium-2.1

Major dependencies:

- Python 3.8
- Selenium 4.15.1
- Chromium version 111.0.5563.146

Changes in syn-python-selenium-2.1:

- **Updated versions of the bundled libraries in Chromium**— The Chromium and Selenium dependencies are updated to new versions.

Deprecated runtime versions for Python and Selenium

The following earlier runtime versions for Python and Selenium have been deprecated. For information about runtime deprecation dates, see CloudWatch Synthetics runtime deprecation dates.

syn-python-selenium-2.0

Major dependencies:

- Python 3.8
- Selenium 4.10.0
- Chromium version 111.0.5563.146

Changes in syn-python-selenium-2.0:

- **Updated dependencies**— The Chromium and Selenium dependencies are updated to new versions.

Bug fixes in syn-python-selenium-2.0:

- **Timestamp added**— A timestamp has been added to canary logs.

- **Session re-use**— A bug was fixed so that canaries are now prevented from reusing the session from their previous canary run.

syn-python-selenium-1.3

Major dependencies:

- Python 3.8
- Selenium 3.141.0
- Chromium version 92.0.4512.0

Changes in syn-python-selenium-1.3:

- **More precise timestamps**— The start time and stop time of canary runs are now precise to the millisecond.

syn-python-selenium-1.2

Major dependencies:

- Python 3.8
- Selenium 3.141.0
- Chromium version 92.0.4512.0

- **Updated dependencies**— The only new features in this runtime are the updated dependencies.

syn-python-selenium-1.1

Major dependencies:

- Python 3.8
- Selenium 3.141.0
- Chromium version 83.0.4103.0

Features:

- **Custom handler function**— You can now use a custom handler function for your canary scripts. Previous runtimes required the script entry point to include `.handler`.

  You can also put canary scripts in any folder and pass the folder name as part of the handler. For example, `MyFolder/MyScriptFile.functionname` can be used as an entry point.
- **Configuration options for adding metrics and step failure configurations**— These options were already available in runtimes for Node.js canaries. For more information, see SyntheticsConfiguration class.
- **Custom arguments in Chrome** — You can now open a browser in incognito mode or pass in proxy server configuration. For more information, see Chrome().
- **Cross-Region artifact buckets**— A canary can store its artifacts in an Amazon S3 bucket in a different Region.
- **Bug fixes, including a fix for the `index.py` issue**— With previous runtimes, a canary file named `index.py` caused exceptions because it conflicted with the name of the library file. This issue is now fixed.

syn-python-selenium-1.0

Major dependencies:

- Python 3.8
- Selenium 3.141.0
- Chromium version 83.0.4103.0

Features:

- **Selenium support**— You can write canary scripts using the Selenium test framework. You can bring your Selenium scripts from elsewhere into CloudWatch Synthetics with minimal changes, and they will work with Amazon services.

Writing a canary script

The following sections explain how to write a canary script and how to integrate a canary with other Amazon services and with external dependencies and libraries.

Topics

Writing a Node.js canary script using the Playwright runtime

Topics

Packaging your Node.js canary files for the Playwright runtime

Your canary script comprises of a `.js` (CommonJS syntax) or `.mjs` (ES syntax) file containing your Synthetics handler code, together with any additional packages and modules your code depends on. Scripts created in ES (ECMAScript) format should either use .mjs as the extension or include a package.json file with the "type": "module" field set. Unlike other runtimes like Node.js Puppeteer, you are not required to save your scripts in a specific folder structure. You can package your scripts directly. Use your preferred `zip` utility to create a `.zip` file with your handler file at the root. If your canary script depends on additional packages or modules that aren't included in the Synthetics runtime, you can add these dependencies to your `.zip` file. To do so, you can install your function's required libraries in the `node_modules` directory by running the `npm install` command. The following example CLI commands create a `.zip` file named `my_deployment_package.zip` containing the `index.js` or `index.mjs` file (Synthetics handler) and its dependencies. In the example, you install dependencies using the npm package manager.

```
~/my_function
### index.mjs
### synthetics.json
### myhelper-util.mjs
### node_modules
    ### mydependency
```

Create a .zip file that contains the contents of your project folder at the root. Use the r (recursive) option, as shown in the following example, to ensure that zip compresses the subfolders.

```
zip -r my_deployment_package.zip .
```

Add a Synthetics configuration file to configure the behavior of CloudWatch Synthetics. You can create a synthetics.json file and save it at the same path as your entry point or handler file.

Optionally, you can also store your entry point file in a folder structure of your choice. However, be sure that the folder path is specified in your handler name.

Handler name

Be sure to set your canary's script entry point (handler) as myCanaryFilename.functionName to match the file name of your script's entry point. You can optionally store the canary in a separate folder such as myFolder/my_canary_filename.mjs. If you store it in a separate folder, specify that path in your script entry point, such as myFolder/my_canary_filename.functionName.

Changing an existing Playwright script to use as a CloudWatch Synthetics canary

You can edit an existing script for Node.js and Playwright to be used as a canary. For more information about Playwright, see the Playwright library documentation.

You can use the following Playwright script that is saved in file exampleCanary.mjs.

```
import { chromium } from 'playwright';
import { expect } from '@playwright/test';

const browser = await chromium.launch();
const page = await browser.newPage();
await page.goto('https://example.com', {timeout: 30000});
await page.screenshot({path: 'example-home.png'});

const title = await page.title();
expect(title).toEqual("Example Domain");

await browser.close();
```

Convert the script by performing the following steps:

1. Create and export a handler function. The handler is the entry point function for the script. You can choose any name for the handler function, but the function that is

used in your script should be the same as in your canary handler. If your script name is `exampleCanary.mjs`, and the handler function name is `myhandler`, your canary handler is named `exampleCanary.myhandler`. In the following example, the handler function name is `handler`.

```
exports.handler = async () => {
  // Your script here
  };
```

2. Import the `Synthetics Playwright module` as a dependency.

```
import { synthetics } from '@amzn/synthetics-playwright';
```

3. Launch a browser using the Synthetics `Launch` function.

```
const browser = await synthetics.launch();
```

4. Create a new Playwright page by using the Synthetics `newPage` function.

```
const page = await synthetics.newPage();
```

Your script is now ready to be run as a Synthetics canary. The following is the the updated script:

Updated script in ES6 format

The script file saved with a `.mjs` extension.

```
import { synthetics } from '@amzn/synthetics-playwright';
import { expect } from '@playwright/test';

export const handler = async (event, context) => {
  try {
        // Launch a browser
        const browser = await synthetics.launch();

        // Create a new page
        const page = await synthetics.newPage(browser);

        // Navigate to a website
        await page.goto('https://www.example.com', {timeout: 30000});
```

```
        // Take screenshot
        await page.screenshot({ path: '/tmp/example.png' });

        // Verify the page title
        const title = await page.title();
        expect(title).toEqual("Example Domain");
    } finally {
        // Ensure browser is closed
        await synthetics.close();
    }
};
```

Updated script in CommonJS format

The script file saved with a `.js` extension.

```
const { synthetics } = require('@amzn/synthetics-playwright');
const { expect } = require('@playwright/test');

exports.handler = async (event) => {
  try {
    const browser = await synthetics.launch();
    const page = await synthetics.newPage(browser);
    await page.goto('https://www.example.com', {timeout: 30000});
    await page.screenshot({ path: '/tmp/example.png' });
    const title = await page.title();
    expect(title).toEqual("Example Domain");
  } finally {
    await synthetics.close();
  }
};
```

CloudWatch Synthetics configurations

You can configure the behavior of the Synthetics Playwright runtime by providing an optional JSON configuration file named `synthetics.json`. This file should be packaged in the same location as the handler file. Though a configuration file is optional, f you don't provide a configuration file, or a configuration key is missing, CloudWatch assumes defaults.

Packaging your configuration file

The following are supported configuration values, and their defaults.

```
{
    "step": {
        "screenshotOnStepStart": false,
        "screenshotOnStepSuccess": false,
        "screenshotOnStepFailure": false,
        "stepSuccessMetric": true,
        "stepDurationMetric": true,
        "continueOnStepFailure": true,
        "stepsReport": true
    },
    "report": {
        "includeRequestHeaders": true,
        "includeResponseHeaders": true,
        "includeUrlPassword": false,
        "includeRequestBody": true,
        "includeResponseBody": true,
        "restrictedHeaders": ['x-amz-security-token', 'Authorization'], // Value of
 these headers is redacted from logs and reports
        "restrictedUrlParameters": ['Session', 'SigninToken'] // Values of these url
 parameters are redacted from logs and reports
    },
    "logging": {
        "logRequest": false,
        "logResponse": false,
        "logResponseBody": false,
        "logRequestBody": false,
        "logRequestHeaders": false,
        "logResponseHeaders": false
    },
    "httpMetrics": {
        "metric_2xx": true,
        "metric_4xx": true,
        "metric_5xx": true,
        "failedRequestsMetric": true,
        "aggregatedFailedRequestsMetric": true,
        "aggregated2xxMetric": true,
        "aggregated4xxMetric": true,
        "aggregated5xxMetric": true
    },
    "canaryMetrics": {
        "failedCanaryMetric": true,
        "aggregatedFailedCanaryMetric": true
    },
```

```
    "userAgent": "",
    "har": true
}
```

Step configurations

- `screenshotOnStepStart` – Determines if Synthetics should capture a screenshot before the step starts. The default is `true`.
- `screenshotOnStepSuccess` – Determines if Synthetics should capture a screenshot after a step has succeeded. The default is `true`.
- `screenshotOnStepFailure` – Determines if Synthetics should capture a screenshot after a step has failed. The default is `true`.
- `continueOnStepFailure` – Determines if a script should continue even after a step has failed. The default is `false`.
- `stepSuccessMetric` – Determines if a step's `SuccessPercent` metric is emitted. The `SuccessPercent` metric for a step is `100` for the canary run if the step succeeds, and `0` if the step fails. The default is `true`.
- `stepDurationMetric` – Determines if a step's `Duration` metric is emitted. The `Duration` metric is emitted as a duration, in milliseconds, of the step's run. The default is `true`.

Report configurations

Includes all reports generated by CloudWatch Synthetics, such as a HAR file and a Synthetics steps report. Sensitive data redaction fields `restrictedHeaders` and `restrictedUrlParameters` also apply to logs generated by Synthetics.

- `includeRequestHeaders` – Whether to include request headers in the report. The default is `false`.
- `includeResponseHeaders` – Whether to include response headers in the report. The default is `false`.
- `includeUrlPassword` – Whether to include a password that appears in the URL. By default, passwords that appear in URLs are redacted from logs and reports, to prevent the disclosure of sensitive data. The default is `false`.
- `includeRequestBody` – Whether to include the request body in the report. The default is `false`.

- `includeResponseBody` – Whether to include the response body in the report. The default is `false`.
- `restrictedHeaders` – A list of header values to ignore, if headers are included. This applies to both request and response headers. For example, you can hide your credentials by passing `includeRequestHeaders` as true and `restrictedHeaders` as `['Authorization']`.
- `restrictedUrlParameters` – A list of URL path or query parameters to redact. This applies to URLs that appear in logs, reports, and errors. The parameter is case-insensitive. You can pass an asterisk (*) as a value to redact all URL path and query parameter values. The default is an empty array.
- `har` – Determines if an HTTP archive (HAR) should be generated. The default is `true`.

The following is an example of a report configurations file.

```
"includeRequestHeaders": true,
"includeResponseHeaders": true,
"includeUrlPassword": false,
"includeRequestBody": true,
"includeResponseBody": true,
"restrictedHeaders": ['x-amz-security-token', 'Authorization'], // Value of these
 headers is redacted from logs and reports
"restrictedUrlParameters": ['Session', 'SigninToken'] // Values of these URL parameters
 are redacted from logs and reports
```

Logging configurations

Applies to logs generated by CloudWatch Synthetics. Controls the verbosity of request and response logs.

- `logRequest` – Whether to log every request in canary logs. For UI canaries, this logs each request sent by the browser. The default is `false`.
- `logResponse` – Whether to log every response in canary logs. For UI canaries, this logs every response received by the browser. The default is `false`.
- `logRequestBody` – Whether to log request bodies along with the requests in canary logs. This configuration applies only if `logRequest` is true. The default is `false`.
- `logResponseBody` – Whether to log response bodies along with the requests in canary logs. This configuration applies only if `logResponse` is true. The default is `false`.

- `logRequestHeaders` – Whether to log request headers along with the requests in canary logs. This configuration applies only if `logRequest` is true. The default is `false`.
- `logResponseHeaders` – Whether to log response headers along with the responses in canary logs. This configuration applies only if `logResponse` is true. The default is `false`.

HTTP metric configurations

Configurations for metrics related to the count of network requests with different HTTP status codes, emitted by CloudWatch Synthetics for this canary.

- `metric_2xx` – Whether to emit the `2xx` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `metric_4xx` – Whether to emit the `4xx` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `metric_5xx` – Whether to emit the `5xx` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `failedRequestsMetric` – Whether to emit the `failedRequests` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregatedFailedRequestsMetric` – Whether to emit the `failedRequests` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregated2xxMetric` – Whether to emit the `2xx` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregated4xxMetric` – Whether to emit the `4xx` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregated5xxMetric` – Whether to emit the `5xx` metric (without the `CanaryName` dimension) for this canary. The default is `true`.

Canary metric configurations

Configurations for other metrics emitted by CloudWatch Synthetics.

- `failedCanaryMetric` – Whether to emit the `Failed` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregatedFailedCanaryMetric` – Whether to emit the `Failed` metric (without the `CanaryName` dimension) for this canary. The default is `true`.

Other configurations

- `userAgent` – A string to append to the user agent. The user agent is a string that is included in request header, and identifies your browser to websites you visit when you use the headless browser. CloudWatch Synthetics automatically adds `CloudWatchSynthetics/canary-arn to the user agent`. The specified configuration is appended to the generated user agent. The default user agent value to append is an empty string ("").

CloudWatch Synthetics environment variables

Configure the logging level and format by using environment variables.

Log format

The CloudWatch Synthetics Playwright runtime creates CloudWatch logs for every canary run. Logs are written in JSON format for convenient querying. Optionally, you can change the log format to `TEXT`.

- `Environment variable name` – CW_SYNTHETICS_LOG_FORMAT
- `Supported values` – JSON, TEXT
- `Default` – JSON

Log levels

Though enabling `Debug` mode increases verbosity, it can be useful for troubleshooting.

- `Environment variable name` – CW_SYNTHETICS_LOG_LEVEL
- `Supported values` – TRACE, DEBUG, INFO, WARN, ERROR, FATAL
- `Default` – INFO

Writing a Node.js canary script using the Puppeteer runtime

Topics

- [Integrating your canary with other Amazon services]
- [Forcing your canary to use a static IP address]

Creating a CloudWatch Synthetics canary from scratch

Here is an example minimal Synthetics Canary script. This script passes as a successful run, and returns a string. To see what a failing canary looks like, change `let fail = false;` to `let fail = true;`.

You must define an entry point function for the canary script. To see how files are uploaded to the Amazon S3 location specified as the canary's `ArtifactS3Location`, create these files in the `/tmp` folder. All canary artifacts should be stored in `/tmp`, because it's the only writable directory. Be sure that the screenshot path is set to `/tmp` for any screenshots or other files created by the script. Synthetics automatically uploads files in `/tmp` to an S3 bucket.

```
/tmp/<name>
```

After the script runs, the pass/fail status and the duration metrics are published to CloudWatch and the files under `/tmp` are uploaded to an S3 bucket.

```
const basicCustomEntryPoint = async function () {

    // Insert your code here

    // Perform multi-step pass/fail check

    // Log decisions made and results to /tmp

    // Be sure to wait for all your code paths to complete 
    // before returning control back to Synthetics.
    // In that way, your canary will not finish and report success
    // before your code has finished executing

    // Throw to fail, return to succeed
    let fail = false;
    if (fail) {
        throw "Failed basicCanary check.";
    }

    return "Successfully completed basicCanary checks.";
};
```

```
exports.handler = async () => {
    return await basicCustomEntryPoint();
};
```

Next, we'll expand the script to use Synthetics logging and make a call using the Amazon SDK. For demonstration purposes, this script will create an Amazon DynamoDB client and make a call to the DynamoDB listTables API. It logs the response to the request and logs either pass or fail depending on whether the request was successful.

```
const log = require('SyntheticsLogger');
const AWS = require('aws-sdk');
// Require any dependencies that your script needs
// Bundle additional files and dependencies into a .zip file with folder structure
// nodejs/node_modules/additional files and folders

const basicCustomEntryPoint = async function () {

    log.info("Starting DynamoDB:listTables canary.");

    let dynamodb = new AWS.DynamoDB();
    var params = {};
    let request = await dynamodb.listTables(params);
    try {
        let response = await request.promise();
        log.info("listTables response: " + JSON.stringify(response));
    } catch (err) {
        log.error("listTables error: " + JSON.stringify(err), err.stack);
        throw err;
    }

    return "Successfully completed DynamoDB:listTables canary.";
};

exports.handler = async () => {
    return await basicCustomEntryPoint();
};
```

Packaging your Node.js canary files

If you are uploading your canary scripts using an Amazon S3 location, your zip file should include your script under this folder structure: `nodejs/node_modules/`*`myCanaryFilename.js file`*.

If you have more than a single `.js` file or you have a dependency that your script depends on, you can bundle them all into a single ZIP file that contains the folder structure `nodejs/node_modules/`*`myCanaryFilename.js file and other folders and files`*. If you are using `syn-nodejs-puppeteer-3.4` or later, you can optionally put your canary files in another folder and creating your folder structure like this: `nodejs/node_modules/`*`myFolder`*`/`*`myCanaryFilename.js file and other folders and files`*.

Handler name

Be sure to set your canary's script entry point (handler) as `myCanaryFilename.functionName` to match the file name of your script's entry point. If you are using a runtime earlier than `syn-nodejs-puppeteer-3.4`, then `functionName` must be `handler`. If you are using `syn-nodejs-puppeteer-3.4` or later, you can choose any function name as the handler. If you are using `syn-nodejs-puppeteer-3.4` or later, you can also optionally store the canary in a separate folder such as `nodejs/node_modules/myFolder/my_canary_filename`. If you store it in a separate folder, specify that path in your script entry point, such as `myFolder/my_canary_filename.functionName`.

Changing an existing Puppeteer script to use as a Synthetics canary

This section explains how to take Puppeteer scripts and modify them to run as Synthetics canary scripts. For more information about Puppeteer, see Puppeteer API v1.14.0.

We'll start with this example Puppeteer script:

```
const puppeteer = require('puppeteer');

(async () => {
  const browser = await puppeteer.launch();
  const page = await browser.newPage();
  await page.goto('https://example.com');
  await page.screenshot({path: 'example.png'});

  await browser.close();
})();
```

The conversion steps are as follows:

- Create and export a `handler` function. The handler is the entry point function for the script. If you are using a runtime earlier than `syn-nodejs-puppeteer-3.4`, the handler function must be named `handler`. If you are using `syn-nodejs-puppeteer-3.4` or later, the function can have any name, but it must be the same name that is used in the script. Also, if you are using `syn-nodejs-puppeteer-3.4` or later, you can store your scripts under any folder and specify that folder as part of the handler name.

```
const basicPuppeteerExample = async function () {};

exports.handler = async () => {
    return await basicPuppeteerExample();
};
```

- Use the `Synthetics` dependency.

```
var synthetics = require('Synthetics');
```

- Use the `Synthetics.getPage` function to get a Puppeteer `Page` object.

```
const page = await synthetics.getPage();
```

The page object returned by the Synthetics.getPage function has the **page.on** `request`, `response` and `requestfailed` events instrumented for logging. Synthetics also sets up HAR file generation for requests and responses on the page, and adds the canary ARN to the user-agent headers of outgoing requests on the page.

The script is now ready to be run as a Synthetics canary. Here is the updated script:

```
var synthetics = require('Synthetics');  // Synthetics dependency

const basicPuppeteerExample = async function () {
    const page = await synthetics.getPage(); // Get instrumented page from Synthetics
    await page.goto('https://example.com');
    await page.screenshot({path: '/tmp/example.png'}); // Write screenshot to /tmp
 folder
};

exports.handler = async () => {  // Exported handler function
    return await basicPuppeteerExample();
};
```

Environment variables

You can use environment variables when creating canaries. This allows you to write a single canary script and then use that script with different values to quickly create multiple canaries that have a similar task.

For example, suppose your organization has endpoints such as `prod`, `dev`, and `pre-release` for the different stages of your software development, and you need to create canaries to test each of these endpoints. You can write a single canary script that tests your software and then specify different values for the endpoint environment variable when you create each of the three canaries. Then, when you create a canary, you specify the script and the values to use for the environment variables.

The names of environment variables can contain letters, numbers, and the underscore character. They must start with a letter and be at least two characters. The total size of your environment variables can't exceed 4 KB. You can't specify any Lambda reserved environment variables as the names of your environment variables. For more information about reserved environment variables, see [Runtime environment variables](#).

> **Important**
>
> Environment variable keys and values are encrypted at rest using Amazon owned Amazon KMS keys. However, the environment variables are not encrypted on the client side. Do not store sensitive information in them.

The following example script uses two environment variables. This script is for a canary that checks whether a webpage is available. It uses environment variables to parameterize both the URL that it checks and the CloudWatch Synthetics log level that it uses.

The following function sets `LogLevel` to the value of the `LOG_LEVEL` environment variable.

```
synthetics.setLogLevel(process.env.LOG_LEVEL);
```

This function sets `URL` to the value of the `URL` environment variable.

```
const URL = process.env.URL;
```

This is the complete script. When you create a canary using this script, you specify values for the LOG_LEVEL and URL environment variables.

```
var synthetics = require('Synthetics');
const log = require('SyntheticsLogger');

const pageLoadEnvironmentVariable = async function () {

    // Setting the log level (0-3)
    synthetics.setLogLevel(process.env.LOG_LEVEL);
    // INSERT URL here
    const URL = process.env.URL;

    let page = await synthetics.getPage();
    //You can customize the wait condition here. For instance,
    //using 'networkidle2' may be less restrictive.
    const response = await page.goto(URL, {waitUntil: 'domcontentloaded', timeout:
 30000});
    if (!response) {
        throw "Failed to load page!";
    }
    //Wait for page to render.
    //Increase or decrease wait time based on endpoint being monitored.
    await page.waitFor(15000);
    await synthetics.takeScreenshot('loaded', 'loaded');
    let pageTitle = await page.title();
    log.info('Page title: ' + pageTitle);
    log.debug('Environment variable:' + process.env.URL);

    //If the response status code is not a 2xx success code
    if (response.status() < 200 || response.status() > 299) {
        throw "Failed to load page!";
    }
};

exports.handler = async () => {
    return await pageLoadEnvironmentVariable();
};
```

Passing environment variables to your script

To pass environment variables to your script when you create a canary in the console, specify the keys and values of the environment variables in the **Environment variables** section on the console. For more information, see Creating a canary.

To pass environment variables through the API or Amazon CLI, use the `EnvironmentVariables` parameter in the `RunConfig` section. The following is an example Amazon CLI command that creates a canary that uses two environment variables with keys of `Environment` and `Region`.

```
aws synthetics create-canary --cli-input-json '{
   "Name":"nameofCanary",
   "ExecutionRoleArn":"roleArn",
   "ArtifactS3Location":"s3://amzn-s3-demo-bucket-123456789012-us-west-2",
   "Schedule":{
      "Expression":"rate(0 minute)",
      "DurationInSeconds":604800
   },
   "Code":{
      "S3Bucket": "canarycreation",
      "S3Key": "cwsyn-mycanaryheartbeat-12345678-d1bd-1234-
abcd-123456789012-12345678-6a1f-47c3-b291-123456789012.zip",
      "Handler":"pageLoadBlueprint.handler"
   },
   "RunConfig": {
      "TimeoutInSeconds":60,
      "EnvironmentVariables": {
         "Environment":"Production",
         "Region": "us-west-1"
      }
   },
   "SuccessRetentionPeriodInDays":13,
   "FailureRetentionPeriodInDays":13,
   "RuntimeVersion":"syn-nodejs-2.0"
}'
```

Integrating your canary with other Amazon services

All canaries can use the Amazon SDK library. You can use this library when you write your canary to integrate the canary with other Amazon services.

To do so, you need to add the following code to your canary. For these examples, Amazon Secrets Manager is used as the service that the canary is integrating with.

- Import the Amazon SDK.

```
const AWS = require('aws-sdk');
```

- Create a client for the Amazon service that you are integrating with.

```
const secretsManager = new AWS.SecretsManager();
```

- Use the client to make API calls to that service.

```
var params = {
  SecretId: secretName
};
return await secretsManager.getSecretValue(params).promise();
```

The following canary script code snippet demonstrates an example of integration with Secrets Manager in more detail.

```
var synthetics = require('Synthetics');
const log = require('SyntheticsLogger');

const AWS = require('aws-sdk');
const secretsManager = new AWS.SecretsManager();

const getSecrets = async (secretName) => {
    var params = {
        SecretId: secretName
    };
    return await secretsManager.getSecretValue(params).promise();
}

const secretsExample = async function () {
    let URL = "<URL>";
    let page = await synthetics.getPage();

    log.info(`Navigating to URL: ${URL}`);
    const response = await page.goto(URL, {waitUntil: 'domcontentloaded', timeout:
 30000});

    // Fetch secrets
    let secrets = await getSecrets("secretname")
```

```
    /**
    * Use secrets to login.
    *
    * Assuming secrets are stored in a JSON format like:
    * {
    *   "username": "<USERNAME>",
    *   "password": "<PASSWORD>"
    * }
    **/
    let secretsObj = JSON.parse(secrets.SecretString);
    await synthetics.executeStep('login', async function () {
        await page.type(">USERNAME-INPUT-SELECTOR<", secretsObj.username);
        await page.type(">PASSWORD-INPUT-SELECTOR<", secretsObj.password);

        await Promise.all([
          page.waitForNavigation({ timeout: 30000 }),
          await page.click(">SUBMIT-BUTTON-SELECTOR<")
        ]);
    });

    // Verify login was successful
    await synthetics.executeStep('verify', async function () {
        await page.waitForXPath(">SELECTOR<", { timeout: 30000 });
    });
};

exports.handler = async () => {
    return await secretsExample();
};
```

Forcing your canary to use a static IP address

You can set up a canary so that it uses a static IP address.

To force a canary to use a static IP address

1. Create a new VPC. For more information, see Using DNS with Your VPC.
2. Create a new internet gateway. For more information, see Adding an internet gateway to your VPC.
3. Create a public subnet inside your new VPC.
4. Add a new route table to the VPC.

5. Add a route in the new route table, that goes from `0.0.0.0/0` to the internet gateway.
6. Associate the new route table with the public subnet.
7. Create an elastic IP address. For more information, see Elastic IP addresses .
8. Create a new NAT gateway and assign it to the public subnet and the elastic IP address.
9. Create a private subnet inside the VPC.
10. Add a route to the VPC default route table, that goes from `0.0.0.0/0` to the NAT gateway
11. Create your canary.

Writing a Python canary script

This script passes as a successful run, and returns a string. To see what a failing canary looks like, change fail = False to fail = True

```
def basic_custom_script():
    # Insert your code here
    # Perform multi-step pass/fail check
    # Log decisions made and results to /tmp
    # Be sure to wait for all your code paths to complete
    # before returning control back to Synthetics.
    # In that way, your canary will not finish and report success
    # before your code has finished executing
    fail = False
    if fail:
        raise Exception("Failed basicCanary check.")
    return "Successfully completed basicCanary checks."
def handler(event, context):
    return basic_custom_script()
```

Packaging your Python canary files

If you have more than one .py file or your script has a dependency, you can bundle them all into a single ZIP file. If you use the `syn-python-selenium-1.1` runtime, the ZIP file must contain your main canary .py file within a `python` folder, such as `python/my_canary_filename.py`. If you use `syn-python-selenium-1.1` or later, you can optionally use a different folder , such as `python/myFolder/my_canary_filename.py`.

This ZIP file should contain all necessary folders and files, but the other files do not need to be in the `python` folder.

Be sure to set your canary's script entry point as `my_canary_filename.functionName` to match the file name and function name of your script's entry point. If you are using the `syn-python-selenium-1.0` runtime, then `functionName` must be `handler`. If you are using `syn-python-selenium-1.1` or later, this handler name restriction doesn't apply, and you can also optionally store the canary in a separate folder such as `python/myFolder/my_canary_filename.py`. If you store it in a separate folder, specify that path in your script entry point, such as `myFolder/my_canary_filename.functionName`.

Changing an existing Selenium script to use a Synthetics canary

You can quickly modify an existing script for Python and Selenium to be used as a canary. For more information about Selenium, see www.selenium.dev/.

For this example, we'll start with the following Selenium script:

```
from selenium import webdriver

def basic_selenium_script():
    browser = webdriver.Chrome()
    browser.get('https://example.com')
    browser.save_screenshot('loaded.png')

basic_selenium_script()
```

The conversion steps are as follows.

To convert a Selenium script to be used as a canary

1. Change the `import` statement to use Selenium from the `aws_synthetics` module:

   ```
   from aws_synthetics.selenium import synthetics_webdriver as webdriver
   ```

   The Selenium module from `aws_synthetics` ensures that the canary can emit metrics and logs, generate a HAR file, and work with other CloudWatch Synthetics features.
2. Create a handler function and call your Selenium method. The handler is the entry point function for the script.

   If you are using `syn-python-selenium-1.0`, the handler function must be named `handler`. If you are using `syn-python-selenium-1.1` or later, the function can have any name, but it must be the same name that is used in the script. Also, if you are using `syn-python-`

selenium-1.1 or later, you can store your scripts under any folder and specify that folder as part of the handler name.

```
def handler(event, context):
    basic_selenium_script()
```

The script is now updated to be a CloudWatch Synthetics canary. Here is the updated script:

```
from aws_synthetics.selenium import synthetics_webdriver as webdriver

def basic_selenium_script():
    browser = webdriver.Chrome()
    browser.get('https://example.com')
    browser.save_screenshot('loaded.png')

def handler(event, context):
    basic_selenium_script()
```

Changing an existing Puppeteer Synthetics script to authenticate non-standard certificates

One important use case for Synthetics canaries is for you to monitor your own endpoints. If you want to monitor an endpoint that isn't ready for external traffic, this monitoring can sometimes mean that you don't have a proper certificate signed by a trusted third-party certificate authority.

Two possible solutions to this scenario are as follows:

- To authenticate a client certificate, see How to validate authentication using Amazon CloudWatch Synthetics – Part 2.
- To authenticate a self-signed certificate, see How to validate authentication with self-signed certificates in Amazon CloudWatch Synthetics

You are not limited to these two options when you use CloudWatch Synthetics canaries. You can extend these features and add your business logic by extending the canary code.

> **Note**
>
> Synthetics canaries running on Python runtimes innately have the `--ignore-certificate-errors` flag enabled, so those canaries shouldn't have any issues reaching sites with non-standard certificate configurations.

Library functions available for canary scripts

CloudWatch Synthetics includes several built-in classes and functions that you can call when writing Node.js scripts to use as canaries.

Some apply to both UI and API canaries. Others apply to UI canaries only. A UI canary is a canary that uses the `getPage()` function and uses Puppeteer as a web driver to navigate and interact with webpages.

> **Note**
>
> Whenever you upgrade a canary to use a new version of the the Synthetics runtime, all Synthetics library functions that your canary uses are also automatically upgraded to the same version of NodeJS that the Synthetics runtime supports.

Topics

Library functions available for Node.js canary scripts using Playwright

This section describes the library functions that are available for canary scripts using the Node.js Playwright runtime.

Topics

- getDefaultLaunchOptions
- executeStep

launch

This function launches a Chromium browser using a Playwright launch function, and returns the browser object. It decompresses browser binaries and launches the chromium browser by using default options suitable for a headless browser. For more information about the `launch` function, see `launch` in the Playwright documentation.

Usage

```
const browser = await synthetics.launch();
```

Arguments

`options` options (optional) is a configurable set of options for the browser.

Returns

Promise <Browser> where Browser is a Playwright browser instance.

If this function is called again, a previously-opened browser is closed before initiating a new browser. You can override launch parameters used by CloudWatch Synthetics, and pass additional parameters when launching the browser. For example, the following code snippet launches a browser with default arguments and a default executable path, but with a viewport of 800 x 600 pixels. For more information, see Playwright launch options in the Playwright documentation.

```
const browser = await synthetics.launch({
  defaultViewport: { 
      "deviceScaleFactor": 1, 
      "width": 800,
      "height": 600 
}});
```

You can also add or override Chromium flags passed on by default to the browser. For example, you can disable web security by adding a `--disable-web-security` flag to arguments in the CloudWatch Synthetics launch parameters:

```
// This function adds the --disable-web-security flag to the launch parameters
```

```
const defaultOptions = await synthetics.getDefaultLaunchOptions();
const launchArgs = [...defaultOptions.args, '--disable-web-security'];
const browser = await synthetics.launch({
    args: launchArgs
  });
```

newPage

The `newPage()` function creates and returns a new Playwright page. Synthetics automatically sets up a Chrome DevTools Protocol (CDP) connection to enable network captures for HTTP archive (HAR) generation.

Usage

Use `newPage()` in either of the following ways:

1. Creating a new page in a new browser context:

```
const page = await synthetics.newPage(browser);
```

2. Creating a new page in a specified browser context:

```
// Create a new browser context
const browserContext = await browser.newContext();

// Create a new page in the specified browser context
const page = await synthetics.newPage(browserContext)
```

Arguments

Accepts either Playwright [Browser](#) instance or Playwright [BrowserContext](#) instance.

Returns

Promise <Page> where Page is a Playwright [Page](#) instance.

close

Closes the currently-opened browser.

Usage

```
await synthetics.close();
```

It is recommended to close the browser in a `finally` block of your script.

Arguments

None

Returns

Returns Promise<void> used by the Synthetics launch function for launching the browser.

getDefaultLaunchOptions

The `getDefaultLaunchOptions()` function returns the browser launch options that are used by CloudWatch Synthetics.

Usage

```
const defaultOptions = await synthetics.getDefaultLaunchOptions();
```

Arguments

None

Returns

Returns Playwright [launch options](#) used by the Synthetics `launch` function for launching the browser.

executeStep

The `executeStep` function is used to execute a step in a Synthetics script. In CloudWatch Synthetics, a Synthetics step is a way to break down your canary script into a series of clearly defined actions, allowing you to monitor different parts of your application journey separately. For each step, CloudWatch Synthetics does the following:

- Automatically captures a screenshot before step starts and after a step is complete. You can also capture screenshots inside a step. Screenshots are captured by default, but can be turned off by using Synthetics configurations *`(Todo: Link)`*.
- A report, including a summary, of step execution details like the duration of a step, `pass` or `fail` status, source and destination page URLs, associated screenshots, etc. is created for each canary

run. When you choose a run in the CloudWatch Synthetics console, you can view execution details of each step on the **Step** tab.

- `SuccessPercent` and `Duration` CloudWatch metrics are emitted for each step, enabling users to monitor availability and latency of each step.

Usage

```
await synthetics.executeStep("mystepname", async function () {
  await page.goto(url, { waitUntil: 'load', timeout: 30000 });
}
```

> **Note**
>
> Steps should run sequentially. Be sure to use `await` on promises.

Arguments

- `stepName` string (required) (boolean)— Name of the Synthetics step.
- `functionToExecute` async function (required)— The function that you want Synthetics to run. This function should contain the logic for the step.
- `stepConfig` object (optional)— Step configuration overrides the global Synthetics configuration for this step.
  - `continueOnStepFailure` boolean (optional) — Whether to continue running the canary script after this step fails.
  - `screenshotOnStepStart` boolean (optional) — Whether to take a screenshot at the start of this step.
  - `screenshotOnStepSuccess` boolean (optional) — Whether to take a screenshot if this step succeeds.
  - `screenshotOnStepFailure` boolean (optional) — Whether to take a screenshot if this step fails.
- `page` — Playwright page object (optional)

  A Playwright page object. Synthetics uses this page object to capture screenshots and URLs. By default, Synthetics uses the Playwright page created when the `synthetics.newPage()` function is called for capturing page details like screenshots and URLs.

Returns

Returns a Promise that resolves with the value returned by the `functionToExecute` function. For an example script, see Sample code for canary scripts in this guide.

Library functions available for Node.js canary scripts using Puppeteer

This section describes the library functions available for Node.js canary scripts.

Topics

Node.js library classes and functions that apply to all canaries

The following CloudWatch Synthetics library functions for Node.js are useful for all canaries.

Topics

Synthetics class

The following functions for all canaries are in the Synthetics class.

Topics

- setLogLevel();

addExecutionError(errorMessage, ex);

`errorMessage` describes the error and `ex` is the exception that is encountered

You can use `addExecutionError` to set execution errors for your canary. It fails the canary without interrupting the script execution. It also doesn't impact your `successPercent` metrics.

You should track errors as execution errors only if they are not important to indicate the success or failure of your canary script.

An example of the use of `addExecutionError` is the following. You are monitoring the availability of your endpoint and taking screenshots after the page has loaded. Because the failure of taking a screenshot doesn't determine availability of the endpoint, you can catch any errors encountered while taking screenshots and add them as execution errors. Your availability metrics will still indicate that the endpoint is up and running, but your canary status will be marked as failed. The following sample code block catches such an error and adds it as an execution error.

```
try {
    await synthetics.takeScreenshot(stepName, "loaded");
} catch(ex) {
    synthetics.addExecutionError('Unable to take screenshot ', ex);
}
```

getCanaryName();

Returns the name of the canary.

getCanaryArn();

Returns the ARN of the canary.

getCanaryUserAgentString();

Returns the custom user agent of the canary.

getRuntimeVersion();

This function is available in runtime version `syn-nodejs-puppeteer-3.0` and later. It returns the Synthetics runtime version of the canary. For example, the return value could be `syn-nodejs-puppeteer-3.0`.

getLogLevel();

Retrieves the current log level for the Synthetics library. Possible values are the following:

- `0` – Debug
- `1` – Info
- `2` – Warn
- `3` – Error

Example:

```
let logLevel = synthetics.getLogLevel();
```

setLogLevel();

Sets the log level for the Synthetics library. Possible values are the following:

- `0` – Debug
- `1` – Info
- `2` – Warn
- `3` – Error

Example:

```
synthetics.setLogLevel(0);
```

SyntheticsConfiguration class

This class is available only in the `syn-nodejs-2.1` runtime version or later.

You can use the `SyntheticsConfiguration` class to configure the behavior of Synthetics library functions. For example, you can use this class to configure the `executeStep()` function to not capture screenshots.

You can set CloudWatch Synthetics configurations at the global level, which are applied to all steps of canaries. You can also override these configurations at the step level by passing configuration key and value pairs.

You can pass in options at the step level. For examples, see async executeStep(stepName, functionToExecute, [stepConfig]); and executeHttpStep(stepName, requestOptions, [callback], [stepConfig])

Topics

- setConfig(options)
- Visual monitoring

setConfig(options)

`options` is an object, which is a set of configurable options for your canary. The following sections explain the possible fields in *`options`*.

setConfig(options) for all canaries

For canaries using `syn-nodejs-puppeteer-3.2` or later, the **(options)** for **setConfig** can include the following parameters:

- `includeRequestHeaders` (boolean)— Whether to include request headers in the report. The default is `false`.
- `includeResponseHeaders` (boolean)— Whether to include response headers in the report. The default is `false`.
- `restrictedHeaders` (array)— A list of header values to ignore, if headers are included. This applies to both request and response headers. For example, you can hide your credentials by passing **includeRequestHeaders** as `true` and **restrictedHeaders** as `['Authorization']`.
- `includeRequestBody` (boolean)— Whether to include the request body in the report. The default is `false`.
- `includeResponseBody` (boolean)— Whether to include the response body in the report. The default is `false`.

  If you enable either `includeResponseBody` or `logResponseBody`, the data object is not returned in the response from some APIs, such as aws-sdk v3 clients. This is because of a limitation of Node.js and the type of response object used.

setConfig(options) regarding CloudWatch metrics

For canaries using `syn-nodejs-puppeteer-3.1` or later, the **(options)** for **setConfig** can include the following Boolean parameters that determine which metrics are published by the canary. The default for each of these options is `true`. The options that start with `aggregated` determine whether the metric is emitted without the `CanaryName` dimension. You can use these metrics to see the aggregated results for all of your canaries. The other options determine whether the metric is emitted with the `CanaryName` dimension. You can use these metrics to see results for each individual canary.

For a list of CloudWatch metrics emitted by canaries, see [CloudWatch metrics published by canaries](#).

- `failedCanaryMetric` (boolean)— Whether to emit the `Failed` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `failedRequestsMetric` (boolean)— Whether to emit the `Failed requests` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `_2xxMetric` (boolean)— Whether to emit the `2xx` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `_4xxMetric` (boolean)— Whether to emit the `4xx` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `_5xxMetric` (boolean)— Whether to emit the `5xx` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `stepDurationMetric` (boolean)— Whether to emit the `Step duration` metric (with the `CanaryName` `StepName` dimensions) for this canary. The default is `true`.
- `stepSuccessMetric` (boolean)— Whether to emit the `Step success` metric (with the `CanaryName` `StepName` dimensions) for this canary. The default is `true`.
- `aggregatedFailedCanaryMetric` (boolean)— Whether to emit the `Failed` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregatedFailedRequestsMetric` (boolean)— Whether to emit the `Failed Requests` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregated2xxMetric` (boolean)— Whether to emit the `2xx` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregated4xxMetric` (boolean)— Whether to emit the `4xx` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregated5xxMetric` (boolean)— Whether to emit the `5xx` metric (without the `CanaryName` dimension) for this canary. The default is `true`.

- `visualMonitoringSuccessPercentMetric` (boolean)— Whether to emit the `visualMonitoringSuccessPercent` metric for this canary. The default is `true`.
- `visualMonitoringTotalComparisonsMetric` (boolean)— Whether to emit the `visualMonitoringTotalComparisons` metric for this canary. The default is `false`.
- `includeUrlPassword` (boolean)— Whether to include a password that appears in the URL. By default, passwords that appear in URLs are redacted from logs and reports, to prevent disclosing sensitive data. The default is `false`.
- `restrictedUrlParameters` (array)— A list of URL path or query parameters to redact. This applies to URLs appearing in logs, reports, and errors. The parameter is case-insensitive. You can pass an asterisk (*) as a value to redact all URL path and query parameter values. The default is an empty array.
- `logRequest` (boolean)— Whether to log every request in canary logs. For UI canaries, this logs each request sent by the browser. The default is `true`.
- `logResponse` (boolean)— Whether to log every response in canary logs. For UI canaries, this logs every response received by the browser. The default is `true`.
- `logRequestBody` (boolean)— Whether to log request bodies along with the requests in canary logs. This configuration applies only if `logRequest` is `true`. The default is `false`.
- `logResponseBody` (boolean)— Whether to log response bodies along with the responses in canary logs. This configuration applies only if `logResponse` is `true`. The default is `false`.

  If you enable either `includeResponseBody` or `logResponseBody`, the data object is not returned in the response from some APIs, such as aws-sdk v3 clients. This is because of a limitation of Node.js and the type of response object used.
- `logRequestHeaders` (boolean)— Whether to log request headers along with the requests in canary logs. This configuration applies only if `logRequest` is `true`. The default is `false`.

  Note that `includeRequestHeaders` enables headers in artifacts.
- `logResponseHeaders` (boolean)— Whether to log response headers along with the responses in canary logs. This configuration applies only if `logResponse` is `true`. The default is `false`.

  Note that `includeResponseHeaders` enables headers in artifacts.

> **Note**
>
> The `Duration` and `SuccessPercent` metrics are always emitted for each canary, both with and without the `CanaryName` metric.

Methods to enable or disable metrics

disableAggregatedRequestMetrics()

Disables the canary from emitting all request metrics that are emitted with no `CanaryName` dimension.

disableRequestMetrics()

Disables all request metrics, including both per-canary metrics and metrics aggregated across all canaries.

disableStepMetrics()

Disables all step metrics, including both step success metrics and step duration metrics.

enableAggregatedRequestMetrics()

Enables the canary to emit all request metrics that are emitted with no `CanaryName` dimension.

enableRequestMetrics()

Enables all request metrics, including both per-canary metrics and metrics aggregated across all canaries.

enableStepMetrics()

Enables all step metrics, including both step success metrics and step duration metrics.

get2xxMetric()

Returns whether the canary emits a `2xx` metric with the `CanaryName` dimension.

get4xxMetric()

Returns whether the canary emits a `4xx` metric with the `CanaryName` dimension.

get5xxMetric()

Returns whether the canary emits a `5xx` metric with the `CanaryName` dimension.

getAggregated2xxMetric()

Returns whether the canary emits a `2xx` metric with no dimension.

getAggregated4xxMetric()

Returns whether the canary emits a `4xx` metric with no dimension.

getAggregatedFailedCanaryMetric()

Returns whether the canary emits a `Failed` metric with no dimension.

getAggregatedFailedRequestsMetric()

Returns whether the canary emits a `Failed requests` metric with no dimension.

getAggregated5xxMetric()

Returns whether the canary emits a `5xx` metric with no dimension.

getFailedCanaryMetric()

Returns whether the canary emits a `Failed` metric with the `CanaryName` dimension.

getFailedRequestsMetric()

Returns whether the canary emits a `Failed requests` metric with the `CanaryName` dimension.

getStepDurationMetric()

Returns whether the canary emits a `Duration` metric with the `CanaryName` dimension for this canary.

getStepSuccessMetric()

Returns whether the canary emits a `StepSuccess` metric with the `CanaryName` dimension for this canary.

with2xxMetric(_2xxMetric)

Accepts a Boolean argument, which specifies whether to emit a `2xx` metric with the `CanaryName` dimension for this canary.

with4xxMetric(_4xxMetric)

Accepts a Boolean argument, which specifies whether to emit a `4xx` metric with the `CanaryName` dimension for this canary.

with5xxMetric(_5xxMetric)

Accepts a Boolean argument, which specifies whether to emit a `5xx` metric with the `CanaryName` dimension for this canary.

withAggregated2xxMetric(aggregated2xxMetric)

Accepts a Boolean argument, which specifies whether to emit a `2xx` metric with no dimension for this canary.

withAggregated4xxMetric(aggregated4xxMetric)

Accepts a Boolean argument, which specifies whether to emit a `4xx` metric with no dimension for this canary.

withAggregated5xxMetric(aggregated5xxMetric)

Accepts a Boolean argument, which specifies whether to emit a `5xx` metric with no dimension for this canary.

withAggregatedFailedCanaryMetric(aggregatedFailedCanaryMetric)

Accepts a Boolean argument, which specifies whether to emit a `Failed` metric with no dimension for this canary.

withAggregatedFailedRequestsMetric(aggregatedFailedRequestsMetric)

Accepts a Boolean argument, which specifies whether to emit a `Failed requests` metric with no dimension for this canary.

withFailedCanaryMetric(failedCanaryMetric)

Accepts a Boolean argument, which specifies whether to emit a `Failed` metric with the `CanaryName` dimension for this canary.

withFailedRequestsMetric(failedRequestsMetric)

Accepts a Boolean argument, which specifies whether to emit a `Failed requests` metric with the `CanaryName` dimension for this canary.

withStepDurationMetric(stepDurationMetric)

Accepts a Boolean argument, which specifies whether to emit a `Duration` metric with the `CanaryName` dimension for this canary.

withStepSuccessMetric(stepSuccessMetric)

Accepts a Boolean argument, which specifies whether to emit a `StepSuccess` metric with the `CanaryName` dimension for this canary.

Methods to enable or disable other features

withHarFile()

Accepts a Boolean argument, which specifies whether to create a HAR file for this canary.

withStepsReport()

Accepts a Boolean argument, which specifies whether to report a step execution summary for this canary.

withIncludeUrlPassword()

Accepts a Boolean argument, which specifies whether to include passwords that appear in URLs in logs and reports.

withRestrictedUrlParameters()

Accepts an array of URL path or query parameters to redact. This applies to URLs appearing in logs, reports, and errors. You can pass an asterisk (*) as a value to redact all URL path and query parameter values

withLogRequest()

Accepts a Boolean argument, which specifies whether to log every request in the canary's logs.

withLogResponse()

Accepts a Boolean argument, which specifies whether to log every response in the canary's logs.

withLogRequestBody()

Accepts a Boolean argument, which specifies whether to log every request body in the canary's logs.

withLogResponseBody()

Accepts a Boolean argument, which specifies whether to log every response body in the canary's logs.

withLogRequestHeaders()

Accepts a Boolean argument, which specifies whether to log every request header in the canary's logs.

withLogResponseHeaders()

Accepts a Boolean argument, which specifies whether to log every response header in the canary's logs.

getHarFile()

Returns whether the canary creates a HAR file.

getStepsReport()

Returns whether the canary reports a step execution summary.

getIncludeUrlPassword()

Returns whether the canary includes passwords that appear in URLs in logs and reports.

getRestrictedUrlParameters()

Returns whether the canary redacts URL path or query parameters.

getLogRequest()

Returns whether the canary logs every request in the canary's logs.

getLogResponse()

Returns whether the canary logs every response in the canary's logs.

getLogRequestBody()

Returns whether the canary logs every request body in the canary's logs.

getLogResponseBody()

Returns whether the canary logs every response body in the canary's logs.

getLogRequestHeaders()

Returns whether the canary logs every request header in the canary's logs.

getLogResponseHeaders()

Returns whether the canary logs every response header in the canary's logs.

Functions for all canaries

- `withIncludeRequestHeaders`(includeRequestHeaders)
- `withIncludeResponseHeaders`(includeResponseHeaders)
- `withRestrictedHeaders`(restrictedHeaders)
- `withIncludeRequestBody`(includeRequestBody)
- `withIncludeResponseBody`(includeResponseBody)
- `enableReportingOptions`()— Enables all reporting options-- **includeRequestHeaders**, **includeResponseHeaders**, **includeRequestBody**, and **includeResponseBody**, .
- `disableReportingOptions`()— Disables all reporting options-- **includeRequestHeaders**, **includeResponseHeaders**, **includeRequestBody**, and **includeResponseBody**, .

setConfig(options) for UI canaries

For UI canaries, **setConfig** can include the following Boolean parameters:

- `continueOnStepFailure` (boolean)— Whether to continue with running the canary script after a step fails (this refers to the **executeStep** function). If any steps fail, the canary run will still be marked as failed. The default is `false`.
- `harFile` (boolean)— Whether to create a HAR file. The default is `True`.
- `screenshotOnStepStart` (boolean)— Whether to take a screenshot before starting a step.
- `screenshotOnStepSuccess` (boolean)— Whether to take a screenshot after completing a successful step.
- `screenshotOnStepFailure` (boolean)— Whether to take a screenshot after a step fails.

Methods to enable or disable screenshots

disableStepScreenshots()

Disables all screenshot options (screenshotOnStepStart, screenshotOnStepSuccess, and screenshotOnStepFailure).

enableStepScreenshots()

Enables all screenshot options (screenshotOnStepStart, screenshotOnStepSuccess, and screenshotOnStepFailure). By default, all these methods are enabled.

getScreenshotOnStepFailure()

Returns whether the canary takes a screenshot after a step fails.

getScreenshotOnStepStart()

Returns whether the canary takes a screenshot before starting a step.

getScreenshotOnStepSuccess()

Returns whether the canary takes a screenshot after completing a step successfully.

withScreenshotOnStepStart(screenshotOnStepStart)

Accepts a Boolean argument, which indicates whether to take a screenshot before starting a step.

withScreenshotOnStepSuccess(screenshotOnStepSuccess)

Accepts a Boolean argument, which indicates whether to take a screenshot after completing a step successfully.

withScreenshotOnStepFailure(screenshotOnStepFailure)

Accepts a Boolean argument, which indicates whether to take a screenshot after a step fails.

Usage in UI canaries

First, import the synthetics dependency and fetch the configuration.

```
// Import Synthetics dependency
const synthetics = require('Synthetics');

// Get Synthetics configuration
const synConfig = synthetics.getConfiguration();
```

Then, set the configuration for each option by calling the setConfig method using one of the following options.

```
// Set configuration values
    synConfig.setConfig({
        screenshotOnStepStart: true,
        screenshotOnStepSuccess: false,
        screenshotOnStepFailure: false
    });
```

Or

```
synConfig.withScreenshotOnStepStart(false).withScreenshotOnStepSuccess(true).withScreenshotOnSt
```

To disable all screenshots, use the `disableStepScreenshots()` function as in this example.

```
synConfig.disableStepScreenshots();
```

You can enable and disable screenshots at any point in the code. For example, to disable screenshots only for one step, disable them before running that step and then enable them after the step.

setConfig(options) for API canaries

For API canaries, **setConfig** can include the following Boolean parameters:

- `continueOnHttpStepFailure` (boolean)— Whether to continue with running the canary script after an HTTP step fails (this refers to the **executeHttpStep** function). If any steps fail, the canary run will still be marked as failed. The default is `true`.

Visual monitoring

Visual monitoring compares screenshots taken during a canary run with screenshots taken during a baseline canary run. If the discrepancy between the two screenshots is beyond a threshold percentage, the canary fails and you can see the areas with differences highlighted in color in the canary run report. Visual monitoring is supported in canaries running **syn-puppeteer-node-3.2** and later. It is not currently supported in canaries running Python and Selenium.

To enable visual monitoring, add the following line of code to the canary script. For more details, see [SyntheticsConfiguration class](#).

```
syntheticsConfiguration.withVisualCompareWithBaseRun(true);
```

The first time that the canary runs successfully after this line is added to the script, it uses the screenshots taken during that run as the baseline for comparison. After that first canary run, you can use the CloudWatch console to edit the canary to do any of the following:

- Set the next run of the canary as the new baseline.
- Draw boundaries on the current baseline screenshot to designate areas of the screenshot to ignore during visual comparisons.
- Remove a screenshot from being used for visual monitoring.

For more information about using the CloudWatch console to edit a canary, see [Edit or delete a canary](#).

Other options for visual monitoring

syntheticsConfiguration.withVisualVarianceThresholdPercentage(desiredPercentage)

Set the acceptable percentage for screenshot variance in visual comparisons.

syntheticsConfiguration.withVisualVarianceHighlightHexColor("#fafa00")

Set the highlight color that designates variance areas when you look at canary run reports that use visual monitoring.

syntheticsConfiguration.withFailCanaryRunOnVisualVariance(failCanary)

Set whether or not the canary fails when there is a visual difference that is more than the threshold. The default is to fail the canary.

Synthetics logger

SyntheticsLogger writes logs out to both the console and to a local log file at the same log level. This log file is written to both locations only if the log level is at or below the desired logging level of the log function that was called.

The logging statements in the local log file are prepended with "DEBUG: ", "INFO: ", and so on to match the log level of the function that was called.

You can use the SyntheticsLogger, assuming you want to run the Synthetics Library at the same log level as your Synthetics canary logging.

Using the SyntheticsLogger is not required to create a log file that is uploaded to your S3 results location. You could instead create a different log file in the `/tmp` folder. Any files created under the `/tmp` folder are uploaded to the results location in S3 as artifacts.

To use the Synthetics Library logger:

```
const log = require('SyntheticsLogger');
```

Useful function definitions:

log.debug(*`message`*, *`ex`*);

Parameters: *`message`* is the message to log. *`ex`* is the exception, if any, to log.

Example:

```
log.debug("Starting step - login.");
```

log.error(*`message`*, *`ex`*);

Parameters: *`message`* is the message to log. *`ex`* is the exception, if any, to log.

Example:

```
try {
  await login();
catch (ex) {
  log.error("Error encountered in step - login.", ex);
}
```

log.info(*message*, *ex*);

Parameters: *message* is the message to log. *ex* is the exception, if any, to log.

Example:

```
log.info("Successfully completed step - login.");
```

log.log(*message*, *ex*);

This is an alias for `log.info`.

Parameters: *message* is the message to log. *ex* is the exception, if any, to log.

Example:

```
 log.log("Successfully completed step - login.");
```

log.warn(*message*, *ex*);

Parameters: *message* is the message to log. *ex* is the exception, if any, to log.

Example:

```
log.warn("Exception encountered trying to publish CloudWatch Metric.", ex);
```

SyntheticsLogHelper class

The `SyntheticsLogHelper` class is available in the runtime `syn-nodejs-puppeteer-3.2` and later runtimes. It is already initialized in the CloudWatch Synthetics library and is configured with Synthetics configuration. You can add this as a dependency in your script. This class enables you to sanitize URLs, headers, and error messages to redact sensitive information.

Note

Synthetics sanitizes all URLs and error messages it logs before including them in logs, reports, HAR files, and canary run errors based on the Synthetics configuration setting `restrictedUrlParameters`. You have to use `getSanitizedUrl` or `getSanitizedErrorMessage` only if you are logging URLs or errors in your script. Synthetics does not store any canary artifacts except for canary errors thrown by the script. Canary run artifacts are stored in your customer account. For more information, see Security considerations for Synthetics canaries.

Topics

- getSanitizedUrl(url, stepConfig = null)
- getSanitizedErrorMessage
- getSanitizedHeaders(headers, stepConfig=null)

getSanitizedUrl(url, stepConfig = null)

This function is available in `syn-nodejs-puppeteer-3.2` and later. It returns sanitized url strings based on the configuration. You can choose to redact sensitive URL parameters such as password and access_token by setting the property `restrictedUrlParameters`. By default, passwords in URLs are redacted. You can enable URL passwords if needed by setting `includeUrlPassword` to true.

This function throws an error if the URL passed in is not a valid URL.

Parameters

- *`url`* is a string and is the URL to sanitize.
- *`stepConfig`* (Optional) overrides the global Synthetics configuration for this function. If `stepConfig` is not passed in, the global configuration is used to sanitize the URL.

Example

This example uses the following sample URL: `https://example.com/learn/home?access_token=12345&token_type=Bearer&expires_in=1200`. In this example, `access_token` contains your sensitive information which shouldn't be logged. Note that the Synthetics services doesn't store any canary run artifacts. Artifacts such as logs, screenshots, and reports are all stored in an Amazon S3 bucket in your customer account.

The first step is to set the Synthetics configuration.

```
// Import Synthetics dependency
const synthetics = require('Synthetics');

// Import Synthetics logger for logging url
const log = require('SyntheticsLogger');

// Get Synthetics configuration
const synConfig = synthetics.getConfiguration();

// Set restricted parameters
synConfig.setConfig({
   restrictedUrlParameters: ['access_token'];
});
// Import SyntheticsLogHelper dependency
const syntheticsLogHelper = require('SyntheticsLogHelper');

const sanitizedUrl = syntheticsLogHelper.getSanitizedUrl('URL');

const urlConfig = {
   restrictedUrlParameters = ['*']
};
const sanitizedUrl = syntheticsLogHelper.getSanitizedUrl('URL', urlConfig);
logger.info('My example url is: ' + sanitizedUrl);
```

Next, sanitize and log the URL

```
// Import SyntheticsLogHelper dependency
const syntheticsLogHelper = require('SyntheticsLogHelper');

const sanitizedUrl = syntheticsLogHelper.getSanitizedUrl('https://example.com/learn/
home?access_token=12345&token_type=Bearer&expires_in=1200');
```

This logs the following in your canary log.

```
My example url is: https://example.com/learn/home?
access_token=REDACTED&token_type=Bearer&expires_in=1200
```

You can override the Synthetics configuration for a URL by passing in an optional parameter containing Synthetics configuration options, as in the following example.

```
const urlConfig = {
   restrictedUrlParameters = ['*']
};
const sanitizedUrl = syntheticsLogHelper.getSanitizedUrl('https://example.com/learn/
home?access_token=12345&token_type=Bearer&expires_in=1200', urlConfig);
logger.info('My example url is: ' + sanitizedUrl);
```

The preceding example redacts all query parameters, and is logged as follows:

```
My example url is: https://example.com/learn/home?
access_token=REDACTED&token_type=REDACTED&expires_in=REDACTED
```

getSanitizedErrorMessage

This function is available in `syn-nodejs-puppeteer-3.2` and later. It returns sanitized error strings by sanitizing any URLs present based on the Synthetics configuration. You can choose to override the global Synthetics configuration when you call this function by passing an optional `stepConfig` parameter.

Parameters

- *`error`* is the error to sanitize. It can be an Error object or a string.
- *`stepConfig`* (Optional) overrides the global Synthetics configuration for this function. If `stepConfig` is not passed in, the global configuration is used to sanitize the URL.

Example

This example uses the following error: `Failed to load url: https://example.com/learn/home?access_token=12345&token_type=Bearer&expires_in=1200`

The first step is to set the Synthetics configuration.

```
// Import Synthetics dependency
const synthetics = require('Synthetics');
```

```
// Import Synthetics logger for logging url
const log = require('SyntheticsLogger');

// Get Synthetics configuration
const synConfig = synthetics.getConfiguration();

// Set restricted parameters
synConfig.setConfig({
   restrictedUrlParameters: ['access_token'];
});
```

Next, sanitize and log the error message

```
// Import SyntheticsLogHelper dependency
const syntheticsLogHelper = require('SyntheticsLogHelper');

try {
   // Your code which can throw an error containing url which your script logs
} catch (error) {
    const sanitizedErrorMessage =
 syntheticsLogHelper.getSanitizedErrorMessage(errorMessage);
    logger.info(sanitizedErrorMessage);
}
```

This logs the following in your canary log.

```
Failed to load url: https://example.com/learn/home?
access_token=REDACTED&token_type=Bearer&expires_in=1200
```

getSanitizedHeaders(headers, stepConfig=null)

This function is available in `syn-nodejs-puppeteer-3.2` and later. It returns sanitized headers based on the `restrictedHeaders` property of `syntheticsConfiguration`. The headers specified in the `restrictedHeaders` property are redacted from logs, HAR files, and reports.

Parameters

- *`headers`* is an object containing the headers to sanitize.
- *`stepConfig`* (Optional) overrides the global Synthetics configuration for this function. If `stepConfig` is not passed in, the global configuration is used to sanitize the headers.

Node.js library classes and functions that apply to UI canaries only

The following CloudWatch Synthetics library functions for Node.js are useful only for UI canaries.

Topics

Synthetics class

The following functions are in the Synthetics class.

Topics

async addUserAgent(page, userAgentString);

This function appends *`userAgentString`* to the specified page's user-agent header.

Example:

```
await synthetics.addUserAgent(page, "MyApp-1.0");
```

Results in the page's user-agent header being set to *`browsers-user-agent-header-value`*`MyApp-1.0`

async executeStep(stepName, functionToExecute, [stepConfig]);

Executes the provided step, wrapping it with start/pass/fail logging, start/pass/fail screenshots, and pass/fail and duration metrics.

> **Note**
>
> If you are using the `syn-nodejs-2.1` or later runtime, you can configure whether and when screenshots are taken. For more information, see SyntheticsConfiguration class.

The `executeStep` function also does the following:

- Logs that the step started.
- Takes a screenshot named `<stepName>-starting`.
- Starts a timer.
- Executes the provided function.
- If the function returns normally, it counts as passing. If the function throws, it counts as failing.
- Ends the timer.
- Logs whether the step passed or failed
- Takes a screenshot named `<stepName>-succeeded` or `<stepName>-failed`.
- Emits the `stepName` `SuccessPercent` metric, 100 for pass or 0 for failure.
- Emits the `stepName` `Duration` metric, with a value based on the step start and end times.
- Finally, returns what the `functionToExecute` returned or re-throws what `functionToExecute` threw.

If the canary uses the `syn-nodejs-2.0` runtime or later, this function also adds a step execution summary to the canary's report. The summary includes details about each step, such as start time, end time, status (PASSED/FAILED), failure reason (if failed), and screenshots captured during the execution of each step.

Example:

```
await synthetics.executeStep('navigateToUrl', async function (timeoutInMillis = 30000)
 {
```

```
        await page.goto(url, {waitUntil: ['load', 'networkidle0'], timeout: 
 timeoutInMillis});});
```

Response:

Returns what `functionToExecute` returns.

Updates with syn-nodejs-2.2

Starting with `syn-nodejs-2.2`, you can optionally pass step configurations to override CloudWatch Synthetics configurations at the step level. For a list of options that you can pass to `executeStep`, see SyntheticsConfiguration class.

The following example overrides the default `false` configuration for `continueOnStepFailure` to `true` and specifies when to take screenthots.

```
var stepConfig = {
    'continueOnStepFailure': true,
    'screenshotOnStepStart': false,
    'screenshotOnStepSuccess': true,
    'screenshotOnStepFailure': false
}

await executeStep('Navigate to amazon', async function (timeoutInMillis = 30000) {
      await page.goto(url, {waitUntil: ['load', 'networkidle0'], timeout: 
 timeoutInMillis});
 }, stepConfig);
```

getDefaultLaunchOptions();

The `getDefaultLaunchOptions()` function returns the browser launch options that are used by CloudWatch Synthetics. For more information, see Launch options type

```
// This function returns default launch options used by Synthetics.
const defaultOptions = await synthetics.getDefaultLaunchOptions();
```

getPage();

Returns the current open page as a Puppeteer object. For more information, see Puppeteer API v1.14.0.

Example:

```
let page = await synthetics.getPage();
```

Response:

The page (Puppeteer object) that is currently open in the current browser session.

getRequestResponseLogHelper();

> **Important**
>
> In canaries that use the `syn-nodejs-puppeteer-3.2` runtime or later, this function is deprecated along with the `RequestResponseLogHelper` class. Any use of this function causes a warning to appear in your canary logs. This function will be removed in future runtime versions. If you are using this function, use [RequestResponseLogHelper class] instead.

Use this function as a builder pattern for tweaking the request and response logging flags.

Example:

```
synthetics.setRequestResponseLogHelper(getRequestResponseLogHelper().withLogRequestHeaders(fals
```

Response:

```
{RequestResponseLogHelper}
```

launch(options)

The options for this function are available only in the `syn-nodejs-2.1` runtime version or later.

This function is used only for UI canaries. It closes the existing browser and launches a new one.

> **Note**
>
> CloudWatch Synthetics always launches a browser before starting to run your script. You don't need to call launch() unless you want to launch a new browser with custom options.

(options) is a configurable set of options to set on the browser. For more information, Launch options type .

If you call this function with no options, Synthetics launches a browser with default arguments, `executablePath`, and `defaultViewport`. The default viewport in CloudWatch Synthetics is 1920 by 1080.

You can override launch parameters used by CloudWatch Synthetics and pass additional parameters when launching the browser. For example, the following code snippet launches a browser with default arguments and a default executable path, but with a viewport of 800 x 600.

```
await synthetics.launch({
        defaultViewport: {
            "deviceScaleFactor": 1,
            "width": 800,
            "height": 600
    }});
```

The following sample code adds a new `ignoreHTTPSErrors` parameter to the CloudWatch Synthetics launch parameters:

```
await synthetics.launch({
        ignoreHTTPSErrors: true
 });
```

You can disable web security by adding a `--disable-web-security` flag to args in the CloudWatch Synthetics launch parameters:

```
// This function adds the --disable-web-security flag to the launch parameters
const defaultOptions = await synthetics.getDefaultLaunchOptions();
const launchArgs = [...defaultOptions.args, '--disable-web-security'];
await synthetics.launch({
     args: launchArgs
  });
```

RequestResponseLogHelper class

Important

In canaries that use the `syn-nodejs-puppeteer-3.2` runtime or later, this class is deprecated. Any use of this class causes a warning to appear in your canary logs. This function will be removed in future runtime versions. If you are using this function, use [RequestResponseLogHelper class](#) instead.

Handles the fine-grained configuration and creation of string representations of request and response payloads.

```
class RequestResponseLogHelper {

    constructor () {
        this.request = {url: true, resourceType: false, method: false, headers: false,
 postData: false};
        this.response = {status: true, statusText: true, url: true, remoteAddress:
 false, headers: false};
    }

    withLogRequestUrl(logRequestUrl);

    withLogRequestResourceType(logRequestResourceType);

    withLogRequestMethod(logRequestMethod);

    withLogRequestHeaders(logRequestHeaders);

    withLogRequestPostData(logRequestPostData);

    withLogResponseStatus(logResponseStatus);

    withLogResponseStatusText(logResponseStatusText);

    withLogResponseUrl(logResponseUrl);

    withLogResponseRemoteAddress(logResponseRemoteAddress);

    withLogResponseHeaders(logResponseHeaders);
```

Example:

```
synthetics.setRequestResponseLogHelper(getRequestResponseLogHelper()
.withLogRequestPostData(true)
.withLogRequestHeaders(true)
```

```
.withLogResponseHeaders(true));
```

Response:

```
{RequestResponseLogHelper}
```

setRequestResponseLogHelper();

> **Important**
>
> In canaries that use the `syn-nodejs-puppeteer-3.2` runtime or later, this function is deprecated along with the `RequestResponseLogHelper` class. Any use of this function causes a warning to appear in your canary logs. This function will be removed in future runtime versions. If you are using this function, use RequestResponseLogHelper class instead.

Use this function as a builder pattern for setting the request and response logging flags.

Example:

```
synthetics.setRequestResponseLogHelper().withLogRequestHeaders(true).withLogResponseHeaders(tru
```

Response:

```
{RequestResponseLogHelper}
```

async takeScreenshot(name, suffix);

Takes a screenshot (.PNG) of the current page with name and suffix (optional).

Example:

```
await synthetics.takeScreenshot("navigateToUrl", "loaded")
```

This example captures and uploads a screenshot named `01-navigateToUrl-loaded.png` to the canary's S3 bucket.

You can take a screenshot for a particular canary step by passing the `stepName` as the first parameter. Screenshots are linked to the canary step in your reports, to help you track each step while debugging.

CloudWatch Synthetics canaries automatically take screenshots before starting a step (the `executeStep` function) and after the step completion (unless you configure the canary to disable screenshots). You can take more screenshots by passing in the step name in the `takeScreenshot` function.

The following example takes screenshot with the `signupForm` as the value of the `stepName`. The screenshot will be named `02-signupForm-address` and will be linked to the step named `signupForm` in the canary report.

```
await synthetics.takeScreenshot('signupForm', 'address')
```

BrokenLinkCheckerReport class

This class provides methods to add a synthetics link. It's supported only on canaries that use the `syn-nodejs-2.0-beta` version of the runtime or later.

To use `BrokenLinkCheckerReport`, include the following lines in the script:

```
const BrokenLinkCheckerReport = require('BrokenLinkCheckerReport');

const brokenLinkCheckerReport = new BrokenLinkCheckerReport();
```

Useful function definitions:

addLink(*syntheticsLink*, isBroken)

`syntheticsLink` is a `SyntheticsLink` object representing a link. This function adds the link according to the status code. By default, it considers a link to be broken if the status code is not available or the status code is 400 or higher. You can override this default behavior by passing in the optional parameter `isBrokenLink` with a value of `true` or `false`.

This function does not have a return value.

getLinks()

This function returns an array of `SyntheticsLink` objects that are included in the broken link checker report.

getTotalBrokenLinks()

This function returns a number representing the total number of broken links.

getTotalLinksChecked()

This function returns a number representing the total number of links included in the report.

How to use BrokenLinkCheckerReport

The following canary script code snippet demonstrates an example of navigating to a link and adding it to the broken link checker report.

1. Import `SyntheticsLink`, `BrokenLinkCheckerReport`, and `Synthetics`.

```
const BrokenLinkCheckerReport = require('BrokenLinkCheckerReport');
const SyntheticsLink = require('SyntheticsLink');

// Synthetics dependency
const synthetics = require('Synthetics');
```

2. To add a link to the report, create an instance of `BrokenLinkCheckerReport`.

```
let brokenLinkCheckerReport = new BrokenLinkCheckerReport();
```

3. Navigate to the URL and add it to the broken link checker report.

```
let url = "https://amazon.com";

let syntheticsLink = new SyntheticsLink(url);

// Navigate to the url.
let page = await synthetics.getPage();

// Create a new instance of Synthetics Link
let link = new SyntheticsLink(url)

try {
    const response = await page.goto(url, {waitUntil: 'domcontentloaded', timeout:
 30000});
} catch (ex) {
    // Add failure reason if navigation fails.
    link.withFailureReason(ex);
```

```
}

if (response) {
    // Capture screenshot of destination page
    let screenshotResult = await synthetics.takeScreenshot('amazon-home', 'loaded');

    // Add screenshot result to synthetics link
    link.addScreenshotResult(screenshotResult);

    // Add status code and status description to the link
    link.withStatusCode(response.status()).withStatusText(response.statusText())
}

// Add link to broken link checker report.
brokenLinkCheckerReport.addLink(link);
```

4. Add the report to Synthetics. This creates a JSON file named `BrokenLinkCheckerReport.json` in your S3 bucket for each canary run. You can see a links report in the console for each canary run along with screenshots, logs, and HAR files.

```
await synthetics.addReport(brokenLinkCheckerReport);
```

SyntheticsLink class

This class provides methods to wrap information. It's supported only on canaries that use the `syn-nodejs-2.0-beta` version of the runtime or later.

To use `SyntheticsLink`, include the following lines in the script:

```
const SyntheticsLink = require('SyntheticsLink');

const syntheticsLink = new SyntheticsLink("https://www.amazon.com");
```

This function returns `syntheticsLink`*`Object`*

Useful function definitions:

withUrl(*`url`*)

`url` is a URL string. This function returns `syntheticsLink`*`Object`*

withText(*`text`*)

text is a string representing anchor text. This function returns syntheticsLink*Object*. It adds anchor text corresponding to the link.

withParentUrl(*parentUrl*)

parentUrl is a string representing the parent (source page) URL. This function returns syntheticsLink*Object*

withStatusCode(*statusCode*)

statusCode is a string representing the status code. This function returns syntheticsLink*Object*

withFailureReason(*failureReason*)

failureReason is a string representing the failure reason. This function returns syntheticsLink*Object*

addScreenshotResult(*screenshotResult*)

screenshotResult is an object. It is an instance of ScreenshotResult that was returned by the Synthetics function takeScreenshot. The object includes the following:

- fileName— A string representing the screenshotFileName
- pageUrl (optional)
- error (optional)

Node.js library classes and functions that apply to API canaries only

The following CloudWatch Synthetics library functions for Node.js are useful only for API canaries.

Topics

- executeHttpStep(stepName, requestOptions, [callback], [stepConfig])

executeHttpStep(stepName, requestOptions, [callback], [stepConfig])

Executes the provided HTTP request as a step, and publishes SuccessPercent (pass/fail) and Duration metrics.

executeHttpStep uses either HTTP or HTTPS native functions under the hood, depending upon the protocol specified in the request.

This function also adds a step execution summary to the canary's report. The summary includes details about each HTTP request, such as the following:

- Start time
- End time
- Status (PASSED/FAILED)
- Failure reason, if it failed
- HTTP call details such as request/response headers, body, status code, status message, and performance timings.

Topics

Parameters

stepName(*String*)

Specifies the name of the step. This name is also used for publishing CloudWatch metrics for this step.

requestOptions(*Object or String*)

The value of this parameter can be a URL, a URL string, or an object. If it is an object, then it must be a set of configurable options to make an HTTP request. It supports all options in http.request(options[, callback]) in the Node.js documentation.

In addition to these Node.js options, **requestOptions** supports the additional parameter body. You can use the body parameter to pass data as a request body.

callback(*response*)

(Optional) This is a user function which is invoked with the HTTP response. The response is of the type Class: http.IncomingMessage.

stepConfig(*object*)

(Optional) Use this parameter to override global synthetics configurations with a different configuration for this step.

Examples of using executeHttpStep

The following series of examples build on each other to illustrate the various uses of this option.

This first example configures request parameters. You can pass a URL as **requestOptions**:

```
let requestOptions = 'https://www.amazon.com';
```

Or you can pass a set of options:

```
let requestOptions = {
        'hostname': 'myproductsEndpoint.com',
        'method': 'GET',
        'path': '/test/product/validProductName',
        'port': 443,
        'protocol': 'https:'
    };
```

The next example creates a callback function which accepts a response. By default, if you do not specify **callback**, CloudWatch Synthetics validates that the status is between 200 and 299 inclusive.

```
// Handle validation for positive scenario
    const callback = async function(res) {
        return new Promise((resolve, reject) => {
            if (res.statusCode < 200 || res.statusCode > 299) {
                throw res.statusCode + ' ' + res.statusMessage;
            }

            let responseBody = '';
            res.on('data', (d) => {
                responseBody += d;
            });

            res.on('end', () => {
                // Add validation on 'responseBody' here if required. For ex, your
 status code is 200 but data might be empty
                resolve();
            });
        });
    };
```

The next example creates a configuration for this step that overrides the global CloudWatch Synthetics configuration. The step configuration in this example allows request headers, response headers, request body (post data), and response body in your report and restrict 'X-Amz-Security-Token' and 'Authorization' header values. By default, these values are not included in the report for security reasons. If you choose to include them, the data is only stored in your S3 bucket.

```
// By default headers, post data, and response body are not included in the report for
 security reasons.
// Change the configuration at global level or add as step configuration for individual
 steps
let stepConfig = {
    includeRequestHeaders: true,
    includeResponseHeaders: true,
    restrictedHeaders: ['X-Amz-Security-Token', 'Authorization'], // Restricted header
 values do not appear in report generated.
    includeRequestBody: true,
    includeResponseBody: true
};
```

This final example passes your request to **executeHttpStep** and names the step.

```
await synthetics.executeHttpStep('Verify GET products API', requestOptions, callback,
 stepConfig);
```

With this set of examples, CloudWatch Synthetics adds the details from each step in your report and produces metrics for each step using **stepName**.

You will see `successPercent` and `duration` metrics for the `Verify GET products API` step. You can monitor your API performance by monitoring the metrics for your API call steps.

For a sample complete script that uses these functions, see Multi-step API canary.

Library functions available for Python canary scripts using Selenium

This section lists the Selenium library functions available for Python canary scripts.

Topics

- Python and Selenium library classes and functions that apply to all canaries
- Python and Selenium library classes and functions that apply to UI canaries only

Python and Selenium library classes and functions that apply to all canaries

The following CloudWatch Synthetics Selenium library functions for Python are useful for all canaries.

Topics

- SyntheticsConfiguration class
- SyntheticsLogger class

SyntheticsConfiguration class

You can use the SyntheticsConfiguration class to configure the behavior of Synthetics library functions. For example, you can use this class to configure the `executeStep()` function to not capture screenshots.

You can set CloudWatch Synthetics configurations at the global level.

Function definitions:

set_config(options)

```
from aws_synthetics.common import synthetics_configuration
```

`options` is an object, which is a set of configurable options for your canary. The following sections explain the possible fields in *`options`*.

- `screenshot_on_step_start` (boolean)— Whether to take a screenshot before starting a step.
- `screenshot_on_step_success` (boolean)— Whether to take a screenshot after completing a successful step.
- `screenshot_on_step_failure` (boolean)— Whether to take a screenshot after a step fails.

with_screenshot_on_step_start(screenshot_on_step_start)

Accepts a Boolean argument, which indicates whether to take a screenshot before starting a step.

with_screenshot_on_step_success(screenshot_on_step_success)

Accepts a Boolean argument, which indicates whether to take a screenshot after completing a step successfully.

with_screenshot_on_step_failure(screenshot_on_step_failure)

Accepts a Boolean argument, which indicates whether to take a screenshot after a step fails.

get_screenshot_on_step_start()

Returns whether to take a screenshot before starting a step.

get_screenshot_on_step_success()

Returns whether to take a screenshot after completing a step successfully.

get_screenshot_on_step_failure()

Returns whether to take a screenshot after a step fails.

disable_step_screenshots()

Disables all screenshot options (get_screenshot_on_step_start, get_screenshot_on_step_success, and get_screenshot_on_step_failure).

enable_step_screenshots()

Enables all screenshot options (get_screenshot_on_step_start, get_screenshot_on_step_success, and get_screenshot_on_step_failure). By default, all these methods are enabled.

setConfig(options) regarding CloudWatch metrics

For canaries using `syn-python-selenium-1.1` or later, the **(options)** for **setConfig** can include the following Boolean parameters that determine which metrics are published by the canary. The default for each of these options is `true`. The options that start with `aggregated` determine whether the metric is emitted without the `CanaryName` dimension. You can use these metrics to see the aggregated results for all of your canaries. The other options determine whether the metric is emitted with the `CanaryName` dimension. You can use these metrics to see results for each individual canary.

For a list of CloudWatch metrics emitted by canaries, see CloudWatch metrics published by canaries.

- `failed_canary_metric` (boolean)— Whether to emit the `Failed` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `failed_requests_metric` (boolean)— Whether to emit the `Failed requests` metric (with the `CanaryName` dimension) for this canary. The default is `true`.

- `2xx_metric` (boolean)— Whether to emit the `2xx` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `4xx_metric` (boolean)— Whether to emit the `4xx` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `5xx_metric` (boolean)— Whether to emit the `5xx` metric (with the `CanaryName` dimension) for this canary. The default is `true`.
- `step_duration_metric` (boolean)— Whether to emit the `Step duration` metric (with the `CanaryName` `StepName` dimensions) for this canary. The default is `true`.
- `step_success_metric` (boolean)— Whether to emit the `Step success` metric (with the `CanaryName` `StepName` dimensions) for this canary. The default is `true`.
- `aggregated_failed_canary_metric` (boolean)— Whether to emit the `Failed` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregated_failed_requests_metric` (boolean)— Whether to emit the `Failed Requests` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregated_2xx_metric` (boolean)— Whether to emit the `2xx` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregated_4xx_metric` (boolean)— Whether to emit the `4xx` metric (without the `CanaryName` dimension) for this canary. The default is `true`.
- `aggregated_5xx_metric` (boolean)— Whether to emit the `5xx` metric (without the `CanaryName` dimension) for this canary. The default is `true`.

with_2xx_metric(2xx_metric)

Accepts a Boolean argument, which specifies whether to emit a `2xx` metric with the `CanaryName` dimension for this canary.

with_4xx_metric(4xx_metric)

Accepts a Boolean argument, which specifies whether to emit a `4xx` metric with the `CanaryName` dimension for this canary.

with_5xx_metric(5xx_metric)

Accepts a Boolean argument, which specifies whether to emit a `5xx` metric with the `CanaryName` dimension for this canary.

withAggregated2xxMetric(aggregated2xxMetric)

Accepts a Boolean argument, which specifies whether to emit a `2xx` metric with no dimension for this canary.

withAggregated4xxMetric(aggregated4xxMetric)

Accepts a Boolean argument, which specifies whether to emit a `4xx` metric with no dimension for this canary.

with_aggregated_5xx_metric(aggregated_5xx_metric)

Accepts a Boolean argument, which specifies whether to emit a `5xx` metric with no dimension for this canary.

with_aggregated_failed_canary_metric(aggregated_failed_canary_metric)

Accepts a Boolean argument, which specifies whether to emit a `Failed` metric with no dimension for this canary.

with_aggregated_failed_requests_metric(aggregated_failed_requests_metric)

Accepts a Boolean argument, which specifies whether to emit a `Failed requests` metric with no dimension for this canary.

with_failed_canary_metric(failed_canary_metric)

Accepts a Boolean argument, which specifies whether to emit a `Failed` metric with the `CanaryName` dimension for this canary.

with_failed_requests_metric(failed_requests_metric)

Accepts a Boolean argument, which specifies whether to emit a `Failed requests` metric with the `CanaryName` dimension for this canary.

with_step_duration_metric(step_duration_metric)

Accepts a Boolean argument, which specifies whether to emit a `Duration` metric with the `CanaryName` dimension for this canary.

with_step_success_metric(step_success_metric)

Accepts a Boolean argument, which specifies whether to emit a `StepSuccess` metric with the `CanaryName` dimension for this canary.

Methods to enable or disable metrics

disable_aggregated_request_metrics()

Disables the canary from emitting all request metrics that are emitted with no `CanaryName` dimension.

disable_request_metrics()

Disables all request metrics, including both per-canary metrics and metrics aggregated across all canaries.

disable_step_metrics()

Disables all step metrics, including both step success metrics and step duration metrics.

enable_aggregated_request_metrics()

Enables the canary to emit all request metrics that are emitted with no `CanaryName` dimension.

enable_request_metrics()

Enables all request metrics, including both per-canary metrics and metrics aggregated across all canaries.

enable_step_metrics()

Enables all step metrics, including both step success metrics and step duration metrics.

Usage in UI canaries

First, import the synthetics dependency and fetch the configuration. Then, set the configuration for each option by calling the setConfig method using one of the following options.

```
from aws_synthetics.common import synthetics_configuration

synthetics_configuration.set_config(
     {
        "screenshot_on_step_start": False,
        "screenshot_on_step_success": False,
        "screenshot_on_step_failure": True
     }
)
```

```
or
```

Or

```
synthetics_configuration.with_screenshot_on_step_start(False).with_screenshot_on_step_success(F
```

To disable all screenshots, use the disableStepScreenshots() function as in this example.

```
synthetics_configuration.disable_step_screenshots()
```

You can enable and disable screenshots at any point in the code. For example, to disable screenshots only for one step, disable them before running that step and then enable them after the step.

set_config(options) for UI canaries

Starting with `syn-python-selenium-1.1`, for UI canaries, `set_config` can include the following Boolean parameters:

- `continue_on_step_failure` (boolean)— Whether to continue with running the canary script after a step fails (this refers to the **executeStep** function). If any steps fail, the canary run will still be marked as failed. The default is `false`.

SyntheticsLogger class

`synthetics_logger` writes logs out to both the console and to a local log file at the same log level. This log file is written to both locations only if the log level is at or below the desired logging level of the log function that was called.

The logging statements in the local log file are prepended with "DEBUG: ", "INFO: ", and so on to match the log level of the function that was called.

Using `synthetics_logger` is not required to create a log file that is uploaded to your Amazon S3 results location. You could instead create a different log file in the `/tmp` folder. Any files created under the `/tmp` folder are uploaded to the results location in the S3 bucket as artifacts.

To use `synthetics_logger`:

```
from aws_synthetics.common import synthetics_logger
```

Useful function definitions:

Get log level:

```
log_level = synthetics_logger.get_level()
```

Set log level:

```
synthetics_logger.set_level()
```

Log a message with a specified level. The level can be `DEBUG`, `INFO`, `WARN`, or `ERROR`, as in the following syntax examples:

```
synthetics_logger.debug(message, *args, **kwargs)
```

```
synthetics_logger.info(message, *args, **kwargs)
```

```
synthetics_logger.log(message, *args, **kwargs)
```

```
synthetics_logger.warn(message, *args, **kwargs)
```

```
synthetics_logger.error(message, *args, **kwargs)
```

For information about debug parameters, see the standard Python documentation at logging.debug

In these logging functions, the `message` is the message format string. The `args` are the arguments that are merged into `msg` using the string formatting operator.

There are three keyword arguments in `kwargs`:

- `exc_info`– If not evaluated as false, adds exception information to the logging message.
- `stack_info`– defaults to false. If true, adds stack information to the logging message, including the actual logging call.
- `extra`– The third optional keyword argument, which you can use to pass in a dictionary that is used to populate the `__dict__` of the `LogRecord` created for the logging event with user-defined attributes.

Examples:

Log a message with the level DEBUG:

```
synthetics_logger.debug('Starting step - login.')
```

Log a message with the level INFO. `logger.log` is a synonym for `logger.info`:

```
synthetics_logger.info('Successfully completed step - login.')
```

or

```
synthetics_logger.log('Successfully completed step - login.')
```

Log a message with the level WARN:

```
synthetics_logger.warn('Warning encountered trying to publish %s', 'CloudWatch Metric')
```

Log a message with the level ERROR:

```
synthetics_logger.error('Error encountered trying to publish %s', 'CloudWatch Metric')
```

Log an exception:

```
synthetics_logger.exception(message, *args, **kwargs)
```

Logs a message with level ERROR. Exception information is added to the logging message. You should call this function only from an exception handler.

For information about exception parameters, see the standard Python documentation at logging.exception

The `message` is the message format string. The `args` are the arguments, which are merged into `msg` using the string formatting operator.

There are three keyword arguments in `kwargs`:

- `exc_info`– If not evaluated as false, adds exception information to the logging message.
- `stack_info`– defaults to false. If true, adds stack information to the logging message, including the actual logging call.

- `extra`– The third optional keyword argument, which you can use to pass in a dictionary that is used to populate the `__dict__` of the `LogRecord` created for the logging event with user-defined attributes.

Example:

```
synthetics_logger.exception('Error encountered trying to publish %s', 'CloudWatch
 Metric')
```

Python and Selenium library classes and functions that apply to UI canaries only

The following CloudWatch Synthetics Selenium library functions for Python are useful only for UI canaries.

Topics

- SyntheticsBrowser class
- SyntheticsWebDriver class

SyntheticsBrowser class

When you create a browser instance by calling `synthetics_webdriver.Chrome()`, the returned browser instance is of the type `SyntheticsBrowser`. The `SyntheticsBrowser` class controls the ChromeDriver, and enables the canary script to drive the browser, allowing the Selenium WebDriver to work with Synthetics.

In addition to the standard Selenium methods, it also provides the following methods.

Topics

- set_viewport_size(width, height)
- save_screenshot(filename, suffix)

set_viewport_size(width, height)

Sets the viewport of the browser. Example:

```
browser.set_viewport_size(1920, 1080)
```

save_screenshot(filename, suffix)

Saves screenshots to the `/tmp` directory. The screenshots are uploaded from there to the canary artifacts folder in the S3 bucket.

filename is the file name for the screenshot, and *suffix* is an optional string to be used for naming the screenshot.

Example:

```
browser.save_screenshot('loaded.png', 'page1')
```

SyntheticsWebDriver class

To use this class, use the following in your script:

```
from aws_synthetics.selenium import synthetics_webdriver
```

Topics

add_execution_error(errorMessage, ex);

`errorMessage` describes the error and `ex` is the exception that is encountered

You can use `add_execution_error` to set execution errors for your canary. It fails the canary without interrupting the script execution. It also doesn't impact your `successPercent` metrics.

You should track errors as execution errors only if they are not important to indicate the success or failure of your canary script.

An example of the use of `add_execution_error` is the following. You are monitoring the availability of your endpoint and taking screenshots after the page has loaded. Because the failure of taking a screenshot doesn't determine availability of the endpoint, you can catch any errors encountered while taking screenshots and add them as execution errors. Your availability metrics will still indicate that the endpoint is up and running, but your canary status will be marked as failed. The following sample code block catches such an error and adds it as an execution error.

```
try:
    browser.save_screenshot("loaded.png")
except Exception as ex:
   self.add_execution_error("Unable to take screenshot", ex)
```

add_user_agent(user_agent_str)

Appends the value of `user_agent_str` to the browser's user agent header. You must assign `user_agent_str` before creating the browser instance.

Example:

```
synthetics_webdriver.add_user_agent('MyApp-1.0')
```

execute_step(step_name, function_to_execute)

Processes one function. It also does the following:

- Logs that the step started.
- Takes a screenshot named `<stepName>-starting`.
- Starts a timer.
- Executes the provided function.
- If the function returns normally, it counts as passing. If the function throws, it counts as failing.
- Ends the timer.
- Logs whether the step passed or failed
- Takes a screenshot named `<stepName>-succeeded` or `<stepName>-failed`.
- Emits the `stepName` `SuccessPercent` metric, 100 for pass or 0 for failure.
- Emits the `stepName` `Duration` metric, with a value based on the step start and end times.
- Finally, returns what the `functionToExecute` returned or re-throws what `functionToExecute` threw.

Example:

```
from selenium.webdriver.common.by import By
```

```
def custom_actions():
        #verify contains
        browser.find_element(By.XPATH, "//*[@id=\"id_1\"][contains(text(),'login')]")
        #click a button
        browser.find_element(By.XPATH, '//*[@id="submit"]/a').click()

    await synthetics_webdriver.execute_step("verify_click", custom_actions)
```

get_http_response(url)

Makes an HTTP request to the provided URL and returns the response code of the HTTP request. If an exception occurred during the HTTP request, a string with value "error" is returned instead.

Example:

```
response_code = syn_webdriver.get_http_response(url)
if not response_code or response_code == "error" or response_code < 200 or
 response_code > 299:
    raise Exception("Failed to load page!")
```

Chrome()

Launches an instance of the Chromium browser and returns the created instance of the browser.

Example:

```
browser = synthetics_webdriver.Chrome()
browser.get("https://example.com/)
```

To launch a browser in incognito mode, use the following:

```
add_argument('—incognito')
```

To add proxy settings, use the following:

```
add_argument('--proxy-server=%s' % PROXY)
```

Example:

```
from selenium.webdriver.chrome.options import Options
chrome_options = Options()
```

```
chrome_options.add_argument("——incognito")
browser = syn_webdriver.Chrome(chrome_options=chrome_options)
```

Scheduling canary runs using cron

Using a cron expression gives you flexibility when you schedule a canary. Cron expressions contain five or six fields in the order listed in the following table. The fields are separated by spaces. The syntax differs depending on whether you are using the CloudWatch console to create the canary, or the Amazon CLI or Amazon SDKs. When you use the console, you specify only the first five fields. When you use the Amazon CLI or Amazon SDKs, you specify all six fields, and you must specify * for the `Year` field.

Field	Allowed values	Allowed special characters
Minutes	0-59	, - * /
Hours	0-23	, - * /
Day-of-month	1-31	, - * ? / L W
Month	1-12 or JAN-DEC	, - * /
Day-of-week	1-7 or SUN-SAT	, - * ? L #
Year	*	

Special characters

- The **,** (comma) includes multiple values in the expression for a field. For example, in the Month field, JAN,FEB,MAR would include January, February, and March.
- The **-** (dash) special character specifies ranges. In the Day field, 1-15 would include days 1 through 15 of the specified month.
- The ***** (asterisk) special character includes all values in the field. In the Hours field, ***** includes every hour. You cannot use ***** in both the Day-of-month and Day-of-week fields in the same expression. If you use it in one, you must use **?** in the other.
- The **/** (forward slash) specifies increments. In the Minutes field, you can enter 1/10 to specify every tenth minute, starting from the first minute of the hour (for example, the eleventh, twenty-first, and thirty-first minute, and so on).

- The **?** (question mark) specifies one or another. If you enter **7** in the Day-of-month field and you don't care what day of the week the seventh is, you can enter **?** in the Day-of-week field.
- The **L** wildcard in the Day-of-month or Day-of-week fields specifies the last day of the month or week.
- The **W** wildcard in the Day-of-month field specifies a weekday. In the Day-of-month field, **3W** specifies the weekday closest to the third day of the month.
- The **#** wildcard in the Day-of-week field specifies a certain instance of the specified day of the week within a month. For example, 3#2 is the second Tuesday of the month. The 3 refers to Tuesday because it is the third day of each week, and the 2 refers to the second day of that type within the month.

Limitations

- You can't specify the Day-of-month and Day-of-week fields in the same cron expression. If you specify a value or `*` (asterisk) in one of the fields, you must use a **?** (question mark) in the other.
- Cron expressions that lead to rates faster than one minute are not supported.
- You can't set a canary to wait for more than a year before running, so you can specify only `*` in the `Year` field.

Examples

You can refer to the following sample cron strings when you create a canary. The following examples are the correct syntax for using the Amazon CLI or Amazon SDKs to create or update a canary. If you are using the CloudWatch console, omit the final `*` in each example.

Expression	Meaning
`0 10 * * ? *`	Run at 10:00 am (UTC) every day
`15 12 * * ? *`	Run at 12:15 pm (UTC) every day
`0 18 ? * MON-FRI *`	Run at 6:00 pm (UTC) every Monday through Friday
`0 8 1 * ? *`	Run at 8:00 am (UTC) on the first day of each month
`0/10 * ? * MON-SAT *`	Run every 10 minutes Monday through Saturday of each week

Expression	Meaning
`0/5 8-17 ? * MON-FRI *`	Run every five minutes Monday through Friday between 8:00 am and 5:55 pm (UTC)

Configuring your canary to retry automatically

When you create or update a canary, you can configure your canaries to automatically attempt additional runs when the scheduled one fails. This helps differentiate between genuine failures and temporary glitches, providing more reliable results. This feature is ideal for building more resilient monitoring systems while reducing false alarms and manual intervention.

To create a auto retry canary

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Synthetics Canaries**.
3. Choose **Create Canary**.
4. Under **Additional configuration**, **Auto-retry,** select the desired maximum retry number.

To update the maximum retry number for a canary

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Synthetics Canaries**.
3. You can do one of the following:
   - Select the canary and choose **Actions**, **Enable auto-retry**, and adjust the maximum retries.
   - Select the canary and choose **Actions**, **Edit**. In the **Edit detail** page, under **Additional configuration**, **Auto-retry**, adjust the retry configuration.

Limitations

Here are the limitations to configure auto retry.

- Supported only on runtime versions `syn-nodejs-puppeteer-10.0` or newer, `syn-nodejs-playwright-2.0` or newer, or `syn-python-selenium-5.1` or newer

- Long running canaries which timeout after ten minutes are limited to one retry. All other canaries can support upto two retries

Groups

You can create *groups* to associate canaries with each other, including cross-Region canaries. Using groups can help you with managing and automating your canaries, and you can also view aggregated run results and statistics for all canaries in a group.

Groups are global resources. When you create a group, it is replicated across all Amazon Regions that support groups, and you can add canaries from any of these Regions to it, and view it in any of these Regions. Although the group ARN format reflects the Region name where it was created, a group is not constrained to any Region. This means that you can put canaries from multiple Regions into the same group, and then use that group to view and manage all of those canaries in a single view.

Groups are supported in all Regions except the Regions that are disabled by default. For more information about these Regions, see Enabling a Region .

Each group can contain as many as 10 canaries. You can have as many as 20 groups in your account. Any single canary can be a member of up to 10 groups.

To create a group

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Synthetics Canaries**.
3. Choose **Create Group**.
4. Under **Group Name**, enter a name for the group.
5. Select canaries to associate with this group. To select a canary, type its complete name in **Exact canary name** and choose **Search**. Then select the check box next to the canary name. If there are multiple canaries with the same name in different Regions, be sure to select the canaries that you want.

   You can repeat this step to associate as many as 10 canaries with the group.
6. (Optional) Under **Tags**, add one or more key-value pairs as tags for this group. Tags can help you identify and organize your Amazon resources and track your Amazon costs. For more information, see Tagging your Amazon CloudWatch resources.

7. Choose **Create Group**.

Test a canary locally

This section explains how to modify, test, and debug CloudWatch Synthetics canaries directly within the Microsoft Visual Studio code editor or the JetBrains IDE code editor. The local debugging environment uses a Serverless Application Model (SAM) container to simulate a Lambda function to emulate the behavior of a Synthetics canary.

> **Note**
>
> It is impractical to perform locally debug canaries that rely on visual monitoring. Visual monitoring rely on capturing base screenshots during an initial run, and then comparing these screenshots to the screenshots from subsequent runs. In a local development environment, runs are not stored or tracked, and each iteration is an independent, standalone run. The absence of a canary run history makes it impractical to debug canaries that rely on visual monitoring.

Prerequisites

1. Choose or create an Amazon S3 bucket to use to store artifacts from local canary test runs, such as HAR files and screenshots. This requires you to be provisioned with IAM. If you skip setting up Amazon S3 buckets you can still test your canary locally, but you will see an error message about the missing bucket and you won't have access to canary artifacts.

   If you use an Amazon S3 bucket, we recommend that you set the bucket lifecycle to delete objects after a few days, to save costs. For more information, see Managing your storage lifecycle.
2. Set up a default Amazon profile for your Amazon account. For more information, see Configuration and credential file settings.
3. Set the debug environment's default Amazon Region to your preferred Region, such as `us-west-2`.
4. Install the Amazon SAM CLI. For more information, see Installing the Amazon SAM CLI.
5. Install Visual Studio Code Editor or JetBrains IDE. For more information, see Visual Studio Code or JetBrains IDE

6. Install Docker to work with the Amazon SAM CLI. Make sure to start the docker daemon. For more information, see Installing Docker to use with the Amazon SAM CLI.

   Alternatively, You can install other container management software such as Rancher, as long as it uses the Docker runtime.

7. Install an Amazon toolkit extension for your preferred editor. For more information, see Installing the Amazon Toolkit for Visual Studio Code or Installing the Amazon Toolkit for JetBrains.

Topics

Set up the testing and debugging environment

First, clone the Github repository that Amazon provides by entering the following command. The repository contains code samples for both Node.js canaries and Python canaries.

```
git clone https://github.com/aws-samples/synthetics-canary-local-debugging-sample.git
```

Then do one of the following, depending on the language of your canaries.

For Node.js canaries

1. Go to the Node.js canary source directory by entering the following command.

   ```
   cd synthetics-canary-local-debugging-sample/nodejs-canary/src
   ```

2. Enter the following command to install canary dependencies.

   ```
   npm install
   ```

For Python canaries

1. Go to the Python canary source directory by entering the following command.

```
cd synthetics-canary-local-debugging-sample/python-canary/src
```

2. Enter the following command to install canary dependencies.

```
pip3 install -r requirements.txt -t .
```

Use Visual Studio Code IDE

The Visual Studio launch configuration file is located at `.vscode/launch.json`. It contains configurations to allow the template file to be discovered by Visual Studio code. It defines a Lambda payload with required parameters to invoke the canary successfully. Here's the launch configuration for a Node.js canary:

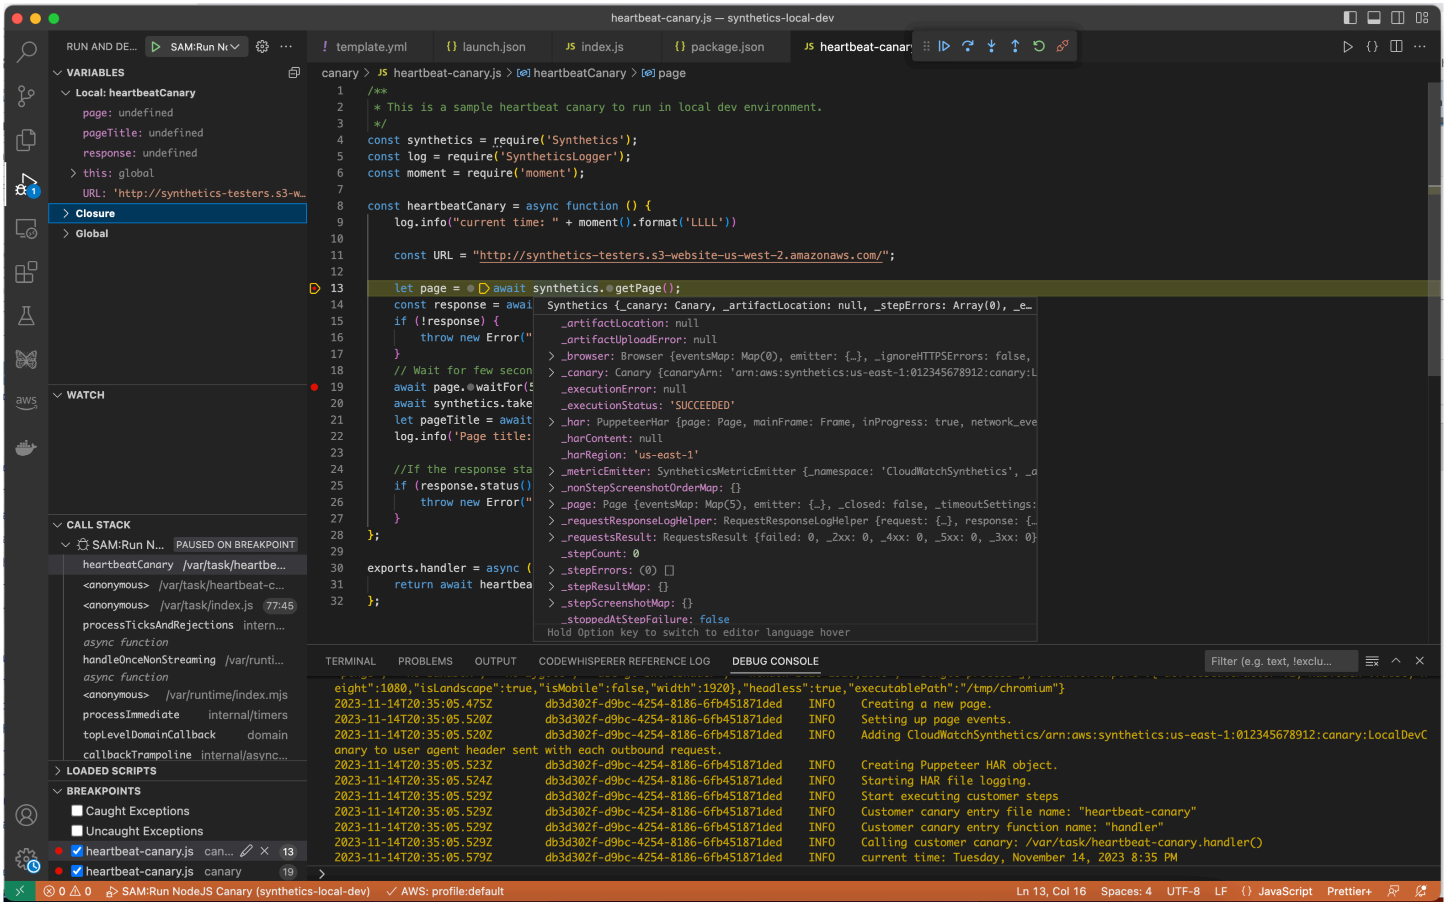
```
{
            ...
            ...
            "lambda": {
                "payload": {
                    "json": {
                        // Canary name. Provide any name you like.
                        "canaryName": "LocalSyntheticsCanary",
                        // Canary artifact location
                        "artifactS3Location": {
                            "s3Bucket": "cw-syn-results-123456789012-us-west-2",
                            "s3Key": "local-run-artifacts",
                        },
                        // Your canary handler name
                        "customerCanaryHandlerName": "heartbeat-canary.handler"
                    }
                },
                // Environment variables to pass to the canary code
                "environmentVariables": {}
            }
        }
    ]
}
```

You can also optionally provide the following fields in the payload JSON:

- `s3EncryptionMode` Valid values: `SSE_S3` | `SSE_KMS`
- `s3KmsKeyArn` Valid value: *`KMS Key ARN`*
- `activeTracing` Valid values: `true` | `false`
- `canaryRunId` Valid value: *`UUID`* This parameter is required if active tracing is enabled.

To debug the canary in Visual Studio, add breakpoints in the canary code where you want to pause execution. To add a breakpoint, choose the editor margin and go to **Run and Debug** mode in the editor. Run the canary by clicking on the play button. When the canary runs, the logs will be tailed in the debug console, providing you with real-time insights into the canary's behavior. If you added breakpoints, the canary execution will pause at each breakpoint, allowing you to step through code and inspect variable values, instance methods, object attributes, and the function call stack.

There is no cost incurred for running and debugging canaries locally, except for the artifacts stored in the Amazon S3 bucket and the CloudWatch metrics generated by each local run.



Use JetBrains IDE

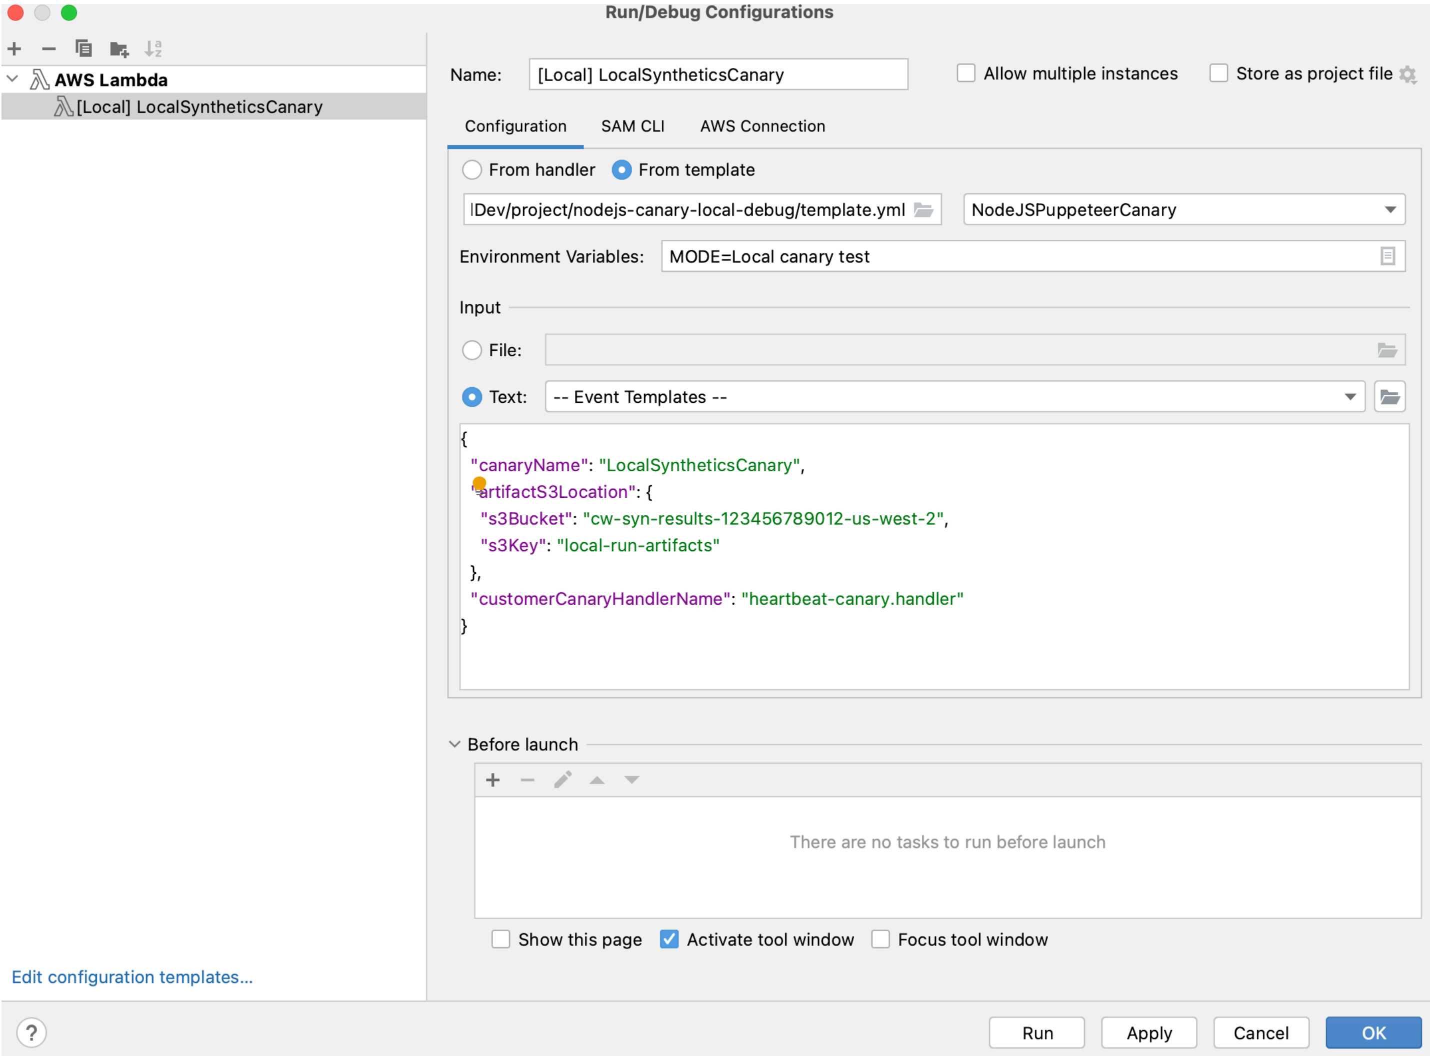
After you have the Amazon Toolkit for JetBrains extension installed, be sure that the Node.js plugin and JavaScript debugger are enabled to run, if you are debugging a Node.js canary. Then follow these steps.

Debug a canary using JetBrains IDE

1. In the left navigation pane of JetBrains IDE, choose **Lambda**, then choose the local configuration template.
2. Enter a name for the run configuration, such as **`LocalSyntheticsCanary`**
3. Choose **From template**, choose the file browser in the template field, then select the **template.yml** file from the project, either from the **nodejs** directory or the **python** directory.
4. In the **Input** section, enter the payload for the canary as shown in the following screen.

```
{
 "canaryName": "LocalSyntheticsCanary",
 "artifactS3Location": {
     "s3Bucket": "cw-syn-results-123456789012-us-west-2",
     "s3Key": "local-run-artifacts"
 },
 "customerCanaryHandlerName": "heartbeat-canary.handler"
}
```

   You can also set other environment variables in the payload JSON, as listed in Use Visual Studio Code IDE.



Run a canary locally with the SAM CLI

Use the one of the following procedures to run your canary locally using the Serverless Application Model (SAM) CLI. Be sure to specify your own Amazon S3 bucket name for `s3Bucket` in `event.json`

To use the SAM CLI to run a Node.js canary

1. Go to the source directory by entering the following command.

```
cd synthetics-canary-local-debugging-sample/nodejs-canary
```

2. Enter the following commands.

```
sam build
```

```
sam local invoke -e ../event.json
```

To use the SAM CLI to run a Python canary

1. Go to the source directory by entering the following command.

```
cd synthetics-canary-local-debugging-sample/python-canary
```

2. Enter the following commands.

```
sam build
sam local invoke -e ../event.json
```

Integrate your local testing environment into an existing canary package

You can integrate local canary debugging into your existing canary package by copying three files:

- Copy the `template.yml` file into your canary package root. Be sure to modify the path for `CodeUri` to point to the directory where your canary code exists.
- If you're working with a Node.js canary, copy the `cw-synthetics.js` file to your canary source directory. If you're working with a Python canary, copy the `cw-synthetics.py` to your canary source directory.
- Copy the launch configuration file `.vscode/launch.json` into the package root. Make sure to put it inside the `.vscode` directory; create it if it doesn't exist already.

Change the CloudWatch Synthetics runtime

As part of your debugging, you might want to try running a canary with a different CloudWatch Synthetics runtime, instead of the latest runtime. To do so, find the runtime that you want to use from one of the following tables. Be sure to select the runtime for the correct Region. Then paste the ARN for that runtime into the appropriate place in your `template.yml` file, and then run the canary.

Node.js and Puppeteer runtimes

ARNs for syn-nodejs-puppeteer-10.0

The following table lists the ARNs to use for version `syn-nodejs-puppeteer-10.0` of the CloudWatch Synthetics runtime in each Amazon Region where it is available.

Region	ARN
US East (N. Virginia)	`arn:aws:lambda:us-east-1:378653112637:layer:Synthetics:58`
US East (Ohio)	`arn:aws:lambda:us-east-2:772927465453:layer:Synthetics:61`
US West (N. California)	`arn:aws:lambda:us-west-1:332033056316:layer:Synthetics:59`
US West (Oregon)	`arn:aws:lambda:us-west-2:760325925879:layer:Synthetics:61`
Africa (Cape Town)	`arn:aws:lambda:af-south-1:461844272066:layer:Synthetics:59`
Asia Pacific (Hong Kong)	`arn:aws:lambda:ap-east-1:129828061636:layer:Synthetics:59`
Asia Pacific (Hyderabad)	`arn:aws:lambda:ap-south-2:280298676434:layer:Synthetics:34`
Asia Pacific (Jakarta)	`arn:aws:lambda:ap-southeast-3:246953257743:layer:Synthetics:41`
Asia Pacific (Malaysia)	`arn:aws:lambda:ap-southeast-5:035872523913:layer:Synthetics:15`
Asia Pacific (Melbourne)	`arn:aws:lambda:ap-southeast-4:200724813040:layer:Synthetics:32`

Region	ARN
Asia Pacific (Mumbai)	arn:aws:lambda:ap-south-1:724929286329:layer:Synthetics:59
Asia Pacific (Osaka)	arn:aws:lambda:ap-northeast-3:608016332111:layer:Synthetics:45
Asia Pacific (Seoul)	arn:aws:lambda:ap-northeast-2:989515803484:layer:Synthetics:62
Asia Pacific (Singapore)	arn:aws:lambda:ap-southeast-1:068035103298:layer:Synthetics:63
Asia Pacific (Sydney)	arn:aws:lambda:ap-southeast-2:584677157514:layer:Synthetics:58
Asia Pacific (Thailand)	arn:aws:lambda:ap-southeast-7:851725245975:layer:Synthetics:6
Asia Pacific (Tokyo)	arn:aws:lambda:ap-northeast-1:172291836251:layer:Synthetics:59
Canada (Central)	arn:aws:lambda:ca-central-1:236629016841:layer:Synthetics:59
Canada West (Calgary)	arn:aws:lambda:ca-west-1:944448206667:layer:Synthetics:90
China (Beijing)	arn:aws-cn:lambda:cn-north-1:422629156088:layer:Synthetics:58
China (Ningxia);	arn:aws-cn:lambda:cn-northwest-1:474974519687:layer:Synthetics:59
Europe (Frankfurt)	arn:aws:lambda:eu-central-1:122305336817:layer:Synthetics:59

Region	ARN
Europe (Ireland)	arn:aws:lambda:eu-west-1:563204233543:layer:Synthetics:60
Europe (London)	arn:aws:lambda:eu-west-2:565831452869:layer:Synthetics:58
Europe (Milan)	arn:aws:lambda:eu-south-1:525618516618:layer:Synthetics:60
Europe (Paris)	arn:aws:lambda:eu-west-3:469466506258:layer:Synthetics:59
Europe (Spain)	arn:aws:lambda:eu-south-2:029793053121:layer:Synthetics:34
Europe (Stockholm)	arn:aws:lambda:eu-north-1:162938142733:layer:Synthetics:59
Europe (Zurich)	arn:aws:lambda:eu-central-2:224218992030:layer:Synthetics:33
Israel (Tel Aviv)	arn:aws:lambda:il-central-1:313249807427:layer:Synthetics:31
Mexico (Central)	arn:aws:lambda:mx-central-1:654654265476:layer:Synthetics:7
Middle East (Bahrain)	arn:aws:lambda:me-south-1:823195537320:layer:Synthetics:58
Middle East (UAE)	arn:aws:lambda:me-central-1:239544149032:layer:Synthetics:34
South America (São Paulo)	arn:aws:lambda:sa-east-1:783765544751:layer:Synthetics:60

Region	ARN
Amazon GovCloud (US-East)	`arn:aws-us-gov:lambda:us-gov-east-1:946759330430:layer:Synthetics:54`
Amazon GovCloud (US-West)	`arn:aws-us-gov:lambda:us-gov-west-1:946807836238:layer:Synthetics:55`

ARNs for syn-nodejs-puppeteer-9.1

The following table lists the ARNs to use for version `syn-nodejs-puppeteer-9.1` of the CloudWatch Synthetics runtime in each Amazon Region where it is available.

Region	ARN
US East (N. Virginia)	`arn:aws:lambda:us-east-1:378653112637:layer:Synthetics:53`
US East (Ohio)	`arn:aws:lambda:us-east-2:772927465453:layer:Synthetics:56`
US West (N. California)	`arn:aws:lambda:us-west-1:332033056316:layer:Synthetics:54`
US West (Oregon)	`arn:aws:lambda:us-west-2:760325925879:layer:Synthetics:56`
Africa (Cape Town)	`arn:aws:lambda:af-south-1:461844272066:layer:Synthetics:54`
Asia Pacific (Hong Kong)	`arn:aws:lambda:ap-east-1:129828061636:layer:Synthetics:54`
Asia Pacific (Hyderabad)	`arn:aws:lambda:ap-south-2:280298676434:layer:Synthetics:29`
Asia Pacific (Jakarta)	`arn:aws:lambda:ap-southeast-3:246953257743:layer:Synthetics:36`

Region	ARN
Asia Pacific (Malaysia)	`arn:aws:lambda:ap-southeast-5:035872523913:layer:Synthetics:10`
Asia Pacific (Melbourne)	`arn:aws:lambda:ap-southeast-4:200724813040:layer:Synthetics:27`
Asia Pacific (Mumbai)	`arn:aws:lambda:ap-south-1:724929286329:layer:Synthetics:54`
Asia Pacific (Osaka)	`arn:aws:lambda:ap-northeast-3:608016332111:layer:Synthetics:40`
Asia Pacific (Seoul)	`arn:aws:lambda:ap-northeast-2:989515803484:layer:Synthetics:57`
Asia Pacific (Singapore)	`arn:aws:lambda:ap-southeast-1:068035103298:layer:Synthetics:58`
Asia Pacific (Sydney)	`arn:aws:lambda:ap-southeast-2:584677157514:layer:Synthetics:53`
Asia Pacific (Thailand)	`arn:aws:lambda:ap-southeast-7:851725245975:layer:Synthetics:1`
Asia Pacific (Tokyo)	`arn:aws:lambda:ap-northeast-1:172291836251:layer:Synthetics:54`
Canada (Central)	`arn:aws:lambda:ca-central-1:236629016841:layer:Synthetics:54`
Canada West (Calgary)	`arn:aws:lambda:ca-west-1:944448206667:layer:Synthetics:85`
China (Beijing)	`arn:aws-cn:lambda:cn-north-1:422629156088:layer:Synthetics:54`

Region	ARN
China (Ningxia);	`arn:aws-cn:lambda:cn-northwest-1:474974519687:layer:Synthetics:55`
Europe (Frankfurt)	`arn:aws:lambda:eu-central-1:122305336817:layer:Synthetics:54`
Europe (Ireland)	`arn:aws:lambda:eu-west-1:563204233543:layer:Synthetics:55`
Europe (London)	`arn:aws:lambda:eu-west-2:565831452869:layer:Synthetics:53`
Europe (Milan)	`arn:aws:lambda:eu-south-1:525618516618:layer:Synthetics:55`
Europe (Paris)	`arn:aws:lambda:eu-west-3:469466506258:layer:Synthetics:54`
Europe (Spain)	`arn:aws:lambda:eu-south-2:029793053121:layer:Synthetics:29`
Europe (Stockholm)	`arn:aws:lambda:eu-north-1:162938142733:layer:Synthetics:54`
Europe (Zurich)	`arn:aws:lambda:eu-central-2:224218992030:layer:Synthetics:28`
Israel (Tel Aviv)	`arn:aws:lambda:il-central-1:313249807427:layer:Synthetics:26`
Mexico (Central)	`arn:aws:lambda:mx-central-1:654654265476:layer:Synthetics:3`
Middle East (Bahrain)	`arn:aws:lambda:me-south-1:823195537320:layer:Synthetics:53`

Region	ARN
Middle East (UAE)	`arn:aws:lambda:me-central-1:239544149032:layer:Synthetics:29`
South America (São Paulo)	`arn:aws:lambda:sa-east-1:783765544751:layer:Synthetics:55`
Amazon GovCloud (US-East)	`arn:aws-us-gov:lambda:us-gov-east-1:946759330430:layer:Synthetics:50`
Amazon GovCloud (US-West)	`arn:aws-us-gov:lambda:us-gov-west-1:946807836238:layer:Synthetics:51`

ARNs for syn-nodejs-puppeteer-9.0

The following table lists the ARNs to use for version `syn-nodejs-puppeteer-9.0` of the CloudWatch Synthetics runtime in each Amazon Region where it is available.

Region	ARN
US East (N. Virginia)	`arn:aws:lambda:us-east-1:378653112637:layer:Synthetics:51`
US East (Ohio)	`arn:aws:lambda:us-east-2:772927465453:layer:Synthetics:54`
US West (N. California)	`arn:aws:lambda:us-west-1:332033056316:layer:Synthetics:52`
US West (Oregon)	`arn:aws:lambda:us-west-2:760325925879:layer:Synthetics:54`
Africa (Cape Town)	`arn:aws:lambda:af-south-1:461844272066:layer:Synthetics:52`
Asia Pacific (Hong Kong)	`arn:aws:lambda:ap-east-1:129828061636:layer:Synthetics:52`

Region	ARN
Asia Pacific (Hyderabad)	arn:aws:lambda:ap-south-2:280298676434:layer:Synthetics:27
Asia Pacific (Jakarta)	arn:aws:lambda:ap-southeast-3:246953257743:layer:Synthetics:34
Asia Pacific (Malaysia)	arn:aws:lambda:ap-southeast-5:035872523913:layer:Synthetics:8
Asia Pacific (Melbourne)	arn:aws:lambda:ap-southeast-4:200724813040:layer:Synthetics:25
Asia Pacific (Mumbai)	arn:aws:lambda:ap-south-1:724929286329:layer:Synthetics:52

Region	ARN
Amazon GovCloud (US-East)	`arn:aws-us-gov:lambda:us-gov-east-1:946759330430:layer:Synthetics:29`
Amazon GovCloud (US-West)	`arn:aws-us-gov:lambda:us-gov-west-1:946807836238:layer:Synthetics:29`

Common errors

Error: Running Amazon SAM projects locally requires Docker. Have you got it installed and running?

Make sure to start Docker on your computer.

SAM local invoke failed: An error occurred (ExpiredTokenException) when calling the GetLayerVersion operation: The security token included in the request is expired

Make sure that the Amazon default profile is set up.

More common errors

For more information about common errors with the SAM, see [Amazon SAM CLI troubleshooting](#).

Troubleshooting a failed canary

If your canary fails, check the following for troubleshooting.

General troubleshooting

- Use the canary details page to find more information. In the CloudWatch console, choose **Canaries** in the navigation pane and then choose the name of the canary to open the canary details page. In the **Availability** tab, check the **SuccessPercent** metric to see whether the problem is constant or intermittent.

  While still in the **Availability** tab, choose a failed data point to see screenshots, logs, and step reports (if available) for that failed run.

  If a step report is available because steps are part of your script, check to see which step has failed and see the associated screenshots to see the issue that your customers are seeing.

You can also check the HAR files to see if one or more requests are failing. You can dig deeper by using logs to drill down on failed requests and errors. Finally, you can compare these artifacts with the artifacts from a successful canary run to pinpoint the issue.

By default, CloudWatch Synthetics captures screenshots for each step in a UI canary. However, your script might be configured to disable screenshots. During debugging, you may want to enable screenshots again. Similarly, for API canaries you might want to see HTTP request and response headers and body during debugging. For information about how to include this data in the report, see executeHttpStep(stepName, requestOptions, [callback], [stepConfig]).

- If you had a recent deployment to your application, roll it back and then debug later.
- Connect to your endpoint manually to see if you can reproduce the same issue.

Topics

Canary fails after Lambda environment update

CloudWatch Synthetics canaries are implemented as Lambda functions in your account. These Lambda functions are subject to regular Lambda runtime updates containing security updates, bug fixes, and other improvements. Lambda strives to provide runtime updates that are backward-compatible with existing functions. However, as with software patching, there are rare cases in which a runtime update can negatively impact an existing function. If you believe your canary has been impacted by a Lambda runtime update, you can use the Lambda runtime management manual mode (in supported Regions) to temporarily roll back the Lambda runtime version. This keeps your canary function working and minimizes disruption, providing time to remedy the incompatibility before returning to the latest runtime version.

If your canary is failing after a Lambda runtime update, the best solution is to upgrade to one of the newest Synthetics runtimes. For more information about the latest runtimes, see Synthetics runtime versions.

As an alternative solution, in Regions where Lambda runtime management controls are available, you can revert a canary back to an older Lambda managed runtime, using manual mode for runtime management controls. You can set manual mode using either the Amazon CLI or by using the Lambda console, using the steps below in the following sections.

> **Warning**
>
> When you change the runtime settings to manual mode, your Lambda function won't receive automatic security updates until it is reverted back to Auto mode. During this period, your Lambda function might be susceptible to security vulnerabilities.

Prerequisites

- Install jq
- Install the latest version of the Amazon CLI. For more information, see Amazon CLI install and update instructions .

Step 1: Obtain the Lambda function ARN

Run the following command to retrieve the `EngineArn` field from the response. This `EngineArn` is the ARN of the Lambda function that is associated with the canary. You will use this ARN in the following steps.

```
aws synthetics get-canary --name my-canary | jq '.Canary.EngineArn'
```

Example output of `EngingArn`:

```
"arn:aws:lambda:us-west-2:123456789012:function:cwsyn-my-canary-dc5015c2-db17-4cb5-
afb1-EXAMPLE991:8"
```

Step 2: Obtain the last good Lambda runtime version ARN

To help understand whether your canary was impacted by a Lambda runtime update, check whether the date and time when the Lambda runtime version ARN changes in your logs appeared to the date and time when you saw impact to your canary. If they do not match, it is probably not a Lambda runtime update that is causing your issues.

If your canary is impacted by a Lambda runtime update, you must identify the ARN of the working Lambda runtime version that you were previously using. Follow the instructions in Identifying runtime version changes to find the ARN of the previous runtime. Record the runtime version ARN, and continue to Step 3. for setting the runtime management configuration.

If your canary has not yet been impacted by a Lambda environment update, then you can find the ARN of the Lambda runtime version that you are currently using. Run the following command to retrieve the `RuntimeVersionArn` of the Lambda function from the response.

```
aws lambda get-function-configuration \
--function-name "arn:aws:lambda:us-west-2:123456789012:function:cwsyn-my-canary-
dc5015c2-db17-4cb5-afb1-EXAMPLE991:8" | jq '.RuntimeVersionConfig.RuntimeVersionArn'
```

Example output of `RuntimeVersionArn`:

```
"arn:aws:lambda:us-
west-2::runtime:EXAMPLE647b82f490a45d7ddd96b557b916a30128d9dcab5f4972911ec0f"
```

Step 3: Updating the Lambda runtime management configuration

You can use either the Amazon CLI or the Lambda console to update the runtime management configuration.

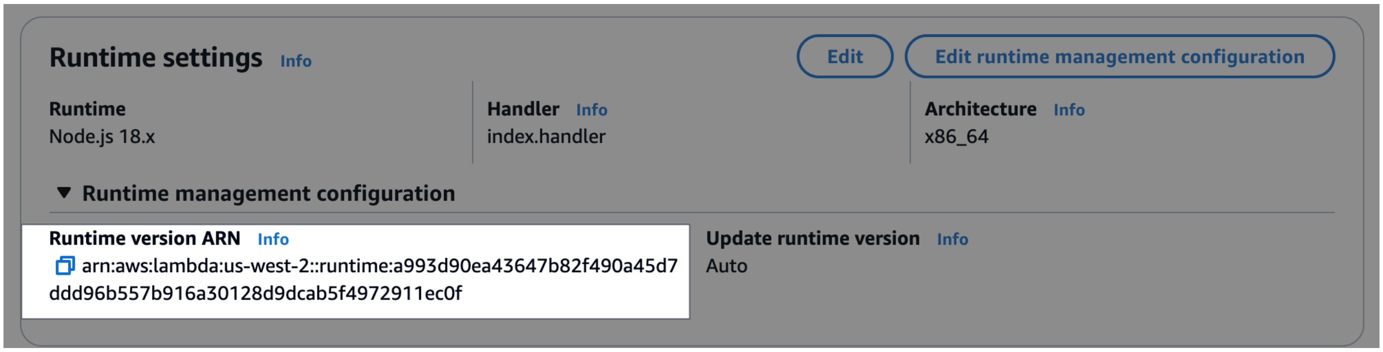
To set Lambda runtime management configuration manual mode using the Amazon CLI

Enter the following command to change the runtime management of the Lambda function to manual mode. Be sure to replace the *`function-name`* and *`qualifier`* with the Lambda function ARN and Lambda function version number respectively, using the values you found in Step 1. Also replace the the *`runtime-version-arn`* with the version ARN that you found in Step 2.

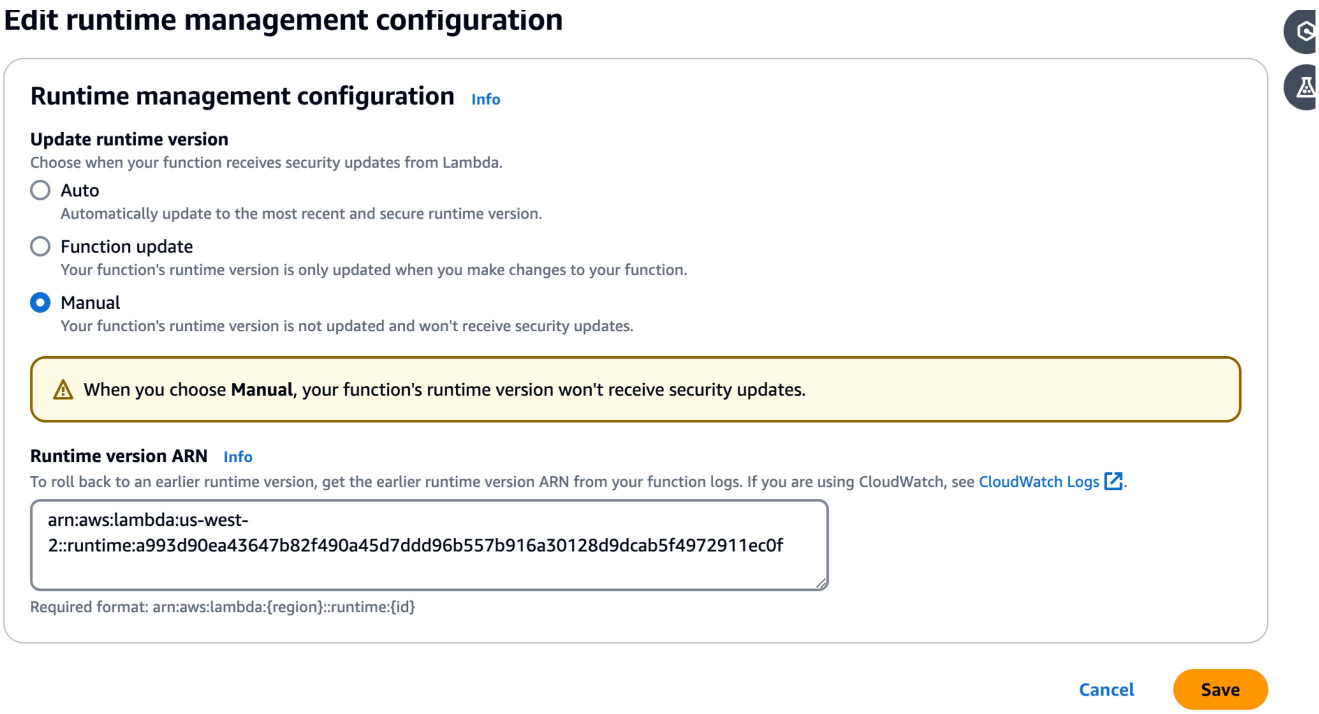
```
aws lambda put-runtime-management-config \
    --function-name "arn:aws:lambda:us-west-2:123456789012:function:cwsyn-my-canary-dc5015c2-db17-4cb5-afb1-EXAMPLE991" \
    --qualifier 8 \
    --update-runtime-on "Manual" \
    --runtime-version-arn "arn:aws:lambda:us-west-2::runtime:a993d90ea43647b82f490a45d7ddd96b557b916a30128d9dcab5f4972911ec0f"
```

To change a canary to manual mode using the Lambda console

1. Open the Amazon Lambda console at https://console.amazonaws.cn/lambda/.
2. Choose the **Versions** tab, choose the version number link that corresponds to your ARN, and choose the **Code** tab.
3. Scroll down to **Runtime settings**, expand **Runtime management configuration**, and copy the the **Runtime version ARN**.



4. Choose **Edit runtime management configuration**, choose **Manual**, paste the runtime version ARN that you copied earlier into the **Runtime version ARN** field. Then choose **Save**.



My canary is blocked by Amazon WAF

To allow canary traffic through Amazon WAF,create a Amazon WAF string match condition that allows a custom string that you specify. For more information, see Working with string match conditions in the Amazon WAF documentation.

We strongly recommend that you use your own custom user-agent string instead of using default values. This provides better control over Amazon WAF filtering and improves security.

To set a custom user-agent string, do the following:

- For Playwright runtimes, you can append your Amazon WAF approved custom user-agent string using the Synthetics configuration file. For more information, see CloudWatch Synthetics configurations.
- For Puppeteer or Selenium runtimes, you can add your custom user-agent string using supported library functions. For Puppeteer runtimes, see async addUserAgent(page, userAgentString);. For Selenium runtimes, see add_user_agent(user_agent_str).

Waiting for an element to appear

After analyzing your logs and screenshots, if you see that your script is waiting for an element to appear on screen and times out, check the relevant screenshot to see if the element appears on the page. Verify your `xpath` to make sure that it is correct.

For Puppetteer-related issues, check [Puppeteer's GitHub page](#) or internet forums.

Node is either not visible or not an HTMLElement for page.click()

If a node is not visible or is not an `HTMLElement` for `page.click()`, first verify the `xpath` that you are using to click the element. Also, if your element is at the bottom of the screen, adjust your viewport. CloudWatch Synthetics by default uses a viewport of 1920 * 1080. You can set a different viewport when you launch the browser or by using the Puppeteer function `page.setViewport`.

Unable to upload artifacts to S3, Exception: Unable to fetch S3 bucket location: Access Denied

If your canary fails because of an Amazon S3 error, CloudWatch Synthetics was unable to upload screenshots, logs, or reports created for the canary because of permission issues. Check the following:

- Check that the canary's IAM role has the `s3:ListAllMyBuckets` permission, the `s3:GetBucketLocation` permission for the correct Amazon S3 bucket, and the `s3:PutObject` permission for the bucket where the canary stores its artifacts. If the canary performs visual monitoring, the role also needs the `s3:GetObject` permission for the bucket. These same permissions are also required in the Amazon VPC S3 Gateway Endpoint Policy, if the canary is deployed in a VPC with a VPC endpoint.
- If the canary uses an Amazon KMS customer managed key for encryption instead of the standard Amazon managed key (default), the canary's IAM role might not have the permission to encrypt or decrypt using that key. For more information, see [Encrypting canary artifacts](#).
- Your bucket policy might not allow the encryption mechanism that the canary uses. For example, if your bucket policy mandates to use a specific encryption mechanism or KMS key, then you must select the same encryption mode for your canary.

If the canary performs visual monitoring, see [Updating artifact location and encryption when using visual monitoring](#) for more information.

Error: Protocol error (Runtime.callFunctionOn): Target closed.

This error appears if there are some network requests after the page or browser is closed. You might have forgotten to wait for an asynchronous operation. After executing your script, CloudWatch Synthetics closes the browser. The execution of any asynchronous operation after the browser is closed might cause `target closed error`.

Canary Failed. Error: No datapoint - Canary Shows timeout error

This means that your canary run exceeded the timeout. The canary execution stopped before CloudWatch Synthetics could publish success percent CloudWatch metrics or update artifacts such as HAR files, logs and screenshots. If your timeout is too low, you can increase it.

By default, a canary timeout value is equal to its frequency. You can manually adjust the timeout value to be less than or equal to the canary frequency. If your canary frequency is low, you must increase the frequency to increase the timeout. You can adjust both the frequency and the timeout value under **Schedule** when you create or update a canary by using the CloudWatch Synthetics console.

Be sure that your canary timeout value is no shorter than 15 seconds to allow for Lambda cold starts and the time it takes to boot up the canary instrumentation.

Canary artifacts are not available to view in the CloudWatch Synthetics console when this error happens. You can use CloudWatch Logs to see the canary's logs.

To use CloudWatch Logs to see the logs for a canary

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, choose **Log groups**.
3. Find the log group by typing the canary name in the filter box. Log groups for canaries have the name **/aws/lambda/cwsyn-*canaryName*-randomId**.

Trying to access an internal endpoint

If you want your canary to access an endpoint on your internal network, we recommend that you set up CloudWatch Synthetics to use VPC. For more information, see [Running a canary on a VPC](#).

Canary runtime version upgrade and downgrade issues

If you recently upgraded the canary from runtime version `syn-1.0` to a later version, it may be a cross-origin request sharing (CORS) issue. For more information, see [Cross-origin request sharing (CORS) issue](#).

If you recently downgraded the canary to an older runtime version, check to make sure that the CloudWatch Synthetics functions that you are using are available in the older runtime version that you downgraded to. For example, the `executeHttpStep` function is available for runtime version `syn-nodejs-2.2` and later. To check on the availability of functions, see [Writing a canary script](#).

> **Note**
>
> When you plan to upgrade or downgrade the runtime version for a canary, we recommend that you first clone the canary and update the runtime version in the cloned canary. Once you have verified that the clone with the new runtime version works, you can update the runtime version of your original canary and delete the clone.

Cross-origin request sharing (CORS) issue

In a UI canary, if some network requests are failing with `403` or `net::ERR_FAILED`, check whether the canary has active tracing enabled and also uses the Puppeteer function `page.setExtraHTTPHeaders` to add headers. If so, the failed network requests might be caused by cross-origin request sharing (CORS) restrictions. You can confirm whether this is the case by disabling active tracing or removing the extra HTTP headers.

Why does this happen?

When active tracing is used, an extra header is added to all outgoing requests to trace the call. Modifying the request headers by adding a trace header or adding extra headers using Puppeteer's `page.setExtraHTTPHeaders` causes a CORS check for XMLHttpRequest (XHR) requests.

If you don't want to disable active tracing or remove the extra headers, you can update your web application to allow cross-origin access or you can disable web security by using the `disable-web-security` flag when you launch the Chrome browser in your script.

You can override launch parameters used by CloudWatch Synthetics and pass additional `disable-web-security` flag parameters by using the CloudWatch Synthetics launch function. For more information, see [Library functions available for Node.js canary scripts using Puppeteer](#).

> **Note**
>
> You can override launch parameters used by CloudWatch Synthetics when you use runtime version `syn-nodejs-2.1` or later.

Canary race condition issues

For the best experience when using CloudWatch Synthetics, ensure that the code written for the canaries is idempotent. Otherwise, in rare cases, canary runs may encounter race conditions when the canary interacts with the same resource across different runs.

Troubleshooting a canary on a VPC

If you have issues after creating or updating a canary on a VPC, one of the following sections might help you troubleshoot the problem.

New canary in error state or canary can't be updated

If you create a canary to run on a VPC and it immediately goes into an error state, or you can't update a canary to run on a VPC, the canary's role might not have the right permissions. To run on a VPC, a canary must have the permissions `ec2:CreateNetworkInterface`, `ec2:DescribeNetworkInterfaces`, and `ec2:DeleteNetworkInterface`. These permissions are all contained in the `AWSLambdaVPCAccessExecutionRole` managed policy. For more information, see Execution Role and User Permissions.

If this issue happened when you created a canary, you must delete the canary, and create a new one. If you use the CloudWatch console to create the new canary, under **Access Permissions**, select **Create a new role**. A new role that includes all permissions required to run the canary is created.

If this issue happens when you update a canary, you can update the canary again and provide a new role that has the required permissions.

"No test result returned" error

If a canary displays a "no test result returned" error, one of the following issues might be the cause:

- If your VPC does not have internet access, you must use VPC endpoints to give the canary access to CloudWatch and Amazon S3. You must enable the **DNS resolution** and **DNS hostname** options in the VPC for these endpoint addresses to resolve correctly. For more information, see

  Using DNS with Your VPC and Using CloudWatch and CloudWatch Synthetics with interface VPC endpoints .

- Canaries must run in private subnets within a VPC. To check this, open the **Subnets** page in the VPC console. Check the subnets that you selected when configuring the canary. If they have a path to an internet gateway (**igw-**), they are not private subnets.

To help you troubleshoot these issues, see the logs for the canary.

To see the log events from a canary

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Log groups**.
3. Choose the name of the canary's log group. The log group name starts with `/aws/lambda/cwsyn-canary-name`.

Troubleshooting an auto retry canary

To understand why your canary is failing or to analyze specific failed attempts, follow these troubleshooting steps.

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Synthetics Canaries**.
3. Choose the **Canary**.
4. Under the **Availability** tab, you can examine the run details by either:

   - Selecting a specific point on the Canary Runs graph
   - Under **Issues**, selecting a record. Note that retry attempts are tagged and share timestamps with their scheduled runs

   You can view additional information under **Steps**, **Screenshot**, **Logs**, **HAR file**, or **Traces (if active tracing is enabled)**.
5. Under **Canary artifacts and Amazon S3 location**, you can access the artifact and navigate to the Amazon S3 folders or buckets through the available links.
6. The **Canary runs** graph uses different colored points to indicate various status:

   - Blue Points – Indicates successful scheduled runs with a consistent value of 100%

- Red Points – Displays failure of both scheduled runs and all retries, marked at 0%
- Orange Points – Displays either 0% or 100%. 0% indicates ongoing retry following previous attempt failures and 100% means success was achieved after retrying

Sample code for canary scripts

This section contains code samples that illustrate some possible functions for CloudWatch Synthetics canary scripts.

Samples for Node.js and Playwright

Playwright canary with multiple steps

The following script is an example of a Node.js Playwright canary with multiple steps.

```
import { synthetics } from '@amzn/synthetics-playwright';

export async function handler(event, context) {
  try {
    console.log('Running Synthetics Playwright canary');
    const browser = await synthetics.launch();
    const browserContext = await browser.newContext();
    const page = await synthetics.getPage(browserContext);

    // Add steps
    // Step 1
    await synthetics.executeStep("home-page", async () => {
      console.log("Verify home page loads")
      await page.goto('https://www.amazon.com', {waitUntil: "load"});
      await new Promise(r => setTimeout(r, 5000));
    });

    // Step 2
    await synthetics.executeStep("search", async () => {
      console.log("Searching for a product")
      const searchInput = page.getByPlaceholder("Search Amazon").first();
      await searchInput.click()
      await searchInput.fill('Amazon echo');
      const btn = page.getByRole('button', { name: 'Go' }).first()
      await btn.click({ timeout: 15000 })
      console.log("Clicked search button")
```

```
    });

    // Step 3
    await synthetics.executeStep("search-results", async () => {
      console.log("Verifying search results")
      const resultsHeading = page.getByText("Results", {exact: true}).first()
      await resultsHeading.highlight();
      await new Promise(r => setTimeout(r, 5000));
    });

  } finally {
    // Close all browser contexts and browser
    await synthetics.close();
  }
}
```

Playwright canaries setting cookies

The following script is an example of a Node.js Playwright canary setting three cookies.

```
import { synthetics } from '@amzn/synthetics-playwright';

export const handler = async (event, context) => {
  try {
    let url = "http://smile.amazon.com/";
    const browser = await synthetics.launch();
    const page = await synthetics.getPage(browser);
    const cookies = [{
        'name': 'cookie1',
        'value': 'val1',
        'url': url
    },
    {
        'name': 'cookie2',
        'value': 'val2',
        'url': url
    },
    {
        'name': 'cookie3',
        'value': 'val3',
        'url': url
    }
   ];
   await page.context().addCookies(cookies);
```

```
    await page.goto(url, {waitUntil: 'load', timeout: 30000});
    await page.screenshot({ path: '/tmp/smile.png' });

  } finally {
    await synthetics.close();
  }
};
```

Samples for Node.js and Puppeteer

Setting cookies

Web sites rely on cookies to provide custom functionality or track users. By setting cookies in CloudWatch Synthetics scripts, you can mimic this custom behavior and validate it.

For example, a web site might display a **Login** link for a revisiting user instead of a **Register** link.

```
var synthetics = require('Synthetics');
const log = require('SyntheticsLogger');

const pageLoadBlueprint = async function () {

    let url = "http://smile.amazon.com/";

    let page = await synthetics.getPage();

    // Set cookies.  I found that name, value, and either url or domain are required
 fields.
    const cookies = [{
      'name': 'cookie1',
      'value': 'val1',
      'url': url
    },{
      'name': 'cookie2',
      'value': 'val2',
      'url': url
    },{
      'name': 'cookie3',
      'value': 'val3',
      'url': url
    }];

    await page.setCookie(...cookies);
```

```
    // Navigate to the url
    await synthetics.executeStep('pageLoaded_home', async function (timeoutInMillis =
 30000) {

        var response = await page.goto(url, {waitUntil: ['load', 'networkidle0'],
 timeout: timeoutInMillis});

        // Log cookies for this page and this url
        const cookiesSet = await page.cookies(url);
        log.info("Cookies for url: " + url + " are set to: " +
 JSON.stringify(cookiesSet));
    });

};

exports.handler = async () => {
    return await pageLoadBlueprint();
};
```

Device emulation

You can write scripts that emulate various devices so that you can approximate how a page looks and behaves on those devices.

The following sample emulates an iPhone 6 device. For more information about emulation, see page.emulate(options) in the Puppeteer documentation.

```
var synthetics = require('Synthetics');
const log = require('SyntheticsLogger');
const puppeteer = require('puppeteer-core');

const pageLoadBlueprint = async function () {

    const iPhone = puppeteer.devices['iPhone 6'];

    // INSERT URL here
    const URL = "https://amazon.com";

    let page = await synthetics.getPage();
    await page.emulate(iPhone);

    //You can customize the wait condition here. For instance,
```

```
    //using 'networkidle2' may be less restrictive.
    const response = await page.goto(URL, {waitUntil: 'domcontentloaded', timeout:
 30000});
    if (!response) {
        throw "Failed to load page!";
    }

    await page.waitFor(15000);

    await synthetics.takeScreenshot('loaded', 'loaded');

    //If the response status code is not a 2xx success code
    if (response.status() < 200 || response.status() > 299) {
        throw "Failed to load page!";
    }
};

exports.handler = async () => {
    return await pageLoadBlueprint();
};
```

Multi-step API canary

This sample code demonstrates an API canary with two HTTP steps: testing the same API for positive and negative test cases. The step configuration is passed to enable reporting of request/ response headers. Additionally, it hides the Authorization header and X-Amz-Security-Token, because they contain user credentials.

When this script is used as a canary, you can view details about each step and the associated HTTP requests such as step pass/fail, duration, and performance metrics like DNS look up time and first byte time. You can view the number of 2xx, 4xx and 5xx for your canary run.

```
var synthetics = require('Synthetics');
const log = require('SyntheticsLogger');

const apiCanaryBlueprint = async function () {

    // Handle validation for positive scenario
    const validatePositiveCase = async function(res) {
        return new Promise((resolve, reject) => {
            if (res.statusCode < 200 || res.statusCode > 299) {
                throw res.statusCode + ' ' + res.statusMessage;
```

```
            }

            let responseBody = '';
            res.on('data', (d) => {
                responseBody += d;
            });

            res.on('end', () => {
                // Add validation on 'responseBody' here if required. For ex, your
 status code is 200 but data might be empty
                resolve();
            });
        });
    };

    // Handle validation for negative scenario
    const validateNegativeCase = async function(res) {
        return new Promise((resolve, reject) => {
            if (res.statusCode < 400) {
                throw res.statusCode + ' ' + res.statusMessage;
            }

            resolve();
        });
    };

    let requestOptionsStep1 = {
        'hostname': 'myproductsEndpoint.com',
        'method': 'GET',
        'path': '/test/product/validProductName',
        'port': 443,
        'protocol': 'https:'
    };

    let headers = {};
    headers['User-Agent'] = [synthetics.getCanaryUserAgentString(), headers['User-
Agent']].join(' ');

    requestOptionsStep1['headers'] = headers;

    // By default headers, post data and response body are not included in the report
 for security reasons.
    // Change the configuration at global level or add as step configuration for
 individual steps
```

```
    let stepConfig = {
        includeRequestHeaders: true,
        includeResponseHeaders: true,
        restrictedHeaders: ['X-Amz-Security-Token', 'Authorization'], // Restricted
 header values do not appear in report generated.
        includeRequestBody: true,
        includeResponseBody: true
    };

    await synthetics.executeHttpStep('Verify GET products API with valid name',
 requestOptionsStep1, validatePositiveCase, stepConfig);

    let requestOptionsStep2 = {
        'hostname': 'myproductsEndpoint.com',
        'method': 'GET',
        'path': '/test/canary/InvalidName(',
        'port': 443,
        'protocol': 'https:'
    };

    headers = {};
    headers['User-Agent'] = [synthetics.getCanaryUserAgentString(), headers['User-
Agent']].join(' ');

    requestOptionsStep2['headers'] = headers;

    // By default headers, post data and response body are not included in the report
 for security reasons.
    // Change the configuration at global level or add as step configuration for
 individual steps
    stepConfig = {
        includeRequestHeaders: true,
        includeResponseHeaders: true,
        restrictedHeaders: ['X-Amz-Security-Token', 'Authorization'], // Restricted
 header values do not appear in report generated.
        includeRequestBody: true,
        includeResponseBody: true
    };

    await synthetics.executeHttpStep('Verify GET products API with invalid name',
 requestOptionsStep2, validateNegativeCase, stepConfig);

};
```

```
exports.handler = async () => {
    return await apiCanaryBlueprint();
};
```

Samples for Python and Selenium

The following sample Selenium code is a canary that fails with a custom error message when a target element is not loaded.

```
from aws_synthetics.selenium import synthetics_webdriver as webdriver
from aws_synthetics.common import synthetics_logger as logger
from selenium.webdriver.support.ui import WebDriverWait
from selenium.webdriver.support import expected_conditions as EC
from selenium.webdriver.common.by import By

def custom_selenium_script():
    # create a browser instance
    browser = webdriver.Chrome()
    browser.get('https://www.example.com/')
    logger.info('navigated to home page')
    # set cookie
    browser.add_cookie({'name': 'foo', 'value': 'bar'})
    browser.get('https://www.example.com/')
    # save screenshot
    browser.save_screenshot('signed.png')
    # expected status of an element
    button_condition = EC.element_to_be_clickable((By.CSS_SELECTOR, '.submit-button'))
    # add custom error message on failure
    WebDriverWait(browser, 5).until(button_condition, message='Submit button failed to
 load').click()
    logger.info('Submit button loaded successfully')
    # browser will be quit automatically at the end of canary run,
    # quit action is not necessary in the canary script
    browser.quit()

# entry point for the canary
def handler(event, context):
    return custom_selenium_script()
```

Canaries and X-Ray tracing

You can choose to enable active Amazon X-Ray tracing on canaries that use the `syn-nodejs-2.0` or later runtime. With tracing enabled, traces are sent for all calls made by the canary that use the browser, the Amazon SDK, or HTTP or HTTPS modules. Canaries with tracing enabled appear on the X-Ray Trace Map, and within Application Signals after you have enabled it for your application.

> **Note**
>
> Activating X-Ray tracing on canaries is not yet supported in Asia Pacific (Jakarta).

When a canary appears on the X-Ray trace map, it appears as a new client node type. You can hover on a canary node to see data about latency, requests, and faults. You can also choose the canary node to see more data at the bottom of the page. From this area of the page, you can choose **View in Synthetics** to jump to the CloudWatch Synthetics console for more details about the canary, or choose **View Traces** to see more details about the traces from this canary's runs.

A canary with tracing enabled also has a **Tracing** tab in its details page, with details about traces and segments from the canary's runs.

Enabling tracing increases canary run time by 2.5% to 7%.

A canary with tracing enabled must use a role with the following permissions. If you use the console to create the role when you create the canary, it is given these permissions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Sid230934",
            "Effect": "Allow",
            "Action": [
                "xray:PutTraceSegments"
            ],
            "Resource": "*"
        }
    ]
}
```

Traces generated by canaries incur charges. For more information about X-Ray pricing, see Amazon X-Ray Pricing.

Running a canary on a VPC

You can run canaries on endpoints on a VPC and public internal endpoints. To run a canary on a VPC, you must have both the **DNS Resolution** and **DNS hostnames** options enabled on the VPC. For more information, see Using DNS with Your VPC.

When you run a canary on a VPC endpoint, you must provide a way for it to send its metrics to CloudWatch and its artifacts to Amazon S3. If the VPC is already enabled for internet access, there's nothing more for you to do. The canary executes in your VPC, but can access the internet to upload its metrics and artifacts.

If the VPC is not already enabled for internet access, you have two options:

- Enable IPv4 internet access to allow the canary to send metrics to CloudWatch and Amazon S3. For more information, see the following section Giving internet access to your canary on a VPC.
- If you want to keep your VPC private, you can configure the canary to send its data to CloudWatch and Amazon S3 through private VPC endpoints. If you have not already done so, you must create a VPC endpoint for CloudWatch (com.amazonaws.*region*.monitoring) and a gateway endpoint for Amazon S3. For more information, see Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints and Amazon VPC Endpoints for Amazon S3.

Giving internet access to your canary on a VPC

Follow these steps to give internet access to your VPC canary, or to assign your canary a static IP address

To give internet access (IPv4) to a canary on a VPC

1. Create a NAT gateway in a public subnet on the VPC. For instructions, see Create a NAT gateway.
2. Add a new route to the route table in the private subnet where the canary is launched. Specify the following:

    - For **Destination**, enter **`0.0.0.0/0`**

- For **Target**, choose **NAT Gateway**, and then choose the ID of the NAT gateway that you created.
- Choose **Save routes**.

For more information about adding the route to the route table, see Add and remove routes from a route table.

To give internet access (IPv6) to a canary on a VPC

1. Configure your VPC to have Dualstack subnets. You must add an Egress-Only Internet Gateway to the VPC, update the route tables to allow traffic to the Internet Gateway, and allow outbound access from the associated Security Groups. For more information, see Add IPv6 support for your VPC .
2. Set the `Ipv6AllowedForDualstack` in your canary VPC configuration using the `CreateCanary` or `UpdateCanary` API. For more information, see VpcConfigInput.

   To enable outbound IPv6 traffic from your canary, the VPC subnets attached to the canary must be enabled for Dualstack.

> **Note**
>
> Be sure that the routes to your NAT gateway are in an **active** status. If the NAT gateway is deleted and you haven't updated the routes, they're in a black hole status. For more information, see Work with NAT gateways.

Encrypting canary artifacts

CloudWatch Synthetics stores canary artifacts such as screenshots, HAR files, and reports in your Amazon S3 bucket. By default, these artifacts are encrypted at rest using an Amazon managed key. For more information, see Customer keys and Amazon keys.

You can choose to use a different encryption option. CloudWatch Synthetics supports the following:

- **SSE-S3–** Server-side encryption (SSE) with an Amazon S3-managed key.

- **SSE-KMS**– Server-side encryption (SSE) with an Amazon KMS customer managed key.

If you want to use the default encryption option with an Amazon managed key, you don't need any additional permissions.

To use SSE-S3 encryption, you specify **SSE_S3** as the encryption mode when you create or update your canary. You do not need any additional permissions to use this encryption mode. For more information, see Protecting data using server-side encryption with Amazon S3-managed encryption keys (SSE-S3).

To use an Amazon KMS customer managed key, you specify **SSE-KMS** as the encryption mode when you create or update your canary, and you also provide the Amazon Resource Name (ARN) of your key. You can also use a cross-account KMS key.

To use a customer managed key, you need the following settings:

- The IAM role for your canary must have permission to encrypt your artifacts using your key. If you are using visual monitoring, you must also give it permission to decrypt artifacts.

```
{
    "Version": "2012-10-17",
    "Statement": {"Effect": "Allow",
        "Action": [
            "kms:GenerateDataKey",
            "kms:Decrypt"
        ],
        "Resource": "Your KMS key ARN"
    }
}
```

- Instead of adding permissions to your IAM role, you can add your IAM role to your key policy. If you use the same role for multiple canaries, you should consider this approach.

```
{
    "Sid": "Enable IAM User Permissions",
    "Effect": "Allow",
    "Principal": {
        "AWS": "Your synthetics IAM role ARN"
    },
    "Action": [
        "kms:GenerateDataKey",
```

```
        "kms:Decrypt"
    ],
    "Resource": "*"
}
```

- If you are using a cross-account KMS key, see Allowing users in other accounts to use a KMS key.

Viewing encrypted canary artifacts when using a customer managed key

To view canary artifacts, update your customer managed key to give Amazon KMS the decrypt permission to the user viewing the artifacts. Alternatively, add decrypt permissions to the user or IAM role that is viewing the artifacts.

The default Amazon KMS policy enables IAM policies in the account to allow access to the KMS keys. If you are using a cross-account KMS key, see Why are cross-account users getting Access Denied errors when they try to access Amazon S3 objects encrypted by a custom Amazon KMS key?.

For more information about troubleshooting access denied issues because of a KMS key, see Troubleshooting key access.

Updating artifact location and encryption when using visual monitoring

To perform visual monitoring, CloudWatch Synthetics compares your screenshots with baseline screenshots acquired in the run selected as the baseline. If you update your artifact location or encryption option, you must do one of the following:

- Ensure that your IAM role has sufficient permission for both the previous Amazon S3 location and the new Amazon S3 location for artifacts. Also ensure that it has permission for both the previous and new encryption methods and KMS keys.
- Create a new baseline by selecting the next canary run as a new baseline. If you use this option, you only need to ensure that your IAM role has sufficient permissions for the new artifact location and encryption option.

We recommend the second option of selecting the next run as the new baseline. This avoids having a dependency on an artifact location or encryption option that you're not using anymore for the canary.

For example, suppose that your canary uses artifact location A and KMS key K for uploading artifacts. If you update your canary to artifact location B and KMS key L, you can ensure that your

IAM role has permissions to both of the artifact locations (A and B) and both of the KMS keys (K and L). Alternatively, you can select the next run as the new baseline and ensure that your canary IAM role has permissions to artifact location B and KMS key L.

Viewing canary statistics and details

You can view details about your canaries and see statistics about their runs.

To be able to see all the details about your canary run results, you must be logged on to an account that has sufficient permissions. For more information, see Required roles and permissions for CloudWatch canaries.

To view canary statistics and details

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Synthetics Canaries**.

   In the details about the canaries that you have created:

   - **Status** visually shows how many of your canaries have passed their most recent runs.
   - **Groups** displays the groups you have created, and displays how many of them have failing or alarming canaries.
   - **Slowest performers** displays the group and the Region with the slowest-performing canaries. These are calculated by adding up the average duration of all canaries (across the time span selected) within a group or Region and dividing it by the number of canaries in the group or Region. If you choose the metric for Slowest group, the table is filtered to display only the slowest groups and their canaries. The table is sorted by Average Duration.
   - Near the bottom of the page is a table displaying all canaries. You can use the filtering bar to filter the table to show canaries by specific canary names, last run results, success percentage, alarms, run rates, canary state, runtimes, and unique tags.

     For the alarms column, only alarms that conform to the naming standard for canary alarms are displayed. This standard is `Synthetics-Alarm-`*`canaryName`*`-`*`index`*. Canary alarms that you create in the **Synthetics** section of the CloudWatch console automatically use this naming convention. If you create canary alarms in the **Alarms** section of the CloudWatch console or by using Amazon CloudFormation, and you don't use this naming convention, the alarms work but they do not appear in this list.

3. To see more details about a single canary, choose the name of the canary in the **Canaries** table.

   In the details about that canary:

   - The **Availability** tab displays information about the recent runs of this canary.

     Under **Canary runs**, you can choose one of the lines to see details about that run.

     Under the graph, you can choose **Steps**, **Screenshot**, **Logs**, or **HAR file** to see these types of details. If the canary has active tracing enabled, you can also choose **Traces** to see tracing information from the canary's runs.

     The logs for canary runs are stored in S3 buckets and in CloudWatch Logs.

     Screenshots show how your customers view your webpages. You can use the HAR files (HTTP Archive files) to view detailed performance data about the webpages. You can analyze the list of web requests and catch performance issues such as time to load for an item. Log files show the record of interactions between the canary run and the webpage and can be used to identify details of errors.

     If the canary uses the `syn-nodejs-2.0-beta` runtime or later, you can sort the HAR files by status code, request size, or duration.

     The **Steps** tab displays a list of the canary's steps, each step's status, failure reason, URL after step execution, screenshots, and duration of step execution. For API canaries with HTTP steps, you can view steps and corresponding HTTP requests if you are using runtime `syn-nodejs-2.2` or later.

     Choose the **HTTP Requests** tab to view the log of each HTTP request made by the canary. You can view request/response headers, response body, status code, error and performance timings (total duration, TCP connection time, TLS handshake time, first byte time, and content transfer time). All HTTP requests which use the HTTP/HTTPS module under the hood are captured here.

     By default in API canaries, the request header, response header, request body, and response body are not included in the report for security reasons. If you choose to include them, the data is stored only in your S3 bucket. For information about how to include this data in the report, see executeHttpStep(stepName, requestOptions, [callback], [stepConfig]).

Response body content types of text, HTML and JSON are supported. Content types like text/HTML, text/plain, application/JSON and application/x-amz-json-1.0 are supported. Compressed responses are not supported.

- The **Monitoring** tab displays graphs of the CloudWatch metrics published by this canary. For more information about these metrics, see CloudWatch metrics published by canaries.

  Below the CloudWatch graphics published by the canary are graphs of Lambda metrics related to the canary's Lambda code.
- The **Configuration** tab displays configuration and schedule information about the canary.
- The **Groups** tab displays the groups that this canary is associated with, if any.
- The **Tags** tab displays the tags associated with the canary.

CloudWatch metrics published by canaries

Canaries publish the following metrics to CloudWatch in the `CloudWatchSynthetics` namespace. For more information about viewing CloudWatch metrics, see View available metrics.

Metric	Description
`2xx`	The number of network requests performed by the canary that returned OK responses, with response codes between 200 and 299. This metric is reported for UI canaries that use runtime version `syn-nodejs-2.0` or later, and is reported for API canaries that use runtime version `syn-nodejs-2.2` or later. Valid Dimensions: CanaryName Valid Statistic: Sum Units: Count
`4xx`	The number of network requests performed by the canary that returned Error responses, with response codes between 400 and 499.

Metric	Description
	This metric is reported for UI canaries that use runtime version `syn-nodejs-2.0` or later, and is reported for API canaries that use runtime version `syn-nodejs-2.2` or later. Valid Dimensions: CanaryName Valid Statistic: Sum Units: Count
`5xx`	The number of network requests performed by the canary that returned Fault responses, with response codes between 500 and 599. This metric is reported for UI canaries that use runtime version `syn-nodejs-2.0` or later, and is reported for API canaries that use runtime version `syn-nodejs-2.2` or later. Valid Dimensions: CanaryName Valid Statistic: Sum Units: Count
`Duration`	The duration in milliseconds of the canary run. Valid Dimensions: CanaryName Valid Statistic: Average Units: Milliseconds
`Error`	The number of times the canary failed to run its full script. Valid Dimensions: CanaryName Valid Statistic: Sum

Metric	Description
`Failed`	The number of canary runs that failed to execute. These failures are related to the canary itself. Valid Dimensions: CanaryName Valid Statistic: Sum Units: Count
`Failed requests`	The number of HTTP requests executed by the canary on the target website that failed with no response. Valid Dimensions: CanaryName Valid Statistic: Sum Units: Count
`RetryCount`	The number of times your canary retried. This metric is only displayed when there are retries. Valid Dimensions: CanaryName Valid Statistic: Sum Units: Count
`SuccessPercent`	The percentage of the runs of this canary that succeed and find no failures. Valid Dimensions: CanaryName Valid Statistic: Average Units: Percent

Metric	Description
`SuccessPercentWithRetries`	The percentage of the runs of this canary that succeed after all attempts. Valid Dimensions: CanaryName Valid Statistic: Average Units: Percent
`VisualMonitoringSuccessPercent`	The percentage of visual comparisons that successfully matched the baseline screenshots during a canary run. Valid Dimensions: CanaryName Valid Statistic: Average Units: Percent
`VisualMonitoringTotalComparisons`	The total number of visual comparisons that happened during a canary run. Valid Dimensions: CanaryName Units: Count

> **Note**
>
> Canaries that use either the `executeStep()` or `executeHttpStep()` methods from the Synthetics library also publish `SuccessPercent` and `Duration` metrics with the dimensions `CanaryName` and `StepName` for each step.

Edit or delete a canary

You can edit or delete an existing canary.

Edit canary

When you edit a canary, even if you don't change its schedule, the schedule is reset corresponding to when you edit the canary. For example, if you have a canary that runs every hour, and you edit that canary, the canary will run immediately after the edit is completed and then every hour after that.

To edit or update a canary

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Synthetics Canaries**.
3. Select the button next to the canary name, and choose **Actions**, **Edit**.
4. (Optional) If this canary performs visual monitoring of screenshots and you want to set the next run of the canary as the baseline, select **Set next run as new baseline**.
5. (Optional) If this canary performs visual monitoring of screenshots and you want to remove a screenshot from visual monitoring or you want to designate parts of the screenshot to be ignored during visual comparisons, under **Visual Monitoring** choose **Edit Baseline**.

   The screenshot appears, and you can do one of the following:

   - To remove the screenshot from being used for visual monitoring, select **Remove screenshot from visual test baseline**.
   - To designate parts of the screenshot to be ignored during visual comparisons, click and drag to draw areas of the screen to ignore. Once you have done this for all the areas that you want to ignore during comparisons, choose **Save**.
6. Make any other changes to the canary that you'd like, and choose **Save**.

Delete canary

When you delete a canary, you can choose whether to also delete other resources used and created by the canary. If the canary’s `ProvisionedResourceCleanup` field is set to `AUTOMATIC` or `DeleteLambda` is specified as `true` when you delete the canary, CloudWatch Synthetics will automatically delete the Lambda functions and layers that are used by the canary.

When you delete a canary, you should also delete the following:

- Lambda functions and layers used by this canary. Their prefix is `cwsyn-MyCanaryName`.

- CloudWatch alarms created for this canary. These alarms have a name that starts with `Synthetics-Alarm-MyCanaryName`. For more information about deleting alarms, see [Edit or delete a CloudWatch alarm](#).
- Amazon S3 objects and buckets, such as the canary's results location and artifact location.
- IAM roles created for the canary. These have the name `role/service-role/CloudWatchSyntheticsRole-MyCanaryName`.
- Log groups in CloudWatch Logs created for the canary. These logs groups have the following names: `/aws/lambda/cwsyn-MyCanaryName-randomId`.

Before you delete a canary, you might want to view the canary details and make note of this information. That way, you can delete the correct resources after you delete the canary.

To delete a canary

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Synthetics Canaries**.
3. If the canary is currently in the `RUNNING` state, you must stop it. Only canaries in the `STOPPED`, `READY(NOT_STARTED)`, or `ERROR` states can be deleted.

   To stop the canary, select the button next to the canary name, and choose **Actions**, **Stop**.
4. Select the button next to the canary name, and choose **Actions**, **Delete**.
5. Choose whether to also delete the other resources created for and used by the canary. Lambda functions and layers will be deleted alongside the canary, but you can additionally choose to delete the canary's IAM role and IAM policy.

   Enter **`Delete`** into the box and choose **Delete**.
6. Delete the other resources used by and created for the canary, as listed earlier in this section.

Start, stop, delete, or update runtime for multiple canaries

You can stop, start, delete, or update the runtime of as many as five canaries with one action. If you update the runtime of a canary, it is updated to the latest runtime available for the language and framework that the canary uses.

If you select multiple canaries and only some of them are in a state that is valid for the action that you select, the action is performed only on the canaries where that action is valid. For example, if you select some canaries that are currently running and some that are not, and you select to start the canaries, the canaries that weren't already running will start, and the canaries that were already running are not affected.

If none of the canaries that you select are valid for an action, that action will not be available in the menu.

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Synthetics Canaries**.
3. Select the check boxes next to the canaries that you want to stop, start, or delete.
4. Choose **Actions** and then choose either **Start**, **Stop**, **Delete**, **Start Dry Run**, or **Update Runtime**.

   In addition, when choosing **Update Runtime**, you can choose to dry run the runtime update first before committing the change.

Monitoring canary events with Amazon EventBridge

Amazon EventBridge event rules can notify you when canaries change status or complete runs. EventBridge delivers a near-real-time stream of system events that describe changes in Amazon resources. CloudWatch Synthetics sends these events to EventBridge on a *best effort* basis. Best effort delivery means that CloudWatch Synthetics attempts to send all events to EventBridge, but in some rare cases an event might not be delivered. EventBridge processes all received events at least once. Additionally, your event listeners might not receive the events in the order that the events occurred.

> **Note**
>
> Amazon EventBridge is an event bus service that you can use to connect your applications with data from a variety of sources. For more information, see What is Amazon EventBridge? in the *Amazon EventBridge User Guide*.

CloudWatch Synthetics emits an event when a canary changes state or completes a run. You can create an EventBridge rule that includes an event pattern to match all event types sent from CloudWatch Synthetics, or that matches only specific event types. When a canary triggers a rule, EventBridge invokes the target actions defined in the rule. This allows you to send notifications, capture event information, and take corrective action, in response to a canary state change or the completion of a canary run. For example, you can create rules for the following use cases:

- Investigating when a canary run fails
- Investigating when a canary has gone into the ERROR state
- Tracking a canary's life cycle
- Monitoring canary run success or failure as part of a workflow

Example events from CloudWatch Synthetics

This section lists example events from CloudWatch Synthetics. For more information about event format, see Events and Event Patterns in EventBridge.

Canary status change

In this event type, the values of `current-state` and `previous-state` can be the following:

CREATING | READY | STARTING | RUNNING | UPDATING | STOPPING | STOPPED | ERROR

```
{
                "version": "0",

```
                                },
                                "message": "Test run result is generated successfully"
                }
}
```

Failed canary run completed

```
{
                "version": "0",
                "id": "2644b18f-3e67-5ebf-cdfd-bf9f91392f41",

                                "test-run-status": "FAILED",
                                "state-reason": "\"Error: net::ERR_NAME_NOT_RESOLVED
 \""
                                "canary-run-timeline": {
                                                "started": 1612909461,
                                                "completed": 1612909467
                                },
                                "message": "Test run result is generated successfully"
                }
}
```

It's possible that events might be duplicated or out of order. To determine the order of events, use the `time` property.

Prerequisites for creating EventBridge rules

Before you create an EventBridge rule for CloudWatch Synthetics, you should do the following:

- Familiarize yourself with events, rules, and targets in EventBridge.

- Create and configure the targets invoked by your EventBridge rules. Rules can invoke many types of targets, including:
  - Amazon SNS topics
  - Amazon Lambda functions
  - Kinesis streams
  - Amazon SQS queues

For more information, see What is Amazon EventBridge? and Getting started with Amazon EventBridge in the *Amazon EventBridge User Guide*.

Create an EventBridge rule (CLI)

The steps in the following example create an EventBridge rule that publishes an Amazon SNS topic when the canary named `my-canary-name` in `us-east-1` completes a run or changes state.

1. Create the rule.

```
aws events put-rule \
  --name TestRule \
  --region us-east-1 \
  --event-pattern "{\"source\": [\"aws.synthetics\"], \"detail\": {\"canary-name\": [\"my-canary-name\"]}}"
```

   Any properties you omit from the pattern are ignored.

2. Add the topic as a rule target.

   - Replace *topic-arn* with the Amazon Resource Name (ARN) of your Amazon SNS topic.

```
aws events put-targets \
  --rule TestRule \
  --targets "Id"="1","Arn"="topic-arn"
```

> **Note**
>
> To allow Amazon EventBridge to call your target topic, you must add a resource-based policy to your topic. For more information, see Amazon SNS permissions in the *Amazon EventBridge User Guide*.

For more information, see Events and event patterns in EventBridge in the *Amazon EventBridge User Guide*.

Performing safe canary updates

CloudWatch synthetics safe canary updates allows you to test the updates on your existing canaries before applying the changes. This feature helps you validate canary compatibility with new run times and other configuration changes such as code or memory changes. This will help minimize potential monitoring disruptions caused by erroneous updates.

By using canary safe updates on runtime version updates, configuration changes, and code script modifications, you can mitigate risk, maintain uninterrupted monitoring, verify the changes before committing, update, and reduce downtime.

Topics

- Prerequisites
- Best practices
- Testing canary using dry run
- Limitations

Prerequisites

Make sure the prequisites are complete.

- Amazon account with CloudWatch synthetics permissions
- Existing canary on the supported runtime versions (see Limitations for compatible runtimes)
- Include compatible runtimes when performing a dry run (see Limitations for compatible runtimes)

Best practices

Here are some best practices to follow while performing a canary .

- Execute a dry run to validate a runtime update
- Perform dry runs before production updates to canary
- Review canary logs and artifacts after a dry run
- Use dry runs to validate dependencies and library compatibility

Testing canary using dry run

You can test the canary update using the following options:

Using the Amazon Web Services Management Console's Edit workflow

1. Go the CloudWatch synthetics console.
2. Select the canary you want to update.
3. From the **Actions** drop down, choose **Edit**.

   Update the canary with the changes you want to test. For example, changing runtime version or editing the script’s code.
4. Under **Canary script**, choose **Start Dry Run** to test and view the results immediately or choose **Validate and save later** at the bottom of the page to start the test and view the results later in your **Canary Details** page.
5. After the dry run succeeds, choose **Submit** to commit your canary updates.

Using the Amazon Web Services Management Console for updating canaries in a batch

1. Go the CloudWatch synthetics console.
2. Choose the **Synthetics** list page.
3. Select upto five canaries for which you want to update the runtime.
4. From the **Actions** drop down, choose **Update Runtime**.
5. Choose **Start dry run for new runtime** to start the dry run and test your changes before an update.

6. On the **Synthetics** list page, you will see a text next to the **Runtime** version for the canary that displays the progress of the dry run (this is only displayed for dry runs involving a runtime update).

   Once the dry run succeeds, you will see an **Initiate Update** text.
7. Choose **Initiate Update** to commit the runtime update.
8. If the dry run fails, you will see an **Update dry run failed** text. Choose the text to view the debug link to the canary details page.

Using the Amazon CLI or SDK

The API starts the dry run for the provided canary name `MyCanary` and updates the runtime version to `syn-nodejs-puppeteer-10.0`.

```
aws synthetics start-canary-dry-run \
    --name MyCanary \
    --runtime-version syn-nodejs-puppeteer-10.0

      // Or if you wanted to update other configurations:

aws synthetics start-canary-dry-run \
    --name MyCanary \
    --execution-role-arn arn:aws:iam::123456789012:role/NewRole
```

The API will return the `DryRunId` inside the `DryRunConfigOutput`.

Call `GetCanary` with the provided `DryRunId` to receive the canary's dry run configurations and an additional field `DryRunConfig` which contains the status of the dry run listed as `LastDryRunExecutionStatus`.

```
aws synthetics get-canary \
    --name MyCanary \
    --dry-run-id XXXX-XXXX-XXXX-XXXX
```

For more details, use `GetCanaryRuns` with the provided `DryRunId` to retrieve the run and additional information.

```
aws synthetics get-canary-runs \
    --name MyCanary \
```

```
    --dry-run-id XXXX-XXXX-XXXX-XXXX
```

After a successful dry run, you can then use `UpdateCanary` with the provided `DryRunId` in order to commit your changes.

```
aws synthetics update-canary \
    --name MyCanary \
    --dry-run-id XXXX-XXXX-XXXX-XXXX
```

When it fails for any reason (result from GetCanaryRuns will have the details), the result from `GetCanaryRuns` has an artifact location that contains logs to debug. When there are no logs, the dry run failed to be created. You can validate by using `GetCanary`.

```
aws synthetics get-canary \
    --name MyCanary \
    --dry-run-id XXXX-XXXX-XXXX-XXXX
```

The *State*, *StateReason*, and *StateReasonCode* displays the status of the dry run.

Using Amazon CloudFormation

In your template for a Synthetics Canary, provide the field `DryRunAndUpdate` which accepts a boolean value `true` or `false`.

when the value is `true` every update executes a dry run to validate the changes before automatically updating the canary. When the dry run fails, the canary does not update and fails the deployment and Amazon CloudFormation deployment with a valid reason. To debug this issue, use the Amazon Synthetics console or if using an API, get the `ArtifactS3Location` using the `GetCanaryRuns` API, and download the `*-log.txt` files to review the canary log executions for errors. After validation, modify the Amazon CloudFormation template and retry the deployment or use the above API to validate.

When the value is `false`, synthetics will not execute a dry run to validate changes and will directly commit your updates.

For information on troubleshooting a failed canary, see Troubleshooting a failed canary.

An example template.

```
SyntheticsCanary:
    Type: 'AWS::Synthetics::Canary'
```

```
    Properties:
      Name: MyCanary
      RuntimeVersion: syn-nodejs-puppeteer-10.0
      Schedule: {Expression: 'rate(5 minutes)', DurationInSeconds: 3600}
      ...
      DryRunAndUpdate: true
```

Limitations

- Supports runtime versions – syn-nodejs-puppeteer-10.0+, syn-nodejs-playwright-2.0+, and syn-python-selenium-5.1+
- You can only execute one dry run per canary at a time
- When a dry run fails, you cannot update the canary
- Dry run cannot test any **Schedule** field changes

> **Note**
>
> When you initiate a dry run with code changes for a Playwright canary and you want to update the canary without providing the associated `DryRunId`, you must explicitly specify the code parameters.

CloudWatch RUM

With CloudWatch RUM, you can perform real user monitoring to collect and view client-side data about your web application performance from actual user sessions in near real time. The data that you can visualize and analyze includes page load times, client-side errors, and user behavior. When you view this data, you can see it all aggregated together and also see breakdowns by the browsers and devices that your customers use.

You can use the collected data to quickly identify and debug client-side performance issues. CloudWatch RUM helps you visualize anomalies in your application performance and find relevant debugging data such as error messages, stack traces, and user sessions. You can also use RUM to understand the range of end user impact including the number of users, geolocations, and browsers used.

End user data that you collect for CloudWatch RUM is retained for 30 days and then automatically deleted. If you want to keep the RUM events for a longer time, you can choose to have the app monitor send copies of the events to CloudWatch Logs in your account. Then, you can adjust the retention period for that log group.

To use RUM, you create an *app monitor* and provide some information. RUM generates a JavaScript snippet for you to paste into your application. The snippet pulls in the RUM web client code. The RUM web client captures data from a percentage of your application's user sessions, which is displayed in a pre-built dashboard. You can specify what percentage of user sessions to gather data from.

CloudWatch RUM is integrated with Application Signals, which can discover and monitor your application services, clients, Synthetics canaries, and service dependencies. Use Application Signals to see a list or visual map of your services, view health metrics based on your service level objectives (SLOs), and drill down to see correlated X-Ray traces for more detailed troubleshooting. To see RUM client page requests in Application Signals, turn on X-Ray active tracing by creating an app monitor, or manually configuring the RUM web client. Your RUM clients are displayed on the Service Map connected to your services, and in the Service detail page of the services they call.

The RUM web client is open source. For more information, see CloudWatch RUM web client.

Performance considerations

This section discusses the performance considerations of using CloudWatch RUM.

- **Load performance impact**— The CloudWatch RUM web client can be installed in your web application as a JavaScript module, or loaded into your web application asynchronously from a content delivery network (CDN). It does not block the application's load process. CloudWatch RUM is designed to have no perceptible impact on application load time.
- **Runtime impact**— The RUM web client performs processing to record and dispatch RUM data to the CloudWatch RUM service. Because events are infrequent and the amount of processing is small, CloudWatch RUM is designed for there to be no detectable impact to the application's performance.
- **Network impact**— The RUM web client periodically sends data to the CloudWatch RUM service. Data is dispatched at regular intervals while the application is running, and also immediately before the browser unloads the application. Data sent immediately before the browser unloads the application are sent as beacons, which, are designed to have no detectable impact on the application's unload time.

RUM Pricing

With CloudWatch RUM, you incur charges for every RUM event that CloudWatch RUM receives. Each data item collected using the RUM web client is considered a RUM event. Examples of RUM events include a page view, a JavaScript error, and an HTTP error. You have options for which types of events are collected by each app monitor. You can activate or deactivate options to collect performance telemetry events, JavaScript errors, HTTP errors, and X-Ray traces. For more information about choosing these options, see Creating a CloudWatch RUM app monitor and Information collected by the CloudWatch RUM web client. For more information about pricing, see Amazon CloudWatch Pricing.

Region availability

CloudWatch RUM is currently available in the following Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Jakarta)
- Asia Pacific (Mumbai)
- Asia Pacific (Hyderabad)
- Asia Pacific (Melbourne)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Asia Pacific (Hong Kong)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Milan)
- Europe (Paris)

- Europe (Spain)
- Europe (Stockholm)
- Europe (Zurich)
- Middle East (Bahrain)
- Middle East (UAE)
- South America (São Paulo)
- Israel (Tel Aviv)

Topics

IAM policies to use CloudWatch RUM

To be able to fully manage CloudWatch RUM, you must be signed in as an IAM user or role that has the **AmazonCloudWatchRUMFullAccess** IAM policy. Additionally, you may need other policies or permissions:

- To create an app monitor that creates a new Amazon Cognito identity pool for authorization, you need to have the **Admin** IAM role or the **AdministratorAccess** IAM policy.
- To create an app monitor that sends data to CloudWatch Logs, you must be logged on to an IAM role or policy that has the following permission:

```
{
    "Effect": "Allow",
    "Action": [
        "logs:PutResourcePolicy"
    ],
    "Resource": [
        "*"
    ]
}
```

- To enable JavaScript source maps in an app monitor, you will need to upload your source map files to a Amazon S3 bucket. Your IAM role or policy needs specific Amazon S3 permissions that allow creating Amazon S3 buckets, setting bucket policies, and managing files in the bucket. For security, scope these permissions to specific resources. The example policy below restricts access to buckets containing `rum` in their names and uses the `aws:ResourceAccount` condition key to limit permissions to the principal account only.

```
{
    "Sid": "AllowS3BucketCreationAndListing",
    "Effect": "Allow",
    "Action": [
        "s3:CreateBucket",
        "s3:ListAllMyBuckets"
    ],
    "Resource": "arn:aws:s3:::*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceAccount": "${aws:PrincipalAccount}"
        }
    }
},
{
    "Sid": "AllowS3BucketActions",
    "Effect": "Allow",
    "Action": [
        "s3:GetBucketLocation",
```

```
            "s3:ListBucket"
        ],
        "Resource": "arn:aws:s3:::*rum*",
        "Condition": {
            "StringEquals": {
                "aws:ResourceAccount": "${aws:PrincipalAccount}"
            }
        }
    },
    {
        "Sid": "AllowS3BucketPolicyActions",
        "Effect": "Allow",
        "Action": [
            "s3:PutBucketPolicy",
            "s3:GetBucketPolicy"
        ],
        "Resource": "arn:aws:s3:::*rum*",
        "Condition": {
            "StringEquals": {
                "aws:ResourceAccount": "${aws:PrincipalAccount}"
            }
        }
    },
    {
        "Sid": "AllowS3ObjectActions",
        "Effect": "Allow",
        "Action": [
            "s3:GetObject",
            "s3:PutObject",
            "s3:DeleteObject",
            "s3:AbortMultipartUpload"
        ],
        "Resource": "arn:aws:s3:::*rum*",
        "Condition": {
            "StringEquals": {
                "aws:ResourceAccount": "${aws:PrincipalAccount}"
            }
        }
    }
```

- To use your own Amazon KMS keys for server-side encryption on your source map bucket, your IAM role or policy will need specific Amazon KMS permissions that allows creating a key, updating the key policy, using the Amazon KMS key with Amazon S3 and setting the encryption configuration of your Amazon S3 bucket. For security, scope these permissions to specific purposes. The example below restricts access to keys for a specific region and accountId and has similar S3 restrictions as the above example.

```
{
    "Sid": "AllowKMSKeyCreation",
    "Effect": "Allow",
    "Action": [
        "kms:CreateKey",
        "kms:CreateAlias"
    ],
    "Resource": "*"
},
{
    "Sid": "KMSReadPermissions",
    "Effect": "Allow",
    "Action": [
        "kms:ListAliases"
    ],
    "Resource": "*"
},
{
    "Sid": "AllowUpdatingKeyPolicy",
    "Effect": "Allow",
    "Action": [
        "kms:PutKeyPolicy",
        "kms:GetKeyPolicy",
        "kms:ListKeyPolicies"
    ],
    "Resource": "arn:aws:kms:REGION:ACCOUNT_ID:key/*"
},
{
    "Sid": "AllowUseOfKMSKeyForS3",
    "Effect": "Allow",
    "Action": [
        "kms:DescribeKey",
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Resource": "arn:aws:kms:REGION:ACCOUNT_ID:key/*"
},
{
```

```
        "Sid": "AllowS3EncryptionConfiguration",
        "Effect": "Allow",
        "Action": [
            "s3:PutEncryptionConfiguration",
            "s3:GetEncryptionConfiguration"
        ],
        "Resource": "arn:aws:s3:::*rum*",
        "Condition": {
            "StringEquals": {
                "aws:ResourceAccount": "${aws:PrincipalAccount}"
            }
        }
    }
```

Other users who need to view CloudWatch RUM data but don't need to create CloudWatch RUM resources, can be granted the **AmazonCloudWatchRUMReadOnlyAccess** policy.

Set up an application to use CloudWatch RUM

Use the steps in these sections to set up your application to begin using CloudWatch RUM to collect performance data from real user sessions.

Topics

Step 1: Authorize your application to send data to Amazon

You have four options to set up data authentication:

- Use Amazon Cognito and let CloudWatch RUM create a new Amazon Cognito identity pool for the application. This method requires the least effort to set up.

  The identity pool will contain an unauthenticated identity. This allows the CloudWatch RUM web client to send data to CloudWatch RUM without authenticating the user of the application.

The Amazon Cognito identity pool has an attached IAM role. The Amazon Cognito unauthenticated identity allows the web client to assume the IAM role that is authorized to send data to CloudWatch RUM.

- Use Amazon Cognito for authentication. If you use this, you can use an existing Amazon Cognito identity pool or create a new one to use with this app monitor. If you use an existing identity pool, you must also modify the IAM role that is attached to the identity pool. Use this option for identity pools that support unauthenticated users. You can use identity pools only from the same Region.
- Use authentication from an existing identity provider that you have already set up. In this case, you must get credentials from the identity provider and your application must forward these credentials to the RUM web client.

  Use this option for identity pools that support only authenticated users.
- Use resource-based policies to manage access to your app monitor. This includes the ability to send unauthenticated requests to CloudWatch RUM without Amazon credentials. To learn more about resource based policies and RUM, see Using resource-based policies with CloudWatch RUM.

The following sections include more details about these options.

Use an existing Amazon Cognito identity pool

If you choose to use a Amazon Cognito identity pool, you specify the identity pool when you add the application to CloudWatch RUM. The pool must support enabling access to unauthenticated identities. You can use identity pools only from the same Region.

You also must add the following permissions to the IAM policy that is attached to the IAM role that is associated with this identity pool.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "rum:PutRumEvents",
            "Resource": "arn:aws:rum:[region]:[accountid]:appmonitor/[app monitor 
 name]"
        }
```

```
    ]
}
```

Amazon Cognito will then send the necessary security token to enable your application to access CloudWatch RUM.

Third-party provider

If you choose to use private authentication from a third-party provider, you must get credentials from the identity provider and forward them to Amazon. The best way to do this is by using a *security token vendor*. You can use any security token vendor, including Amazon Cognito with Amazon Security Token Service. For more information about Amazon STS, see Welcome to the Amazon Security Token Service API Reference.

If you want to use Amazon Cognito as the token vendor in this scenario, you can configure Amazon Cognito to work with an authentication provider. For more information, see Getting Started with Amazon Cognito Identity Pools (Federated Identities).

After you configure Amazon Cognito to work with your identity provider, you also need to do the following:

- Create an IAM role with the following permissions. Your application will use this role to access Amazon.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "rum:PutRumEvents",
            "Resource": "arn:aws:rum:[region]:[accountID]:appmonitor/[app monitor
 name]"
        }
    ]
}
```

- Add the following to your application to have it pass the credentials from your provider to CloudWatch RUM. Insert the line so that it runs after a user has signed in to your application and the application has received the credentials to use to access Amazon.

```
cwr('setAwsCredentials', {/* Credentials or CredentialProvider */});
```

For more information about credential providers in the Amazon JavaScript SDK, see Setting credentials in a web browser in the v3 developer guide for SDK for JavaScript, Setting credentials in a web browser in the v2 developer guide for SDK for JavaScript, , and @aws-sdk/credential-providers.

You can also use the SDK for the CloudWatch RUM web client to configure the web client authentication methods. For more information about the web client SDK, see CloudWatch RUM web client SDK.

Creating a CloudWatch RUM app monitor

To start using CloudWatch RUM with your application, you create an *app monitor*. When the app monitor is created, RUM generates a JavaScript snippet for you to paste into your application. The snippet pulls in the RUM web client code. The RUM web client captures data from a percentage of your application's user sessions and sends it to RUM.

To create an app monitor

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **RUM**.
3. Choose **Add app monitor**.
4. Enter the information and settings for your application:

   - For **App monitor name**, enter a name to be used to identify this app monitor within the CloudWatch RUM console.
   - For **Application domain list**, enter the registered domain names where your application has administrative authority. You can also use a wildcard character * to allow any sub-domain or top-level domains (for example, *.amazon.com, amazon.*, *.amazon.*).
5. For **Configure RUM data collection**, specify whether you want the app monitor to collect each of the following:

   - **Performance telemetry** – Collects information about page load and resource load times
   - **JavaScript errors** – Collects information about unhandled JavaScript errors raised by your application

     You can select **Unminify JavaScript error stack traces** to debug unminified JavaScript errors. To use this feature, upload your source map files to an Amazon S3 bucket or folder and provide the Amazon S3 URI. Once enabled, RUM will use these source maps and enrich

JavaScript error events by adding the unminified stack trace. Note that after enabling, this feature only processes new JavaScript error events and cannot be used on previously collected data. For more information, see Enabling unminification of JavaScript error stack traces.

- **HTTP errors –** Collects information about HTTP errors thrown by your application

Selecting these options provides more information about your application, but also generates more CloudWatch RUM events and thus incurs more charges.

If you don't select any of these, the app monitor still collects session start events and page IDs so that you can see how many users are using your application, including breakdowns by operating system type and version, browser type and version, device type, and location.

6. Select **Check this option to allow the CloudWatch RUM Web Client to set cookies** if you want to be able to collect user IDs and session IDs from sampled user sessions. The user IDs are randomly generated by RUM. For more information, see CloudWatch RUM web client cookies (or similar technologies).
7. For **Session samples**, enter the percentage of user sessions that will be used to gather RUM data. The default is 100%. Reducing this number gives you less data, but reduces your charges. For more information about RUM pricing, see RUM pricing.
8. End user data that you collect for CloudWatch RUM is retained for 30 days and then deleted. If you want to keep copies of RUM events in CloudWatch Logs and configure how long to retain these copies, choose **Check this option to store your application telemetry data in your CloudWatch Logs account** under **Data storage**. By default, the CloudWatch Logs log group retains the data for 30 days. You can adjust the retention period in the CloudWatch Logs console.
9. (Optional) Choose to add a resource-based policy to your app monitor to control who can send `PutRumEvents` requests to your app monitor. If you choose **Create public policy**, a resource policy will be attached to your app monitor that enables anyone to send `PutRumEvents` requests to your app monitor. For more information about this method, see Using resource-based policies with CloudWatch RUM.
10. If you attached a resource-based policy in step 9, then you don't need to sign requests to CloudWatch RUM with Amazon credentials, and you can skip setting up authorization. Otherwise, for **Authorization**, specify whether to use a new or existing Amazon Cognito identity pool or use a different identity provider. Creating a new identity pool is the simplest

option that requires no other setup steps. For more information, see see Step 1: Authorize your application to send data to Amazon.

Creating a new Amazon Cognito identity pool requires administrative permissions. For more information, see IAM policies to use CloudWatch RUM.

11. (Optional) By default, when you add the RUM code snippet to your application, the web client injects the JavaScript tag to monitor usage into the HTML code of all pages of your application. To change this, choose **Configure pages** and then choose either **Include only these pages** or **Exclude these pages**. Then, specify the pages to include or exclude. To specify a page to include or exclude, enter its complete URLs. To specify additional pages, choose **Add URL**.
12. To enable Amazon X-Ray tracing of the user sessions that are sampled by the app monitor, choose **Active tracing** and select **Trace my service with Amazon X-Ray.**

    If you select this, `XMLHttpRequest` and `fetch` requests made during user sessions sampled by the app monitor are traced. You can then see traces and segments from these user sessions in the RUM dashboard, and the X-Ray trace map and trace details pages. These user sessions will also show up as client pages in Application Signals after you have enabled it for your application.

    By making additional configuration changes to the CloudWatch RUM web client, you can add an X-Ray trace header to HTTP requests to enable end-to-end tracing of user sessions through to downstream Amazon managed services. For more information, see Enabling X-Ray end-to-end tracing.
13. (Optional) To add tags to the app monitor, choose **Tags**, **Add new tag**.

    Then, for **Key**, enter a name for the tag. You can add an optional value for the tag in **Value**.

    To add another tag, choose **Add new tag** again.

    For more information, see Tagging Amazon Resources.
14. Choose **Add app monitor**.
15. In the **Sample code** section, you can copy the code snippet to use to add to your application. We recommend that you choose **JavaScript** or **TypeScript** and use NPM to install the CloudWatch RUM web client as a JavaScript module.

Alternatively, you can choose **HTML** to use a content delivery network (CDN) to install the CloudWatch RUM web client. The disadvantage of using a CDN is that the web client is often blocked by ad blockers.

16. Choose **Copy** or **Download**, and then choose **Done**.

Modifying the code snippet to configure the CloudWatch RUM web client (optional)

You can modify the code snippet before inserting it into your application, to activate or deactivate several options. For more information, see the [CloudWatch RUM web client documentation.]

There are four configuration options that you should definitely be aware of, as discussed in these sections.

Preventing the collection of resource URLs that might contain personal information

By default, the CloudWatch RUM web client is configured to record the URLs of resources downloaded by the application. These resources include HTML files, images, CSS files, JavaScript files, and so on. For some applications, URLs may contain personally identifiable information (PII).

If this is the case for your application, we strongly recommend that you disable the collection of resource URLs by setting `recordResourceUrl: false` in the code snippet configuration, before inserting it into your application.

Manually recording page views

By default, the web client records page views when the page first loads and when the browser's history API is called. The default page ID is `window.location.pathname`. However, in some cases you might want to override this behavior and instrument the application to record page views programmatically. Doing so gives you control over the page ID and when it is recorded. For example, consider a web application that has a URI with a variable identifier, such as `/entity/123` or `/entity/456`. By default, CloudWatch RUM generates a page view event for each URI with a distinct page ID matching the pathname, but you might want to group them by the same page ID instead. To accomplish this, disable the web client's page view automation by using the `disableAutoPageView` configuration, and use the `recordPageView` command to set the desired page ID. For more information, see [Application-specific Configurations] on GitHub.

Embedded script example:

```
cwr('recordPageView', { pageId: 'entityPageId' });
```

JavaScript module example:

```
awsRum.recordPageView({ pageId: 'entityPageId' });
```

Enabling X-Ray end-to-end tracing

When you create the app monitor, selecting **Trace my service with Amazon X-Ray** enables the tracing of `XMLHttpRequest` and `fetch` requests made during user sessions that are sampled by the app monitor. You can then see traces from these HTTP requests in the CloudWatch RUM dashboard, and the X-Ray Trace Map and Trace details pages.

By default, these client-side traces are not connected to downstream server-side traces. To connect client-side traces to server-side traces and enable end-to-end tracing, set the `addXRayTraceIdHeader` option to `true` in the web client. This causes the CloudWatch RUM web client to add an X-Ray trace header to HTTP requests.

The following code block shows an example of adding client-side traces. Some configuration options are omitted from this sample for readibility.

```
<script>
    (function(n,i,v,r,s,c,u,x,z){...})(
        'cwr',
        '00000000-0000-0000-0000-000000000000',
        '1.0.0',
        'us-west-2',
        'https://client.rum.us-east-1.amazonaws.com/1.0.2/cwr.js',
        {
            enableXRay: true,
            telemetries: [
                'errors',
                'performance',
                [ 'http', { addXRayTraceIdHeader: true } ]
            ]
        }
    );
</script>
```

> **Warning**
>
> Configuring the CloudWatch RUM web client to add an X-Ray trace header to HTTP requests can cause cross-origin resource sharing (CORS) to fail or invalidate the request's signature if the request is signed with SigV4. For more information, see the CloudWatch RUM web client documentation. We strongly recommend that you test your application before adding a client-side X-Ray trace header in a production environment.

For more information, see the CloudWatch RUM web client documentation

Sending unsigned requests to CloudWatch RUM

By default, the RUM web client signs all requests sent to RUM. If you set `signing:false` in the client configuration, requests will be unsigned when they are sent to CloudWatch RUM. Data will be ingested to RUM only if there is a public resource based policy attached to the app monitor. For more information, see Using resource-based policies with CloudWatch RUM.

Inserting the CloudWatch app monitor code snippet into your application

Next, you insert the code snippet that you created in the previous section into your application.

> **Warning**
>
> The web client, downloaded and configured by the code snippet, uses cookies (or similar technologies) to help you collect end user data. Before you insert the code snippet, see Filtering by metadata attributes in the console.

If you don't have the code snippet that was previously generated, you can find it by following the directions in How do I find a code snippet that I've already generated?.

To insert the CloudWatch RUM code snippet into your application

1. Insert the code snippet that you copied or downloaded in the previous section inside the `<head>` element of your application. Insert it before the `<body>` element or any other `<script>` tags.

   The following is an example of a generated code snippet:

```
<script>
(function (n, i, v, r, s, c, x, z) {
    x = window.AwsRumClient = {q: [], n: n, i: i, v: v, r: r, c: c};
    window[n] = function (c, p) {
        x.q.push({c: c, p: p});
    };
    z = document.createElement('script');
    z.async = true;
    z.src = s;
    document.head.insertBefore(z, document.getElementsByTagName('script')[0]);
})('cwr',
    '194a1c89-87d8-41a3-9d1b-5c5cd3dafbd0',
    '1.0.0',
    'us-east-2',
    'https://client.rum.us-east-1.amazonaws.com/1.0.2/cwr.js',
    {
        sessionSampleRate: 1,
        identityPoolId: "us-east-2:c90ef0ac-e3b8-4d1a-b313-7e73cfd21443",
        endpoint: "https://dataplane.rum.us-east-2.amazonaws.com",
        telemetries: ["performance", "errors", "http"],
        allowCookies: true,
        enableXRay: false
    });
</script>
```

2. If your application is a multipage web application, you must repeat step 1 for each HTML page that you want included in the data collection.

Testing your CloudWatch app monitor setup by generating user events

After you have inserted the code snippet and your updated application is running, you can test it by manually generating user events. To test this, we recommend that you do the following. This testing incurs standard CloudWatch RUM charges.

- Navigate between pages in your web application.
- Create multiple user sessions, using different browsers and devices.
- Make requests.
- Cause JavaScript errors.

After you have generated some events, view them in the CloudWatch RUM dashboard. For more information, see Viewing the CloudWatch RUM dashboard.

Data from user sessions might take up to 15 minutes to appear in the dashboard.

If you don't see data 15 minutes after you generated events in the application, see Troubleshooting CloudWatch RUM.

Using resource-based policies with CloudWatch RUM

You can attach a resource policy to a CloudWatch RUM app monitor. By default, app monitors do not have a resource policy attached to them. CloudWatch RUM resource based policies do not support cross-account access.

To learn more about Amazon resource policies, see Identity-based policies and resource-based policies.

To learn more about how resource policies and identity policies are evaluated, see Policy evaluation logic.

To learn more about IAM policy grammar, see IAM JSON policy element reference.

Supported actions

Resource-based policies on app monitors support the `rum:PutRumEvents` action.

Sample policies to use with CloudWatch RUM

The following example allows anyone to write data to your app monitor, including those without SigV4 credentials.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "rum:PutRumEvents",
            "Resource": "arn:aws:rum:region:accountID:appmonitor/app monitor name",
            "Principal" : "*"

        }
```

```
    ]
}
```

You can modify the policy to block specified source IP addresses by using the `aws:SourceIp` condition key. With this example, Using this policy, PutRumEvents from the IP address listed will be rejected. All other requests from other IP addresses will be accepted. For more information about this condition key, see Properties of the network in the IAM User Guide.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "rum:PutRumEvents",
            "Resource": "arn:aws:rum:region:accountID:appmonitor/app monitor name",
            "Principal" : "*"

        },
        {
            "Effect": "Deny",
            "Action": "rum:PutRumEvents",
            "Resource": "arn:aws:rum:region:accountID:appmonitor/app monitor name",
            "Principal" : "*",
           "Condition": {
                "NotIpAddress": {
                    "aws:SourceIp": "************"
                }
            }
        }
    ]
}
```

Additionally, you can also choose to only accept PutRumEvents requests that are signed with a certain alias using the `rum:alias` service context key. In the following example, `PutRumEvents` will have to set the optional `Alias` request parameter to either `alias1` or `alias2` for the event to be accepted. To configure your web client to send `Alias` you must use version 1.20 or later of the CloudWatch RUM web client, as described in Application-specific Configurations on GitHub.

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Effect": "Allow",
            "Action": "rum:PutRumEvents",
            "Resource": "arn:aws:rum:region:accountID:appmonitor/app monitor name",
            "Principal" : "*",
             "Condition": {
             "StringEquals": { "rum:alias": [ "alias1", "alias2"] } }
        }
    ]
}
```

Configuring the CloudWatch RUM web client

Your applications can use one of the code snippets generated by CloudWatch RUM to install the CloudWatch RUM web client. The generated snippets support two installation methods: as a JavaScript module through NPM, or from a content delivery network (CDN). For best performance, we recommend using the NPM installation method. For more information about using this method, see [Installing as a JavaScript Module](#).

If you use the CDN installation option, ad blockers might block the default CDN provided by CloudWatch RUM. This disables application monitoring for users who have ad blockers installed. Because of this, we recommend that you use the default CDN only for initial onboarding with CloudWatch RUM. For more information about the ways to mitigate this issue, see [Instrument the application](#).

The code snippet sits in the `<head>` tag of an HTML file and installs the web client by downloading the web client, and then configuring the web client for the application it is monitoring. The snippet is a self-executing function which looks similar to the following. In this example, the body of the snippet's function has been omitted for readability.

```
<script>
(function(n,i,v,r,s,c,u,x,z){...})(
'cwr',
'00000000-0000-0000-0000-000000000000',
'1.0.0',
'us-west-2',
'https://client.rum.us-east-1.amazonaws.com/1.0.2/cwr.js',
{ /* Configuration Options Here */ }
);
<script>
```

Arguments

The code snippet accepts six arguments:

- A namespace for running commands on the web client, such as `'cwr'`
- The ID of the app monitor, such as `'00000000-0000-0000-0000-000000000000'`
- The application version, such as `'1.0.0'`
- The Amazon Region of the app monitor, such as `'us-west-2'`
- The URL of the web client, such as `'https://client.rum.us-east-1.amazonaws.com/1.0.2/cwr.js'`
- Application-specific configuration options. For more information, see the following section.

Ignoring errors

The CloudWatch RUM web client listens to all types of errors that happen in your applications. If your application emits JavaScript errors that you do not want to view in the CloudWatch RUM dashboard, you can configure the CloudWatch RUM web client to filter out these errors so that you see only the relevant error events on the CloudWatch RUM dashboard. For example, you might choose not to view some JavaScript errors in the dashboard because you have already identified a fix for them and the volume of these errors is masking other errors. You might also want to ignore errors that you can't fix because they are owned by a library owned by a third party.

For more information about how to instrument the web client to filter out specific JavaScript errors, see the example in Errors in the web client Github documentation.

Configuration options

For information about the configuration options available for the CloudWatch RUM web client, see the CloudWatch RUM web client documentation

Enabling unminification of JavaScript error stack traces

When your web application JavaScript source code is minified, error stack traces can be difficult to read. You can enable unminification to the stack traces by uploading your source maps to Amazon S3. CloudWatch RUM will retrieve the source maps to map the line and column numbers in the minified source code back to the original unminified source code. This will improve readability of your error stack traces and help identify the location of the error in the original source code.

Requirements and syntax

Source maps are crucial for debugging and tracking issues in your web application across different releases. Make sure that each web application release has a unique source map. Each release should have its own unique releaseId. A releaseId must be a string between 1 and 200 characters long and can only contain letters, numbers, underscores, hyphens, colons, forward slashes, and periods. To add the `releaseId` as metadata to RUM events, configure the CloudWatch RUM web client.

Source maps are expected to be plain JSON files following the structure defined by the Source Map V3 specification. The required fields are: `version`, `file`, `sources`, `names`, and `mappings`.

Make sure the size of each source map does not exceed the limit of 50 MB. In addition, RUM service will only retrieve up to 50 MB of source maps per stack trace. If needed, split the source code into multiple smaller chunks. For more information, see Code Splitting with WebpackJS.

Topics

Configure your Amazon S3 bucket resource policy to allow RUM service access

Make sure your Amazon S3 bucket is in the same region as your RUM appMonitor. Configure your Amazon S3 bucket to allow RUM service access for retrieving source map files. Include the `aws:SourceArn` and `aws:SourceAccount` global condition context keys to limit the service's permissions to the resource. This is the most effective way to protect against the confused deputy problem.

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon S3 to prevent the confused deputy problem.

```
{
    "Version": "2012-10-17",
    "Statement": [
```

```
        {
            "Sid": "RUM Service S3 Read Permissions",
            "Effect": "Allow",
            "Principal": {
                "Service": "rum.amazonaws.com"
            },
            "Action": [
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": [
                "arn:aws:s3:::BUCKET_NAME",
                "arn:aws:s3:::BUCKET_NAME/*"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "ACCOUNT_ID",
                    "aws:SourceArn":
 "arn:aws:rum:REGION:ACCOUNT_ID:appmonitor/APP_MONITOR_NAME"
                }
            }
        }
    ]
}
```

If you are using Amazon KMS keys to encrypt the data, make sure the key's resource policy is configured similarly to include the `aws:SourceArn` and `aws:SourceAccount` global condition context keys to give RUM service access to use the keys to retrieve the source map files.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RUM Service KMS Read Permissions",
            "Effect": "Allow",
            "Principal": {
                "Service": "rum.amazonaws.com"
            },
            "Action": "kms:Decrypt",
            "Resource": "arn:aws:kms:REGION:ACCOUNT_ID:key/KEY_ID",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "ACCOUNT_ID",
```

```
                    "aws:SourceArn": "arn:aws:rum:REGION:ACCOUNT_ID/APP_MONITOR_NAME"
                }
            }
        }
    ]
}
```

Upload source maps

Configure your JavaScript bundle to generate source maps during minification. When you build your application, the bundle will create a directory (for example, dist) containing the minified JavaScript files and their corresponding source maps. See below for an example.

```
./dist
    |-index.d5a07c87.js
    |-index.d5a07c87.js.map
```

Upload the source map files to your Amazon S3 bucket. The files should be located in a folder with the `releaseId` as the name. For example, if my bucket name is `my-application-source-maps` and the `releaseId` is 2.0.0, then the source map file is located at the following location:

```
my-application-source-maps
    |-2.0.0
        |-index.d5a07c87.js.map
```

To automate uploading your source maps, you can create the following bash script and execute it as part of your build process.

```
#!/bin/bash
# Ensure the script is called with required arguments
if [ "$#" -ne 2 ]; then
 echo "Usage: $0 S3_BUCKET_NAME RELEASE_ID"
 exit 1
fi

# Read arguments
S3_BUCKET="$1"
RELEASE_ID="$2"

# Set the path to your build directory
BUILD_DIR="./dist"
```

```
# Upload all .map files recursively
 if aws s3 cp "$BUILD_DIR" "s3://$S3_BUCKET/$RELEASE_ID/" --recursive --exclude "*" --
include "*.map"; then
    echo "Successfully uploaded all source map files"
else
    echo "Failed to upload source map files"
fi
```

Configure releaseId in your CloudWatch RUM web client

CloudWatch RUM uses the configured `releaseId` to determine the folder to retrieve the source map files. Name the `releaseId` the same as your source map files folder. If you used the provided bash script above or a similar one, the `releaseId` configured in the script should be the same as the one configured in your CloudWatch RUM web client. You must use version 1.21.0 or later of the CloudWatch RUM web client.

```
import { AwsRum, AwsRumConfig } from "aws-rum-web";

try {
    const config: AwsRumConfig = {
        sessionSampleRate: 1,
        endpoint: "https://dataplane.rum.us-west-2.amazonaws.com",
        telemetries: ["performance", "errors", "http"],
        allowCookies: true,
        releaseId: "RELEASE_ID", //Add this
    };

    const APPLICATION_ID: string = "APP_MONITOR_ID";
    const APPLICATION_VERSION: string = "1.0.0";
    const APPLICATION_REGION: string = "us-west-2";

    new AwsRum(APPLICATION_ID, APPLICATION_VERSION, APPLICATION_REGION, config);
} catch (error: any) {
    // Ignore errors thrown during CloudWatch RUM web client initialization
}
```

Enabling CloudWatch RUM app monitor to unminify JavaScript stack traces

To unminify JavaScript stack traces, set the app monitor's SourceMap status to ENABLED. Provide the Amazon S3 URI to the bucket or folder containing all source maps for your app monitor.

When storing source maps directly in the main bucket (not in a subfolder), then the Amazon S3 URI should be formatted as `Amazon S3://BUCKET_NAME`. In this case, source map files should be located at the following location.

```
BUCKET_NAME
    |- RELEASE_ID
        |-index.d5a07c87.js.map
```

When a child directory is the root, then the Amazon S3 URI should be formatted as `Amazon S3://BUCKET_NAME/DIRECTORY`. In this case, source map files should be located at the following location.

```
BUCKET_NAME
    |- DIRECTORY
        |-RELEASE_ID
            |-index.d5a07c87.js.map
```

Viewing unminified stack traces in the RUM console

After uploading your source maps to Amazon S3, enabling source maps on your RUM app monitor, and deploying your web application with the `releaseId` configured in the CloudWatch RUM web client, select **Events** in the RUM console. This tab displays the raw RUM event data. Filter by the JS error event type and view the latest JS error event. You will see the unminified stack trace in the new `event_details.unminifiedStack` field for events ingested after the feature was enabled.

Viewing unminified stack traces in CloudWatch Logs

Enable RUM event storage in CloudWatch Logs by turning on **Data storage**. Once enabled, you can search the new **event_details.unminifiedStack** field. This allows you to analyze trends and relate issues across multiple sessions using CloudWatch Logs queries.

Troubleshooting source maps

CloudWatch RUM provides out of the box metrics to troubleshoot your source map setup. These metrics are published in the metric namespace named `AWS/RUM`. The following metrics are published with an application_name dimension. The value of this dimension is the name of the app monitor. The metrics are also published with an `aws:releaseId` dimension. The value of this dimension is the `releaseId` associated with the JavaScript error event.

MetricName	Unit	Description
UnminifyLineFailureCount	Count	The count of stack trace lines in the JS error event that failed to be unminified. Additional details regarding the failure will be added to the specific line that failed in the event_details.unmi nifiedStack field.
UnminifyLineSuccessCount	Count	The count of stack trace lines in the JS error event that were successfully unminified.
UnminifyEventFailureCount	Count	The count of JS error events that failed to have any lines unminified. Additional details regarding the failure will be added in the event_det ails.unminifiedStack field.
UnminifyEventSuccessCount	Count	The count of JS error events that succeeded to have at least one stack trace line unminified.

CloudWatch RUM may fail to unminify a line in the stack trace for various reasons, including but not limited to:

- Failure to retrieve corresponding source map file due to permission issues. Make sure the bucket resource policy is configured correctly.
- Corresponding source map file does not exist. Make sure the source map files have been uploaded to the correct bucket or folder that has the same name as the releaseId configured in your CloudWatch RUM web client.
- Corresponding source map file is too big. Split your source code into smaller chunks.

- 50 MB worth of source map files already retrieved for the stack trace. Reduce the stack trace length as 50 MB is service side limitation.
- Source map is invalid and could not be indexed. Make sure the source map is a plain JSON following the structure defined by the Source Map V3 specification and includes the following fields: version, file, sources, names, mappings.
- Source map could not map the minified source code back to the unminified stack trace. Make sure the source map is the correct source map for the given releaseId.

Regionalization

This section illustrates strategies for using CloudWatch RUM with applications in different Regions.

My web application is deployed in multiple Amazon Regions

If your web application is deployed in multipled Amazon Regions, you have three options:

- Deploy one app monitor in one Region, in one account, serving all Regions.
- Deploy separate app monitors for each Region, in unique accounts.
- Deploy separate app monitors for each Region, all in one account.

The advantage of using one app monitor is that all data will be centralized into one visualization, and all logs are written to the same log group in CloudWatch Logs. With a single app monitor there is a small amount of extra latency for requests, and a single point of failure.

Using multiple app monitors removes the single point of failure, but prevents all data from being combined into one visualization.

CloudWatch RUM hasn't launched in some Regions that my application is deployed in

CloudWatch RUM is launched into many Regions and has wide geographical coverage. By setting up CloudWatch RUM in the Regions where it is available, you can get the benefits. End users can be anywhere and still have their sessions included if you have set up an app monitor in the Region that they are connecting to.

However, CloudWatch RUM is not yet launched in Amazon GovCloud (US-East), Amazon GovCloud (US-West), or any Regions in China. You are not able to send data to CloudWatch RUM from these Regions.

Use page groups

Use page groups to associate different pages in your application with each other so that you can see aggregated analytics for groups of pages. For example, you might want to see the aggregated page load times of all of your landing pages.

You put pages into page groups by adding one or more tags to page view events in the CloudWatch RUM web client. The following examples put the `/home` page into the page group named `en` and the page group named `landing`.

Embedded script example

```
cwr('recordPageView', { pageId: '/home', pageTags: ['en', 'landing']});
```

JavaScript module example

```
awsRum.recordPageView({ pageId: '/home', pageTags: ['en', 'landing']});
```

> **Note**
>
> Page groups are intended to facilitate aggregating analytics across different pages. For information about how to define and manipulate `pageIds` for your application, see the **Manually recording page views** section in Modifying the code snippet to configure the CloudWatch RUM web client (optional).

Specify custom metadata

CloudWatch RUM attaches additional data to each event as metadata. Event metadata consists of attributes in the form of key-value pairs. You can use these attributes to search or filter events in the CloudWatch RUM console. By default, CloudWatch RUM creates some metadata for you. For more information about the default metadata, see RUM event metadata.

You can also use the CloudWatch RUM web client to add custom metadata to CloudWatch RUM events. The custom metadata can include session attributes and page attributes.

To add custom metadata, you must use version 1.10.0 or later of the CloudWatch RUM web client.

Requirements and syntax

Each event can include as many as 10 custom attributes in the metadata. The syntax requirements for custom attributes are as follows:

- **Keys**
  - Maximum of 128 characters
  - Can include alphanumeric characters, colons (:), and underscores (_)
  - Can't begin with `aws:`.
  - Can't consist entirely of any of the reserved keywords listed in the following section. Can use those keywords as part of a longer key name.
- **Values**
  - Maximum of 256 characters
  - Must be strings, numbers, or Boolean values

Reserved keywords

You can't use the following reserved keywords as complete key names. You can use the following keywords as part of a longer key name, such as `applicationVersion`.

- `browserLanguage`
- `browserName`
- `browserVersion`
- `countryCode`
- `deviceType`
- `domain`
- `interaction`
- `osName`
- `osVersion`
- `pageId`
- `pageTags`
- `pageTitle`
- `pageUrl`

- parentPageId
- platformType
- referrerUrl
- subdivisionCode
- title
- url
- version

> **Note**
>
> CloudWatch RUM removes custom attributes from RUM events if an attribute includes a key or value that is not valid, or if the limit of 10 custom attributes per event has already been reached.

Add session attributes

If you configure custom session attributes, they are added to all events in a session. You configure session attributes either during CloudWatch RUM web client initialization or at runtime by using the addSessionAttributes command.

For example, you can add your application's version as a session attribute. Then, in the CloudWatch RUM console, you can filter errors by version to find whether an increased error rate is associated with a particular version of your application.

Adding a session attribute at initialization, NPM example

The code section in bold adds the session attribute.

```
import { AwsRum, AwsRumConfig } from 'aws-rum-web';

try {
  const config: AwsRumConfig = {
    allowCookies: true,
    endpoint: "https://dataplane.rum.us-west-2.amazonaws.com",
    guestRoleArn: "arn:aws:iam::000000000000:role/RUM-Monitor-us-
west-2-000000000000-00xx-Unauth",
```

```
    identityPoolId: "us-west-2:00000000-0000-0000-0000-000000000000",
    sessionSampleRate: 1,
    telemetries: ['errors', 'performance'],
    sessionAttributes: {
        applicationVersion: "1.3.8"
    }
  };

  const APPLICATION_ID: string = '00000000-0000-0000-0000-000000000000';
  const APPLICATION_VERSION: string = '1.0.0';
  const APPLICATION_REGION: string = 'us-west-2';

  const awsRum: AwsRum = new AwsRum(
    APPLICATION_ID,
    APPLICATION_VERSION,
    APPLICATION_REGION,
    config
  );
} catch (error) {
  // Ignore errors thrown during CloudWatch RUM web client initialization
}
```

Adding a session attribute at runtime, NPM example

```
awsRum.addSessionAttributes({
    applicationVersion: "1.3.8"
})
```

Adding a session attribute at initialization, embedded script example

The code section in bold adds the session attribute.

```
<script>
    (function(n,i,v,r,s,c,u,x,z){...})(
        'cwr',
        '00000000-0000-0000-0000-000000000000',
        '1.0.0',
        'us-west-2',
        'https://client.rum.us-east-1.amazonaws.com/1.0.2/cwr.js',
        {
            sessionSampleRate:1,
            guestRoleArn:'arn:aws:iam::000000000000:role/RUM-Monitor-us-
west-2-000000000000-00xx-Unauth',
```

```
            identityPoolId:'us-west-2:00000000-0000-0000-0000-000000000000',
            endpoint:'https://dataplane.rum.us-west-2.amazonaws.com',
            telemetries:['errors','http','performance'],
            allowCookies:true,
            sessionAttributes: {
                applicationVersion: "1.3.8"
            }
        }
    );
</script>
```

Adding a session attribute at runtime, embedded script example

```
<script>
    function addSessionAttribute() {
        cwr('addSessionAttributes', {
            applicationVersion: "1.3.8"
        })
    }

</script>
```

Add page attributes

If you configure custom page attributes, they are added to all events on the current page. You configure page attributes either during CloudWatch RUM web client initialization or at runtime by using the `recordPageView` command.

For example, you can add your page template as a page attribute. Then, in the CloudWatch RUM console, you can filter errors by page templates to find whether an increased error rate is associated with a particular page template of your application.

Adding a page attribute at initialization, NPM example

The code section in bold adds the page attribute.

```
const awsRum: AwsRum = new AwsRum(
    APPLICATION_ID,
    APPLICATION_VERSION,
    APPLICATION_REGION,
    { disableAutoPageView:  true // optional }
);
```

```
awsRum.recordPageView({
    pageId:'/home',
    pageAttributes: {
      template: 'artStudio'
    }
});
const credentialProvider = new CustomCredentialProvider();
if(awsCreds) awsRum.setAwsCredentials(credentialProvider);
```

Adding a page attribute at runtime, NPM example

```
awsRum.recordPageView({
    pageId: '/home',
    pageAttributes: {
        template: 'artStudio'
    }
});
```

Adding a page attribute at initialization, embedded script example

The code section in bold adds the page attribute.

```
<script>
    (function(n,i,v,r,s,c,u,x,z){...})(
        'cwr',
        '00000000-0000-0000-0000-000000000000',
        '1.0.0',
        'us-west-2',
        'https://client.rum.us-east-1.amazonaws.com/1.0.2/cwr.js',
        {
            disableAutoPageView: true //optional
        }
    );
    cwr('recordPageView', {
       pageId: '/home',
       pageAttributes: {
           template: 'artStudio'
       }
    });
    const awsCreds = localStorage.getItem('customAwsCreds');
    if(awsCreds) cwr('setAwsCredentials', awsCreds)
</script>
```

Adding a page attribute at runtime, embedded script example

```
<script>
    function recordPageView() {
        cwr('recordPageView', {
            pageId: '/home',
            pageAttributes: {
                template: 'artStudio'
            }
        });
    }
</script>
```

Filtering by metadata attributes in the console

To filter the visualizations in the CloudWatch RUM console with any built-in or custom metadata attribute, use the search bar. In the search bar, you can specify as many as 20 filter terms in the form of **key=value** to apply to the visualizations. For example, to filter data for only the Chrome browser, you could add the filter term **browserName=Chrome**.

By default, the CloudWatch RUM console retrieves the 100 most common attributes keys and values to display in the dropdown in the search bar. To add more metadata attributes as filter terms, enter the complete attribute key and value into the search bar.

A filter can include as many as 20 filter terms, and you can save up to 20 filters per app monitor. When you save a filter, it is saved in the **Saved filters** dropdown. You can also delete a saved filter.

Send custom events

CloudWatch RUM records and ingests the events listed in Information collected by the CloudWatch RUM web client. If you use version 1.12.0 or later of the CloudWatch RUM web client, you can define, record, and send additional custom events. You define the event type name and the data to send for each event type that you define. Each custom event payload can be up to 6 KB.

Custom events are ingested only if the app monitor has custom events enabled. To update the configuration settings of your app monitor, use the CloudWatch RUM console or the UpdateAppMonitor API.

After you enable custom events, and then define and send custom events, you can search for them. To search for them, use the **Events** tab in the CloudWatch RUM console. Search by using the event type.

Requirements and syntax

Custom events consist of an event type and event details. The requirements for these are as follows:

- **Event type**
  - This can be either the **type** or **name** of your event. For example, the CloudWatch RUM built-in event type called **JsError** has an event type of `com.amazon.rum.js_error_event`.
  - Must be between 1 and 256 characters.
  - Can be a combination of alphanumeric characters, underscores, hyphens, and periods.
- **Event details**
  - Contains the actual data that you want to record in CloudWatch RUM.
  - Must be an object that consists of fields and values.

Examples of recording custom events

There are two ways to record custom events in the CloudWatch RUM web client.

- Use the CloudWatch RUM web client's `recordEvent` API.
- Use a customized plugin.

Send a custom event using the `recordEvent` API, NPM example

```
awsRum.recordEvent('my_custom_event', {
        location: 'IAD',
        current_url: 'amazonaws.com',
        user_interaction: {
            interaction_1 : "click",
            interaction_2 : "scroll"
        },
        visit_count:10
    }
)
```

Send a custom event using the `recordEvent` API, embedded script example

```
cwr('recordEvent', {
    type: 'my_custom_event',
```

```
    data: {
        location: 'IAD',
        current_url: 'amazonaws.com',
        user_interaction: {
            interaction_1 : "click",
            interaction_2 : "scroll"
        },
        visit_count:10
    }
})
```

Example of sending a custom event using a customized plugin

```
// Example of a plugin that listens to a scroll event, and
// records a 'custom_scroll_event' that contains the timestamp of the event.
class MyCustomPlugin implements Plugin {
    // Initialize MyCustomPlugin.
    constructor() {
        this.enabled;
        this.context;
        this.id = 'custom_event_plugin';
    }
    // Load MyCustomPlugin.
    load(context) {
        this.context = context;
        this.enable();
    }
    // Turn on MyCustomPlugin.
    enable() {
        this.enabled = true;
        this.addEventHandler();
    }
    // Turn off MyCustomPlugin.
    disable() {
        this.enabled = false;
        this.removeEventHandler();
    }
    // Return MyCustomPlugin Id.
    getPluginId() {
        return this.id;
    }
    // Record custom event.
    record(data) {
```

```
        this.context.record('custom_scroll_event', data);
    }
    // EventHandler.
    private eventHandler = (scrollEvent: Event) => {
        this.record({timestamp: Date.now()})
    }
    // Attach an eventHandler to scroll event.
    private addEventHandler(): void {
        window.addEventListener('scroll', this.eventHandler);
    }
    // Detach eventHandler from scroll event.
    private removeEventHandler(): void {
        window.removeEventListender('scroll', this.eventHandler);
    }
}
```

Viewing the CloudWatch RUM dashboard

CloudWatch RUM helps you collect data from user sessions about your application's performance, including page load times, Apdex score, browsers and devices used, geolocation of user sessions, and sessions with errors. All of this information is displayed in a dashboard.

To view the RUM dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **RUM**.

   The **Overview** tab displays information collected by one of the app monitors that you have created.

   The top row of panes displays the following information for this app monitor:

   - Number of page loads
   - Average page load speed
   - Apdex score
   - Status of any alarms associated with the app monitor

   The application performance index (Apdex) score indicates end users' level of satisfaction. Scores range from 0 (least satisfied) to 1 (most satisfied). The scores are based on application performance only. Users are not asked to rate the application. For more information about Apdex scores, see How CloudWatch RUM sets Apdex scores.

Several of these panes include links that you can use to further examine the data. Choosing any of these links displays a detailed view with **Performance**, **Errors**, **HTTP requests**, **Sessions**, **Events Browsers & Devices**, and **User Journey** tabs at the top of the display.

3. To focus further, choose the **List view** tab and then choose the name of the app monitor that you want to focus on. This displays the following tabs for the chosen app monitor.

   - The **Performance** tab displays page performance information including load times, request information, web vitals, and page loads over time. This view features interactive web vitals graphs where you can see the different percentile values of core web vitals for your pages and choose datapoints on the graph to view associated events captured by CloudWatch RUM. From there, you can either explore more events related to the metric spike or view page details for a selected event to identify specific conditions causing performance issues.

     On this tab you can also toggle the view between **Page loads**, **Requests**, and **Location** to see more details about page performance.
   - The **Errors** tab displays Javascript error information including the error message most frequently seen by users and the devices and browsers with the most errors. This view includes a histogram of the errors and a list view of errors. You can filter the list of errors by user and event details. Choose an error message to see more details.
   - The **HTTP requests** tab displays HTTP request information including the request URL with most errors and the devices and browsers with the most errors. This tab includes a histogram of the requests, a list view of requests, and a list view of network errors. You can filter the lists by user and event details. Choose a response code or an error message to s ee more details about the request or network error, respectively.
   - The **Sessions** tab displays session metrics. This tab includes a histogram of session start events and a list view of sessions. You can filter the list of sessions by event type, user details, and event details. Choose a **sessionId** to see more details about a session.
   - The **Events** tab displays a histogram of RUM events and a list view of the events. You can filter the list of events by event type, user details, and event details. Choose a RUM event to see the raw event.
   - The **Browsers & Devices** tab displays information such as the performance and usage of different browsers and devices to access your application. This view includes controls to toggle the view between focusing on **Browsers** and **Devices**.

If you narrow the scope to a single browser, you see the data broken down by browser version.

- The **User Journey** tab displays the paths that your customers use to navigate your application. You can see where your customers enter your application and what page they exit your application from. You can also see the paths that they take and the percentage of customers that follow those paths. You can pause on a node to get more details about that page. You can choose a single path to highlight the connections for easier viewing.

4. (Optional) On any of the first six tabs, you can choose the **Pages** button and select a page or page group from the list. This narrows down the displayed data to a single page or group of pages of your application. You can also mark pages and page groups in the list as favorites.

How CloudWatch RUM sets Apdex scores

Apdex (Application Performance Index) is an open standard that defines a method to report, benchmark, and rate application response time. An Apdex score helps you understand and identify the impact on application performance over time.

The Apdex score indicates the end users' level of satisfaction Scores range from 0 (least satisfied) to 1 (most satisfied). The scores are based on application performance only. Users are not asked to rate the application.

Each individual Apdex score falls into one of three thresholds. Based on the Apdex threshold and actual application response time, there are three kinds of performance, as follows:

- **Satisfied**– The actual application response time is less than or equal to the Apdex threshold. For CloudWatch RUM, this threshold is 2000 ms or less.
- **Tolerable**– The actual application response time is greater than the Apdex threshold, but less than or equal to four times the Apdex threshold. For CloudWatch RUM, this range is 2000–8000 ms.
- **Frustrating**– The actual application response time is greater than four times the Apdex threshold. For CloudWatch RUM, this range is over 8000 ms.

The total 0-1 Apdex score is calculated using the following formula:

```
(positive scores + tolerable scores/2)/total scores * 100
```

CloudWatch metrics that you can collect with CloudWatch RUM

The table in this section lists the metrics that you automatically collect with CloudWatch RUM. You can see these metrics in the CloudWatch console. For more information, see View available metrics.

You can also optionally send extended metrics to CloudWatch or CloudWatch Evidently. For more information, see Extended metrics.

These metrics are published in the metric namespace named `AWS/RUM`. All of the following metrics are published with an `application_name` dimension. The value of this dimension is the name of the app monitor. Some metrics are also published with additional dimensions, as listed in the table.

Metric	Unit	Description
`HttpStatusCodeCount`	Count	The count of HTTP responses in the application, by their response status code. Additional dimension s: • `event_details.response.status` is the response status code, such as 200, 400, 404, and so on. • `event_type` The type of event. Currently, the only possible value for this dimension is `http`.
`Http4xxCount`	Count	The count of HTTP responses in the

Metric	Unit	Description
		application, with 4xx response status code. These are calculated based on `http_event` RUM events that result in 4xx codes.
`Http4xxCountPerSession`	Count	The count of HTTP responses in a session, with 4xx response status code. These are calculated based on `http_event` RUM events that result in 4xx codes.
`Http4xxCountPerPageView`	Count	The count of HTTP responses in a page review, with 4xx response status code. These are calculated based on `http_event` RUM events that result in 4xx codes.
`Http5xxCount`	Count	The count of HTTP responses in the application, with 5xx response status code. These are calculated based on `http_event` RUM events that result in 5xx codes.

Metric	Unit	Description
Http5xxCountPerSession	Count	The count of HTTP responses in the session, with 5xx response status code. These are calculated based on http_event RUM events that result in 5xx codes.
Http5xxCountPerPageView	Count	The count of HTTP responses in a page review, with 5xx response status code. These are calculated based on http_event RUM events that result in 5xx codes.
JsErrorCount	Count	The count of JavaScript error events ingested.
JsErrorCountPerSession	Count	The count of JavaScript error events ingested in a session.
JsErrorCountPerPageView	Count	The count of JavaScript error events ingested in a page review.

Metric	Unit	Description
`NavigationFrustratedTransaction`	Count	The count of navigation events with a `duration` higher than the frustrating threshold, which is 8000ms. The duration of navigation events is tracked in the `PerformanceNavigationDuration` metric.
`NavigationSatisfiedTransaction`	Count	The count of navigation events with a `duration` that is less than the Apdex objective, which is 2000ms. The duration of navigation events is tracked in the `PerformanceNavigationDuration` metric.

Metric	Unit	Description
`NavigationToleratedTransaction`	Count	The count of navigation events with a `duration` between 2000ms and 8000ms. The duration of navigation events is tracked in the `PerformanceNavigationDuration` metric.
`PageViewCount`	Count	The count of page view events ingested by the app monitor. This is calculated by counting the `page_view_event` RUM events.
`PageViewCountPerSession`	Count	The count of page view events in a session.

Metric	Unit	Description
`PerformanceResourceDuration`	Milliseconds	The `duration` of a resource event. Additional dimensions: • `event_details.file.type` is the file type of the resource event, such as a stylesheet, document, image, script, or font. • `event_type` The type of event. Currently, the only possible value for this dimension is `resource`.
`PerformanceNavigationDuration`	Milliseconds	The `duration` of a navigation event.
`RumEventPayloadSize`	Bytes	The size of every event ingested by CloudWatch RUM. You can also use the `SampleCount` statistic for this metric to monitor the number of events that an app monitor is ingesting.

Metric	Unit	Description
SessionCount	Count	The count of session start events ingested by the app monitor. In other words, the number of new sessions started.
SessionDuration	Milliseconds	The duration of a session. These are calculated based on the time between first and last events in a session.
TimeOnPage	Milliseconds	The duration of a page view. These are calculate d based on the time until next page view, except for the final page in a session where it's the time between first and last events on that page.
WebVitalsCumulativeLayoutShift	None	Tracks the value of the cumulative layout shift events.
WebVitalsFirstInputDelay	Milliseconds	Tracks the value of the first input delay events.

Metric	Unit	Description
`WebVitalsLargestContentfulPaint`	Milliseconds	Tracks the value of the largest contentful paint events.
`WebVitalsInteractionToNextPaint`	Milliseconds	Tracks the value of the interaction to next paint events.

Custom metrics and extended metrics that you can send to CloudWatch and CloudWatch Evidently

By default, RUM app monitors send metrics to CloudWatch. These default metrics and dimensions are listed in CloudWatch metrics that you can collect with CloudWatch RUM.

You can also set up an app monitor to export metric. The app monitor can send extended metrics, custom metrics, or both. It can send them to CloudWatch or to CloudWatch Evidently, or to both.

- **Custom metrics**– Custom metrics are metrics that you define. With custom metrics, you can use any metric name and namespace. To derive the metrics, you can use any custom events, built-in events, custom attributes, or default attributes.

  You can send custom metrics to both CloudWatch and CloudWatch Evidently.
- **Extended metrics**– Lets you send the default CloudWatch RUM metrics to CloudWatch Evidently to be used in Evidently experiments. You can also send any of the default CloudWatch RUM metrics to CloudWatch with additional dimensions. This way, these metrics can give you a more fine-grained view.

Topics

- Custom metrics
- Extended metrics

Custom metrics

To send custom metrics, you must use the Amazon APIs or Amazon CLI instead of the console. For more information about using the Amazon APIs, see PutRumMetricsDestination and BatchCreateRumMetricDefinitions.

The maximum number of extended metric and custom metric definitions that one destination can contain is 2000. For each custom metric or extended metric that you send to each destination, each combination of dimension name and dimension value counts toward this limit. You are not charged for custom metrics derived from any kind of events or attributes of CloudWatch RUM.

The following example shows how to create a custom metric derived from a custom event. Here is the example custom event that is used:

```
cwr('recordEvent', {
    type: 'my_custom_event',
    data: {
        location: 'IAD',
        current_url: 'amazonaws.com',
        user_interaction: {
            interaction_1 : "click",
            interaction_2 : "scroll"
        },
        visit_count:10
    }
})
```

Given this custom event, you can create a custom metric that counts the number of visits to the `amazonaws.com` URL from Chrome browsers. The following definition creates a metric named `AmazonVisitsCount` in your account, in the `RUM/CustomMetrics/PageVisits` namespace.

```
{
    "AppMonitorName":"customer-appMonitor-name",
    "Destination":"CloudWatch",
    "MetricDefinitions":[
        {
            "Name":"AmazonVisitsCount",
            "Namespace":"PageVisit",
            "ValueKey":"event_details.visit_count",
            "UnitLabel":"Count",
            "DimensionKeys":{
                "event_details.current_url": "URL"
```

```
            },
            "EventPattern":"{\"metadata\":{\"browserName\":[\"Chrome\"]},\"event_type
\":[\"my_custom_event\"],\"event_details\": {\"current_url\": [\"amazonaws.com\"]}}"
        }
    ]
}
```

Extended metrics

If you set up extended metrics, you can do one or both of the following:

- Send default CloudWatch RUM metrics to CloudWatch Evidently to be used in Evidently experiments. Only the **PerformanceNavigationDuration**, **PerformanceResourceDuration**, **WebVitalsCumulativeLayoutShift**, **WebVitalsFirstInputDelay**, and **WebVitalsLargestContentfulPaint** metrics can be sent to Evidently.
- Send any of the default CloudWatch RUM metrics to CloudWatch with additional dimensions so that the metrics give you a more fine-grained view. For example, you can see metrics specific to a certain browser that's used by your users, or metrics for users in a specific geolocation.

For more information about the default CloudWatch RUM metrics, see [CloudWatch metrics that you can collect with CloudWatch RUM](#).

The maximum number of extended metric and custom metric definitions that one destination can contain is 2000. For each extended or custom metric that you send to each destination, each combination of dimension name and dimension value counts as an extended metric for this limit.

When you send extended metrics to CloudWatch, you can use the CloudWatch RUM console to create CloudWatch alarms on them.

You are not charged for extended metrics that are created for the default metrics of CloudWatch RUM.

The following dimensions are supported for extended metrics for all the metric names that app monitors can send. These metric names are listed in [CloudWatch metrics that you can collect with CloudWatch RUM](#).

- `BrowserName`

  Example dimension values: `Chrome`, `Firefox`, `Chrome Headless`

- `CountryCode` This uses the ISO-3166 format, with two-letter codes.

  Example dimension values: `US`, `JP`, `DE`
- `DeviceType`

  Example dimension values: `desktop`, `mobile`, `tablet`, `embedded`
- `FileType`

  Example dimension values: `Image`, `Stylesheet`
- `OSName`

  Example dimension values: `Linux`, `Windows, iOS`, `Android`
- `PageId`

Set up extended metrics using the console

To use the console to send extended metrics to CloudWatch, use the following steps.

To send extended metrics to CloudWatch Evidently, you must use the Amazon APIs or Amazon CLI instead of the console. For information about using the Amazon APIs to send extended metrics to either CloudWatch or Evidently, see PutRumMetricsDestination and BatchCreateRumMetricDefinitions.

To use the console to set up an app monitor and send RUM extended metrics to CloudWatch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **RUM**.
3. Choose **List view** and then choose the name of the app monitor that is to send the metrics.
4. Choose the **Configuration** tab and then choose **RUM extended metrics**.
5. Choose **Send metrics**.
6. Select one or more metric names to send with additional dimensions.
7. Select one or more factors to use as dimensions for these metrics. As you make your choices, the number of extended metrics that your choices create is displayed in **Number of extended metrics**.

   This number is calculated by multiplying the number of chosen metric names by the number of different dimensions that you create.

a. To send a metric with page ID as a dimension, choose **Browse for page ID** and then select the page IDs to use.

b. To send a metric with device type as a dimension, choose either **Desktop devices** or **Mobile and tablets**.

c. To send a metric with operating system as a dimension, select one or more operating systems under **Operating system**.

d. To send a metric with browser type as a dimension, select one or more browsers under **Browsers**.

e. To send a metric with geolocation as a dimension, select one or more locations under **Locations**.

   Only the locations where this app monitor has reported metrics from will appear in the list to choose from.

8. When you are finished with your choices, choose **Send metrics**.

9. (Optional) In the **Extended metrics** list, to create an alarm that watches one of the metrics, choose **Create alarm** in that metric's row.

   For general information about CloudWatch alarms, see Using Amazon CloudWatch alarms. For a tutorial for setting an alarm on a CloudWatch RUM extended metric, see Tutorial: create an extended metric and alarm it.

Stop sending extended metrics

To use the console to stop sending extended metrics

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **RUM**.
3. Choose **List view** and then choose the name of the app monitor that is to send the metrics.
4. Choose the **Configuration** tab and then choose **RUM extended metrics**.
5. Select one or more metric name and dimension combinations to stop sending. Then choose **Actions**, **Delete**.

Tutorial: create an extended metric and alarm it

This tutorial demonstrates how to set up an extended metric to be sent to CloudWatch, and then how to set an alarm on that metric. In this tutorial, you create a metric that tracks JavaScript errors on the Chrome browser.

To set up this extended metric and set an alarm on it

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **RUM**.
3. Choose **List view** and then choose the name of the app monitor that is to send the metric.
4. Choose the **Configuration** tab and then choose **RUM extended metrics**.
5. Choose **Send metrics**.
6. Select **JSErrorCount**.
7. Under **Browsers**, select **Chrome**.

   This combination of **JSErrorCount** and **Chrome** will send one extended metric to CloudWatch. The metric counts JavaScript errors only for user sessions that use the Chrome browser. The metric name will be **JsErrorCount** and the dimension name will be **Browser**.
8. Choose **Send metrics**.
9. In the **Extended metrics** list, choose **Create alarm** in the row that displays **JsErrorCount** under **Name** and displays **Chrome** under **BrowserName**.
10. Under **Specify metric and conditions**, confirm that the **Metric name** and **BrowserName** fields are pre-filled with the correct values.
11. For **Statistic**, select the statistic that you want to use for the alarm. **Average** is a good choice for this type of counting metric.
12. For **Period**, select **5 minutes**.
13. Under **Conditions**, do the following:

    - Choose **Static**.
    - Choose **Greater** to specify that the alarm should go into ALARM state when the number of errors is higher than the threshold you are about to specify.
    - Under **than...**, enter the number for the alarm threshold. The alarm goes into ALARM state when the number of errors over a 5-minute period exceeds this number.

14. (Optional) By default, the alarm goes into ALARM state as soon as the number of errors exceeds the threshold number you set during a 5-minute period. You can optionally change this so that the alarm goes into ALARM state only if this number is exceeded for more than one 5-minute period.

    To do so, choose **Additional configuration** and then for **Datapoints to alarm**, specify how many 5-minute periods need to have the error number over the threshold to trigger the alarm. For example, you can select 2 out of 2 to have the alarm trigger only when two consecutive 5-minute periods are over the threshold, or 2 out of 3 to have the alarm trigger if any two of three consecutive 5-minute periods are over the threshold.

    For more information about this type of alarm evaluation, see Evaluating an alarm.
15. Choose **Next**.
16. For **Configure actions**, specify what should happen when the alarm goes into alarm state. To receive a notification with Amazon SNS, do the following:
    - Choose **Add notification**.
    - Choose **In alarm**.
    - Either select an existing SNS topic or create a new one. If you create a new one, specify a name for it and add at least one email address to it.
17. Choose **Next**.
18. Enter a name and optional description for the alarm, and choose **Next**.
19. Review the details and choose **Create alarm**.

Data protection and data privacy with CloudWatch RUM

The Amazon shared responsibility model applies to data protection and data privacy in Amazon CloudWatch RUM. As described in this model, Amazon is responsible for protecting the global infrastructure that runs all of the Amazon cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see The Amazon Shared Responsibility Model and GDPR blog post on the Amazon Security Blog. For more resources about complying with GDPR requirements, see the General Data Protection Regulation (GDPR) Center.

Amazon CloudWatch RUM generates a code snippet for you to embed into your website or web application code, based on your input of end user data that you want to collect. The web client, downloaded and configured by the code snippet, uses cookies (or similar technologies) to help you collect end user data. The use of cookies (or similar technologies) is subject to data privacy regulations in certain jurisdictions. Before using Amazon CloudWatch RUM, we strongly recommend that you assess your compliance obligations under applicable law, including any applicable legal requirements to provide legally adequate privacy notices and obtain any necessary consents for the use of cookies and the processing (including collection) of end user data. For more information about how the web client uses cookies (or similar technologies) and what end-user data the web client collects, see Information collected by the CloudWatch RUM web client and CloudWatch RUM web client cookies (or similar technologies).

We strongly recommend that you never put sensitive identifying information, such as your end users' account numbers, email addresses, or other personal information, into free-form fields. Any data that you enter into Amazon CloudWatch RUM or other services might be included in diagnostic logs.

CloudWatch RUM web client cookies (or similar technologies)

The CloudWatch RUM web client collects certain data about user sessions by default. You can choose to enable cookies to have the web client collect a user ID and session ID that persist across page loads. The user ID is randomly generated by RUM.

If these cookies are enabled, RUM is able to display the following types of data when you view the RUM dashboard for this app monitor.

- Aggregated data based on user IDs, such as number of unique users and the number of different users who experienced an error.
- Aggregated data based on session IDs, such as number of sessions and the number of sessions that experienced an error.
- The *user journey*, which is the sequence of pages that each sampled user session includes.

Important

If you do not enable these cookies (or similar technologies), the web client still records certain information about end user sessions such as browser type/version, operating system type/version, device type, and so on. These are collected to provide aggregated page-specific insights, such as web vitals, page views, and pages that experienced errors. For more information about the data recorded, see Information collected by the CloudWatch RUM web client.

Information collected by the CloudWatch RUM web client

This section documents the **PutRumEvents** schema, which defines the structure of the data that you can collect from user sessions using CloudWatch RUM.

A **PutRumEvents** request sends a data structure with the following fields to CloudWatch RUM.

- The ID of this batch of RUM events
- App monitor details, which includes the following:
  - App monitor ID
  - Monitored application version
- User details, which includes the following. **This is collected only if the app monitor has cookies enabled.**
  - A user ID generated by the web client
  - Session ID
- The array of RUM events in this batch.

RUM event schema

The structure of each RUM event includes the following fields.

- The ID of the event
- A timestamp
- The event type
- The user agent
- Metadata
- RUM event details

RUM event metadata

The metadata includes page metadata, user agent metadata, geolocation metadata, and domain metadata.

Page metadata

The page metadata includes the following:

- Page ID
- Page title
- Parent page ID. – **This is collected only if the app monitor has cookies enabled.**
- Interaction depth – **This is collected only if the app monitor has cookies enabled.**
- Page tags – You can add tags to page events to group pages together. For more information, see Use page groups.

User agent metadata

The user agent metadata includes the following:

- Browser language
- Browser name
- Browser version
- Operating system name
- Operating system version
- Device type
- Platform type

Geolocation metadata

The geolocation metadata includes the following:

- Country code
- Subdivision code

Domain metadata

The domain metadata includes the URL domain.

RUM event details

The details of an event follow one of the following type of schemas, depending on the event type.

Session start event

This event contains no fields. **This is collected only if the app monitor has cookies enabled.**

Page view schema

A **Page view** event contains the following properties. You can deactivate page view collection by configuring the web client. For more information, see the CloudWatch RUM web client documentation.

Name	Type	Description
Page ID	String	An ID that uniquely represents this page within the application. By default, this is the URL path.
Parent page ID	String	The ID of the page that the user was on when they navigated to the current page. **This is collected only if the app monitor has cookies enabled.**
Interaction depth	String	**This is collected only if the app monitor has cookies enabled.**

JavaScript error schema

JavaScript error events generated by the agent contain the following properties. The web client collects these events only if you selected to collect the errors telemetry.

Name	Type	Description
Error type	String	The error's name, if one exists. For more information, see Error.prototype.name.

Name	Type	Description
		Some browsers might not support error types.
Error message	String	The error's message. For more information, see Error.prototype.message. If the error field does not exist, this is the message of the error event. For more information, see ErrorEvent. Error messages might not be consistent across different browsers.
Stack trace	String	The error's stack trace, if one exists, truncated to 150 characters. For more information, see Error.prototype.stack. Some browsers might not support stack traces.

DOM event schema

Document object model (DOM) events generated by the agent contain the following properties. These events are not collected by default. They are collected only if you activate the interactions telemetry. For more information, see the CloudWatch RUM web client documentation.

Name	Type	Description
Event	String	The type of DOM event, such as click, scroll, or hover. For more information, see Event reference.
Element	String	The DOM element type
Element ID	String	If the element that generated the event has an ID, this property stores that ID. For more information, see Element.id.
CSSLocator	String	The CSS locator used to identify the DOM element.
InteractionId	String	A unique ID for the interaction between the user and the UI.

Navigation event schema

Navigation events are collected only if the app monitor has performance telemetry activated.

Navigation events use Navigation timing Level 1 and Navigation timing Level 2 APIs. Level 2 APIs are not supported on all browsers, so these newer fields are optional.

> **Note**
>
> Timestamp metrics are based on DOMHighResTimestamp. With Level 2 APIs, all timings are by default relative to the `startTime`. But for Level 1, the `navigationStart` metric is subtracted from timestamp metrics to obtain relative values. All timestamp values are in milliseconds.

Navigation events contain the following properties.

Name	Type	Description	Notes
initiatorType	String	Represents the type of resource that initiated the performance event.	**Value:** "navigation" **Level 1:** "navigation" **Level 2:** entryData .initiatorType
navigationType	String	Represents the type of navigation. This attribute is not required.	**Value:** The value must be one of the following: • `navigate` is a navigation started by choosing

Name	Type	Description	Notes
			a link, entering a URL in a browser's address bar, form submission, or initializing through a script operation other than `reload` or `back_forward` . • `reload` is a navigation through the browser's reload operation or `location.reload()` . • `back_forward` is a navigation through the browser's history

Name	Type	Description	Notes
			traversal operation. • `prerender` is a navigation initiated by a prerender hint. For more information, see [Prerender]().
startTime	Number	Indicates when the event is triggered.	**Value:** 0 **Level 1:** entryData .navigationStart - entryData .navigationStart **Level 2:** entryData .startTime

Name	Type	Description	Notes
unloadEventStart	Number	Indicates the time when the previous document in the window began to unload after the `unload` event was thrown.	**Value:** If there is no previous document or if the previous document or one of the needed redirects is not of the same origin, the value returned is 0. **Level 1:** `entryData.unloadEventStart > 0 ? entryData.unloadEventStart - entryData.navigationStart : 0` **Level 2:** entryData.unloadEventStart

Name	Type	Description	Notes
promptForUnload	Number	The time taken to unload the document. In other words, the time between `unloadEventStart` and `unloadEventEnd`. `UnloadEventEnd` represents the moment in milliseconds when the unload event handler finishes.	**Value:** If there is no previous document or if the previous document or one of the needed redirects is not of the same origin, the value returned is 0. **Level 1:** entryData.unloadEventEnd - entryData.unloadEventStart **Level 2:** entryData.unloadEventEnd - entryData.unloadEventStart

Name	Type	Description	Notes
redirectCount	Number	A number representing the number of redirects since the last non-redirect navigation under the current browsing context. This attribute is not required.	**Value:** If there is no redirect or if there is any redirect that is not of the same origin as the destination document, the value returned is 0. **Level 1:** Not available **Level 2:** entryData.redirectCount

Name	Type	Description	Notes
redirectStart	Number	The time when the first HTTP redirect starts.	**Value:** If there is no redirect or if there is any redirect that is not of the same origin as the destination document, the value returned is 0. **Level 1:** `entryData.redirectStart > 0 ? entryData.redirectStart - entryData.navigationStart : 0` **Level 2:** entryData .redirectStart

Name	Type	Description	Notes
redirectTime	Number	The time taken for the HTTP redirect. This is the difference between `redirectStart` and `redirectEnd` .	**Level 1:** : entryData .redirectEnd - entryData .redirectStart **Level 2:** : entryData .redirectEnd - entryData .redirectStart

Name	Type	Description	Notes
workerStart	Number	This is a property of the `PerformanceResourceTiming` interface. It marks the beginning of worker thread operation. This attribute is not required.	**Value:** If a Service Worker thread is already running, or immediately before starting the Service Worker thread, this property returns the time immediately before dispatching `FetchEvent`. It returns 0 if the resource is not intercepted by a Service Worker. **Level 1:** Not available **Level 2:** entryData.workerStart

Name	Type	Description	Notes
workerTime	Number	If the resource is intercepted by a Service Worker, this returns the time required for worker thread operation. This attribute is not required.	**Level 1:** Not available **Level 2:** `entryData.workerStart > 0 ? entryData.fetchStart - entryData.workerStart : 0`
fetchStart	Number	The time when the browser is ready to fetch the document using an HTTP request. This is before checking any application cache.	**Level 1:** `: entryData.fetchStart > 0 ? entryData.fetchStart - entryData.navigationStart : 0` **Level 2:** entryData .fetchStart

Name	Type	Description	Notes
domainLookupStart	Number	The time when the domain lookup starts.	**Value:** If a persistent connection is used or if the information is stored in a cache or local resource, the value will be the same as `fetchStart` . **Level 1:** `entryData.domainLookupStart > 0 ? entryData.domainLookupStart - entryData.navigationStart : 0` **Level 2:** entryData.domainLookupStart

Name	Type	Description	Notes
dns	Number	The time required for domain lookup.	**Value:** If the resources and DNS records are cached, the expected value is 0. **Level 1:** entryData .domainLo okupEnd - entryData .domainLo okupStart **Level 2:** entryData .domainLo okupEnd - entryData .domainLo okupStart
nextHopPr otocol	String	A string representing the network protocol used to fetch the resource. This attribute is not required.	**Level 1:** Not available **Level 2:** entryData .nextHopP rotocol

Name	Type	Description	Notes
connectStart	Number	The time immediately before the user agent starts establishing the connection to the server to retrieve the document.	**Value:** If an RFC2616 persistent connection is used, or if the current document is retrieved from relevant applicati on caches or local resources, this attribute returns the value of `domainLoo kupEnd` . **Level 1:** `entryData .connectS tart > 0 ? entryData .connectS tart - entryData .navigati onStart : 0` **Level 2:** entryData .connectStart

Name	Type	Description	Notes
connect	Number	Measures the time required to establish the transport connections or to perform SSL authentication. It also includes the blocked time that is taken when there are too many concurrent requests issued by the browser.	**Level 1:** entryData .connectEnd - entryData .connectStart **Level 2:** entryData .connectEnd - entryData .connectStart
secureCon nectionStart	Number	If the URL scheme of the current page is "https", this attribute returns the time immediately before the user agent starts the handshake process to secure the current connection. It returns 0 if HTTPS is not used. For more information about URL schemes, see [URL representation]().	**Formula:** entryData .secureCo nnectionS tart

Name	Type	Description	Notes
tlsTime	Number	The time taken to complete an SSL handshake.	**Level 1:** `entryData.secureConnectionStart > 0 ? entryData.connectEnd - entryData.secureConnectionStart : 0` **Level 2:** `entryData.secureConnectionStart > 0 ? entryData.connectEnd - entryData.secureConnectionStart : 0`

Name	Type	Description	Notes
requestStart	Number	The time immediately before the user agent starts requesting the resource from the server, or from relevant application caches, or from local resources.	**Level 1:** `: entryData.requestStart > 0 ? entryData.requestStart - entryData.navigationStart : 0` **Level 2:** entryData .requestStart
timeToFirstByte	Number	The time taken to receive the first byte of information after a request is made. This time is relative to the `startTime` .	**Level 1:** entryData .response Start - entryData .requestStart **Level 2:** entryData .response Start - entryData .requestStart

Name	Type	Description	Notes
responseStart	Number	The time immediately after the user agent's HTTP parser receives the first byte of the response from the relevant application caches, or from local resources, or from the server.	**Level 1:** `entryData.responseStart > 0 ? entryData.responseStart - entryData.navigationStart : 0` **Level 2:** entryData.responseStart

Name	Type	Description	Notes
responseTime	String	The time taken to receive a complete response in the form of bytes from the relevant application caches, or from local resources, or from the server.	**Level 1:** `entryData.responseStart > 0 ? entryData.responseEnd - entryData.responseStart : 0` **Level 2:** `entryData.responseStart > 0 ? entryData.responseEnd - entryData.responseStart : 0`

Name	Type	Description	Notes
domInteractive	Number	The time when the parser finished its work on the main document, and the HTML DOM is constructed. At this time, its `Document.readyState` changes to "interactive" and the corresponding `readystatechange` event is thrown.	**Level 1:** `entryData.domInteractive > 0 ? entryData.domInteractive - entryData.navigationStart : 0` **Level 2:** entryData.domInteractive

Name	Type	Description	Notes
domContentLoadedEventStart	Number	Represents the time value equal to the time immediately before the user agent fires the DOMContentLoaded event at the current document. TheDOMContentLoaded event fires when the initial HTML document has been completely loaded and parsed. At this time, the main HTML document has finished parsing, the browser begins constructing the render tree, and subresources still have to be loaded. This does not wait for style sheets, images, and subframes to finish loading.	**Level 1:** `entryData.domContentLoadedEventStart > 0 ? entryData.domContentLoadedEventStart - entryData.navigationStart : 0` **Level 2:** entryData.domContentLoadedEventStart

Name	Type	Description	Notes
domContentLoaded	Number	This start and end time of render tree construction is marked by the `domContentLoadedEventStart` and `domContentLoadedEventEnd`. It lets CloudWatch RUM track execution. This property is the difference between `domContentLoadedStart` and `domContentLoadedEnd`. During this time, DOM and CSSOM are ready. This property waits on script execution, except for asynchronous and dynamically created scripts. If the scripts depend on style sheets, `domContentLoaded` waits on the style sheets, too. It does not wait on images. **Note** The actual values of `domContentLoadedStart` and `domContentLoadedEnd` approximate to `domContentLoaded` in Google Chrome's Network panel. It indicates HTML DOM + CSSOM render tree construction time from the beginning of the page loading process. In the case of navigation metrics, the `domContentLoaded` value represents the difference between start and end values, which is the time required for downloading subresources and render-tree construction only.	**Level 2:** entryData.domContentLoadedEventEnd - entryData.domContentLoadedEventStart **Level 2:** entryData.domContentLoadedEventEnd - entryData.domContentLoadedEventStart

Name	Type	Description	Notes
domComplete	Number	The time immediately before the browser sets the current document readiness of the current document to complete. At this point, the loading of subresources, such as images, is complete. This includes the time taken for downloading blocking content such as CSS and synchronous JavaScript. This approximates to `loadTime` in Google Chrome's Network panel.	**Level 1:** `entryData.domComplete > 0 ? entryData.domComplete - entryData.navigationStart : 0` **Level 2:** entryData.domComplete
domProcessingTime	Number	The total time between the response and the load event start.	**Level 1:** entryData.loadEventStart - entryData.responseEnd **Level 2:** entryData.loadEventStart - entryData.responseEnd

Name	Type	Description	Notes
loadEvent Start	Number	The time immediately before the `load` event of the current document is fired.	**Level 1:** `entryData.loadEventStart > 0 ? entryData.loadEventStart - entryData.navigationStart : 0` **Level 2:** entryData.loadEventStart
loadEvent Time	Number	The difference between `loadEventStart` and `loadEventEnd` . Additional functions or logic waiting for this load event will be fired during this time.	**Level 1:** entryData.loadEventEnd - entryData.loadEventStart **Level 2:** entryData.loadEventEnd - entryData.loadEventStart

Name	Type	Description	Notes
duration	String	Duration is the total page load time. It records the timing for downloading the main page and all of its synchronous subresources, and also for rendering the page. Asynchronous resources such as scripts continue to download later. This is the difference between the `loadEventEnd` and `startTime` properties.	**Level 1:** entryData .loadEven tEnd - entryData .navigati onStart **Level 2:** entryData .duration
headerSize	Number	Returns the difference between `transferSize` and `encodedBodySize`. This attribute is not required.	**Level 1:** Not available **Level 2:** entryData .transferSize - entryData .encodedB odySize **Level 2:** entryData .transferSize - entryData .encodedB odySize

Name	Type	Description	Notes
compressionRatio	Number	The ratio of `encodedBodySize` and `decodedBodySize`. The value of `encodedBodySize` is the compressed size of the resource excluding the HTTP headers. The value of `decodedBodySize` is the decompressed size of the resource excluding the HTTP headers. This attribute is not required.	**Level 1:** Not available. **Level 2:** `entryData.encodedBodySize > 0 ? entryData.decodedBodySize / entryData.encodedBodySize : 0`
navigationTimingLevel	Number	The navigation timing API version.	**Value:** 1 or 2

Resource event schema

Resource events are collected only if the app monitor has performance telemetry activated.

Timestamp metrics are based on [The DOMHighResTimeStamp typedef](). With Level 2 APIs, by default all timings are relative to the `startTime`. But for Level 1 APIs, the `navigationStart` metric is subtracted from timestamp metrics to obtain relative values. All timestamp values are in milliseconds.

Resource events generated by the agent contain the following properties.

Name	Type	Description	Notes
targetUrl	String	Returns the resource's URL.	**Formula:** entryData .name
initiatorType	String	Represents the type of resource that initiated the performance resource event.	**Value:** "resource" **Formula:** entryData .initiatorType
duration	String	Returns the difference between the `responseEnd` and `startTime` properties. This attribute is not required.	**Formula:** entryData .duration
transferSize	Number	Returns the size (in octets) of the fetched resource, including the response header fields and the response payload body. This attribute is not required.	**Formula:** entryData .transferSize
fileType	String	Extensions derived from the target URL pattern.	

Largest contentful paint event schema

Largest contentful paint events contain the following properties.

These events are collected only if the app monitor has performance telemetry activated.

Name	Description		
Value	For more information, see Web Vitals.		

First input delay event

First input delay events contain the following properties.

These events are collected only if the app monitor has performance telemetry activated.

Name	Description		
Value	For more information, see Web Vitals.		

Cumulative layout shift event

Cumulative layout shift events contain the following properties.

These events are collected only if the app monitor has performance telemetry activated.

Name	Description		
Value	For more information, see Web Vitals.		

HTTP event

HTTP events can contain the following properties. It will contain either a `Response` field or an `Error` field, but not both.

These events are collected only if the app monitor has HTTP telemetry activated.

Name	Description
Request	The request field includes the following: • The `Method` field, which can have values such as GET, POST, and so on.

Name	Description
	• The URL
Response	The response field includes the following: • Status, such as 2xx, 4xx, or 5xx • Status text
Error	The error field includes the following: • Type • Message • File name • Line number • Column number • Stack trace

X-Ray trace event schema

These events are collected only if the app monitor has X-Ray tracing activated.

For information about X-Ray trace event schemas, see Amazon X-Ray segment documents.

Route change timing for single-page applications

In a traditional multi-page application, when a user requests for new content to be loaded, the user is actually requesting a new HTML page from the server. As a result, the CloudWatch RUM web client captures the load times using the regular performance API metrics.

However, single-page web applications use JavaScript and Ajax to update the interface without loading a new page from the server. Single-page updates are not recorded by the browser timing API, but instead use route change timing.

CloudWatch RUM supports the monitoring of both full page loads from the server and single-page updates, with the following differences:

- For route change timing, there are no browser-provided metrics such as `tlsTime`, `timeToFirstByte`, and so on.

- For route change timing, the `initiatorType` field will be `route_change`.

The CloudWatch RUM web client listens to user interactions that may lead to a route change, and when such a user interaction is recorded, the web client records a timestamp. Then route change timing will begin if both of the following are true:

- A browser history API (except browser forward and back buttons) was used to perform the route change.
- The difference between the time of route change detection and latest user interaction timestamp is less than 1000 ms. This avoids data skew.

Then, once route change timing begins, that timing completes if there are no ongoing AJAX requests and DOM mutations. Then the timestamp of the latest completed activity will be used as the completion timestamp.

Route change timing will time out if there are ongoing AJAX requests or DOM mutations for more than 10 seconds (by default). In this case, the CloudWatch RUM web client will no longer record timing for this route change.

As a result, the duration of a route change event is calculated as the following:

```
(time of latest completed activity) - (latest user interaction timestamp)
```

Manage your applications that use CloudWatch RUM

Use the steps in these sections to manage your applications' use of CloudWatch RUM.

Topics

- How do I find a code snippet that I've already generated?
- Editing your CloudWatch RUM app monitor settings
- Stopping using CloudWatch RUM or deleting an app monitor

How do I find a code snippet that I've already generated?

To find a CloudWatch RUM code snippet that you've already generated for an application, follow these steps.

To find a code snippet that you've already generated

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **RUM**.
3. Choose **List view**.
4. Next to the name of the app monitor, choose **View JavaScript**.
5. In the **JavaScript Snippet** pane, choose **Copy to clipboard**.

Editing your CloudWatch RUM app monitor settings

To change an app monitor's settings, follow these steps. You can change any settings except the app monitor name.

To edit how your application uses CloudWatch RUM

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **RUM**.
3. Choose **List view**.
4. Choose the button next to the name of the application, and then choose **Actions**, **Edit**.
5. Change any settings except the application name. For more information about the settings, see Creating a CloudWatch RUM app monitor.
6. When finished, choose **Save**.

   Changing the settings changes the code snippet. You must now paste the updated code snippet into your application.
7. After the JavaScript code snippet is created, choose **Copy to clipboard** or **Download**, and then choose **Done**.

   To start monitoring with the new settings, you insert the code snippet into your application. Insert the code snippet inside the `<head>` element of your application, before the `<body>` element or any other `<script>` tags.

Stopping using CloudWatch RUM or deleting an app monitor

To stop using CloudWatch RUM with an application, remove the code snippet that RUM generated from your application's code.

To delete a RUM app monitor, follow these steps.

To delete an app monitor

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **RUM**.
3. Choose **List view**.
4. Choose the button next to the name of the application, and then choose **Actions**, **Delete**.
5. In the confirmation box, enter **`Delete`** and then choose **Delete**.
6. If you haven't done so already, delete the CloudWatch RUM code snippet from your application's code.

CloudWatch RUM quotas

CloudWatch RUM has the following quotas.

Resource	Default quota
App monitors	20 per account You can request a quota increase.
RUM ingestion rate	50 **PutRumEvents** requests per second (TPS). You can request a quota increase.

Troubleshooting CloudWatch RUM

This section contains tips to help you troubleshoot CloudWatch RUM.

There is no data for my application

First, make sure that the code snippet has been correctly inserted into your application. For more information, see Inserting the CloudWatch app monitor code snippet into your application.

If that is not the issue, then maybe there has been no traffic to your application yet. Generate some traffic by accessing your application the same way that a user would.

Data has stopped being recorded for my application

Your application might have been updated and now no longer contains a CloudWatch RUM code snippet. Check your application code.

Another possibility is that someone may have updated the code snippet but then didn't insert the updated snippet into the application. Find the current correct code snippet by following the directions in How do I find a code snippet that I've already generated? and compare it to the code snippet that is pasted into your application.

Perform launches and A/B experiments with CloudWatch Evidently

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

You can use Amazon CloudWatch Evidently to safely validate new features by serving them to a specified percentage of your users while you roll out the feature. You can monitor the performance of the new feature to help you decide when to ramp up traffic to your users. This helps you reduce risk and identify unintended consequences before you fully launch the feature.

You can also conduct A/B experiments to make feature design decisions based on evidence and data. An experiment can test as many as five variations at once. Evidently collects experiment data and analyzes it using statistical methods. It also provides clear recommendations about which variations perform better. You can test both user-facing features and backend features.

Evidently pricing

Evidently charges your account based on Evidently events and Evidently analysis units. Evidently events include both data events such as clicks and page views, and assignment events that determine the feature variation to serve to a user.

Evidently analysis units are generated from Evidently events, based on rules that you have created in Evidently. Analysis units are the number of rule matches on events. For example, a user click event might produce a single Evidently analysis unit, a click count. Another example is a user checkout event that might produce two Evidently analysis units, checkout value and the number of items in cart. For more information about pricing, see Amazon CloudWatch Pricing.

CloudWatch Evidently is currently available in the following Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (Oregon)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (Stockholm)

Topics

IAM policies to use Evidently

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

To fully manage CloudWatch Evidently, you must be signed in as an IAM user or role that has the following permissions:

- The **AmazonCloudWatchEvidentlyFullAccess** policy
- The **ResourceGroupsandTagEditorReadOnlyAccess** policy

Additionally, to be able to create a project that stores evaluation events in Amazon S3 or CloudWatch Logs, you need the following permissions:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:GetBucketPolicy",
                "s3:PutBucketPolicy",
                "s3:GetObject",
                "s3:ListBucket"
            ],
            "Resource": "arn:aws:s3:::*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogDelivery",
                "logs:DeleteLogDelivery",
                "logs:DescribeResourcePolicies",
                "logs:PutResourcePolicy"
            ],
            "Resource": [
```

```
                "*"
            ]
        }
    ]
}
```

Additional permissions for CloudWatch RUM integration

Additionally, if you intend to manage Evidently launches or experiments that integrate with Amazon CloudWatch RUM and use CloudWatch RUM metrics for monitoring, you need the **AmazonCloudWatchRUMFullAccess** policy. To create an IAM role to give the CloudWatch RUM web client permission to send data to CloudWatch RUM, you need the following permissions:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:CreateRole",
                "iam:CreatePolicy",
                "iam:AttachRolePolicy"
            ],
            "Resource": [
                "arn:aws:iam::*:role/service-role/CloudWatchRUMEvidentlyRole-*",
                "arn:aws:iam::*:policy/service-role/CloudWatchRUMEvidentlyPolicy-*"
            ]
        }
    ]
}
```

Permissions for read-only access to Evidently

For other users who need to view Evidently data but don't need to create Evidently resources, you can grant the **AmazonCloudWatchEvidentlyReadOnlyAccess** policy.

Create projects, features, launches, and experiments

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

To get started with CloudWatch Evidently, for either a feature launch or an A/B experiment, you first create a *project*. A project is a logical grouping of resources. Within the project, you create *features* that have variations that you want to test or launch. You can create a feature either before you create a launch or experiment, or at the same time.

Topics

Create a new project

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

Use these steps to set up a new CloudWatch Evidently project.

To create a new CloudWatch Evidently project

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose **Create project**.
4. For **Project name**, enter a name to be used to identify this project within the CloudWatch Evidently console.

   You can optionally add a project description.
5. For **Evaluation event storage**, choose whether you want to store the evaluation events that you collect with Evidently. Even if you don't store these events, Evidently aggregates them to create metrics and other experiment data that you can view in the Evidently dashboard. For more information, see Evidently project data storage in CloudWatch.
6. For **Use client-side evaluation**, choose whether you want to enable client-side evaluation for this project. With client-side evaluation, your application can assign variations to user sessions locally instead of by calling the EvaluateFeature operation. This mitigates the latency and availability risks that come with an API call. For more information, see Use client-side evaluation - powered by Amazon AppConfig.

   To create a project with client-side evaluation, you must have the `evidently:ExportProjectAsConfiguration` permission.

   If you enable client-side evaluation, also do the following:

   a. Choose whether to use an existing Amazon AppConfig application or create a new one.
   b. Choose whether to use an existing Amazon AppConfig environment or create a new one.

      For more information about applications and environments in Amazon AppConfig, see How Amazon AppConfig works.
7. (Optional) To add tags to this project, choose **Tags**, **Add new tag**.

   Then, for **Key**, enter a name for the tag. You can add an optional value for the tag in **Value**.

   To add another tag, choose **Add new tag** again.

   For more information, see Tagging Amazon Resources.
8. Choose **Create project**.

Use client-side evaluation - powered by Amazon AppConfig

Important

End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

You can use *client-side evaluation - powered by Amazon AppConfig (client-side evaluation)* in a project, which lets your application assign variations to user sessions locally instead of assigning variations by calling the EvaluateFeature operation. This mitigates the latency and availability risks that come with an API call.

To use client-side evaluation, attach the Amazon AppConfig Lambda extension as a layer to your Lambda functions and configure the environment variables. The client-side evaluation runs as a side process on the local host. Then, you can call the **EvaluationFeature** and **PutProjectEvent** operations against `localhost`. The client-side evaluation process handles the variation assignment, caching, and data synchronization. For more information about Amazon AppConfig, see How Amazon AppConfig works.

When you integrate with Amazon AppConfig, you specify an Amazon AppConfig *application ID* and an Amazon AppConfig *environment ID* to Evidently. You can use the same application ID and environment ID across Evidently projects.

When you create a project with client-side evaluation enabled, Evidently creates an Amazon AppConfig configuration profile for that project. The configuration profile for each project will be different.

Client-side evaluation access control

Evidently client-side evaluation uses a different access control mechanism than the rest of Evidently does. We strongly recommend that you understand this so that you can implement the proper security measures.

With Evidently, you can create IAM policies that limit the actions a user can perform on individual resources. For example, you can create a user role that disallows a user from having the **EvaluateFeature** action. For more information about the Evidently actions that can be controlled with IAM policies, see Actions defined by Amazon CloudWatch Evidently.

The client-side evaluation model allows local evaluations of Evidently features that use project metadata. A user of a project with client-side evaluation enabled can call the **EvaluateFeature** API against a local host endpoint, and this API call does not reach Evidently and is not authenticated by the Evidently service's IAM policies. This call is successful even if the user doesn't have the IAM permission to use the **EvaluateFeature** action. However, a user still needs the **PutProjectEvents** permission for the agent to buffer the evaluation events or custom events and to offload data to Evidently asynchronously.

Additionally, a user must have the `evidently:ExportProjectAsConfiguration` permission to be able to create a project that uses client-side evaluation. This helps you control access to **EvaluateFeature** actions that are called during client-side evaluation.

If you aren't careful, the client-side evaluation security model can subvert the policies that you have set on the rest of Evidently. A user who has the `evidently:ExportProjectAsConfiguration` permission can create a project with client-side evaluation enabled, and then use the **EvaluateFeature** action for client-side evaluation with that project even if they are expressly denied the **EvaluateFeature** action in an IAM policy.

Get started with Lambda

Evidently currently supports client-side evaluation by using an Amazon Lambda environment. To get started, first decide which Amazon AppConfig application and environment to use. Choose an existing application and environment, or create new ones.

The following sample Amazon AppConfig Amazon CLI commands create an application and environment.

```
aws appconfig create-application --name YOUR_APP_NAME
```

```
aws appconfig create-environment --application-id YOUR_APP_ID --
name YOUR_ENVIRONMENT_NAME
```

Next, create an Evidently project by using these Amazon AppConfig resources. For more information, see Create a new project.

Client-side evaluation is supported in Lambda by using a Lambda layer. This is a public layer that is part of `AWS-AppConfig-Extension`, a public Amazon AppConfig extension created by the Amazon AppConfig service. For more information about Lambda layers, see Layer.

To use client-side evaluation, you must add this layer to your Lambda function and configure permissions and environment variables.

To add the Evidently client-side evaluation Lambda layer to your Lambda function and configure it

1. Create a Lambda function if you haven't already.
2. Add the client-side evaluation layer to your function. You can either specify its ARN or select it from the list of Amazon layers if you haven't already. For more information, see [Configuring functions to use layers] and [Available versions of the Amazon AppConfig Lambda extension].
3. Create an IAM policy named **EvidentlyAppConfigCachingAgentPolicy** with the following contents, and attach it to the function's execution role. For more information, see [Lambda execution role].

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "appconfig:GetLatestConfiguration",
                "appconfig:StartConfigurationSession",
                "evidently:PutProjectEvents"
            ],
            "Resource": "*"
        }
    ]
}
```

4. Add the required environment variable `AWS_APPCONFIG_EXTENSION_EVIDENTLY_CONFIGURATIONS` to your Lambda function. This environment variable specifies the mapping between the Evidently project and the Amazon AppConfig resources.

   If you are using this function for one Evidently project, set the value of the environment variable to: `applications/APP_ID/environments/ENVIRONMENT_ID/configurations/PROJECT_NAME`

If you are using this function for multiple Evidently projects, use a comma to separate the values, as in the following example: `applications/`*`APP_ID_1`*`/environments/`*`ENVIRONMENT_ID_1`*`/configurations/`*`PROJECT_NAME_1`*`,applications/`*`APP_ID_2`*`/environments/`*`ENVIRONMENT_ID_2`*`/configurations/`*`PROJECT_NAME_2`*

5. (Optional) Set other environment variables. For more information, see [Configuring the Amazon AppConfig Lambda extension](#).
6. In your application, get Evidently evaluations locally by sending `EvaluateFeature` to `localhost`.

   Python example:

```
import boto3
from botocore.config import Config

def lambda_handler(event, context):
    local_client = boto3.client(
        'evidently',
        endpoint_url="http://localhost:2772",
        config=Config(inject_host_prefix=False)
    )
    response = local_client.evaluate_feature(
        project=event['project'],
        feature=event['feature'],
        entityId=event['entityId']
    )
    print(response)
```

   Node.js example:

```
const AWS = require('aws-sdk');
const evidently = new AWS.Evidently({
    region: "us-west-2",
    endpoint: "http://localhost:2772",
    hostPrefixEnabled: false
});

exports.handler = async (event) => {

    const evaluation = await evidently.evaluateFeature({
```

```
        project: 'John_ETCProject_Aug2022',
        feature: 'Feature_IceCreamFlavors',
        entityId: 'John'
    }).promise()

    console.log(evaluation)
    const response = {
        statusCode: 200,
        body: evaluation,
    };
    return response;
};
```

Kotlin example:

```
String localhostEndpoint = "http://localhost:2772/"
public AmazonCloudWatchEvidentlyClient getEvidentlyLocalClient() {
    return AmazonCloudWatchEvidentlyClientBuilder.standard()

 .withEndpointConfiguration(AwsClientBuilder.EndpointConfiguration(localhostEndpoint,
 region))

 .withClientConfiguration(ClientConfiguration().withDisableHostPrefixInjection(true))
        .withCredentials(credentialsProvider)
        .build();
}

AmazonCloudWatchEvidentlyClient evidently = getEvidentlyLocalClient();

// EvaluateFeature via local client.
EvaluateFeatureRequest evaluateFeatureRequest = new
 EvaluateFeatureRequest().builder()
   .withProject(${YOUR_PROJECT}) //Required.
   .withFeature(${YOUR_FEATURE}) //Required.
   .withEntityId(${YOUR_ENTITY_ID}) //Required.
   .withEvaluationContext(${YOUR_EVAL_CONTEXT}) //Optional: a JSON object of
 attributes that you can optionally pass in as part of the evaluation event sent to
 Evidently.
   .build();

EvaluateFeatureResponse evaluateFeatureResponse =
 evidently.evaluateFeature(evaluateFeatureRequest);
```

```
// PutProjectEvents via local client.
PutProjectEventsRequest putProjectEventsRequest = new
 PutProjectEventsRequest().builder()
     .withData(${YOUR_DATA})
     .withTimeStamp(${YOUR_TIMESTAMP})
     .withType(${YOUR_TYPE})
     .build();

PutProjectEvents putProjectEventsResponse =
 evidently.putProjectEvents(putProjectEventsRequest);
```

Configure how often the client sends data to Evidently

To specify how often client-side evaluation sends data to Evidently, you can optionally configure two environment variables.

- `AWS_APPCONFIG_EXTENSION_EVIDENTLY_EVENT_BATCH_SIZE` specifies the number of events per project to batch before sending them to Evidently. Valid values are integers between 1 and 50, and the default is 40.
- `AWS_APPCONFIG_EXTENSION_EVIDENTLY_BATCH_COLLECTION_DURATION` specifies the duration in seconds to wait for events before sending them to Evidently. The default is 30.

Troubleshooting

Use the following information to help troubleshoot problems with using CloudWatch Evidently with client-side evaluation - powered by Amazon AppConfig.

An error occurred (BadRequestException) when calling the EvaluateFeature operation: HTTP method not supported for provided path

Your environment variables might be configured incorrectly. For example, you might have used `EVIDENTLY_CONFIGURATIONS` as the environment variable name instead of `AWS_APPCONFIG_EXTENSION_EVIDENTLY_CONFIGURATIONS`.

ResourceNotFoundException: Deployment not found

Your update to the project metadata has not been deployed to Amazon AppConfig. Check for an active deployment in the Amazon AppConfig environment that you used for client-side evaluation.

ValidationException: No Evidently configuration for project

Your `AWS_APPCONFIG_EXTENSION_EVIDENTLY_CONFIGURATIONS` environment variable might be configured with the incorrect project name.

Add a feature to a project

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

A *feature* in CloudWatch Evidently represents a feature that you want to launch or that you want to test variations of.

Before you can add a feature, you must create a project. For more information, see [Create a new project](#).

To add a feature to a project

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose the name of the project.
4. Choose **Add feature**.
5. For **Feature name**, enter a name to be used to identify this feature within this project.

   You can optionally add a feature description.
6. For **Feature variations**, for **Variation type** choose **Boolean**, **Long**, **Double**, or **String**. For more information, see [Variation types](#).
7. Add up to five variations for your feature. The **Value** for each variation must be valid for the **Variation type** that you selected.

   Specify one of the variations to be the default. This is the baseline that the other variations will be compared to, and should be the variation that is being served to your users now. This is also the variation that is served to users who are not added to a launch or experiment for this feature.

8. Choose **Sample code**. The code example shows what you need to add to your application to set up the variations and assign user sessions to them. You can choose between JavaScript, Java, and Python for the code.

   You don't need to add the code to your application right now, but you must do so before you start a launch or an experiment.

   For more information, see Adding code to your application.

9. (Optional) To specify that certain users always see a certain variation, choose **Overrides**, **Add override**. Then, specify a user by entering their user ID, account ID, or some other identifier in **Identifier**, and specify which variation they should see.

   This can be useful for members of your own testing team or other internal users when you want to make sure they see a specific variation. The sessions of users who are assigned overrides do not contribute to launch or experiment metrics.

   You can repeat this for as many as 20 users by choosing **Add override** again.

10. (Optional) To add tags to this feature, choose **Tags**, **Add new tag**.

    Then, for **Key**, enter a name for the tag. You can add an optional value for the tag in **Value**.

    To add another tag, choose **Add new tag** again.

    For more information, see Tagging Amazon Resources.

11. Choose **Add feature**.

Variation types

When you create a feature and define the variations, you must select a *variation type*. The possible types are:

- Boolean
- Long integer
- Double precision floating-point number
- String

The variation type sets how the different variations are differentiated in your code. You can use the variation type to simplify the implementation of CloudWatch Evidently and also to simplify the process of modifying the features in your launches and experiments.

For example, if you define a feature with the long integer variation type, the integers that you specify to differentiate the variations can be numbers passed directly into your code. One example might be testing the pixel size of a button The values for the variation types can be the number of pixels used in each variation. The code for each variation can read the variation type value and use that as the button size. To test a new button size, you can change the number used for the value of the variation, without making any other code changes.

When you set the values for your variation types within a feature, you should avoid assigning the same values to multiple variations, unless you want to do A/A testing to initially try out CloudWatch Evidently, or have other reasons to do so.

Evidently doesn't have native support for JSON as a type, but you can pass in JSON in the String variation type, and parse that JSON in your code.

Use segments to focus your audience

Important

End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

You can define audience *segments* and use them in your launches and experiments. A segment is a portion of your audience that shares one or more characteristics. Examples could be Chrome browser users, users in Europe, or Firefox browser users in Europe who also fit other criteria that your application collects, such as age.

Using a segment in an experiment limits that experiment to evaluating only the users who match the segment criteria. When you use one or more segments in a launch, you can define different traffic splits for the different audience segments.

Segment rule pattern syntax

To create a segment, define a segment rule *pattern*. Specify the attributes that you want to use to evaluate whether a user session will be in the segment. The pattern that you create is compared to the value of `evaluationContext` that Evidently finds in a user session. For more information, see Using EvaluateFeature.

To create an segment rule pattern, specify the fields that you want the pattern to match. You can also use logic in your pattern, such as `And`, `Or`, `Not` and `Exists`.

For an `evaluationContext` to match a pattern, the `evaluationContext` must match all parts of the rule pattern. Evidently ignores the fields in the `evaluationContext` that aren't included in the rule pattern.

The values that rule patterns match follow JSON rules. You can include strings enclosed in quotation marks ("), numbers, and the keywords `true`, `false`, and `null`.

For strings, Evidently uses exact character-by-character matching without case-folding or any other string normalization. Therefore, rule matches are case-sensitive. For example, if your `evaluationContext` includes a `browser` attribute but your rule pattern checks for `Browser`, it will not match.

For numbers, Evidently uses string representation. For example, 300, 300.0, and 3.0e2 are not considered equal.

When you write rule patterns to match `evaluationContext`, you can use the `TestSegmentPattern` API or the `test-segment-pattern` CLI command to test that your pattern matches the correct JSON. For more information, see TestSegmentPattern.

The following summary shows all the comparison operators that are available in Evidently segment patterns.

Comparison	Example	Rule syntax
Null	UserID is null	`{ "UserID": [ null ] }`
Empty	LastName is empty	`{ "LastName": [""] }`

Comparison	Example	Rule syntax
Equals	Browser is "Chrome"	`{ "Browser": [ "Chrome" ] }`
And	Country is "France" and Device is "Mobile"	`{ "Country": [ "France" ], "Device": ["Mobile"] }`
Or (multiple values of a single attribute)	Browser is "Chrome" or "Firefox"	`{ "Browser": ["Chrome", "Firefox"] }`
Or (different attributes)	Browser is "Safari" or Device is "Tablet"	`{ "$or": [ {"Browser": ["Safari"]}, {"Device": ["Tablet"]} ] }`
Not	Browser is anything but "Safari"	`{ "Browser": [ { "anything-but": [ "Safari" ] } ] }`

Comparison	Example	Rule syntax
Numeric (equals)	Price is 100	`{ "Price": [ { "numeric": [ "=", 100 ] } ] }`
Numeric (range)	Price is more than 10, and less than or equal to 20	`{ "Price": [ { "numeric": [ ">", 10, "<=", 20 ] } ] }`
Exists	Age field exists	`{ "Age": [ { "exists": true } ] }`
Does not exist	Age field does not exist	`{ "Age": [ { "exists": false } ] }`
Begins with a prefix	Region is in the United States	`{ "Region": [ {"prefix": "us-" } ] }`
Ends with a suffix	Location has a suffix "West"	`{ "Region": [ {"suffix": "West" } ] }`

Segment rule examples

All of the following examples assume that you are passing values for `evaluationContext` with the same field labels and values that you are using in your rule patterns.

The following example matches if `Browser` is Chrome or Firefox and `Location` is US-West.

```
{
  "Browser": ["Chrome", "Firefox"],
  "Location": ["US-West"]
}
```

The following example matches if `Browser` is any browser except Chrome, the `Location` starts with `US`, and an `Age` field exists.

```
{
  "Browser": [ {"anything-but": ["Chrome"]}],
  "Location": [{"prefix": "US"}],
  "Age": [{"exists": true}]
}
```

The following example matches if the `Location` is Japan and either `Browser` is Safari or `Device` is Tablet.

```
{
 "Location": ["Japan"],
 "$or": [
   {"Browser": ["Safari"]},
   {"Device": ["Tablet"]}
 ]
}
```

Create a segment

After you create a segment, you can use it in any launch or experiment in any project.

To create a segment

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.

3. Choose the **Segments** tab.
4. Choose **Create segment**.
5. For **Segment name**, enter a name to use to identify this segment.

   Optionally, add a description.
6. For **Segment pattern**, enter a JSON block that defines the rule pattern. For more information about rule pattern syntax, see Segment rule pattern syntax.

Create a launch

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

To expose a new feature or change to a specified percentage of your users, create a launch. You can then monitor key metrics such as page load times and conversions before you roll out the feature to all of your users.

Before you can add a launch, you must have created a project. For more information, see Create a new project.

When you add a launch, you can use a feature that you have already created, or create a new feature while you create the launch.

To add a launch to a project

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Select the button next to the name of the project and choose **Project actions**, **Create launch**.
4. For **Launch name**, enter a name to be used to identify this feature within this project.

   You can optionally add a description.
5. Choose either **Select from existing features** or **Add new feature**.

   If you are using an existing feature, select it under **Feature name**.

If you choose **Add new feature**, do the following:

a. For **Feature name**, enter a name to be used to identify this feature within this project. You can optionally add a description.

b. For **Feature variations**, for **Variation type** choose **Boolean**, **Long**, **Double**, or **String**. For more information, see Variation types.

c. Add up to five variations for your feature. The **Value** for each variation must be valid for the **Variation type** that you selected.

   Specify one of the variations to be the default. This is the baseline that the other variations will be compared to, and should be the variation that is being served to your users now. If you stop an experiment, this default variation will then be served to all users.

d. Choose **Sample code**. The code example shows what you need to add to your application to set up the variations and assign user sessions to them. You can choose between JavaScript, Java, and Python for the code.

   You don't need to add the code to your application right now, but you must do so before you start the launch.

   For more information, see Adding code to your application.

6. For **Launch configuration**, choose whether to start the launch immediately or schedule it to start later.

7. (Optional) To specify different traffic splits for audience segments that you have defined, instead of the traffic split that you will use for your general audience, choose **Add Segment Overrides**.

   In **Segment Overrides**, select a segment and define the traffic split to use for that segment.

   You can optionally define more segments to define traffic splits for by choosing **Add Segment Override**. A launch can have up to six segment overrides.

   For more information, see Use segments to focus your audience.

8. For **Traffic configuration**, select the traffic percentage to assign to each variation for the general audience that doesn't match the segment overrides. You can also choose to exclude variations from being served to users.

   The **Traffic summary** shows how much of your overall traffic is available for this launch.

9. If you choose to schedule the launch to start later, you can add multiple steps to the launch. Each step can use different percentages for serving the variations. To do this, choose **Add another step** and then specify the schedule and traffic percentages for the next step. You can include as many as five steps in a launch.

10. If you want to track your feature performance with metrics during the launch, choose **Metrics**, **Add metric**. You can use either CloudWatch RUM metrics or custom metrics.

    To use a custom metric, you can create the metric here using an Amazon EventBridge rule. To create a custom metric, do the following:

    - Choose **Custom metrics** and enter a name for the metric.
    - Under **Metric rule**, for **Entity ID**, enter the way to identify the entity. This can be a user or session that does an action that causes a metric value to be recorded. An example is `userDetails.userID`.
    - For **Value key**, enter the value that is to be tracked to produce the metric.
    - Optionally, enter a name for the units for the metric. This unit name is for display purposes only, for use on graphs in the Evidently console.

    As you enter those fields, the box shows examples of how to code the EventBridge rule to create the metric. For more information about EventBridge, see [What Is Amazon EventBridge?](#)

    To use RUM metrics, you must already have a RUM app monitor set up for your application. For more information, see [Set up an application to use CloudWatch RUM](#).

    > **Note**
    >
    > If you use RUM metrics, and the app monitor is not configured to sample 100% of user sessions, then not all of the user sessions that participate in the launch will send metrics to Evidently. To ensure that the launch metrics are accurate, we recommend that the app monitor uses 100% of user sessions for sampling.

11. (Optional) If you create at least one metric for the launch, you can associate an existing CloudWatch alarm with this launch. To do so, choose **Associate CloudWatch alarms**.

    When you associate an alarm with a launch, CloudWatch Evidently must add tags to the alarm with the project name and launch name. This is so that CloudWatch Evidently can display the correct alarms in the launch information in the console.

To acknowledge that CloudWatch Evidently will add these tags, choose **Allow Evidently to tag the alarm resource identified below with this launch resource.** Then, choose **Associate alarm** and enter the alarm name.

For information about creating CloudWatch alarms, see [Using Amazon CloudWatch alarms].

12. (Optional) To add tags to this launch, choose **Tags**, **Add new tag**.

    Then, for **Key**, enter a name for the tag. You can add an optional value for the tag in **Value**.

    To add another tag, choose **Add new tag** again.

    For more information, see [Tagging Amazon Resources].
13. Choose **Create launch**.

Create an experiment

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

Use experiments to test different versions of a feature or website and collect data from real user sessions. This way, you can make choices for your application based on evidence and data.

Before you can add an experiment, you must have created a project. For more information, see [Create a new project].

When you add an experiment, you can use a feature that you have already created, or create a new feature while you create the experiment.

To add an experiment to a project

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Select the button next to the name of the project and choose **Project actions**, **Create experiment**.

4. For **Experiment name**, enter a name to be used to identify this feature within this project.

   You can optionally add a description.

5. Choose either **Select from existing features** or **Add new feature**.

   If you are using an existing feature, select it under **Feature name**.

   If you choose **Add new feature**, do the following:

   a. For **Feature name**, enter a name to be used to identify this feature within this project. You can also optionally enter a description.
   b. For **Feature variations**, for **Variation type** choose **Boolean**, **Long**, **Double**, or **String**. The type defines which type of value is used for each variation. For more information, see Variation types.
   c. Add up to five variations for your feature. The **Value** for each variation must be valid for the **Variation type** that you selected.

      Specify one of the variations to be the default. This is the baseline that the other variations will be compared to, and should be the variation that is being served to your users now. If you stop an experiment that uses this feature, the default variation is then served to the percentage of users that were in the experiment previously.
   d. Choose **Sample code**. The code example shows what you need to add to your application to set up the variations and assign user sessions to them. You can choose between JavaScript, Java, and Python for the code.

      You don't need to add the code to your application right now, but you must do so before you start the experiment. For more information, see Adding code to your application.

6. For **Audience**, optionally select a segment that you have created if you want this experiment to apply only to the users who match that segment. For more information about segments, see Use segments to focus your audience.

7. For **Traffic split for the experiment**, specify the percentage of the selected audience whose sessions will be used in the experiment. Then allocate the traffic for the different variations that the experiment uses.

   If a launch and an experiment are both running at the same time for the same feature, the audience is first directed to the launch. Then, the percentage of traffic specified for the launch is taken from the overall audience. After that, the percentage that you specify here is the percentage of the remaining audience that is used for the experiment. Any remaining traffic after that is served the default variation.

8. For **Metrics**, choose the metrics to use to evaluate the variations during the experiment. You must use at least one metric for evaluation.

   a. For **Metric source**, choose whether to use CloudWatch RUM metrics or custom metrics.

   b. Enter a name for the metric. For **Goal**, choose **Increase** if you want a higher value for the metric to indicate a better variation. Choose **Decrease** if you want a lower value for the metric to indicate a better variation.

   c. If you are using a custom metric, you can create the metric here using an Amazon EventBridge rule. To create a custom metric, do the following:

      - Under **Metric rule**, for **Entity ID**, enter a way to identify the entity, This can be a user or session that does an action that causes a metric value to be recorded. An example is `userDetails.userID`.
      - For **Value key**, enter the value that is to be tracked to produce the metric.
      - Optionally, enter a name for the units for the metric. This unit name is for display purposes only, for use on graphs in the Evidently console.

   You can use RUM metrics only if you have set up RUM to monitor this application. For more information, see CloudWatch RUM.

   > **Note**
   >
   > If you use RUM metrics, and the app monitor is not configured to sample 100% of user sessions, then not all of the user sessions in the experiment will send metrics to Evidently. To ensure that the experiment metrics are accurate, we recommend that the app monitor uses 100% of user sessions for sampling.

   d. (Optional) To add more metrics to evaluate, choose **Add metric**. You can evaluate as many as three metrics during the experiment.

9. (Optional) To create CloudWatch alarms to use with this experiment, choose **CloudWatch alarms**. The alarms can monitor whether the difference in results between each variation and the default variation is larger than a threshold that you specify. If a variation's performance is worse than the default variation, and the difference is greater than your threshold, it goes into alarm state and notifies you.

Creating an alarm here creates one alarm for each variation that is not the default variation.

If you create an alarm, specify the following:

- For **Metric name**, choose the experiment metric to use for the alarm.
- For **Alarm condition** choose what condition causes the alarm to go into alarm state, when the variation metric values are compared to the default variation metric values. For example, choose **Greater** or **Greater/Equal** if higher numbers indicate for the variation indicates that it is performing poorly. This would be appropriate if the metric is measuring page load time, for example.
- Enter a number for the threshold, which is the percentage difference in performance that will cause the alarm to go into `ALARM` state.
- For **Average over period**, choose how much metric data for each variation is aggregated together before being compared.

You can choose **Add new alarm** again to add more alarms to the experiment.

Next, choose **Set notifications for the alarm** and select or create an Amazon Simple Notification Service topic to send alarm notifications to. For more information, see Setting up Amazon SNS notifications,

10. (Optional) To add tags to this experiment, choose **Tags**, **Add new tag**.

    Then, for **Key**, enter a name for the tag. You can add an optional value for the tag in **Value**.

    To add another tag, choose **Add new tag** again.

    For more information, see Tagging Amazon Resources.
11. Choose **Create experiment**.
12. If you haven't already, build the feature variants into your application.
13. Choose **Done**. The experiment does not start until you start it.

After you complete the steps in the following procedure, the experiment starts immediately.

To start an experiment that you have created

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose the name of the project.
4. Choose the **Experiments** tab.
5. Choose the button next to the name of the experiment, and choose **Actions**, **Start experiment**.
6. (Optional) To view or modify the experiment settings you made when you created it, choose **Experiment setup**.
7. Choose a time for the experiment to end.
8. Choose **Start experiment**.

   The experiment starts immediately.

Manage features, launches, and experiments

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

Use the procedures in these sections to manage the features, launches, and experiments that you have created.

Topics

- See the current evaluation rules and audience traffic for a feature
- Modify launch traffic
- Modify a launch's future steps
- Modify experiment traffic
- Stop a launch
- Stop an experiment

See the current evaluation rules and audience traffic for a feature

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

You can use the CloudWatch Evidently console to see how the feature's evaluation rules are allocating the audience traffic among the feature's current launches, experiments, and variations.

To view the audience traffic for a feature

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose the name of the project that contains the feature.
4. Choose the **Features** tab.
5. Choose the name of the feature.

   In the **Evaluation rules** tab, you can see the flow of audience traffic for your feature, as follows:

   - First, the overrides are evaluated. These specify that certain users are always served a specific variation. The sessions of users who are assigned overrides do not contribute to launch or experiment metrics.
   - Next, the remaining traffic is available for the ongoing launch, if there is one. If there is a launch in progress, the table in the **Launches** section displays the launch name and the launch traffic split among the feature variations. On the right side of the **Launches** section, a **Traffic** indicator displays how much of the available audience (after overrides) is allocated to this launch. The rest of the traffic not allocated to the launch flows to the experiment (if any) and then the default variation.
   - Next, the remaining traffic is available for the ongoing experiment, if there is one. If there is an experiment in progress, the table in the **Experiments** section displays the experiment name and progress. On the right side of the **Experiments** section, a **Traffic** indicator displays how much of the available audience (after overrides and launches) is allocated to this

experiment. The rest of the traffic not allocated to the launch or the experiment is served the default variation of the feature.

Modify launch traffic

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

You can modify the traffic allocation for a launch at any time, including while the launch is ongoing.

If you have both an ongoing launch and an ongoing experiment for the same feature, any changes to the feature traffic will cause a change in the experiment traffic. This is because the audience available to the experiment is the portion of your total audience that is not already allocated to the launch. Increasing launch traffic will descrease the audience available to the experiment, and decreasing launch traffic or ending the launch will increase the audience available to the experiment.

To modify the traffic allocation for a launch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose the name of the project that contains the launch.
4. Choose the **Launches** tab.
5. Choose the name of the launch.

   Choose **Modify launch traffic**.
6. For **Serve**, select the new traffic percentage to assign to each variation. You can also choose to exclude variations from being served to users. As you change these values, you can see the updated effects on your overall feature traffic under **Traffic summary**.

   The **Traffic summary** shows how much of your overall traffic is available for this launch, and how much of that available traffic is allocated to this launch.

7. Choose **Modify**.

Modify a launch's future steps

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

You can modify the configuration of launch steps that haven't happened yet, and also add more steps to a launch.

To modify the steps for a launch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose the name of the project that contains the launch.
4. Choose the **Launches** tab.
5. Choose the name of the launch.

   Choose **Modify launch traffic**.
6. Choose **Schedule launch**.
7. For any steps that have not started yet, you can modify the percentage of the available audience to use in the experiment. You can also modify how their traffic is allocated among the variations.

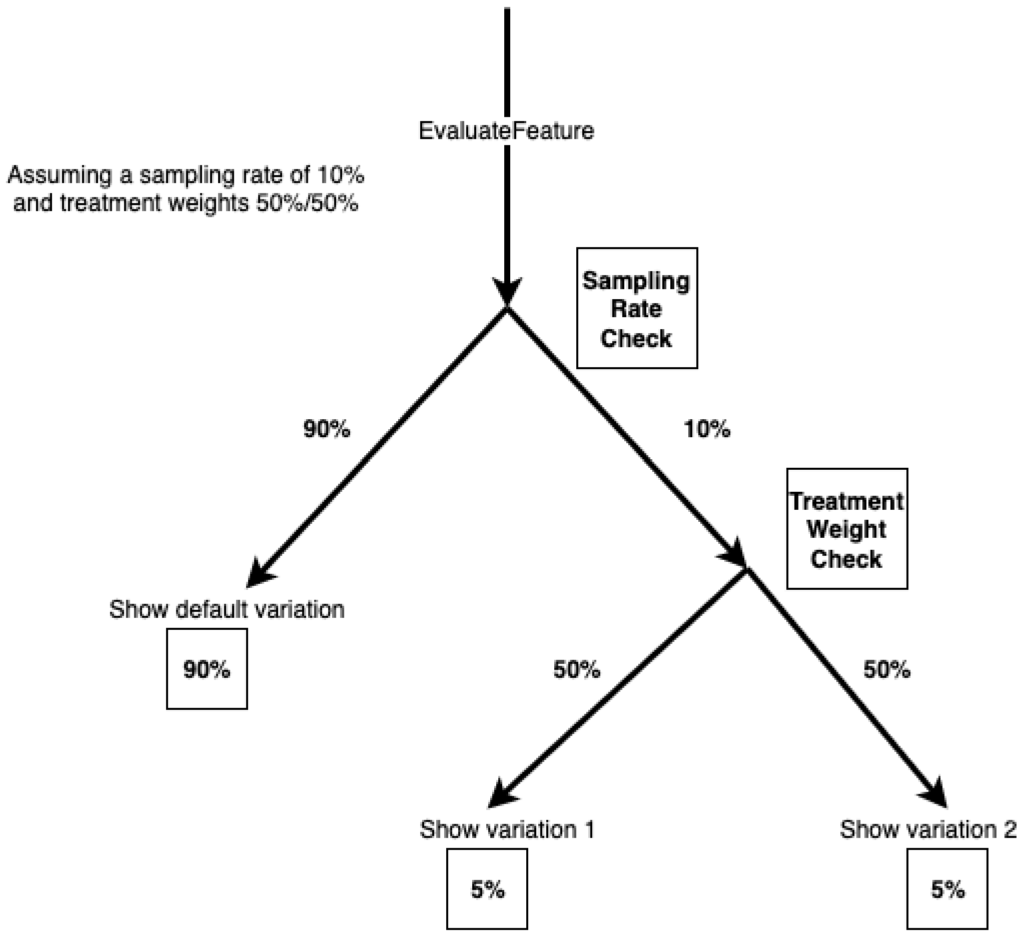
   You can add more steps to the launch by choosing **Add another step**. A launch can have a maximum of five steps.
8. Choose **Modify**.

Modify experiment traffic

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

You can modify the sampling rate for an experiment at any time, including while the experiment is ongoing. However, you can't update the treatment weights after an experiment is running. Therefore, you can change the total traffic exposed to the experiment after an experiment is running, but not the relative allocation to each treatment. If you modify the traffic of an ongoing experiment, we recommend that you only increase the traffic allocation, so that you don't introduce bias.

The following diagram shows how client traffic is allocated to different variations in an experiment. In this experiment, the sampling rate is 10% and the treatment weights for the two variations are 50% each.



To modify the traffic allocation for an experiment

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application monitoring**, **Evidently**.
3. Choose the name of the project that contains the launch.
4. Choose the **Experiments** tab.
5. Choose the name of the launch.
6. Choose **Modify experiment traffic**.
7. Enter a percentage or use the slider to specify how much of the available traffic to allocate to this experiment. The available traffic is the total audience minus the traffic that is allocated to a current launch, if there is one. The traffic that is not allocated to the launch or experiment is served the default variation.
8. Choose **Modify**.

Stop a launch

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

If you stop an ongoing launch, you will not be able to resume it or restart it. Also, it will not be evaluated as a rule for traffic allocation, and the traffic that was allocated to the launch will instead be available to the feature's experiment, if there is one. Otherwise, all traffic will be served the default variation after the launch is stopped.

To permanently stop a launch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose the name of the project that contains the launch.
4. Choose the **Launch** tab.
5. Choose the button to the left of the name of the launch.
6. Choose **Actions**, **Cancel launch** or **Actions**, **Mark as complete**.

Stop an experiment

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

If you stop an ongoing experiment, you will not be able to resume it or restart it. The portion of traffic that was previously used in the experiment will be served the default variation.

When an experiment is not manually stopped and passes its end date, the traffic does not change. The portion of traffic allocated to the experiment still goes to the experiment. To stop this, and cause the experiment traffic to instead be served the default variation, mark the experiment as complete.

When you stop an experiment, you can choose to cancel it or mark it as complete. If you cancel, it will be shown as **Cancelled** in the list of experiments. If you choose to mark it as complete, it is shown as **Completed**.

To permanently stop an experiment

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose the name of the project that contains the experiment.
4. Choose the **Experiments** tab.
5. Choose the button to the left of the name of the experiment.
6. Choose **Actions**, **Cancel experiment** or **Actions**, **Mark as complete**.

Adding code to your application

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

To work with CloudWatch Evidently, you add code to your application to assign a variation to each user session, and to send metrics to Evidently. You use the CloudWatch Evidently `EvaluateFeature` operation to assign variations to user sessions, and you use the `PutProjectEvents` operation to send events to Evidently to be used to calculate metrics for your launches or experiments.

When you create variations or custom metrics, the CloudWatch Evidently console provides samples of the code you need to add.

For an end-to-end example, see Tutorial: A/B testing with the Evidently sample application.

Using EvaluateFeature

When feature variations are used in a launch or experiment, the application uses the EvaluateFeature operation to assign each user session a variation. The assignment of a variation to a user is an *evaluation event*. When you call this operation, you pass in the following:

- **Feature name**– Required. Evidently processes the evaluation according to the feature evaluation rules of the launch or experiment, and selects a variation for the entity.
- **entityId**– Required. Represents a unique user.
- **evaluationContext**– Optional. A JSON object representing additional information about a user. Evidently will use this value to match the user to a *segment* of your audience during feature evaluations, if you have created segments. For more information, see Use segments to focus your audience.

  The following is an example of an `evaluationContext` value that you can send to Evidently.

```
{
    "Browser": "Chrome",
    "Location": {
        "Country": "United States",
        "Zipcode": 98007
    }
}
```

Sticky evaluations

CloudWatch Evidently uses "sticky" evaluations. A single configuration of `entityId`, feature, *feature configuration*, and `evaluationContext` always receives the same variation assignment. The only time this variation assignment changes is when an entity is added to an override or the experiment traffic is dialed up.

A feature configuration includes the following:

- The feature variations
- The variation configuration (percentages assigned to each variation) for a currently running experiment for this feature, if any.
- The variation configuration for a currently running launch for this feature, if any. The variation configuration includes the defined segment overrides, if any.

If an experiment's traffic allocation is *increased*, any `entityId` that was previously assigned to an experiment treatment group will continue to receive the same treatment. Any `entityId` that was previously assigned to the control group, might be assigned to an experiment treatment group, according to the variation configuration specified for the experiment.

If an experiment's traffic allocation is *decreased*, an `entityId` might go from a treatment group to a control group, but it will not go into a different treatment group.

Using PutProjectEvents

To code a custom metric for Evidently, you use the [PutProjectEvents] operation. The following is a simple payload example.

```
{
    "events": [
        {
            "timestamp": {{$timestamp}},
            "type": "aws.evidently.custom",
            "data": "{\"details\": {\"pageLoadTime\": 800.0}, \"userDetails\":
 {\"userId\": \"test-user\"}}"
        }
    ]
}
```

The `entityIdKey` can just be an `entityId` or you can rename it to anything else, such as `userId`. In the actual event, `entityId` can be a username, a session ID, and so on.

```
"metricDefinition":{
    "name": "noFilter",
    "entityIdKey": "userDetails.userId", //should be consistent with jsonValue in
 events "data" fields
    "valueKey": "details.pageLoadTime"
},
```

To ensure that events are associated with the correct launch or experiment, you must pass the same `entityId` when you call both `EvaluateFeature` and `PutProjectEvents`. Be sure to call `PutProjectEvents` after the `EvaluateFeature` call, otherwise data is dropped and won't be used by CloudWatch Evidently.

The `PutProjectEvents` operation does not require the feature name as an input parameter. This way, you can use a single event in multiple experiments. For example, suppose you call

`EvaluateFeature` with the `entityId` set to `userDetails.userId`. If you have two or more experiments running, you can have a single event from that user's session emit metrics for each of those experiments. To do this, you call `PutProjectEvents` once for each experiment, using that same `entityId`.

Timing

After your application calls `EvaluateFeature`, there is a one-hour time period where metric events from `PutProjectEvents` are attributed based on that evaluation. If any more events occur after the one-hour period, they are not attributed.

However, if the same `entityId` is used for a new `EvaluateFeature` call during that initial call's one-hour window, the later `EvaluateFeature` result is now used instead, and the one-hour timer is restarted. This can only happen in certain circumstances, such as when experiment traffic is dialed up between the two assignments, as explained in the previous **Sticky evaluations** section.

For an end-to-end example, see [Tutorial: A/B testing with the Evidently sample application](#).

Evidently project data storage in CloudWatch

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

Evidently collects two types of events:

- **Evaluation events** are related to which feature variation is assigned to a user session. Evidently uses these events to produce metrics and other experiment and launch data, which you can view in the Evidently console.

  You can also choose to store these evaluation events in Amazon CloudWatch Logs or Amazon S3.
- **Custom events** are used to generate metrics from user actions such as clicks and checkouts. Evidently doesn't provide a method for you to store custom events. If you want to save them, you must modify your application code to send them to a storage option outside of Evidently.

Format of evaluation event logs

If you choose to store evaluation events in CloudWatch Logs or Amazon S3, each evaluation event is stored as a log event with the following format:

```
{
    "event_timestamp": 1642624900215,
    "event_type": "evaluation",
    "version": "1.0.0",
    "project_arn": "arn:aws:evidently:us-east-1:123456789012:project/petfood",
    "feature": "petfood-upsell-text",
    "variation": "Variation1",
    "entity_id": "7",
    "entity_attributes": {},
    "evaluation_type": "EXPERIMENT_RULE_MATCH",
    "treatment": "Variation1",
    "experiment": "petfood-experiment-2"
}
```

Here are more details about the preceding evaluation event format:

- The timestamp is in UNIX time with milliseconds
- The variation is the name of the variation of the feature which was assigned to this user session.
- The entity ID is a string.
- Entity attributes are a hash of arbitrary values sent by the client. For example, if the `entityId` is mapped to blue or green, then you can optionally send userIDs, session data, or whatever else that you want want from a correlation and data warehouse perspective.

IAM policy and encryption for evaluation event storage in Amazon S3

If you choose to use Amazon S3 to store evaluation events, you must add an IAM policy like the following to allow Evidently to publish logs to the Amazon S3 bucket. This is because Amazon S3 buckets and the objects they contain are private, and they don't allow access to other services by default.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AWSLogDeliveryWrite",
```

```
            "Effect": "Allow",
            "Principal": {"Service": "delivery.logs.amazonaws.com"},
            "Action": "s3:PutObject",
            "Resource": "arn:aws:s3:::bucket_name/optional_folder/AWSLogs/account_id/
*",
            "Condition": {"StringEquals": {"s3:x-amz-acl": "bucket-owner-full-
control"}}
        },
        {
            "Sid": "AWSLogDeliveryCheck",
            "Effect": "Allow",
            "Principal": {"Service": "delivery.logs.amazonaws.com"},
            "Action": ["s3:GetBucketAcl", "s3:ListBucket"],
            "Resource": "arn:aws:s3:::bucket_name"
        }
    ]
}
```

If you store Evidently data in Amazon S3, you can also choose to encrypt it with Server-Side Encryption with Amazon Key Management Service Keys (SSE-KMS). For more information, see Protecting data using server-side encryption.

If you use a customer managed key from Amazon KMS, you must add the following to the IAM policy for your key. This allows Evidently to write to the bucket.

```
{
    "Sid": "AllowEvidentlyToUseCustomerManagedKey",
    "Effect": "Allow",
    "Principal": {
        "Service": [
            "delivery.logs.amazonaws.com"
        ]
    },
   "Action": [
       "kms:Encrypt",
       "kms:Decrypt",
       "kms:ReEncrypt*",
       "kms:GenerateDataKey*",
       "kms:DescribeKey"
    ],
    "Resource": "*"
}
```

How Evidently calculates results

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

You can use Amazon CloudWatch Evidently A/B testing as a tool for data-driven decision making. In an A/B test, users are randomly assigned to either the control group (also called the default variation), or one of the treatment groups (also called the tested variations). For example, users in the control group might experience the website, service, or application in the same way that they did before the experiment started. Meanwhile, users in the treatment group might experience the change.

CloudWatch Evidently supports up to five different variations in an experiment. Evidently randomly assigns traffic to these variations. This way, you can track business metrics (such as revenue) and performance metrics (such as latency) for each group. Evidently does the following:

- Compares the treatment with the control. (For example, compares whether revenue increases or decreases with a new checkout process.)
- Indicates whether the observed difference between the treatment and the control is *significant*. For this, Evidently offers two approaches: *Frequentist significance levels* and *Bayesian probabilities*.

Why use Frequentist and Bayesian approaches?

Consider a case where the treatment has no effect compared to the control, or a case where the treatment is identical to the control (an *A/A test*). You would still observe a small difference between the treatment and the control in the data. This is because the test participants consist of a finite sample of users, representing a small percentage of all users of the website, service, or application. Frequentist significance levels and Bayesian probabilities provide insights into whether the observed difference is significant or due to chance.

Evidently considers the following to determine whether the observed difference is significant:

- How big the difference is

- How many samples are part of the test
- How the data is distributed

Frequentist analysis in Evidently

Evidently uses sequential testing, which avoids the usual problems of *peeking*, a common pitfall of frequentist statistics. Peeking is the practice of checking the results of an ongoing A/B test in order to stop it and make a decision based on the observed results. For more information about sequential testing, see Time-uniform, nonparametric, nonasymptotic confidence sequences by Howard et al. (Ann. Statist. 49 (2) 1055 - 1080, 2021).

Because Evidently's results are valid at any time (*anytime-valid* results), you can peek at results during the experiment and still draw sound conclusions. This can reduce some of the costs of experimentation, because you can stop an experiment before the scheduled time if the results already have significance.

Evidently generates anytime-valid significance levels and anytime-valid 95% confidence intervals of the difference between the tested variation and the default variation in the target metric. The **Result** column in the experiment results indicates the tested variation performance, which can be one of the following:

- **Inconclusive** – The significance level is less than 95%
- **Better** – The significance level is 95% or higher and one of the following is true:
  - The lower bound of the 95%-confidence interval is higher than zero and the metric should increase
  - The upper bound of the 95%-confidence interval is lower than zero and the metric should decrease
- **Worse** – The significance level is 95% or higher and one of the following is true:
  - The upper bound of the 95%-confidence interval is higher than zero and the metric should increase
  - The lower bound of the 95%-confidence interval is lower than zero and the metric should decrease
- **Best** – The experiment has two or more tested variations in addition to the default variation, and the following conditions are met:
  - The variation qualifies for the *Better* designation
  - One of the following is true:

- The lower bound of the 95%-confidence interval is higher than the upper bound of the 95%-confidence intervals of all the other variations and the metric should increase
- The upper bound of the 95%-confidence interval is lower than the lower bound of the 95%-confidence intervals of all the other variations and the metric should decrease

Bayesian analysis in Evidently

With Bayesian analysis, you can calculate the probability that the mean in the tested variation is larger or smaller than the mean in the default variation. Evidently performs Bayesian inference for the mean of the target metric by using *conjugate priors*. With conjugate priors, Evidently can more efficiently infer the posterior distribution needed for the Bayesian analysis.

Evidently waits until the end date of the experiment to compute the results of the Bayesian analysis. The results page displays the following:

- *probability of increase* – The probability that the mean of the metric in the tested variation is at least 3% larger than the mean in the default variation
- *probability of decrease* – The probability that the mean of the metric in the tested variation is at least 3% smaller than the mean in the default variation
- *probability of no change* – The probability that the mean of the metric in the tested variation lies within ±3% of the mean in the default variation

The **Result** column indicates the performance of the variation, and can be one of the following:

- **Better** – The probability of increase is at least 90% and the metric should increase, or the probability of decrease is at least 90% and the metric should decrease
- **Worse** – The probability of decrease is at least 90% and the metric should increase, or the probability of increase is at least 90% and the metric should decrease

View launch results in the dashboard

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

You can see the progress and metric results of an experiment while it is ongoing and after it is completed.

To see the progress and results of a launch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose the name of the project that contains the launch.
4. Choose the **Launch** tab.
5. Choose the name of the launch.
6. To see the launch steps and the traffic allocations for each step, choose the **Launch** tab.
7. To see the number of user sessions assigned to each variation over time, and to view the performance metrics for each variation in the launch, choose the **Monitoring** tab.

   This view also displays whether any launch alarms have gone into `ALARM` state during the launch.
8. To see the variations, metrics, alarms, and tags for this launch, choose the **Configuration** tab.

View experiment results in the dashboard

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

You can see the statistical results of an experiment while it is ongoing and after it is completed. Experiment results are available up to 63 days after the start of the experiment. They are not available after that because of CloudWatch data retention policies.

No statistical results are displayed until each variation has at least 100 events.

Evidently performs an additional offline p-value analysis at the end of the experiment. Offline p-value analysis can detect statistical significance in some cases where the anytime p-values used during the experiment do not find statistical significance.

For more information about how CloudWatch Evidently calculates experiment results, see How Evidently calculates results.

To see the results of an experiment

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose the name of the project that contains the experiment.
4. Choose the **Experiments** tab.
5. Choose the name of the experiment, and then choose the **Results** tab.
6. By **Variation performance**, there is a control where you can select which experiment statistics to display. If you select more than one statistic, Evidently displays a graph and table for each statistic.

   Each graph and table displays the results of the experiment so far.

   Each graph can display the following results. You can use the control at the right of the graph to determine which of the following items is displayed:

   - The number of user session events recorded for each variation.
   - The average value of the metric that is selected at the top of the graph, for each variation.
   - The statistical significance of the experiments. This compares the difference for the metric selected at the top of the graph with the default variation and each of the other variations.
   - The 95% upper and lower confidence bounds on the difference of the selected metric, between each of the variations and the default variation.

   The table displays a row for each variation. For each variation that is not the default, Evidently displays whether it has received enough data to declare the results statistically significant. It also shows whether the variation's improvement in the statistical value has reached a 95% confidence level.

Finally, in the **Result** column, Evidently provides a recommendation about which variation performs best based on this statistic, or whether the results are inconclusive.

How CloudWatch Evidently collects and stores data

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

Amazon CloudWatch Evidently collects and stores data related to project configurations so that customers can run experiments and launches. The data includes the following:

- Metadata about projects, features, launches, and experiments
- Metric events
- Evaluation data

Resource metadata is stored in Amazon DynamoDB. The data is encrypted at rest by default, using Amazon owned keys. These keys are a collection of Amazon KMS keys that an Amazon Web Services service owns and manages for use in multiple Amazon Web Services accounts. Customers can’t view, manage, or audit the use of these keys. Customers are also not required to take action or change programs to protect the keys that encrypt their data.

For more information, see Amazon owned keys in the Amazon Key Management Service Developer Guide.

Evidently metric events and evaluation events are delivered directly to customer-owned locations.

Data in transit is automatically encrypted with HTTPS. This data will be delivered to customer-owned locations.

You can also choose to store evaluation events in Amazon Simple Storage Service or Amazon CloudWatch Logs. For more information about how you can secure your data in these services, see

Enabling Amazon S3 default bucket encryption and Encrypting log data in CloudWatch Logs using Amazon KMS.

Retrieving data

You can retrieve your data using CloudWatch Evidently APIs. To retrieve project data, use GetProject or ListProjects.

To retrieve feature data, use GetFeature or ListFeatures.

To retrieve launch data, use GetLaunch or ListLaunches.

To retrieve experiment data, use GetExperiment, ListExperiments, or GetExperimentResults.

Modifying and deleting data

You can modify and delete your data using CloudWatch Evidently APIs. For project data, use UpdateProject or DeleteProject.

For feature data, use UpdateFeature or DeleteFeature.

For launch data, use UpdateLaunch or DeleteLaunch.

For experiment data, use UpdateExperiment or DeleteExperiment.

Using service-linked roles for Evidently

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

CloudWatch Evidently uses Amazon Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Evidently. Service-linked roles are predefined by Evidently and include all the permissions that the service requires to call other Amazon services on your behalf.

A service-linked role makes setting up Evidently easier because you don't have to manually add the necessary permissions. Evidently defines the permissions of its service-linked roles, and unless defined otherwise, only Evidently can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting its related resources. This protects your Evidently resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see Amazon Services That Work with IAM and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Evidently

Evidently uses the service-linked role named **AWSServiceRoleForCloudWatchEvidently –** Allows CloudWatch Evidently to manage associated Amazon resourcees on behalf of the customer.

The AWSServiceRoleForCloudWatchEvidently service-linked role trusts the following services to assume the role:

- `CloudWatch Evidently`

The role permissions policy named AmazonCloudWatchEvidentlyServiceRolePolicy allows Evidently to complete the following actions on the specified resources:

- Actions: `appconfig:StartDeployment`, `appconfig:StopDeployment`, `appconfig:ListDeployments`, and `appconfig:TagResource` on Evidently thick clients.

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the *IAM User Guide*.

Creating a service-linked role for Evidently

You don't need to manually create a service-linked role. When you start using an Evidently thick client in the Amazon Web Services Management Console, the Amazon CLI, or the Amazon API, Evidently creates the service-linked role for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you start using an Evidently thick client, Evidently creates the service-linked role for you again.

Editing a service-linked role for Evidently

Evidently does not allow you to edit the AWSServiceRoleForCloudWatchEvidently service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see [Editing a service-linked role](#) in the *IAM User Guide*.

Deleting a service-linked role for Evidently

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it. You must delete all Evidently projects that are using thick clients.

> **Note**
>
> If the Evidently service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete Evidently resources used by AWSServiceRoleForCloudWatchEvidently

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application monitoring**, **Evidently**.
3. In the list of projects, select the check box next to the projects that used thick clients.
4. Choose **Project actions**, **Delete project**.

To manually delete the service-linked role using IAM

Use the IAM console, the Amazon CLI, or the Amazon API to delete the AWSServiceRoleForCloudWatchEvidently service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Supported regions for Evidently service-linked roles

Evidently supports using service-linked roles in all of the regions where the service is available. For more information, see Amazon regions and endpoints.

Evidently quotas in CloudWatch

> **Important**
>
> End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

CloudWatch Evidently has the following quotas.

Resource	Default quota
Projects	50 per Region per account You can request a quota increase.
Segments	500 per Region per account You can request a quota increase.
Quotas per project	• 100 total features • 500 total launches • 50 running launches • 500 total experiments • 50 running experiments You can request a quota increase for all of these quotas.
API quotas (all quotas are per Region)	• PutProjectEvents: 1000 transactions per second (TPS) in US East (N. Virginia), US West (Oregon), and Europe (Ireland). 200 TPS in all other Regions. • EvaluateFeature: 1000 TPS in US East (N. Virginia), US West (Oregon), and Europe (Ireland). 200 TPS in all other Regions. • BatchEvaluateFeature: 50 TPS

Resource	Default quota
	• Create, Read, Update, Delete (CRUD) APIs: 10 TPS combined across all CRUD APIs You can request a quota increase for all of these quotas.

Tutorial: A/B testing with the Evidently sample application

Important

End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.

This section provides a tutorial for using Amazon CloudWatch Evidently for A/B testing. This tutorial the Evidently sample application, which is a simple react application. The sample app will be configured to either display a `showDiscount` feature or not. When the feature is shown to a user, the price displayed on the shopping website it shown at a 20% discount.

In addition to showing the discount to some users and not to others, in this tutorial you set up Evidently to collect page load time metrics from both variations.

Warning

This scenario requires IAM users with programmatic access and long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed. Access keys can be updated if necessary. For more information, see Update access keys in the *IAM User Guide*.

Step 1: Download the sample application

Start by downloading the Evidently sample application.

To download the sample application

1. Download the sample application from the following Amazon S3 bucket:

```
https://evidently-sample-application.s3.us-west-2.amazonaws.com/evidently-sample-
shopping-app.zip
```

2. Unzip the package.

Step 2: Add the Evidently endpoint and set up credentials

Next, add the Region and endpoint for Evidently to the `config.js` file in the `src` directory in the sample app package, as in the following example:

```
evidently: {
    REGION: "us-west-2",
    ENDPOINT: "https://evidently.us-west-2.amazonaws.com (https://evidently.us-
west-2.amazonaws.com/)",
},
```

You also must make sure that the application has permission to call CloudWatch Evidently.

To grant the sample app permissions to call Evidently

1. Federate to your Amazon account.
2. Create an IAM user and attach the **AmazonCloudWatchEvidentlyFullAccess** policy to this user.
3. Make a note of the IAM user's access key id and secret access key, because you will need them in the next step.
4. In the same `config.js` file that you modified earlier in this section, enter the values of the access key ID and the secrect access key, as in the following example:

```
credential: {
   accessKeyId: "Access key ID",
   secretAccessKey: "Secret key"
}
```

> **Important**
>
> We use this step to make the sample app as simple as possible for you to try out. We do not recommend that you put your IAM user credential into your actual production application. Instead, we recommend that you use Amazon Cognito for authentication. For more information, see [Integrating Amazon Cognito with web and mobile apps](#).

Step 3: Set up code for the feature evaluation

When you use CloudWatch Evidently to evaluate a feature, you must use the **EvaluateFeature** operation to randomly select a feature variation for each user session. This operation assigns user sessions to each variation of the feature, according to the percentages that you specified in the experiment.

To set up the feature evaluation code for the bookstore demo app

1. Add the client builder in the `src/App.jsx` file so that the sample app can call Evidently.

```
import Evidently from 'aws-sdk/clients/evidently';
import config from './config';

const defaultClientBuilder = (
    endpoint,
    region,
) => {
    const credentials = {
        accessKeyId: config.credential.accessKeyId,
        secretAccessKey: config.credential.secretAccessKey
    }
    return new Evidently({
        endpoint,
        region,
        credentials,
    });
};
```

2. Add the following to the `const App` code section to initiate the client.

```
  if (client == null) {
```

```
      client = defaultClientBuilder(
        config.evidently.ENDPOINT,
        config.evidently.REGION,
      );
```

3. Construct `evaluateFeatureRequest` by adding the following code. This code pre-fills the project name and feature name that we recommend later in this tutorial. You can substitute your own project and feature names, as long as you also specify those project and feature names in the Evidently console.

```
const evaluateFeatureRequest = {
              entityId: id,
              // Input Your feature name
              feature: 'showDiscount',
              // Input Your project name'
              project: 'EvidentlySampleApp',
            };
```

4. Add the code to call Evidently for feature evaluation. When the request is sent, Evidently randomly assigns the user session to either see the `showDiscount` feature or not.

```
client.evaluateFeature(evaluateFeatureRequest).promise().then(res => {
    if(res.value?.boolValue !== undefined) {
        setShowDiscount(res.value.boolValue);
    }
    getPageLoadTime()
 })
```

Step 4: Set up code for the experiment metrics

For the custom metric, use Evidently's `PutProjectEvents` API to send metric results to Evidently. The following examples show how to set up the custom metric and send experiment data to Evidently.

Add the following function to calculate the page load time and use `PutProjectEvents` to send the metric values to Evidently. Add the following function to into `Home.tsx` and call this function within the `EvaluateFeature` API:

```
const getPageLoadTime = () => {
    const timeSpent = (new Date().getTime() - startTime.getTime()) * 1.000001;
```

```
    const pageLoadTimeData = `{
      "details": {
        "pageLoadTime": ${timeSpent}
      },
      "UserDetails": { "userId": "${id}", "sessionId": "${id}"}
    }`;
    const putProjectEventsRequest = {
      project: 'EvidentlySampleApp',
      events: [
        {
          timestamp: new Date(),
          type: 'aws.evidently.custom',
          data: JSON.parse(pageLoadTimeData)
        },
      ],
    };
    client.putProjectEvents(putProjectEventsRequest).promise();
  }
```

Here is what the `App.js` file should look like after all the editing that you have done since downloading it.

```
import React, { useEffect, useState } from "react";
import { BrowserRouter as Router, Switch } from "react-router-dom";
import AuthProvider from "contexts/auth";
import CommonProvider from "contexts/common";
import ProductsProvider from "contexts/products";
import CartProvider from "contexts/cart";
import CheckoutProvider from "contexts/checkout";
import RouteWrapper from "layouts/RouteWrapper";
import AuthLayout from "layouts/AuthLayout";
import CommonLayout from "layouts/CommonLayout";
import AuthPage from "pages/auth";
import HomePage from "pages/home";
import CheckoutPage from "pages/checkout";
import "assets/scss/style.scss";
import { Spinner } from 'react-bootstrap';

import Evidently from 'aws-sdk/clients/evidently';
import config from './config';

const defaultClientBuilder = (
  endpoint,
```

```
  region,
) => {
  const credentials = {
    accessKeyId: config.credential.accessKeyId,
    secretAccessKey: config.credential.secretAccessKey
  }
  return new Evidently({
    endpoint,
    region,
    credentials,
  });
};

const App = () => {
  const [isLoading, setIsLoading] = useState(true);
  const [startTime, setStartTime] = useState(new Date());
  const [showDiscount, setShowDiscount] = useState(false);
  let client = null;
  let id = null;

  useEffect(() => {
    id = new Date().getTime().toString();
    setStartTime(new Date());
    if (client == null) {
      client = defaultClientBuilder(
        config.evidently.ENDPOINT,
        config.evidently.REGION,
      );
    }
    const evaluateFeatureRequest = {
      entityId: id,
      // Input Your feature name
      feature: 'showDiscount',
      // Input Your project name'
      project: 'EvidentlySampleApp',
    };

    // Launch
    client.evaluateFeature(evaluateFeatureRequest).promise().then(res => {
      if(res.value?.boolValue !== undefined) {
        setShowDiscount(res.value.boolValue);
      }
    });
```

```
    // Experiment
    client.evaluateFeature(evaluateFeatureRequest).promise().then(res => {
      if(res.value?.boolValue !== undefined) {
        setShowDiscount(res.value.boolValue);
      }
      getPageLoadTime()
    })

    setIsLoading(false);
  },[]);

  const getPageLoadTime = () => {
    const timeSpent = (new Date().getTime() - startTime.getTime()) * 1.000001;
    const pageLoadTimeData = `{
      "details": {
        "pageLoadTime": ${timeSpent}
      },
      "UserDetails": { "userId": "${id}", "sessionId": "${id}"}
    }`;
    const putProjectEventsRequest = {
      project: 'EvidentlySampleApp',
      events: [
        {
          timestamp: new Date(),
          type: 'aws.evidently.custom',
          data: JSON.parse(pageLoadTimeData)
        },
      ],
    };
    client.putProjectEvents(putProjectEventsRequest).promise();
  }
  return (
    !isLoading? (
    <AuthProvider>
      <CommonProvider>
        <ProductsProvider>
          <CartProvider>
            <CheckoutProvider>
              <Router>
                <Switch>
                  <RouteWrapper
                    path="/"
                    exact
                    component={() => <HomePage showDiscount={showDiscount}/>}
```

```
                    layout={CommonLayout}
                  />
                  <RouteWrapper
                    path="/checkout"
                    component={CheckoutPage}
                    layout={CommonLayout}
                  />
                  <RouteWrapper
                    path="/auth"
                    component={AuthPage}
                    layout={AuthLayout}
                  />
                </Switch>
              </Router>
            </CheckoutProvider>
          </CartProvider>
        </ProductsProvider>
      </CommonProvider>
    </AuthProvider> ) : (
      <Spinner animation="border" />
    )
  );
};

export default App;
```

Each time a user visits the sample app, a custom metric is sent to Evidently for analysis. Evidently analyzes each metric and displays results in real time on the Evidently dashboard. The following example shows a metric payload:

```
[ {"timestamp": 1637368646.468, "type": "aws.evidently.custom", "data": "{\"details
\":{\"pageLoadTime\":2058.002058},\"userDetails\":{\"userId\":\"1637368644430\",
\"sessionId\":\"1637368644430\"}}" } ]
```

Step 5: Create the project, feature, and experiment

Next, you create the project, feature, and experiment in the CloudWatch Evidently console.

To create the project, feature, and experiment for this tutorial

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.

3. Choose **Create project** and fill out the fields. You must use **`EvidentlySampleApp`** for the project name for the sample to work correctly. For **Evaluation event storage**, choose **Don't store Evaluation events**.

   After filling out the fields, choose **Create Project**.

   For more details, see [Create a new project](#).

4. After the project is created, create a feature in that project. Name the feature **`showDiscount`**. In this feature, create two variations of the **`Boolean`** type. Name the first variation **`disable`** with a value of **`False`** and name the second variation **`enable`** with a value of **`True`**.

   For more information about creating a feature, see [Add a feature to a project](#).

5. After you have finished creating the feature, create an experiment in the project. Name the experiment **`pageLoadTime`**.

   This experiment will use a custom metric called `pageLoadTime` that measures the page load time of the page being tested. Custom metrics for experiments are created using Amazon EventBridge. For more information about EventBridge, see [What Is Amazon EventBridge?](#).

   To create that custom metric, do the following when you create the experiment:

   - Under **Metrics**, for **Metric source**, choose **Custom metrics**.
   - For **Metric name**, enter **`pageLoadTime`**.
   - For **Goal** choose **Decrease**. This indicates that we want a lower value of this metric to indicate the best variation of the feature.
   - For **Metric rule**, enter the following:
     - For **Entity ID**, enter **`UserDetails.userId`**.
     - For **Value key**, enter **`details.pageLoadTime`**.
     - For **Units**, enter **`ms`**.
   - Choose **Add metric**.

   For **Audiences**, select **100%** so that all users are entered in the experiment. Set up the traffic split between the variations to be 50% each.

   Then, choose **Create experiment** to create the experiment. After you create it, it does not start until you tell Evidently to start it.

Step 6: Start the experiment and test CloudWatch Evidently

The final steps are starting the experiment and starting the sample app.

To start the tutorial experiment

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Application Signals**, **Evidently**.
3. Choose the **EvidentlySampleApp** project.
4. Choose the **Experiments** tab.
5. Choose the button next to **pageLoadTime** and choose **Actions**, **Start experiment**.
6. Choose a time for the experiment to end.
7. Choose **Start experiment**.

   The experiment starts immediately.

Next, start the Evidently sample app with the following command:

```
npm install -f && npm start
```

Once the app has started, you will be assigned to one of the two feature variations being tested. One variation displays "20% discount" and the other doesn't. Keep refreshing the page to see the different variations.

> **Note**
>
> Evidently has sticky evaluations. Feature evaluations are deterministic, meaning for the same `entityId` and feature, a user will always receive the same variation assignment. The only time variation assignments change is when an entity is added to an override or experiment traffic is dialed up.
> However, to make the use of the sample app tutorial easy for you, Evidently reassigns the sample app feature evaluation every time that you refresh the page, so that you can experience both variations without having to add overrides.

Troubleshooting

We recommend that you use `npm` version 6.14.14. If you see any errors about building or starting the sample app and you are using a different version of npm, do the following.

To install npm version 6.14.14

1. Use a browser to connect to https://nodejs.org/download/release/v14.17.5/.
2. Download [node-v14.17.5.pkg](https://nodejs.org/download/release/v14.17.5/node-v14.17.5.pkg) and run this pkg to install npm.

   If you see a `webpack not found` error, navigate to the `evidently-sample-shopping-app` folder and try the following:

   a. Delete `package-lock.json`
   b. Delete `yarn-lock.json`
   c. Delete `node_modules`
   d. Delete the webpack dependency from `package.json`
   e. Run the following:

      ```
      npm install -f && npm
      ```

Amazon Q Developer operational investigations (Preview)

> **Note**
>
> The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:
>
> - US East (N. Virginia)
> - US East (Ohio)
> - US West (Oregon)
> - Asia Pacific (Hong Kong)
> - Asia Pacific (Mumbai)
> - Asia Pacific (Singapore)
> - Asia Pacific (Sydney)
> - Asia Pacific (Tokyo)
> - Europe (Frankfurt)
> - Europe (Ireland)
> - Europe (Spain)
> - Europe (Stockholm)

The Amazon Q Developer operational investigations feature is a generative AI-powered assistant that can help you respond to incidents in your system. It uses generative AI to scan your system's telemetry and quickly surface suggestions that might be related to your issue. These suggestions include metrics, logs, deployment events, and root-cause hypotheses. For a complete list of types of data that the AI assistant can surface, see Insights that Amazon Q Developer can surface in investigations

For each suggestion, you decide whether to add it to the investigation findings or to discard it. This helps Amazon Q Developer refine and iterate toward the root cause of the issue. Amazon Q Developer can help you find the root cause without having to manually identify and query multiple metrics and other sources of telemetry and events. A troubleshooting issue that would have taken hours of searching and switching between different consoles can be solved in a much shorter time.

You can create investigations in three ways:

- From within many Amazon consoles. For example, you can start an investigation when viewing a CloudWatch metric or alarm in the CloudWatch console, or from a Lambda function's **Monitor** tab on its properties page.
- By asking a question in Amazon Q chat. The question could be something like "Why is my Lambda function slow today?" or "What's wrong with my database?"
- By configuring a CloudWatch alarm action to automatically start an investigation when the alarm goes into ALARM state.

After you start an investigation with any of these methods, Amazon Q Developer scans your system to find telemetry that might be relevant to the situation, and also generates hypotheses based on what it finds. Amazon Q Developer surfaces both the telemetry data and the hypotheses, and enables you to accept or discard each one.

> **Important**
>
> To help Amazon Q Developer operational investigations (Preview) provide the most relevant information, we might use certain content from Amazon Q, including but not limited to questions that you ask Amazon Q and its response, insights, user interactions, telemetry, and metadata for service improvements. Your trust and privacy, as well as the security of your content, is our highest priority. For more information, see **Amazon Service Terms** and **Amazon responsible AI policy**.
> You can opt out of having your content collected to develop or improve the quality of Amazon Q Developer operational investigations (Preview) by creating an AI service opt-out policy for either Amazon Q or CloudWatch. For more information, see AI services opt-out policies in the Amazon Organizations User Guide.

How investigations find data for suggestions

Investigations use a wide range of data sources to determine dependency relationships and plan analysis paths, including telemetry data configurations, service configurations, and observed relationships. These dependency relationships are found more easily if you use CloudWatch Application Signals and Amazon X-Ray. When Application Signals and X-Ray aren't available, Amazon Q Developer will attempt to infer dependency relationships through co-occurring telemetry anomalies.

While Amazon Q Developer will continue to analyze telemetry data and provide suggestions without these features enabled, in order to ensure optimal quality and performance for Amazon Q Developer operational investigations, we strongly recommend that you enable the services and features listed in (Recommended) Best practices to enhance investigations.

Costs associated with Amazon Q Developer operational investigations

The Amazon Q Developer operational investigations feature is provided at no additional cost while in Preview release. During investigations, Amazon Q Developer might incur Amazon service usage including telemetry and resource queries and other API usage. While the majority of these will not be charged to your Amazon bill, there are exceptions including but not limited to CloudWatch APIs (`ListMetrics`, `GetDashboard`, `ListDashboards`, and `GetInsightRuleReport`), X-Ray APIs (`GetServiceGraph`, `GetTraceSummaries`, and `BatchGetTraces`). Amazon Q Developer also uses Amazon Cloud Control APIs which might incur usage of Amazon services such as Amazon Kinesis Data Streams and Amazon Lambda. Additionally, integration with Amazon Q Developer in chat applications which might incur usage of Amazon Simple Notification Service. For usage of these services exceeding the Amazon Free Tier, you will see charges on your Amazon bill. These charges are expected to be minimal for normal usage of Amazon Q Developer operational investigations. For more information, see Amazon Kinesis Data Streams pricing, Amazon Lambda pricing for Automation, and Amazon Simple Notification Service pricing.

Topics

- Amazon services where investigations are supported
- Getting started
- Investigate operational issues in your environment
- Manage your current investigations
- Security in operational investigations
- Troubleshooting
- Integrations with other systems
- (Recommended) Best practices to enhance investigations
- Operational investigation data retention
- Insights that Amazon Q Developer can surface in investigations

Amazon services where investigations are supported

Note

The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (Oregon)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (Spain)
- Europe (Stockholm)

You can launch investigations from telemetry data (such as CloudWatch metrics, alarms, and logs), review generated anomaly signals, and explore hypotheses on investigations. Amazon Q Developer operational investigations work best when helping you with automated troubleshooting guidance on the Amazon services listed below:

- Amazon EC2[1]
- Amazon ECS on Amazon EC2[2]
- Amazon ECS on Fargate[2]
- Amazon EKS[2]
- Amazon DynamoDB
- Amazon S3
- Amazon EBS[1]

- Lambda
- Amazon Kinesis Data Streams
- Amazon Data Firehose
- Amazon API Gateway
- Amazon SQS
- Amazon SNS

The list of services will continue to be expanded over time. Amazon Q Developer operational investigations utilizes a wide range of data sources to determine dependency relationships and plan analysis paths, including telemetry data configurations, service configurations, and observed relationships through CloudWatch Application Signals and X-Ray. Where none of the above is available, Amazon Q Developer operational investigations will attempt to infer dependency relationships through co-occurring telemetry anomalies.

Best practice setup

While Amazon Q Developer operational investigations will continue to analyze telemetry data and provide suggestions without the following features enabled, in order to ensure optimal quality and performance for Amazon Q Developer operational investigations, we highly recommend to complete the following steps:

- [1]For both Amazon EC2 and Amazon EBS, update your CloudWatch agent to version 1.30049.1 or later. For more information, see Collect metrics, logs, and traces with the CloudWatch agent.
- [2]For both Amazon ECS and Amazon EKS, enable CloudWatch Container Insights. For more information, see Container Insights.
- We recommend that you enable CloudWatch Application Signals and X-Ray. For more information, see Application Signals and **What is Amazon X-Ray**.

Getting started

Note

The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:

- US East (N. Virginia)

- US East (Ohio)
- US West (Oregon)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (Spain)
- Europe (Stockholm)

To set up Amazon Q Developer operational investigations, you create an investigation group. You can also see a sample investigation to get an overall idea of how they work.

Topics

- See a sample investigation
- Set up operational investigations

See a sample investigation

If you'd like to see the Amazon Q Developer operational investigations feature in action before you configure it for your account, you can walk through a sample investigation. The sample investigation doesn't use your data and doesn't make data calls or start API operations in your account.

To view the sample investigation

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, choose **AI Operations**, **Overview**.
3. Choose **Try a sample investigation**.

   The console displays the sample investigation, with suggestions and findings in the right pane. In each popup, choose **Next** to advance to the next part of the sample walkthrough.

Set up operational investigations

To set up Amazon Q Developer operational investigations in your account, you create an *investigation group*. Creating an investigation group is a one-time setup task. Settings in the investigation group help you centrally manage the common properties of your investigations, such as the following:

- Who can access the investigations
- Whether investigation data is encrypted with a customer managed Amazon Key Management Service key.
- How long investigations and their data are retained by default.

Currently, you can have one investigation group per account. Each investigation in your account will be part of this investigation group.

To create an investigation group and set up Amazon Q Developer operational investigations, you must be signed in to an IAM principal that has the either the **AIOpsConsoleAdminPolicy** or the **AdministratorAccess** IAM policy attached, or to an account that has similar permissions.

> **Note**
>
> To be able to choose the recommended option of creating a new IAM role for Amazon Q Developer operational investigations, you must be signed in to an IAM principal that has the `iam:CreateRole`, `iam:AttachRolePolicy`, and `iam:PutRolePolicy` permissions.

> **Important**
>
> Amazon Q Developer operational investigations uses *cross-Region inference* to distribute traffic across different Amazon Regions. For more information, see Cross-Region inference.

To create an investigation group and enable Amazon Q Developer operational investigations in your account

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, choose **AI Operations**, **Investigations**.

3. Choose **Configure for this account**.
4. Enter a name for the investigation group.
5. Optionally change the retention period for investigations. For more information about what the retention period governs, see Operational investigation data retention.
6. (Optional) To encrypt your investigation data with a customer managed Amazon KMS key, choose **Customize encryption settings** and follow the steps to create or specify a key to use. If you don't specify a customer managed key, Amazon Q Developer operational investigations uses an Amazon owned key for encryption. For more information, see Encryption of investigation data.
7. If you haven't already done so, use the IAM console to provision access for your users to be able to see and manage investigations. We provide IAM roles for administrators, operators, and viewers. For more information, see User permissions.
8. (Optional) In the US East (N. Virginia) Region, you can have investigations attribute investigation actions such as adding a suggestion to the **Feed** to individual users. You do this by integrating Amazon Q Developer operational investigations with IAM Identity Center. To do so, validate that you meet the pre-requisites and then choose to allow the creation of a managed IAM Identity Center application for Amazon Q Developer operational investigations. For more information about the pre-requisites, see Amazon IAM Identity Center.
9. For **Amazon Q Developer permissions**, choose one of the following. For more information about these options, see How to control what data Amazon Q Developer has access to during investigations.

   To be able to choose either of the first two options, you must be signed in to an IAM principal that has the `iam:CreateRole`, `iam:AttachRolePolicy`, and `iam:PutRolePolicy` permissions.

   - The recommended option is to choose **Auto-create a new role with default investigation permissions**. If you choose this option, the assistant is granted the **AIOpsAssistantPolicy** IAM policy. For more information about the contents of this policy, see IAM policy for Amazon Q Developer operational investigations (AIOpsAssistantPolicy).
   - Choose **Create a new role from Amazon policy templates** to customize the permissions that Amazon Q Developer will have during investigations. If you choose this option, you must be sure to scope down the policy to only the permissions that you want Amazon Q Developer to have during investigations.
   - Choose **Assign an existing role** if you already have a role with the permissions that you want to use.

If you choose this option, you must make sure the role includes a trust policy that names `aiops.amazonaws.com` as the service principal. For more information about using service principals in trust policies, see [Amazon service principals]

We also recommend that you include a `Condition` section with the account number, to prevent a confused deputy situation. The following example trust policy illustrates both the service principal and the `Condition` section.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "aiops.amazonaws.com"
            },
            "Action": "sts:AssumeRole",
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "123456789012"
                },
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:aiops:us-east-1:123456789012:*"
                }
            }
        }
    ]
}
```

10. (Optional) For **Enhanced integrations**, choose to allow Amazon Q Developer access to additional services in your system, to enable it to gather more data and be more useful.

    a. In the **Tags for application boundary detection** section, enter the existing custom tag keys for custom applications in your system. Resource tags help Amazon Q Developer narrow the search space when it is unable to discover definite relationships between resources. For example, to discover that an Amazon ECS service depends on an Amazon RDS database, Amazon Q Developer can discover this relationship using data sources such as X-Ray and CloudWatch Application Signals. However, if you haven't deployed these features, Amazon Q Developer will attempt to identify possible relationships. Tag boundaries can be used to narrow the resources that will be discovered by Amazon Q Developer in these cases.

You don't need to enter tags created by myApplications or Amazon CloudFormation, because Amazon Q Developer can automatically detect those tags.

b. CloudTrail records events about changes in your system including deployment events. These events can often be useful to Amazon Q Developer to create hypotheses about root causes of issues in your system. In the **CloudTrail for change event detection** section, you can do one or both of the following.

   - Give Amazon Q Developer some access to the events logged by Amazon CloudTrail by enabling **Allow the assistant access to CloudTrail change events through the CloudTrail Event history**. For more information, see Working with CloudTrail Event history.
   - Give Amazon Q Developer access to additional CloudTrail data by entering one or more CloudTrail trails, which are records of activities within your Amazon account. This is supported only for trails that are sent to log groups in CloudWatch Logs. For more information about trails see Working with CloudTrail trails.

c. The **X-Ray for topology mapping** and **Application Signals for health assessment** sections point out other Amazon services that can help Amazon Q Developer find information. If you have deployed them and you have granted the **AIOpsAssistantPolicy** IAM policy to Amazon Q Developer, it will be able to access X-Ray and Application Signals telemetry.

   For more information about how these services help Amazon Q Developer, see X-Ray and CloudWatch Application Signals

11. (Optional) If you are in the US East (N. Virginia) Region, you can integrate Amazon Q Developer operational investigations with a third-party ticketing system. Integrating with a ticketing tool enables Amazon Q Developer to send information about an investigation to that ticketing tool. This feature is available only in US East (N. Virginia).

> **Important**
>
> When you create an integration with a third-party ticketing system, the system creates a secret in Amazon Secrets Manager. This secret contains your basic authentication credentials for the third-party tool and is used to connect your Amazon Web Services

account to that tool. If you delete the integration, the secret that contains your authentication credentials is also deleted.

To integrate Amazon Q Developer operational investigations with a third-party ticketing tool, do the following in the **Third-party integrations** area:

a. Choose **Add integration**.

b. In the **Add integration** dialog box, do the following:

   i. For **Name**, enter a name to identify this integration in your investigations.

   ii. For **Instance type**, choose from the available third-party tools, such as Jira or ServiceNow.

   > **Note**
   >
   > Integration with Jira is supported only for Jira Cloud.

   iii. Provide the additional information required to integrate with your selected tool:

   Jira

   - **Username** – A valid email address with access to the project being onboarded.
   - **Password** – Your API token value from Atlassian. For more information, see Manage API tokens for your Atlassian account on the Atlassian website.
   - **Jira site name** – The application name for your Jira project. This is typically the first component of the URL for your project in Atlassian. For example, in the URL `https://AnyCompany.atlassian.net`, the application name is `AnyCompany`. If you are uncertain, contact your Jira project manager to verify this information.
   - **Project key** – The project key for your Jira project.

     To retrieve this project key, sign in to your Jira project, choose **Administration, Project, View all projects**, and then copy the **Key** value from the appropriate project.

> **Important**
>
> Ensure that your Jira account and email address both have access to the project. If you are uncertain, contact your Jira project manager to verify this information.

ServiceNow

- **Username** – Your ServiceNow username.
- **Password** – Your ServiceNow instance password.
- **Instance ID** – Your ServiceNow instance ID.

You can view this information by signing in to your ServiceNow account. If you are uncertain, contact your ServiceNow administrator to verify this information.

c. Choose **Connect**.

> **Important**
>
> After you have completed this configuration procedure, we recommend that you create a test investigation and try out the integration before using it in an active investigation.

12. (Optional) You can integrate Amazon Q Developer operational investigations with a *chat channel* using Amazon Q Developer in chat applications. This makes it possible to receive notifications about an investigation through the chat channel. Amazon Q Developer operational investigations and Amazon Q Developer in chat applications support chat channels in the following applications:

    - Slack
    - Microsoft Teams

If you want to integrate with a chat channel, we recommend that you complete some other steps before performing this step in the create an investigation group process. For more information, see Integration with third-party chat systems.

To then perform the steps here to integrate with a chat channel in Amazon Q Developer in chat applications, do the following:

a. In the **Chat client integration** section, choose **Select SNS topic**.

b. Select the SNS topic to use for sending notifications about your investigations.

13. Choose **Complete setup**.

Investigate operational issues in your environment

Note

The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (Oregon)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (Spain)
- Europe (Stockholm)

Contents

Create an investigation

Create an investigation from an Amazon console page

You can start an investigation from several Amazon consoles, including (but not limited to) CloudWatch alarm pages, CloudWatch metric pages, and Lambda monitoring pages.

To start an investigation from an Amazon console page

1. In the graph of the metric or alarm that you want to investigate, select the time range that you want the investigation to include.
2. If the top of the page has an **Investigate** button, choose it and then choose **Start new investigation**.

   Otherwise, choose the vertical ellipsis menu icon

   for the metric, and choose **Investigate**, **Start a new investigation**.
3. In the **Investigation** pane, enter a name for the investigation in **New investigation title**, and optionally enter notes about the selected metric or alarm. Then choose **Start investigation**.

   The investigation starts. Amazon Q Developer scans your telemetry data to find data that might be associated with this situation.
4. To move the investigation data to the larger pane, choose **Open in full page**.
5. For detailed instructions about steps that you can take while continuing the investigation, see View and continue an open investigation.

Create an investigation from Amazon Q chat

You can ask questions about issues in your deployment in Amazon Q Developer chat. The question could be something like "Why is my Lambda function slow today?"

When you do so, Amazon Q Developer might ask follow up questions and run a health check regarding the issue. After the health check, the chat will prompt you about whether you want to start an investigation.

For more information and more sample questions, see Chatting with Amazon Q Developer about Amazon..

For detailed instructions about steps that you can take while continuing the investigation after it has been started, see View and continue an open investigation.

Create an investigation from a CloudWatch alarm action

When you create a CloudWatch alarm, you can specify for it to automatically start an investigation when it goes into ALARM state. You can do this for both metric alarms and composite alarms. For more information about creating alarms, see Alarming on metrics and Create a composite alarm.

View and continue an open investigation

Use the steps in this section to view and continue and existing investigation

To view and continue an investigation

1. If you aren't already on the page for the investigation, do the following:

   a. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.

   b. In the left navigation pane, choose **AI Operations**, **Investigations**.

   c. Choose the name of the investigation.

   > **Tip**
   >
   > If your investigation is in US East (N. Virginia) and you have integrated Amazon Q Developer operational investigations with ServiceNow or Jira, you can associate the investigation with the integrated tool from the investigations heading. For example, for Jira integrations, hover over **Jira Cloud** in the investigation header, and then choose from **Add existing ticket**, **Create new ticket**, or **Edit integration**.

> If no integration has been set up yet, you can configure one. For information, see step 3 in [Set up operational investigations](#).

2. The **Feed** section displays the items that have been added to the investigation findings, including the metric or alarm that was originally selected to start the investigation with.

   The pane on the right includes tabs. Choose the **Suggestions** tab.

3. The **Suggestions** tab displays *observations* of other telemetry that Amazon Q Developer has found that might be related to the investigation. It might also include *hypotheses*, which are possible reasons or root causes that Amazon Q Developer has found for the situation.

   Both observations and hypotheses are written in natural language by Amazon Q Developer.

   You have several options:

   - For each suggestion, you can choose **Accept** or **Discard**.

     When you choose **Accept**, the suggestion is added to the **Feed** section, and Amazon Q Developer uses this information to direct further scanning and suggestions.

     If you choose **Discard**, the suggestion is moved to the **Discarded** tab.

   - For each observation-type suggestion, you can choose to expand the graph in the **Suggestions** tab, or open it in the CloudWatch console to see more details about it.

   - Some of the observations might be results of CloudWatch Logs Insights queries that Amazon Q Developer ran as part of the investigation. When an observation is a CloudWatch Logs Insights query result, the query itself is displayed as part of the observation. You can edit the query and re-run it. To do so, choose the vertical ellipsis menu icon

     by the results, and then choose **Open in Logs Insights**. For more information, see [Analyzing log data with CloudWatch Logs Insights](#).

   - If you know of telemetry in an Amazon service that might apply to this investigation, you can go to that service's console and add the telemetry to the investigation. For example, to add a Lambda metric to the investigation, you can do the following:

     1. Open the Lambda console.
     2. In the **Monitor** section, find the metric.

3. Open the vertical ellipsis context menu

⋮

for the metric, choose **Investigate**, **Add to investigation** Then, in the **Investigate** pane, select the name of the investigation.

- When you view a hypothesis in the **Suggestions** tab, you can choose **Show reasoning** to display the data that Amazon Q Developer used to generate the hypothesis.
- If your investigation is in the US East (N. Virginia) Region and you have integrated Amazon Q Developer operational investigations with a third-party ticketing system, you can attach this investigation to a ticket in that system. To do so, hover on **No ticket attached** above the **Feed**, and then choose either **Attach ticket** or **Create ticket**.
- You can choose the **Discarded** tab and view the suggestions that have been previously discarded. To add one of them to the findings, choose **Restore to findings**.
- To add notes to the findings, choose **New note** in the **Feed** pane. Then enter your notes and choose **Add**.

4. When you add a hypothesis to the **Feed** area, it might display **Show suggested actions**. If so, choosing this displays possible actions that you can take, assuming that hypothesis is correct about the issue. Possible actions include the following:

   - **Documentation suggestions** are links to Amazon documentation that can help you understand the issue that you are working on, and how to solve it. To view suggested documentation, choose its **Review** link
   - **Runbook suggestions** are suggestions that leverage the pre-defined *runbooks* in Systems Manager Automation. Each runbook defines a number of steps for performing a task on an Amazon resource.

   > **Important**
   >
   > There is a charge for executing an Automation runbook. However, Amazon Q Developer operational investigations provides you with a preview of actions that a suggested runbook takes, giving you an opportunity to better evaluate whether to execute the runbook. For information about Automation pricing, see [Amazon Systems Manager pricing for Automation](#).

For information about continuing with a runbook action, see [Reviewing and executing suggested runbook remediations for Amazon Q Developer operational investigations]() before continuing with the following step in this procedure.

5. To end an investigation, choose **End investigation** and then optionally add final notes. Then choose **Save**.

   The investigation status changes to **Archived**. You can restart archived investigations by opening the investigation page and choosing **Restart investigation**.

   We recommend that you don't leave investigations open indefinitely, because alarm state transitions related to the investigation will keep being added to the investigation as long as it is open.

> **Note**
>
> At some points, you might see **Completed the analysis. Finished with the investigation.** displayed above the **Feed** area. If you then add more telemetry to the findings, this message changes and Amazon Q Developer begins scanning your telemetry again, based on the new data that you added to the findings.

Reviewing and executing suggested runbook remediations for Amazon Q Developer operational investigations

When you add a hypothesis to the **Feed** area of an active investigation, Amazon Q Developer operational investigations might display **Show suggested actions**. One suggested action might be to view documentation with information to help you remediate a problem manually.

Another suggestion might be to use an *Automation runbook* to attempt to automatically resolve the issue. Automation is a capability in Systems Manager, another Amazon Web Services service. Automation runbooks define a series of steps, or actions, to be run on the resources that you select. Each runbook is designed to address a specific issue. Runbooks can address a variety of operational needs: Creating, repairing, reconfiguring, installing, troubleshooting, remediating, duplicating, and more. For more information about Automation, see [Integration with Amazon Systems Manager Automation]().

Before you begin

Before working with Automation runbooks in an investigation, be aware of the following important considerations:

- Choosing to execute a runbook incurs charges. For information, see Amazon Systems Manager pricing.
- Root causes and runbook suggestions are powered by automated reasoning and generative artificial intelligence services.

> **Important**
>
> You are responsible for actions that result from executing runbook steps and the choice of parameter values entered during runbook execution. You might need to edit the suggested runbook to make sure the runbook performs as expected. For more information, see **Amazon responsible AI policy**.

- Depending on the runbook, you might need to enter values for the runbook's **Input parameters** before the execution can run.
- The runbook executes using the IAM permissions assigned to the operator. If necessary, sign in with different IAM permissions to execute the runbook. In addition to permissions for the actions being taken, you'll need additional Systems Manager permissions to execute runbook steps. For more information, see Setting up Automation in the *Amazon Systems Manager User Guide*.

To review and execute suggested runbook actions for Amazon Q Developer operational investigations

1. To view information about a suggested runbook, choose **Review** for information about how to execute the runbook steps.

   On the investigation details page, choose **Suggestions**.

2. In the **Suggestions** pane, review the list of hypotheses based on the system's analysis of the issue under investigation.

   For each hypothesis, you can choose from the following options:

   - **Show reasoning** – View more information about why the system has generated the hypothesis.

- **View actions** – View the suggested actions for the issue. Not all hypotheses will include suggested actions.
- **Accept** – Accept the hypothesis and add it to the investigation's **Feed** section.

> **Note**
>
> Accepting the hypothesis doesn't automatically run the associated runbook solution. You can view suggested runbooks before accepting a hypothesis, but you must accept the hypothesisto execute a runbook.

- **Discard** – Reject the hypothesis and don't engage with it any further.

3. After you choose **View action**, in the **Suggested actions** pane, review the list of suggested actions you can take to address the issue. Suggested actions can include one or more of the following:

   - **Amazon knowledge articles** – Provides information about steps you can take to manually address the issue, plus a link to more information.
   - **Amazon documentation** – Provides links to user documentation topics related to the issue.
   - **Amazon-owned runbooks** – Lists one or more Automation runbooks that are managed by Amazon that you can run to attempt issue resolution.
   - **Runbooks owned by you** – Lists one or more custom Automation runbooks created by you or someone else in your account or organization, which you can run to attempt issue resolution.

   > **Note**
   >
   > The system automatically generates this list of runbooks by evaluating keywords in your custom runbooks and then comparing them to terms related to the issue being investigated.
   > More keyword matches mean a particular custom runbook appears higher in the **Runbooks owned by you** list.

4. After reviewing the hypothesis, you can examine a specific suggested action further and read related documentation by choosing **Learn more**. You can also choose **Review details** to inspect suggested runbooks owned by Amazon and you.
5. When choosing **Review details** for runbooks, do the following:

a. For **Runbook description**, review the content, which provides an overview of the actions the runbook can take to remediate the issue being investigated. Choose **View steps** to visualize the runbook's workflow and drill into the details of individual steps.

b. For **Input parameters**, specify values for any parameters required by the runbook. These parameters vary from runbook to runbook.

c. For **Execution preview**, carefully review the information. This information explains what the scope and impact would be if you choose to execute the runbook.

   The **Execution preview** content provides the following information:

   - How many accounts and Regions the runbook operation would occur in.
   - The types of actions that would be taken, and how many of each type.

     Action types include the following:

     - `Mutating`: A runbook step would make changes to the targets through actions that create, modify, or delete resources.
     - `Non-Mutating`: A runbook step would retrieve data about resources but not make changes to them. This category generally includes `Describe`, `List`, `Get`, and similar read-only API actions.
     - `Undetermined`: An undetermined step invokes executions performed by another orchestration service like Amazon Lambda, Amazon Step Functions, or Run Command, a capability of Amazon Systems Manager. An undetermined step might also call a third-party API or run a Python or PowerShell script. Systems Manager Automation can't detect what the outcome would be of the orchestration processes or third-party API executions, and therefore can't evaluate them. The results of those steps would have to be manually reviewed to determine their impact.

     For information about supported actions and their impact types, see Remediation impact types of runbook actions in the *Amazon Systems Manager User Guide*.

d. Review the preview information carefully before deciding whether to proceed.

   At this point, you can choose one of the following actions:

   - Stop and do not execute the runbook.
   - Change the input parameters before executing the runbook.
   - Execute the runbook with the options you have already selected.

> **Important**
>
> Choosing to execute the runbook incurs charges. For information, see Amazon Systems Manager pricing.

6. If you want to execute the runbook, choose **Execute**.

   If you already accepted the hypothesis, the execution runs.

   If you have not already accepted the hypothesis, a dialog box prompts you to accept it before the execution runs.

After you choose **Execute** for a runbook, that action is added to the **Feed** pane of the investigation. From the investigation, you can monitor new data in the metrics in the findings to see if the runbook actions are correcting the issue.

Manage your current investigations

> **Note**
>
> The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:
>
> - US East (N. Virginia)
> - US East (Ohio)
> - US West (Oregon)
> - Asia Pacific (Hong Kong)
> - Asia Pacific (Mumbai)
> - Asia Pacific (Singapore)
> - Asia Pacific (Sydney)
> - Asia Pacific (Tokyo)
> - Europe (Frankfurt)
> - Europe (Ireland)
> - Europe (Spain)

- Europe (Stockholm)

You can view a list of your current investigations, end active investigations, re-open archived investigations, rename, and delete investigations. You can take these actions on individual investigations, or in bulk.

To manage your current investigations

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, choose **AI Operations**, **Investigations**.
3. (Optional) Filter the investigations displayed in the list by name or investigation state.
4. Select the checkboxes for the investigation or investigations that you want to take action on.
5. Choose **End investigation**, **Rename**, or **Delete**.

   You will be prompted to confirm your action or to input a new investigation title.

Restart an archived investigation

You can restart archived investigations.

To restart an archived investigation

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, choose **AI Operations**, **Investigations**.
3. Choose the name of an archived investigation.
4. Choose **Restart investigation**.
5. For instructions for working in an existing investigation, see View and continue an open investigation.

Security in operational investigations

Note

The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (Oregon)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (Spain)
- Europe (Stockholm)

This section includes topics about how Amazon Q Developer operational investigations integrate with Amazon security and permissions features.

Topics

User permissions

Amazon has created three managed IAM policies that you can use for your users who will be working with Amazon Q Developer operational investigations.

- AIOpsConsoleAdminPolicy– grants an administrator the ability to set up Amazon Q Developer operational investigations in the account, access to Amazon Q Developer operational investigations actions, the management of trusted identity propagation, and the management of integration with IAM Identity Center and organizational access.

- AIOpsOperatorAccess– grants a user access to investigation actions including starting an investigation. It also grants additional permissions that are necessary for accessing investigation events.
- AIOpsReadOnlyAccess– grants read-only permissions for Amazon Q Developer operational investigations and other related services.

We recommend that you use three IAM principals, granting one of them the **AIOpsConsoleAdminPolicy** IAM policy, granting another the **AIOpsOperatorAccess** policy, and granting the third the **AIOpsReadOnlyAccess** policy. These principals could be either IAM roles (recommended) or IAM users. Then your users who work with Amazon Q Developer operational investigations would sign on with one of these principals.

How to control what data Amazon Q Developer has access to during investigations

When you enable the Amazon Q Developer operational investigations feature, you specify what permissions that Amazon Q Developer has to access your resources during investigations. You do this by assigning an IAM role to the assistant.

To enable Amazon Q Developer to access resources and be able to make suggestions and hypotheses, the recommended method is to attach the **AIOpsAssistantPolicy** to the assistant's role. This grants the assistant permissions to analyze your Amazon resources during your investigations. For information about the complete contents of this policy, see IAM policy for Amazon Q Developer operational investigations (AIOpsAssistantPolicy).

You can also choose to attach the general Amazon **ReadOnlyAccess** to the assistant's role, in addition to attaching **AIOpsAssistantPolicy**. The reason to do this is that Amazon updates **ReadOnlyAccess** more frequently with permissions for new Amazon services and actions that are released. The **AIOpsAssistantPolicy** will also be updated for new actions, but not as frequently.

If you want to scope down the permissions granted to Amazon Q Developer, you can attach a custom IAM policy to the assistant's IAM role instead of attaching the **AIOpsAssistantPolicy** policy. To do this, start your custom policy with the contents of AIOpsAssistantPolicy and then remove permissions that you don't want to grant to Amazon Q Developer. This will prevent the assistant from being able to make suggestions based on the Amazon services or actions that you don't grant access to.

> **Note**
>
> Anything that Amazon Q Developer can access can be added to the investigation and seen by your investigation operators. We recommend that you align Amazon Q Developer operational investigations permissions with the permissions that your investigation group operators have.

Allowing Amazon Q Developer to decrypt encrypted data during investigations

If you encrypt your data in any of the following services with a customer managed key in Amazon KMS, and you want Amazon Q Developer to be able to decrypt the data from these services and include them in investigations, you'll need to attach one or more additional IAM policies to the assistant's IAM role.

- Amazon Step Functions

The policy statement should include a context key for encryption context to help scope down the permissions. For example, the following policy would enable the Amazon Q Developer to decrypt data for a Step Functions state machine.

```
{
  "Version": "2012-10-17",
  "Statement": [
        {
            "Sid": "AIOPSKMSAccessForStepFunctions",
            "Effect": "Allow",
            "Principal": {
                "Service": "aiops.amazonaws.com"
            },
            "Action":
            [
                "kms:Decrypt"
            ],
            "Resource": "*",
            "Condition":
            {
                "StringEquals":
                {
                     "kms:ViaService": "states.*.amazonaws.com",
```

```
                        "kms:EncryptionContext:aws:states:stateMachineArn":
 "arn:aws:states:region:accountId:stateMachine:*"
                    }
                }
            }
        ]
}
```

For more information about these types of policies and using these context keys, see kms:ViaService and kms:EncryptionContext:*context-key* in the Amazon Key Management Service Developer Guide, and aws:SourceArn in the IAM User Guide.

Encryption of investigation data

For the encryption of your investigation data, Amazon offers two options:

- **Amazon owned keys**– By default, Amazon Q Developer encrypts investigation data at rest with an Amazon owned key. You can't view or manage Amazon owned keys, and you can't use them for other purposes or audit their use. However, you don't have to take any action or change any settings to use these keys. For more information about Amazon owned keys, see Amazon owned keys.
- **Customer managed keys**– These are keys that you create and manage yourself. You can choose to use a customer managed key instead of an Amazon owned key for your investigation data. For more information about customer managed keys, see Customer managed keys.

> **Note**
>
> Amazon Q Developer automatically enables encryption at rest using Amazon owned keys at no charge. If you use a customer managed key, Amazon KMS charges apply. For more information about pricing, see Amazon Key Management Service pricing.

For more information about Amazon KMS, see Amazon Key Management Service.

Using a customer managed key for your investigation group

You can associate an investigation group with a customer managed key, and then all investigations created in that group will use the customer managed key to encrypt your investigation data at rest.

Amazon Q Developer operational investigations customer managed key usage has the following conditions:

- Amazon Q Developer operational investigations supports only symmetric encryption Amazon KMS keys with the default key spec, `SYMMETRIC_DEFAULT`, and that have usage defined as `ENCRYPT_DECRYPT`.
- For a user to create or update an investigation group with a customer managed key, that user must have the `kms:DescribeKey`, `kms:GenerateDataKey`, and `kms:Decrypt` permissions.
- For a user to create or update an investigation in an investigation group that uses a customer managed key, that user must have the `kms:GenerateDataKey` and `kms:Decrypt` permissions.
- For a user to view investigation data in an investigation group that uses a customer managed key, that user must have the `kms:Decrypt` permission.

Setting up investigations to use a Amazon KMS customer managed key

First, if you don't already have a symmetric key that you want to use, create a new key with the following command.

```
aws kms create-key
```

The command output includes the key ID and the Amazon Resource Name (ARN) of the key. You will need those in later steps in this section. The following is an example of this output.

```
{
"KeyMetadata": {
"Origin": "AWS_KMS",
        "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
        "Description": "",
        "KeyManager": "CUSTOMER",
        "Enabled": true,
        "CustomerMasterKeySpec": "SYMMETRIC_DEFAULT",
        "KeyUsage": "ENCRYPT_DECRYPT",
        "KeyState": "Enabled",
        "CreationDate": 1478910250.94,
        "Arn": "arn:aws:kms:us-west-2:111122223333:key/6f815f63-e628-448c-8251-
e4EXAMPLE",
        "AWSAccountId": "111122223333",
        "EncryptionAlgorithms": [
            "SYMMETRIC_DEFAULT"
```

```
        ]
    }
}
```

Set permissions on the key

Next, set permissions on the key. By default, all Amazon KMS keys are private. Only the resource owner can use it to encrypt and decrypt data. However, the resource owner can grant permissions to access the key to other users and resources. With this step, you give the AI Operations service principal permission to use the key. This service principal must be in the same Amazon Region where the KMS key is stored.

As a best practice, we recommend that you restrict the use of the KMS key to only those Amazon accounts or resources that you specify.

The first step to set the permissions is to save the default policy for your key as `policy.json`. Use the following command to do so. Replace *`key-id`* with the ID of your key.

```
aws kms get-key-policy --key-id key-id --policy-name default --output text > ./
policy.json
```

Open the `policy.json` file in a text editor and add the following policy sections into that policy. Separate the existing statement from the new sections with a comma. These new sections use `Condition` sections to enhance the security of the Amazon KMS key. For more information, see [Amazon KMS keys and encryption context](#).

This policy provides permissions for service principals for the following reasons:

- The `aiops` service needs `GenerateDataKey` permissions to get the data key and use that data key to encrypt your data while it is stored in rest. The `Decrypt` permission is needed to decrypt your data while reading from the data store. The decryption happens when you read the data using `aiops` APIs or when you update the investigation or investigation event. The update operation fetches the existing data after decrypting it, updates the data, and stores the updated data in the data store after encrypting
- The CloudWatch alarms service can create investigations or investigation events. These create operations verify that the caller has access to the Amazon KMS key defined for the investigation group. The policy statement gives the `GenerateDataKey` and `Decrypt` permissions to the CloudWatch alarms service to create investigations on behalf of you.

> **Note**
>
> The following policy assumes that you follow the recommendation of using three IAM principals, and granting one of them the **AIOpsConsoleAdminPolicy** IAM policy, granting another the **AIOpsOperatorAccess** policy, and granting the third the **AIOpsReadOnlyAccess** policy. These principals could be either IAM roles (recommended) or IAM users. Then your users who work with Amazon Q Developer operational investigations would sign on with one of these principals.
> For the following policy, you'll need the ARNs of those three principals.

```
{
    "Sid": "Enable AI Operations Admin for the DescribeKey permissions",
    "Effect": "Allow",
    "Principal": {
        "AWS": "arn:aws:iam::{account-id}:role/{AIOpsConsoleAdmin}"
    },
    "Action": [
        "kms:DescribeKey"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "kms:ViaService": "aiops.{region}.amazonaws.com"
        }
    }
},
{
   "Sid": "Enable AI Operations Admin and Operator for the Decrypt and GenerateDataKey
 permissions",
   "Effect": "Allow",
    "Principal": {
        "AWS": [
            "arn:aws:iam::{account-id}:role/{AIOpsConsoleAdmin}",
            "arn:aws:iam::{account-id}:role/{AIOpsOperator}"
         ]
    },
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
```

```
     "Resource": "*",
     "Condition": {
        "StringEquals": {
             "kms:ViaService": "aiops.{region}.amazonaws.com"
         },
         "ArnLike": {
             "kms:EncryptionContext:aws:aiops:investigation-group-arn": "arn:aws:aiops:
{region}:{account-id}:investigation-group/*"
         }
     }
 },
 {
    "Sid": "Enable AI Operations ReadOnly for the Decrypt permission",
    "Effect": "Allow",
     "Principal": {

             "kms:ViaService": "aiops.{region}.amazonaws.com"
         },
         "ArnLike": {
             "kms:EncryptionContext:aws:aiops:investigation-group-arn": "arn:aws:aiops:
{region}:{account-id}:investigation-group/*"
         }
     }
 },
 {
    "Sid": "Enable the AI Operations service to have the DescribeKey permission",
    "Effect": "Allow",
     "Principal": {
         "Service": "aiops.amazonaws.com"
     },
     "Action": [
         "kms:DescribeKey"
     ],
     "Resource": "*",
     "Condition": {
        "StringEquals": {
             "aws:SourceAccount": "{account-id}"
```

```
        },
        "StringLike": {
            "aws:SourceArn": "arn:aws:aiops:{region}:{account-id}:investigation-group/
*"
        }
    }
 },
 {
   "Sid": "Enable the AI Operations service to have the Decrypt and GenerateDataKey
 permissions",
   "Effect": "Allow",
    "Principal": {
        "Service": "aiops.amazonaws.com"
    },
    "Action": [
        "kms:Decrypt",
        "kms:GenerateDataKey"
    ],
    "Resource": "*",
    "Condition": {
       "StringEquals": {
            "aws:SourceAccount": "{account-id}"
        },
        "StringLike": {
            "aws:SourceArn": "arn:aws:aiops:{region}:{account-id}:investigation-group/
*"
        },
        "ArnLike": {
            "kms:EncryptionContext:aws:aiops:investigation-group-arn": "arn:aws:aiops:
{region}:{account-id}:investigation-group/*"
        }
    }
 },
 {
    "Sid": "Enable CloudWatch to have the Decrypt and GenerateDataKey permissions",
    "Effect": "Allow",
    "Principal": {
        "Service": "aiops.alarms.cloudwatch.amazonaws.com"
    },
    "Action": [
        "kms:GenerateDataKey",
        "kms:Decrypt"
    ],
    "Resource": "*",
```

```
    "Condition": {
        "ArnLike": {
            "kms:EncryptionContext:aws:aiops:investigation-group-arn": "arn:aws:aiops:
{region}:{account-id}:investigation-group/*"
        },
        "StringEquals": {
            "aws:SourceAccount": "{account-id}",
            "kms:ViaService": "aiops.{region}.amazonaws.com"
        },
        "StringLike": {
            "aws:SourceArn": "arn:aws:cloudwatch:{region}:{account-id}:alarm:*"
        }
    }
  }
```

After you've updated the policy, assign it to the key by entering the following command.

```
aws kms put-key-policy --key-id key-id --policy-name default --policy file://
policy.json
```

Associate the key with the investigation group

When you use the CloudWatch console to create an investigation group, you can choose to associate the Amazon KMS key with the investigation group. For more information, see Set up operational investigations.

You can also associate a customer managed key with an existing investigation group.

Changing your encryption configuration

You can update an investigation group to change between using a customer managed key or a service owned key. You can also change from using one customer managed key to using another. When you make such a change, the change applies to new investigations created after the change. Previous investigations are still associated with the old encryption configuration. Current ongoing investigations also continue using the original key for new data.

As long as a previously-used key is active and Amazon Q has access to it for investigations, you can retrieve the older investigations encrypted with that method, as well as data in current investigations that was encrypted with the previous key. If you delete a previously-used key or revoke access to it, the investigation data encrypted with that key can't be retrieved.

Cross-Region inference

Amazon Q Developer operational investigations uses *cross-Region inference* to distribute traffic across different Amazon Region. Although the data remains stored only in the primary Region, when using cross-Region inference, your investigation data might move outside of your primary Region. All data will be transmitted encrypted across Amazon's secure network. For more information see Cross-Region inference in the Amazon Q Developer user guide.

For details about where cross-Region inference distribution occurs for each Region, see the following table.

Supported Amazon Q Developer operational investigations geography	Investigation Region	Possible inference Regions
United States (US)	US East (N. Virginia)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	US East (Ohio)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	US West (Oregon)	US East (N. Virginia), US East (Ohio), US West (Oregon)
Europe (EU)	Europe (Frankfurt)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Europe (Ireland)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Europe (Spain)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Europe (Stockholm)	US East (N. Virginia), US East (Ohio), US West (Oregon)
Asia-Pacific (AP)	Asia Pacific (Hong Kong)	US East (N. Virginia), US East (Ohio), US West (Oregon)

Supported Amazon Q Developer operational investigations geography	Investigation Region	Possible inference Regions
	Asia Pacific (Mumbai)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Asia Pacific (Singapore)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Asia Pacific (Sydney)	US East (N. Virginia), US East (Ohio), US West (Oregon)
	Asia Pacific (Tokyo)	US East (N. Virginia), US East (Ohio), US West (Oregon)

Troubleshooting

Note

The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (Oregon)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (Spain)

- Europe (Stockholm)

Topics

Amazon Q Developer cannot assume the necessary IAM roles or permissions. Please verify required roles and permissions are correctly configured

Amazon Q Developer operational investigations use an IAM role to be able to access information in your topology. This IAM role must be configured with adequate permissions. For more information about the necessary permissions, see How to control what data Amazon Q Developer has access to during investigations.

Unable to identify event source. Verify that the resource exists in your application topology and the resource type is supported.

There are several Amazon services and features that we recommend you to enable to provide additional valuable information to Amazon Q Developer. These services and features can help Amazon Q Developer identify event sources. For more information, see (Recommended) Best practices to enhance investigations.

Analysis complete. Submit additional findings to receive updated suggestions

When you see this message, Amazon Q Developer has finished analyzing your topology and telemetry based on the findings that it has found so far. If you think that the root cause hasn't been found, you can manually add more telemetry to the investigation, and this might cause Amazon Q Developer to scan your system again based on the new information.

To add new telemetry, navigate to that service's console and add the telemetry to the investigation. For example, to add a Lambda metric to the investigation, you can do the following:

1. Open the Lambda console.
2. In the **Monitor** section, find the metric.
3. Open the vertical ellipsis context menu

   ⋮

   for the metric, choose **Investigate**, **Add to investigation** Then, in the **Investigate** pane, select the name of the investigation.

Integrations with other systems

> **Note**
>
> The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:
>
> - US East (N. Virginia)
> - US East (Ohio)
> - US West (Oregon)
> - Asia Pacific (Hong Kong)
> - Asia Pacific (Mumbai)
> - Asia Pacific (Singapore)
> - Asia Pacific (Sydney)

Topics

- Integration with third-party chat systems
- Amazon IAM Identity Center

Integration with Amazon Systems Manager Automation

Amazon Q Developer operational investigations is integrated with Automation, a capability of Amazon Systems Manager. You don't need to configure integration, but you might need to update Amazon Identity and Access Management (IAM) permissions so you can use Automation runbooks.

What is Amazon Systems Manager?

Systems Manager helps you centrally view, manage, and operate *managed nodes* at scale in Amazon, on-premises, and multicloud environments. In Systems Manager, a managed node is any machine configured for use with Systems Manager. For information, see the *Amazon Systems Manager User Guide*.

What is Systems Manager Automation?

Automation performs common maintenance, deployment, troubleshooting, and remediation tasks through the use of *runbooks*. Each runbook defines a number of steps for performing tasks. Each step is associated with a particular *action*. The action determines the inputs, behavior, and outputs of the step. For descriptions of the nearly two dozen actions that are supported for runbooks, see the Systems Manager Automation actions reference in the *Amazon Systems Manager User Guide*.

Automation provides over 400 Amazon managed runbooks. For details about each runbook, including a step-by-step description of the actions performed when executed, see the Systems Manager Automation runbook reference. Customers can also design their own runbooks to address specific scenarios in their environments. For information, see Creating your own runbooks in the *Amazon Systems Manager User Guide*.

For information about working with runbooks in an investigation, see Reviewing and executing suggested runbook remediations for Amazon Q Developer operational investigations.

Third-party ticketing systems

In the US East (N. Virginia) Region, you can integrate Amazon Q Developer operational investigations with a third-party ticketing system. Integrating with a ticketing tool enables Amazon Q Developer to send information about an investigation to that ticketing tool. For information about how to create this integration when you create an investigation group, see step 11b in Set up operational investigations.

This feature is available only in the US East (N. Virginia) Region.

Integration with third-party chat systems

By integrating Amazon Q Developer operational investigations with Amazon Q Developer in chat applications, you can have updates from investigations sent to third-party chat services, including Slack, and Microsoft Teams. The integration is facilitated by Amazon Simple Notification Service.

To integrate with Amazon Q Developer in chat applications, you must complete three steps. We recommend completing the steps in the following order.

- Create an Amazon SNS topic and add an access policy to it
- Configure in the Amazon Q Developer in chat applications console
- Configure in the CloudWatch console

Topics

Create and configure the Amazon SNS topic

Create an Amazon SNS topic in US East (N. Virginia) to use for the integration. For more information, see Creating an Amazon Simple Notification Service topic.

To enable Amazon Q Developer operational investigations to send notifications, you must add an the following access policy to the Amazon SNS topic

```
{
    "Sid": "AIOPS-CHAT-PUBLISH",
    "Effect": "Allow",
    "Principal": {
        "Service": "aiops.amazonaws.com"
    },
    "Action": "sns:Publish",
```

```
    "Resource": "SNS-TOPIC-ARN",
    "Condition": {
        "StringEquals": {
            "aws:SourceAccount": "account-Id"
        }
    }
}
```

Configure Amazon Q Developer in chat applications

To configure Amazon Q Developer in chat applications for communication with a third-party chat service, follow the instructions in one of the following links:

- Tutorial: Get started with Slack.
- Tutorial: Get started with Microsoft Teams.

Then, to support using AI assistant actions within chat channels you must provide the Amazon Q Developer in chat applications role with appropriate permissions. When you create a new IAM channel role for the channel, select the **Notifications** and **Amazon Q operations assistant permissions** policy templates.

Attach the **AIOpsOperatorAccess** managed IAM policy to the guardrail policies in Amazon Q Developer in chat applications. This grants permissions to Amazon Q Developer in chat applications to interact with Amazon Q Developer operational investigations and perform required actions on your behalf.

In the channel configuration, you must also subscribe to the Amazon SNS topic that you created in the previous step.

Amazon SNS

You must use the CloudWatch console to configure Amazon Q Developer operational investigations to integrate with Amazon SNS. You can do this while you create the investigation group in your account, or later.

For information about completing the step while you create the investigation group, see Step 9b at Set up operational investigations.

If you have already created an investigation group and want to add chat integration, follow these steps.

To add chat integration to an existing investigation group

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **AI operations**, **Configuration**.
3. Choose the **Third-party integrations** tab.
4. In the **Chat integration** section, do the following:

   - If you have already integrated Amazon Q Developer in chat applications with a third-party chat system, you can choose **Select SNS topic** to choose the Amazon SNS topic to use to send updates to about investigations. This Amazon SNS topic will relay those updates to the chat client.
   - If you want to integrate Amazon Q Developer in chat applications with a third-party chat system, choose **Configure new chat client**. For more information about setting up this configuration, see Getting started with Amazon Q Developer in chat applications.

Amazon IAM Identity Center

In the US East (N. Virginia) Region, you can integrate Amazon Q Developer operational investigations with Amazon IAM Identity Center. Before you create an Amazon Q Developer operational investigations application in IAM Identity Center, make sure you complete the following prerequisites:

- Enable an organization-level **IAM Identity Center instance** in your management account and **connect the identity source** in IAM Identity Center. Amazon Q Developer operational investigations doesn't support account-level IAM Identity Center instances.

  > **Note**
  >
  > To minimize latency, we recommend that you use an IAM Identity Center instance created in the same Region as your Amazon Q Developer operational investigations application. However, you can also use an IAM Identity Center instance created in an Amazon Region not yet supported by Amazon Q Developer operational investigations. For more information, see Cross-Region IAM Identity Center integration.

- Enable the **identity-aware session** on your IAM Identity Center instance.

Cross-Region IAM Identity Center integration

Amazon Q Developer operational investigations can integrate with IAM Identity Center in any commercial region where IAM Identity Center is available, including opt-in Regions. This integration works even if the Region isn't directly supported by Amazon Q Developer operational investigations. You have the flexibility to use an IAM Identity Center instance configured in a Rgion different from where Amazon Q Developer operational investigations is available.

When your IAM Identity Center instance is in a different Region than Amazon Q Developer operational investigations, you enable Amazon Q to make inter-Region calls to access information from your IAM Identity Center instance, such as user and application attributes. This capability allows Amazon Q Developer operational investigations to support IAM Identity Center-enabled applications regardless of regional differences. In this setup, your Amazon Q Developer operational investigations application will have access to user and application information from an IAM Identity Center instance deployed in another Region.

If your IAM Identity Center instance is in a different Region than your Amazon Q Developer operational investigations application, you might experience higher latency when using Amazon Q Developer operational investigations. This is caused by the increased overhead of making inter-Region calls. The increase in latency will be proportional to the distance between the two Regions.

(Recommended) Best practices to enhance investigations

As a best practice, we recommend that you enable several Amazon services and features in your account that can help Amazon Q Developer discover more information in your topology and make better suggestions during investigations.

> **Note**
>
> The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:
>
> - US East (N. Virginia)
> - US East (Ohio)
> - US West (Oregon)
> - Asia Pacific (Hong Kong)
> - Asia Pacific (Mumbai)

- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (Spain)
- Europe (Stockholm)

Topics

CloudWatch agent

We recommend that you install the latest version of the CloudWatch agent on your servers. Using a recent version of the CloudWatch agent enhances the ability to find issues in Amazon EC2 and Amazon EBS during investigations. At a minimum, you should use Version 1.300049.1 or later of the CloudWatch agent. For more information about the CloudWatch agent and how to install it, see Collect metrics, logs, and traces with the CloudWatch agent.

Amazon CloudTrail

We recommend that you enable CloudTrail including trails in your investigations. CloudTrail records events about changes in your system including deployment events. These events can often be useful to Amazon Q Developer to create hypotheses about root causes of issues in your system. For more information, see **What is Amazon CloudTrail** and **Working with CloudTrail trails**.

CloudWatch Application Signals

CloudWatch Application Signals discovers the topology of your environment, including your applications and their dependencies. It also automatically collects standard metrics such as latency and availability. By enabling Application Signals, Amazon Q Developer can use this topology and metric information during investigations.

For more information about application signals, see Application Signals.

X-Ray

We recommend that you enable Amazon X-Ray. X-Ray collects traces about requests that your applications serve. For any traced request to your application, you can see detailed information not only about the request and response, but also about calls that your application makes to downstream Amazon resources, microservices, databases, and web APIs. This information can help Amazon Q Developer during investigations.

For more information, see **What is Amazon X-Ray**

Container insights

If you use Amazon ECS or Amazon EKS, we recommend that you install Container insights. This improves the ability of Amazon Q Developer to find issues in your containers. For more information about the CloudWatch agent and how to install it, see Container Insights.

Operational investigation data retention

> **Note**
>
> The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:
>
> - US East (N. Virginia)
> - US East (Ohio)
> - US West (Oregon)
> - Asia Pacific (Hong Kong)
> - Asia Pacific (Mumbai)
> - Asia Pacific (Singapore)
> - Asia Pacific (Sydney)
> - Asia Pacific (Tokyo)
> - Europe (Frankfurt)

- Europe (Ireland)
- Europe (Spain)
- Europe (Stockholm)

The retention period that you set for an investigation group determines how long that investigation data is kept. Valid values are seven days to 90 days.

After you first create an investigation, if you don't end it manually, it moves to a CLOSED state automatically after seven days. Then, the retention period determines how long the data is kept after the investigation moves to the CLOSED state. The data that is kept during the retention period includes the data in the investigation, accepted and discarded findings, and AI assistant audit log messages.

When this retention period expires, the investigation data is deleted.

If you manually end an investigation, that also moves the investigation to the CLOSED state and the retention period time begins to be in effect.

Insights that Amazon Q Developer can surface in investigations

Note

The Amazon Q Developer operational investigations feature is in preview release and is subject to change. It is currently available in the following Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (Oregon)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Europe (Frankfurt)
- Europe (Ireland)

- Europe (Spain)
- Europe (Stockholm)

Amazon Q Developer can surface the following types of items and add them to the **Suggestions** tab of an investigation.

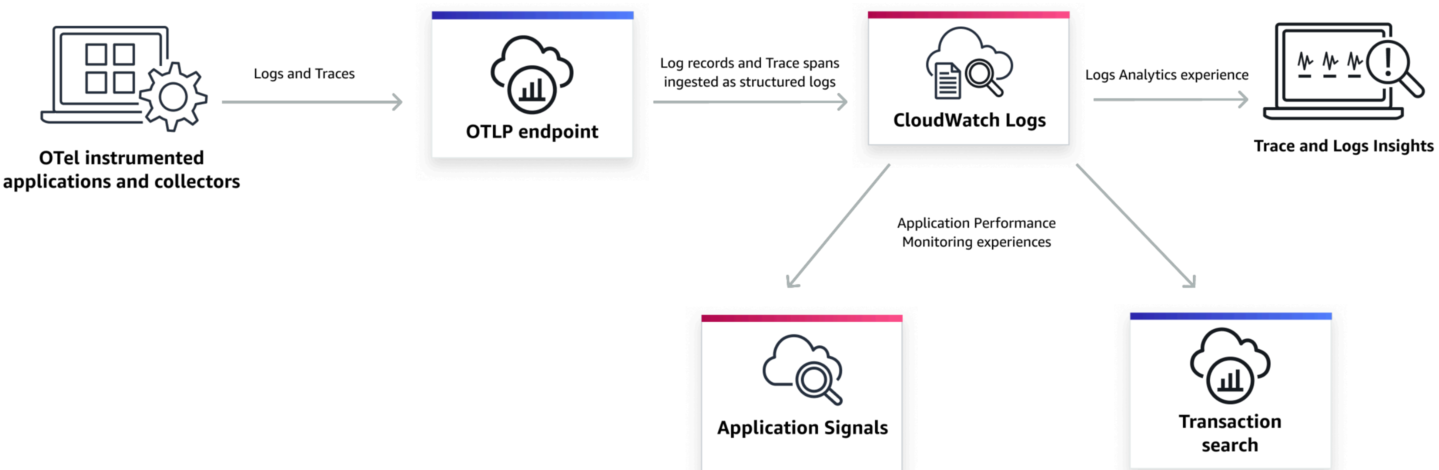
- Hypotheses about root causes
- CloudWatch alarms, including both metric alarms and composite alarms
- CloudWatch metrics
- Amazon Health events
- Change events logged in CloudTrail
- X-Ray trace data
- CloudWatch Logs Insights queries for log groups in the Standard log class
- CloudWatch Contributor Insights data
- CloudWatch Application Signals data

OpenTelemetry

OpenTelemetry is an open-source observability framework that provides IT teams with standardized protocols and tools for collecting and routing telemetry data. It delivers a unified format for instrumenting, generating, gathering, and exporting application telemetry data, such as metrics, logs, and traces to monitoring platforms for analysis and insights. By using OpenTelemetry, you can avoid vendor lock-in, ensuring flexibility in the observability solutions.

You can use OpenTelemetry to directly send logs and traces to an OpenTelemetry Protocol (OTLP) endpoint, and get out-of-the box features like Logs Insights, LiveTail, and application performance monitoring experiences in [CloudWatch Application Signals](#).

Application Signals provides you with a unified, application-centric view of your applications, services, and dependencies, and helps you monitor and triage application health. You can also explore OTLP spans using the interactive search and analytics experience in CloudWatch to answer any questions related to application performance or end-user impact with [Transaction Search](#). You can also detect the impact on end users, find transactions in context of those issues using relevant attributes such as customer name or order number, correlate transactions to business events such as failed payments, and dive into interactions between application components to establish a root cause. Using CloudWatch, you can get complete application transaction coverage with correlated insights, helping you to accelerate mean time to resolution.



Topics

- [OTLP Endpoints](#)
- [Getting started](#)
- [Troubleshooting](#)

OTLP Endpoints

OpenTelemetry Protocol (OTLP) is a general-purpose telemetry data delivery protocol designed for the OpenTelemetry. CloudWatch OpenTelemetry endpoints are HTTP 1.1 endpoints. You need to configure your OpenTelemetry collector to start sending open telemetry data to CloudWatch. For more information, see Getting started. The endpoint authenticates callers using Signature 4 authentication. For more information, see Amazon Signature Version 4 for API requests.

Traces endpoint

The traces endpoint follows the pattern `https://xray.`*`Amazon Region`*`.amazonaws.com/v1/traces`. For example, for the US West (Oregon) (us-west-2) Region, the endpoint will be `https://xray.us-west-2.amazonaws.com/v1/traces`.

You need to configure your OpenTelemetry collector to start sending traces to CloudWatch. To get started, see Getting started.

Logs endpoint

The logs endpoint follows the pattern `https://logs.`*`Amazon Web Services Region`*`.amazonaws.com/v1/logs`. For example, for the `US West (Oregon) (us-west-2) Region`, the endpoint will be `https://logs.us-west-2.amazonaws.com/v1/logs`. You can use the above endpoint to forward logs to an existing `LogGroup` and `LogStream`. For more information on setting up `LogGroup` to ingest log data, see Amazon CloudWatch Logs concepts. You must configure `LogGroup` and `LogStream` when you invoke CloudWatch Logs OpenTelemetry endpoint by setting `x-aws-log-group` and `x-aws-log-stream` HTTP headers to `LogGroup` and `LogStream` name respectively. For more information, see Getting started.

Endpoint limits and restrictions

The table lists the common endpoint limits and restrictions for traces and logs.

Limit	Endpoint	Additional informati on
Required collector extension	sigv4authextension	To send traces to OTLP endpoint you

Limit	Endpoint	Additional informati on
		must use sigv4auth extension
Supported protocol	HTTP	The endpoint supports only HTTP and doesn't support gRPC
Supported OTLP versions	OTLP 1.x	
Payload format	binary, json	The endpoint accepts requests using binary and json formats
Compression methods	gzip, none	The endpoint only supports gzip and none compression methods

The table lists the endpoint limits and restrictions for traces.

Limit	Traces endpoint	Additional informati on
Maximum uncompressed bytes / request	5 MB	The OTLP endpoint will reject requests larger than 5MB when payload is uncompressed.
Maximum events / request	10,000 spans	The max allowed number of spans in one request is 10,000. Exceeding this limit will cause

Limit	Traces endpoint	Additional information
		rejection of the API call.
Single resource and scope size	16 KB	Each unique resource and corresponding scope should not exceed 16 KB of size. Exceeding this limit for any resource will cause rejection of the entire API call.
Single span maximum size	200 KB	Spans more than 200KB will be rejected by the endpoint.
Span created timestamps	2 hours in the future and 14 days in the past	None of the spans in the batch can be more than two hours in the future or more than 14 days in the past.
Maximum time gap in events / request	24 hours	

The table lists the endpoint limits and restrictions for logs.

Limit	Logs endpoint	Additional information
Maximum uncompressed bytes / request	1 MB	The OTLP endpoint will reject requests larger than 1MB

Limit	Logs endpoint	Additional information
		when payload is uncompressed. The maximum request size is 1,048,576 bytes after decompression and deserialization of binary data serialized by Protocol buffers. This size is calculated as the sum of all event messages in UTF-8, plus 26 bytes for each log record.
Request per second	5000	5000 transactions per second per account per Region You can request an increase to the per-second throttling quota by using the Service Quotas service.
Maximum events / request	10,000 logs	The max allowed number of spans in one request is 10,000. Exceeding this limit will cause rejection of the API call.

Limit	Logs endpoint	Additional information
Single resource and scope size	16 KB	Each unique resource and corresponding scope should not exceed 16 KB of size. Exceeding this limit for any resource will cause rejection of the entire API call.
Single LogEvent size	1 MB	LogEvent size is calculated as sum of sizes for each LogRecord, Scope and Resource. This quota can't be changed.
Logs created timestamps	2 hours in future and 14 days old	The log records in the batch does not have to be in a chronological order. However, the log records in the batch cannot be more than 2 hours in the future and cannot be more than 14 days in the past. Also, none of the log records can be earlier than the retention period of the log group.
Maximum time gap in events / request	24 hours	

Note

The account limits for Logs are shared across the SDK and the new Logs endpoint.

Getting started

To get started with OpenTelemetry in CloudWatch, you can use the pre-packaged OpenTelemetry setup that is available with the CloudWatch agent along with the Amazon Distro for OpenTelemetry SDKs. This gives you the most integrated monitoring experience in CloudWatch.

Note

Make sure Transaction Search is enabled before you use the OTLP Endpoint.

Alternatively, you have the flexibility to use the OpenTelemetry Collector or your own custom OpenTelemetry Collector to directly send telemetry to the OTLP endpoint. You can use the Amazon Distro for OpenTelemetry to go collector-less and to send telemetry directly to the OTLP endpoint. Make an informed choice based on the feature support:

Feature	OpenTelemetry Collector Contrib	Custom OpenTelemetry Collector	Amazon Distro for OpenTelemetry
CloudWatch application signals (Application performance metrics, service discovery, and service map)	Yes	Yes	Yes
Search and analyze spans and trace summaries	Yes	Yes	Yes
Search and analyze logs summaries	Yes	Yes	Yes

Feature	OpenTelemetry Collector Contrib	Custom OpenTelemetry Collector	Amazon Distro for OpenTelemetry
Application performance monitoring telemetry enrichment with Amazon infrastructure attributes that your application is hosted in.	No	Yes	Yes
Runtime metrics correlated with your application. For example, JVM metrics	No	Yes	No
Amazon Support	Data received by Amazon	Data received by Amazon	Data received by Amazon
Telemetry supported	Logs, Traces	Logs, Traces, Metrics	Traces

Topics

- OpenTelemetry Collector Contrib
- Build your own custom OpenTelemetry Collector
- Amazon Distro for OpenTelemetry

OpenTelemetry Collector Contrib

You can use the OpenTelemetry Collector Contrib to get started with OpenTelemetry in CloudWatch.

Prerequisite

Make sure *Transaction Search* is enabled in CloudWatch. For more information, see Transaction Search.

Download the OpenTelemetry Collector Contrib

Download the latest release of the OpenTelemetry Collector Contrib distribution.

Install the OpenTelemetry Collector Contrib

Install the OpenTelemetry Collector Contrib on any operating system and platform. For more information, see Install the Collector.

Setup Amazon credentials on your Amazon EC2 or on-premise hosts

You can setup Amazon credentials on your Amazon EC2 or on-premise hosts.

Setup IAM permissions for Amazon EC2

Follow the below procedure to attach the `CloudWatchAgentServerPolicy` IAM policy to the IAM role of your Amazon EC2 instance.

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. Choose **Roles** and find and select the role used by your Amazon EC2 instance.
3. Under the **Permissions** tab, choose **Add permissions**, **Attach policies**.
4. Using the search box, search for `CloudWatchAgentServerPolicy` policy.
5. Select the **CloudWatchAgentServerPolicy** policy and choose **Add permissions**.

Setup IAM permissions for on-premise hosts

You can create an IAM user that can be used to provide permissions to your on-premise hosts.

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. Choose **Users**, **Create User**.
3. Under **User details**,for **User name**, enter a name for the new IAM user. This is the sign-in name for Amazon that will be used to authenticate your host.
4. Choose **Next**.
5. On the **Set permissions** page, under **Permissions options**, select **Attach policies directly**.
6. From the **Permissions policies** list, select the **CloudWatchAgentServerPolicy** policy to add to your user.

7. Choose **Next**.
8. On the **Review and create** page, ensure that you are satisfied with the user name and that the **CloudWatchAgentServerPolicy** policy is under the **Permissions summary**.
9. Choose **Create user**.
10. **Create and retrieve your Amazon access key and secret key** – In the navigation pane in the IAM console, choose **Users** and then select the user name of the user that you created in the previous step.
11. On the user's page, choose the **Security credentials** tab.
12. Under the **Access keys** section, choose **Create access key**.
13. For **Create access key Step 1**, choose **Command Line Interface (CLI)**.
14. For **Create access key Step 2**, optionally enter a tag and then choose **Next**.
15. For **Create access key Step 3,** select **Download .csv file** to save a .csv file with your IAM user's access key and secret access key. You need this information for the next steps.
16. Choose **Done**.
17. Configure your Amazon credentials in your on-premises host by entering the following command. Replace *ACCESS_KEY_ID* and *SECRET_ACCESS_ID* with your newly generated access key and secret access key from the .csv file that you downloaded in the previous step.

```
$ aws configure
AWS Access Key ID [None]: ACCESS_KEY_ID
AWS Secret Access Key [None]: SECRET_ACCESS_ID
Default region name [None]: MY_REGION
Default output format [None]: json
```

Setup Amazon credentials for your Amazon EKS or Kubernetes clusters

To setup Amazon credentials for your Amazon EKS or Kubernetes clusters to send telemetry to CloudWatch, follow the below procedure.

Setup IAM permissions for Amazon EKS

1. Create an IAM OIDC identity provider for your cluster using the following command.

```
eksctl utils associate-iam-oidc-provider --cluster ${CLUSTER_NAME} --region
 ${REGION} --approve
```

2. Assign IAM roles to Kubernetes service account for OTel Collector using the following command.

```
eksctl create iamserviceaccount \
--name ${COLLECTOR_SERVICE_ACCOUNT}\
--namespace ${NAMESPACE} \
--cluster ${CLUSTER_NAME} \
--region ${REGION} \
--attach-policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy \
--approve \
--override-existing-serviceaccounts
```

Setup IAM permissions for Kubernetes

1. Configure your Amazon credentials in your on-premises host by entering the following command. Replace *ACCESS_KEY_ID* and *SECRET_ACCESS_ID* with your newly generated access key and secret access key from the .csv file that you downloaded in the previous step. By default, the credential file is saved under */home/user/.aws/credentials.*.

```
aws configure
AWS Access Key ID [None]: ACCESS_KEY_ID
AWS Secret Access Key [None]: SECRET_ACCESS_ID
Default region name [None]: MY_REGION
Default output format [None]: json
```

2. Edit OpenTelemetry Collector resource to add the newly created AWS credentials secret by using the command: `kubectl edit OpenTelemetryCollector otel_collector`
3. Using the file editor, add the Amazon credentials into the OpenTelemetryCollector container by adding the following configuration to the top of the deployment. Replace the path `/home/user/.aws/credentials` with the location of your local Amazon credentials file.

```
spec:
volumeMounts:
- mountPath: /rootfs
volumeMounts:
- name: aws-credentials
mountPath: /root/.aws
readOnly: true
volumes:
- hostPath:
path: /home/user/.aws/credentials
name: aws-credentials
```

Configure the OpenTelemetry Collector

Copy and paste the content below to configure your collector to send logs and traces to the OTLP endpoints.

```
receivers:
  otlp:
    protocols:
      grpc:
        endpoint: 0.0.0.0:4317
      http:
        endpoint: 0.0.0.0:4318

exporters:
  otlphttp/logs:
    compression: gzip
    logs_endpoint: logs_otlp_endpoint
    headers:
      x-aws-log-group: ency_log_group
      x-aws-log-stream: default
    auth:
      authenticator: sigv4auth/logs

  otlphttp/traces:
    compression: gzip
    traces_endpoint: traces_otlp_endpoint
    auth:
      authenticator: sigv4auth/traces
```

```
extensions:
  sigv4auth/logs:
    region: "region"
    service: "logs"
  sigv4auth/traces:
    region: "region"
    service: "xray"

service:
  telemetry:
  extensions: [sigv4auth/logs, sigv4auth/traces]
  pipelines:
    logs:
      receivers: [otlp]
      exporters: [otlphttp/logs]
    traces:
      receivers: [otlp]
      exporters: [otlphttp/traces]
```

The following is an example to send logs and traces using sigv4 to us-east-1.

```
receivers:
  otlp:
    protocols:
      grpc:
        endpoint: 0.0.0.0:4317
      http:
        endpoint: 0.0.0.0:4318

exporters:
  otlphttp/logs:
    compression: gzip
    logs_endpoint: https://logs.us-east-1.amazonaws.com/v1/logs
    headers:
      x-aws-log-group: MyApplicationLogs
      x-aws-log-stream: default
    auth:
      authenticator: sigv4auth/logs

  otlphttp/traces:
    compression: gzip
```

```
    traces_endpoint: https://xray.us-east-1.amazonaws.com/v1/traces
    auth:
      authenticator: sigv4auth/traces

extensions:
  sigv4auth/logs:
    region: "us-east-1"
    service: "logs"
  sigv4auth/traces:
    region: "us-east-1"
    service: "xray"

service:
  telemetry:
  extensions: [sigv4auth/logs, sigv4auth/traces]
  pipelines:
    logs:
     receivers: [otlp]
      exporters: [otlphttp/logs]
    traces:
      receivers: [otlp]
      exporters: [otlphttp/traces]
```

Note

Configure your OpenTelemetry SDKs to *always_on* sampling configuration to reliably record 100% spans and get full visibility into your critical applications with CloudWatch Application Signals. For more information, see an OpenTelemetry Java SDK sampler configuration example. For an example on setting up OpenTelemetry Collector with X-Ray OTLP endpoint, see the application signals demo repository.

Build your own custom OpenTelemetry Collector

You can build your own custom OpenTelemetry Collector to get the best application observability experience in CloudWatch with OpenTelemetry. In this setup, you need to build your own OpenTelemetry Collector with open source CloudWatch components.

Prerequisite

Make sure *Transaction Search* is enabled in CloudWatch. For more information, see Transaction Search.

Build your own collector

You can build your own collector with the following configuration to monitor your application in CloudWatch with OpenTelemetry. For more information, see Building a custom collector.

The common configuration for CloudWatch.

```
dist:
  name: otelcol-dev
  description: OTel Collector for sending telemetry to CloudWatch.
  output_path: ./otelcol-dev
extensions:
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/extension/
sigv4authextension v0.111.0
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/extension/awsproxy
 v0.113.0
exporters:
  - gomod: go.opentelemetry.io/collector/exporter/otlpexporter v0.111.0
  - gomod: go.opentelemetry.io/collector/exporter/otlphttpexporter v0.111.0
receivers:
  - gomod: go.opentelemetry.io/collector/receiver/otlpreceiver v0.111.0
```

Additional configuration for traces.

```
# Enable Tracing
dist:
  name: otelcol-dev
  description: OTel Collector for sending telemetry to CloudWatch.
  output_path: ./otelcol-dev
extensions:
    #Include common configurations and your custom extensions

exporters:
    #Include common configurations and your custom extensions
```

```
receivers:
  - gomod: go.opentelemetry.io/collector/receiver/otlpreceiver v0.111.0
processors:
  - gomod: github.com/amazon-contributing/opentelemetry-collector-contrib/processor/
awsapplicationsignalsprocessor v0.113.0
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/processor/
resourcedetectionprocessor v0.113.0
  - gomod: github.com/open-telemetry/opentelemetry-collector-contrib/processor/
metricstransformprocessor v0.113.0
replaces:
  - github.com/open-telemetry/opentelemetry-collector-contrib/internal/aws/awsutil
 v0.113.0 => github.com/amazon-contributing/opentelemetry-collector-contrib/internal/
aws/awsutil v0.113.0
  - github.com/open-telemetry/opentelemetry-collector-contrib/internal/aws/cwlogs
 v0.113.0 => github.com/amazon-contributing/opentelemetry-collector-contrib/internal/
aws/cwlogs v0.113.0
  - github.com/open-telemetry/opentelemetry-collector-contrib/exporter/awsemfexporter
 v0.113.0 => github.com/amazon-contributing/opentelemetry-collector-contrib/exporter/
awsemfexporter v0.113.0
  - github.com/openshift/api v3.9.0+incompatible => github.com/openshift/api
 v0.0.0-20180801171038-322a19404e37
```

Note

Note the following:

- After the collector is built, deploy and configure the custom collector in a host or kubernetes environment by following the procedure under OpenTelemetry Collector Contrib.
- For information on setting up custom OpenTelemetry collector with Application Signals Processor, see an Application Signals custom configurationexample. Application Signals Processor only supports the latest versions of the OpenTelemetry Collectors for custom builds. For information on the supported versions, see opentelemetry-collector-contrib repository.

Amazon Distro for OpenTelemetry

You can use the Amazon Distro for OpenTelemetry to go collector-less and to send traces directly to the OTLP endpoint (for traces).

> **Note**
>
> By default, Application Signals is enabled when you enable Transaction Search. Application Signals is not supported on Amazon Distro for OpenTelemetry and must be disabled.

Topics

Prerequisite

Make sure Transaction Search is enabled to send spans to the X-Ray OTLP endpoint. For more information, see Getting started with Transaction Search.

Set up IAM permissions for Amazon EC2

Follow these steps to attach the `AWSXrayWriteOnlyPolicy` IAM policy to the IAM role of your Amazon EC2 instance:

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Roles** and find and select the role used by your Amazon EC2 instance.
3. Under the **Permissions** tab, choose **Add permissions**, then **Attach policies**.
4. Using the search box, search for the `AWSXrayWriteOnlyPolicy` policy.
5. Select the `AWSXrayWriteOnlyPolicy` policy and choose **Add permissions**.

Set up IAM permissions for on-premise hosts

Follow these steps to create an IAM user that can be used to provide permissions to your on-premise hosts.

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Users** and then **Create User**.

3. Choose **Users**, **Create User**.
4. Under **User details**, for **User name**, enter a name for the new IAM user. This is the sign-in name for Amazon that will be used to authenticate your host.
5. Choose **Next**.
6. On the **Set permissions** page, under **Permissions options**, select **Attach policies directly**.
7. From the **Permissions policies** list, select the `AWSXrayWriteOnlyPolicy` policy to add to your user.
8. Choose **Next**.
9. On the **Review and create** page, make sure that you are satisfied with the user name and that the `AWSXrayWriteOnlyPolicy` policy is under the **Permissions summary**.
10. Choose **Create user**.
11. Create and retrieve your Amazon access key and secret key:

    1. In the navigation pane in the IAM console, choose **Users** and then select the user name of the user that you created in the previous step.
    2. On the user's page, choose the **Security credentials** tab.
    3. Under the **Access keys** section, choose **Create access key**.
    4. For **Create access key Step 1**, choose **Command Line Interface (CLI)**.
    5. For **Create access key Step 2**, optionally enter a tag and then choose **Next**.
    6. For **Create access key Step 3**, select **Download .csv file** to save a .csv file with your IAM user's access key and secret access key. You need this information for the next steps.
    7. Choose **Done**.
12. Configure your Amazon credentials in your on-premises host by entering the following command. Replace **`ACCESS_KEY_ID`** and **`SECRET_ACCESS_ID`** with your newly generated access key and secret access key from the .csv file that you downloaded in the previous step.

```
$ aws configure
AWS Access Key ID [None]: ACCESS_KEY_ID
AWS Secret Access Key [None]: SECRET_ACCESS_ID
Default region name [None]: MY_REGION
Default output format [None]: json
```

Enabling Amazon Distro for OpenTelemetry

You can enable traces for your application to be sent directly to the OTLP endpoint from Amazon Distro for OpenTelemetry on Java, Node.js, Python, and .Net.

Java

1. Download the latest version of the Amazon Distro for OpenTelemetry Java auto-instrumentation agent. You can download the latest version by using this command:

   ```
   curl -L -O https://github.com/aws-observability/aws-otel-java-instrumentation/
   releases/latest/download/aws-opentelemetry-agent.jar
   ```

   To view all the released versions, see aws-otel-java-instrumentation releases.
2. To enable the exporter that directly sends traces to the X-Ray OTLP traces endpoint and to optimize benefits, use the environment variables to provide additional information before you start your application.
3. For the `OTEL_RESOURCE_ATTRIBUTES` variable, specify the following information as key-value pairs:

   (Optional) `service.name` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. When you don't provide a value for this key, the default of `UnknownService` is used.

   (Optional) `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application. When you don't specify this, one of the following defaults is used:

   - If this is an instance that is part of an Auto Scaling group, it is set to `ec2:name-of-Auto-Scaling-group`
   - If this is an Amazon EC2 instance that is not part of an Auto Scaling group, it is set to `ec2:default`
   - If this is an on-premises host, it is set to `generic:default`

   This environment variable is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions

4. For the OTEL_EXPORTER_OTLP_TRACES_ENDPOINT variable, specify the X-Ray OTLP traces endpoint: https://xray.[*AWSRegion*].amazonaws.com/v1/traces. For example:

```
export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT="https://xray.us-west-2.amazonaws.com/
v1/traces"
```

5. For the JAVA_TOOL_OPTIONS variable, specify the path where the Amazon Distro for OpenTelemetry Java auto-instrumentation agent is stored.

```
export JAVA_TOOL_OPTIONS=" -javaagent:$AWS_ADOT_JAVA_INSTRUMENTATION_PATH"
```

   For example:

```
export AWS_ADOT_JAVA_INSTRUMENTATION_PATH="./aws-opentelemetry-agent.jar"
```

6. For the OTEL_METRICS_EXPORTER variable, it is recommended to set the value to none.
7. For the OTEL_LOGS_EXPORTER variable, it is recommended to set the value to none.
8. For the OTEL_TRACES_EXPORTER variable, you have to set the value for otlp (this is optional and is the default value if this environment variable is not set).
9. For the OTEL_EXPORTER_OTLP_PROTOCOL variable, you have to set the value to http/protobuf (this is optional and is the default value if this environment variable is not set). The X-Ray OTLP endpoint currently only supports the HTTP protocol.
10. Your application should now be running with Amazon Distro for OpenTelemetry Java instrumentation and will generate spans. These spans are stored in the aws/spans CloudWatch LogsLogGroup in your account. You can also view the traces and metrics correlated with your spans in the CloudWatch Traces and Metrics Console.
11. Start your application with the environment variables you set. Here is an example of a starting script.

   (Note: The following configuration supports only versions 1.32.2 and later of the Amazon Distro for OpenTelemetry auto-instrumentation agent for Java.)

```
JAVA_TOOL_OPTIONS=" -javaagent:$AWS_ADOT_JAVA_INSTRUMENTATION_PATH" \
OTEL_METRICS_EXPORTER=none \
OTEL_LOGS_EXPORTER=none \
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
```

```
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces \
OTEL_RESOURCE_ATTRIBUTES="service.name=$YOUR_SVC_NAME" \
java -jar $MY_JAVA_APP.jar
```

Node.js

1. Download the latest version of the Amazon Distro for OpenTelemetry JavaScript auto-instrumentation agent for Node.js. You can install using the command:

```
npm install @aws/aws-distro-opentelemetry-node-autoinstrumentation
```

   To view information about all released versions, see [Amazon Distro for OpenTelemetry JavaScript instrumentation]().

2. To enable the exporter that directly sends traces to the X-Ray OTLP endpoint and to optimize benefits, use the environment variables to provide additional information before you start your application.

3. For the `OTEL_RESOURCE_ATTRIBUTES` variable, specify the following information as key-value pairs:

   (Optional) `service.name` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. When you don't provide a value for this key, the default of `UnknownService` is used.

   (Optional) `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. When you don't specify this variable, one of the following defaults is used:

   - If this is an instance that is part of an Auto Scaling group, it is set to `ec2:name-of-Auto-Scaling-group`
   - If this is an Amazon EC2 instance that is not part of an Auto Scaling group, it is set to `ec2:default`
   - If this is an on-premises host, it is set to `generic:default`

This environment variable is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.

4. For the `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` variable, specify the X-Ray OTLP traces endpoint: `https://xray.[AWSRegion].amazonaws.com/v1/traces`.

   For example:

   ```
   export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT="https://xray.us-west-2.amazonaws.com/
   v1/traces"
   ```

5. For the `OTEL_METRICS_EXPORTER` variable, it is recommended to set the value to none. Application Signals metrics are generated by the OTLP endpoint.
6. For the `OTEL_LOGS_EXPORTER` variable, it is recommended to set the value to none.
7. For the `OTEL_TRACES_EXPORTER` variable, you have to set the value for `otlp` (this is optional and is the default value if this environment variable is not set).
8. For the `OTEL_EXPORTER_OTLP_PROTOCOL` variable, you have to set the value to `http/protobuf` (this is optional and is the default value if this environment variable is not set). The X-Ray OTLP endpoint currently only supports the HTTP protocol.
9. Your application should now be running with Amazon Distro for OpenTelemetry Java instrumentation and will generate spans. These spans are stored in the `aws/spans` CloudWatch LogsLogGroup in your account. You can also view the traces and metrics correlated with your spans in the CloudWatch Traces and Metrics Console.
10. Start your application with the environment variables you set. Here is an example of a starting script.

    (Note: Replace $*SVC_NAME* with your application name. This is displayed as the name of the application.

    ```
    OTEL_METRICS_EXPORTER=none \
    OTEL_LOGS_EXPORTER=none \
    OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
    OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
    traces \
    OTEL_RESOURCE_ATTRIBUTES="service.name=$SVC_NAME" \
    node —require '@aws/aws-distro-opentelemetry-node-autoinstrumentation/register'
     your-application.js
    ```

Python

1. Download the latest version of the Amazon Distro for OpenTelemetry Python auto-instrumentation agent. You can install using the command:

```
pip install aws-opentelemetry-distro
```

2. To enable the exporter to directly send traces to the X-Ray OTLP endpoint and to optimize benefits, use the environment variables to provide additional information before you start your application.

3. For the `OTEL_RESOURCE_ATTRIBUTES` variable, specify the following information as key-value pairs:

   (Optional) `service.name` sets the name of the service. This will be displayed as the service name for your application in Application Signals dashboards. When you don't provide a value for this key, the default of `UnknownService` is used.

   (Optional) `deployment.environment` sets the environment that the application runs in. This will be diplayed as the **Hosted In** environment of your application in Application Signals dashboards. When you don't specify this, one of the following defaults is used:

   - If this is an instance that is part of an Auto Scaling group, it is set to `ec2:name-of-Auto-Scaling-group`
   - If this is an Amazon EC2 instance that is not part of an Auto Scaling group, it is set to `ec2:default`
   - If this is an on-premises host, it is set to `generic:default`

   This environment variable is used only by Application Signals, and is converted into X-Ray trace annotations and CloudWatch metric dimensions.

4. For the `OTEL_EXPORTER_OTLP_TRACES_ENDPOINT` variable, specify the X-Ray OTLP traces endpoint: `https://xray.[`*`AWSRegion`*`].amazonaws.com/v1/traces`.

   For example:

```
export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT="https://xray.us-west-2.amazonaws.com/
v1/traces"
```

5. For the OTEL_METRICS_EXPORTER variable, it is recommended to set the value to none. Application Signals metrics are generated by the OTLP endpoint.
6. For the OTEL_LOGS_EXPORTER variable, it is recommended to set the value to none.
7. For the OTEL_TRACES_EXPORTER variable, you have to set the value for otlp (this is optional and is the default value if this environment variable is not set).
8. For the OTEL_EXPORTER_OTLP_PROTOCOL variable, you have to set the value to http/protobuf (this is optional and is the default value if this environment variable is not set). The X-Ray OTLP endpoint currently only supports the HTTP protocol.
9. Your application should now be running with Amazon Distro for OpenTelemetry Java instrumentation and will generate spans. These spans are stored in the aws/spans CloudWatch LogsLogGroup in your account. You can also view the traces and metrics correlated with your spans in the CloudWatch Traces and Metrics Console.
10. Start your application with the environment variables you set. Here is an example of a starting script.

    (Note: Replace $*SVC_NAME* with your application name and replace $*PYTHON_APP* with the location and name of your application.

```
OTEL_METRICS_EXPORTER=none \
OTEL_LOGS_EXPORTER=none \
OTEL_PYTHON_DISTRO=aws_distro \
 OTEL_PYTHON_CONFIGURATOR=aws_configurator \
OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf \
OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces \
OTEL_RESOURCE_ATTRIBUTES="service.name=$SVC_NAME" \
opentelemetry-instrument python $MY_PYTHON_APP.py
```

.Net

To enable the exporter that directly sends traces to the X-Ray OTLP traces endpoint and to optimize benefits, set the environment variables to provide additional information before you start your application. These variables are also necessary to set up the .NET instrumentation.

1. Replace dotnet-service-name in the OTEL_RESOURCE_ATTRIBUTES environment variable with the service name of your choice.
2. Set OTEL_TRACES_EXPORTER=none.

3. Set OTEL_AWS_SIG_V4_ENABLED=true.

   An example for Linux.

```
export INSTALL_DIR=OpenTelemetryDistribution
export CORECLR_ENABLE_PROFILING=1
export CORECLR_PROFILER={918728DD-259F-4A6A-AC2B-B85E1B658318}
export CORECLR_PROFILER_PATH=${INSTALL_DIR}/linux-x64/
OpenTelemetry.AutoInstrumentation.Native.so
export DOTNET_ADDITIONAL_DEPS=${INSTALL_DIR}/AdditionalDeps
export DOTNET_SHARED_STORE=${INSTALL_DIR}/store
export DOTNET_STARTUP_HOOKS=${INSTALL_DIR}/net/
OpenTelemetry.AutoInstrumentation.StartupHook.dll
export OTEL_DOTNET_AUTO_HOME=${INSTALL_DIR}

export
 OTEL_DOTNET_AUTO_PLUGINS="AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"
export OTEL_TRACES_EXPORTER=none
export OTEL_AWS_SIG_V4_ENABLED=true

export OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
export OTEL_METRICS_EXPORTER=none
export OTEL_LOGS_EXPORTER=none
export OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
export OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/
v1/traces
```

   An example for Windows Server.

```
$env:INSTALL_DIR = "OpenTelemetryDistribution"
$env:CORECLR_ENABLE_PROFILING = 1
$env:CORECLR_PROFILER = "{918728DD-259F-4A6A-AC2B-B85E1B658318}"
$env:CORECLR_PROFILER_PATH = Join-Path $env:INSTALL_DIR "win-x64/
OpenTelemetry.AutoInstrumentation.Native.dll"
$env:DOTNET_ADDITIONAL_DEPS = Join-Path $env:INSTALL_DIR "AdditionalDeps"
$env:DOTNET_SHARED_STORE = Join-Path $env:INSTALL_DIR "store"
$env:DOTNET_STARTUP_HOOKS = Join-Path $env:INSTALL_DIR "net/
OpenTelemetry.AutoInstrumentation.StartupHook.dll"
$env:OTEL_DOTNET_AUTO_HOME = $env:INSTALL_DIR
$env:OTEL_DOTNET_AUTO_PLUGINS =
 "AWS.Distro.OpenTelemetry.AutoInstrumentation.Plugin,
 AWS.Distro.OpenTelemetry.AutoInstrumentation"
```

```
$env:OTEL_TRACES_EXPORTER=none
$env:OTEL_AWS_SIG_V4_ENABLED=true

$env:OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
$env:OTEL_METRICS_EXPORTER=none
$env:OTEL_LOGS_EXPORTER=none
$env:OTEL_EXPORTER_OTLP_PROTOCOL=http/protobuf
$env:OTEL_EXPORTER_OTLP_TRACES_ENDPOINT=https://xray.us-east-1.amazonaws.com/v1/
traces
```

4. Start your application with the environment variables.
5. (Optional) Alternatively, you can use the installation scripts provided to help installation and setup of Amazon Distro for OpenTelemetry .NET auto-instrumentation package.

   For Linux, download and install the Bash installation script from the GitHub releases page:

```
# Download and Install
curl -L -O https://github.com/aws-observability/aws-otel-dotnet-instrumentation/
releases/latest/download/aws-otel-dotnet-install.sh
chmod +x ./aws-otel-dotnet-install.sh
./aws-otel-dotnet-install.sh
# Instrument
. $HOME/.otel-dotnet-auto/instrument.shexport
 OTEL_RESOURCE_ATTRIBUTES=service.name=dotnet-service-name
```

   For Windows Server, download and install the PowerShell installation script from the GitHub releases page:

```
# Download and Install
$module_url = "https://github.com/aws-observability/aws-otel-dotnet-
instrumentation/releases/latest/download/AWS.Otel.DotNet.Auto.psm1"
$download_path = Join-Path $env:temp "AWS.Otel.DotNet.Auto.psm1"
Invoke-WebRequest -Uri $module_url -OutFile $download_path
Import-Module $download_path
Install-OpenTelemetryCore
# Instrument
Import-Module $download_path
Register-OpenTelemetryForCurrentSession -OTelServiceName "dotnet-service-name"
Register-OpenTelemetryForIIS
```

You can find the NuGet package of the Amazon Distro for OpenTelemetry .NET auto-instrumentation package in the official NuGet repository. Make sure to check the README file for instructions.

Troubleshooting

The following are the common troubleshooting scenarios and solutions for OTLP endpoint.

Issue	Description	Solution
Non-existing Amazon credentials when launching OCB collector	Collector throws the following error when starting. *Error: invalid configura tion: extensions::sigv4auth: could not retrieve credentia l provider: failed to refresh cached credentials, no EC2 IMDS role found, operation error ec2imds: GetMetada ta, request canceled, context deadline exceeded*.	Enter the correct credentials.
Invalid Amazon credentials	Collector throws HTTP Status Code 403, Message=The security token included in the request is invalid., Details=[ ]“ when sending requests though OTLP endpoint.	Refresh the Amazon credentia ls on the collector server.
Transactions Search disabled	Collector throws Message=T he OTLP API is supported with CloudWatch Logs as a Trace Segment Destination.	Make sure Transaction Search is enabled in CloudWatc h before using the OTLP endpoint for traces. For more information, see Transaction Search.

Issue	Description	Solution
Batching and timeout issues	Collector throws one of these issues: • max elapsed time expired failed to make an HTTP request • io.opentelemetry.exporter.internal.http.HttpExporter - Failed to export spans. The request could not be executed. Full error message: timeout • io.opentelemetry.exporter.internal.grpc.GrpcExporter - Failed to export spans. Server responded with gRPC status code 2. Error message: timeout • rpc error: code = DeadlineExceeded desc = context deadline exceeded • rpc error: code = ResourceExhausted desc = Too many requests", "dropped_items": 1024	Tune batching and timeout policies using batchprocessor.

Issue	Description	Solution
Retry issues	Transient network issues between the collector and OTLP endpoint. • rpc error: code = Unavailab le desc = error reading from server: read tcp • rpc error: code = Unavailab le desc = unexpected HTTP status code received from server: 502 (Bad Gateway); • rpc error: code = Unavailab le desc = unexpected HTTP status code received from server: 503 (Service Unavailable)	Tune retry policy using exporter.
Payload rejected	NA	Make sure the payload sent to the trace endpoint is within the limits and restrictions. For more information, see Endpoint limits and restricti ons.

Network Monitoring

The topics in this section describe CloudWatch network and internet monitoring capabilities provided by Network Flow Monitor, Internet Monitor and Network Synthetic Monitor. These services help you to gain operational visibility into the network and internet performance and availability of your applications hosted on Amazon.

- Network Flow Monitor provides near real-time visibility into network performance, such as packet loss and latency, for traffic between Amazon EC2 instances, as well as traffic toward other Amazon services, such as Amazon S3 and Amazon DynamoDB. Network Flow Monitor works by using data from lightweight software agents that you install to run on your instances. These fully-managed agents gather performance statistics from TCP connections and send them to the Network Flow Monitor backend. By creating monitors for specific agents and then using Network Flow Monitor dashboards, you can quickly visualize packet loss and latency of your network connections, and use attribution information to determine where to focus your troubleshooting efforts to improve your end users' experience.
- Internet Monitor uses the connectivity data that Amazon captures from its global networking footprint to calculate a baseline of performance and availability for internet-facing traffic. You can see a global view of traffic patterns and health events, and easily drill down into information about events. You can also get alerts for internet health events that affect your application clients. In addition, you can use insights that Internet Monitor provides to explore potential improvements to your client experience, by using Amazon CloudFront or routing through different Amazon Web Services Regions.
- Network Synthetic Monitor uses fully-managed agents to enable you to track and visualize latency and packet loss for hybrid network connections. To gather measurements and enable Network Synthetic Monitor to create health event alerts for your application, you create probes that are sent from your resources hosted on Amazon to on-premises destination IP addresses. You don't need to install additional agents to monitor your network performance. As with Internet Monitor, you can set alerts and thresholds, get information to help you quickly troubleshoot issues, and then take action to improve your end user experience.

Topics

- Using Network Flow Monitor
- Using Internet Monitor
- Using Network Synthetic Monitor

Using Network Flow Monitor

Network Flow Monitor provides near real-time visibility into network performance, such as packet loss and latency, for traffic between Amazon EC2 instances, as well as traffic toward other Amazon services, such as Amazon S3 and Amazon DynamoDB. Network Flow Monitor receives data from lightweight software agents that you install on your instances. The agents gather performance statistics from TCP connections. This data is sent to the Network Flow Monitor backend service, and the top contributors for each metric type are calculated. Network Flow Monitor also determines if Amazon is the cause of a detected network issue, and reports that information for network flows that you choose to monitor details for.

You can view network performance information for network flows for resources in a single account, or you can configure Network Flow Monitor with Amazon Organizations to view performance information for multiple accounts in an organization, by signing in with a management or delegated administrator account.

Network Flow Monitor is intended for network operators and application developers who want near real-time insights into network performance. In the Network Flow Monitor console in CloudWatch, you can see performance data for your resources' network traffic that has been aggregated from agents and grouped into different categories. For example, you can see data for flows between Availability Zones or between VPCs. Then, you can create monitors for specific flows that you want to see more details for and track more closely over time.

Using a monitor, you can quickly visualize packet loss and latency of your network connections over a time frame that you specify. For each monitor, Network Flow Monitor also generates a network health indicator (NHI). The NHI value informs you whether there were Amazon network issues for the network flows tracked by your monitor during the time period that you're evaluating. Using the NHI information, you can quickly decide whether to focus troubleshooting efforts on an Amazon network issue or network problems originating with your workloads.

To see an example of configuring and using Network Flow Monitor, see the following blog post: [Visualizing network performance of your Amazon Cloud workloads with Network Flow Monitor]().

What is Network Flow Monitor?

Network Flow Monitor is a feature of Amazon CloudWatch Network Monitoring. Network Flow Monitor uses fully-managed agents that you install in your Amazon workloads to return performance and availability metrics about network flows. Using Network Flow Monitor, you can access near real-time metrics, including retransmissions and data transferred, for your actual workloads. You can also identify whether an underlying Amazon network issue occurred for the network flows tracked by a monitor, by checking network health indicator (NHI) values.

Key features of Network Flow Monitor

- With Network Flow Monitor, you receive near real-time metrics for the latency and packet-loss experienced by TCP-based traffic within your VPC network, so that you can track and investigate network issues for your workload traffic.
- When your Amazon workloads experience network degradation, Network Flow Monitor helps you to determine if the problem is caused by your application workload or the underlying Amazon infrastructure. Then, you can quickly focus troubleshooting on the area where the issue is occurring.

How to use Network Flow Monitor

With Network Flow Monitor, you install lightweight agents on your instances, which collect and aggregate performance metrics. Network Flow Monitor agents analyze TCP traffic, and then export performance metrics to the Network Flow Monitor service backend.

Agents gather the following metrics for your workloads: TCP round-trip time (RTT), TCP retransmission timeouts, TCP retransmissions, and data (bytes) transferred. After you install agents on your instances, the agents detect the corresponding workloads that are hosted by the instances. The agents then generate network performance metrics and send the metrics to the Network Flow Monitor backend. Metrics are aggregated into categories such as subnets, Availability Zones, VPCs, and Amazon services.

Performance metrics for top contributors (by metric type) from all network flows that are in your Network Flow Monitor scope are shown on the **Workload insights** tab in the Amazon Web Services Management Console. By reviewing the tables and graphs of top contributors, you can determine where there might be impairments that you want to troubleshoot and which workloads you want to monitor on an ongoing basis, by creating a monitor.

With a monitor, you can monitor specific workloads more closely over time and see detailed information about specific network flows. In addition to viewing performance metrics for the top contributors for the network flows that you've selected, you can view topological information about the network hops that a network flow has traversed, to help you troubleshoot issues. In addition, Network Flow Monitor generates a network health indicator (NHI) for monitors. An

NHI value of **Degraded** indicates that there were Amazon network issues for at least one of the network flows tracked by your monitor, during the time period that you've selected.

In addition to reviewing the information in monitors that you create, we recommend that you also check back regularly to review metrics on the **Workload insights** page, to see the latest top contributors for performance metrics for your network flows. As you review the latest information, consider if it would be helpful to add or remove workloads from your current monitors, or create new monitors.

Contents

Supported Amazon Web Services Regions for Network Flow Monitor

Network Flow Monitor is currently available in the following Amazon Web Services Regions:

Region name	Region
Asia Pacific (Mumbai)	ap-south-1
Asia Pacific (Osaka)	ap-northeast-3
Asia Pacific (Seoul)	ap-northeast-2
Asia Pacific (Singapore)	ap-southeast-1
Asia Pacific (Sydney)	ap-southeast-2
Asia Pacific (Tokyo)	ap-northeast-1
Canada (Central)	ca-central-1
Europe (Frankfurt)	eu-central-1
Europe (Ireland)	eu-west-1

Region name	Region
Europe (London)	eu-west-2
Europe (Paris)	eu-west-3
Europe (Stockholm)	eu-north-1
South America (São Paulo)	sa-east-1
US East (N. Virginia)	us-east-1
US East (Ohio)	us-east-2
US West (N. California)	us-west-1
US West (Oregon)	us-west-2

Components and features of Network Flow Monitor

Network Flow Monitor uses or references the following concepts.

Agents

An *agent* in Network Flow Monitor is a software application that you install on your Amazon EC2 instance resources. The application has two parts:

- The first part receives events related to TCP connections and is registered within the Linux kernel using eBPF. eBPF is the Linux extended Berkley Packet Filter (eBPF) capability that allows a designated program to receive certain events raised by the Linux kernel.
- The second part aggregates the statistics collected by the eBPF portion. The agent sends the aggregated metrics to the Network Flow Monitor backend about every 30 seconds, with a 5 second potential jitter (in other words, 25 to 35 seconds).

For more information about agents, see [How it works](#).

Top contributors

Top contributors are the network flows that have the highest values for a specific metric (such as retransmissions) in your Network Flow Monitor scope or among the network flows you're tracking in a monitor. Reviewing the flows with the highest reported numbers for performance metric measurements can help you see where there might be impairments to investigate. Network Flow Monitor returns performance metrics for top contributors in your monitoring scope for *workload insights*. In addition, if you create a monitor, Network Flow Monitor returns performance metrics for top contributors for the network flows that you choose for the monitor.

Local and remote resources

A *local resource*, in a bi-directional flow of a workload, is the host where the agent is installed. For example, if a workload consists of an interaction between a web service and a backend database (for example, Amazon RDS), the EC2 instance hosting the web service, which also runs the agent, is the local resource. A local resource can be a subnet, a VPC, or an Availability Zone. The local resource is identified by the IP address and the transport protocol port, at a minimum.

A *remote resource* is the other endpoint in the bi-directional flow of a workload. In this example of a web service with a backend RDS database, Amazon RDS is the remote resource. A remote resource can be a subnet, a VPC, an Availability Zone, or an Amazon service. Just like a local resource, a remote resource is identified by the IP address of the endpoint and the transport protocol port.

Workload insights

Workload insights includes the performance metrics returned for all the network flows in your scope. In the Amazon Web Services Management Console, the **Workload insights** page provides performance data about workloads where you've installed Network Flow Monitor agents on workload instances. The **Workload insights** page provides a view into your applications that includes the amount of data transferred and several other metrics, grouped into categories of workloads. For example, you can see all the metrics for workloads with traffic between Availability Zones (AZs) or within an AZ. By using these insights, you can select workloads for which you want to create a monitor to see more details and to track network performance on an ongoing basis.

Monitors

You create a *monitor* so that you can monitor, on an ongoing basis, the network performance for one or several specific workloads, and see more detailed information about the network flows. For each monitor, Network Flow Monitor publishes end-to-end performance metrics, and a network health indicator (NHI), which you can use to help determine attribution for impairments. We recommend that you review information on the **Workload insights** page to see which network flows you want to focus on, and then create a monitor for those flows. Then, by regularly reviewing **Workload insights**, you can decide if you have the monitors that you need, or if creating new monitors would be helpful.

Network health indicator (NHI)

The *network health indicator* (NHI) is a binary value that informs you whether there were Amazon network issues for one or more of the network flows tracked by a monitor, during a time period that you choose. When the NHI value is 1, or **Degraded**, there was an Amazon network issue for at least one network flow. With the NHI indicator, you can quickly decide whether to focus troubleshooting efforts on an Amazon network issue or network problems originating with your workloads.

For more information about agents, see View Network Flow Monitor metrics in CloudWatch.

Scope

In Network Flow Monitor, the *scope* is the account or accounts that you have observability for when you look at network performance indicators. If you sign in as a management account and configure Amazon Organizations with CloudWatch, you can set your scope to more than one account in your organization (up to 100 accounts total). Otherwise, if you sign in with an Amazon Web Services account that does not have management permissions in Organizations, or if you have not configured Organizations with CloudWatch, Network Flow Monitor sets your scope to the account that you're signed in with.

Network Flow Monitor generates a unique **scope ID** for the scope. Queries for metrics data use the scope ID to determine the resources that the Network Flow Monitor generates metrics for. (You must install agents to gather and submit metrics data before you can view the performance metrics for an account with Network Flow Monitor.)

Query ID

Network Flow Monitor generates a unique *query ID* for each query that is created to retrieve performance metrics data, such as a query for top contributors for a monitor. By using a query ID with an API call in Network Flow Monitor, you can check the status of a query, stop a query, run the query again, or work with the query in other ways.

Performance metrics

Network Flow Monitor gathers and calculates end-to-end *performance metrics*, including TCP round-trip time (RTT), TCP retransmissions, TCP retransmission time outs, and bytes transferred for each flow that is in your Network Flow Monitor scope. The service aggregates these metrics and returns them to the service backend. You can view top contributors by metric type. When you see an anomaly in Network Flow Monitor, you can also check the network health indicator (NHI) to see if there is an underlying Amazon network issue.

Be aware that RTT data can be sparse because RTT is not always calculated.

You can also use Amazon CloudWatch features to create dashboards, alarms, and notifications based on these metrics. For example, you can learn about setting up alarms with Network Flow Monitor metrics by reviewing the information in [Create alarms with Network Flow Monitor].

How it works

This section provides information about how agents in Network Flow Monitor work.

How Network Flow Monitor agents work

Agents in Network Flow Monitor are installed on Amazon EC2 instances, where they gather performance metrics and send them to the Network Flow Monitor backend. Agents do not have access to the payload of your TCP connections. Agents receive only what is called the "bpf_sock_ops" structure from the Linux kernel. This structure provides the local and remote IP address and the source and destination TCP port, as well as counters and round-trip times. For list of the TCP statistics collected and published by the agent, see [View Network Flow Monitor metrics in CloudWatch].

The agent uses the Network Flow Monitor `Publish` API to send metrics to the Network Flow Monitor backend server.

Pricing for Network Flow Monitor

With Network Flow Monitor, there are no upfront costs or long-term commitments. Pricing for Network Flow Monitor has two components: resources monitored (agents installed and actively sending data) and CloudWatch metrics vended. Note that you are also charged standard CloudWatch prices for any additional metrics, dashboards, alarms, or insights that you create.

For more information about Network Flow Monitor and Amazon CloudWatch pricing, see Network Monitoring on the [Amazon CloudWatch pricing] page.

Get started with Network Flow Monitor

To help you get started, the section provides a high level overview of the steps to configure, and then gain insights, with Network Flow Monitor. For details, see the additional sections in this guide about initializing Network Flow Monitor, configuring agents, and creating monitors.

- Initialize Network Flow Monitor, to accept service-linked role permissions, create a *scope* for monitoring in Network Flow Monitor, and create an initial topology. If you want to observe network performance for network flows for instances in multiple accounts, you must integrate with Amazon Organizations, and then add the accounts to your scope. To learn more, see Initialize Network Flow Monitor.
- Deploy *agents* on your instances, by using Amazon Systems Manager or by configuring Kubernetes, depending on how your resources are deployed. If you install agents on VPC EC2 instances, make sure that you enable permissions for agents on each instance to send metrics to the Network Flow Monitor backend. To learn more, see Install Network Flow Monitor agents on instances.
- Review top contributor metrics for network flows returned by the agents, to gain *workload insights*. Workload insights provide a high-level view of the performance for network flows in the scope you're monitoring.
- Based on the network flows that you want to see detailed network information about, create one or more *monitors*. Using a monitor, you can see details metrics and information, as well as view topologies for specific network flows, over time periods that you select.
- On a regular basis:
  - Review network flow information in the monitors that you've created, to learn about and help troubleshoot network impairments in your workloads.
  - Review workload insights for the network flows that you're monitoring, to determine if the monitors that you've created are covering the most relevant network flows or if it would be helpful to create new monitors.

Network Flow Monitor API operations

The following table lists Network Flow Monitor API operations that you can use with Network Flow Monitor. The table also includes links to relevant documentation.

Action	API operation	More information
Create a flow monitor.	See CreateMonitor	See Create a monitor in Network Flow Monitor
Generate metrics for a scope of resources.	See CreateScope	See Evaluate network flows with workload insights
Remove a monitor.	See DeleteMonitor	See Delete a monitor in Network Flow Monitor
Delete a defined scope.	See DeleteScope	See Delete a monitor in Network Flow Monitor
Get information about a monitor.	See GetMonitor	See Monitor and analyze network flows using Network Flow Monitor performance metrics
Get query data for the top contributors in a specific monitor.	See GetQueryResultsMonitorTopContributors	See Monitor and analyze network flows using Network Flow Monitor performance metrics
Query the top contributors for a defined scope for workload insights.	See GetQueryResultsWorkloadInsightsTopContributors	See Evaluate network flows with workload insights
Query workload insights data for the top contributors in a specific scope.	See GetQueryResultsWorkloadInsightsTopContributorsData	See Evaluate network flows with workload insights
Check the status of a query for top contributors in a monitor to ensure that it has succeeded before reviewing the results.	See GetQueryStatusMonitorTopContributors	N/A

Action	API operation	More information
Check the status of a query on workload insights for top contributors to ensure that it has succeeded before reviewing the results.	See GetQueryStatusWorkloadInsightsTopContributors	N/A
Check the status of a query on workload insights data for top contributors to ensure that it has succeeded before reviewing the results.	See GetQueryStatusWorkloadInsightsTopContributorsData	N/A
Get information about an account, or scope, including name, status, tags, and target details.	See GetScope	See Monitor and analyze network flows using Network Flow Monitor performance metrics
List all monitors in an account.	See ListMonitors	Monitor and analyze network flows using Network Flow Monitor performance metrics
List all scopes for an account.	See ListScopes	N/A
List all tags for a specific resource.	See ListTagsForResource	See Monitor and analyze network flows using Network Flow Monitor performance metrics
See query data for top contributors in a monitor.	See StartQueryMonitorTopContributors	See Monitor and analyze network flows using Network Flow Monitor performance metrics
Start a query to gather workload insights data for top contributors.	See StartQueryWorkloadInsightsTopContributors	See Evaluate network flows with workload insights

Action	API operation	More information
Stop a query for top contributors in a monitor.	See StopQueryMonitorTopContributors	N/A
Stop a query on workload insights data for top contributors.	See StopQueryWorkloadInsightsTopContributors	N/A
Stop a query on workload insights data for top contributors.	See StopQueryWorkloadInsightsTopContributorsData	N/A
Add a tag to a resource.	See TagResource	See Edit a monitor in Network Flow Monitor
Remove a tag from a resource.	See UntagResource	See Edit a monitor in Network Flow Monitor
Update a monitor to add or remove local or remote resources.	See UpdateMonitor	See Edit a monitor in Network Flow Monitor
Modify a scope to add or remove resources that Network Flow Monitor will generate metrics on.	See UpdateScope	N/A

Examples of using the CLI with Network Flow Monitor

This section includes examples for using the Amazon Command Line Interface with Network Flow Monitor operations.

Before you begin, make sure that you log in to use the Amazon CLI with the Amazon account that provides the scope that you want to use to monitor network flows. For more information about using API actions with Network Flow Monitor, see the Network Flow Monitor API Reference Guide.

Topics

Create a monitor

To create a monitor with the Amazon CLI, use the `create-monitor` command. The following example creates a monitor named demo in the specified account.

```
aws networkflowmonitor create-monitor \
        --monitor-name demo \
        --local-resources type="AWS::EC2::VPC",identifier="arn:aws:ec2:us-
east-1:111122223333:vpc/vpc-11223344556677889"  \
        --scope-arn arn:aws:networkflowmonitor:us-east-1:111122223333:scope/sample-
aaaa-bbbb-cccc-44556677889
```

Output:

```
{
        "monitorArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/demo",
        "monitorName": "demo",
        "monitorStatus": "ACTIVE",
        "tags": {}
```

```
    }
```

For more information, see Create a monitor in Network Flow Monitor.

View monitor details

To view information about a monitor with the Amazon CLI, use the `get-monitor` command.

```
aws networkflowmonitor get-monitor --monitor-name "TestMonitor"
```

Output:

```
{
    "ClientLocationType": "city",
    "CreatedAt": "2022-09-22T19:27:47Z",
    "ModifiedAt": "2022-09-22T19:28:30Z",
    "MonitorArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/
TestMonitor",
    "MonitorName": "TestMonitor",
    "ProcessingStatus": "OK",
    "ProcessingStatusInfo": "The monitor is actively processing data",
    "Resources": [
        "arn:aws:ec2:us-east-1:111122223333:vpc/vpc-11223344556677889"
    ],
    "MaxCityNetworksToMonitor": 10000,
    "Status": "ACTIVE"
}
```

Create a scope

The following `create-scope` example creates a scope that is the set of resources for which Network Flow Monitor will generate network traffic metrics.

```
aws networkflowmonitor create-scope \
        --targets '[{"targetIdentifier":{"targetId":
{"accountId":"111122223333"},"targetType":"ACCOUNT"},"region":"us-east-1"}]'
```

Output:

```

    {
```

```
        "scopeId": "sample-aaaa-bbbb-cccc-11112222333",
        "status": "IN_PROGRESS",
        "tags": {}
    }
```

For more information, see Components and features of Network Flow Monitor.

Delete a monitor

The following `delete-monitor` example deletes a monitor named `Demo` in your account.

```
aws networkflowmonitor delete-monitor \
        --monitor-name Demo
```

This command produces no output.

For more information, see Delete a monitor in Network Flow Monitor.

Delete a scope

The following `delete-scope` example deletes the specified scope.

```
aws networkflowmonitor delete-scope \
        --scope-id sample-aaaa-bbbb-cccc-44556677889
```

This command produces no output.

For more information, see Components and features of Network Flow Monitor.

Get information about a monitor

The following `get-monitor` example displays information about the monitor named `demo` in the specified account.

```
aws networkflowmonitor get-monitor \
        --monitor-name Demo
```

Output:

```
{
        "monitorArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/Demo",
```

```
        "monitorName": "Demo",
        "monitorStatus": "ACTIVE",
        "localResources": [
            {
                "type": "AWS::EC2::VPC",
                "identifier": "arn:aws:ec2:us-east-1:111122223333:vpc/
vpc-11223344556677889"
            }
        ],
        "remoteResources": [],
        "createdAt": "2024-12-09T12:21:51.616000-06:00",
        "modifiedAt": "2024-12-09T12:21:55.412000-06:00",
        "tags": {}
    }
```

For more information, see Components and features of Network Flow Monitor.

Retrieve data on a specific queries

The following sections provide example CLI commands to retrieve query statuses.

get-query-results-workload-insights-top-contributors-data

The `get-query-results-workload-insights-top-contributors-data` example returns the data for the specified query.

```
aws networkflowmonitor get-query-results-workload-insights-top-contributors-data \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

Output:

```
{
        "datapoints": [
            {
                "timestamps": [
                    "2024-12-09T19:00:00+00:00",
                    "2024-12-09T19:05:00+00:00",
                    "2024-12-09T19:10:00+00:00"
                ],
                "values": [
                    259943.0,
```

```
                    194856.0,
                    216432.0
                ],
                "label": "use1-az6"
            }
        ],
        "unit": "Bytes"
    }
```

get-query-results-workload-insights-top-contributors

The following `get-query-results-workload-insights-top-contributors` example returns the data for the specified query.

```
aws networkflowmonitor get-query-results-workload-insights-top-contributors \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

Output:

```
{
        "topContributors": [
            {
                "accountId": "111122223333",
                "localSubnetId": "subnet-SAMPLE1111",
                "localAz": "use1-az6",
                "localVpcId": "vpc-SAMPLE2222",
                "localRegion": "us-east-1",
                "remoteIdentifier": "",
                "value": 333333,
                "localSubnetArn": "arn:aws:ec2:us-east-1:111122223333:subnet/
subnet-2222444455556666",
                "localVpcArn": "arn:aws:ec2:us-east-1:111122223333:vpc/
vpc-11223344556677889"
            }
        ]
    }
```

get-query-status-monitor-top-contributors

The following `get-query-status-monitor-top-contributors` example displays the current status of the query in the specified account.

```
aws networkflowmonitor get-query-status-monitor-top-contributors \
        --monitor-name Demo \
        --query-id sample-dddd-eeee-ffff-44556677889
```

Output:

```
{
        "status": "SUCCEEDED"
    }
```

get-query-status-workload-insights-top-contributors-data

The following `get-query-status-workload-insights-top-contributors-data` example displays the current status of the query in the specified account.

```
aws networkflowmonitor get-query-status-workload-insights-top-contributors-data \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

Output:

```
{
        "status": "SUCCEEDED"
    }
```

get-query-results-workload-insights-top-contributors

The following `get-query-results-workload-insights-top-contributors` example displays the current status of the query in the specified account.

```
aws networkflowmonitor get-query-status-workload-insights-top-contributors \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

Output:

```
{
        "status": "SUCCEEDED"
    }
```

For more information, see Evaluate network flows with workload insights.

See scope information

The following `get-scope` example displays information about a scope, such as status, tags, name, and target details.

```
aws networkflowmonitor get-scope \
        --scope-id sample-aaaa-bbbb-cccc-11112222333
```

Output:

```
{
        "scopeId": "sample-aaaa-bbbb-cccc-11112222333",
        "status": "SUCCEEDED",
        "scopeArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:scope/sample-
aaaa-bbbb-cccc-11112222333",
        "targets": [
            {
                "targetIdentifier": {
                    "targetId": {
                        "accountId": "111122223333"
                    },
                    "targetType": "ACCOUNT"
                },
                "region": "us-east-1"
            }
        ],
        "tags": {}
    }
```

For more information, see Components and features of Network Flow Monitor.

See a list of monitors for an account

The following `list-monitors` example returns all the monitors in the specified account.

```
aws networkflowmonitor list-monitors
```

Output:

```
{
```

```
        "monitors": [
            {
                "monitorArn": "arn:aws:networkflowmonitor:us-
east-1:111122223333:monitor/Demo",
                "monitorName": "Demo",
                "monitorStatus": "ACTIVE"
            }
        ]
    }
```

For more information, see Components and features of Network Flow Monitor.

See a list of scopes for an account

The following `list-scopes` example lists all the scopes in the specified account.

```
aws networkflowmonitor list-scopes
```

Output:

```
{
        "scopes": [
            {
                "scopeId": "sample-aaaa-bbbb-cccc-11112222333",
                "status": "SUCCEEDED",
                "scopeArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:scope/
sample-aaaa-bbbb-cccc-11112222333"
            }
        ]
    }
```

For more information, see Components and features of Network Flow Monitor.

See the list of tags for a monitor

The following `list-tags-for-resource` example returns all the tags associated with the specified resource.

```
aws networkflowmonitor list-tags-for-resource \
        --resource-arn arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/Demo
```

Output:

```
{
        "tags": {
            "Value": "Production",
            "Key": "stack"
        }
    }
```

For more information, see Tagging your Amazon CloudWatch resources.

Starting and stopping queries

The following sections provide example CLI commands for starting and stopping queries in Network Flow Monitor.

start-query-monitor-top-contributors

The following `start-query-monitor-top-contributors` example starts the query which returns a queryId to retrieve the top contributors.

```
aws networkflowmonitor start-query-monitor-top-contributors \
        --monitor-name Demo \
        --start-time 2024-12-09T19:00:00Z \
        --end-time 2024-12-09T19:15:00Z \
        --metric-name DATA_TRANSFERRED \
        --destination-category UNCLASSIFIED
```

Output:

```
{
        "queryId": "sample-dddd-eeee-ffff-44556677889"
    }
```

For more information, see Evaluate network flows with workload insights.

start-query-workload-insights-top-contributors-data

The following `start-query-workload-insights-top-contributors-data` example starts the query which returns a queryId to retrieve the top contributors.

```
aws networkflowmonitor start-query-workload-insights-top-contributors-data \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --start-time 2024-12-09T19:00:00Z \
        --end-time 2024-12-09T19:15:00Z \
        --metric-name DATA_TRANSFERRED \
        --destination-category UNCLASSIFIED
```

Output:

```
{
        "queryId": "sample-dddd-eeee-ffff-44556677889"
    }
```

For more information, see Evaluate network flows with workload insights.

start-query-workload-insights-top-contributors

The following `start-query-workload-insights-top-contributors` example starts the query which returns a queryId to retrieve the top contributors.

```
aws networkflowmonitor start-query-workload-insights-top-contributors \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --start-time 2024-12-09T19:00:00Z \
        --end-time 2024-12-09T19:15:00Z \
        --metric-name DATA_TRANSFERRED \
        --destination-category UNCLASSIFIED
```

Output:

```
{
        "queryId": "sample-dddd-eeee-ffff-44556677889"
    }
```

For more information, see Evaluate network flows with workload insights.

stop-query-monitor-top-contributors

The following `stop-query-monitor-top-contributors` example stops the query in the specified account.

```
aws networkflowmonitor stop-query-monitor-top-contributors \
        --monitor-name Demo \
        --query-id sample-dddd-eeee-ffff-44556677889
```

This command produces no output.

For more information, see [Evaluate network flows with workload insights].

stop-query-workload-insights-top-contributors-data

The following `stop-query-workload-insights-top-contributors-data` stops the query in the specified account.

```
aws networkflowmonitor stop-query-workload-insights-top-contributors-data \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

This command produces no output.

For more information, see [Evaluate network flows with workload insights].

stop-query-workload-insights-top-contributors

The following `stop-query-workload-insights-top-contributors` example stops the query in the specified account.

```
aws networkflowmonitor stop-query-workload-insights-top-contributors \
        --scope-id sample-aaaa-bbbb-cccc-11112222333 \
        --query-id sample-dddd-eeee-ffff-44556677889
```

This command produces no output.

For more information, see [Evaluate network flows with workload insights].

Tag a monitor

The following `tag-resource` adds a tag to the monitor in the specified account.

```
aws networkflowmonitor tag-resource \
        --resource-arn arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/Demo \
```

```
        --tags Key=stack,Value=Production
```

This command produces no output.

For more information, see Tagging your Amazon CloudWatch resources.

Remove a tag from a monitor

The following `untag-resource` example removes a tag to the monitor in the specified account.

```
aws networkflowmonitor untag-resource \
        --resource-arn arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/Demo \
        --tag-keys stack
```

This command produces no output.

For more information, see Tagging your Amazon CloudWatch resources.

Update an existing monitor

The following `update-monitor` example updates the monitor named ``Demo`` in the specified account.

```
aws networkflowmonitor update-monitor \
        --monitor-name Demo \
        --local-resources-to-add type="AWS::EC2::VPC",identifier="arn:aws:ec2:us-
east-1:111122223333:vpc/vpc-11223344556677889"
```

Output:

```
{
        "monitorArn": "arn:aws:networkflowmonitor:us-east-1:111122223333:monitor/Demo",
        "monitorName": "Demo",
        "monitorStatus": "ACTIVE",
        "tags": {
            "Value": "Production",
            "Key": "stack"
        }
    }
```

For more information, see Components and features of Network Flow Monitor.

Install Network Flow Monitor agents on instances

To provide performance metrics for network flows in your Amazon workloads, Network Flow Monitor relies on *agents* that you install, which send the metrics to Network Flow Monitor. You install Network Flow Monitor agents on your instances, and then set the correct permissions for the agents so that they can send metrics to the Network Flow Monitor backend.

An agent is a lightweight software application that you install on your resources, such as your VPC EC2 instances. Agents send performance metrics to the Network Flow Monitor backend on an ongoing basis. Then, you can view the metrics on the **Workload insights** page in the Network Flow Monitor console. You can also track detailed metrics for a specific network flow, or set of flows, by creating a monitor.

The instances that you install agents on must be running supported versions and distributions of Linux. Network Flow Monitor supports agents to run only on Linux, and the Linux kernel version must be 5.8 or later. The following Linux distributions are supported. Note that agents are tested to run on the latest versions of these distributions.

- Amazon Linux
- Ubuntu
- Red Hat
- Suse Linux
- Debian distributions for both x86 and aarch64

You can establish a private connection between your VPC and Network Flow Monitor agents by using Amazon PrivateLink. For more information, see Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints.

The steps that you follow to deploy agents in your instances depend on the type of instance: VPC EC2 instances, Amazon EKS Kubernetes instances, or self-managed (non-EKS) Kubernetes instances.

Contents

Install and manage agents for EC2 instances

Follow the steps in this section to install Network Flow Monitor agents for workloads on Amazon EC2 instances. You can install agents by using SSM or by downloading and installing prebuilt packages for the Network Flow Monitor agent by using the command line.

Regardless of the method that you use to install agents on EC2 instances, you must configure permissions for the agents to enable them to send performance metrics to the Network Flow Monitor backend.

Contents

Configure permissions for agents

To enable agents to send metrics to the Network Flow Monitor ingestion backend, the EC2 instances that the agents run in must use a role that has a policy attached with the correct permissions. To provide the required permissions, use a role that has the following Amazon managed policy attached: CloudWatchNetworkFlowMonitorAgentPublishPolicy. Attach this policy to the IAM roles of the EC2 instances where you plan to install Network Flow Monitor agents.

We recommend that you add the permissions before you install agents on the EC2 instances. You can choose to wait until after you install agents, but the agents won't be able to send metrics to the service until the permissions are in place.

To add permissions for Network Flow Monitor agents

1. In the Amazon Web Services Management Console, in the Amazon EC2 console, locate the EC2 instances that you plan to install Network Flow Monitor agents on.
2. Attach the CloudWatchNetworkFlowMonitorAgentPublishPolicy to the IAM role for each instance.

   If an instance doesn't have an IAM role attached, choose a role by doing the following:

   1. Under **Actions**, choose **Security**.
   2. Choose **Modify IAM role**, or create a new role by choosing **Create new IAM role**.

3. Choose a role for the instance, and attach the CloudWatchNetworkFlowMonitorAgentPublishPolicy policy.

Install agents on EC2 instances with SSM

Network Flow Monitor agents provide performance metrics about network flows. Follow the steps in this section to install and work with Network Flow Monitor agents on EC2 instances, by using Amazon Systems Manager. If you use Kubernetes, skip to the next sections for information about installing agents with Amazon EKS clusters or self-managed Kubernetes clusters.

Network Flow Monitor provides a Distributor package for you in Systems Manager to use to install or uninstall agents. In addition, Network Flow Monitor provides a document to activate or deactivate agents, by using the Document Type command. Use standard Systems Manager procedures to use the package and the document, or follow the steps provided here for detailed guidance.

For more information in general about using Systems Manager, see the following documentation:

- Amazon Systems Manager Run Command
- Amazon Systems Manager Distributor

Complete the steps in the following sections to configure permissions, install, and work with Network Flow Monitor agents.

Contents

Install or uninstall agents by using Systems Manager

Network Flow Monitor provides a distributor package in Amazon Systems Manager for you to install Network Flow Monitor agents: **AmazonCloudWatchNetworkFlowMonitorAgent**. To access and run the package to install agents, follow the steps provided here.

To install agents in EC2 instances

1. In the Amazon Web Services Management Console, in Amazon Systems Manager, under **Node Tools**, choose **Distributor**.

2. Under **Owned by Amazon**, locate the Network Flow Monitor package, **AmazonCloudWatchNetworkFlowMonitorAgent**, and select it.
3. In the **Run command** flow, choose **Install one time** or **Install on schedule**.
4. In the **Target selection** section, choose how you want to select your EC2 instances to install agents on. You can select instances based on tags, choose instances manually, or base the choice on resource groups.
5. In the **Commmand parameters** section, under **Action**, choose **Install**.
6. Scroll down, if necessary, and then choose **Run** to start the installation.

If the installation is successful and the instances have permissions to access Network Flow Monitor endpoints, the agent will start collecting metrics and send reports to the Network Flow Monitor backend.

Agents that are active (sending metrics data) incur billing costs. For more information about Network Flow Monitor and Amazon CloudWatch pricing, see Network Monitoring on the Amazon CloudWatch pricing page. If you don't need metrics data temporarily, you can deactivate an agent. For more information, see Activate or deactivate agents. If you no longer need Network Flow Monitor agents, you can uninstall them from the EC2 instances.

To uninstall agents from EC2 instances

1. In the Amazon Web Services Management Console, in Amazon Systems Manager, under **Node Tools**, choose **Distributor**.
2. Under **Owned by Amazon**, locate the Network Flow Monitor package, **AmazonCloudWatchNetworkFlowMonitorAgent**, and select it.
3. In the **Commmand parameters** section, under **Action**, choose **Uninstall**.
4. Select the EC2 instances to uninstall agents from.
5. Scroll down, if necessary, and then choose **Run** to start the installation.

Activate or deactivate agents by using Systems Manager

After you install a Network Flow Monitor agent with SSM, you must activate it to receive network flow metrics from the instance where it's installed. Agents that are active (sending metrics data) incur billing costs. For more information about Network Flow Monitor and Amazon CloudWatch pricing, see Network Monitoring on the Amazon CloudWatch pricing page. If you don't need metrics data temporarily, you can deactivate an agent to prevent ongoing billing for the agent.

Network Flow Monitor provides a document in Amazon Systems Manager that you can use activate or deactivate agents that you've installed on your EC2 instances. By running this document to manage the agents, you can activate them to begin receiving performance metrics. Or, you can deactivate them to temporarily stop metrics from being sent,without uninstalling the agents.

The document in SSM that you can use to activate or deactivate agents is called **AmazonCloudWatch-NetworkFlowMonitorManageAgent**. To access and run the document, follow the steps in the procedure.

To activate or deactivate Network Flow Monitor agents

1. In the Amazon Web Services Management Console, in Amazon Systems Manager, under **Change Management Tools**, choose **Documents**.
2. Under **Owned by Amazon**, locate the Network Flow Monitor document, **AmazonCloudWatch-NetworkFlowMonitorManageAgent**, and select the document.
3. In the **Target selection** section, choose how you want to select your EC2 instances to install agents on. You can select instances based on tags, choose instances manually, or base the choice on resource groups.
4. In the **Command parameters** section, under **Action**, choose **Activate** or **Deactivate**, depending on the action that you want to take for the agents.
5. Scroll down, if necessary, and then choose **Run** to start the installation.

Download prebuilt packages of the Network Flow Monitor agent by using the command line

You can use the command line to install the Network Flow Monitor agent as a package in Amazon Linux 2023, or download and install prebuilt packages of the Network Flow Monitor agent.

Before or after you download a prebuilt package, you can optionally verify the package signature. For more information, see [Verify the signature of the Network Flow Monitor agent package].

Choose from the following instructions, depending on the Linux operating system that you're using and the type of installation that you want.

Amazon Linux AMIs

The Network Flow Monitor agent is available as a package in Amazon Linux 2023. If you're using this operating system, you can install the package by entering the following command:

```
sudo yum install network-flow-monitor-agent
```

You must also make sure that the IAM role attached to the instance has the CloudWatchNetworkFlowMonitorAgentPublishPolicy policy attached. For more information, see Configure permissions for agents.

Amazon Linux 2023

Install the package for your architecture by using one of the following commands:

- **x86_64**: `sudo yum install https://networkflowmonitoragent.awsstatic.com/latest/x86_64/network-flow-monitor-agent.rpm`
- **ARM64 (Graviton)**: `sudo yum install https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.rpm`

Verify that Network Flow Monitor agent is successfully installed by running the following command and verifying that the response shows that the agent is enabled and active:

```
service network-flow-monitor status
network-flow-monitor.service - Network Flow Monitor Agent
     Loaded: loaded (/usr/lib/systemd/system/network-flow-monitor.service; enabled;
 preset: enabled)
     Active: active (running) since Wed 2025-04-23 19:17:16 UTC; 1min 9s ago
```

DEB-based distributions (Debian, Ubuntu)

Install the package for your architecture by using one of the following commands:

- **x86_64**: `wget https://networkflowmonitoragent.awsstatic.com/latest/x86_64/network-flow-monitor-agent.deb`
- **ARM64 (Graviton)**: `wget https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.deb`

Install the package by using the following command: `$ sudo apt-get install ./network-flow-monitor-agent.deb`

Verify that Network Flow Monitor agent is successfully installed by running the following command and verifying that the response shows that the agent is enabled and active:

```
service network-flow-monitor status
network-flow-monitor.service - Network Flow Monitor Agent
```

```
    Loaded: loaded (/usr/lib/systemd/system/network-flow-monitor.service; enabled;
preset: enabled)
    Active: active (running) since Wed 2025-04-23 19:17:16 UTC; 1min 9s ago
```

Verify the signature of the Network Flow Monitor agent package

The Network Flow Monitor agent rpm and deb installer packages for Linux instances are cryptographically signed. You can use a public key to verify that the agent package is original and unmodified. If the files are damaged or have been altered, the verification fails. You can verify the signature of the installer package using either RPM or GPG. The following information is for Network Flow Monitor agent versions 0.1.3 or later.

To find the correct signature file for each architecture and operating system, use the following table.

Architecture	Platform	Download link	Signature file link
x86-64	Amazon Linux 2023	https://networkflowmonitoragent.awsstatic.com/latest/x86_64/network-flow-monitor-agent.rpm	https://networkflowmonitoragent.awsstatic.com/latest/x86_64/network-flow-monitor-agent.rpm.sig
ARM64	Amazon Linux 2023	https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.rpm	https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.rpm.sig
x86-64	Debian/Ubuntu	https://networkflowmonitoragent.awsstatic.com/latest/x86_64/network-flow-monitor-agent.deb	https://networkflowmonitoragent.awsstatic.com/latest/x86_64/network-flow-monitor-agent.deb.sig
ARM64	Debian/Ubuntu	https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.deb	https://networkflowmonitoragent.awsstatic.com/latest/arm64/network-flow-monitor-agent.deb.sig

Follow the steps here to verify the signature of the Network Flow Monitor agent.

To verify the signature of the Network Flow Monitor agent for Amazon S3 package

1. Install GnuPG so that you can run the gpg command. GnuPG is required to verify the authenticity and integrity of a downloaded Network Flow Monitor agent for an Amazon S3 package. GnuPG is installed by default on Amazon Linux Amazon Machine Images (AMIs).

2. Copy the following public key and save it to a file named `nfm-agent.gpg`.

```

=INr5
-----END PGP PUBLIC KEY BLOCK-----
```

3. Import the public key into your keyring and note the returned value.

```
PS>  gpg --import nfm-agent.gpg
gpg: key 3B789C72: public key "Network Flow Monitor Agent" imported
gpg: Total number processed: 1
```

```
gpg: imported: 1 (RSA: 1)
```

Make a note of the key value because you need it in the next step. In this example, the key value is 3B789C72.

4. Verify the fingerprint by running the following command. Be sure to replace *key-value* with the value from the preceding step. We recommend that you use GPG to verify the fingerprint even if you use RPM to verify the installer package.

```
PS>  gpg --fingerprint key-value
pub   rsa4096 2025-04-08 [SC] [expires: 2028-04-07]
      7673 6CA9 97AD D3E9 D277  26A8 EFBD A4CC BC95 FAD1
uid   Network Flow Monitor Agent <network-flow-monitor-agent@amazon.com>
```

The fingerprint string should be equal to the following:

`7673 6CA9 97AD D3E9 D277 26A8 EFBD A4CC BC95 FAD1`

If the fingerprint string doesn't match, don't install the agent. Contact Amazon Web Services.

After you have verified the fingerprint, you can use it to verify the signature of the Network Flow Monitor agent package.

5. Download the package signature file, if you haven't already done so, based on your instance's architecture and operating system.

6. Verify the installer package signature. Be sure to replace the `signature-filename` and `agent-download-filename` with the values that you specified when you downloaded the signature file and agent, as shown in the table earlier in this topic.

```
PS> gpg --verify sig-filename agent-download-filename
gpg: Signature made Tue Apr  8 00:40:02 2025 UTC
gpg:                using RSA key 77777777EXAMPLEKEY
gpg:                issuer "network-flow-monitor-agent@amazon.com"
gpg: Good signature from "Network Flow Monitor Agent <network-flow-monitor-
agent@amazon.com>" [unknown]
gpg: WARNING: Using untrusted key!
```

If the output includes the phrase `BAD signature`, check to make sure that you performed the procedure correctly. If you continue to get this response, contact [Amazon Support](#) and avoid using the downloaded file.

Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

Next, follow the steps here to verify the RPM package.

To verify the signature of the RPM package

1. Copy the following public key and save it to a file named `nfm-agent.gpg`.

```
-----BEGIN PGP PUBLIC KEY BLOCK-----

mQINBGf0b5IBEAC6YQc0aYrTbcHNWWMbLuqsqfspzWrtCvoU0yQ62ld7nvCGBha9

-----END PGP PUBLIC KEY BLOCK-----
```

2. Import the public key into your keyring.

```
PS>  gpg --import nfm-agent.gpg
```

3. Verify the installer package signature. Be sure to replace the `agent-download-filename` with the value that you specified when you downloaded the agent, as shown in the table earlier in this topic.

```
PS>  rpm --checksig agent-download-filename
```

For example, for the x86_64 architecture on Amazon Linux 2023, use the following command:

```
PS>  rpm --checksig network-flow-monitor-agent.rpm
```

This command returns output similar to the following.

```
network-flow-monitor-agent.rpm: digests signatures OK
```

If the output contains the phrase `NOT OK (MISSING KEYS: (MD5) key-id)`, check to make sure that you performed the procedure correctly. If you continue to get this response, contact Amazon Support and don't install the agent.

Install agents for self-managed Kubernetes instances

Follow the steps in this section to install Network Flow Monitor agents for workloads on self-managed Kubernetes clusters. After you complete the steps, Network Flow Monitor agent pods will be running on all of your self-managed Kubernetes cluster nodes.

If you use Amazon Elastic Kubernetes Service (Amazon EKS), the installation steps to follow are in the following section: Install the EKS Amazon Network Flow Monitor Agent add-on.

Contents

Before you begin

Before you start the installation process, follow the steps in this section to make sure that your environment is set up to successfully install agents on the right Kubernetes clusters.

Ensure that your version of Kubernetes is supported

Network Flow Monitor agent installation requires Kubernetes Version 1.25, or a more recent version.

Ensure that you have installed required tools

The scripts that you use for this installation process require that you install the following tools. If you don't have the tools installed already, see the provided links for more information.

- The Amazon Command Line Interface (CLI). For more information, see Installing or updating to the latest version of the Amazon Command Line Interface in the Amazon Command Line Interface Reference Guide.
- The Helm package manager. For more information, see Installing Helm on the Helm website.
- The `kubectl` command line tool. For more information, see Install kubectl on the Kubernetes website.
- The `make` Linux command dependency. For more information, see the following blog post: Intro to make Linux Command: Installation and Usage. For example, do one of the following:
  - For Debian based distributions, such as Ubuntu, use the following command: `sudo apt-get install make`
  - For RPM-based distributions, such as CentOS, use the following command: `sudo yum install make`

Ensure that you have valid, correctly configured KubeConfig environment variables

Network Flow Monitor agent installation uses the Helm package manager tool, which uses the kubeconfig variable, `$HELM_KUBECONTEXT`, to determine the target Kubernetes clusters to work with. Also, be aware that when Helm runs installation scripts, by default, it references the standard `~/.kube/config` file. You can change the configuration environment variables, to use a different config file (by updating `$KUBECONFIG`) or to define the target cluster you want to work with (by updating `$HELM_KUBECONTEXT`).

Create a Network Flow Monitor Kubernetes namespace

The Network Flow Monitor agent's Kubernetes application installs its resources into a specific namespace. The namespace must exist for the installation to succeed. To ensure that the required namespace is in place, you can do one of the following:

- Create the default namespace, `amazon-network-flow-monitor`, before you begin.
- Create a different namespace, and then define it in the `$NAMESPACE` environment variable when you run the installation to make targets.

Download Helm charts and install agents

You can download the Network Flow Monitor agent Helm charts from the Amazon public repository by using the following command. Make sure that you first authenticate with your GitHub account.

`git clone https://github.com/aws/network-flow-monitor-agent.git`

In the `./charts/amazon-network-flow-monitor-agent` directory, you can find the Network Flow Monitor agent Helm charts and Makefile that contain the installation make targets that you use for installing agents. You install agents for Network Flow Monitor by using the following Makefile target: `helm/install/customer`

You can customize the installation if you like, for example, by doing the following:

```
# Overwrite the kubeconfig files to use
KUBECONFIG=<MY_KUBECONFIG_ABS_PATH> make helm/install/customer

# Overwrite the Kubernetes namespace to use
NAMESPACE=<MY_K8S_NAMESPACE> make helm/install/customer
```

To verify that the Kubernetes application pods for the Network Flow Monitor agents have been created and deployed successfully, check to be sure that their state is `Running`. You can check state of the agents by running the following command: `kubectl get pods -o wide -A | grep amazon-network-flow-monitor`

Configure permissions for agents to deliver metrics

After you install agents for Network Flow Monitor, you must enable the agents to send network metrics to the Network Flow Monitor ingestion APIs. Agents in Network Flow Monitor must have permission to access the Network Flow Monitor ingestion APIs so that they can deliver network flow metrics that they've collected for each instance. You grant this access by implementing IAM roles for service accounts (IRSA).

To enable agents to deliver network metrics to Network Flow Monitor, follow the steps in this section.

1. **Implement IAM roles for service accounts**

   IAM roles for service accounts provides the ability to manage credentials for your applications, similar to the way that Amazon EC2 instance profiles provide credentials to Amazon EC2 instances. Implementing IRSA is the recommended way to provide all permissions required by Network Flow Monitor agents to successfully access Network Flow Monitor ingestion APIs. For more information, see [IAM roles for service accounts] in the Amazon EKS User Guide.

   When you set up IRSA for Network Flow Monitor agents, use the following information:

   - **ServiceAccount:** When you define your IAM role trust policy, for `ServiceAccount`, specify `aws-network-flow-monitor-agent-service-account`.
   - **Namespace:** For the `namespace`, specify `amazon-network-flow-monitor`.
   - **Temporary credentials deployment:** When you configure permissions after you have deployed Network Flow Monitor agent pods, updating the `ServiceAccount` with your IAM role, Kubernetes does not deploy the IAM role credentials. To ensure that the Network Flow Monitor agents acquire the IAM role credentials that you've specified, you must rolling out a restart of `DaemonSet`. For example, use a command like the following:

     ```
     kubectl rollout restart daemonset -n amazon-network-flow-monitor aws-network-flow-monitor-agent
     ```

2. **Confirm that the Network Flow Monitor agent is successfully accessing the Network Flow Monitor ingestion APIs**

   You can check to make sure that your configuration for agents is working correctly by using the HTTP 200 logs for Network Flow Monitor agent pods. First, search for a Network Flow Monitor agent pod, and then search through the log files to find successful HTTP 200 requests. For example, you can do the following:

   a. Locate a Network Flow Monitor agent Pod name. For example, you can use the following command:

   ```
   RANDOM_AGENT_POD_NAME=$(kubectl get pods -o wide -A | grep amazon-network-flow-monitor | grep Running | head -n 1 | tr -s ' ' | cut -d " " -f 2)
   ```

b. Grep all the HTTP logs for the pod name that you've located. If you've changed the NAMESPACE, make sure that you use the new one.

```
NAMESPACE=amazon-network-flow-monitor
kubectl logs $RANDOM_AGENT_POD_NAME -\-namespace ${NAMESPACE} | grep HTTP
```

If access has been granted successfully, you should see log entries similar to the following:

```
...
{"level":"INFO","message":"HTTP request
 complete","status":200,"target":"amzn_nefmon::reports::publisher_endpoint","timestamp":17370
{"level":"INFO","message":"HTTP request
 complete","status":200,"target":"amzn_nefmon::reports::publisher_endpoint","timestamp":17370
```

Note that the Network Flow Monitor agent publishes network flow reports every 30 seconds, by calling the Network Flow Monitor ingestion APIs.

Install the EKS Amazon Network Flow Monitor Agent add-on

Follow the steps in this section to install the Amazon Network Flow Monitor Agent add-on for Amazon Elastic Kubernetes Service (Amazon EKS), to send Network Flow Monitor metrics to the Network Flow Monitor backend from Kubernetes clusters. After you complete the steps, Amazon Network Flow Monitor Agent pods will be running on all of your Kubernetes cluster nodes.

If you use self-managed Kubernetes clusters, the installation steps to follow are in the previous section: Install agents for self-managed Kubernetes instances.

Be aware that Customer Managed prefix lists Customer Managed prefix lists are not supported for Network Flow Monitor.

You can install the add-on by using the console or by using API commands with the Amazon Command Line Interface.

Contents

- Install the Amazon Network Flow Monitor Agent add-on by using the Amazon Command Line Interface

Prerequisites for installing the add-on

Regardless of whether you use the console or the CLI to install the Amazon Network Flow Monitor Agent add-on, there are several requirements for installing the add-on with Kubernetes.

Ensure that your version of Kubernetes is supported

Network Flow Monitor agent installation requires Kubernetes Version 1.25, or a more recent version.

Amazon EKS Pod Identity Agent add-on installation

You can install the Amazon EKS Pod Identity Agent add-on in the console or by using the CLI.

Amazon EKS Pod Identity associations provide the ability to manage credentials for your applications, similar to the way that Amazon EC2 instance profiles provide credentials to Amazon EC2 instances. Amazon EKS Pod Identity provides credentials to your workloads with an additional Amazon EKS Auth API and an agent pod that runs on each node.

To learn more and see the steps for installing the Amazon EKS Pod Identity add-on, see Set up the Amazon EKS Pod Identity Agent in the Amazon EKS User Guide.

Install the Amazon Network Flow Monitor Agent add-on by using the console

Follow the steps in this section to install and configure the Amazon Network Flow Monitor Agent add-on in the Amazon EKS console.

If you have already installed the add-on and have issues upgrading to a new version, see Troubleshoot issues in EKS agents installation.

Before you begin, make sure that you have installed the Amazon EKS Pod Identity Agent add-on. For more information, see the previous section.

To install the add-on using the console

1. In the Amazon Web Services Management Console, navigate to the Amazon EKS console.
2. On the page for installing add-ons, in the list of add-ons, choose **Amazon Network Flow Monitor Agent**.

3. Configure the add-on settings.

   1. For **Add-on access**, choose **EKS Pod Identity**.
   2. For the IAM role to use with the add-on, use a role that has the following Amazon managed policy attached: CloudWatchNetworkFlowMonitorAgentPublishPolicy. This policy gives permission for an agent to send telemetry reports to the Network Flow Monitor endpoint. If you don't already have a role with the policy attached, create a role by choosing **Create recommended role**, and following the steps in the IAM console.
   3. Choose **Next**.

4. On the **Review and add** page, make sure that the add-on configuration looks correct, and then choose **Create**.

Install the Amazon Network Flow Monitor Agent add-on by using the Amazon Command Line Interface

Follow the steps in this section to install the Amazon Network Flow Monitor Agent add-on for Amazon EKS by using the Amazon Command Line Interface.

1. Install the EKS Pod Identity Agent add-on

Before you begin, make sure that you have installed the Amazon EKS Pod Identity Agent add-on. For more information, see the earlier section.

2. Create the required IAM role

The Amazon Network Flow Monitor Agent add-on must have permission to send metrics to the Network Flow Monitor backend. You must attach a role with the required permissions when you create the add-on. Create a role that has the following Amazon managed policy attached: CloudWatchNetworkFlowMonitorAgentPublishPolicy. You need the ARN of this IAM role to install the add-on.

3. Install the Amazon Network Flow Monitor Agent add-on

To install the Amazon Network Flow Monitor Agent add-on for your cluster, run the following command:

```
aws eks create-addon --cluster-name CLUSTER NAME --addon-name aws-
network-flow-monitoring-agent --region Amazon REGION --pod-identity-
associations serviceAccount=aws-network-flow-monitor-agent-service-
account,roleArn=IAM ROLE ARN
```

The result should be similar to the following:

```
{
    "addon": {
        "addonName": "aws-network-flow-monitoring-agent",
        "clusterName": "ExampleClusterName",
        "status": "CREATING",
        "addonVersion": "v1.0.0-eksbuild.1",
        "health": {
            "issues": []
        },
        "addonArn": "arn:aws:eks:us-west-2:000000000000:addon/ExampleClusterName/
aws-network-flow-monitoring-agent/eec11111-bbbb-EXAMPLE",
        "createdAt": "2024-10-25T16:38:07.213000+00:00",
        "modifiedAt": "2024-10-25T16:38:07.240000+00:00",
        "tags": {},
         "podIdentityAssociations": [
            "arn:aws:eks:us-west-2:000000000000:podidentityassociation/
ExampleClusterName/a-3EXAMPLE5555555"
         ]
    }
  }
```

4. Make sure that the add-on is active

Review the installed Amazon Network Flow Monitor Agent add-on to ensure that it's active for your cluster. Run the following command to verify that the status is `ACTIVE`:

```
aws eks describe-addon --cluster-name CLUSTER NAME --addon-name aws-network-flow-monitoring-agent --region AWS REGION
```

The result should be similar to the following:

```
{
    "addon": {
        "addonName": "aws-network-flow-monitoring-agent",
        "clusterName": "ExampleClusterName",
        "status": "ACTIVE",
        "addonVersion": "v1.0.0-eksbuild.1",
        "health": {
            "issues": []
        },
```

```
        "addonArn": "arn:aws:eks:us-west-2:000000000000:addon/ExampleClusterName/
aws-network-flow-monitoring-agent/eec11111-bbbb-EXAMPLE",
        "createdAt": "2024-10-25T16:38:07.213000+00:00",
        "modifiedAt": "2024-10-25T16:38:07.240000+00:00",
        "tags": {},
         "podIdentityAssociations": [
            "arn:aws:eks:us-west-2:000000000000:podidentityassociation/
ExampleClusterName/a-3EXAMPLE5555555"
         ]
    }
  }
```

Initialize Network Flow Monitor

Before you can view performance metrics for network flows, you must initialize Network Flow Monitor, which grants required permissions and creates an initial topology for your account or accounts. If you plan to monitor resources for multiple accounts, you must also configure Amazon Organizations with Amazon CloudWatch. Then, you specify accounts for your Network Flow Monitor scope, so that Network Flow Monitor can create an initial topology for all the accounts that you'll be tracking performance metrics for.

In addition, you must install agents on your instances, to send performance metrics to the Network Flow Monitor backup ingestion server. For more information, see Install Network Flow Monitor agents on instances.

The steps that you take to initialize Network Flow Monitor vary depending on whether you are measuring performance metrics for resources in a single account, or you want to monitor metrics from resources that are owned by multiple accounts in your organization.

- Single account monitoring initialization
- Multi-account monitoring initialization

Initialize Network Flow Monitor for single account monitoring

To initialize Network Flow Monitor to monitor network performance metrics, you must grant permissions and Network Flow Monitor must create the initial topology for your account. When you monitor resources in just one account, Network Flow Monitor sets your account as the scope for network monitoring and creates a topology for that scope.

Initializing Network Flow Monitor does the following:

- Grants permissions for Network Flow Monitor to use required service-linked roles with your account. Network Flow Monitor requires you to grant it specific permissions so that the feature can send metrics to Amazon CloudWatch on your behalf, as well as create topologies of network flows. For more information, see Service-linked roles for Network Flow Monitor.
- Sets your monitoring scope for Network Flow Monitor to the Amazon account that you're signed in with. For more information, see **Scope** in Components and features of Network Flow Monitor.
- Creates an initial topology for your scope.

To initialize Network Flow Monitor by setting up the service-linked roles that provide the required permissions, setting the scope to your account, and creating a topology for network flow performance monitoring, follow these steps.

To initialize Network Flow Monitor

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. In the **Getting started with Network Flow Monitor** section, under Step 1, choose **Start initialization**.
4. On the **Configure Network Flow Monitor** page, scroll down, and then choose **Initialize Network Flow Monitor**.

Completing the initialization can take 20-30 minutes.

After you initialize Network Flow Monitor for your account, before you can view network flow performance metrics, you must also install Network Flow Monitor agents for your resources that send performance metrics to the Network Flow Monitor backed ingestion server. For more information, see Install Network Flow Monitor agents on instances.

Initialize Network Flow Monitor for multi-account monitoring

If you want to monitor network flows in Network Flow Monitor for resources that are owned by different accounts, you must first configure Amazon CloudWatch with Amazon Organizations. To use multiple accounts in Network Flow Monitor, you're required to turn on trusted access for CloudWatch, and it's a best practice to also register a delegated administrator.

In addition, if you plan to create monitors for network flows from the console, you must add a Network Flow Monitor policy to the role that is attached to your resources. The policy enables you to view resources from other accounts in the console, so that you can add the resources in multiple accounts to a monitor.

To monitor network flows for resources that are owned by different accounts, there are additional configuration steps to take. First, as the management account, you must configure CloudWatch with Amazon Organizations to turn on trusted access, and, typically, you'll also register a delegated administrator account. Then, using the delegated administrator account, you can add more accounts in your organization, to set the scope for your network observability to include resources in those accounts. (You can also add multiple accounts with a management account, but it's a best practice in Organizations to use the delegated administrator account when you work with resources in a service. We provide steps that follow that guidance in the instructions here for Network Flow Monitor.)

Note that if you don’t need to monitor network flows for instances from multiple accounts, you can use Network Flow Monitor with a single account. The scope for Network Flow Monitor is automatically set to the Amazon account that you sign in with.

Use the guidance in the following sections to complete these steps.

Contents

Overview of steps for using multiple accounts in Network Flow Monitor

To get started with Network Flow Monitor, any account that has not used Network Flow Monitor before must initialize Network Flow Monitor. When you initialize Network Flow Monitor for an account, Network Flow Monitor adds the required service-linked role permissions and creates a scope of the account or accounts to be included in network observability. To work with multiple accounts in Network Flow Monitor, there are additional steps, to integrate with Amazon Organizations, and then add the accounts to work with.

In summary, you take the following steps:

1. Sign in to the Amazon Web Services Management Console as the management account, and then do the following:
   - Complete the required steps for integrating with Amazon Organizations in CloudWatch.
2. Sign in to the Amazon Web Services Management Console as the delegated administrator account, and then do the following:
   - Initialize Network Flow Monitor, including adding accounts to include in your scope.
   - Add the required permissions for accessing resources that are in other accounts from the console.

If you're setting up Network Flow Monitor to work with multiple accounts and you're not familiar with Amazon Organizations, review the following resources to learn about concepts such as the management account, trusted access, and the delegated administrator account, and to learn how to integrate Organizations with CloudWatch.

- Managing accounts in an organization with Amazon Organizations in the Amazon Organizations User Guide.
- Amazon CloudWatch and Amazon Organizations in the Amazon Organizations User Guide.

Follow the steps in the following sections for specific guidance in configuring Network Flow Monitor for multiple accounts.

Configure Amazon Organizations in CloudWatch

To configure Network Flow Monitor with Amazon Organizations, sign in to the management account, and turn on trusted access for CloudWatch. Then, register a delegated administrator account to use for initializing Network Flow Monitor and adding multiple accounts.

If you've already configured Organizations in CloudWatch to turn on trusted access for Organizations in CloudWatch and register a delegated administrator account, you don't need to configure anything more for Organizations that is specific to Network Flow Monitor. You can sign in with the delegated administrator account for CloudWatch, and then initialize Network Flow Monitor, including adding multiple accounts for your network observability scope.

If you haven't yet configured Organizations in CloudWatch, follow the steps here to turn on trusted access and register a delegated administrator account.

Turn on trusted access in CloudWatch

Before you can use Network Flow Monitor with more than one account in your organization, you must turn on trusted access for Amazon Organizations in Amazon CloudWatch. Use the following steps to turn on trusted access in the CloudWatch console.

To turn on trusted access

1. Sign in to the console with your organization's management account.
2. In the CloudWatch console, in the navigation pane, choose **Settings**.
3. Choose the **Organizations** tab.
4. In **Organizational Management Settings**, choose **Turn on**. The **Enable trusted access** page appears.
5. To review the role policy, choose **View permission** details to see the role policy.
6. Choose **Enable trusted access**.

Now, as CloudWatch discovers resources, it automatically updates information about accounts that you have permission to access the resources for in Network Flow Monitor.

Register a delegated administrator account

As a best practice with Amazon Organizations, the management account for your organization should register a member account as a delegated administrator account for CloudWatch. After you register a delegated administrator account in CloudWatch, members of your organization can sign in with the delegated administrator account to monitor the network performance for resources in multiple accounts in Network Flow Monitor.

Using the delegated administrator account, you can add multiple accounts for your network observability scope in Network Flow Monitor. Although the management account can also create a scope that includes multiple accounts, we recommend that you follow the best practices for Amazon Organizations and use a delegated administrator account for adding multiple accounts in Network Flow Monitor. For member accounts that are not the delegated administrator account, the scope is limited to the signed-in account, which is automatically set for the scope.

A delegated administrator account for Organizations is a member account that shares administrator access for service-managed permissions. The account that you choose to register as a delegated administrator account must be a member account in your organization. A delegated administrator account for your organization can be used outside of CloudWatch, so make sure that you understand this account type before following this procedure. For more information, see Amazon CloudWatch and Amazon Organizations in the Amazon Organizations User Guide.

To register a delegated administrator account

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Organization** tab.
4. Choose **Register delegated administrator**.
5. In the **Register delegated administrator** window, in the **Delegated administrator account ID** field, enter the 12-digit Organization member account ID.
6. Choose **Register delegated administrator**. At the top of the page, a message appears indicating the account was registered successfully. The **Organization Settings** page appears. To see information about the delegated administrator account, hover over the number below **Delegated administrators**.

To remove or change the delegated administrator account, deregister the account first. For more information, see Deregistering a delegated administrator account.

Add multiple accounts to your scope

To add accounts to your Network Flow Monitor scope, sign in with the delegated administrator account. (You can add accounts to a scope if you're signed in with the management account, but it's a best practice in Amazon Organizations to use the delegated administrator account to work with resources.)

After you sign in with the delegated administrator account, initialize Network Flow Monitor to authorize the required service-linked role permissions, set the scope for your network observability by adding accounts, and create an initial topology for the accounts in your scope. The account that you sign in with—in this case, the delegated administrator account—is automatically included in your Network Flow Monitor scope. To add accounts to your scope so that you can monitor network flows for resources in multiple accounts, follow the steps here.

To add accounts to your scope

1. Sign in to the console with your organization’s management account.
2. In the navigation pane for the CloudWatch console, under **Network Monitoring**, choose **Flow monitors**.

3. Under **Getting started with Network Flow Monitor**, in Step 1, choose **Start initialization**.
4. On the **Network Flow Monitor** page, under **Add accounts**, choose **Add**. The account that you're signed in with is automatically included in the scope and already appears in the **Accounts in scope** table as **(this account)**.
5. On the **Add accounts** dialog page, optionally filter the accounts, and then select up to 99 additional accounts to add to your scope. The maximum number of accounts in a scope is 100.
6. Choose **Add**.
7. Choose **Initialize Network Flow Monitor**. Network Flow Monitor adds the required service-linked role permissions, creates a scope that includes all the accounts you specified, and then creates an initial topology of the resources in the accounts in your scope.

Set up permissions for multi-account resource access (console only)

If you plan to create monitors for network flows from the console, a specific policy is required for each member account in your scope. This policy enables you to view resources from other accounts when you add local and remote resources to a monitor.

For each of the account in your scope, create a role, **NetworkFlowMonitorAccountResourceAccess**, and attach the **AmazonEC2ReadOnlyAccess** policy. To see permission details for the policy, see AmazonEC2ReadOnlyAccess in the Amazon Managed Policy Reference Guide.

This policy is in addition to the policy that you must add to each instance so that the Network Flow Monitor agent can send performance metrics from the instance to the Network Flow Monitor ingestion backend server. For more information about requirements for agents, see Install Network Flow Monitor agents on instances.

The following procedure provides a summary of the steps to create the required role for accessing resources in your scope in the Network Flow Monitor console. For general guidance on how to create a role in IAM, see Create a role to give permissions to an IAM user in the Amazon Identity and Access Management User Guide.

To create a role for resource access in the Network Flow Monitor console

1. Sign in to the Amazon Web Services Management Console and open the IAM console.
2. In the navigation pane of the console, choose **Roles**, and then choose **Create role**.
3. Specify the **Amazon account** trusted entity. This trusted entity type enables principals in other Amazon accounts to assume the role and access resources in other accounts.

4. Choose **Next**.
5. In the list of Amazon managed policies, choose the **AmazonEC2ReadOnlyAccess** policy.
6. Choose **Next**.
7. For role name, enter **NetworkFlowMonitorAccountResourceAccess**.
8. Review the role, and then choose **Create role**.

Install agents on instances

To track network performance with Network Flow Monitor, you must initialize the service, but you must also install Network Flow Monitor agents on your workload's EC2 instances and add permissions for the agents to send networking performance metrics to Network Flow Monitor. After you install the agents, wait a short period of time (about 20 minutes), for data to begin being sent to the Network Flow Monitor backend. Then, you can view network performance metrics, on the **Workload insights** tab, and also create monitors, to view detailed information.

For example, you can view the top contributor performance metrics for data transferred and retransmission timeouts, for network flows between your local and remote resources, collected by Network Flow Monitor agents. By viewing and analyzing these metrics, you can choose specific flows that you want to see more details for and track more closely with a monitor. By creating a monitor for specific flows, you can see detailed information about them, including metrics, sorted by the top contributors for each metric type and topologies for each network flow.

With a monitor, Network Flow Monitor also provides a network health indicator (NHI), which you can use to see if there have been Amazon network impairments for network flows that you're tracking in the monitor, during a time period that you've selected. That information can help you decide where to focus your network troubleshooting efforts.

For more information, and instructions for how to install agents, see [Install Network Flow Monitor agents on instances](#).

Monitor and analyze network flows in Network Flow Monitor

With Network Flow Monitor, you can learn about network flows and performance for traffic that you're monitoring with your scope. You can get workload insights about top contributors, by each metric type, and then create monitors to explore network performance in detail, over different time frames, for the network flows that you select.

After you initialize Network Flow Monitor and install agents on your instances, you can view performance metrics for the network flows from those instances. Review the sections here to learn more about how to use Network Flow Monitor to evaluate network performance in Network Flow Monitor, create monitors for more in-depth information, and learn about the specific metrics provided by Network Flow Monitor.

The steps provided in these sections use the Amazon Web Services Management Console. You can also use Network Flow Monitor API operations with the Amazon Command Line Interface (Amazon CLI) or Amazon SDKs to create and configure a monitor.

For detailed information about working with Network Flow Monitor API operations, see the following resources:

- If you plan to work with Network Flow Monitor with the CLI, see Examples of using the CLI with Network Flow Monitor.
- For detailed information about working with Network Flow Monitor API operations, see the Network Flow Monitor API Reference Guide.

Contents

Evaluate network flows with workload insights

Network Flow Monitor provides workload insights for the network flows for top contributors in the scope (account) that you enable monitoring for. Top contributors are network flows that have the highest values for each network performance metric. Top contributors are determined for workload insights, which includes all the network flows that you're receiving performance information about, as well as for the network flows you specify for each monitor that you create.

For example, Network Flow Monitor determines the network flows that have the highest values for retransmissions, retransmission timeouts, and data transferred. These network flows are the *top contributors* for each metric type. On the **Workload insights** page in the Network Flow Monitor console, Network Flow Monitor displays the top contributor network performance statistics for the network flows between all the resources in your monitoring scope where you've deployed agents.

Note that if you have multiple accounts in your scope that each have resources that you want to monitor network flows between, you must configure Amazon Organizations integration with CloudWatch before you can view performance metrics gathered by the Network Flow Monitor agents that you've installed. When you configure Organizations with Network Flow Monitor, you can add accounts to the scope for your Network Flow Monitor coverage.

Performance metrics on **Workload insights** are shown in separate tables for each metric type: Retransmissions, retransmission timeouts, and data transferred. The data provided is for the top contributors for each type. Note that after you first install Network Flow Monitor agents, there is a waiting period (about 20 minutes) before you can view performance metrics, while agents gather and send data to the Network Flow Monitor backend.

As you review performance metrics, when you see specific resources or network flows that you want to explore more details for, you can create a monitor that includes just those flows.

Create and work with monitors in Network Flow Monitor

You create a monitor to see details about the network performance for one or several network flows for a workload. For each monitor, Network Flow Monitor publishes end-to-end performance metrics and a network health indicator (NHI), and generates topologies of individual network flows. After you create a monitor, you can view information provided by the monitor in the console on the **Monitors** page.

After you create a monitor, you can edit the monitor to make changes or delete the monitor at any time.

The following sections includes procedures for creating, editing, and deleting monitors in the Network Flow Monitor console.

Contents

Create a monitor in Network Flow Monitor

You create a monitor by providing the local and remote resources to monitor flows between. You can select network flows on the **Workload insights** page, and then choose to create a monitor.

When you create a monitor in this way, the **Create monitor** wizard pre-populates local and remote resources for you. Alternatively, you can choose **Create monitor**, and then select local and remote resources for the monitor from drop-down menus.

By reviewing the top contributors on **Workload insights** on an ongoing basis, you can regularly evaluate if you have the monitors that you need, or if creating new monitors would be helpful.

> **Important**
>
> These steps are designed to be completed all at once. You won't be able to save any in-process work to continue later.

To create a monitor using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. Choose **Create monitor**.
4. For **Monitor name**, enter the name you want to use for this monitor in Network Flow Monitor.
5. Select the local resources (one or more) for the network flows that you want to monitor. If your scope includes multiple accounts, choose an account for the resources that you want to specify for your local resources. Then, choose Subnet, VPC, or Availability Zone, and then choose a resource.

   If you started by choosing specific network flows that you wanted to monitor on the **Workload insights** page before starting the **Create monitor** process, network flows are pre-populated for you. If you like, modify your original choices by selecting resources to add or remove in this step.
6. Select the remote resources for the network flows that you want to monitor. To monitor all network flows that originate with the local resources that you chose, select **Everywhere**.

   If you want to select specific resources for your remote resources and your scope includes multiple accounts, choose an account for the resources that you want to specify. Then, choose Subnet, VPC, or Availability Zone, and then choose a resource.
7. Optionally, you can add a tag for your monitor.
8. When you're finished adding remote and local resources, choose **Next** to review and confirm the network flows to monitor.

9. Choose **Create monitor**.

After you create a monitor, you can edit the monitor at any time, to add or remove network flows, or add or edit tags. You can also delete the monitor. Select a monitor, and then choose **Edit**. Note that you can’t change the name of a monitor.

To view the Network Flow Monitor dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Network monitoring**, then **Flow monitors**.

   The **Monitors** tab displays a list of the monitors that you have created.

To see more information about a specific monitor, choose a monitor.

Edit a monitor in Network Flow Monitor

You can edit a monitor at any time, to add or remove network flows, or add or edit tags.

Note that you can't change the name of a monitor after you create it.

> **Important**
>
> These steps are designed to be completed all at once. You won't be able to save any in-process work to continue later.

To edit a monitor using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. On the **Monitors** tab, select a monitor, and then choose **Edit**.
4. Select the local or remote resources that you want add or remove for the monitor. If you have multiple accounts in your scope, specify the account where the resources are located, and then choose resources.
5. Optionally, you can add or remove a tag for your monitor.
6. When you're finished updating the monitor, choose **Next** to review and confirm the network flows to monitor.

7. Choose **Save monitor**.

Delete a monitor in Network Flow Monitor

To delete a monitor in Network Flow Monitor, follow the steps here.

To delete a monitor

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. Select a monitor, and then choose **Delete**.
4. In the dialog that appears, enter confirmation text, and then choose **Delete**.

Monitor and analyze network flows using Network Flow Monitor performance metrics

Network Flow Monitor data and graphs help you to visualize and track network issues. You can create monitors to see detailed information about specific network segments for your Amazon workloads, including a view of the topology for individual network flows. After you create one or more monitors in Network Flow Monitor, you can observe performance and metrics, and explore historical data, to find anomalies.

To see the information provided by a monitor, on the **Monitors** tab, choose a monitor in the **Monitors** table. Then, choose one of the following tabs for more information: **Overview**, **Historical explorer**, or **Monitor details**.

Overview tab

On the **Overview** tab, you can review the following, for time periods that you specify. To see a broader or narrower range of historical information, including the NHI and traffic summary data, adjust the time period selection at the top of the page.

Metrics are shown only for traffic flows that Network Flow Monitor classifies into designated destination categories. Metrics are displayed for flows between AZs (`INTER_AZ`), within AZs (`INTRA_AZ`), between VPCs (`INTER_VPC`), toward Amazon S3 buckets (`AMAZON_S3`), and toward Amazon DynamoDB (`AMAZON_DYNAMODB`). Flows are not classified into a destination category for scenarios such as the following: when traffic goes to another Region or to the internet, or when traffic goes through a shared resource in another account.

- **Network health indicator (NHI):** NHI alerts you to whether there there were Amazon network issues for one or more of the network flows tracked by your monitor, during the time frame that you've selected for viewing performance metrics. NHI is a binary value, that is, 1 or 0, which is shown in the console as **Degraded** or **Healthy**.
  - NHI is shown as **Degraded** if there were issues with the portion of the Amazon network that any network flow in the monitor traversed, at any time during the time frame that you select.
  - Otherwise, NHI is shown as **Healthy**.

  If the NHI is **Degraded**, you can view the **Network health indicator** bar graph for more information. The graph shows you when, during the selected time frame, there were Amazon network issues for the network flows tracked by your monitor.
- **Traffic summary:** Observe overall metrics for the flows tracked by this monitor, for the time period that you've selected. You can see average round-trip time, sums (totals) of transmission timeouts and retransmissions, and the average amount of data transferred for the flows in the monitor. Be aware that RTT data can be sparse because RTT is not always calculated.

Historical explorer tab

On the **Historical explorer** tab, you can dive deep into information about specific flows. You can review metrics and topologies for top contributor network flows for specified time frames. In the tables of metrics, you can filter the data by different categories of flows, such as flows between Availability Zones (`INTER-AZ`).

- **Metrics:** View detailed information for the top contributors for each metric type that Network Flow Monitor aggregates data for. Separate tables of top contributors are provided for retransmission timeouts, retransmissions, round-trip time, and data transferred.
- **Topologies:** To get an idea about where anomalies are occurring, you can view the path or *topology*of a network flow. When you choose a specific metric in a metrics table, the topology for that flow is displayed below the table.

Monitor details tab

On the **Monitor details** tab, you can see details about the monitor, including the monitor state, the ARN, when it was created and last updated, and the flows that are included.

As part of your regular use of Network Flow Monitor, we recommend that you periodically review the data on the **Workload insights** page to determine if there are new flows that show metrics anomalies that you want to track more closely over time. When you see a set of flows on the **Workload insights** page that you want to see details about, select the flows and create a monitor for them.

Delete scope for Network Flow Monitor

If you decide that you no longer want to monitor network flows using Network Flow Monitor, you can delete your Network Flow Monitor scope. When you delete your scope, you can no longer see network performance information.

Before you can delete your scope, you must delete all monitors. Be aware that it can take about 15 minutes to complete removing monitors after you request to delete them. For more information, see Delete a monitor in Network Flow Monitor.

To delete your scope

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Flow monitors**.
3. On the **Settings** tab, choose **Delete scope**.
4. In the dialog box, enter confirmation text, and then choose **Delete scope**.

View Network Flow Monitor metrics in CloudWatch

Network Flow Monitor publishes the following network flow performance metrics to your account: round-trip time, TCP retransmissions, TCP retransmission timeouts, data transferred, and network health indicator. You can view these metrics in CloudWatch Metrics in the Amazon CloudWatch console.

To find all metrics for your monitor, in the CloudWatch Metrics dashboard, see the custom namespace `AWS/NetworkFlowMonitor`. Metrics are aggregated for each monitor that is deployed and active.

Network Flow Monitor provides the following metrics. Be aware that RoundTripTime data can be sparse, as this metric is not always calculated.

Metric	Description
DataTransferred	The number of bytes transferred for all flows for a monitor.
Retransmissions	Total number of retransmissions for a monitor. Retransmissions occur when the sender needs to resend packets that have been either damaged or lost.
Timeouts	Total retransmission timeouts for a monitor. This occurs when the sender is missing too many acknowledgments, and therefore decides to take a time out and stop sending altogether.
RoundTripTime	Average round-trip time for network flows for a monitor. This metric, measured in microseco nds, is a measure of performance. It records the time it takes for traffic to be transmitted from a local resource to a remote IP address, and for the associated response to be received. The time is an average over the aggregation period. Data can be sparse, as this metric is not always calculated.
HealthIndicator	Network health indicator (NHI) for a monitor overall. Network health indicator (NHI) is a value that surfaces an Amazon network impairment. The NHI value is 1 (degraded) if there was an Amazon network issue during a specified time frame. It's set to 0 (healthy) if no Amazon network issues were detected. Observing the NHI can help you to prioritize troubleshooting for either your workload or the Amazon network.

Create alarms with Network Flow Monitor

You can create Amazon CloudWatch alarms based on Network Flow Monitor metrics, just as you can for other CloudWatch metrics.

For example, you can create an alarm based on the Network Flow Monitor metric `Retransmissions`, and configure it to send a notification when the metric is higher than a value that you choose. You configure alarms for Network Flow Monitor metrics following the same guidelines as for other CloudWatch metrics.

Following are example Network Flow Monitor metrics that you might choose to create an alarm for:

- **Retransmissions**
- **Timeouts**
- **RoundTripTime**

To see all the metrics available for Network Flow Monitor see [Create a CloudWatch alarm based on a static threshold](#).

The following procedure provides an example of setting an alarm on **Retransmissions** by navigating to the metric in the CloudWatch dashboard. Then, you follow the standard CloudWatch steps to create an alarm based on a threshold that you choose, and set up a notification or choose other options.

To create an alarm for Retransmissions in CloudWatch Metrics

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Metrics**, and then choose **All metrics**.
3. Filter for Network Flow Monitor by choosing `AWS/NetworkFlowMonitor`.
4. Choose **MeasurementSource, MonitorName**.
5. In the list, select **Retransmissions**.
6. On the **GraphedMetrics** tab, under **Actions**, choose the bell icon to create an alarm based on a static threshold.

Now, follow the standard CloudWatch steps to choose options for the alarm. For example, you can choose to be notified by an Amazon SNS message if **Retransmissions** is below a specific threshold number. Alternatively, or in addition, you can add the alarm to a dashboard.

Keep in mind the following:

- Network Flow Monitor metrics are typically aggregated and sent to the Network Flow Monitor backend every 30 seconds, with a 5 second potential jitter (in other words, 25 to 35 seconds).
- When you create an alarm based on Network Flow Monitor metrics, make sure that you take into account the short delay before publication when you set an alarm's lookback period. We recommend that you configure **Evaluation Periods** with lookback period that is a minimum of 25 minutes.

For more information about options when you create a CloudWatch alarm, see Create a CloudWatch alarm based on a static threshold.

Amazon CloudTrail for Network Flow Monitor

Monitoring a service is an important part of maintaining reliability, availability, and performance. of Network Flow Monitor and your other Amazon solutions. *Amazon CloudTrail* captures API calls and related events made by or on behalf of your Amazon Web Services account and delivers the log files to an Amazon S3 bucket that you specify. You can identify which users and accounts called Amazon, the source IP address from which the calls were made, and when the calls occurred. For more information, see the Amazon CloudTrail User Guide.

For more information about Network Flow Monitor CloudTrail logging, see Network Flow Monitor in CloudTrail.

Troubleshoot issues in Network Flow Monitor

This section provides guidance for troubleshooting errors with Network Flow Monitor, including solving issues with installing agents.

Troubleshoot issues in EKS agents installation

When you try to upgrade the Amazon Network Flow Monitor Agent add-on for EKS from v1.0.0 to v1.0.1 in Amazon Web Services Management Console, you might receive the following error message:

"Service account `aws-network-flow-monitoring-agent-service-account` in pod identity configuration is not supported for addon `aws-network-flow-monitoring-agent`."

This error is returned because a resource was renamed. The EKS add-on v1.0.1 changes the service account name from `aws-network-flow-monitoring-agent-service-account` to `aws-network-flow-monitor-agent-service-account`.

Then, if **Not set** is not selected in the console, the pod identity association is not reset to the new resource name.

To fix this issue, do the following when you upgrade to the new version by using the console:

1. Under **Pod Identity IAM role for service account**, select **Not set**.
2. Select **New version (v1.0.1)**.
3. Select **Upgrade**.
4. Choose **Save changes**.

Data security and data protection in Network Flow Monitor

Cloud security at Amazon is the highest priority. As an Amazon customer, you benefit from data centers and network architectures that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between Amazon and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – Amazon is responsible for protecting the infrastructure that runs Amazon services in the Amazon Web Services Cloud. Amazon also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the Amazon Compliance Programs. To learn about the compliance programs that apply to Network Flow Monitor, see Amazon Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the Amazon service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Network Flow Monitor. The following topics show you how to configure Network Flow

Monitor to meet your security and compliance objectives. You also learn how to use other Amazon services that help you to monitor and secure your Network Flow Monitor resources.

Topics

Data protection in Network Flow Monitor

The Amazon shared responsibility model applies to data protection in Network Flow Monitor. As described in this model, Amazon is responsible for protecting the global infrastructure that runs all of the Amazon Web Services Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the Amazon Web Services services that you use. For more information about data privacy, see the Data Privacy FAQ.

For data protection purposes, we recommend that you protect Amazon Web Services account credentials and set up individual users with Amazon IAM Identity Center or Amazon Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with Amazon resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with Amazon CloudTrail. For information about using CloudTrail trails to capture Amazon activities, see Working with CloudTrail trails in the *Amazon CloudTrail User Guide*.
- Use Amazon encryption solutions, along with all default security controls within Amazon Web Services services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing Amazon through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Network Flow Monitor or other Amazon Web Services services using the console, API, Amazon CLI, or Amazon SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Infrastructure Security in Network Flow Monitor

As a managed service, Network Flow Monitor is protected by the Amazon global network security procedures that are described in the [Amazon Web Services: Overview of Security Processes](#) whitepaper.

You use Amazon published API calls to access Network Flow Monitor through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [Amazon Security Token Service](#) (Amazon STS) to generate temporary security credentials to sign requests.

Identity and Access Management for Network Flow Monitor

Amazon Identity and Access Management (IAM) is an Amazon Web Services service that helps an administrator securely control access to Amazon resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Network Flow Monitor resources. IAM is an Amazon Web Services service that you can use with no additional charge.

Contents

How Network Flow Monitor works with IAM

Before you use IAM to manage access to Network Flow Monitor, learn what IAM features are available to use with Network Flow Monitor.

To see tables showing a similar high-level view of how Amazon services work with most IAM features, see Amazon services that work with IAM in the *IAM User Guide*.

IAM features you can use with Network Flow Monitor

IAM feature	Network Flow Monitor support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
ABAC (tags in policies)	Yes
Temporary credentials	Yes
Principal permissions	Yes
Service roles	No
Service-linked roles	Yes

Identity-based policies for Network Flow Monitor

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see [IAM JSON policy elements reference](#) in the *IAM User Guide*.

Resource-based policies within Network Flow Monitor

Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource.

Policy actions for Network Flow Monitor

Supports policy actions: Yes

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated Amazon API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

To see a list of Network Flow Monitor actions, see [Actions defined by Network Flow Monitor](#) in the *Service Authorization Reference*.

Policy actions in Network Flow Monitor use the following prefix before the action:

```
networkflowmonitor
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "networkflowmonitor:action1",
```

```
        "networkflowmonitor:action2"
           ]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Describe`, include the following action:

```
"Action": "networkflowmonitor:Describe*"
```

Policy resources for Network Flow Monitor

Supports policy resources: Yes

In the *Service Authorization Reference*, you can see the following information related to Network Flow Monitor:

- To see a list of Network Flow Monitor resource types and their ARNs, see Resources defined by Network Flow Monitor.
- To learn the actions that you can specify with the ARN of each resource, see Actions defined by Network Flow Monitor.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. Statements must include either a `Resource` or a `NotResource` element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

Policy condition keys for Network Flow Monitor

Supports service-specific policy condition keys: Yes

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Condition element (or Condition *block*) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, Amazon evaluates them using a logical AND operation. If you specify multiple values for a single condition key, Amazon evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the *IAM User Guide*.

Amazon supports global condition keys and service-specific condition keys. To see all Amazon global condition keys, see Amazon global condition context keys in the *IAM User Guide*.

To see a list of Network Flow Monitor condition keys, see Condition keys for Network Flow Monitor in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Network Flow Monitor.

ACLs in Network Flow Monitor

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

ABAC with Network Flow Monitor

Supports ABAC (tags in policies): Yes

Network Flow Monitor has *partial* support for tags in policies. It supports tagging for one resource, monitors.

To use tags with Network Flow Monitor, use the Amazon Command Line Interface or an Amazon SDK. Tagging for Network Flow Monitor is not supported with the Amazon Web Services Management Console.

To learn more about using tags in policies in general, review the following information.

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In Amazon, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many Amazon resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

Using temporary credentials with Network Flow Monitor

Supports temporary credentials: Yes

Some Amazon Web Services services don't work when you sign in using temporary credentials. For additional information, including which Amazon Web Services services work with temporary credentials, see Amazon Web Services services that work with IAM in the *IAM User Guide*.

You are using temporary credentials if you sign in to the Amazon Web Services Management Console using any method except a user name and password. For example, when you access Amazon using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switch from a user to an IAM role (console) in the *IAM User Guide*.

You can manually create temporary credentials using the Amazon CLI or Amazon API. You can then use those temporary credentials to access Amazon. Amazon recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

Cross-service principal permissions for Network Flow Monitor

Supports forward access sessions (FAS): Yes

When you use an IAM user or role to perform actions in Amazon, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an Amazon Web Services service, combined with the requesting Amazon Web Services service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other Amazon Web Services services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

Service roles for Network Flow Monitor

Supports service roles: No

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an Amazon Web Services service in the *IAM User Guide*.

Service-linked role for Network Flow Monitor

Supports service-linked roles: Yes

A service-linked role is a type of service role that is linked to an Amazon Web Services service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your Amazon Web Services account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For more information about the service-linked role for Network Flow Monitor, see Service-linked roles for Network Flow Monitor.

For details about creating or managing service-linked roles in general in Amazon, see Amazon services that work with IAM. Find a service in the table that includes a `Yes` in the **Service-linked role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

Amazon managed policies for Network Flow Monitor

An Amazon managed policy is a standalone policy that is created and administered by Amazon. Amazon managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that Amazon managed policies might not grant least-privilege permissions for your specific use cases because they're available for all Amazon customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in Amazon managed policies. If Amazon updates the permissions defined in an Amazon managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. Amazon is most likely to update an Amazon managed policy when a new Amazon Web Services service is launched or new API operations become available for existing services.

For more information, see Amazon managed policies in the *IAM User Guide*.

Amazon managed policy: CloudWatchNetworkFlowMonitorServiceRolePolicy

You can't attach `CloudWatchNetworkFlowMonitorServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role named **AWSServiceRoleForNetworkFlowMonitor**, which publishes network telemetry aggregation results, collected by Network Flow Monitor agents, to CloudWatch. It also allows the service to use Amazon Organizations to get information for multi-account scenarios.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorServiceRolePolicy in the *Amazon Managed Policy Reference*.

For more information, see Service-linked roles for Network Flow Monitor.

Amazon managed policy: CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy

You can't attach `CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy` to your IAM entities. This policy is attached to a service-linked role named **AWSServiceRoleForNetworkFlowMonitor_Topology**. Using these permissions, as well as internal meta data information gathering (for performance efficiencies), this service-linked role gathers meta data about resource network configurations, such as describing route tables and gateways, for resources that this service monitors network traffic for. This meta data enables Network Flow Monitor to generate topology snapshots of the resources. When there is network degradation, Network Flow Monitor uses the topologies to provide insights into the location of issues in the network and to help determine attribution for issues.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy in the *Amazon Managed Policy Reference*.

For more information, see Service-linked roles for Network Flow Monitor.

Amazon managed policy: CloudWatchNetworkFlowMonitorAgentPublishPolicy

You can use this policy in IAM roles that are attached to Amazon EC2 and Amazon EKS instance resources to send telemetry reports (metrics) to a Network Flow Monitor endpoint.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorAgentPublishPolicy in the *Amazon Managed Policy Reference*.

Updates to the Network Flow Monitor service-linked roles

For updates to the Amazon managed policies for the Network Flow Monitor service-linked roles, see the Amazon managed policies updates table for CloudWatch. You can also subscribe to automatic RSS alerts on the CloudWatch Document history page.

Service-linked roles for Network Flow Monitor

Network Flow Monitor uses Amazon Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Network Flow Monitor. The service-linked role is predefined by Network Flow Monitor and includes all the permissions that the service requires to call other Amazon services on your behalf.

Network Flow Monitor defines the permissions of the service-linked roles, and unless defined otherwise, only Network Flow Monitor can assume the roles. The defined permissions include the trust policies and the permissions policies, and the permissions policies cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This restriction protects your Network Flow Monitor resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see Amazon services that work with IAM and look for the services that have **Yes** in the **Service-linked role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Network Flow Monitor

Network Flow Monitor uses the following service-linked roles:

- **AWSServiceRoleForNetworkFlowMonitor**
- **AWSServiceRoleForNetworkFlowMonitor_Topology**

Service-linked role permissions for AWSServiceRoleForNetworkFlowMonitor

Network Flow Monitor uses the service-linked role named **AWSServiceRoleForNetworkFlowMonitor**. This role allows Network Flow Monitor to publish CloudWatch aggregated telemetry metrics gathered for network traffic between instances, and between instances and Amazon locations. It also allows the service to use Amazon Organizations to get information for multi-account scenarios.

This service-linked role uses the managed policy `CloudWatchNetworkFlowMonitorServiceRolePolicy`.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorServiceRolePolicy in the *Amazon Managed Policy Reference*.

The **AWSServiceRoleForNetworkFlowMonitor** service-linked role trusts the following service to assume the role:

- `networkflowmonitor.amazonaws.com`

Service-linked role permissions for AWSServiceRoleForNetworkFlowMonitor_Topology

Network Flow Monitor uses the service-linked role named **AWSServiceRoleForNetworkFlowMonitor_Topology**. This role allows Network Flow Monitor to generate a topology snapshot of the resources that you use with Network Flow Monitor.

This service-linked role uses the managed policy `CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy`.

To view the permissions for this policy, see CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy in the *Amazon Managed Policy Reference*.

The **AWSServiceRoleForNetworkFlowMonitor_Topology** service-linked role trusts the following service to assume the role:

- `topology.networkflowmonitor.amazonaws.com`

Creating a service-linked role for Network Flow Monitor

You do not need to manually create the service-linked roles for Network Flow Monitor. The first time that you initialize Network Flow Monitor, Network Flow Monitor creates **AWSServiceRoleForNetworkFlowMonitor** and **AWSServiceRoleForNetworkFlowMonitor_Topology** for you.

For more information, see Creating a service-linked role in the *IAM User Guide*.

Editing a service-linked role for Network Flow Monitor

After Network Flow Monitor creates a service-linked role in your account, you cannot change the name of the role because various entities might reference the role. You can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for Network Flow Monitor

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete the role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for the service-linked role before you can manually delete it.

> **Note**
>
> If the Network Flow Monitor service is using the role when you try to delete it, then the deletion might fail. If that happens, wait for a few minutes and then try again.

To manually delete the service-linked role using IAM

Use the IAM console, the Amazon CLI, or the Amazon API to delete the **AWSServiceRoleForNetworkFlowMonitor** or the **AWSServiceRoleForNetworkFlowMonitor_Topology** service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Updates to the Network Flow Monitor service-linked role

For updates to `CloudWatchNetworkFlowMonitorServiceRolePolicy` or `CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy`, the Amazon managed policies for the Network Flow Monitor service-linked roles, see CloudWatch updates to Amazon managed policies. For automatic alerts about managed policy changes in CloudWatch, subscribe to the RSS feed on the CloudWatch Document history page.

Network Flow Monitor quotas

Network Flow Monitor has the following quotas.

Resource	Default quota	Adjustable?
Scopes per account per Amazon Web Services Region	1	No
Monitors per account per Amazon Web Services Region	50	Yes
Local resources per monitor	25	No
Remote resources per monitor	25	No

Using Internet Monitor

Internet Monitor provides visibility into how internet issues impact the performance and availability between your applications hosted on Amazon and your end users. It can reduce the time it takes for you to diagnose internet issues from days to minutes. Internet Monitor uses the connectivity data that Amazon captures from its global networking footprint to calculate a baseline of performance and availability for internet-facing traffic. This is the same data that Amazon uses to monitor internet uptime and availability. With those measurements as a baseline, Internet Monitor raises awareness for you when there are significant problems for your end users (clients) in the different geographic locations where your application runs.

In the Amazon CloudWatch console, you can see a global view of traffic patterns and health events, and easily drill down into information about events, at different geographic granularities (locations). You can clearly visualize impact, and pinpoint the client locations and networks (ASNs, typically internet service providers or ISPs) that are affected. If Internet Monitor determines that an internet availability or performance issue is caused by a specific ASN or by the Amazon network, it provides that information.

To get started, create a monitor that includes one or more resources, so Internet Monitor can create a traffic profile for your Amazon application. Then, view information in the Internet Monitor dashboard to visualize data and get insights and suggestions about your application's internet traffic.

For information about Regional support, pricing, how Internet Monitor works, and other overview content, see What is Internet Monitor?. To begin working with Internet Monitor, see Getting started with Internet Monitor using the console.

What is Internet Monitor?

With Internet Monitor, you can monitor your application's internet performance and availability, so that you can visualize data and get insights and suggestions about your Amazon application's internet traffic. You can also get suggestions for ways to reduce latency for your application, by using different Regions or Amazon services, like Amazon CloudFront.

Key features of Internet Monitor

- Internet Monitor suggests insights and recommendations that can help you improve your end users' experience. You can explore, in near real-time, how to improve the projected latency of your application by switching to use other services, or by rerouting traffic to your workload through different Amazon Web Services Regions.
- Internet Monitor stores internet measurements for pairs of your client locations and ASNs, or *city-networks*. Internet Monitor also creates aggregated CloudWatch metrics for traffic to your application, and to each Amazon Web Services Region and edge location. With the Internet Monitor dashboard, you can quickly identify what's impacting your application's performance and availability, so that you can track down and address issues.
- Internet Monitor also publishes internet measurements to CloudWatch Logs and CloudWatch Metrics, to support using CloudWatch tools to explore data for city-networks that are specific to your monitored application traffic. Optionally, you can also publish internet measurements to Amazon S3.
- Internet Monitor sends overall (global) health events to Amazon EventBridge so that you can set up notifications. (Local health events are not published to EventBridge.) If an issue is caused by the Amazon network, you also automatically receive an Amazon Health Dashboard notification with the steps that Amazon is taking to mitigate the problem.

How to use Internet Monitor

To use Internet Monitor, you create a *monitor* and associate your application's resources with it—VPCs, Network Load Balancers, CloudFront distributions, or WorkSpaces directories—to enable Internet Monitor to know where your application's internet-facing traffic is. Internet Monitor then publishes internet measurements from Amazon that are specific to the *city-networks*, that is, the client locations and ASNs (typically internet service providers or ISPs), where clients access your application. For more information, see How Internet Monitor works. To begin working with Internet Monitor, see Getting started with Internet Monitor using the console.

Contents

Supported Amazon Web Services Regions for Internet Monitor

The Amazon Web Services Regions and Amazon Local Zones where Amazon CloudWatch Internet Monitor is supported are listed in this section. For more information about Regions that Internet Monitor is supported in, including opt-in Regions, see Amazon CloudWatch Internet Monitor endpoints and quotas in the *Amazon Web Services General Reference*.

Note that Internet Monitor stores data for a monitor in only the Amazon Web Services Region in which you create the monitor, although a monitor can include resources in multiple Regions.

Region name (Opt-in support)	Region
Africa (Cape Town)	`af-south-1`
Asia Pacific (Hong Kong)	`ap-east-1`
Asia Pacific (Hyderabad)	`ap-south-2`
Asia Pacific (Jakarta)	`ap-southeast-3`

Region name (Opt-in support)	Region
Asia Pacific (Melbourne)	ap-southeast-4
Europe (Milan)	eu-south-1
Europe (Spain)	eu-south-2

For Local Zones support, you must enable the Local Zone and attach it to the VPC that you want to monitor internet traffic for. Internet Monitor does not support Local Zones for other resources types. The Local Zones that are supported are listed in the following table.

Local Zone	Parent Region	Type
us-east-1-dfw-2a	us-east-1	Availability Zone
us-east-1-mia-2a	us-east-1	Availability Zone
us-east-1-qro-1a	us-east-1	Frontier Zone

us-east-1-atl-2a	us-east-1	Availability Zone
us-east-1-bue-1a	us-east-1	Frontier Zone
us-east-1-mci-1a	us-east-1	Frontier Zone
us-west-2-lax-1a	us-west-2	Availability Zone
us-west-2-lax-1b	us-west-2	Availability Zone
af-south-1-los-1a	af-south-1	Frontier Zone

Components and terms for Internet Monitor

Internet Monitor uses or references the following concepts.

Monitor

A monitor includes the resources for a single application that you want to view internet performance and availability measurements for, and that you want to get health event alerts about. When you create a monitor for an application, you add resources for the application to define the cities (locations) for Internet Monitor to monitor. Internet Monitor uses the traffic patterns from the application resources that you add so that it can publish internet performance and availability measurements specific to just the locations and ASNs (typically, internet service providers or ISPs) that communicate with your application. In other words, the resources that you add create a scope of the *city-networks* that you want Internet Monitor to monitor and that you want it to publish measurements for.

Resource added to monitor ("monitored resource")

A resource that you add to a monitor is a "monitored resource" in Internet Monitor. That is:

- Each VPC that you add in a Region is a monitored resource. When you add a VPC, Internet Monitor monitors the traffic for any internet-facing application in the VPC, for example, an application hosted on an Amazon EC2 instance, behind a Network Load Balancer, or an Amazon Fargate container.
- Each Network Load Balancer that you add in a Region is a monitored resource.
- Each WorkSpaces directory that you add in a Region is a monitored resource.
- Each CloudFront distribution that you add is a monitored resource.

Autonomous System Number (ASN)

In Internet Monitor, an ASN typically refers to an internet service provider (ISP), such as Verizon or Comcast. An ASN is a network provider that a client uses to access your internet application. An Autonomous System (AS) is a set of internet routable internet protocol (IP) prefixes that belong to a network or a collection of networks that are all managed, controlled, and supervised by one organization.

City-network (location and ASN)

A city-network is the location (such as a city) that clients access your application resources from and the ASN, typically an internet service provider (ISP), that clients access the resources through. To help control your bill, you can set a limit for the maximum number of city-networks for Internet Monitor to monitor for each monitor. You pay only for the actual number of city-networks that you monitor, up to the maximum number. For more information, see Choosing a city-network maximum limit.

Internet measurements

Internet Monitor also publishes internet measurements to log files in CloudWatch Logs every five minutes for the top 500 city-networks for your monitored application traffic.

These measurements quantify the performance score, availability score, bytes transferred (bytes in and bytes out), and round-trip time for your application's city-networks. These are measurements for the city-networks specific to your VPCs, Network Load Balancers, CloudFront distributions, or WorkSpaces directories. Optionally, you can choose to publish internet measurements and events for all monitored city-networks (up to the 500,000 city-networks service limit) to an Amazon S3 bucket.

Metrics

Internet Monitor generates aggregated metrics for CloudWatch metrics, for global traffic to your application and global traffic to each Amazon Web Services Region. For more information, see View Internet Monitor metrics or set alarms in CloudWatch Metrics.

Health event

Internet Monitor creates a health event to alert you to a specific problem that affects your application. Internet Monitor detects internet issues, such as increased network latency, across the world. It then uses its historical internet measurements from across the Amazon global infrastructure footprint to calculate the impact of current issues on your application, and creates health events. Internet Monitor, by default, creates health events based on both overall impact and local impact thresholds. To learn more about health events, see When Internet Monitor creates and resolves health events.

The default health event threshold, for both performance scores and availability scores, is 95%. If you like, you can specify your own custom thresholds for when Internet Monitor creates health events. For more information about configuring thresholds, see Change health event thresholds.

Each health event includes information about the impacted city-networks. You can view health events in the CloudWatch console, or by using an Amazon SDK or Amazon CLI with Internet Monitor API actions. Internet Monitor also sends Amazon EventBridge notifications for health events. For more information, see When Internet Monitor creates and resolves health events.

Internet event

Internet Monitor displays information about recent global health events, called internet events, on an internet weather map that is available to all Amazon customers. You don't need to create a monitor in Internet Monitor to view the internet weather map. Unlike health events, internet events are not specific to individual customers or their application traffic. For more information, see Global internet weather map in Internet Monitor.

Thresholds

Internet Monitor creates health events based on both overall thresholds and local thresholds. You can change the default thresholds and configure other options, such as turning off local thresholds. For more information about configuring thresholds, see Change health event thresholds.

Performance and availability scores

By analyzing the data that Amazon collects, Internet Monitor can detect when the performance and availability for your application has dropped, compared to estimated baselines that Internet Monitor calculates. To make it easier to see those drops, Internet Monitor reports the information to you as scores. A performance score represents the estimated percentage of traffic that is **not** seeing a performance drop. Similarly, an availability score represents the estimated percentage of traffic that is **not** seeing a availability drop. For more information, see How Amazon calculates performance and availability scores.

Bytes transferred and monitored bytes transferred

Bytes transferred is the total number of bytes of ingress and egress traffic between an application in Amazon and the city-network (that is, the location and the ASN, typically the internet service provider) where clients access an application. Monitored bytes transferred is a similar metric, but includes only bytes for monitored traffic.

Round-trip time

Round-trip time (RTT) is how long it takes for a request from a client user to return a response to the user. When RTT is aggregated across client locations (cities or other geographies), the value is weighted by how much of your application traffic is driven by each client location.

How Internet Monitor works

This section provides information about how Internet Monitor works. This includes descriptions of how Amazon collects the data that it uses to help detect connectivity issues across the internet, and how performance and availability scores are calculated.

Contents

How Internet Monitor focuses on just your application traffic footprint

Internet Monitor focuses monitoring on just the subset of the internet that's accessed by the users of your Amazon resources, instead of broadly monitoring your website from every Region in the world as other tools do. It's also a cost effective solution, affordable for large and small companies.

Internet Monitor uses the same powerful probes and issue-detection algorithms that Amazon takes advantage of internally and alerts you to connectivity issues that affect your application by creating health events in Internet Monitor. Internet Monitor then gives you access to the resulting performance and availability map, by overlaying the traffic profile that it creates from your active viewers, based on your application resources.

Using this information, Internet Monitor shows you just relevant events (that is, the events from places where you have active viewers), and just the impact those events have on your overall viewer volume. So, how much impact an event has, percentage-wise, is based on your total traffic worldwide.

Internet Monitor stores internet measurements for pairs of your client locations and ASNs, or *city-networks*. Internet Monitor also creates aggregated CloudWatch metrics for traffic to your application, and to each Amazon Web Services Region and edge location.

In addition, Internet Monitor publishes internet measurements to CloudWatch Logs internet every five minutes for the top 500 city-networks that send traffic to each monitor, to support using CloudWatch tools and other methods with your data. Optionally, you can choose to publish internet measurements for all monitored city-networks (up to the 500,000 city-networks service limit) to an Amazon S3 bucket. For more information, see Publish internet measurements to Amazon S3 in Internet Monitor.

The benefits of Internet Monitor include the following:

- Using Internet Monitor doesn't place additional load or cost on your application that's hosted on Amazon.
- You don't need to include performance measurement code in your client-side resources, or in your application.
- You can get visibility into performance and availability across the internet that your application is connected to, including "last mile" information.

Note that because Internet Monitor creates measurements based on your Amazon resources, Internet Monitor only creates events that are specific to your application traffic. Global internet issues in general are not reported. In addition, when the service location is an Amazon Web Services Region, the measurements and events emitted are designed to represent connectivity at a Regional level and don't accurately represent connectivity between an end user location and an Availability Zone.

How Amazon measures connectivity issues and calculates measurements

Internet Monitor uses internet connectivity data between different Amazon Web Services Regions and Amazon CloudFront points of presence (POPs) to different client locations through Autonomous System Numbers (ASNs), typically internet service providers (ISPs). This is the connectivity data that is used internally by Amazon operators, on a daily basis, to proactively detect connectivity issues across the global internet.

For every Amazon Web Services Region, we know which portions of the internet communicate with the Region and do the following:

- We actively monitor those portions of the internet, with a rolling 30-day window.
- We use both network and higher-level protocol probes, including both inbound and outbound probing.

Amazon has active and passive probes that measure the latency (performance) at the 90th percentile and reachability (availability) from every Amazon Web Services Region and from the

CloudFront service to the entire internet. Abnormal patterns in connectivity between a service and a customer location are monitored, and then reported as alerts to the customer.

See the following sections for details:

- Calculating availability and RTT
- Calculating performance and availability scores
- Calculating TTFB and RTT (latency)
- Regional and Availability Zone measurements and aggregation

Calculating availability and RTT

Round-trip time (RTT) is how long it takes for a request from the user to return a response to the user. When round-trip time is aggregated across end user locations, the value is weighted by the amount of your traffic that is driven by each end user location.

As an example, with two end user locations, one serving 90% of traffic with a 5 ms RTT, and the other serving 10% of traffic with a 10 ms RTT, the result is an aggregated RTT of 5.5 ms (which comes from 5 ms * 0.9 + 10 ms * 0.1).

Note that there are differences for resources about measuring last-mile latency. For Internet Monitor latency measurements, VPCs, Network Load Balancers, and WorkSpaces directories do not include last-mile latency.

Calculating performance and availability scores

Amazon has substantial historical data about internet performance and availability between Amazon services and different city-networks (locations and ASNs). By applying statistical analysis to the data, Internet Monitor can detect when the performance and availability for your application has dropped, compared to an estimated baseline that it has calculated. To make it easier to see those drops, that information is reported to you in the form of health scores: a performance score and an availability score.

Health scores are calculated at different granularities. At the finest granularity, we compute the health score for a geographic region, such as a city or a metro area, and an ASN (a *city-network*). We also roll up the individual health scores to overall health score numbers for an application in a monitor. If you view performance or availability scores without filtering for any specific geography or service provider, Internet Monitor provides overall health scores.

Overall health scores span your whole application for the specified time period. When the performance or availability score for your application's city-network pairs across your application reaches or drops below the corresponding health event threshold for performance or availability Internet Monitor triggers a health event. By default, the threshold is 95% for both overall performance and availability. Internet Monitor also creates health events based on local thresholds—if the option is enabled, as it is by default—based on values that you configure. To learn more about configuring health event thresholds, see Change health event thresholds.

When you explore information in the monitor and log files to investigate issues and learn more, you can filter by specific cities (locations), networks (ASNs or internet service providers), or both. So, you can use filters to see health scores for different cities, ASNs, or city-network pairs, depending on the filters that you choose.

- An *availability score* represents the estimated percentage of traffic that is **not** seeing an availability drop. Internet Monitor estimates the percentage of traffic experiencing a drop from the total traffic seen and availability metrics measurements. For example, an availability score of 99% for an end user and service location pair is equivalent to 1% of the traffic experiencing an availability drop for that pair.
- A *performance score* represents the percentage of traffic that is **not** seeing a performance drop. For example, a performance score of 99% for an end user and service location pair is equivalent to 1% of the traffic experiencing a performance drop for that pair.

Calculating TTFB and RTT (latency)

Time to first byte (TTFB) refers to the time between when a client makes a request and when it receives the first byte of information from the server. Amazon calculations for TTFB measure the time elapsed from Amazon EC2 or Amazon CloudFront to the Internet Monitor measurement node (including the last mile of the node). That is, Internet Monitor measures time from the user to the Amazon EC2 Region for TTFB for EC2, and from the user to CloudFront for TTFB for CloudFront.

For round-trip time (RTT), Internet Monitor includes the time from the city-network (that is, the client location and ASN, typically an internet service provider), as mapped by the public IP address, to the Amazon Web Services Region. This means that Internet Monitor does not have last mile visibility for users who access the internet from behind a gateway or VPN.

Note that there are differences for resources about measuring last-mile latency. For Internet Monitor latency measurements, VPCs, Network Load Balancers, and WorkSpaces directories do not include last-mile latency.

Internet Monitor includes average TTFB information in the **Traffic optimization suggestions** section of the **Traffic insights** tab on the CloudWatch dashboard, to help you evaluate options for different setups for your application that can improve performance.

Regional and Availability Zone measurements and aggregation

Although Internet Monitor aggregates measurements and shares impact at a Regional level, it calculates impact at an Availability Zone (AZ) level. This means that, if, for an event, only one AZ is impacted and most of your traffic flows through that AZ, you do see impact for your traffic. However, for the same event, if your application traffic does not flow through an impacted AZ, you do not see impact.

Note that this applies only to resources that aren't WorkSpaces directories. WorkSpaces directories are measured only on a Regional level.

Geolocation accuracy in Internet Monitor

For location information, Internet Monitor uses IP-geolocation data supplied by MaxMind. The accuracy of the location information in Internet Monitor measurements depends on the accuracy of MaxMind's data.

Be aware that `Metro` level measurements might not be accurate for locations outside of the United States.

When Internet Monitor creates and resolves health events

Internet Monitor creates and closes health events for the application traffic that you monitor based on the current thresholds that are set. Internet Monitor has a default threshold configuration, and you can also set your own configuration for thresholds. Internet Monitor determines the overall impact that connectivity issues are having on your application, and the impact on local areas where your application has clients, and creates health events when the thresholds are crossed.

Internet Monitor calculates the impact of connectivity issues on a client location based on the historical data about internet performance and availability for network traffic that's available to the service through Amazon. It applies the information relevant to your application, based on the geographic locations for ASNs and services where clients use your application: the city-network pairs that are affected. The locations are determined from the resources that you add to your monitor. Then Internet Monitor uses statistical analysis to detect when performance and availability has dropped, affecting the client experience for your application.

The performance and availability scores that Internet Monitor calculates are represented as the percentage of traffic that is **not** seeing a drop. Impact is the opposite of this: it's a representation of how much an issue is problematic for a customer's end users. So if there is a global availability drop of 93%, for example, the corresponding impact would be 7%.

When the performance or availability score for your application's city-network pairs globally reaches or drops below the corresponding health event threshold for performance or availability, this triggers Internet Monitor to generate a health event. By default, the threshold is 95% for both performance and availability. The values to meet, or drop below, the threshold are cumulative, so it could mean several smaller events combine to meet the threshold percentage, or that a single event meets or falls below the threshold level.

As long as performance or availability scores that triggered the event are at or below the corresponding health event threshold percentage for overall impact, the health event stays active. When the score or combined scores that triggered the event rise above the threshold, Internet Monitor resolves the health event.

Internet Monitor also creates health events based on local thresholds and the percentage of overall traffic that an issue has an impact on. You can configure options for local thresholds, or turn off local thresholds altogether.

The default health event threshold, for both performance scores and availability scores, is 95%. If you like, you can specify your own custom thresholds for when Internet Monitor creates health events. For more information about configuring thresholds, see [Change health event thresholds](#).

Health event report timing

Internet Monitor uses an aggregator to gather all signals about internet issues, to create health events in monitors within minutes.

When possible, Internet Monitor analyzes the origin of a health event, to determine whether it was caused by Amazon or an ASN. Health event analysis continues after an event is resolved. Internet Monitor can update events with new information for up to an hour.

How Internet Monitor works with IPv4 and IPv6 traffic

Internet Monitor measures health toward a network over only IPv4, and shows you health events, and availability and performance metrics, if you serve traffic to that network over any IP family (IPv4 or IPv6). If you serve traffic from a dual-stack resource, such as a dual-stack CloudFront distribution, Internet Monitor raises a health event and shows a drop in a performance score or availability score only if IPv4 traffic has the same issues for the resource as IPv6 traffic does.

Note that the Internet Monitor metrics for overall bytes in and bytes out accurately reflect all internet traffic (IPv4 and IPv6).

How Internet Monitor selects the subset of city-networks to include

When you set a maximum limit for the number of city-networks monitored by your monitor or choose a percentage of traffic to monitor, Internet Monitor chooses the city-networks to include (monitor) based on highest recent traffic volume.

For example, if you set a maximum city-networks limit of 100, Internet Monitor monitors (up to) 100 city-networks based on your application traffic during a recent one hour period. Specifically, Internet Monitor monitors the top 100 city-networks that have had the most traffic in the most recent one hour window *before* the latest one hour window.

To illustrate this, say that the current time is 2:30 PM. In this scenario, the traffic that you see in your monitor was captured between 1:00 PM and 2:00 PM, and the traffic volume measurement that Internet Monitor uses to determine the top 100 city-networks was captured between 12:00 PM and 1:00 PM.

How the global internet weather map is created (Frequently Asked Questions)

The Internet Monitor internet weather map is available on the Internet Monitor console to all authenticated Amazon customers. This section includes details about how the internet weather map is created and how to use it.

What is the Internet Monitor internet weather map?

The internet weather map provides a visual representation of internet issues across the world. It highlights impacted client locations, that is, cities plus ASN (typically internet service providers). The map shows a combination of availability and performance issues that have recently impacted clients' internet experience for top client locations and Amazon services globally.

Where does data for the map come from?

The data is based on a combination of active and passive probing of the internet. To learn more about how Internet Monitor measures data you can read the section [How Amazon measures connectivity issues](#).

How often is the map updated?

The internet weather map is updated every 15 minutes.

Which networks are tracked for outages?

Amazon tracks networks all around the world that represent important IP prefixes used by customers for making internet connections to Amazon. We scope outages to client locations that are top talkers for volume of traffic sent to and received from the Amazon network.

What determines whether an internet event is included on the map?

Here are some high level criteria that we use to determine whether an internet event is included on the internet weather map:

- Amazon detects that there is an availability or performance event.
- If the event is short lived, for example, it lasts less than 5 minutes, we ignore it.
- Then, if the event is in a client location that is classified as a top talker, it's considered an outage.

What thresholds are used for the internet weather map?

Thresholds for determining outages are not static for the internet weather map. Internet Monitor determines what constitutes an event based on detecting a deviation from expected values. You can learn more about how this works by reviewing how Internet Monitor determines when to create health events for monitors that you create with the service. When you create a monitor, Internet Monitor generates internet traffic health measurements that are specific to your own application traffic. Internet Monitor also alerts you to health events for issues that affect your application's internet traffic.

What can I do with this data?

The internet weather map provides a quick summary of key internet events that happened around the world in the last 24 hours. It helps you to get a sense of the internet monitoring experience, without needing to onboard your own internet traffic to Internet Monitor. To leverage the full potential of the internet monitoring capabilities of Amazon and to personalize it for your applications and services hosted on Amazon, you can create a monitor in Internet Monitor.

When you create a monitor, you enable Internet Monitor to identify the specific internet paths that affect your application clients, and you get access to features and capabilities that can help you improve your client experience. You'll also be proactively notified of new internet issues that specifically impact your application traffic and clients.

How can I get more details about events?

Click an outage on the map to see details that include when an event started and ended, the impacted city and ASN, and what type of issue it was (that is, a performance issue or an availability issue).

To get more detailed information about events, and to get custom measurements for your application traffic, create a monitor in Internet Monitor.

Internet Monitor example use cases

This section describes several specific examples of use cases for Internet Monitor, with links to blog posts with more details. These examples illustrate how you can use the capabilities of Internet Monitor to monitor your application health and improve latency to enhance your users' experience.

Set up alerts and decide on actions to take

You can use Internet Monitor to get insights about average internet performance metrics over time, and about health events by city-network (client location and ASN, typically an internet service provider). Using Internet Monitor, you can identify the events that are impacting end user experience for applications hosted on Amazon Virtual Private Clouds (VPCs), Network Load Balancers, Amazon WorkSpaces, or Amazon CloudFront.

After you create a monitor, you have several options for how to be alerted about Internet Monitor health events. These include notifications based on CloudWatch Alarms using event metrics or Amazon EventBridge rules to filter for health events. You can choose different options for notifications or actions based on alarms, including, for example, Amazon SMS notifications or updates to a CloudWatch log group.

To see an example with detailed guidance, see the following blog post: Introducing Internet Monitor.

Identify latency issues and improve TTFB to improve multiplayer gameplay experience

Use Internet Monitor to help you to quickly identify where game players in global cloud gaming apps are experiencing latency issues globally, and provide insights into improving performance. By identifying where the most players currently have the slowest time to first byte (TTFB), you know how to improve latency to make your biggest player base happier.

Now, when you're ready to deploy the next EC2 server for your game, choose the Amazon Web Services Region that Internet Monitor suggests will lower TTFB in the area with the high latency and large group of players.

For details about setting up and using Internet Monitor for this use case, see the following blog post: Using Internet Monitor for a Better Gaming Experience.

Identify potential performance and internet connection issues for users on Amazon WorkSpaces

Internet Monitor provides you with the IP prefixes and ASN (typically, the internet service provider or ISP) for your users, which can be helpful to diagnose performance and internet connection issues for users to their WorkSpaces. You can also use this data to view your fleet as a whole and monitor your WorkSpaces user connections.

For more information about how to use Internet Monitor for this use case, see the following blog post: Using Internet Monitor with Amazon WorkSpaces Personal.

Global internet weather map in Internet Monitor

Internet Monitor displays a global internet weather map that is available to all Amazon customers. To view the map, in the Amazon CloudWatch console, navigate to **Network Monitoring**, and then choose **Internet monitors**.

The internet weather map highlights internet events ("outages") all over the world that affect Amazon customers, with the specific cities and networks (ASNs, typically internet service providers) where there are issues with performance or availability. The map includes internet events from the past 24 hours.

You don't need to create a monitor in Internet Monitor to view the internet weather map. Unlike health events in Internet Monitor, internet events are not specific to individual customers or their application traffic.

On the internet weather map, you can choose an internet event to learn details about it. For an internet event, you can see the start time, end time (if the event is over), the current status (Active or Resolved), and the outage issue type (Availability or Performance). To learn more about how the internet weather map is created and what is included, see the global internet weather map FAQ.

To view and work with detailed information that is specific to your application traffic and client locations, you can create a monitor in Internet Monitor for your application. Then, you'll see performance and availability patterns and events, current and historical, as well as get health event alerts, tailored to just your application footprint and customers. The internet weather map gives you an overall view, while a specific monitor filters the information to just the measurements and details that are relevant to your application. With a monitor, you can also explore historical metrics and get recommendations for improving client experience for your application. To learn more, see Getting started with Internet Monitor using the console.

Internet Monitor cross-account observability

With Internet Monitor cross-account observability, you can monitor your applications that span multiple Amazon accounts within a single Amazon Web Services Region.

You can use Amazon CloudWatch Observability Access Manager to set up one or more of your Amazon accounts as a monitoring account. You'll provide the monitoring account with the ability to view data in your source account by creating a *sink* in your monitoring account. A sink is a resource that represents an attachment point in a monitoring account. For Internet Monitor, the resource attachment point is a monitor. You use the sink to create a link from your source account to your monitoring account. For more information, see CloudWatch cross-account observability.

Required resources

For proper functionality of CloudWatch Application Insights cross-account observability, ensure that the following telemetry types are shared through the CloudWatch Observability Access Manager.

- Monitors in Internet Monitor
- Metrics in Amazon CloudWatch
- Log groups in Amazon CloudWatch Logs

Pricing for Internet Monitor

With Internet Monitor, there are no upfront costs or long-term commitments. Pricing for Internet Monitor has two components: a per monitored resource fee and a per city-network fee. A *city-network* is the location where clients access your application resources from and the network (ASN, such as an internet service provider or ISP) that clients access the resources through. Note that you are also charged standard CloudWatch prices for logs and any additional metrics, dashboards, alarms, or insights that you create.

You choose a percentage of traffic to monitor when you create a monitor. To help control your bill, you can also set a limit for the maximum number of city-networks to monitor. You can update the percentage of traffic to monitor or the maximum city-networks limit at any time by editing your monitor. The first 100 city-networks (across all monitors per account) are included. After that, you only pay for the actual additional number of city-networks that you monitor, up to the maximum number.

You pay only the actual additional number of city-networks that you monitor, up to the maximum number, with no charge for the first 100 city-networks (across all monitors per account). A flat amount equivalent to the cost of 100 city-networks is deducted from your monthly bill.

For example, a large global company could choose to monitor 100% of its internet-facing traffic, and set a city-networks maximum of 50,000, for one monitor with one resource. Assuming the traffic reached 50,000 city-networks, that portion of its bill would be around 2,700 USD/month. For another company, in fewer geographic areas, with one monitor with one resource and 200 city-networks, this portion of the bill would be around 13 USD/month. For more information, see Choose a city-networks maximum limit.

You can try out different options with the pricing calculator. To explore pricing options, on the Pricing calculator for CloudWatch page, scroll down to Internet Monitor.

For more information about Internet Monitor and CloudWatch pricing, see the Amazon CloudWatch pricing page.

Getting started with Internet Monitor using the console

To help you get started with Internet Monitor, this chapter provides the steps for creating and configuring a *monitor*. You create a monitor in Internet Monitor for your application by naming it, and then adding Amazon resources that your application uses.

You create a monitor in Internet Monitor for your application by adding Amazon resources that it uses, and then setting several configuration options. The resources that you add, Amazon Virtual Private Cloud VPCs, Network Load Balancers (NLBs), CloudFront distributions, or WorkSpaces directories, provide the information for Internet Monitor to map internet traffic information for your application. After you create your monitor, wait 15-30 minutes to generate the traffic profile specific to where your application is used.

Then, use the Internet Monitor dashboard, or other tools, to visualize and explore performance and availability about your client usage. These tools provide insights for you using your application traffic's measurements gathered for you by the monitor.

The steps here walk you through setting up your monitor by using the console. To see examples of using the Amazon Command Line Interface with the Internet Monitor API actions, to create a monitor, view events, and so on, see Examples of using the CLI with Internet Monitor.

Tasks

Step 1: Create a monitor

To create a monitor using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose **Create monitor**.
4. For **Monitor name**, enter the name you want to use for this monitor in Internet Monitor.
5. Choose **Add resources**, and then select the resources to set the monitoring boundaries for Internet Monitor to use for this monitor.

   > **Note**
   >
   > Be aware of the following:
   >
   > - To generate meaningful output with Internet Monitor, VPCs that you add must be connected to the internet by having an Internet Gateway configured.
   > - You can add only one type of resource to a single monitor. For example, VPCs or CloudFront distributions or WorkSpaces directories, but not a combination of different types.

6. Leave the default percentage of traffic as 100%, or choose another percentage of your internet traffic to monitor.
7. Choose **Create monitor**.

Step 2: Configure the monitor

After you create a monitor, you can edit the monitor at any time, for example, to change the application traffic percentage, update the maximum city-networks limit or add or remove resources. To make updates in the Internet Monitor console, follow the procedure in this section. Note that you can't change the name of a monitor.

For more information about configuring a monitor, see Edit a monitor in Internet Monitor.

To configure a monitor using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Update monitor**.
5. Make the desired updates. For example, to change the percentage of traffic to monitor, under **Application traffic to monitor**, select or enter a percentage.
6. Choose **Update**.

Step 3: View metrics and explore history

Visualize data about your internet traffic, from an overview perspective or by drilling down into details.

To visualize data and get insights for application traffic using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose a monitor to work with.
4. Choose from the following tabs:

   - **Overview** — Review a general summary of your monitor and your application traffic performance.
   - **Health events** — View current and historical health events that currently impact, or previously impacted, locations where clients access your application.

- **Analyze** — See information about top monitored traffic in client locations (by traffic volume), summarized in several customizable ways. Visualize metrics and historical trends for health scores and metrics.

In the next section, learn about how Internet Monitor provides suggestions for improving latency for your application traffic.

Step 4: Get suggestions to improve latency

Get suggestions for how to optimize latency, so that your clients experience the best internet performance for your application.

Internet Monitor evaluates your monitored application traffic, and then makes suggestion about whether you can reduce latency, for example, by changing the Amazon Web Services Regions that you've configured for your application.

For more information, see Get suggestions to optimize application performance in Internet Monitor (Optimize page).

To get suggestions for improving application latency using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose a monitor to work with.
4. Choose **Optimize**, and then view the top suggestions.

Step 5 (Optional): Delete the monitor

If you created a monitor as a test or if you're no longer using a monitor, you can delete it. Before you can delete a monitor, you must disable it.

To delete a monitor

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Disable**.

5. Choose the **Action** menu again, and then choose **Delete**.
6. Follow the guidance in the modal dialog to confirm deleting the monitor.

Configure a monitor using the console

This chapter includes procedures and recommendations for creating and configuring monitors in Internet Monitor.

The steps provided in these sections primarily use the Amazon Web Services Management Console. You can also use Internet Monitor API operations with the Amazon Command Line Interface (Amazon CLI) or Amazon SDKs to create and configure a monitor. For detailed information about working with Internet Monitor API operations, see the following resources:

- If you plan to work with Internet Monitor with the CLI, see Examples of using the CLI with Internet Monitor.
- For detailed information about working with Internet Monitor API operations, see the Internet Monitor API Reference.

Contents

Create a monitor in Internet Monitor using the console

You create a monitor in Internet Monitor to visualize and explore performance and availability data about your application's client traffic. You create a monitor by adding Amazon resources that your application uses, and then setting several configuration options. The resources that you add to the monitor provide the information — for example, through resource flow logs — for Internet Monitor to learn which internet traffic is specific to your Amazon application.

After you create your monitor, wait 15 to 30 minutes before reviewing the monitor dashboard. Internet Monitor needs a few minutes to generate a traffic profile for where your application is used by your end users, and then to begin publishing data for your traffic.

Typically, it's simplest to create one monitor in Internet Monitor for one application. Within the same monitor, you can search through and sort measurements and metrics by different locations and ASNs, or other information. You don't need to create separate monitors for applications in different areas.

The steps provided here walk you through setting up your monitor by using the console. To work with Internet Monitor API actions using the Amazon Command Line Interface, see Examples of using the CLI with Internet Monitor.

To create a monitor using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose **Create monitor**.
4. For **Monitor name**, enter the name that you want to use for this monitor.
5. Choose **Add resources**, and then select the resources that will determine the internet traffic profile for this monitor.

   > **Note**
   >
   > Be aware of the following:
   >
   > - To generate meaningful output with Internet Monitor, VPCs that you add must be connected to the internet by having an Internet Gateway configured.
   > - You can specify only one type of resource for each monitor.

6. Choose a percentage of your application's internet traffic to monitor.
7. Optionally, under **Advanced settings**, specify one or more of the following additional options.

   - **City-networks maximum** — The default city-networks maximum value is `500000`. If you like, you can lower this limit, to restrict the number of city-networks (locations and ASNs) that Internet Monitor will monitor traffic for. You can change the city-networks maximum at any time by editing your monitor. For more information, see Choose a city-networks maximum limit.

- **Amazon S3 bucket storage** — You can specify an Amazon S3 bucket name and custom prefix to publish internet measurements for your application's internet traffic to Amazon S3, for all monitored city-networks.

  Internet Monitor stores internet measurements for pairs of your client locations and ASNs, or *city-networks*. Internet Monitor also creates aggregated CloudWatch metrics for traffic to your application, and to each Amazon Web Services Region and edge location. In addition, Internet Monitor publishes internet measurements for your application traffic to CloudWatch Logs every five minutes, to support using CloudWatch tools and other methods with your data. If you choose to publish measurements to S3, measurements are still published to CloudWatch Logs. For more information, see Publish internet measurements to Amazon S3 in Internet Monitor.
- **Tags** — Add one or more tags for your monitor.

8. Choose **Create monitor**.

After you create a monitor, wait about 15-30 minutes for Internet Monitor to create a traffic profile and begin publishing your data. Then, you can view information about your application's internet traffic performance by navigating to the monitor dashboard in the console.

To view the Internet Monitor dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Network Monitoring**, then **Internet monitors**.
3. To see more information about a specific monitor, on the **Monitors** tab, choose a monitor.

Add resources to your monitor

When you create a monitor, you must associate your application's resources with it: Amazon Virtual Private Clouds (VPCs), Network Load Balancers, Amazon CloudFront distributions, Network Load Balancers (NLBs), or Amazon WorkSpaces directories. Then, Internet Monitor knows where your application's internet-facing traffic and clients are located, and it can create and maintain a traffic profile that determines the relevant measurements to publish for your monitor.

You can add the following types of resources to a monitor in Internet Monitor as *monitored resources*.

- **VPCs:** Each VPC that you add in a Region is a monitored resource. When you add a VPC, Internet Monitor monitors the traffic for any internet-facing application in the VPC, for example, an application hosted on an Amazon EC2 instance, behind a Network Load Balancer, or in an Amazon Fargate container.
- **Network Load Balancers:** Each NLB that you add is a monitored resource.
- **CloudFront distributions:** Each CloudFront distribution that you add is a monitored resource.
- **WorkSpaces directories:** Each WorkSpaces directory that you add in a Region is a monitored resource.

When you monitor traffic for VPCs, traffic for applications that are hosted on load balancers behind the VPC is monitored. You can choose to monitor traffic for individual Network Load Balancer load balancers instead of monitoring a VPC with multiple load balancers. This can be helpful, for example, if you need to understand and configure features for better performance or efficiencies at the load balancer level. Or, you might need compliance information at the Network Load Balancer level.

When you add resources to a monitor in Internet Monitor, be aware of the following:

- Internet Monitor doesn't support adding different types of resources together in one monitor.
- To generate meaningful output with Internet Monitor, VPCs that you add must be connected to the internet by having an Internet Gateway configured.
- Internet Monitor doesn't support adding different types of resources together in one monitor.
- There are Regional differences for opt-in Regions to keep in mind when you add VPCs or NLBs as resources. For more information, see [Supported Amazon Web Services Regions for Internet Monitor](#).
- In addition, there are differences for resources about measuring last-mile latency. For Internet Monitor latency measurements, VPCs, NLBs, and WorkSpaces directories do not include last-mile latency.

Choose a percentage of traffic to monitor for your application

The coverage that you choose for the percentage of application traffic to monitor determines how many city-networks (client locations and ASNs, typically internet service providers) for your application are monitored, up to an optional city-networks maximum limit that you can also set.

You can choose the percentage of traffic to monitor when you create a monitor, or, with an existing monitor, by choosing **Edit monitor** on any Internet Monitor dashboard page in the console.

If you choose to monitor less than 100% of your application traffic, you might have an observability gap in with your monitor. That's because if there are health events that Internet Monitor creates where you aren't monitoring traffic, you won't be aware of those issues. With a traffic percentage set to less than 100%, you might also have less coverage for the performance and availability score information about client access to your application.

The following sections describe options to explore traffic percentage settings and coverage, and to get an idea about the impact of increasing or decreasing coverage.

- Explore changing your application traffic percentage
- View the number of city-networks monitored at different traffic percentage settings

Explore changing your application traffic percentage

You can explore values that you might want to change your application traffic percentage to, by viewing the number of city-networks monitored when you change the percentage. The procedure in this section provides step-by-step information.

In the Internet Monitor console, you can try increasing or decreasing the application traffic percentage for your monitor, and view the estimated number of your city-networks that would be covered as a result. With this option, you can quickly see how changing your traffic percentage affects the number of city-monitors are monitored. This can help you to get a feel for what a good application traffic percentage to choose might be, for your application.

To explore monitoring coverage and update percentage of traffic monitored

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. In your list of monitors, choose a monitor.
4. On the **Configure** tab, in the **View and evaluate traffic coverage** section, you can evaluate the impact on the total number of city-networks that are monitored, depending on a traffic percentage that you choose. You can also update the percentage of traffic that you monitor or change the city-networks limit for your monitor.

    - **Explore traffic percentage options:** Under **Compare options for traffic coverage**, in the drop-down menu, choose one or more traffic percentages to graph and compare. For each traffic percentage that you choose, you can see the number of city-networks that will be monitored when you set that traffic percentage coverage.

To learn more, see View number of city-networks monitored at different percentages.

- **Change monitoring coverage:** Under **Explore other traffic coverage options**, choose **Update monitoring coverage**.

  In the **Explore and set traffic monitoring coverage** dialog, click the arrows to increase or decrease the percentage of traffic to monitor. By choosing 100% traffic, you can see how many city-networks are monitored with full coverage for monitoring your application.

  Note: To learn more about how the number of city-networks monitored (estimated here) might affect your costs, choose the link to the CloudWatch Pricing calculator, and then scroll down to Internet Monitor.

  To set a new percentage of traffic to monitor, choose **Update monitor coverage**. Or, to keep the current coverage level, choose **Cancel**.

View the number of city-networks monitored at different traffic percentage settings

You can view the number of city-networks that would be monitored for your application at different application traffic percentages. The procedure in this section provides step-by-step information.

In the Internet Monitor console, you can view graphs that show how coverage for your city-networks would change at different of application traffic percentages, over a time interval that you specify. This is a quick way to visualize and compare the monitoring coverage for your application at specific traffic percentages, all on one graph.

To view graphs of application traffic percentage and corresponding city-networks coverage

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. In your list of monitors, choose a monitor.
4. Choose the **Configure** page, and scroll down to **Traffic coverage**.
5. Under **Compare options for traffic coverage**, in the drop-down list, select one or more percentages. You can choose one or more application traffic percentages, and the graph of **Total monitored city-networks** is updated to display the monitoring coverage Internet

Monitor provides for that traffic percentage. By choosing **City-networks at 100% traffic**, you can see how many city-networks are monitored with full coverage for monitoring your application.

Keep in mind the following:

- Traffic coverage is computed based on the number of city-networks in the previous hour of your application traffic. This means that, after you choose a specific percentage of traffic to monitor, fewer city-networks might be monitored for your application than is shown here in a traffic coverage comparison graph.
- To make sure that all your application traffic is monitored, set `TrafficPercentageToMonitor` to 100 and don't set `MaxCityNetworksToMonitor`. Alternatively, you can set `MaxCityNetworksToMonitor` to 500,000, the upper limit in Internet Monitor.
- If you set a city-networks maximum limit, the total number of monitored city-networks never exceeds that limit, regardless of the application traffic percentage option that you select.
- You can learn more about how the number of city-networks monitored might affect your costs. On the Pricing calculator for CloudWatch page, scroll down to Internet Monitor.

To set a new percentage of traffic to monitor, under **Explore other traffic coverage options**, choose **Update monitoring coverage**. In the dialog, choose a percentage of traffic, and then choose **Update monitor coverage**.

Use a monitor in Internet Monitor

There are several ways to use an Internet Monitor monitor after you create it: for example, you can view information in the CloudWatch dashboard, get information by using the Amazon Command Line Interface, and set health alerts.

Your monitor provides information about your application and configuration preferences so that Internet Monitor can customize measurements and metrics to publish in events for you. Internet Monitor collects measurements from the global infrastructure footprint for Amazon. These measurements are a tremendous amount of network performance and availability information, from all over the world. By using information from the resources that you add for your application, Internet Monitor publishes performance and availability measurements for you that is scoped to the city-networks (that is, client locations and ASNs, typically internet service providers or ISPs) where your application is active. So, the measurements and metrics in the Internet Monitor dashboard and in CloudWatch Logs —about availability, performance, monitored bytes transferred, and round-trip time—are specific to your client locations and ASNs.

Internet Monitor also determines when there are anomalies in performance and availability. By default, Internet Monitor overlays your traffic with the availability and performance measurements that Amazon has collected for each source-destination pair in your client locations, to determine when there are notable drops in performance or availability. When there's significant degradation for your application's locations and scope, Internet Monitor generates a *health event*, and publishes information about the issue to your monitor.

After you create a monitor, you can use it to access or be alerted to the information that Internet Monitor provides, in the following ways:

- **Use the CloudWatch dashboard** to view and explore performance, availability, and health events; explore your application's historical data; and get insights into new ways to configure your application for better performance. To learn more, see the following:
  - Track real-time performance and availability in Internet Monitor (Overview page)
  - Analyze historical data in Internet Monitor (Analyze page)
  - Get suggestions to optimize application performance in Internet Monitor (Optimize page)
- **Configure health event thresholds** to change what triggers Internet Monitor to create a health event for your application. You can configure overall thresholds and local (city-network) thresholds. To learn more, see Change health event thresholds.
- **Use Amazon CLI commands** with Internet Monitor API actions to view traffic profile information, view measurements, list health events, and so on. To learn more, see Examples of using the CLI with Internet Monitor.
- **Use standard CloudWatch tools,** such as CloudWatch Contributor Insights, CloudWatch Metrics explorer, and CloudWatch Logs Insights to visualize the data in CloudWatch. To learn more, see Exploring your data with CloudWatch tools and the Internet Monitor query interface.
- **Use Athena with S3 logs** to access and analyze Internet Monitor internet measurements for your application, if you turned on publishing measurements to S3.
- **Create Amazon EventBridge notifications** to alert you when Internet Monitor determines there is a health event. To learn more, see Using Internet Monitor with Amazon EventBridge.
- **Receive an Amazon Health Dashboard notification** automatically, when Internet Monitor determines that an issue is caused by the Amazon network. The notification includes the steps that Amazon is taking to mitigate the problem.

Edit a monitor in Internet Monitor

Using the **Action** menu, you can edit a monitor in Amazon CloudWatch Internet Monitor after you create it. For example, you can edit a monitor to do the following:

- Change the percentage of application traffic to monitor
- Set or update the city-networks maximum limit
- Change health event thresholds for availability or performance scores
- Add or remove resources
- Enable or update publishing events to Amazon S3

Note that you can't change the name of a monitor after you create it.

To make changes to a monitor, use the following procedure.

To edit a monitor

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Update monitor**.
5. Make the desired updates. For example, to change the percentage of traffic to monitor, under **Application traffic to monitor**, select or enter a percentage.
6. Choose **Update**.

For more information about the options that you can update, see the following:

- To learn more about resources that you add in Internet Monitor, see Add resources to your monitor.
- To learn more about the application traffic percentage, see Choose a percentage of traffic to monitor for your application.
- To learn more about changing the threshold for health events, see Change health event thresholds.
- To learn more about the city-networks maximum limit, see Choose a city-networks maximum limit.

- To learn more about opting to publish events to S3, see Publish internet measurements to Amazon S3 in Internet Monitor.

Delete a monitor in Internet Monitor

Using the **Action** menu, you can delete a monitor in Amazon CloudWatch Internet Monitor. You first disable the monitor, and then delete it.

To delete a monitor

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network monitoring**, choose **Internet Monitor**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Disable**.
5. Choose the **Action** menu again, and then choose **Delete**.

Advanced configuration options for a monitor

This section provides the steps for configuring advanced options for a monitor in Internet Monitor. These configuration options are optional but can be useful in some scenarios.

For example, you might choose to set a city-network maximum limit if traffic for the application that you monitor with Internet Monitor occasionally spikes, and you want to help make sure that your bill for Internet Monitor is predictable.

Or, you might want to set custom or local thresholds for health events, because you want to pay close attention to issues in specific geographies where you have a concentration of clients.

The topics in this section provide detailed descriptions of each feature, and list the steps to configure options for your needs.

Contents

Choose a city-networks maximum limit

In addition to setting a traffic percentage for your monitor in Internet Monitor, you can also set a maximum limit for the number of city-networks monitored. This section describes how the city-networks limit can help you manage billing costs, and provides information and an example to help you determine a limit to set, if you choose to set one.

Internet Monitor can monitor traffic for some or all of the locations where clients access your Amazon application resources. You can set a monitoring limit for the number of *city-networks*, that is, the client locations and the ASNs (typically internet service providers) that clients access your application through.

You choose a percentage of application traffic to monitor when you create your monitor. The default percentage is 100%. You can update the percentage at any time, by editing the monitor.

The maximum limit that you set for the number of city-networks helps to make sure that your bill is predictable. For more information, see Amazon CloudWatch Pricing. You can also learn how different values for the number of city-networks actually monitored can affect your bill by using the CloudWatch price calculator. To explore options, on the Pricing calculator for CloudWatch page, scroll down to Internet Monitor.

To update your monitor and change the maximum city-networks limit, see Edit a monitor in Internet Monitor.

How billing works with city-networks maximum limits

Setting a maximum limit for the number of city-networks monitored can help prevent unexpected costs in your bill. This is useful, for example, if your traffic patterns vary widely. Billing costs increase for each city-network that is monitored after the first 100 city-networks, which are included (across all monitors per account). If you set a city-networks maximum limit, it caps the number of city-networks that Internet Monitor monitors for your application, regardless of the percentage of traffic that you choose to monitor.

You only pay for the number of city-networks that are actually monitored. The city-network maximum limit that you choose lets you set a cap on the total that can be included when Internet Monitor monitors traffic with your monitor. You can change the maximum limit at any time by editing your monitor.

To explore options, on the Pricing calculator for CloudWatch page, scroll down to Internet Monitor. For more information on Internet Monitor pricing, see the Internet Monitor section on the Amazon CloudWatch Pricing page.

How to choose a city-networks maximum limit

Optionally, you can set a city-networks maximum limit. To help you decide on a maximum limit that you might want to select, consider how much traffic you want to monitor for your application. Be aware that if you choose 100% for the *traffic percentage to monitor* for your monitor, and then specify a city-networks maximum limit, depending on the limit that you choose, you might not monitor 100% of your application traffic. The city-networks maximum that you set takes precedence over the traffic percentage to monitor that you set.

To view how the percentage of traffic to monitor that you choose affects the number of city-monitors that are included for your application monitoring, which can help you decide whether to set a city-networks maximum limit, follow the steps in [View the number of city-networks monitored at different traffic percentage settings](#).

To explore your options in more detail, you can use Internet Monitor metrics, as described in the following examples. These examples show how to select a maximum city-networks limit that is best for you, depending on the breadth of application internet traffic coverage you want. Using the [queries for Internet Monitor metrics in CloudWatch Metrics](#) can help you understand more about your application internet traffic coverage.

Example of determining a city-networks maximum limit

As an example, say that you've set a monitoring maximum limit of 100 city-networks and that your application is accessed by clients across 2637 city-networks. In CloudWatch Metrics, you'd see the following Internet Monitor metrics returned:

```
CityNetworksMonitored 100
TrafficMonitoredPercent  12.5
CityNetworksFor90PercentTraffic  2143
CityNetworksFor100PercentTraffic  2637
```

From this example, you can see that you're currently monitoring 12.5% of your internet traffic, with the maximum limit set to 100 city-networks. If you want to monitor 90% of your traffic, the next metric provides information about that: `CityNetworksFor90PercentTraffic` indicates that you would need to monitor 2,143 city-networks for 90% coverage. To do that, you would update your monitor and set the maximum city-networks limit to 2,143.

Similarly, say you'd like to have 100% internet traffic monitoring for your application. The next metric, `CityNetworksFor100PercentTraffic`, indicates that to do this, you should update your monitor to set the maximum city-networks limit to 2,637.

If you now set the maximum to 5,000 city-networks, since that's greater than 2,637, you see the following metrics returned:

```
CityNetworksMonitored 2637
TrafficMonitoredPercent  100
CityNetworksFor90PercentTraffic  2143
CityNetworksFor100PercentTraffic  2637
```

From these metrics, you can see that with the higher limit, you monitor all 2,637 city-networks, which is 100% of your internet traffic.

Change health event thresholds for a monitor

Internet Monitor uses a default threshold to determine when to create a health event for your monitor. Optionally, you can change that default global threshold, to set another value. You can also set local threshold. This section describes how global and local thresholds work together, and provides steps for setting custom thresholds.

You can change the overall threshold that triggers Internet Monitor to create a health event. The default health event threshold, for both performance scores and availability scores, is 95%. That is, when the overall performance or availability score for your application falls to 95% or below, Internet Monitor creates a health event. For the overall threshold, the health event can be triggered by a single large issue, or by the combination of multiple smaller issues.

You can also change the local—that is, city-network—threshold, combined with a percentage of the overall level of impact, that—in combination—will trigger a health event. By setting a threshold that creates a health event when a score drops below the threshold for one or more city-networks (locations and ASNs, typically ISPs), you can get insights into when there are issues in locations with lower traffic, for example.

An additional local threshold option works together with the local threshold for availability or performance scores. The second factor is the percentage of your overall traffic that must be impacted before Internet Monitor creates a health event based on the local threshold.

By configuring the threshold options for overall traffic and local traffic, you can fine-tune how frequently health events are created, to align with your application usage and your needs. Be aware that when you set the local threshold to be lower, typically more health events are created, depending on your application and the other threshold configuration values that you set.

In summary, you can configure health event thresholds—for performance scores, availability scores, or both—in the following ways:

- Choose different global thresholds for triggering a health event.
- Choose different local thresholds for triggering a health event. With this option, you can also change the percentage of impact on your overall application that must be exceeded before Internet Monitor creates an event.
- Choose to turn off triggering a health event based on local thresholds, or enable local threshold options.

To update health event thresholds for performance scores, availability scores, or both, follow these steps.

To change threshold configuration options

1. In the Amazon Web Services Management Console, navigate to CloudWatch, and then, in the left navigation pane, choose Internet Monitor.
2. On the **Configure** page, in the **Health event thresholds** section, choose **Update thresholds**.
3. On the **Set health event threshold**page, choose the new values and options that you want for thresholds and other options that trigger Internet Monitor to create a health event. You can do any of the following:
   - Choose a new value for **Availability score threshold**, **Performance score threshold**, or both.

     The graphs in the sections for each setting display the current threshold setting and the actual recent health event scores, for availability or performance, for your application. By viewing the typical values, you can get an idea of values that you might want to change a threshold to.

     Tip: To view a larger graph and change the timeframe, choose the expander in the upper right corner of the graph.
   - Choose to turn on or off a local threshold for availability or performance, or both. When an option is enabled, you can set the threshold and impact level for when you want Internet Monitor to create a health event.
4. After you configure threshold options, save your updates by choosing **Update health event thresholds**.

To learn more about how health events work, see [When Internet Monitor creates and resolves health events](#).

Publish internet measurements to Amazon S3 in Internet Monitor

You can choose to have Internet Monitor publish internet measurements to Amazon S3 for your internet-facing traffic to the monitored city-networks (client locations and ASNs, typically internet service providers) in your monitor, up to the 500,000 city-networks service limit. Internet Monitor automatically publishes internet measurements to CloudWatch Logs every five minutes for the top 500 (by traffic volume) city-networks for each monitor. Measurements that it publishes to S3 include the top 500 that are published to CloudWatch Logs.

You can choose the option to publish to S3, and specify the bucket to publish the measurements, to when you create or update your monitor. The bucket must already be created in S3 before you can specify it in Internet Monitor. There's a service limit of 500,000 city-networks for internet measurements published to S3. Internet Monitor publishes internet measurements to S3 as events, a series of compressed log file objects that are stored in the bucket.

When you create the S3 bucket for Internet Monitor to publish measurements to, make sure that you follow the permissions guidance provided by CloudWatch Logs. Doing so ensures that Internet Monitor can publish logs directly to S3, and that Amazon can, if needed, create and change the resource policies associated with the log group receiving the logs. For more information, see Logs sent to CloudWatch Logs in the Amazon CloudWatch Logs User Guide.

The published log files are compressed. If you open the log files using the Amazon S3 console, they are decompressed and the internet measurement events are displayed. If you download the files, you must decompress them to view the events.

You can also query the internet measurements in the log files using Amazon Athena. Amazon Athena is an interactive query service that makes it easier to analyze data in Amazon S3, by using standard SQL. For more information, see Use Amazon Athena to query internet measurements in Amazon S3 log files.

Examples of using the CLI with Internet Monitor

This section includes examples for using the Amazon Command Line Interface with Internet Monitor operations.

Before you begin, make sure that you log in to use the Amazon CLI with the same Amazon account that has the Amazon VPC VPCs, Network Load Balancers, Amazon CloudFront distributions, or Amazon WorkSpaces directories that you want to monitor. Internet Monitor doesn't support accessing resources across accounts. For more information about using the Amazon CLI, see the

Amazon CLI Command Reference. For more information about using API actions with Internet Monitor, see the Internet Monitor API Reference Guide.

Topics

Create a monitor

When you create a monitor in Internet Monitor, you provide a name and associate resources with the monitor to show where your application's internet traffic is. You specify a traffic percentage that defines how much of your application traffic is monitored. That also determines the number of city-networks, that is, client locations and ASNs, typically internet service providers or ISPs, that are monitored. You can also opt to set a limit for the maximum number of city-networks to monitor for your application resources, to help control your bill. For more information, see Choose a city-networks maximum limit.

Finally, you can choose if you want to publish all internet measurements for your application to Amazon S3. Internet measurements for the top 500 city-networks (by traffic volume) are automatically published to CloudWatch Logs by Internet Monitor, but you can choose to publish all measurements to S3 as well.

To create a monitor with the Amazon CLI, you use the `create-monitor` command. The following command creates a monitor that monitors 100% of traffic but sets a maximum city-networks limit of 10,000, adds a VPC resource, and opts to publish internet measurements to Amazon S3.

> **Note**
>
> Internet Monitor publishes to CloudWatch Logs internet measurements every five minutes for the top 500 city-networks (client locations and ASNs, typically internet service providers or ISPs) that send traffic to each monitor. Optionally, you can choose to publish internet measurements for all monitored city-networks (up to the 500,000 city-networks service

limit) to an Amazon S3 bucket. For more information, see Publish internet measurements to Amazon S3 in Internet Monitor.

```
aws internetmonitor create-monitor --monitor-name "TestMonitor" \
    --traffic-percentage-to-monitor 100 \
    --max-city-networks-to-monitor 10000 \
    --resources "arn:aws:ec2:us-east-1:111122223333:vpc/vpc-11223344556677889" \
    --internet-measurements-log-delivery S3Config="{BucketName=amzn-s3-demo-
bucket,LogDeliveryStatus=ENABLED}"
```

```
{
    "Arn": "arn:aws:internetmonitor:us-east-1:111122223333:monitor/TestMonitor",
    "Status": "ACTIVE"
}
```

Note

You can't change the name of a monitor.

View monitor details

To view information about a monitor with the Amazon CLI, you use the `get-monitor` command.

```
aws internetmonitor get-monitor --monitor-name "TestMonitor"
```

```
{
    "ClientLocationType": "city",

List health events

When performance degrades for your application's internet traffic, Internet Monitor creates health events in your monitor. To see a list of current health events with the Amazon CLI, use the `list-health-events` command.

```
aws internetmonitor list-health-events --monitor-name "TestMonitor"
```

```
{

```

View monitor list

To see a list of all monitors in your account with the CLI, run the `list-monitors` command.

```
aws internetmonitor list-monitors
```

```
{
    "Monitors": [
        {
            "MonitorName": "TestMonitor",
            "ProcessingStatus": "OK",
            "Status": "ACTIVE"
        }
    ],
    "NextToken": " zase12"
```

```
}
```

Edit monitor

To update information about your monitor by using the CLI, use the `update-monitor` command and specify the name of the monitor to update. For example, you can update the percentage of traffic to monitor, the limit of the maximum number of city-networks to monitor, add or remove the resources that Internet Monitor uses to monitor traffic, and change the monitor status from `ACTIVE` to `INACTIVE`, or vice versa. Note that you can't change the name of the monitor.

The response for an `update-monitor` call returns just the `MonitorArn` and the `Status`.

The following example shows how to use the `update-monitor` command to change the maximum number of city-networks to monitor to *50000*:

```
aws internetmonitor update-monitor --monitor-name "TestMonitor" --max-city-networks-to-
monitor 50000
```

```
{
    "MonitorArn": "arn:aws:internetmonitor:us-east-1:111122223333:monitor/TestMonitor",
    "Status": " ACTIVE "
}
```

The following example shows how to add and remove resources:

```
aws internetmonitor update-monitor --monitor-name "TestMonitor" \
    --resources-to-add "arn:aws:ec2:us-east-1:111122223333:vpc/vpc-11223344556677889" \
    --resources-to-remove "arn:aws:ec2:us-east-1:111122223333:vpc/vpc-2222444455556666"
```

```
{
    "MonitorArn": "arn:aws:internetmonitor:us-east-1:111122223333:monitor/TestMonitor",
    "Status": "ACTIVE"
}
```

The following example shows how to use the `update-monitor` command to change the monitor status to `INACTIVE`:

```
aws internetmonitor update-monitor --monitor-name "TestMonitor" --status "INACTIVE"
```

```
{
```

```
    "MonitorArn": "arn:aws:internetmonitor:us-east-1:111122223333:monitor/TestMonitor",
    "Status": "INACTIVE"
}
```

Delete monitor

You can delete a monitor with the CLI by using the `delete-monitor` command. First, you must set the monitor to be inactive. To do that, use the `update-monitor` command to change the status to `INACTIVE`. Confirm that the monitor is inactive by using the `get-monitor` command and checking the status.

When the monitor status is `INACTIVE`, then you can use the CLI to run the `delete-monitor` command to delete the monitor. The response for a successful `delete-monitor` call is empty.

```
aws internetmonitor delete-monitor --monitor-name "TestMonitor"
```

```
{}
```

Monitor and optimize with the Internet Monitor dashboard

Using the Internet Monitor dashboard in the Amazon Web Services Management Console, you can visualize data and get insights and suggestions about your Amazon application's internet traffic, and configure options for your monitor.

After you create a monitor to monitor your application's internet performance and availability, Internet Monitor stores internet measurements for pairs of your client locations and ASNs, or *city-networks*. Internet Monitor also creates aggregated CloudWatch metrics for traffic to your application, and to each Amazon Web Services Region and edge location. You can filter, explore, and get action-oriented suggestions from your monitor's information in several different ways. The Internet Monitor dashboard guides you through viewing and getting insights about the data for your monitored traffic.

To get started, on the CloudWatch console, under **Network Monitoring**, choose **Internet monitors**. Then, select a monitor to work with.

> **Note**
>
> This section primarily describes how to filter and view Internet Monitor metrics using the Amazon Web Services Management Console. Alternatively, you can use Internet Monitor

API operations with the Amazon CLI or an SDK to work directly with Internet Monitor events stored in CloudWatch Logs files. For more information, see Using your monitor and measurements information. For more information about using API operations, see Examples of using the CLI with Internet Monitor and the Internet Monitor API Reference.

There are five pages (tabs) in the Internet Monitor dashboard:

- On the **Overview** page, you can get an overall view of your monitored traffic, including current performance and availability information, a summary of recent and current health events, and the top suggestion for potentially improving performance for your clients.
- On the **Health events** page, you can see current and historical health events that currently impact, or previously impacted, locations where clients access your application.
- On the **Analyze** page, you can view information about top monitored traffic in client locations (by traffic volume), summarized in several customizable ways. You can also see historical trends for health scores and metrics. You can filter by location, ASN, date, and so on, and visualize metrics for your internet traffic over time.
- On the **Optimize** page, Internet Monitor predicts your application's performance improvement for top Amazon Web Services Regions (or Amazon CloudFront), based on your traffic patterns and past performance. For each top configuration, associated tables provide a breakdown of reduced latency by client location. On a second page, you can select multiple Regions (and, if you like, include CloudFront configurations) to compare latency reductions. For each configuration (Region) that you selected, the page displays an associated table of latency details, listed by city location.
- On the **Configure** page, you can see monitor details and configure options, such as the percentage of traffic to monitor.

In addition to these dashboard options, you can use tools for deeper dives into details of the metrics that Internet Monitor collects with your monitor. Internet Monitor generates and publishes log files with the measurements about your traffic, so you can use other CloudWatch tools in the console to further visualize the data published by Internet Monitor, including CloudWatch Contributor Insights, CloudWatch Metrics, and CloudWatch Logs Insights. For more information, see Exploring your data with CloudWatch tools and the Internet Monitor query interface.

Learn about using Internet Monitor to explore your performance and availability measurements in the following sections.

Topics

Track real-time performance and availability in Internet Monitor (Overview page)

The **Overview** page in the Internet Monitor console shows you a high-level view of performance and availability for the traffic that your monitor tracks, and a timeline of when health events have impacted your monitored traffic. The page also provides the top suggestion for a configuration change that could reduce latency for clients who use your application in your top client location (by traffic volume).

Traffic overview and Status

The **Traffic overview** section provides an overall look at your application's availability and performance. Note that this section shows *aggregated* overall performance and availability scores that consider all of the traffic for applications towards all end users and service locations. You can see health scores for specific client locations and service locations by searching and filtering measurements information on the **Analyze** tab.

Under **Status**, you can see if your monitor is actively creating data for your monitor or is waiting for data to be available. You can also see the percentage of your application's traffic that you're monitoring. If you want to change the percentage, see the **Configure** page.

Internet Monitor uses a statistical process to create availability and performance scores for your monitored traffic. Amazon has substantial historical data about internet performance and availability for network traffic between geographic locations for different ASNs and Amazon services. Internet Monitor uses the connectivity data that Amazon has captured from its global networking footprint to calculate a baseline of availability and performance for internet traffic. This is the same data that we use at Amazon to monitor our own internet uptime and availability.

With those measurements as a baseline, Internet Monitor can detect when the performance and availability for your application has dropped, compared to the baseline. To make it easier to see those drops, we report that information to you as a performance score and an availability score.

For more information, see How Amazon calculates performance and availability scores.

Health events timeline

The **Health events timeline** graph displays health events that have occurred during the past 24 hours. A summary below the graph shows your application's current and recent impact. For details, you can choose **See more health events**.

To change the thresholds for health events, go to the **Configure** page.

Reduce latency for your top Region

Internet Monitor automatically evaluates the Amazon Web Services Region that your current application configuration uses most (that is, the Region with the highest client volume), and determines if another Region could provide a better aggregate time to first byte (TTFB) for your clients.

Note that because this is the aggregate TTFB, if you move traffic from one Region to another, TTFB for most locations is expected to improve but clients in some Regions could see no change or reduced performance..

To explore more latency improvement suggestions, including details at more granular levels (such as by client location), see the **Optimize** page.

View health events and metrics in Internet Monitor (Health events page)

The **Health events** page in the Internet Monitor console provides a map of health events that impact the client locations and ASNs for your application. You can click circles on the map for more details about an event. The **Health events** tables lists locations that have been impacted by an event, and specifics about the impact.

Internet traffic overview

The **Internet traffic overview** map shows you the internet traffic and health events that are specific to the locations and ASNs that your clients access your application from. The countries that are gray on the map are those that include traffic for your application.

Each circle on the map indicates a health event in an area, for a time period that you select. Internet Monitor creates health events when it detects a problem, at a specific (but customizable) threshold, with connectivity between one of your resources hosted in Amazon and a city-network where a client is accessing your application.

Choose a circle on the map to display more details about the health event for that location. In addition, for clusters that have health events, you can see detailed information in the **Health events** table below the map.

Note that Internet Monitor creates health events in a monitor when it determines that an event has significant impact on your application. The map is blank if there aren't any health events that exceed the threshold for impact on traffic for your client locations in the time period that you've selected. For more information, see When Internet Monitor creates and resolves health events.

Health events

The **Health events** table lists client locations that have been affected by health events, along with information about the events. The following columns are included in the table.

Column	Description
Event type	Specifies whether current events are *overall* health events or *local* health events, or if the health event is in the *past*.
Client location	The location of the end users who were impacted by the event, who experienced increased latency or reduced availability. To learn more about client location accuracy in Internet Monitor, see Geolocation information and accuracy in Internet Monitor.
ISP name (ASN)	The network that the traffic traveled over. Typically, this is the internet service provider (ISP) or Autonomous System Number (ASN) for the network traffic.
Service location	The Amazon location for the network traffic, which can be an Amazon Web Services Region or an internet edge location.

Column	Description
Traffic impact	How much impact was caused by the event, in increased latency or reduced availability. For latency, this is the percentage of how much latency increased during the event compared to typical performance for traffic, from this client location to this Amazon location using this client network.
Impact type	The type of impact for the health event. Health events are typically caused by latency increases (performance issues) or reachabil ity (availability issues). You might also be able to click on the impact type to see the cause of the impairment. When possible, Internet Monitor analyzes the origin of a health event, to determine whether it was caused by Amazon or an ASN (internet service provider). Note that this analysis continues after the event is resolved. Internet Monitor can update events with new information for up to an hour.

If you choose one of the client locations in the **Health events** table, you can see more details about the health event at that location. For example, you can see when the event started, when it ended, and the local traffic impact.

Network path visualization

If Internet Monitor has finished impairment analysis for an event, you can view **Network path visualization** to see the full network path for traffic to a client location. The full path shows you each node along the network path for your application for the health event, between the Amazon location and the client, for a client-location pair.

When Internet Monitor has determined the cause of an impairment, Internet Monitor adds a dashed red circle around the node. Impairments can be caused by ASNs, typically internet service providers (ISPs), or the cause can be Amazon. If there were multiple causes for an impairment, multiple nodes are circled.

Analyze historical data in Internet Monitor (Analyze page)

On the **Analyze** page in the Internet Monitor console, you can view your application's the top client locations for the traffic that you monitor, by traffic volume. You can also view graphs showing performance and availability scores for your traffic over time, as well as graphs of other internet traffic metrics for your application's monitored traffic.

To start exploring Internet Monitor data for your application traffic, select a time period. Then, choose a specific geographical location, such a city, and (optionally) other filters. Internet Monitor applies the filters to your data, and then you can see graphs of the data that show measurements for your application. The graphs included on the **Analyze** page include your application's performance score, availability score, monitored bytes transferred (for VPCs, Network Load Balancers, and CloudFront distributions) or client connection counts (for WorkSpaces directories), and round-trip time (RTT) for your application over time.

The options at the top of the **Analyze** page determine the timeframe and types of traffic shown in the graphs on the page. You can filter by client locations or ASN, or choose to show traffic graphs at a specific granularity (the default is city level).

Top client locations

The **Top client locations** graph displays your top monitored traffic locations, by default. You can choose another field to sort the graph by, or you can sort the graph in other ways, for example, by lowest traffic locations.

The filters that you choose for the page determine the Regions, timeframe, and so on for the locations.

Traffic health scores

This section shows you graphs of traffic health scores and metrics for your monitored traffic. These graphs reflect data for the filters that you choose at the top of the page.

The **Traffic health scores** graph shows you performance and availability information for your local and overall traffic by calling out health events that have impacted your monitored client traffic. Amazon has substantial historical data about internet performance and availability for network traffic between geographic locations for different ASNs and Amazon services. Internet Monitor uses the connectivity data that Amazon has captured from its global networking footprint to calculate a baseline of performance and availability for internet traffic. This is the same data that we use at Amazon to monitor our own internet uptime and availability.

With those measurements as a baseline, Internet Monitor can detect when the performance and availability for your application has dropped, compared to the baseline. To make it easier to see those drops, we report that information to you as a performance score and an availability score. For more information, see How Amazon calculates performance and availability scores.

Additional graphs show the monitored bytes transferred (for VPCs, Network Load Balancers, and CloudFront distributions) or client connection counts (for WorkSpaces directories), and round-trip time (RTT) for your application traffic.

Note that when round-trip time (RTT) is aggregated across end-user locations, the value is weighted by the amount of your traffic that is driven by each client location. For example, with two client locations, one serving 90% of traffic with a 5 ms RTT, and the other serving 10% of traffic with a 10 ms RTT, the result is an aggregated RTT of 5.5 ms (which comes from 5 ms * 0.9 + 10 ms * 0.1).

You can also explore the internet measurements that Internet Monitor stores for your monitored traffic by using CloudWatch tools or other methods. For more information, see Exploring your data with CloudWatch tools and the Internet Monitor query interface. In addition, you can create CloudWatch alarms based on Internet Monitor data, for example, to notify you of health events. For more information, see Create alarms with Internet Monitor.

Get suggestions to optimize application performance in Internet Monitor (Optimize page)

Use the **Optimize** page in the Internet Monitor console to get suggestions for how to optimize application performance for your clients. Internet Monitor evaluates your monitored application traffic, and determines if you can reduce latency by changing the Amazon Web Services Regions that you've configured for your application. Optionally, you can also view latency changes if you choose to include Amazon CloudFront in the suggestions.

You can review suggestions for your application's top Regions by traffic volume, or for top client locations, also by traffic volume.

Suggestions to reduce latency for top Regions

To help you quickly understand your best options for reducing latency for your clients, Internet Monitor automatically provides suggestions for improving latency in your application for your top Regions (by traffic volume).

You can also explore configuration changes for all the Regions where your application serves clients. This includes getting details about each suggested change at deeper levels of granularity, for example, by specific client location. To explore all Regional configurations and expected latency changes for your application, choose **Optimization suggestions for all Regions**.

Suggestions to reduce latency for all Regions

To explore suggestions for reducing latency for all Regions where clients access your application, choose **Optimization suggestions for all Regions** to open a new dashboard page. On this page, you can select different Regions to configure, with the option of including CloudFront as a configuration comparison, and then compare the times to first byte (TTFBs) for each selected configuration.

Then, for each comparison, you can also see a table with at a more granular level (by client location), with the average expected TTFB for each one.

Suggestions to reduce latency for top locations

Internet Monitor also provides suggestions for reducing application latency for your clients by specific location. When the table lists multiple suggestions for the same location, expand the city location for that row to see details.

Be aware that if you change a configuration to use a different Region or to use CloudFront, latency improvements can vary by client location. For example, latency might improve for some locations, but stay the same or worsen for others.

Suggestions to reduce latency by updating routing configurations

Note: These suggestions are only relevant for application traffic to Regional load balancers. The table is not shown for monitors that you create for CloudFront distributions or WorkSpaces resources.

With Internet Monitor, you can view information about latency toward Amazon locations for IPv4 IP prefixes that access your application using different DNS resolvers (typically ISPs). Using this information, you can take steps to reduce latency for specific groups of users by routing a set of IP address prefixes, specified by a CIDR collection, to your endpoints in a Region that results in lower latency for your users. If you don't already have a CIDR collection for the prefixes, you can go to Amazon Route 53 to create one. Then, you can update your routing in Route 53 to route IP addresses in the collection to a specific Region.

If you want to create a CIDR collection for a set of IP address prefixes, you can easily do so by selecting a row or rows that includes the IP prefixes that you want, and then choosing **Add to CIDR collection**. Then, in the Route 53 console, you can configure a routing policy that routes IP addresses in the collection to the Region with lower latency for your application.

To learn more about IP-based routing in Route 53, see IP-based routing.

By viewing the suggestions on this page, you can start planning configurations and deployments that can improve performance for your clients. Note that you might see a dash (-) instead of a value in a column, when data is not available to display.

For more information about TTFB calculations, see Amazon calculations for TTFB and latency. To review a specific example of how to improve performance, see Using Internet Monitor for a Better Gaming Experience.

Monitoring details in Internet Monitor (Configure page)

On the **Configure** page, you can see details about your monitor, including a list of resources that you monitor traffic for and the thresholds for when health events are triggered. You can also explore and compare values for the traffic percentage for your monitor, and its impact on how many city-networks are included for (monitored by) your monitor. Finally, you can view information about measurements that are published to an Amazon S3 bucket.

You can configure a monitor to change most options, such as the percentage of traffic to monitor. For more information, see Configure your monitor.

Monitor details

The **Monitor details** section includes basic information about your monitor, including the name, the percentage of traffic currently being monitored for your application, a city-networks maximum limit (if you've set one), and status information about the monitor.

The following explains the values that you might see for **Status** and **Status info** (data processing status).

Status	Description
Active	Monitor is created and active.
Pending	Monitor is currently being created and is not yet active.
Inactive	Monitor is created but has been set to inactive.
Error	Monitor is in an error state.

Status details (Data processing status)	Description
OK	Monitor is actively processing data.
Inactive	Monitor is inactive and is not processing data.
Collecting data	Monitor is actively collecting data.
Insufficient data	Monitor is actively processing data, but there aren't enough datapoints to produce insights.
Fault access CloudWatch	Monitor has encountered a problem delivering CloudWatch metrics data and log events.

Health event thresholds

In this section, you can see the current thresholds for health events that are configured for this monitor. If you haven't configured any custom thresholds, the values shown here are the default values.

By default, health events are not triggered based on local thresholds. If local health event thresholds would be useful for your Internet Monitor scenario, you can enable the option and specify the thresholds to use.

You can learn more about how health event thresholds work, and review the potential impact of adding local thresholds or changing existing thresholds. For more information, see Change health event thresholds.

Traffic coverage

In this section, you can explore options for the traffic coverage for your monitor. When you change the traffic percentage for a monitor, Internet Monitor monitors different amounts of application traffic. If you set a traffic percentage to less than 100% (100% is the default value), some portion of the city-networks that your clients use to access your application might not be monitored. By exploring the impact of different traffic percentage values, you can see how different values that you might set would impact your city-networks coverage.

The **Total monitored city-networks** graph shows you how many city-networks are currently monitored, and how many would be monitored if you set the traffic percentage to 100%. To view different traffic percentage values on the graph, select percentages in the drop-down menu.

After you explore the options, you can change the traffic percentage to monitor by choosing **Update monitoring coverage**.

If you want to set a maximum city-networks limit, at the top of the page, choose **Edit monitor**. Then, under **Advanced options**, set a maximum city-networks value.

Configure your monitor

As on every page in the Internet Monitor dashboard, you can choose **Edit monitor** to change options for your monitor, including adding or removing resources. For details about how to update the following configuration options, see the provided links.

View health event thresholds

> In this section, you can see the current thresholds for health events that are configured for this monitor.
>
> To update health thresholds, see Change health event thresholds.

View and evaluate traffic coverage

In this section, you can compare the effect of changing the percentage of traffic that you monitor for your application on the number of city-networks that are included (for monitoring) when you choose different percentage values.

You can also change the percentage of traffic that you monitor, or change the limit for the number of city-networks your monitor includes. To change the percentage of traffic, choose **Update monitoring coverage**.

For detailed steps and information, see Explore changing your application traffic percentage.

Configuration details for publishing internet measurements to Amazon S3

If you have configured Internet Monitor to publish internet measurements for your monitor to an Amazon S3 bucket, the information about your configuration is shown here.

To configure this option, see Publishing internet measurements to S3.

Exploring your data with CloudWatch tools and the Internet Monitor query interface

In addition to visualizing your performance and availability for your application with the Internet Monitor dashboard, there are several methods that you can use to dive deeper into the data that Internet Monitor generates for you. These methods include using CloudWatch tools with Internet Monitor data stored in CloudWatch Log files and using the Internet Monitor query interface. The tools that you can use include CloudWatch Logs Insights, CloudWatch Metrics, CloudWatch Contributor Insights, and Amazon Athena. You can use some or all these tools, as well as the dashboard, to explore Internet Monitor data, depending on your needs.

Internet Monitor aggregates CloudWatch metrics about traffic to your application and to each Amazon Web Services Region, and includes data such as total traffic impact, availability, and round-trip time. This data is published to CloudWatch Logs and is also available to use with the Internet Monitor query interface. Details about geo-granularity and other aspects of the information available to explore for each one varies.

Internet Monitor publishes data for your monitor at 5 minute intervals, and then makes the data available in several ways. The following table lists scenarios for accessing Internet Monitor data, and describes features of the data that is collected for each one.

Feature	CloudWatch Logs	Export to S3	Query interface	CloudWatch dashboard
Enabled by default	Yes	No	Yes	Yes
Number of city-networks that data is collected for	Top 500 (see note below)	All	All	All
Data retention	User controlled	User controlled	30 days	30 days
Geo-granularities that data is collected for	All (city-network, metro+network, subdivision+network, country+network)	City-network	All (city-network, metro+network, subdivision+network, country+network)	All (city-network, metro+network, subdivision+network, country+network)
How to query and filter data	Use CloudWatch Logs Insights to explore Internet Monitor measurements	Use Amazon Athena to query internet measurements in Amazon S3 log files	Use the Internet Monitor query interface	Monitor and optimize with the Internet Monitor dashboard

Note: Top 500 measurements are captured for city-networks; top 250 for metro+networks, top 100 for subdivision+networks, top 50 for country+networks.

This chapter describes how to query and explore your data by using CloudWatch tools or the Internet Monitor query interface, together with examples for each method.

Contents

- Use Amazon Athena to query internet measurements in Amazon S3 log files
- Use the Internet Monitor query interface

Use CloudWatch Logs Insights to explore Internet Monitor measurements

You can use CloudWatch Logs Insights queries to filter a subset of logs for a specific city or geography (client location), client ASN (ISP), and Amazon source location. Internet Monitor publishes granular measurements of availability and round-trip time to CloudWatch Logs that you can explore using CloudWatch Logs Insights.

To learn more about client location accuracy in Internet Monitor, see Geolocation information and accuracy in Internet Monitor.

The examples in this section can help you create CloudWatch Logs Insights queries to learn more about your own application traffic measurements and metrics. If you use these examples in CloudWatch Logs Insights, replace *monitorName* with your own monitor name.

View traffic optimization suggestions

On the **Traffic insights** tab in Internet Monitor, you can view traffic optimization suggestions, filtered by a location. To see the same information that is displayed in the **Traffic optimization suggestions** section on that tab, but without the location granularity filter, you can use the following CloudWatch Logs Insights query.

1. In the Amazon Web Services Management Console, navigate to CloudWatch Logs Insights.
2. For **Log Group**, select `/aws/internet-monitor/monitorName/byCity` and `/aws/internet-monitor/monitorName/byCountry`, and then specify a time range.
3. Add the following query, and then run the query.

```
fields @timestamp,
clientLocation.city as @city, clientLocation.subdivision as @subdivision,
 clientLocation.country as @country,
`trafficInsights.timeToFirstByte.currentExperience.serviceName` as @serviceNameField,
concat(@serviceNameField, ` (`, `serviceLocation`, `)`) as @currentExperienceField,
concat(`trafficInsights.timeToFirstByte.ec2.serviceName`, ` (`,
 `trafficInsights.timeToFirstByte.ec2.serviceLocation`, `)`) as @ec2Field,
`trafficInsights.timeToFirstByte.cloudfront.serviceName` as @cloudfrontField,
concat(`clientLocation.networkName`, ` (AS`, `clientLocation.asn`, `)`) as @networkName
```

```
| filter ispresent(`trafficInsights.timeToFirstByte.currentExperience.value`)
| stats avg(`trafficInsights.timeToFirstByte.currentExperience.value`) as @averageTTFB,
avg(`trafficInsights.timeToFirstByte.ec2.value`) as @ec2TTFB,
avg(`trafficInsights.timeToFirstByte.cloudfront.value`) as @cloudfrontTTFB,
sum(`bytesIn` + `bytesOut`) as @totalBytes,
latest(@ec2Field) as @ec2,
latest(@currentExperienceField) as @currentExperience,
latest(@cloudfrontField) as @cloudfront,
count(*) by @networkName, @city, @subdivision, @country
| display @city, @subdivision, @country, @networkName, @totalBytes, @currentExperience,
 @averageTTFB, @ec2, @ec2TTFB, @cloudfront, @cloudfrontTTFB
| sort @totalBytes desc
```

View internet availability and RTT (p50, p90, and p95)

To view the internet availability and round-trip time (p50, p90, and p95) for traffic, you can use the following CloudWatch Logs Insights query.

End user geography: Chicago, IL, United States

End user network (ASN): AS7018

Amazon service location: US East (N. Virginia) Region

To view the logs, do the following:

1. In the Amazon Web Services Management Console, navigate to CloudWatch Logs Insights.
2. For **Log Group**, select `/aws/internet-monitor/`*`monitorName`*`/byCity` and `/aws/internet-monitor/`*`monitorName`*`/byCountry`, and then specify a time range.
3. Add the following query, and then run the query.

The query returns all the performance data for users connecting from AS7018 in Chicago, IL towards US East (N. Virginia) Region over the selected time period.

```
fields @timestamp,
internetHealth.availability.experienceScore as availabilityExperienceScore,
internetHealth.availability.percentageOfTotalTrafficImpacted as
 percentageOfTotalTrafficImpacted,
internetHealth.performance.experienceScore as performanceExperienceScore,
internetHealth.performance.roundTripTime.p50 as roundTripTimep50,
internetHealth.performance.roundTripTime.p90 as roundTripTimep90,
```

```
internetHealth.performance.roundTripTime.p95 as roundTripTimep95
 | filter clientLocation.country == `United States`
 and clientLocation.city == `Chicago`
 and serviceLocation == `us-east-1`
 and clientLocation.asn == 7018
```

For more information, see Analyzing log data with CloudWatch Logs Insights.

Use Contributor Insights to identify top locations and ISPs

CloudWatch Contributor Insights can help you identify top client locations and ASNs (typically, internet service providers or ISPs) for your Amazon application. Use the following sample Contributor Insights rules to get started with rules that are useful with Internet Monitor. For more information, see Create a Contributor Insights rule in CloudWatch.

To learn more about client location accuracy in Internet Monitor, see Geolocation information and accuracy in Internet Monitor.

> **Note**
>
> Internet Monitor stores internet measurements data every five minutes, so after you set up a Contributor Insights rule, you must adjust the period to five minutes to see a graph.

View top locations and ASNs impacted by an availability impact

To view top client locations and ASNs impacted by a drop in availability, you can use the following Contributor Insights rule in the Syntax editor. Replace *monitor-name* with your own monitor name.

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "AggregateOn": "Sum",
    "Contribution": {
        "Filters": [
            {
                "Match": "$.clientLocation.city",
                "IsPresent": true
```

```
            }
        ],
        "Keys": [
            "$.clientLocation.city",
            "$.clientLocation.networkName"
        ],
        "ValueOf": "$.awsInternetHealth.availability.percentageOfTotalTrafficImpacted"
    },
    "LogFormat": "JSON",
    "LogGroupNames": [
        "/aws/internet-monitor/monitor-name/byCity"
    ]
}
```

View top client locations and ASNs impacted by a latency impact

To view top client locations and ASNs impacted by an increase in round-trip time (latency), you can use the following Contributor Insights rule in the Syntax editor. Replace *`monitor-name`* with your own monitor name.

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "AggregateOn": "Sum",
    "Contribution": {
        "Filters": [            {
                "Match": "$.clientLocation.city",
                "IsPresent": true
            }
        ],
        "Keys": [
            "$.clientLocation.city",
            "$.clientLocation.networkName"
        ],
        "ValueOf": "$.awsInternetHealth.performance.percentageOfTotalTrafficImpacted"
    },
    "LogFormat": "JSON",
    "LogGroupNames": [
        "/aws/internet-monitor/monitor-name/byCity"
    ]
}
```

View top client locations and ASNs impacted by total percentage of traffic

To view top client locations and ASNs impacted by total percentage of traffic, you can use the following Contributor Insights rule in the Syntax editor. Replace *monitor-name* with your own monitor name.

```
{
    "Schema": {
        "Name": "CloudWatchLogRule",
        "Version": 1
    },
    "AggregateOn": "Sum",
    "Contribution": {
        "Filters": [
            {
                "Match": "$.clientLocation.city",
                "IsPresent": true
            }
        ],
        "Keys": [
            "$.clientLocation.city",
            "$.clientLocation.networkName"
        ],
        "ValueOf": "$.percentageOfTotalTraffic"
    },
    "LogFormat": "JSON",
    "LogGroupNames": [
        "/aws/internet-monitor/monitor-name/byCity"
    ]
}
```

View Internet Monitor metrics or set alarms in CloudWatch Metrics

You can view or set alarms on Internet Monitor metrics by using CloudWatch alarms and CloudWatch Metrics in the CloudWatch console. Internet Monitor publishes metrics to your account, including metrics for performance, availability, round-trip time, and throughput (bytes per second). To find all metrics for your monitor, in the CloudWatch Metrics dashboard, see the custom namespace `AWS/InternetMonitor`.

To see examples for using several of these metrics to help determine values to choose for a city-networks maximum limit for your monitor, see Choosing a city-network maximum value. To learn more about setting alarms for Internet Monitor, see Create alarms with Internet Monitor.

Metrics are aggregated across all internet traffic to your VPCs, Network Load Balancers, CloudFront distributions, or WorkSpaces directories in the monitor, and to all traffic to each Amazon Web Services Region and internet edge location that is monitored. Regions are defined by the service location, which can either be all locations or a specific Region, such as `us-east-1`.

Note: *city-networks* are pairs of client locations and the ASNs the clients use (typically internet service providers or ISPs).

Internet Monitor provides the following metrics.

Metric	Description
PerformanceScore	A performance score represents the estimated percentage of traffic that is not seeing a performance drop.
AvailabilityScore	An availability score represents the estimated percentage of traffic that is not seeing an availability drop.
BytesIn	Bytes transferred in for your application internet traffic at all application city-networks.
BytesOut	Bytes transferred out for your application internet traffic at all application city-networks.
BytesInMonitored	Bytes transferred in for your application internet traffic at monitored city-networks.
BytesOutMonitored	Bytes transferred out for your application internet traffic at monitored city-networks.
Round-trip time (RTT)	Round-trip time between the Amazon Web Services Regions, ASNs (typically internet service providers or ISPs), and locations (such as cities) specific to your VPCs, Network Load Balancers, CloudFront distributions, or WorkSpaces directories.

Metric	Description
CityNetworksMonitored	The number of city-networks Internet Monitor monitored for your application internet traffic. This is never more than the upper limit that you set as the maximum city-networks for the monitor.
TrafficMonitoredPercent	The percentage of total application internet traffic for this monitor that is represented (included) by the city-networks that Internet Monitor is monitoring. This is less than 100 (that is, less than 100%) if clients access your application in more city-networks than the maximum city-networks limit that you have set for the monitor.
CityNetworksFor100PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 100% of your application internet traffic in Internet Monitor.
CityNetworksFor99PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 99% of your application internet traffic in Internet Monitor.
CityNetworksFor95PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 95% of your application internet traffic in Internet Monitor.
CityNetworksFor90PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 90% of your application internet traffic in Internet Monitor.

Metric	Description
CityNetworksFor75PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 75% of your application internet traffic in Internet Monitor.
CityNetworksFor50PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 50% of your application internet traffic in Internet Monitor.
CityNetworksFor25PercentTraffic	The number that you should set your city-networks maximum limit to if you want to monitor 25% of your application internet traffic in Internet Monitor.

For more information, see Metrics in Amazon CloudWatch.

Use Amazon Athena to query internet measurements in Amazon S3 log files

You can use Amazon Athena to query and view the internet measurements that Internet Monitor publishes to an Amazon S3 bucket. There's an option in Internet Monitor to publish internet measurements for your application to an S3 bucket for internet-facing traffic for your monitored city-networks (client locations and ASNs, typically internet service providers or ISPs). Regardless of whether you choose to publish measurements to S3, Internet Monitor automatically publishes internet measurements to CloudWatch Logs every five minutes for the top 500 (by traffic volume) city-networks for each monitor.

This chapter includes steps for how to create a table in Athena for internet measurements located in an S3 log file, and then provides example queries to see different views of the measurements. For example, you can query for your top 10 impacted city-networks by latency impact.

Using Amazon Athena to create a table for internet measurements in Internet Monitor

To start using Athena with your Internet Monitor S3 log files, you first create a table for the internet measurements.

Follow the steps in this procedure to create a table in Athena based on the S3 log files. Then, you can run Athena queries on the table, such as these example internet measurements queries, to get information about your measurements.

To create an Athena table

1. Open the Athena console at https://console.aws.amazon.com/athena/.
2. In the Athena query editor, enter a query statement to generate a table with Internet Monitor internet measurements. Replace the value for the LOCATION parameter with the location of S3 bucket where your Internet Monitor internet measurements are stored.

```
CREATE EXTERNAL TABLE internet_measurements (
    version INT,
    timestamp INT,
    clientlocation STRING,
    servicelocation STRING,
    percentageoftotaltraffic DOUBLE,
    bytesin INT,
    bytesout INT,
    clientconnectioncount INT,
    internethealth STRING,
    trafficinsights STRING
)
PARTITIONED BY (year STRING, month STRING, day STRING)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
LOCATION
's3://amzn-s3-demo-bucket/bucket_prefix/AWSLogs/account_id/
internetmonitor/AWS_Region/'
TBLPROPERTIES ('skip.header.line.count' = '1');
```

3. Enter a statement to create a partition to read the data. For example, the following query creates a single partition for a specified date and location:

```
ALTER TABLE internet_measurements
ADD PARTITION (year = 'YYYY', month = 'MM', day = 'dd')
LOCATION
's3://amzn-s3-demo-bucket/bucket_prefix/AWSLogs/account_id/
internetmonitor/AWS_Region/YYYY/MM/DD';
```

4. Choose **Run**.

Example Athena statements for internet measurements

The following is an example of a statement to generate a table:

```
CREATE EXTERNAL TABLE internet_measurements (
    version INT,
    timestamp INT,
    clientlocation STRING,
    servicelocation STRING,
    percentageoftotaltraffic DOUBLE,
    bytesin INT,
    bytesout INT,
    clientconnectioncount INT,
    internethealth STRING,
    trafficinsights STRING
)
PARTITIONED BY (year STRING, month STRING, day STRING)
ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
LOCATION 's3://internet-measurements/TestMonitor/AWSLogs/1111222233332/internetmonitor/
us-east-2/'
TBLPROPERTIES ('skip.header.line.count' = '1');
```

The following is an example of a statement to create a partition to read the data:

```
ALTER TABLE internet_measurements
ADD PARTITION (year = '2023', month = '04', day = '07')
LOCATION 's3://internet-measurements/TestMonitor/AWSLogs/1111222233332/internetmonitor/
us-east-2/2023/04/07/'
```

Sample Amazon Athena queries to use with internet measurements in Internet Monitor

This section includes example queries that you can use with Amazon Athena to get information about your application's internet measurements published to Amazon S3.

Query your top 10 impacted (by total percentage of traffic) client locations and ASNs

Run this Athena query to return your top 10 impacted (by total percentage of traffic) city-networks—that is, client locations and ASNs, typically internet service providers.

```
SELECT json_extract_scalar(clientLocation, '$.city') as city,
    json_extract_scalar(clientLocation, '$.networkname') as networkName,
```

```
    sum(percentageoftotaltraffic) as percentageoftotaltraffic
FROM internet_measurements
GROUP BY json_extract_scalar(clientLocation, '$.city'),
    json_extract_scalar(clientLocation, '$.networkname')
ORDER BY percentageoftotaltraffic desc
limit 10
```

Query your top 10 impacted (by availability) client locations and ASNs

Run this Athena query to return your top 10 impacted (by total percentage of traffic) city-networks—that is, client locations and ASNs, typically internet service providers.

```
SELECT json_extract_scalar(clientLocation, '$.city') as city,
    json_extract_scalar(clientLocation, '$.networkname') as networkName,
    sum(
        cast(
            json_extract_scalar(
                internetHealth,
                '$.availability.percentageoftotaltrafficimpacted'
            )
        as double )
    ) as percentageOfTotalTrafficImpacted
FROM internet_measurements
GROUP BY json_extract_scalar(clientLocation, '$.city'),
    json_extract_scalar(clientLocation, '$.networkname')
ORDER BY percentageOfTotalTrafficImpacted desc
limit 10
```

Query your top 10 impacted (by latency) client locations and ASNs

Run this Athena query to return your top 10 impacted (by latency impact) city-networks—that is, client locations and ASNs, typically internet service providers.

```
SELECT json_extract_scalar(clientLocation, '$.city') as city,
    json_extract_scalar(clientLocation, '$.networkname') as networkName,
    sum(
        cast(
            json_extract_scalar(
                internetHealth,
                '$.performance.percentageoftotaltrafficimpacted'
            )
        as double )
```

```
    ) as percentageOfTotalTrafficImpacted
FROM internet_measurements
GROUP BY json_extract_scalar(clientLocation, '$.city'),
    json_extract_scalar(clientLocation, '$.networkname')
ORDER BY percentageOfTotalTrafficImpacted desc
limit 10
```

Query traffic highlights for your client locations and ASNs

Run this Athena query to return traffic highlights, including availability score, performance score, and time to first byte for your city-networks—that is, client locations and ASNs, typically internet service providers. .

```

SELECT json_extract_scalar(clientLocation, '$.city') as city,
    json_extract_scalar(clientLocation, '$.subdivision') as subdivision,
    json_extract_scalar(clientLocation, '$.country') as country,
    avg(cast(json_extract_scalar(internetHealth, '$.availability.experiencescore') as
 double)) as availabilityScore,
    avg(cast(json_extract_scalar(internetHealth, '$.performance.experiencescore') as
 double)) performanceScore,
    avg(cast(json_extract_scalar(trafficinsights,
 '$.timetofirstbyte.currentexperience.value') as double)) as averageTTFB,
    sum(bytesIn) as bytesIn,
    sum(bytesOut) as bytesOut,
    sum(bytesIn + bytesOut) as totalBytes
FROM internet_measurements
where json_extract_scalar(clientLocation, '$.city') != 'N/A'
GROUP BY
json_extract_scalar(clientLocation, '$.city'),
    json_extract_scalar(clientLocation, '$.subdivision'),
    json_extract_scalar(clientLocation, '$.country')
ORDER BY totalBytes desc
limit 100
```

For more information about using Athena, see the [Amazon Athena User Guide](#).

Use the Internet Monitor query interface

An option for understanding more about internet traffic for your Amazon application is to use the Internet Monitor *query interface*. To use the query interface, you create a query with data filters that you choose, and then run the query to return a subset of your Internet Monitor data. Exploring the data that the query returns can give you insights into how your application is performing on the internet.

You can query and explore all the metrics that Internet Monitor captures with your monitor, including availability and performance scores, bytes transferred, round-trip times, and time to first byte (TTFB).

Internet Monitor uses the query interface to provide the data that you can explore in the Internet Monitor console dashboard. By using search options in the dashboard—on the **Analyze** page or the **Optimize** page—you can query and filter internet data for your application.

If you'd like more flexibility to explore and filter your data than the dashboard provides, you can use the query interface yourself, by using Internet Monitor API operations with the Amazon Command Line Interface or with an Amazon SDK. This section introduces the types of queries that you can use with the query interface, and the filters that you can specify to create a subset of data, to get insights about internet traffic for your application.

Topics

How to use the query interface

You create a query with the query interface by choosing a *query type*, and then specifying filter values, to return a specific desired subset of your log file data. Then, you can work with the data subset, to further filter and sort, create reports, and so on.

The query process works like this:

1. When you run a query, Internet Monitor returns a `query ID` that is unique to the query. This section describes the query types that are available, and options for filtering data in queries. To understand how this works, you can also review the section on query examples.
2. You specify the query ID with your monitor name with the GetQueryResults API operation to return data results for the query. Each query type returns a different set of data fields. To learn more, see Get query results.

The query interface provides the following query types. Each query type returns a different set of information about your traffic from the log files, as shown.

- **Measurements:** Provides availability score, performance score, total traffic, and round-trip times, at 5 minute intervals.
- **Top locations:** Provides availability score, performance score, total traffic, and time to first byte (TTFB) information, for the top location and ASN combinations that you're monitoring, by traffic volume.
- **Top locations details:** Provides TTFB for Amazon CloudFront, your current configuration, and the best performing Amazon EC2 configuration, at 1 hour intervals.
- **Overall traffic suggestions:** Provides TTFB, using a 30-day weighted average, for all traffic in each Amazon location that is monitored.
- **Overall traffic suggestions details:** Provides TTFB, using a 30-day weighted average, for each top location, for a proposed Amazon location.
- **Routing suggestions:** Provides the predicted average round-trip time (RTT) from an IP prefix toward an Amazon location for a DNS resolver. The RTT is calculated at one hour intervals, over a one hour period.

You can filter the data more by using specific criteria. With most query types, except routing suggestions, you can filter by specifying one or more of the following criteria:

- **Amazon location:** For Amazon location, you can specify CloudFront or an Amazon Web Services Region, such as `us-east-2`.
- **ASN:** Specify the autonomous system number (ASN) of a DNS resolver (typically, an ISP), for example, 4225.
- **Client location:** For location, specify a city, metro, subdivision, or country.
- **Proposed Amazon location:** Specify an Amazon Web Services Region, such as `us-east-2`, or an Amazon Local Zone. You can use this filter with the overall traffic suggestions details query type.
- **Geo:** Specify `geo` for some queries. This is required for queries that use the `Top locations` query type, but not allowed for other query types. To understand when to specify `geo` for filter parameters, see the query examples section.

For the routing suggestions query type, you can filter the data more by specifying one or more of the following criteria:

- **Current Amazon location:** Specify an Amazon Web Services Region, such as `us-east-2`.
- **Proposed Amazon location:** Specify an Amazon Web Services Region, such as `us-east-2`, or an Amazon Local Zone.
- **IPv4 prefix:** Specify an IPv4 prefix in the standard format, similar to `192.0.2.0/24`.
- **Monitor ARN:** Specify the ARN for a specific monitor.
- **DNS resolver IP:** Specify the IP address of a DNS resolver.
- **DNS resolver ISP:** Specify the name of a DNS resolver (typically an ISP), for example, `Cloudflare`.
- **DNS resolver ASN:** Specify the autonomous system number (ASN) of a DNS resolver, for example, 4225.

The operators that you can use for filtering your data are `EQUALS` and `NOT_EQUALS`. For details about filtering parameters, see the FilterParameter API operation.

To see details about the query interface operations, see the following API operations in the Internet Monitor API Reference Guide:

- To create and run a query, see the StartQuery API operation.
- To stop a query, see the StopQuery API operation.
- To return data for a query that you've created, see the GetQueryResults API operation.
- To retrieve the status of a query, see the GetQueryStatus API operation.

Query examples

To create a query that you can use to retrieve a filtered set of data from your monitor's log file, you use the StartQuery API operation. You specify a query type and filter parameters for the query. Then, when you use the Internet Monitor query interface API operation to get query results using the query, it will retrieve the subset of your data that you want to work with.

To illustrate how query types and filter parameters work, let's look at some examples.

Example 1

Let's say that you want to retrieve all of your monitor's log file data for a specific country, except for one city. The following example shows filter parameters for a query that you could create with the `StartQuery` operation for this scenario.

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "MEASUREMENTS"
   FilterParameters: [
      {
       Field: "country",
       Operator: "EQUALS",
       Values: ["Germany"]
      },
      {
       Field: "city",
       Operator: "NOT_EQUALS",
       Values: ["Berlin"]
      },
    ]
}
```

Example 2

As another example, let's say that you want to see your top locations by metropolitan area. You could use the following example query for this scenario.

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "TOP_LOCATIONS"
   FilterParameters: [
      {
       Field: "geo",
       Operator: "EQUALS",
       Values: ["metro"]
      },
    ]
}
```

Example 3

Now, let's say that you want to see the top city-network combinations in the Los Angeles metro area. To do this, specify `geo=city`, and then set `metro` to Los Angeles. Now, the query returns the top city-networks in the Los Angeles metro area instead of the top metro+networks overall.

Here's the example query that you could use:

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "TOP_LOCATIONS"
   FilterParameters: [
      {
       Field: "geo",
       Operator: "EQUALS",
       Values: ["city"]
      },
      {
       Field: "metro",
       Operator: "EQUALS",
       Values: ["Los Angeles"]
      }
    ]
}
```

Example 4

Next, let's say that you want to retrieve TTFB data for a specific subdivision (for example, a U.S. state).

The following is an example query for this scenario:

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "TOP_LOCATION_DETAILS"
   FilterParameters: [
      {
       Field: "subdivision",
       Operator: "EQUALS",
       Values: ["California"]
      },
```

```
    ]
}
```

Example 5

Now, let's say that you want to retrieve TTFB data for every location where your application has client traffic.

The following is an example query for this scenario:

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "OVERALL_TRAFFIC_SUGGESTIONS"
   FilterParameters: []
}

Results:
[us-east-1, 40, us-west-2, 30],
[us-east-1, 40, us-west-1, 35],
[us-east-1, 40, us-east-1, 44],
[us-east-1, 40, CloudFront, 22],
...
[us-east-2, 44, us-west-2, 30],
[us-east-2, 44, us-west-1, 35],
...
```

Example 6

Let's say that you want to retrieve TTFB data for a specific new Amazon Web Services Region.

The following is an example query for this scenario:

```
{
   MonitorName: "TestMonitor"
   StartTime: "2023-07-12T20:00:00Z"
   EndTime: "2023-07-12T21:00:00Z"
   QueryType: "OVERALL_TRAFFIC_SUGGESTIONS_DETAILS"
   FilterParameters: [
      {
       Field: "proposed_aws_location",
```

```
         Operator: "EQUALS",
         Values: ["us-west-2"]
        },
    ]
}

Results:
[San Jose, San Jose-Santa Clara, California, United States, 7922, us-east-1, 40, 350,
 350, us-west-2, 45]
[San Jose, San Jose-Santa Clara, California, United States, 7922, us-west-1, 35, 450,
 450, us-west-2, 45]
```

Example 7

A final example is to retrieve data for specific DNS resolvers.

The following is an example query for this scenario:

```
{
    MonitorName: "TestMonitor"
    StartTime: "2023-07-12T20:00:00Z"
    EndTime: "2023-07-12T21:00:00Z"
    QueryType: "ROUTING_SUGGESTIONS"
    FilterParameters: [
        {
         Field: "proposed_aws_location",
         Operator: "EQUALS",
         Values: ["us-east-1"]
        },
    ]
}

Results:
[162.158.180.245, 13335, Cloudflare, [5.4.0.0/14], us-east-2, 200.0, us-east-1, 160.0]
[162.158.180.243, 13313, Cloudflare, [5.4.0.0/10], us-east-2, 150.0, us-east-1, 125.0]
```

Get query results

After you define a query, you can return a set of results with the query by running another Internet Monitor API operation, GetQueryResults. When you run `GetQueryResults`, you specify the query ID for the query that you've defined, along with the name of your monitor. `GetQueryResults` retrieves data for the specified query into a result set.

When you run a query, make sure that the query has finished running before you use `GetQueryResults` to look at the results. You can determine if the query has completed by using the [GetQueryStatus](#) API operation. When the `Status` for the query is `SUCCEEDED`, you can go ahead with reviewing the results.

When your query completes, you can use the following information to help you review the results. Each query type that you use to create a query includes a unique set of data fields from the log files, as described in the following list:

Measurements

The `measurements` query type returns the following data:

`timestamp, availability, performance, bytes_in, bytes_out, rtt_p50, rtt_p90, rtt_p95`

Top locations

The `top locations` query type groups data by location, and provides the data averaged over the time period. The data that it returns includes the following:

`aws_location, city, metro, subdivision, country, asn, availability, performance, bytes_in, bytes_out, current_fbl, best_ec2, best_ec2_region, best_cf_fbl`

Note that `city`, `metro`, and `subdivision` are only returned if you choose that location type for the geo field. The following location fields are returned, depending on the location type that you specify for geo:

```
city = city, metro, subdivision, country
metro = metro, subdivision, country
subdivision = subdivision, country
country = country
```

Top locations details

The `top locations details` query type returns data grouped hour by hour. The query returns the following data:

`timestamp, current_service, current_fbl, best_ec2_fbl, best_ec2_region, best_cf_fbl`

Overall traffic suggestions

The `overall traffic suggestions` query type returns data grouped hour by hour. The query returns the following data:

`current_aws_location, proposed_aws_location, average_fbl, traffic, optimized_traffic_excluding_cf, optimized_traffic_including_cf`

Overall traffic suggestions details

The `overall traffic suggestions details` query type returns data grouped hour by hour. The query returns the following data:

`aws_location, city, metro, subdivision, country, asn, traffic, current_aws_location, fbl_data`

Routing suggestions

The `routing suggestions` query type returns data grouped hour by hour. The query returns the following data:

`dns_resolver_ip, dns_resolver_asn, dns_resolver_isp, ipv4_prefixes, current_aws_location, current_latency, proposed_aws_location, proposed_latency`

When you run the `GetQueryResults` API operation, Internet Monitor returns the following in the response:

- A *data string array* that contains the results that the query returns. The information is returned in arrays that are aligned with the `Fields` field, also returned by the API call. Using the `Fields` field, you can parse the information from the `Data` repository and then further filter or sort it for your purposes.
- An *array of fields* that lists the fields that the query returned data for (in the `Data` field response). Each item in the array is a name-datatype pair, such as `availability_score-float`.

Troubleshooting

If errors are returned when you use query interface API operations, verify that you have the required permissions to use Internet Monitor. Specifically, make sure that you have the following permissions:

```
internetmonitor:StartQuery
internetmonitor:GetQueryStatus
internetmonitor:GetQueryResults
internetmonitor:StopQuery
```

These permissions are included in the recommended Amazon Identity and Access Management policy to use the Internet Monitor dashboard in the console. For more information, see Amazon managed policies for Internet Monitor.

Add a monitor using other Amazon services

A simple way to add monitoring with Internet Monitor is to choose to create a monitor when you add a supported resource when you create a resource—or use monitoring for the resource—in console.

Resources with an integrated option for adding Internet Monitor include the following:

- VPCs
- Network Load Balancers
- Amazon CloudFront distributions

The following sections provide more information about Internet Monitor integrations in the service consoles for supported resources.

Contents

Add a monitor with a Network Load Balancer

When you create a Network Load Balancer in the Amazon Web Services Management Console, you can optionally choose to also set up monitoring for traffic to and from the Network Load Balancer using a monitor in Internet Monitor. You can add the Network Load Balancer to an existing monitor, or you can opt to create a new monitor for your Network Load Balancer traffic.

By using Internet Monitor with your Network Load Balancer, you can view and evaluate measurements and metrics about availability, performance, monitored bytes transferred, and round-trip times that are specific to your application's client locations and ASNs (typically, internet service providers). Internet Monitor also determines when there are anomalies in performance and availability, and then creates health events in your monitor, which you can choose to be notified about. To learn more about how you can use a monitor to manage and improve your clients' experience with your application, see Use a monitor in Internet Monitor.

> **Important**
>
> To create a monitor, or add a Network Load Balancer to an existing monitor, you must have the correct permissions in place. For more information, see Identity and Access Management for Internet Monitor.

Add a Network Load Balancer to an existing monitor

When you create the Network Load Balancer in the Amazon Web Services Management Console, you can choose to have Internet Monitor add the new Network Load Balancer to an existing monitor. Under **Integrations**, choose Internet Monitor, and then choose **Add monitor**. Choose **Select an existing monitor**, and then enter a monitor name. Or choose **View monitors** to go to the Internet Monitor console, and then scroll down to see a list of available monitors.

After you add the Network Load Balancer to a monitor, wait a few minutes, and then metrics for traffic to and from the load balancer will start being shown on the Internet Monitor console. To learn more about the **Status** and **Data processing status** values, see Monitoring details in Internet Monitor (Configure page).

You can edit the monitor at any time, to remove the load balancer or add another Network Load Balancer, or other resources. You can also change the percentage of traffic that you're monitoring, or make other changes. If you choose to remove the Network Load Balancer from the monitor, traffic from clients to that load balancer is no longer monitored by Internet Monitor.

To learn more about updating a monitor, see Edit a monitor in Internet Monitor.

Create a monitor for a Network Load Balancer

Under **Integrations**, choose Internet Monitor, and then choose **Monitor resource traffic**. Choose **Create a new monitor**, and then enter a monitor name. Leave the default traffic percentage to monitor, 100%, or specify a custom percentage, and then choose **Create monitor**.

After you create the monitor, wait a few minutes, and then metrics for traffic to and from the Network Load Balancer will start being shown on the Internet Monitor console. If you like, you can also choose a percentage of client traffic that you want to monitor for your application (the default is 100%).

You can learn more by reviewing the information in Step 1: Create a monitor.

Pricing

With Internet Monitor, you pay only for what you use. Pricing for Internet Monitor has two components: a per monitored resource fee and a per city-network fee. A city-network is the location that clients access your application resources from and the network (an ASN, such as an internet service provider or ISP) that clients access the resources through.

For more information, including pricing examples, see Pricing for Internet Monitor.

Stop monitoring a Network Load Balancer

If you'd like to stop monitoring your Network Load Balancer resource with Internet Monitor, do the following in the Internet Monitor console:

To remove a resource from a monitor

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Update monitor**.
5. Under **Added resources**, choose **Remove resources**.
6. Choose the Network Load Balancer to remove, and then choose **Remove**.
7. Choose **Update**.

Add an Internet Monitor monitor with Amazon VPC

When you create a Amazon Virtual Private Cloud VPC in the Amazon Web Services Management Console, you can optionally choose to also set up monitoring for it in Internet Monitor. You can add the VPC to an existing monitor, or you can opt to create a new monitor for the VPC in the Amazon VPC console.

By using Internet Monitor with your VPC, you can view and evaluate measurements and metrics about availability, performance, monitored bytes transferred, and round-trip times that are specific to your application's client locations and ASNs (typically internet service providers). Internet Monitor also determines when there are anomalies in performance and availability and creates health events in your monitor, which you can choose to be notified about. To learn more about how you can use a monitor to manage and improve your clients' experience with your application, see Use a monitor in Internet Monitor.

> **Important**
>
> To create a monitor, or add a VPC to an existing monitor, you must have the correct permissions in place. For more information, see Identity and Access Management for Internet Monitor.

Add a VPC to an existing monitor

You can choose to have Internet Monitor add a new VPC to an existing monitor for you when you create the VPC in the Amazon Web Services Management Console. After you add the VPC, wait a few minutes, and then metrics for the VPC will start being shown on the Internet Monitor console.

You can edit the monitor at any time, to remove the VPC or add another VPC or other resources. You can also change the percentage of traffic that you're monitoring, or make other changes. If you choose to remove the VPC from the monitor, traffic from clients to that VPC is no longer monitored by Internet Monitor.

To learn more about updating a monitor, see Edit a monitor in Internet Monitor.

Create a monitor for a VPC

If you opt to create a monitor for a VPC, the **Create monitor** wizard walks you through the steps. You add the VPC as a monitored resource when you create the monitor. If you like, you can also choose a percentage of client traffic that you want to monitor for your application (the default is 100%).

You can learn more by reviewing the information in Step 1: Create a monitor.

Pricing

With Internet Monitor, you pay only for what you use. Pricing for Internet Monitor has two components: a per monitored resource fee and a per city-network fee. A city-network is the location that clients access your application resources from and the network (an ASN, such as an internet service provider or ISP) that clients access the resources through.

For more information, including pricing examples, see Pricing for Internet Monitor

Stop monitoring a VPC

If you'd like to stop monitoring your VPC resource with Internet Monitor, do the following in the Internet Monitor console:

To remove a resource from a monitor

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Update monitor**.
5. Under **Added resources**, choose **Remove resources**.
6. Choose the VPC to remove, and then choose **Remove**.
7. Choose **Update**.

Add an Internet Monitor monitor with CloudFront

On the metrics dashboard for a distribution in Amazon CloudFront console, you can set up additional monitoring for a distribution in Internet Monitor. You can add the distribution to an existing monitor, or you can create a new monitor for the distribution.

By using Internet Monitor with your CloudFront distribution, you can view and evaluate measurements and metrics about availability, performance, monitored bytes transferred, and round-trip times that are specific to your application's client locations and ASNs (typically internet service providers). Internet Monitor also determines when there are anomalies in performance and availability and creates health events in your monitor, which you can choose to be notified about. To learn more about how you can use a monitor to manage and improve your clients' experience with your application, see Use a monitor in Internet Monitor.

> **Important**
>
> To create a monitor, or add a distribution to an existing monitor, you must have the correct permissions in place. For more information, see Identity and Access Management for Internet Monitor.

Add a distribution to an existing monitor

You can choose to have Internet Monitor add a distribution to an existing monitor directly from the CloudFront metrics dashboard in the Amazon Web Services Management Console. After you add the distribution, wait a few minutes, and then metrics for the distribution will start being shown on the Internet Monitor console.

You can edit the monitor at any time, to remove the distribution or add another distribution or other resources. You can also change the percentage of traffic that you're monitoring, or make other changes. If you choose to remove the distribution from the monitor, traffic from clients to that distribution is no longer monitored by Internet Monitor.

To learn more about updating a monitor, see Edit a monitor in Internet Monitor.

Create a monitor for a distribution

If you opt to create a monitor for a distribution, the **Create monitor** wizard walks you through the steps. You add the distribution as a monitored resource when you create the monitor. If you like, you can also choose a percentage of client traffic that you want to monitor for your application (the default is 100%).

You can learn more by reviewing the information in Step 1: Create a monitor.

Pricing

With Internet Monitor, you pay only for what you use. Pricing for Internet Monitor has two components: a per monitored resource fee and a per city-network fee. A city-network is the location that clients access your application resources from and the network (an ASN, such as an internet service provider or ISP) that clients access the resources through.

For more information, including pricing examples, see Pricing for Internet Monitor.

Stop monitoring a distribution

If you'd like to stop monitoring your distribution resource with Internet Monitor, do the following in the Internet Monitor console:

To remove a resource from a monitor

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the left navigation pane, under **Network Monitoring**, choose **Internet monitors**.
3. Choose your monitor, and then choose the **Action** menu.
4. Choose **Update monitor**.
5. Under **Added resources**, choose **Remove resources**.
6. Choose the distribution to remove, and then choose **Remove**.
7. Choose **Update**.

Create alarms with Internet Monitor

You can create Amazon CloudWatch alarms based on Internet Monitor metrics, just as you can for other Amazon CloudWatch metrics.

For example, you can create an alarm based on the Internet Monitor metric `PerformanceScore`, and configure it to send a notification when the metric is lower than a value that you choose. You configure alarms for Internet Monitor metrics following the same guidelines as for other CloudWatch metrics.

Following are the example Internet Monitor metrics that you might choose to create an alarm for:

- **PerformanceScore**
- **AvailabilityScore**
- **RoundtripTime**

To see all the metrics available for Internet Monitor, see [View Internet Monitor metrics or set alarms in CloudWatch Metrics](#).

The following procedure provides an example of setting an alarm on **PerformanceScore** by navigating to the metric in the CloudWatch dashboard. Then, you follow the standard CloudWatch steps to create an alarm based on a threshold that you choose, and set up a notification or choose other options.

To create an alarm for PerformanceScore in CloudWatch Metrics

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Metrics**, and then choose **All metrics**.
3. Filter for Internet Monitor by choosing `AWS/InternetMonitor`.
4. Choose **MeasurementSource, MonitorName**.
5. In the list, select **PerformanceScore**.
6. On the **GraphedMetrics** tab, under **Actions**, choose the bell icon to create an alarm based on a static threshold.

Now, follow the standard CloudWatch steps to choose options for the alarm. For example, you can choose to be notified by an Amazon SNS message if **PerformanceScore** is below a specific threshold number. Alternatively, or in addition, you can add the alarm to a dashboard.

Keep in mind the following:

- Internet Monitor metrics are typically calculated and published within 20 minutes.
- When you create an alarm based on Internet Monitor metrics, make sure that you take into account the short delay before publication when you set an alarm's lookback period. We recommend that you configure **Evaluation Periods** with lookback period that is a minimum of 25 minutes.

To learn more about using CloudWatch alarms with Internet Monitor, see the following blog post: Using Internet Monitor for enhanced internet observability.

For more information about options when you create a CloudWatch alarm, see Create a CloudWatch alarm based on a static threshold.

Using Internet Monitor with Amazon EventBridge

Overall (global) health events that Internet Monitor creates for networking issues are published with Amazon EventBridge, so that you can send notifications about a degradation in end users' experience for your application due to a global health event.

> **Note**
>
> Local health events are not published with EventBridge.

To use EventBridge to work with Internet Monitor health events, follow the guidance here.

To set up a rule for Internet Monitor in EventBridge

1. In the Amazon Web Services Management Console, in EventBridge, choose **Rules**, then enter a name and a description. Create the rule on the **Default** event bus.
2. In Step 2, select **Other** for the event source, and then, under **Event pattern**, match the following source.

```
{
  "source": ["aws.internetmonitor"]
}
```

3. In Step 3, for the target, select **Amazon Service** and **CloudWatch Logs Group**, then select an existing log group or create a new one.
4. Add any desired tags, and then create the rule. This should populate your selected CloudWatch Logs Group with events from EventBridge.

For more information about how EventBridge rules work with event patterns, see [Amazon EventBridge event patterns] in the Amazon EventBridge User Guide.

Troubleshoot CloudWatch logs and metrics access errors

To support some features, Internet Monitor must interact with certain Amazon CloudWatch resources, including logs and metrics. If Internet Monitor can't access the CloudWatch resources that it requires access to, Internet Monitor sets a status code of `FAULT_ACCESS_CLOUDWATCH` for the monitor.

There are several reasons that your monitor might have the state `FAULT_ACCESS_CLOUDWATCH`. The following sections list possible causes for these errors, and suggested troubleshooting steps.

Internet Monitor couldn't access CloudWatch logs in your account

Internet Monitor publishes diagnostic logs about your monitored application traffic. It publishes these logs to log groups in CloudWatch Logs in the following location: `/aws/internet-monitor/monitor_name/[byCity|byMetro|bySubdivision|byCountry]`. Internet Monitor was unable to access these log groups.

Error states and potential solutions:

- **PutLogEvents throttling error:** The Internet Monitor service might have been throttled when it tried to publish your monitor's logs to CloudWatch. Review the throttling limits for your account, and, if necessary, request an increase in the limit.
- **Log group not found:** Disable, and then re-enable your monitor. Enabling a monitor restarts log group creation, which might correct the problem.
- **PutLogEvents access denied error:** Contact Amazon support for assistance.
- **PutLogEvents unknown or general error:** Contact Amazon support for assistance.

Internet Monitor couldn't access CloudWatch metrics in your account

Internet Monitor delivers specific CloudWatch metrics about the application traffic that is tracked by a monitor. An error occurred when Internet Monitor tried to deliver these metrics to CloudWatch.

Error states and potential solutions:

- **PutMetricData throttling error:** The Internet Monitor service might have been throttled when it tried to publish your monitor's metrics to CloudWatch. Review the throttling limits for your account, and, if necessary, request an increase in the limit.
- **PutMetricData access denied error:** Contact Amazon support for assistance.
- **PutMetricData unknown or general error:** Contact Amazon support for assistance.

Data protection and data privacy with Internet Monitor

The Amazon shared responsibility model applies to data protection and data privacy in Internet Monitor. As described in this model, Amazon is responsible for protecting the global infrastructure that runs all of the Amazon cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see The Amazon Shared Responsibility Model and GDPR blog post on the Amazon Security Blog. For more resources about complying with GDPR requirements, see the General Data Protection Regulation (GDPR) Center.

We strongly recommend that you never put sensitive identifying information, such as your end users' account numbers, email addresses, or other personal information, into free-form fields. Any data that you enter into Internet Monitor or other services might be included in diagnostic logs.

Identity and Access Management for Internet Monitor

Amazon Identity and Access Management (IAM) is an Amazon Web Services service that helps an administrator securely control access to Amazon resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Internet Monitor resources. IAM is an Amazon Web Services service that you can use with no additional charge.

Important

Internet Monitor resource changes on July 8, 2024
If you created IAM policies that included Internet Monitor resources before July 8, 2024, be aware of the following change to Internet Monitor resources and resource types:

- Resource-level permissions for the **GetHealthEvent** action are now supported only on the **Monitor** resource type. The permissions are not supported on the **HealthEvent** resource.

To see more information about the actions, resources, and condition keys that you can specify in policies to manage access to Amazon resources in Internet Monitor, see Actions, resources, and condition keys for Internet Monitor.

Contents

Upgrade IAM policies to IPv6

Internet Monitor customers use IAM policies to set an allowed range of IP addresses, to prevent any IP addresses outside the configured range from being able to access Internet Monitor APIs.

The *internetmonitor.`region`.api.aws* endpoint, where you access Internet Monitor APIs, is being upgraded to support dual-stack (IPv4 and IPv6).

IP address filtering policies that are not updated to handle IPv6 addresses might result in clients losing access to Internet Monitor APIs.

Customers impacted by the upgrade to include IPv6

Customers who are using dual-stack with policies that contain the *aws:sourceIp* filter are impacted by this upgrade. Dual-stack means that the network supports both IPv4 and IPv6.

If you use dual-stack, you must update your IAM policies that are currently configured with IPv4 format addresses to include IPv6 format addresses.

The following summarizes recommended actions, depending on your scenario. To confirm the endpoint that your SDK uses, see Identify the Internet Monitor endpoint used by your code.

Endpoint	Using IAM policy with `aws:sourceIp` condition?	Recommended action
`internetmonitor.region.amazonaws.com` (not dual-stack)	Yes	To restrict access to IPv4 only, take no further action. Or, if you anticipate that you will need IPv6 support in the future, you can take action to ensure compatibility with both IPv4 and IPv6. To ensure future compatibility, on or after November 1, 2024, update your SDK, and then update your application to use the dual-stack endpoint by setting `useDualstackEndpoi`

Endpoint	Using IAM policy with `aws:sourceIp` condition?	Recommended action
		`nt=true` . For more information, see Dual-stack and FIPS endpoints. If you choose to use both IPv4 and IPv6, you must also update the IP address filtering condition (`aws:sourceIp`) in your IAM policies to include IPv6 addresses.
`internetmonitor.region.amazonaws.com` (not dual-stack)	No	To restrict access to IPv4 only, take no further action. Or, if you anticipate that you will need IPv6 support in the future, you can take action to ensure compatibility with both IPv4 and IPv6. To ensure future compatibility, on or after November 1, 2024, update your SDK, and then update your application to use the dual-stack endpoint by setting `useDualstackEndpoint=true` . For more information, see Dual-stack and FIPS endpoints.

Endpoint	Using IAM policy with `aws:sourceIp` condition?	Recommended action
`internetmonitor.region.api.aws`	Yes	Currently, this endpoint supports only IPV4. On November 1, 2024, IPv6 will be enabled on this endpoint. To ensure future compatibility with both IPv4 and IPv6, on or after November 1, 2024, update your SDK, and then update your application to use the dual-stack endpoint by setting `useDualstackEndpoint=true` . For more information, see [Dual-stack and FIPS endpoints](#). When you make the change to use both IPv4 and IPv6, you must also update the IP address filtering condition (`aws:sourceIp`) in your IAM policies to include IPv6 addresses. If you instead want to restrict access to IPv4 only, set `useDualstackEndpoint=false` . For more information, see [Dual-stack and FIPS endpoints](#).

Endpoint	Using IAM policy with `aws:sourceIp` condition?	Recommended action
`internetmonitor.region.api.aws`	No	Currently, this endpoint supports only IPV4. On November 1, 2024, IPv6 will be enabled on this endpoint. To ensure future compatibility with both IPv4 and IPv6, on or after November 1, 2024, update your SDK, and then update your application to use the dual-stack endpoint by setting `useDualstackEndpoint=true` . For more information, see [Dual-stack and FIPS endpoints](#). If you instead want to restrict access to IPv4 only, set `useDualstackEndpoint=false` . For more information, see [Dual-stack and FIPS endpoints](#).

For help with access issues, contact Amazon Web Services Support.

What is IPv6?

IPv6 is the next generation IP standard intended to eventually replace IPv4. IPv4 uses a 32-bit addressing scheme, to support 4.3 billion devices. IPv6 instead uses 128-bit addressing, to support approximately 340 trillion trillion trillion (or 2 to the 128th power) devices.

The following are examples of IPv6 addresses:

```
2001:cdba:0000:0000:0000:0000:3257:9652
2001:cdba:0:0:0:0:3257:9652
```

```
2001:cdba::3257:965
```

IPv6 offers a larger address space, improved routing efficiency, and better support for new internet services. By updating to dual-stack and supporting IPv6, Internet Monitor enables improved performance and scalability. Follow the steps in this section to update your configurations and take advantage of dual-stack support.

Identify the Internet Monitor endpoint used by your code

If you use an Internet Monitor SDK, start by verifying which endpoint your code is using: the IPv4 endpoint or the dual-stack (IPv4 and IPv6) endpoint. If you don't use an SDK with Internet Monitor, you can skip this section.

You can run the following code example to determine the Internet Monitor endpoint that you're using. For this example, we're using the Internet Monitor SDK for Go in the US East (N. Virginia) Region.

```
package main

import (
    "fmt"
    "log"

    "github.com/aws/aws-sdk-go/aws"
    "github.com/aws/aws-sdk-go/aws/session"
    "github.com/aws/aws-sdk-go/service/internetmonitor"
)

func main() {
    // Create a new session with the default configuration
    sess := session.Must(session.NewSession(&aws.Config{
        Region: aws.String("us-east-1"),
    }))

    // Create a new Internet Monitor client
    internetMonitorClient := internetmonitor.New(sess)

    // Get the endpoint URL
    endpoint := internetMonitorClient.Endpoint

    fmt.Printf("Internet Monitor endpoint URL: %s\n", endpoint)
}
```

When you run this code, it returns the Internet Monitor endpoint. If you see the following response, you're using the Internet Monitor domain that supports only IPv4. You can tell because the format of the endpoint URL includes `amazonaws.com`.

```
Internet Monitor endpoint URL: https://internetmonitor.us-east-1.amazonaws.com
```

If you see the following response instead, then you're using the domain which is being upgraded to support dual-stack (IPv4 and IPv6). Here, you can tell because the endpoint URL includes `api.aws`. However, note that until the upgrade is complete, this endpoint supports only IPv4.

```
Internet Monitor endpoint URL: https://internetmonitor.us-east-1.api.aws
```

Update an IAM policy for IPv6

IAM policies use the `aws:SourceIp` filter to set an allowed range of IP addresses.

Dual-stack supports both IPv4 and IPV6 traffic. If your network uses dual-stack, you must ensure that any IAM polices that are used for IP address filtering are updated to include IPv6 address ranges.

For example, this policy allows IPv4 address ranges `192.0.2.0.*` and `203.0.113.0.*`, identified in the `Condition` element.

```
# https://docs.aws.amazon.com/IAM/latest/UserGuide/
reference_policies_examples_aws_deny-ip.html
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Deny",
        "Action": "*",
        "Resource": "*",
        "Condition": {
            "NotIpAddress": {
                "*aws:SourceIp*": [
                    "*192.0.2.0/24*",
                    "*203.0.113.0/24*"
                ]
            },
            "Bool": {
                "aws:ViaAWSService": "false"
```

```
            }
        }
    }
}
```

To update this policy, we'll change the policy's `Condition` element to add IPv6 address ranges, as shown in the following example:

```
"Condition": {
            "NotIpAddress": {
                "*aws:SourceIp*": [
                    "*192.0.2.0/24*", <<Existing IPv4 address - DO NOT REMOVE>>
                    "*203.0.113.0/24*", <<Existing IPv4 address  - DO NOT REMOVE>>
                    "*2001:DB8:1234:5678::/64*", <<New IPv6 IP address>>
                    "*2001:cdba:3257:8593::/64*" <<New IPv6 IP address>>
                ]
            },
            "Bool": {
                "aws:ViaAWSService": "false"
            }
        }
```

> **Important**
>
> Do not remove the existing IPv4 addresses in the policy. They are required for backward compatibility.

For more information about managing access permissions with IAM, see [Managed policies and inline policies](#) in the *Amazon Identity and Access Management User Guide*.

Test the network after updating policies

After you update your IAM policies to include support for IPv6 addresses, we recommend that you test that your network can access an IPv6 endpoint. This section provides several examples, depending on the operating system that you use.

Test network with Linux/Unix or Mac OS X

If you use Linux/Unix or Mac OS X, you can test that your network can access the IPv6 endpoint by using the following curl command.

```
curl -v -s -o /dev/null http://ipv6.ec2-reachability.amazonaws.com/
```

If you are connected over IPv6, the connected IP address displays information similar to the following:

```
* About to connect() to aws.amazon.com port 443 (#0)
*   Trying IPv6 address... connected
* Connected to aws.amazon.com (IPv6 address) port 443 (#0)
> GET / HTTP/1.1
> User-Agent: curl/7.18.1 (x86_64-unknown-linux-gnu) libcurl/7.18.1 OpenSSL/1.0.1t
 zlib/1.2.3
> Host: aws.amazon.com
```

Test network with Windows

If you use Windows, you can test that your network can access a dual-stack endpoint over IPv6 or IPv4 by using a `ping` command, such as the following:

```
ping aws.amazon.com
```

If `ping` accesses the endpoint over IPv6, the command returns IPv6 addresses.

Verify that clients can support IPv6

We recommend that before you switch to using the *internetmonitor.{region}.api.aws* endpoint, that you first verify that your clients can access other Amazon Web Services service endpoints that are already IPv6-enabled. The following steps describe how to verify this by using an existing IPv6 endpoint.

This example uses Linux and curl version 8.6.0, and uses the [Amazon Athena service](https://docs.aws.amazon.com/athena/latest/ug/what-is.html), which has IPv6-enabled endpoints located at the *api.aws* domain.

> **Note**
>
> Switch your Amazon Web Services Region to the same Region where the client is located. In this example, we use the US East (N. Virginia) – `us-east-1` endpoint.

Use the following example to verify that your clients can access an IPv6-enabled Amazon endpoint.

1. Verify that the Athena endpoint resolves with an IPv6 address by using the following command.

```
dig +short AAAA athena.us-east-1.api.aws
2600:1f18:e2f:4e05:1a8a:948e:7c08:d2d6
2600:1f18:e2f:4e03:4a1e:83b0:8823:4ce5
2600:1f18:e2f:4e04:34c3:6e9a:2b0d:dc79
```

2. Now, determine if your client network can make a connection using IPv6 by using the following command:

```
curl --ipv6 -o /dev/null --silent -w "\nremote ip: %{remote_ip}\nresponse code:
 %{response_code}\n" https://athena.us-east-1.api.aws

remote ip: 2600:1f18:e2f:4e05:1a8a:948e:7c08:d2d6
response code: 404
```

If the remote IP address was identified **and** the response code is not `0`, a network connection was successfully made to the endpoint using IPv6.

If the remote IP address is blank or the response code is `0`, the client network or the network path to the endpoint is IPv4-only. You can verify this with the following curl command:

```
curl -o /dev/null --silent -w "\nremote ip: %{remote_ip}\nresponse code:
 %{response_code}\n" https://athena.us-east-1.api.aws

remote ip: 3.210.103.49
response code: 404
```

If you run this command, and a remote IP address was identified **and** the response code is not `0`, a network connection was successfully made to the endpoint using IPv4.

How Internet Monitor works with IAM

Before you use IAM to manage access to Internet Monitor, learn what IAM features are available to use with Internet Monitor.

To see tables showing a similar high-level view of how Amazon services work with most IAM features, see Amazon services that work with IAM in the *IAM User Guide*.

IAM features you can use with Internet Monitor

IAM feature	Internet Monitor support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Principal permissions	Yes
Service roles	No
Service-linked roles	Yes

Identity-based policies for Internet Monitor

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Resource-based policies within Internet Monitor

Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource.

Policy actions for Internet Monitor

Supports policy actions: Yes

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated Amazon API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

To see a list of Internet Monitor actions, see [Actions defined by Internet Monitor]() in the *Service Authorization Reference*.

Policy actions in Internet Monitor use the following prefix before the action:

```
internetmonitor
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "internetmonitor:action1",
      "internetmonitor:action2"
         ]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word `Describe`, include the following action:

```
"Action": "internetmonitor:Describe*"
```

Policy resources for Internet Monitor

Supports policy resources: Yes

In the *Service Authorization Reference*, you can see the following information related to Internet Monitor:

- To see a list of Internet Monitor resource types and their ARNs, see Resources defined by Internet Monitor.
- To learn the actions that you can specify with the ARN of each resource, see Actions defined by Internet Monitor.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. Statements must include either a `Resource` or a `NotResource` element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

Policy condition keys for Internet Monitor

Supports service-specific policy condition keys: Yes

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element (or `Condition` *block*) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, Amazon evaluates them using a logical `AND` operation. If you specify multiple values for a single condition key, Amazon evaluates the condition using a logical `OR` operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see [IAM policy elements: variables and tags] in the *IAM User Guide*.

Amazon supports global condition keys and service-specific condition keys. To see all Amazon global condition keys, see [Amazon global condition context keys] in the *IAM User Guide*.

To see a list of Internet Monitor condition keys, see [Condition keys for Internet Monitor] in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see [Actions defined by Internet Monitor].

ACLs in Internet Monitor

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

ABAC with Internet Monitor

Supports ABAC (tags in policies): Partial

Internet Monitor has *partial* support for tags in policies. It supports tagging for one resource, monitors.

To use tags with Internet Monitor, use the Amazon Command Line Interface or an Amazon SDK. Tagging for Internet Monitor is not supported with the Amazon Web Services Management Console.

To learn more about using tags in policies in general, review the following information.

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In Amazon, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many Amazon resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

Using temporary credentials with Internet Monitor

Supports temporary credentials: Yes

Some Amazon Web Services services don't work when you sign in using temporary credentials. For additional information, including which Amazon Web Services services work with temporary credentials, see Amazon Web Services services that work with IAM in the *IAM User Guide*.

You are using temporary credentials if you sign in to the Amazon Web Services Management Console using any method except a user name and password. For example, when you access Amazon using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switch from a user to an IAM role (console) in the *IAM User Guide*.

You can manually create temporary credentials using the Amazon CLI or Amazon API. You can then use those temporary credentials to access Amazon. Amazon recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

Cross-service principal permissions for Internet Monitor

Supports forward access sessions (FAS): Yes

When you use an IAM user or role to perform actions in Amazon, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an Amazon Web Services service, combined with the requesting Amazon Web Services service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other Amazon Web Services services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

Service roles for Internet Monitor

Supports service roles: No

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an Amazon Web Services service in the *IAM User Guide*.

Service-linked role for Internet Monitor

Supports service-linked roles: Yes

A service-linked role is a type of service role that is linked to an Amazon Web Services service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your Amazon Web Services account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For more information about the service-linked role for Internet Monitor, see Service-linked role for Internet Monitor.

For details about creating or managing service-linked roles in general in Amazon, see Amazon services that work with IAM. Find a service in the table that includes a `Yes` in the **Service-linked role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

Amazon managed policies for Internet Monitor

An Amazon managed policy is a standalone policy that is created and administered by Amazon. Amazon managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that Amazon managed policies might not grant least-privilege permissions for your specific use cases because they're available for all Amazon customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in Amazon managed policies. If Amazon updates the permissions defined in an Amazon managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. Amazon is most likely to update an Amazon managed policy when a new Amazon Web Services service is launched or new API operations become available for existing services.

For more information, see Amazon managed policies in the *IAM User Guide*.

Amazon managed policy: CloudWatchInternetMonitorServiceRolePolicy

This policy is attached to the service-linked role named **AWSServiceRoleForInternetMonitor** to allow Internet Monitor to access resources in your account, such as Amazon Virtual Private Cloud resources or Network Load Balancers, so that you can select them when you create a monitor. For more information, see Service-linked role for Internet Monitor.

Amazon managed policy: CloudWatchInternetMonitorReadOnlyAccess

You can attach `CloudWatchInternetMonitorReadOnlyAccess` to your IAM entities. This policy grants access to read-only actions to work with monitors and data in with Internet Monitor. Attach it to IAM users and other principals who need access to only read-only actions.

Specifically, the scope of this policy includes `internetmonitor:` so that users can use read-only Internet Monitor actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch metrics. It includes some `logs:` policies to manage log queries.

To view the permissions for this policy, see CloudWatchInternetMonitorReadOnlyAccess in the *Amazon Managed Policy Reference*.

Amazon managed policy: CloudWatchInternetMonitorFullAccess

You can attach `CloudWatchInternetMonitorFullAccess` to your IAM entities. This policy grants full access to Actions for Internet Monitor for working with Internet Monitor. Attach it to IAM users and other principals who need full access to Internet Monitor actions.

Specifically, scope of this policy includes `internetmonitor:` so that users can use Internet Monitor actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `logs:` policies to manage log queries. It includes some `ec2:`, `cloudfront:`, `elasticloadbalancing:`, and `workspaces:` policies to work with resources that you add to monitors so that Internet Monitor can create a traffic profile for your application. It contains some `iam:` policies to manage IAM roles.

To view the permissions for this policy, see CloudWatchInternetMonitorFullAccess in the *Amazon Managed Policy Reference*.

Internet Monitor updates to Amazon managed policies

To view details about updates to Amazon managed policies for Internet Monitor since this service began tracking these changes, see CloudWatch updates to Amazon managed policies. For automatic alerts about managed policy changes in CloudWatch, subscribe to the RSS feed on the CloudWatch Document history page.

Service-linked role for Internet Monitor

Internet Monitor uses an Amazon Identity and Access Management (IAM) service-linked role. A service-linked role is a unique type of IAM role that is linked directly to Internet Monitor. The service-linked role is predefined by Internet Monitor and includes all the permissions that the service requires to call other Amazon services on your behalf.

Internet Monitor defines the permissions of the service-linked role, and unless defined otherwise, only Internet Monitor can assume the role. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the role only after first deleting its related resources. This restriction protects your Internet Monitor resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see Amazon services that work with IAM and look for the services that have **Yes** in the **Service-linked role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for Internet Monitor

Internet Monitor uses the service-linked role named **AWSServiceRoleForInternetMonitor**. This role allows Internet Monitor to access resources in your account, such as Amazon Virtual Private Cloud resources, Amazon CloudFront distributions, Amazon WorkSpaces directories, and Network Load Balancers, so that you can select them when you create a monitor.

This service-linked role uses the managed policy `CloudWatchInternetMonitorServiceRolePolicy`.

The **AWSServiceRoleForInternetMonitor** service-linked role trusts the following service to assume the role:

- `internetmonitor.amazonaws.com`

To view the permissions for this policy, see [CloudWatchInternetMonitorServiceRolePolicy] in the *Amazon Managed Policy Reference*.

Creating a service-linked role for Internet Monitor

You do not need to manually create the service-linked role for Internet Monitor. The first time that you create a monitor, Internet Monitor creates **AWSServiceRoleForInternetMonitor** for you.

For more information, see Creating a service-linked role in the *IAM User Guide*.

Editing a service-linked role for Internet Monitor

After Internet Monitor creates a service-linked role in your account, you cannot change the name of the role because various entities might reference the role. You can edit the description of the role using IAM. For more information, see Editing a service-linked role in the *IAM User Guide*.

Deleting a service-linked role for Internet Monitor

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete the role. That way you don’t have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for the service-linked role before you can manually delete it.

After you've removed your resources from your monitors in Internet Monitor and then deleted the monitors, you can delete the service-linked role **AWSServiceRoleForInternetMonitor**.

> **Note**
>
> If the Internet Monitor service is using the role when you try to delete it, then the deletion might fail. If that happens, wait for a few minutes and then try again.

To manually delete the service-linked role using IAM

Use the IAM console, the Amazon CLI, or the Amazon API to delete the **AWSServiceRoleForInternetMonitor** service-linked role. For more information, see Deleting a service-linked role in the *IAM User Guide*.

Updates to the Internet Monitor service-linked role

For updates to **AWSServiceRoleForInternetMonitor**, the Amazon managed policy for the Internet Monitor service-linked role, see CloudWatch updates to Amazon managed policies. For automatic alerts about managed policy changes in CloudWatch, subscribe to the RSS feed on the CloudWatch Document history page.

Quotas in Internet Monitor

Internet Monitor has the following quotas.

Resource	Default quota
Monitors per Region	50
Resources per monitor	50
Days that resolved Internet Monitor health events are retained	400

Using Network Synthetic Monitor

Network Synthetic Monitor provides visibility into the performance of the network connecting your Amazon hosted applications to your on-premises destinations, and allows you to identify the source of any network performance degradation within minutes. Network Synthetic Monitor is fully managed by Amazon, and doesn't require separate agents on monitored resources. Use Network Synthetic Monitor to visualize packet loss and latency of your hybrid network connections, and set alerts and thresholds. Then, based on this information, you can take action to improve your end users’ experience.

Network Synthetic Monitor is intended for network operators and application developers who want real-time insights into network performance.

Network Synthetic Monitor key features

- Use Network Synthetic Monitor to benchmark your changing hybrid network environment with continuous real-time packet loss and latency metrics.

- When you connect by using Amazon Direct Connect, Network Synthetic Monitor can help you to rapidly diagnose network degradation within the Amazon network with the network health indicator (NHI), which Network Synthetic Monitor writes to your Amazon CloudWatch account. The NHI metric is a binary value, based on a probabilistic score about whether network degradation is within Amazon.
- Network Synthetic Monitor provides a fully-managed agent approach to monitoring, so you don't need to install agents either on VPCs or on-premises. To get started, you just need to specify a VPC subnet and an on-premises IP address. You can establish a private connection between your VPC and Network Synthetic Monitor resources by using Amazon PrivateLink. For more information, see Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints.
- Network Synthetic Monitor publishes metrics to CloudWatch Metrics. You can create dashboards to view your metrics, and also create actionable thresholds and alarms on the metrics that are specific to your application.

For more information, see How Network Synthetic Monitor works.

Network Synthetic Monitor terminology and components

- **Probes** — A probe is the traffic that's sent from an Amazon-hosted resource to an on-premises destination IP address. Network Synthetic Monitor metrics measured by the probe are written into your CloudWatch account for every probe that's configured in a monitor.
- **Monitor** — A monitor displays network performance and other health information for traffic that you have created Network Synthetic Monitor *probes* for. You add probes as part of creating a monitor, and then you can view network performance metrics information using the monitor. When you create a monitor for an application, you add an Amazon hosted resource as the network source. Network Synthetic Monitor then creates a list of all possible probes between the Amazon hosted resource and your destination IP addresses. You select the destinations that you want to monitor traffic for.
- **Amazon network source** — An Amazon network source is a monitor probe's originating Amazon source, which is a subnet in one of your VPCs.
- **Destination** — A destination is the target in your on-premises network for the Amazon network source. A destination is a combination of your on-premises IP addresses, network protocols, ports, and network packet size. IPv4 and IPv6 addresses are both supported.

Network Synthetic Monitor requirements and limitations

The following summarizes requirements and limitations for Network Synthetic Monitor. For specific quotas (or limits), see Network Synthetic Monitor quotas.

- Monitor subnets must be owned by the same account as the monitor.
- Network Synthetic Monitor doesn't provide automatic network failover in the event of an Amazon network issue.
- There's a charge for each probe that you create. For pricing details, see Pricing for Network Synthetic Monitor.

How Network Synthetic Monitor works

Network Synthetic Monitor is fully managed by Amazon, and doesn't require separate agents on monitored resources. Instead, you specify *probes* by providing a VPC subnet and on-premises IP addresses.

When you create a monitor in Network Synthetic Monitor for Amazon-hosted resources, Amazon creates and manages the infrastructure in the background that is required to perform round-trip time and packet loss measurements. Because Amazon manages the required configurations, you can scale your monitoring rapidly, without needing to install or uninstall agents within your Amazon infrastructure.

When probes are created, customized elastic network interfaces (ENIs) are created and attached to probe instances and customer subnets. If Network Synthetic Monitor replaces a probe instance, for example, if it becomes unhealthy, Network Synthetic Monitor detaches the ENIs and reattaches them to the probe replacement. This means that ENI IP addresses are not changed after they are created, unless you delete a probe and create a new one for the same source and destination.

Network Synthetic Monitor focuses monitoring on the routes taken by flows from your Amazon-hosted resources instead of broadly monitoring all flows from your Amazon Web Services Region. If your workloads spread across multiple Availability Zones, Network Synthetic Monitor can monitor routes from each of your private subnets.

Network Synthetic Monitor publishes round-trip time and packet loss metrics to your Amazon CloudWatch account, based on the aggregation interval that you set when you create a monitor. You can also use CloudWatch to set individual latency and packet loss thresholds for each monitor.

For example, you might create an alarm for a packet loss sensitive workload to notify you if the packet loss average is higher than a static 0.1% threshold. You can also use CloudWatch anomaly detection to alarm on packet loss or latency metrics that are outside your desired ranges.

Availability and performance measurements

Network Synthetic Monitor sends periodic active probes from your Amazon resource to your on-premises destinations. When you create a monitor, you specify the following:

- **Aggregation interval:** The time, in seconds, that CloudWatch receives the measured results. This will be either every 30 or 60 seconds. The aggregation period you choose for the monitor applies to all probes in that monitor.
- **Probe sources (Amazon resources):** A source for a probe is a VPC and associated subnets, or just a VPC subnet, in the Regions where your network operates.
- **Probe destinations (customer resources):** A destination for a probe is the combination of on-premises IP addresses, network protocols, ports, and network packet size.
- **Probe protocol:** One of the supported protocols, ICMP or TCP. For more information, see Supported communication protocols.
- **Port (for TCP):** The port that your network uses to connect.
- **Packet size (for TCP):** The size, in bytes, of each packet transmitted between your Amazon hosted resource and your destination on a single probe. You can specify a different packet size for each probe in a monitor.

A monitor publishes the following metrics:

- **Round-trip time:** This metric, measured in microseconds, is a measure of performance. It records the time it takes for the probe to be transmitted to the destination IP address and for the associated response to be received. The round-trip time is the average time observed during the aggregation interval.
- **Packet loss:** This metric measures the percentage of total packets sent and records the number of transmissions that didn't receive an associated response. No response implies that the packets were lost along the network path.

Supported communication protocols

Network Synthetic Monitor supports two protocols for probes: ICMP and TCP.

ICMP-based probes carry ICMP echo requests from your Amazon hosted resources to the destination address, and expect an ICMP echo reply in response. Network Synthetic Monitor uses the information on the ICMP echo request and reply messages to calculate round-trip time and packet loss metrics.

TCP-based probes carry TCP SYN packets from your Amazon hosted resources to the destination address and port, and expect a TCP SYN+ACK packet in response. Network Synthetic Monitor uses the information on the TCP SYN and TCP SYN+ACK messages to calculate round-trip time and packet loss metrics. Network Synthetic Monitor periodically switches source TCP ports to increase network coverage, which increases the probability of detecting packet loss.

Network health indicator for Amazon

Network Synthetic Monitor publishes a network health indicator (NHI) metric that provides information on issues with the Amazon network for paths that include destinations connected through Amazon Direct Connect. NHI is not supported for Amazon Direct Connect attachments that are created using Cloud WAN or that use Amazon Transit Gateway. The NHI binary value is based on a statistical measure of the health of the Amazon-controlled network path from the Amazon hosted resource, where the monitor is deployed, to the Direct Connect location.

Network Synthetic Monitor uses anomaly detection to calculate availability drops or lower performance along the network paths.

> **Note**
>
> Each time that you create a new monitor, add a probe, or re-activate a probe, the NHI for the monitor is delayed by a few hours while Amazon collects data to perform anomaly detection.

To provide the NHI value, Network Synthetic Monitor applies statistical correlation across Amazon sample datasets, as well as to the packet loss and round-trip latency metrics for traffic simulating your network path. NHI can be one of two values: 1 or 0. A value of 1 indicates that Network Synthetic Monitor observed a network degradation within the Amazon controlled network path. A value of 0 indicates that Network Synthetic Monitor did not observe any network degradation for the Amazon network along the path. Using the NHI value enables you to more quickly gain awareness of the cause of network issues. For example, you can set alerts on the NHI metric so you're notified about ongoing issues with the Amazon network along your network paths.

Support for IPv4 and IPv6 addresses

Network Synthetic Monitor provides availability and performance metrics over IPv4 or IPv6 networks, and can monitor either IPv4 or IPv6 addresses from dual-stack VPCs. Network Synthetic Monitor doesn't allow both IPv4 and IPv6 destinations to be configured in the same monitor; you can create separate monitors for IPv4-only and IPv6-only destinations.

Supported Amazon Web Services Regions for Network Synthetic Monitor

The Amazon Web Services Regions where Network Synthetic Monitor is supported are listed in this section. For more information about Regions that Network Synthetic Monitor is supported in, including opt-in Regions, see Network Synthetic Monitor endpoints and quotas in the *Amazon Web Services General Reference*.

Region name	Region
Asia Pacific (Hong Kong)	ap-east-1
Asia Pacific (Mumbai)	ap-south-1
Asia Pacific (Seoul)	ap-northeast-2
Asia Pacific (Singapore)	ap-southeast-1
Asia Pacific (Sydney)	ap-southeast-2
Asia Pacific (Tokyo)	ap-northeast-1
Canada (Central)	ca-central-1
Europe (Frankfurt)	eu-central-1
Europe (Ireland)	eu-west-1
Europe (London)	eu-west-2
Europe (Paris)	eu-west-3
Europe (Stockholm)	eu-north-1

Region name	Region
Middle East (Bahrain)	me-south-1
South America (São Paulo)	sa-east-1
US East (N. Virginia)	us-east-1
US East (Ohio)	us-east-2
US West (N. California)	us-west-1
US West (Oregon)	us-west-2

Pricing for Network Synthetic Monitor

With Network Synthetic Monitor, there are no upfront costs or long-term commitments. Pricing for Network Synthetic Monitor has the following two components:

- An hourly fee per monitored Amazon resource
- CloudWatch metrics fees

When you create a monitor in Network Synthetic Monitor, you associate Amazon resources (sources) with it to be monitored. For Network Synthetic Monitor, these resources are subnets in Amazon Virtual Private Cloud (VPC). For each resource, you can create up to four probes, each of which is for traffic from a subnet in the VPC to four of your destination IP addresses. To help control your bill, you can adjust your subnet coverage and on-premises IP address destination coverage by reducing the number of resources that you monitor.

For more information about pricing, see the Amazon CloudWatch pricing page.

Network Synthetic Monitor API operations

The following table lists Network Synthetic Monitor API operations that you can use with Amazon CloudWatch. Refer to this table for links to relevant documentation.

Action	API reference	More information
Create a monitor between a source subnet and destination IP address.	See CreateMonitor	See Create a monitor
Create a probe within a monitor.	See CreateProbe	See Activate or deactivate a probe
Remove a monitor.	See DeleteMonitor	See Delete a monitor
Delete a specific probe.	See DeleteProbe	See Delete a probe
Get information about a monitor.	See GetMonitor	See Working with monitors and probes in Network Synthetic Monitor
Get information about a specific probe.	See GetProbe	See Working with monitors and probes in Network Synthetic Monitor
Get a list of all your monitors.	See ListMonitors	See Working with monitors and probes in Network Synthetic Monitor
List tags assigned to a resource.	See ListTagsForResource	See Tag or untag resources
Add key-value pairs, or tags, to a monitor or probe.	See TagResource	See Tag or untag resources
Remove a key-value pair, or tag, from a monitor or probe.	See UntagResource	See Tag or untag resources
Update an aggregation period for a monitor.	See UpdateMonitor	See Edit a monitor
Update a probe in a monitor.	See UpdateProbe	See Edit a probe

Working with monitors and probes in Network Synthetic Monitor

To get started, create a monitor with probes in Network Synthetic Monitor to measure network performance over a specified aggregation period. Then, you can update a monitor to make desired changes, for example, to change the aggregation period, deactivate or activate probes, or add or remove tags.

The following sections provide step-by-step instructions for completing these tasks for your monitors and probes by using the Amazon CloudWatch console. You can also make changes to your monitor by using the Amazon Command Line Interface.

Topics

Create a monitor

The following sections describe how to create a monitor in Network Synthetic Monitor, including the required probes. When you create a monitor, you specify probes by choosing source subnets, and then adding up to four destinations for each one. Each source-destination pair is a probe.

You can make changes to a monitor after you create it, for example, to add, remove, or deactivate probes. For more information, see Working with monitors and probes in Network Synthetic Monitor.

You can work with monitors and probes by using either the Amazon CloudWatch console or the Amazon Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the Amazon Command Line Interface Command Reference.

The following procedures provide step-by-step instructions for how to create a monitor by using the Amazon CloudWatch console.

- Define monitor details
- Choose sources and destinations
- Confirm probes
- Review and create monitor

> **Important**
>
> These steps are designed to be completed all at once. You can't save in-process work to continue later.

Define monitor details

The first step to create a monitor is to define the basic details, by giving the monitor a name and defining the aggregation period. Optionally, you can also add tags.

To define monitor details

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. Choose **Create monitor**.
3. For **Monitor name**, enter a name for the monitor.
4. For **Aggregation period**, choose how often you want to send metrics to CloudWatch: **30 seconds** or **60 seconds**.

   > **Note**
   >
   > A shorter aggregation period provides faster detection of network issues. However, the aggregation period that you choose can affect your billing costs. For more information about pricing, see the Amazon CloudWatch pricing page.

5. (Optional) For **Tags**, add **Key** and **Value** pairs to help identify this resource, so that you can search or filter on specific information.

1. Choose **Add new tag**.
2. Enter a **Key** name and associated **Value**.
3. Choose **Add new tag** to add the new tag.

   You can add multiple tags by choosing **Add new tag**, or you can remove a tag by choosing **Remove**.
4. If you want to associate your tags with the probes for the monitor, keep **Add tags to probes created by monitor** selected. This adds the tags to the monitor probes, which can be helpful for tag-based authentication or metering.

6. Choose **Next**. On the next page, you'll specify sources and destinations, to create probes for the monitor.

Choose sources and destinations

For each monitor in Network Synthetic Monitor, you specify one or more probes, which are a combination of an Amazon source and a destination.

- A source for a probe is a VPC and associated subnets (or just a VPC subnet) in the Regions where your network operates.
- A destination is the combination of on-premises IP addresses, network protocols, ports, and network packet size.

> **Important**
>
> These steps are designed to be completed all at once. You can't save in-process work to continue later.

To choose sources and destinations

1. Prerequisite: Define monitor details.
2. Under **Amazon network source**, choose one or more subnets to include in the monitor. To choose all subnets within a VPC, choose the VPC. Or, choose specific subnets within a VPC. The subnets that you choose are the monitor sources.

3. For **Destination 1**, enter a destination IP address of the on-premises network. IPv4 and IPv6 addresses are both supported.
4. Choose **Advanced settings**.
5. For **Protocol**, choose the network protocol for the on-premises destination. The protocol can be either **ICMP** or **TCP**.
6. If you choose **TCP**, enter the following information:
    1. Enter the **Port** that your network uses to connect. The port must be a number from **1** to **65535**.
    2. Enter the **Packet size**. This is the size, in bytes, of each packet that's sent on the probe, between the source and destination. Packet size must be a number from **56** to **8500**.
7. Choose **Add destination** to add another on-premises destination to the monitor. Repeat these steps for each destination that you want to add.
8. When you're finished adding sources and destinations, choose **Next** to confirm the probes for the monitor.

Confirm probes

On the **Confirm probes** page, review all the probes that will be created for the monitor, to make sure that they're the correct set of sources and destinations.

The **Confirm probes** page shows all the possible combinations of the sources and destinations for the probe specifications that you provided in the previous step. For example, if you have six source subnets and four destination IP addresses, there are 24 possible probe combinations, so 24 probes will be created.

> **Important**
>
> - These steps are intended to be completed in one session. You can't save in-process work to continue later.
> - The **Confirm probes** page does not indicate whether a probe is valid. We recommend that you review this page carefully, and then delete any probes that aren't valid. You might be charged for probes that aren't valid if you don't remove them.

To confirm monitor probes

1. Prerequisite: Choose sources and destinations.
2. On the **Confirm probes** page, review the list of source and destination probe combinations.
3. Choose any probes that you want to remove from the monitor, and then choose **Remove**.

> **Note**
>
> You are not prompted to confirm deleting a probe. If you delete a probe and want to restore it, you must set it up again. You can add a probe to an existing monitor by following the steps in Add a probe to a monitor.

4. Choose **Next**, and then review the monitor details.

Review and create monitor

The final step is to review the details of the monitor and the probes for the monitor, and then create the monitor. You can change any information about the monitor at this point.

When you have finished reviewing and updating any information that isn't correct, create the monitor.

As soon as you create the monitor, Network Synthetic Monitor begins tracking metrics and you'll start being charged for probes in the monitor.

> **Important**
>
> - This step is intended to be completed in one session. You can't save in-process work to continue later.
> - If you choose to edit a section, you must step through the process to create a monitor from the point that you make the edits. Earlier monitor creation pages maintain the information that you already entered.

To review and create a monitor

1. On the **Review and create probes** page, choose **Edit** for any section where you want to make changes.

2. Make changes in that section, and then choose **Next**.
3. When you're finished making edits, choose **Create monitor**.

   The Network Synthetic Monitor page displays the current state of monitor creation in the **Monitors** section. When Network Synthetic Monitor is still creating the monitor, the **State** is **Pending**. When the **State** changes to **Active**, you can view CloudWatch metrics in the monitor dashboard.

   For information on working with the monitor dashboard, see Network Synthetic Monitor dashboards.

> **Note**
>
> It can take several minutes for a newly-added monitor to begin collecting network metrics.

Edit a monitor

You can edit information for a Network Synthetic Monitor, including change the name, setting a new aggregation period, or adding or removing tags. Changing a monitor's information does not change any of its associated probes.

You can work with monitors and probes by using either the Amazon CloudWatch console or the Amazon Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the Amazon Command Line Interface Command Reference.

To edit a monitor using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. In the **Monitors** section, choose the monitor that you want to edit.
3. On the monitor dashboard page, choose **Edit**.
4. For the **Monitor name**, enter the new name for the monitor.
5. For the **Aggregation period**, choose how often you want to send metrics to CloudWatch. Valid periods are:

   - **30 seconds**

- **60 seconds**

> **Note**
>
> A shorter aggregation period provides faster detection of network issues. However, the aggregation period that you choose can affect your billing costs. For more information about pricing, see the [Amazon CloudWatch pricing] page.

6. (Optional) In the **Tags** section, add **Key** and **Value** pairs to further help identify this resource, allowing you to search or filter on specific information. You can also just change the **Value** of any current **Key**.

    1. Choose **Add new tag**.
    2. Enter a **Key** name and associated **Value**.
    3. Choose **Add new tag** to add the new tag.

        You can add multiple tags by choosing **Add new tag**, or you can remove a tag by choosing **Remove**.
    4. If you want to associate your tags with the monitor, keep **Add tags to probes created by monitor** checked. This adds the tags to the monitor probes, which can be helpful if you're using tag-based authentication or metering.

7. Choose **Save changes**.

Delete a monitor

Before you can delete a monitor in Network Synthetic Monitor, you must deactivate or delete all probes associated with the monitor, regardless of the monitor **State**. After a monitor is deleted, you are no longer be charged for probes in the monitor. Be aware that you can't restore a deleted monitor.

You can work with monitors and probes by using either the Amazon CloudWatch console or the Amazon Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the Amazon Command Line Interface Command Reference.

To delete a monitor using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. In the **Monitors** section, choose the monitor that you want to delete.
3. Choose **Actions**, and then choose **Delete**.
4. If you have any active probes for the monitor, you're prompted to deactivate them. Choose **Deactivate probes**.

   > **Note**
   >
   > You can't cancel or undo this action after you choose **Deactivate probes**. Deactivated probes, however, aren't removed from the monitor. If you like, you can reactivate them later. For more information, see Activate or deactivate a probe.

5. Enter **`confirm`** in the confirmation field, and then choose **Delete**.

Alternatively, you can delete a monitor programmatically, for example, by using the Amazon Command Line Interface.

To delete a monitor by using the CLI

1. To delete a monitor, you need the monitor name. If you don't know the name, get a list of your monitors by running the list-monitors command. Note the name of the monitor that you want to delete.
2. Verify whether the monitor contains any active probes. Use get-monitor with the monitor name from the previous step. This returns a list of any probes associated with that monitor.
3. If the monitor contains active probes, you must first either set the probes to inactive or delete them.
   - To set a probe to inactive, use update-probe, and set the state to `INACTIVE`.
   - To delete a probe, use delete-probe.
4. After the probes are set to `INACTIVE` or deleted, you can delete the monitor by running the delete-monitor command. Inactive probes are not deleted when you delete the monitor.

Activate or deactivate a probe

You can activate or deactivate a probe in a monitor in Network Synthetic Monitor. You might want to deactivate a probe, for example, if you aren't currently using it but might want to use it again in the future. By deactivating a probe instead of deleting it, you won't need to spend time setting it up again. You are not billed for deactivated probes.

You can work with monitors and probes by using either the Amazon CloudWatch console or the Amazon Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the Amazon Command Line Interface Command Reference.

To set a probe to active or inactive by using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. Choose the **Monitor details** tab.
3. In the **Probes** section, choose the probe that you want to activate or deactivate.
4. Choose **Actions**, and then choose **Activate** or **Deactivate**.

> **Note**
>
> When you reactivate a probe, you begin incurring billing charges on the probe again.

Add a probe to a monitor

You can add a probe to an existing monitor in Network Synthetic Monitor. Note that when you add probes to a monitor, your billing structure is updated to include the new probe.

You can work with monitors and probes by using either the Amazon CloudWatch console or the Amazon Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the Amazon Command Line Interface Command Reference.

To add a probe to a monitor using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.

2. In the **Monitors** section, do one of the following:

   - Choose the **Name** link of the monitor that you want to add a probe to. Choose the **Monitor details** tab, and then in the **Probes** section, choose **Add probe**.
   - Choose the monitor check box, choose **Actions**, and then choose **Add probe**.

3. On the **Add probe** page, do the following:

   1. Under **Amazon network source**, choose a subnet to add to the monitor.

      > **Note**
      >
      > You can only add one probe at a time and up to four probes per monitor.

   2. Enter the destination **IP address** of the on-premises network. Both IPv4 and IPv6 addresses are supported.
   3. Choose **Advanced settings**.
   4. Choose the network **Protocol** for the destination. It can be either **ICMP** or **TCP**.
   5. If the **Protocol** is **TCP**, enter the following information. Otherwise, skip to the next step:
      - Enter the **Port** that your network uses to connect. The port must be a number from **1** to **65535**.
      - Enter the **Packet size**. This is the size, in bytes, of each packet sent along the probe between the source and destination. Packet size must be a number from **56** to **8500**.

4. (Optional) In the **Tags** section, add **Key** and **Value** pairs to further help identify this resource, allowing you to search or filter on specific information.

   1. Choose **Add new tag**.
   2. Enter a **Key** name and associated **Value**.
   3. Choose **Add new tag** to add the new tag.

      You can add multiple tags by choosing **Add new tag**, or you can remove any tag by choosing **Remove**.

5. Choose **Add probe**.

   While the probe is being activated, the **State** shows **Pending**. It might take several minutes for the probe to become **Active**.

Edit a probe

You can change any information for an existing probe, regardless of whether that probe is active or inactive.

You can work with monitors and probes by using either the Amazon CloudWatch console or the Amazon Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the Amazon Command Line Interface Command Reference.

To edit a probe by using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.

   Under **Name**, choose a monitor link to open the monitor dashboard.
2. Choose the **Monitor details** tab.
3. In the **Probes** section, choose the link for the probe that you want to edit.
4. On the probe details page, choose **Edit**.
5. On the **Edit *probe*** page, enter the new destination **IP address** for the probe. IPv4 and IPv6 addresses are both supported.
6. Choose **Advanced settings**.
7. Choose a network **Protocol**, **ICMP** or **TCP**.
8. If the **Protocol** is **TCP**, enter the following information:

   - Enter the **Port** that your network uses to connect. The port must be a number from **1** to **65535**.
   - Enter the **Packet size**. This is the size, in bytes, of each packet sent along the probe between the source and destination. Packet size must be a number from **56** to **8500**.
9. (Optional) Add, change, or remove Tags for the probe.
10. Choose **Save changes**.

Delete a probe

You can delete a probe rather than deactivating it if you know that you won't need it again later. You can't recover a deleted probe; instead, you must recreate it. Billing charges end for a probe when the probe is deleted.

You can work with monitors and probes by using either the Amazon CloudWatch console or the Amazon Command Line Interface. To work with Network Synthetic Monitor programmatically, see the Network Synthetic Monitor API Reference and networkmonitor in the Amazon Command Line Interface Command Reference.

To delete a probe using the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.
2. In the **Monitors** section, under **Name**, choose a monitor link to open the monitor dashboard.
3. Choose the **Monitor details** tab.
4. Choose the monitor check box, choose **Actions**, and then choose **Delete**.
5. In the **Delete probe** dialog box, do the following:
6. Choose **Delete** to confirm that you want to delete the probe.

   The **State** of the probe in the **Probes** section shows **Deleting**. After it's deleted, the probe is removed from the **Probes** section.

Tag or untag resources

You can work with resource tags in Network Synthetic Monitor, to add or remove tags.

You can update tags by updating monitors or probes in the console. Or, you can work with tags programmatically, for example, by using the Amazon Command Line Interface.

To update monitor tags by using the CLI

- To list resource tags, use list-tags-for-resources.
- To tag a resource, use tag-resource.
- To untag a resource, use untag-resource.

Network Synthetic Monitor dashboards

You can use dashboards in Network Synthetic Monitor to determine if a network issue is caused by Amazon, by using the network health indicator (NHI), and view probe round-trip time and packet loss. You can view this information and metrics for monitors, as well as for individual probes.

Network Synthetic Monitor creates several metrics that you can view in CloudWatch Metrics. You can specify alarms for the metrics that Network Synthetic Monitor returns. For more information, see Probe alarms.

Topics

Monitor dashboards

You can use the monitor dashboard in Network Synthetic Monitor to view the network health indicator (NHI), as well as probe round-trip time and packet loss at a monitor level. That is, a monitor dashboard shows this information for all the probes created for the monitor.

Network Synthetic Monitor also has dashboards for probes, to view the information at a probe level. For more information, see Probe dashboards.

To access a monitor dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/, and then under **Network Monitoring**, choose **Synthetic monitors**.
2. In the **Monitors** section, choose the **Name** link to open the monitor dashboard.

Overview page

The **Overview** page displays the following information for a monitor:

- **Network health** — Network health displays the network health indicator (NHI) value, which pertains to health of only the Amazon network. The NHI status is displayed as **Healthy** or **Degraded**. A **Healthy** status indicates that Network Synthetic Monitor did not observe issues with the Amazon network. A **Degraded** status indicates that Network Synthetic Monitor observed an issue with the Amazon network. The status bar in this section shows the status of the network health indicator over a default time of one hour. Hover over any point in the status bar to view additional details.

- **Probe traffic summary** — Displays the current state of the traffic between the source Amazon subnets specified for the probes in the monitor and the probes' destination IP addresses. This summary displays the following:
  - **Probes in alarm** — This number indicates how many of your probes in this monitor are in a degraded state. An alarm is triggered when a metric that you've set up as an alarm is triggered. For information on creating alarms for metrics in Network Synthetic Monitor, see Probe alarms.
  - **Packet loss** — The number of packets that were lost from the source subnet to the destination IP address. This is represented as a percentage of the total packets sent.
  - **Round-trip time** — The time it takes, displayed in milliseconds, for a packet from the source subnet to reach the destination IP address, and then come back again. Round-trip time is the average RTT observed during the aggregation period.

The data is represented on an interactive graph, so you can explore to learn details.

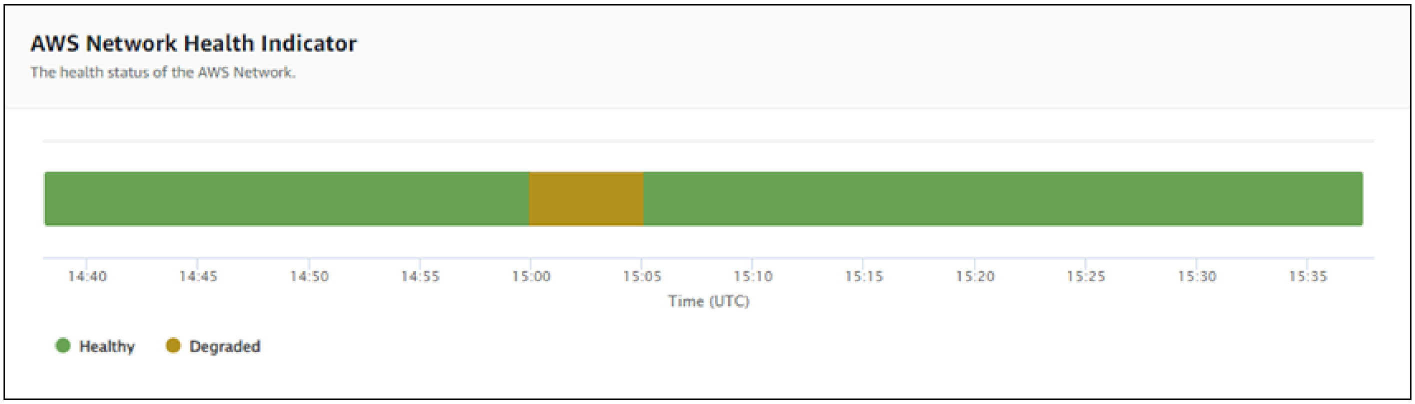
By default, data is displayed for a two-hour time frame, calculated from the current date and time. However, you can change the range to fit your needs. For more information, see Specify metrics time frame.

Tracking metrics

The **Overview** dashboard in Network Synthetic Monitor displays a graphical representation of a monitor and probes. The following graphs are shown:

- **Network health indicator** — This represents the the NHI values over a specified period. NHI indicates whether a network issue is due to problems with the Amazon network. NHI is displayed as **Healthy** (no issue with the Amazon network) or **Degraded** (there is an issue with the Amazon network).

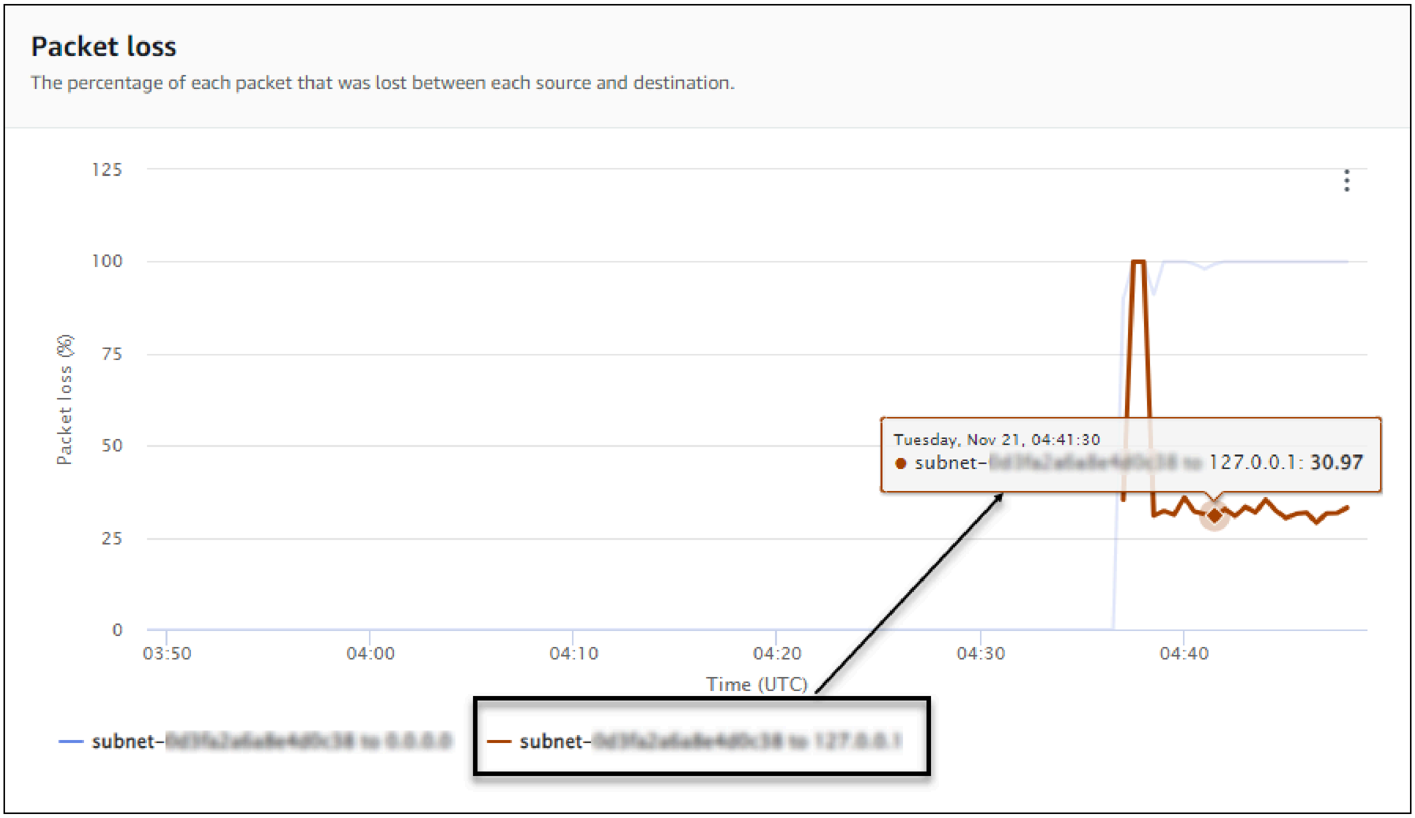
  In the following example, you can see that from 15:00 UTC until 15:05 UTC, there was a network issue that was due to an Amazon network issue **(Degraded**). After 15:05, the network issue with the Amazon network ended, so the value returned to **Healthy**. You can hover over any section of the graph to see additional details.



> **Note**
>
> The NHI indicates that an issue is due to the Amazon network. It does not describe the overall health of the Amazon network nor the health of Network Synthetic Monitor probes.

- **Packet loss** — This graph displays a line that shows the percentage of packet loss for each probe in a monitor. The legend at the bottom of the page displays each of the probes in the monitor, color-coded for uniqueness. You can hover over a probe in the chart to see the source subnet, the destination IP address, and the percentage of packet loss.

  In the following example, a packet loss alarm was created for a probe from a subnet to IP address 127.0.0.1. The alarm was triggered when the packet loss threshold was exceeded for the probe. If you hover over the graph, you can see the probe source and destination, and that there was a 30.97% packet loss for this probe on November 21 at 02:41:30.



- **Round-trip time** — This graph displays a line that shows the round-trip time for each probe. The legend at the bottom of the page displays each of the probes in the monitor, color-coded for uniqueness. You can hover over a probe in the chart to see the source subnet, the destination IP address, and the round-trip time.

  The following example shows that on Tuesday, Nov 21, at 21:45:30, the round-trip time for a probe from a subnet to IP address 127.0.0.1 was 0.075 seconds.

Monitor details

The **Monitor details** page displays details about your monitor, including a list of the probes for the monitor. You can update or add tags, or add a probe. The page includes the following sections:

- **Monitor details** — This page provides details about your monitor. You can't edit information in this section. However, you can view details of the Network Synthetic Monitor service-linked role: choose the **Role name** link to see details.
- **Probes** — This section displays a list of all probes associated with the monitor. Choose a **VPC** or **Subnet ID** link to open the VPC or subnet details in the Amazon VPC Console. You can modify a probe, to activate or deactivate it. For more information, see Working with monitors and probes in Network Synthetic Monitor.

  The **Probes** section displays information about each probe set up for that monitor, including the probe **ID**, the **VPC ID**, the **Subnet ID**, **IP address**, **Protocol**, and whether the probe is **Active** or **Inactive**.

  If you've created an alarm for a probe, the current **Status** of the alarm is shown. A status of **OK** indicates that there are no metrics events have triggered any alarms. A status of **In alarm** indicates that a metric that you created in CloudWatch triggered an alarm. If no status is displayed for a probe, then there isn't a CloudWatch alarm for it. For information on the types of Network Synthetic Monitor probe alarms that you can create, see Probe alarms.
- **Tags** — View the current tags for a monitor. You can add or remove tags by choosing **Manage tags**. This opens the **Edit probe** page. For more information on editing tags, see Edit a monitor.

Probe dashboards

You can use a **Probe** dashboard in Network Synthetic Monitor to view the network health indicator (NHI) for a probe, as well as information about round-trip time and packet loss for specific probes. There are two dashboards for probes: an **Overview** page and **Probe details** page.

You can create CloudWatch alarms to set packet loss and round-trip time metric thresholds. When a threshold is reached for a metric, a CloudWatch alarm notifies you. For information on creating probe alarms, see Probe alarms.

To access a probe dashboard

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/, and then, under **Network Monitoring**, choose **Synthetic monitors**.

2. In the **Monitors** section, choose the **Name** link to open the dashboard for a specific monitor.
3. To view the dashboard for a specific probe, choose the **ID** link for the probe.

Overview page

The **Overview** page displays the following information for a probe:

- **Network health** — Network health displays the network health indicator (NHI) value, which pertains only to health of the Amazon network. The NHI status is provided as **Healthy** or **Degraded**. A **Healthy** status indicates that Network Synthetic Monitor did not observe issues with the Amazon network for a probe. A **Degraded** status indicates that Network Synthetic Monitor observed an issue with the Amazon network. The status bar in this section shows the status of the network health indicator over a default time of one hour. Hover over any point in the status bar to view additional details.
- **Packet loss** — The number of packets that were lost from the source subnet to the destination IP address for this probe.
- **Round-trip time** — The time it takes, in milliseconds, for a packet from the source subnet to reach the destination IP address, and then come back again. Round-trip time (RTT) is the average RTT observed during the aggregation period.

Probe details

The **Probe details** page displays information about a probe, including the source and destination. You can also edit the probe, for example, to activate or deactivate it. For more information, see Working with monitors and probes in Network Synthetic Monitor.

- **Probe details** — This section provides general information about the probe, which can't be edited.
- **Probe source and destination** — This section displays details about the probe. Choose a **VPC** or **Subnet ID** link to open the VPC or subnet details in the Amazon VPC Console. You can modify a probe, for example, to activate or deactivate it.
- **Tags** — View the current tags for a monitor. You can add or remove tags by choosing **Manage tags**. This opens the **Edit probe** page. For more information on editing tags, see Edit a probe.

Specify metrics time frame

Metrics and events on the dashboards in Network Synthetic Monitor use a default time of two hours, calculated from the current time, but you can set a custom metrics default time frame to use. You can change the default to one of the following presets for the metrics time frame:

- **1h** — one hour
- **2h** — two hours
- **1d** — one day
- **1w** — one week

You can also set a custom time frame. Choose **Custom**, choose an **Absolute** or **Relative** time, and then set the time frame to a time of your own choosing. Relative time supports only 15 days back from today's date, following CloudWatch guidelines.

Additionally, you can choose the time displayed in the charts to be based on either the UTC time zone or a local time zone.

For more information, see Changing the time range or time zone format of a CloudWatch dashboard.

Probe alarms

You can create Amazon CloudWatch alarms based on Network Synthetic Monitor metrics, just as you can for other Amazon CloudWatch metrics. Any alarm that you create will appear in the probe's **Status** column of the **Monitor details** section of the Network Synthetic Monitor dashboard when the alarm is triggered. The status will either be **OK** or **In Alarm**. If no status displays for a probe, then no alarm was created for that probe.

For example, you can create an alarm based on the Network Synthetic Monitor metric `PacketLoss`, and configure it to send a notification when the metric is higher than a value that you choose. You configure alarms for Network Synthetic Monitor metrics following the same guidelines as for other CloudWatch metrics.

The following metrics are available under `AWS/NetworkMonitor` when creating a CloudWatch alarm for Network Synthetic Monitor.

- **HealthIndicator**

- **PacketLoss**
- **RTT (Round-trip time)**

For the steps to create a Network Synthetic Monitor alarm in CloudWatch, see Create a CloudWatch alarm based on a static threshold.

Data security and data protection in Network Synthetic Monitor

Cloud security at Amazon is the highest priority. As an Amazon customer, you benefit from data centers and network architectures that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between Amazon and you. The shared responsibility model describes this as security *of* the cloud and security *in* the cloud:

- **Security of the cloud** – Amazon is responsible for protecting the infrastructure that runs Amazon services in the Amazon Web Services Cloud. Amazon also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the Amazon Compliance Programs. To learn about the compliance programs that apply to Network Synthetic Monitor, see Amazon Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the Amazon service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Network Synthetic Monitor. The following topics show you how to configure Network Synthetic Monitor to meet your security and compliance objectives. You also learn how to use other Amazon services that help you to monitor and secure your Network Synthetic Monitor resources.

Topics

Data protection in Network Synthetic Monitor

The Amazon shared responsibility model applies to data protection in Network Synthetic Monitor. As described in this model, Amazon is responsible for protecting the global infrastructure that runs all of the Amazon Web Services Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the Amazon Web Services services that you use. For more information about data privacy, see the Data Privacy FAQ.

For data protection purposes, we recommend that you protect Amazon Web Services account credentials and set up individual users with Amazon IAM Identity Center or Amazon Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with Amazon resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with Amazon CloudTrail. For information about using CloudTrail trails to capture Amazon activities, see Working with CloudTrail trails in the *Amazon CloudTrail User Guide*.
- Use Amazon encryption solutions, along with all default security controls within Amazon Web Services services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing Amazon through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with Network Synthetic Monitor or other Amazon Web Services services using the console, API, Amazon CLI, or Amazon SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Infrastructure Security in Network Synthetic Monitor

As a managed service, Network Synthetic Monitor is protected by the Amazon global network security procedures that are described in the Amazon Web Services: Overview of Security Processes whitepaper.

You use Amazon published API calls to access Network Synthetic Monitor through the network. Clients must support Transport Layer Security (TLS) 1.0 or later. We recommend TLS 1.2 or later. Clients must also support cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the [Amazon Security Token Service](#) (Amazon STS) to generate temporary security credentials to sign requests.

Identity and access management for Network Synthetic Monitor

Amazon Identity and Access Management (IAM) is an Amazon service that helps an administrator securely control access to Amazon resources. IAM administrators control who can be authenticated (signed in) and authorized (have permissions) to use Network Synthetic Monitor resources. IAM is an Amazon service that you can use with no additional charge. You can use features of IAM to allow other users, services, and applications to use your Amazon resources fully or in a limited way, without sharing your security credentials.

By default, IAM users don't have permission to create, view, or modify Amazon resources. To allow an IAM user to access resources, such as a global network, and perform tasks, you must:

- Create an IAM policy that grants the user permission to use the specific resources and API actions they need
- Attach the policy to the IAM user or to the group to which the user belongs

When you attach a policy to a user or group of users, it allows or denies the user permissions to perform the specified tasks on the specified resources.

Condition keys

The `Condition` element (or Condition block) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can build conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request. For more information, see [IAM JSON policy elements: Condition operators](#) in the *Amazon Identity and Access Management User Guide*.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, Amazon evaluates them using a logical AND operation. If you specify multiple values for a single condition key, Amazon evaluates the condition using a logical `OR` operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name.

You can attach tags to Network Synthetic Monitor resources or pass tags in a request to Cloud WAN. To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys. See IAM JSON policy elements: Condition in the *Amazon Identity and Access Management User Guide* for more information.

To see all Amazon global condition keys, see Amazon global condition context keys in the *Amazon Identity and Access Management User Guide*.

Tag core network resources

A tag is a metadata label that either you or Amazon assigns to an Amazon resource. Each tag consists of a key and a value. For tags that you assign, you define the key and the value. For example, you might define the key as `purpose` and the value as `test` for one resource. Tags help you do the following:

- Identify and organize your Amazon resources. Many Amazon services support tagging, so you can assign the same tag to resources from different services to indicate that the resources are related.
- Control access to your Amazon resources. For more information, see Controlling access to Amazon resources using tags in the *Amazon Identify and Access Management User Guide*.

How Network Synthetic Monitor works with IAM

Before you use IAM to manage access to Network Synthetic Monitor, learn what IAM features are available to use with Network Synthetic Monitor.

IAM features you can use with Network Synthetic Monitor

IAM feature	Network Synthetic Monitor support
Identity-based policies	Yes

IAM feature	Network Synthetic Monitor support
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys	Yes
ACLs	No
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Principal permissions	Yes
Service roles	No
Service-linked roles	Yes

To get a high-level view of how Network Synthetic Monitor and other Amazon services work with most IAM features, see Amazon services that work with IAM in the *IAM User Guide*.

Identity-based policies for Network Synthetic Monitor

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for Network Synthetic Monitor

To view examples of Network Synthetic Monitor identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Resource-based policies within Network Synthetic Monitor

Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or Amazon Web Services services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different Amazon Web Services accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Policy actions for Network Synthetic Monitor

Supports policy actions: Yes

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated Amazon API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

To see a list of Network Synthetic Monitor actions, see Actions defined by Network Synthetic Monitor in the *Service Authorization Reference*.

Policy actions in Network Synthetic Monitor use the following prefix before the action:

```
networkmonitor
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "networkmonitor:action1",
      "networkmonitor:action2"
         ]
```

To view examples of Network Synthetic Monitor identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Policy resources for Network Synthetic Monitor

Supports policy resources: Yes

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. Statements must include either a `Resource` or a `NotResource` element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

To see a list of Network Synthetic Monitor resource types and their ARNs, see Resources defined by Network Synthetic Monitor in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions defined by Network Synthetic Monitor.

Policy condition keys for Network Synthetic Monitor

Supports service-specific policy condition keys: Yes

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element (or `Condition` *block*) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, Amazon evaluates them using a logical `AND` operation. If you specify multiple values for a single condition key, Amazon evaluates the condition using a logical `OR` operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the *IAM User Guide*.

Amazon supports global condition keys and service-specific condition keys. To see all Amazon global condition keys, see Amazon global condition context keys in the *IAM User Guide*.

To see a list of Network Synthetic Monitor condition keys, see Condition keys for Network Synthetic Monitor in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Network Synthetic Monitor.

ACLs in Network Synthetic Monitor

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

ABAC with Network Synthetic Monitor

Supports ABAC (tags in policies): Partial

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In Amazon, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many Amazon resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the [condition element](#) of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

Using temporary credentials with Network Synthetic Monitor

Supports temporary credentials: Yes

Some Amazon Web Services services don't work when you sign in using temporary credentials. For additional information, including which Amazon Web Services services work with temporary credentials, see Amazon Web Services services that work with IAM in the *IAM User Guide*.

You are using temporary credentials if you sign in to the Amazon Web Services Management Console using any method except a user name and password. For example, when you access Amazon using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switch from a user to an IAM role (console) in the *IAM User Guide*.

You can manually create temporary credentials using the Amazon CLI or Amazon API. You can then use those temporary credentials to access Amazon. Amazon recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

Cross-service principal permissions for Network Synthetic Monitor

Supports forward access sessions (FAS): Yes

When you use an IAM user or role to perform actions in Amazon, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an Amazon Web Services service, combined with the requesting Amazon Web Services service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other Amazon Web Services services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

Service roles for Network Synthetic Monitor

Supports service roles: No

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an Amazon Web Services service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break Network Synthetic Monitor functionality. Edit service roles only when Network Synthetic Monitor provides guidance to do so.

Using a service-linked role for Network Synthetic Monitor

Supports service-linked roles: Yes

A service-linked role is a type of service role that is linked to an Amazon Web Services service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your Amazon Web Services account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about creating or managing service-linked roles, see Amazon services that work with IAM. Find a service in the table that includes a `Yes` in the **Service-linked role** column. Choose the **Yes** link to view the service-linked role documentation for that service.

Identity-based policy examples for Network Synthetic Monitor

By default, users and roles don't have permission to create or modify Network Synthetic Monitor resources. They also can't perform tasks by using the Amazon Web Services Management Console, Amazon Command Line Interface (Amazon CLI), or Amazon API. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Create IAM policies (console) in the *IAM User Guide*.

For details about actions and resource types defined by Network Synthetic Monitor, including the format of the ARNs for each of the resource types, see Actions, resources, and condition keys for Network Synthetic Monitor in the *Service Authorization Reference*.

Topics

- Policy best practices
- Using the Network Synthetic Monitor console
- Allow users to view their own permissions
- Troubleshooting Network Synthetic Monitor identity and access

Policy best practices

Identity-based policies determine whether someone can create, access, or delete Network Synthetic Monitor resources in your account. These actions can incur costs for your Amazon Web Services account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with Amazon managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *Amazon managed policies* that grant permissions for many common use cases. They are available in your Amazon Web Services account. We recommend that you reduce permissions further by defining Amazon customer managed policies that are specific to your use cases. For more information, see Amazon managed policies or Amazon managed policies for job functions in the *IAM User Guide*.
- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific Amazon Web Services service, such as Amazon CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.

- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your Amazon Web Services account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the Network Synthetic Monitor console

To access the Network Synthetic Monitor console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the Network Synthetic Monitor resources in your Amazon Web Services account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the Amazon CLI or the Amazon API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

To ensure that users and roles can still use the Network Synthetic Monitor console, also attach the Network Synthetic Monitor `ConsoleAccess` or `ReadOnly` Amazon managed policy to the entities. For more information, see Adding permissions to a user in the *IAM User Guide*.

Allow users to view their own permissions

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the Amazon CLI or Amazon API.

```
{
    "Version": "2012-10-17",
```

```
    "Statement": [
        {
            "Sid": "ViewOwnUserInfo",
            "Effect": "Allow",
            "Action": [
                "iam:GetUserPolicy",
                "iam:ListGroupsForUser",
                "iam:ListAttachedUserPolicies",
                "iam:ListUserPolicies",
                "iam:GetUser"
            ],
            "Resource": ["arn:aws-cn:iam::*:user/${aws:username}"]
        },
        {
            "Sid": "NavigateInConsole",
            "Effect": "Allow",
            "Action": [
                "iam:GetGroupPolicy",
                "iam:GetPolicyVersion",
                "iam:GetPolicy",
                "iam:ListAttachedGroupPolicies",
                "iam:ListGroupPolicies",
                "iam:ListPolicyVersions",
                "iam:ListPolicies",
                "iam:ListUsers"
            ],
            "Resource": "*"
        }
    ]
}
```

Troubleshooting Network Synthetic Monitor identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Network Synthetic Monitor and IAM.

Topics

- I am not authorized to perform an action in Network Synthetic Monitor
- I am not authorized to perform iam:PassRole
- I want to allow people outside of my Amazon Web Services account to access my Network Synthetic Monitor resources

I am not authorized to perform an action in Network Synthetic Monitor

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a fictional *my-example-widget* resource but doesn't have the fictional `networkmonitor:GetWidget` permissions.

```
User: arn:aws-cn:iam::123456789012:user/mateojackson is not authorized to perform:
 networkmonitor:GetWidget on resource: my-example-widget
```

In this case, the policy for the `mateojackson` user must be updated to allow access to the *my-example-widget* resource by using the `networkmonitor:GetWidget` action.

If you need help, contact your Amazon administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to Network Synthetic Monitor.

Some Amazon Web Services services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in Network Synthetic Monitor. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws-cn:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your Amazon administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my Amazon Web Services account to access my Network Synthetic Monitor resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Network Synthetic Monitor supports these features, see How Amazon CloudWatch works with IAM.
- To learn how to provide access to your resources across Amazon Web Services accounts that you own, see Providing access to an IAM user in another Amazon Web Services account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party Amazon Web Services accounts, see Providing access to Amazon Web Services accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

Amazon managed policies for Network Synthetic Monitor

To add permissions to users, groups, and roles, it is easier to use Amazon managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our Amazon managed policies. These policies cover common use cases and are available in your Amazon account. For more information about Amazon managed policies, see Amazon managed policies in the *IAM User Guide*.

Amazon services maintain and update Amazon managed policies. You can't change the permissions in Amazon managed policies. Services occasionally add additional permissions to an Amazon managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an Amazon managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an Amazon managed policy, so policy updates won't break your existing permissions.

Additionally, Amazon supports managed policies for job functions that span multiple services. For example, the `ReadOnlyAccess` Amazon managed policy provides read-only access to all Amazon services and resources. When a service launches a new feature, Amazon adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see Amazon managed policies for job functions in the *IAM User Guide*.

Amazon managed policy: CloudWatchNetworkMonitorServiceRolePolicy

The `CloudWatchNetworkMonitorServiceRolePolicy` is attached to a service-linked role that allows the service to perform actions on your behalf and access resources associated with CloudWatch Network Synthetic Monitor. You cannot attach this policy to your IAM identities. For more information, see Using a service-linked role for Network Synthetic Monitor.

Network Synthetic Monitor updates to Amazon managed policies

View details about updates to Amazon managed policies for Network Synthetic Monitor since this service began tracking these changes in November 2023.

Change	Description	Date
CloudWatchNetworkMonitorServiceRolePolicy: New policy.	New policy added to Network Synthetic Monitor.	November 27, 2023
the section called "`AWSServiceRoleForNetworkMonitor`". New role.	New role added to Network Synthetic Monitor.	November 27, 2023

IAM permissions for Network Synthetic Monitor

To use Network Synthetic Monitor users must have the correct permissions.

For more information about security in Amazon CloudWatch, see Identity and access management for Amazon CloudWatch.

Permissions required to view a monitor

To view a monitor for Network Synthetic Monitor in the Amazon Web Services Management Console, you must be signed in as a user or role that has the following permissions:

```
{
"Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:GetMetricData",
                "networkmonitor:Get*",
                "networkmonitor:List*"
                ],
            "Resource": "*"
        }
    ]
}
```

Permissions required to create a monitor

To create a monitor in Network Synthetic Monitor, users must have permission to create a service-linked role that is associated with Network Synthetic Monitor. To learn more about the service-linked role, see [Using a service-linked role for Network Synthetic Monitor](#).

To create a monitor for Network Synthetic Monitor in the Amazon Web Services Management Console, you must be signed in as a user or role that has the permissions included in the following policy.

> **Note**
>
> If you create an identity-based permissions policy that is more restrictive, users with that policy won't be able to create a monitor.

```
{
"Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Effect": "Allow",
            "Action": [
                "networkmonitor:*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "iam:CreateServiceLinkedRole",
            "Resource": "arn:aws:iam::*:role/aws-service-role/
networkmonitor.amazonaws.com/AWSServiceRoleForNetworkMonitor",
            "Condition": {
                "StringLike": {
                    "iam:AWSServiceName": "networkmonitor.amazonaws.com"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:AttachRolePolicy",
                "iam:GetRole",
                "iam:PutRolePolicy"
            ],
            "Resource": "arn:aws:iam::*:role/aws-service-role/
networkmonitor.amazonaws.com/AWSServiceRoleForNetworkMonitor"
        },
        {
            "Action": [
                "ec2:CreateSecurityGroup",
                "ec2:CreateNetworkInterface",
                "ec2:CreateTags"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

Using a service-linked role for Network Synthetic Monitor

Network Synthetic Monitor uses the following service-linked role for the permissions that it requires to call other Amazon services on your behalf:

- [AWSServiceRoleForNetworkMonitor]

AWSServiceRoleForNetworkMonitor

Network Synthetic Monitor uses the service-linked role named `AWSServiceRoleForNetworkMonitor` to update and manage monitors.

The `AWSServiceRoleForNetworkMonitor` service-linked role trusts the following service to assume the role:

- `networkmonitor.amazonaws.com`

The `CloudWatchNetworkMonitorServiceRolePolicy` is attached to the service linked role and grants access for the service to access VPC and EC2 resources in your account, as well as manage the monitors that you create.

Permissions groupings

The policy is grouped into the following sets of permissions:

- **`cloudwatch`** - This allows the service principal to publish network monitoring metrics to CloudWatch resources.
- **`ec2`** - This allows the service principal to describe VPCs and subnets in your account to create or update monitors and probes. This also allows the service principal to create, modify, and delete security groups, network interfaces, and their associated permissions to configure the monitor or probe to send monitoring traffic to your endpoints.

To view the permissions for this policy, see [CloudWatchNetworkMonitorServiceRolePolicy] in the *Amazon Managed Policy Reference*.

Create the service-linked role

`AWSServiceRoleForNetworkMonitor`

You don't need to manually create the `AWSServiceRoleForNetworkMonitor` role.

- Network Synthetic Monitor creates the `AWSServiceRoleForNetworkMonitor` role when you create your first monitor with the feature. This role then applies to all additional monitors that you create.

To create a service-linked role on your behalf, you must have the required permissions. For more information, see [Service-Linked Role Permissions](#) in the *IAM User Guide*.

Edit the service-linked role

You can edit the `AWSServiceRoleForNetworkMonitor` descriptions using IAM. For more information, see [Editing a Service-Linked Role](#) in the *IAM User Guide*.

Delete the service-linked role

If you no longer need to use Network Synthetic Monitor, we recommend that you delete the `AWSServiceRoleForNetworkMonitor` role.

You can delete these service-linked roles only after you delete your monitors. For more information, see [Delete a monitor](#).

You can use the IAM console, the IAM CLI, or the IAM API to delete service-linked roles. For more information, see [Deleting a Service-Linked Role](#) in the *IAM User Guide*.

After you delete `AWSServiceRoleForNetworkMonitor` Network Synthetic Monitor will create the role again when you create a new monitor.

Supported Regions for the Network Synthetic Monitor service-linked role

Network Synthetic Monitor supports the service-linked role in all of Amazon Web Services Regions where the service is available. For more information, see [Amazon endpoints](#) in the *Amazon Web Services General Reference*.

Delete the service-linked role

If you no longer need to use Network Synthetic Monitor, we recommend that you delete the `AWSServiceRoleForNetworkMonitor` role.

You can delete these service-linked roles only after you delete your monitors. For more information, see [Delete a monitor](#).

You can use the IAM console, the IAM CLI, or the IAM API to delete service-linked roles. For more information, see [Deleting a Service-Linked Role](#) in the *IAM User Guide*.

After you delete `AWSServiceRoleForNetworkMonitor` Network Synthetic Monitor will create the role again when you create a new monitor.

Network Synthetic Monitor quotas

The following are the Network Synthetic Monitor quotas:

Quota	Default	Adjustable
Maximum number of monitors per account per Amazon Web Services Region	100	Yes
Maximum number of probes per monitor	24	Yes
Maximum number of probes per subnet per monitor	4	Yes

CloudWatch observability solutions

CloudWatch observability solutions offer a catalog of readily available configurations to help you quickly implement monitoring for various Amazon services and common workloads, such as Java Virtual Machines (JVM), Apache Kafka, Apache Tomcat, and NGINX. These solutions provide focused guidance on key monitoring tasks, including the installation and configuration of the CloudWatch agent, deployment of pre-defined custom dashboards, and setup of metric alarms. They are designed to assist developers and operations teams in leveraging Amazon monitoring and observability tools more effectively.

The solutions include guidance on when to use specific observability features like Detailed Monitoring metrics for infrastructure, Container Insights for container monitoring, and Application Signals for application monitoring. By providing working examples and practical configurations, these solutions aim to simplify the initial setup process, allowing you to establish functional monitoring more quickly and customize as needed for their specific requirements.

To get started with observability solutions, visit the observability solutions page in the CloudWatch console.

For open-source solutions that work with Amazon Managed Grafana, see Amazon Managed Grafana solutions

Solutions that require CloudWatch agent are detailed below:

Topics

- CloudWatch solution: JVM workload on Amazon EC2
- CloudWatch solution: NGINX workload on Amazon EC2
- CloudWatch solution: NVIDIA GPU workload on Amazon EC2
- CloudWatch solution: Kafka workload on Amazon EC2
- CloudWatch solution: Tomcat workload on Amazon EC2
- CloudWatch solution: Amazon EC2 health

How do solution dashboards work?

The dashboards for CloudWatch solutions use search-powered variables (dropdowns) that allow you to explore and visualize different aspects of your workloads dynamically.

By combining the flexibility of search-powered variables with the pre-configured metric widgets, the dashboard provides deep insights into your workloads, enabling proactive monitoring, troubleshooting, and optimization. This dynamic approach ensures that you can quickly adapt the dashboard to your specific monitoring needs, without the need for extensive customization or configuration.

Do solutions support cross-Region observability?

CloudWatch solution dashboards display metrics of the Region where the solution dashboard is created. However, the solution dashboard doesn't display metrics across multiple Regions. If you have a use case to view data from multiple Regions in a single dashboard, you'll need to customize the dashboard JSON to add the Regions that you want to view. To do this, use the `region` attribute of the metric format to query the metrics from different Regions. For more information about modifying dashboard JSON, see Metric Widget: Format for Each Metric in the Array.

Do solution dashboards support Cross-account cross-Region CloudWatch console?

When using CloudWatch cross-account observability, solution dashboards in the central monitoring account display metrics from source accounts in the same Region. To differentiate metrics for similar workloads across accounts, provide unique grouping dimension values in agent configurations. For instance, assign distinct `ClusterName` values for Kafka brokers in different accounts for Kafka workload, enabling precise cluster selection and metric viewing in the dashboard.

Do solution dashboards support CloudWatch cross-account observability?

If you have enabled cross-account using Cross-account cross-Region CloudWatch console, you won't be able to use the solution dashboard created in the monitoring account to view metrics from source accounts. Instead, you'll need to create dashboards in the respective source accounts. However, you can create the dashboard in the source account and view it from the monitoring account by switching the account ID setting in the console.

What are the limitations for a solution dashboard?

Solution dashboards leverage Search expressions to filter and analyze metrics for the workloads. This enables dynamic views based on dropdown option selections. These search expressions might return more than 500 time series, but each dashboard widget can't display more than 500 time series. If a metric search in the solution dashboard results in more than 500 time series across all Amazon EC2; instances, the graph displaying the top contributors might show inaccurate results. For more information about search expressions, see CloudWatch search expression syntax.

CloudWatch displays the metric information on the dashboards if you click the `i` icon on the dashboard widget. However, this currently doesn't work for dashboard widgets that use search expressions. The solution dashboards use search expressions, so you won't be able to see the metric description in the dashboard.

Can I customize the agent configuration or the dashboard provided by a solution?

You can customize the agent configuration and the dashboard. Be aware that if you customize the agent configuration, you must update the dashboard accordingly or it will display empty metric widgets. Also be aware that if CloudWatch releases a new version of a solution, you might have to repeat your customizations if you apply the newer version of the solution.

How are solutions versioned?

Each solution provides the most up-to-date instructions and resources. We always recommend using the latest version available. While the solutions themselves are not versioned, the associated artifacts (such as Amazon CloudFormation templates for dashboards and agent installations) are versioned.

You can identify the version of a previously deployed artifact by checking the Amazon CloudFormation template's description field or the filename of the template you downloaded. To determine if you're using the latest version, compare your deployed version with the one currently referenced in the solution documentation.

CloudWatch solution: JVM workload on Amazon EC2

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for JVM application running on EC2 instances. Additionally, it helps you set up a pre-configured CloudWatch dashboard. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions.

Topics

Requirements

This solution is relevant for the following conditions:

- Supported versions: Java LTS versions 8, 11, 17, and 21
- Compute: Amazon EC2
- Supports up to 500 EC2 instances across all JVM workloads in a given Amazon Web Services Region
- Latest version of CloudWatch agent
- SSM agent installed on EC2 instance

> **Note**
>
> Amazon Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by Amazon and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
> - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
> - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

The solution delivers JVM monitoring, providing valuable insights for the following use cases:

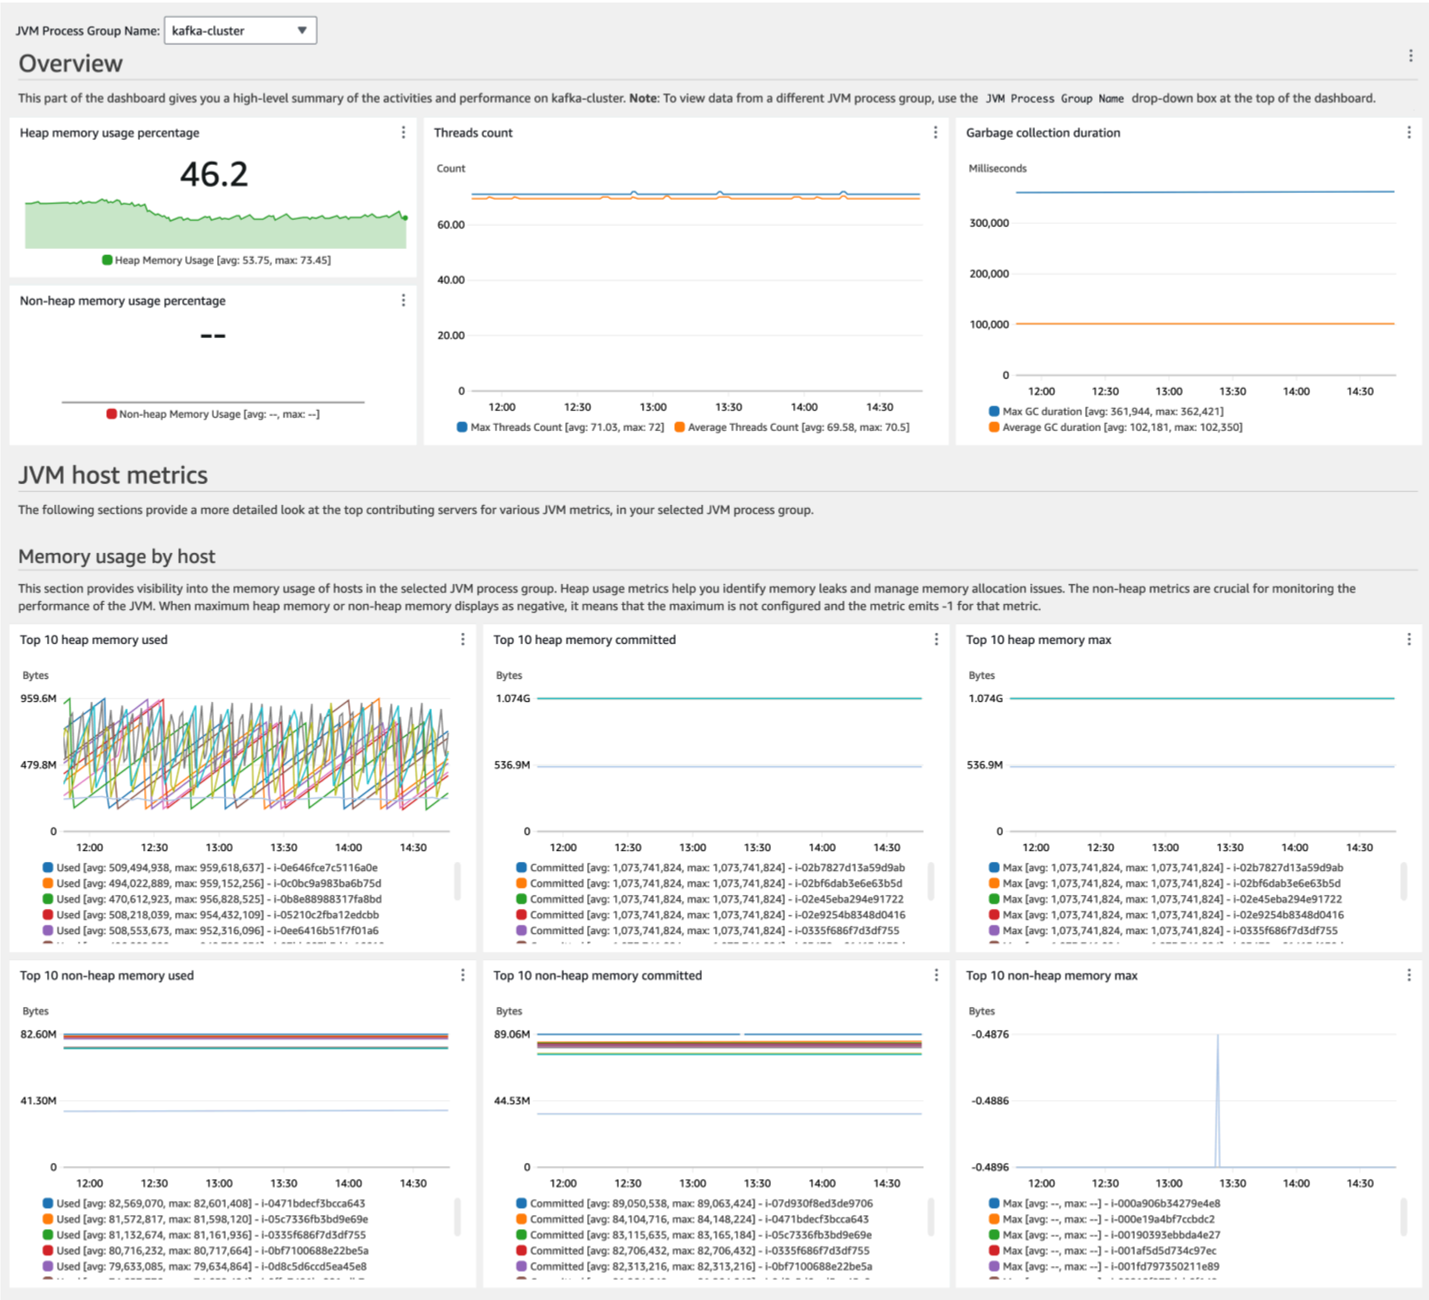
- Monitor JVM heap and non-heap memory usage.
- Analyze thread and class loading for concurrency issues.
- Track garbage collection to identify memory leaks.
- Switch between different JVM applications configured via the solution under the same account.

Below are the key advantages of the solution:

- Automates metric collection for JVM using CloudWatch agent configuration, eliminating manual instrumentation.
- Provides a pre-configured, consolidated CloudWatch dashboard for JVM metrics. The dashboard will automatically handle metrics from new JVM EC2 instances configured using the solution,

even if those metrics don't exist when you first create the dashboard. It also allows you to group the metrics into logical applications for easier focus and management.

The following image is an example of the dashboard for this solution.



Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.
  - Each JVM host configured for the solution publishes a total of 18 metrics plus one metric (`disk_used_percent`) for which the metric count depends on the number of paths for the host.
- One custom dashboard.
- API operations requested by the CloudWatch agent to publish the metrics. With the default configuration for this solution, the CloudWatch agent calls the **PutMetricData** once every minute for each EC2 host. This means the **PutMetricData** API will be called `30*24*60=43,200` in a 30-day month for each EC2 host.

For more information about CloudWatch pricing, see [Amazon CloudWatch Pricing](https://aws.amazon.com/cloudwatch/pricing/).

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the [Amazon CloudWatch pricing calculator](https://calculator.aws/#/createCalculator/CloudWatch).
2. For **Choose a Region**, select the Region where you would like to deploy the solution.
3. In the **Metrics** section, for **Number of metrics**, enter **`(18 + average number of disk paths per EC2 host) * number of EC2 instances configured for this solution`**.
4. In the **APIs** section, for **Number of API requests**, enter **`43200 * number of EC2 instances configured for this solution`**.

   By default, the CloudWatch agent performs one **PutMetricData** operation each minute for each EC2 host.
5. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
6. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see [Collect metrics, logs, and traces with the CloudWatch agent](#).

The agent configuration in this solution collects the foundational metrics for the solution. The CloudWatch agent can be configured to collect more JVM metrics than the dashboard displays by default. For a list of all JVM metrics that you can collect, see [Collect JVM metrics](#). For general information about CloudWatch agent configuration, see [Metrics collected by the CloudWatch agent](#).

Expose JMX ports for the JVM application

The CloudWatch agent relies on JMX to collect the metrics related to the JVM process. To make this possible, you must expose the JMX port from your JVM application. Instructions for exposing the JMX port depend on the workload type you are using for your JVM application. See the documentation for your application to find these instructions.

In general, to enable a JMX port for monitoring and management, you would set the following system properties for your JVM application. Be sure to specify an unused port number. The following example sets up unauthenticated JMX. If your security policies/requirements require you to enable JMX with password authentication or SSL for remote access, refer to the [JMX documentation](#) to set the required property.

```
-Dcom.sun.management.jmxremote
-Dcom.sun.management.jmxremote.port=port-number
-Dcom.sun.management.jmxremote.authenticate=false
-Dcom.sun.management.jmxremote.ssl=false
```

Review the starting scripts and configuration files of your application to find the best place to add these arguments. When you run a `.jar` file from the command line, this command could look like the following, where *`pet-search.jar`* is the name of the application jar.

```
$ java -jar -Dcom.sun.management.jmxremote -Dcom.sun.management.jmxremote.port=9999 -
Dcom.sun.management.jmxremote.authenticate=false -
Dcom.sun.management.jmxremote.ssl=false pet-search.jar
```

Agent configuration for this solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution’s dashboard.

The steps for deploying the solution are described later in Deploy the agent for your solution. The following information is intended to help you understand how to customize the agent configuration for your environment.

You must customize some parts of the following agent configuration for your environment:

- The JMX port number is the port number that you configured in the previous section of this documentation. It is in the `endpoint` line in the configuration.
- `ProcessGroupName`– Provide meaningful names for the `ProcessGroupName` dimension. These names should represent the cluster, application, or services grouping for EC2 instances running the same application or process. This helps you to group metrics from instances belonging to the same JVM process group, providing a unified view of cluster, application, and service performance in the solution dashboard.

For example, if you have two Java applications running in the same account, one for the `order-processing` application and another for the `inventory-management` application, you should set the `ProcessGroupName` dimensions accordingly in the agent configuration of each instance.

- For the `order-processing` application instances, set `ProcessGroupName=order-processing`.
- For the `inventory-management` application instances, set `ProcessGroupName=inventory-management`.

When you follow these guidelines, the solution dashboard will automatically group the metrics based on the `ProcessGroupName` dimension. The dashboard will include dropdown options to select and view metrics for a specific process group, allowing you to monitor the performance of individual process groups separately.

Agent configuration for JVM hosts

Use the following CloudWatch agent configuration on EC2 instances where your Java applications is deployed. Configuration will be stored as a parameter in SSM's Parameter Store, as detailed later in Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store.

Replace *`ProcessGroupName`* with the name of your process group. Replace *`port-number`* with the JMX port of your Java application. If JMX was enabled with password authentication or SSL for remote access, see [Collect Java Management Extensions (JMX) metrics] for information about setting up TLS or authorization in agent configuration as required.

The EC2 metrics shown in this configuration (configuration shown outside the JMX block) only work for Linux and macOS instances. If you are using Windows instances, you can choose to omit these metrics in the configuration. For information about metrics collected on Windows instances, see [Metrics collected by the CloudWatch agent on Windows Server instances].

```
{
  "metrics": {
    "namespace": "CWAgent",
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "jvm": {
            "measurement": [
              "jvm.classes.loaded",
              "jvm.gc.collections.count",
              "jvm.gc.collections.elapsed",
              "jvm.memory.heap.committed",
              "jvm.memory.heap.max",
              "jvm.memory.heap.used",
              "jvm.memory.nonheap.committed",
              "jvm.memory.nonheap.max",
              "jvm.memory.nonheap.used",
              "jvm.threads.count"
            ]
          },
          "append_dimensions": {
            "ProcessGroupName": "ProcessGroupName"
          }
        }
      ],
      "disk": {
        "measurement": [
          "used_percent"
        ]
      },
      "mem": {
```

```
          "measurement": [
            "used_percent"
          ]
        },
        "swap": {
          "measurement": [
            "used_percent"
          ]
        },
        "netstat": {
          "measurement": [
            "tcp_established",
            "tcp_time_wait"
          ]
        }
      }
    }
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single Amazon account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts where the workload is deployed and managing the agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge the agent configuration of JVM with your existing agent configuration, and then deploy the merged configuration. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances.

You can modify this configuration to suit your unique environment or use case. The metrics defined in this solution are the minimum required for the recommended dashboard.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.
- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an Amazon CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must also grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** and **AmazonSSMManagedInstanceCore** IAM policies attached.

- To create a role, see Create IAM roles to use with the CloudWatch agent on Amazon EC2 instances.
- After the role is created, attach the role to your EC2 instances. Follow the steps in Launch an instance with an IAM role to attach a role while launching a new EC2 instance. To attach a role to an existing EC2 instance, follow the steps in Attach an IAM role to an instance.

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. From the navigation pane, choose **Application Management**, **Parameter Store**.
3. Follow these steps to create a new parameter for the configuration.

    a. Choose **Create parameter**.

    b. In the **Name** box, enter a name that you'll use to reference the CloudWatch agent configuration file in later steps. For example, **`AmazonCloudWatch-JVM-Configuration`**.

    c. (Optional) In the **Description** box, type a description for the parameter.

    d. For **Parameter tier**, choose **Standard**.

    e. For **Type**, choose **String**.

    f. For **Data type**, choose **text**.

    g. In the **Value** box, paste the corresponding JSON block that was listed in Agent configuration for JVM hosts. Be sure to customize the grouping dimension value and port number as described.

    h. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an Amazon CloudFormation template

You can use Amazon CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json .
2. Verify that the selected Region on the console is the Region where the JVM workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.

4. In the **Parameters** section, specify the following:

   a. For **CloudWatchAgentConfigSSM**, enter the name of the Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-JVM-Configuration`**.

   b. To select the target instances, you have two options.

      i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.

      ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)

      If you specify both the **InstanceIds** and the **TagKeys** parameters, the **InstanceIds** will take precedence and the tags will be ignored.

5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see [Creating a stack on Amazon CloudFormation console](). You can use the following link to download the template: [https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json]().

> **Note**
>
> After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:
>
> 1. If the Systems Manager parameter is deleted, the agent will stop.
> 2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.

3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in Step 1: Ensure the target EC2 instances have the required IAM permissions.
- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in ???.

If everything is set up correctly, then you should see the JVM metrics being published to CloudWatch. You can check the CloudWatch console to verify they are being published.

To verify that JVM metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Metrics**, **All metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for the metrics mentioned in Agent configuration for JVM hosts, such as `jvm.memory.heap.used`. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the JVM solution dashboard

The dashboard provided by this solution presents metrics for the underlying Java Virtual Machine (JVM) for the server. It offers an overview of the JVM by aggregating and presenting metrics across all instances, providing a high-level summary of the overall health and operational state. Additionally, the dashboard shows a breakdown of the top contributors (top 10 per metric widget) for each metric. This helps you to quickly identify outliers or instances that significantly contribute to the observed metrics.

The solution dashboard doesn't display EC2 metrics. To view EC2 metrics, you'll need to use the EC2 automatic dashboard to see EC2 vended metrics and use the EC2 console dashboard to see EC2 metrics that are collected by the CloudWatch agent. For more information about automatic dashboards for Amazon services, see Viewing a CloudWatch dashboard for a single Amazon service.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use Amazon CloudFormation console to deploy the dashboard.
- Download the Amazon CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with Amazon CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the Amazon CloudFormation stack in the Region where your JVM metrics are published.
> If CloudWatch agent metrics are getting published to a different namespace than `CWAgent` (for example, if you've provided a customized namespace), you'll have to change the CloudFormation configuration to replace `CWAgent` with the customized namespace you are using.

To create the dashboard via CloudWatch Console

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage

collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=JvmOnEc2&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the JVM workload is running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`JVMDashboard-us-east-1`**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via Amazon CloudFormation

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.amazonaws.cn/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/JVM_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json .
2. Verify that the selected Region on the console is the Region where the JVM workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`JVMDashboardStack`**.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`JVMDashboard-us-east-1`**.
5. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that CloudFormation doesn't add any IAM resources.
6. Review the settings, then choose **Create stack**.

7. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file to customize it for any purpose, you can use **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on Amazon CloudFormation console. You can use this link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/JVM_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

Get started with the JVM dashboard

Here are a few tasks that you can try out with the new JVM dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor a JVM process group. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Select a process group

Use the **JVM Process Group Name** dropdown list to select the process group that you want to monitor. The dashboard automatically updates to display metrics for the selected process group. If you have multiple Java applications or environments, each might be represented as a separate process group. Selecting the appropriate process group ensures that you're viewing metrics specific to the application or environment that you want to analyze.

Review memory usage

From the dashboard overview section, find the **Heap Memory Usage Percentage** and **Non-Heap Memory Usage Percentage** widgets. These show the percentage of heap and non-heap memory being used across all JVMs in the selected process group. A high percentage indicates potential memory pressure that could lead to performance issues or `OutOfMemoryError` exceptions. You can also drill down to heap usage by host under **Memory usage by host** to check the hosts with high usage.

Analyze threads and classes loaded

In the **Threads and Classes Loaded by Host** section, find the **Top 10 Threads Count** and **Top 10 Classes Loaded** widgets. Look for any JVMs with an abnormally high number of threads or classes compared to others. Too many threads can indicate thread leaks or excessive concurrency, while a large number of loaded classes could point to potential class loader leaks or inefficient dynamic class generation.

Identify garbage collection issues

In the **Garbage Collection** section, find the **Top 10 Garbage Collections Invocations Per Minute** and **Top 10 Garbage Collection Duration** widgets for the different garbage collector types: **Young**, **Concurrent**, and **Mixed**. Look for any JVMs that have an unusually high number of collections or long collection durations compared to others. This could indicate configuration issues or memory leaks.

CloudWatch solution: NGINX workload on Amazon EC2

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for NGINX application running on EC2 instances. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions.

Topics

Requirements

This solution is relevant for the following conditions:

- Supported versions: NGINX version 1.24
- Compute: Amazon EC2
- Supports up to 500 EC2 instances across all NGINX workloads in a given Amazon Web Services Region
- Latest version of CloudWatch agent
- Prometheus Exporter: nginxinc/nginx-prometheus-exporter (Apache 2.0 license)
- SSM agent installed on EC2 instance

> **Note**
>
> Amazon Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by Amazon and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
> - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
> - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

The solution delivers NGINX monitoring, providing valuable insights for the following use cases:

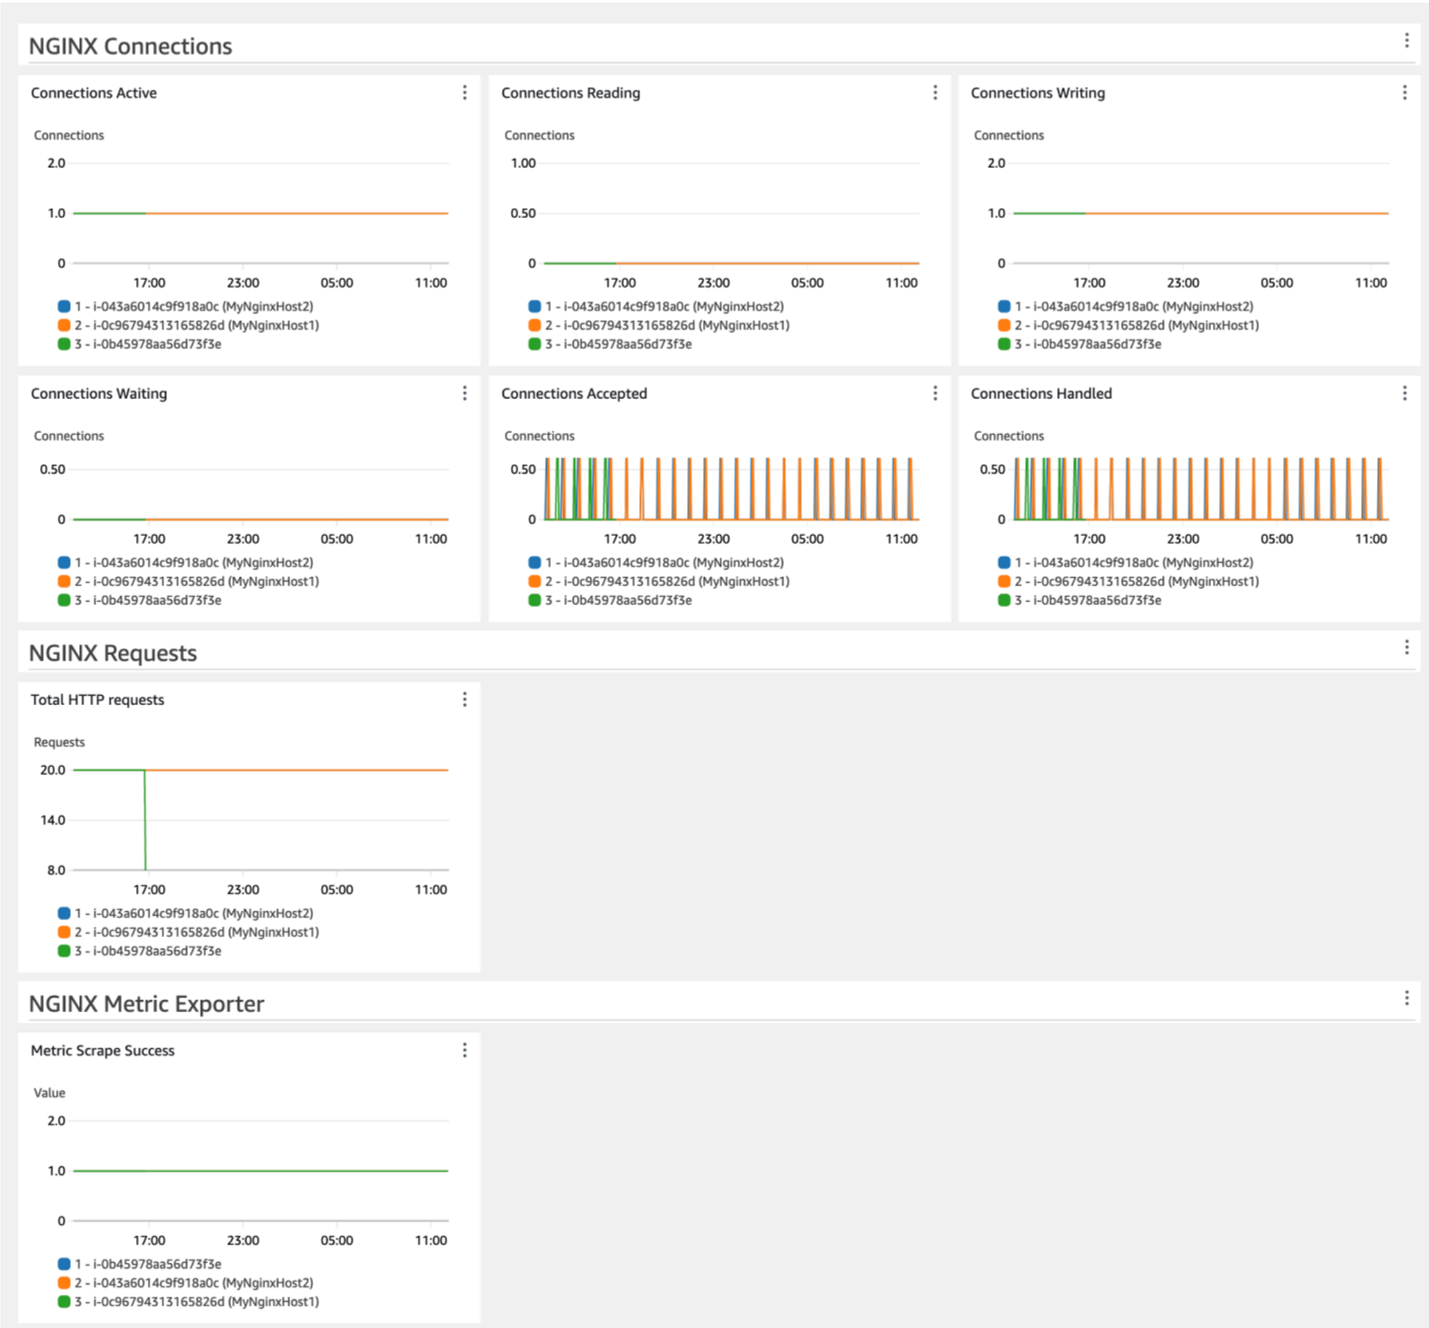
- Review connection metrics to identify potential bottlenecks, connection issues, or unexpected usage.
- Analyze HTTP request volume to understand overall traffic load on the NGINX.

Below are the key advantages of the solution:

- Automates metric collection for NGINX using CloudWatch agent configuration, eliminating manual instrumentation.

- Provides a pre-configured, consolidated CloudWatch dashboard for NGINX metrics. The dashboard will automatically handle metrics from new NGINX EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard.

The following image is an example of the dashboard for this solution.



Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent for this solution are published to CloudWatch Logs using the Embedded Metric Format (EMF). These CloudWatch logs are charged based on their volume and retention period. Therefore, you will not be billed for any **PutMetricData** API calls for this solution. The metrics extracted and ingested from your logs are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.
  - Each NGINX EC2 host configured for the solution publishes a total of eight metrics.
- One custom dashboard.

For more information about CloudWatch pricing, see [Amazon CloudWatch Pricing](#).

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the [Amazon CloudWatch pricing calculator](#).
2. For **Choose a Region**, select the Amazon Web Services Region where you would like to deploy the solution.
3. In the **Metrics** section, for **Number of metrics**, enter **`8 * number of EC2 instances configured for this solution`**.
4. In the **Logs** section, for **Standard Logs: Data Ingested**, enter the estimated daily log volume generated by the CloudWatch Agent across all EC2 hosts. For example, five EC2 instances produce less than 1000 bytes per day. Once set up, you can check your byte usage using the `IncomingBytes` metric, vended by CloudWatch Logs. Be sure to select the appropriate log group.
5. In the **Logs** section, for **Log Storage/Archival (Standard and Vended Logs)**, select **`Yes to Store Logs: Assuming 1 month retention`**. Modify this value if you decide to make custom changes to the retention period.
6. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
7. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces with the CloudWatch agent.

The agent configuration in this solution collects a set of metrics to help you get started monitoring and observing your NGINX workload. The CloudWatch agent can be configured to collect more NGINX metrics than the dashboard displays by default. For a list of all NGINX metrics that you can collect, see Metrics for NGINX OSS.

Before configuring the CloudWatch agent, you must first configure NGINX to expose its metrics. Secondly, you must install and configure the third party Prometheus metric exporter.

Expose NGINX metrics

Note

The following commands are for Linux. Check NGINX for Windows page for equivalent commands in Windows Server.

You must first enable the `stub_status` module. Add a new location block in your NGINX configuration file. Add the following lines in the `server` block of your `nginx.conf` to enable NGINX's `stub_status` module:

```
location /nginx_status {
          stub_status on;
          allow 127.0.0.1; # Allow only localhost to access
          deny all; # Deny all other IPs
        }
```

Before reloading NGINX, validate your NGINX configuration:

```
sudo nginx -t
```

This validation command helps to prevent any unforeseen errors, which can cause your website to gown down. The following example demonstrates a successful response:

```
nginx: the configuration file /etc/nginx/nginx.conf syntax is ok
nginx: configuration file /etc/nginx/nginx.conf test is successful
```

Once you've successfully validated the updated configuration, reload NGINX (no output is expected):

```
sudo systemctl reload nginx
```

This command instructs the NGINX process to reload the configuration. Reloads are more graceful compared to a full restart. A reload starts the new worker process with a new configuration, gracefully shutting down old worker processes.

Test the NGINX status endpoint:

```
curl http://127.0.0.1/nginx_status
```

The following example demonstrates a successful response:

```
Active connections: 1
server accepts handled requests
6 6 6
Reading: 0 Writing: 1 Waiting: 0
```

The following example demonstrates a failure response (review the previous steps before proceeding):

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN" "http://www.w3.org/TR/xhtml11/DTD/
xhtml11.dtd">
  <html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en">
      <head>
          <title>The page is not found</title>
          ...
```

Configure Prometheus metric exporter

Download the latest NGINX Prometheus exporter release from the official GitHub repository. You must download the relevant binary for your platform.

The following example demonstrates commands for AMD64:

```
cd /tmp
wget https://github.com/nginxinc/nginx-prometheus-exporter/releases/download/v1.3.0/
nginx-prometheus-exporter_1.3.0_linux_amd64.tar.gz
tar -xzvf nginx-prometheus-exporter_1.3.0_linux_amd64.tar.gz
sudo cp nginx-prometheus-exporter /usr/local/bin/
rm /tmp/nginx-prometheus-exporter*
```

Run the Prometheus exporter and point it to the NGINX stub status page:

```
nohup /usr/local/bin/nginx-prometheus-exporter -nginx.scrape-uri http://127.0.0.1/
nginx_status &>/dev/null &
```

The following example demonstrates a response (background job ID and PID):

```
[1] 74699
```

Test the NGINX Prometheus endpoint

Validate that the NGINX Prometheus exporter has started to expose the relevant metrics:

```
curl http://localhost:port-number/metrics
```

The following example demonstrates a successful response:

```
# HELP go_gc_duration_seconds A summary of the pause duration of garbage collection
 cycles.
# TYPE go_gc_duration_seconds summary
go_gc_duration_seconds{quantile="0"} 0
go_gc_duration_seconds{quantile="0.25"} 0
...
# HELP nginx_connections_accepted Accepted client connections
# TYPE nginx_connections_accepted counter
nginx_connections_accepted 14
# HELP nginx_connections_active Active client connections
# TYPE nginx_connections_active gauge
nginx_connections_active 1
...
# TYPE promhttp_metric_handler_requests_total counter
promhttp_metric_handler_requests_total{code="200"} 1
```

```
promhttp_metric_handler_requests_total{code="500"} 0
promhttp_metric_handler_requests_total{code="503"} 0
```

Agent configuration for this solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard.

The steps for deploying the solution are described later in Deploy the agent for your solution. The following information is intended to help you understand how to customize the agent configuration for your environment.

You must customize some parts of the agent and Prometheus configurations for your environment such as the port number used by the Prometheus exporter.

The port used by the Prometheus exporter can be verified using the following command:

```
sudo netstat -antp | grep nginx-prom
```

The following example demonstrates a response (see port value 9113):

```
tcp6 0 0 :::9113 :::* LISTEN 76398/nginx-prometh
```

Agent configuration for NGINX hosts

The CloudWatch agent with Prometheus monitoring needs two configurations to scrape the Prometheus metrics. Each configuration will be stored as a separate parameter in SSM's Parameter Store, as detailed later in Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store.

The first configuration is for the Prometheus exporter, as documented in Prometheus' scrape_config documentation. The second configuration is for the CloudWatch agent.

Prometheus configuration

Replace *port-number* with the port of your server.

```
global:
  scrape_interval: 30s
```

```
  scrape_timeout: 10s

scrape_configs:
- job_name: 'nginx'
  metrics_path: /metrics
  static_configs:
    - targets: ['localhost:port-number']
  ec2_sd_configs:
    - port: port-number
  relabel_configs:
    - source_labels: ['__meta_ec2_instance_id']
      target_label: InstanceId
  metric_relabel_configs:
    - source_labels: ['__name__']
      regex: 'nginx_up|nginx_http_requests_total|nginx_connections_.*'
      action: keep
```

CloudWatch agent configuration

As per the previous CloudWatch agent configuration, these metrics are published via CloudWatch Logs using the embedded metric format (EMF). These logs are configured to use the log group `nginx`. You can customize the *log_group_name* with a different name that represents the CloudWatch logs.

If you are using Windows Server, set *prometheus_config_path* in the following configuration to `C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\prometheus.yaml`.

```
{
"agent": {
  "metrics_collection_interval": 60
},
"logs": {
  "metrics_collected": {
      "prometheus": {
          "log_group_name": "nginx",
          "prometheus_config_path": "/opt/aws/amazon-cloudwatch-agent/etc/
prometheus.yaml",
          "emf_processor": {
              "metric_declaration_dedup": true,
              "metric_namespace": "CWAgent",
              "metric_declaration":[
                  {
                      "source_labels":["InstanceId"],
```

```
                        "metric_selectors":["nginx_up", "nginx_http_requests_total",
 "nginx_connections*"],
                        "dimensions": [["InstanceId"]]
                    }
                ]
            }
        }
    }
}
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single Amazon account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts where the workload is deployed and managing agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge new CloudWatch agent and Prometheus configurations with your existing configurations, and then deploy the merged configurations. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances. You can modify this configuration to suit your unique environment or use case. The metrics defined in configuration are the minimum required for the dashboard provided the solution.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.

- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an Amazon CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. You must also grant the CloudWatch agent EC2 read access. EC2 read access is required for the EC2 InstanceId to be added as a metric dimension. This additional requirement is driven by `prometheus.yaml` as detailed above because it uses `__meta_ec2_instance_id` via EC2 Service Discovery.

Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy**, **AmazonSSMManagedInstanceCore**, and **AmazonEC2ReadOnlyAccess** IAM policies attached.

- To create a role, see [Create IAM roles to use with the CloudWatch agent on Amazon EC2 instances](#).
- After the role is created, attach the role to your EC2 instances. To attach a role to an EC2 instance, follow the steps in [Attach an IAM role to an instance](#).

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.

2. Verify that the selected Region on the console is the Region where NGINX is running.
3. From the navigation pane, choose **Application Management**, **Parameter Store**
4. Follow these steps to create a new parameter for the configuration.

   a. Choose **Create parameter**.
   b. In the **Name** box, enter a name that you'll use to reference the CloudWatch agent configuration file in later steps. For example, **`AmazonCloudWatch-NGINX-CloudWatchAgent-Configuration`**.
   c. (Optional) In the **Description** box, type a description for the parameter.
   d. For **Parameter tier**, choose **Standard**.
   e. For **Type**, choose **String**.
   f. For **Data type**, choose **text**.
   g. In the **Value** box, paste the corresponding JSON block that was listed in [Agent configuration for NGINX hosts](). Be sure to customize as required. For example, the relevant `log_group_name`.
   h. Choose **Create parameter**.

To create the Prometheus configuration file as a parameter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. From the navigation pane, choose **Application Management**, **Parameter Store**
3. Follow these steps to create a new parameter for the configuration.

   a. Choose **Create parameter**.
   b. In the **Name** box, enter a name that you'll use to reference the configuration file in later steps. For example, **`AmazonCloudWatch-NGINX-Prometheus-Configuration`**.
   c. (Optional) In the **Description** box, type a description for the parameter.
   d. For **Parameter tier**, choose **Standard**.
   e. For **Type**, choose **String**.
   f. For **Data type**, choose **text**.
   g. In the **Value** box, paste the corresponding YAML block that was listed in the [Agent configuration for NGINX hosts](). Be sure to customize as required. For example, the relevant port number as per `targets`.

h. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an Amazon CloudFormation template

You can use Amazon CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-with-prometheus-config-1.0.0.json .
2. Verify that the selected Region on the console is the Region where the NGINX workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.
4. In the **Parameters** section, specify the following:
   a. For **CloudWatchAgentConfigSSM**, enter the name of the Amazon Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-NGINX-CloudWatchAgent-Configuration`**.
   b. For **PrometheusConfigSSM**, enter the name of the Amazon Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-NGINX-Prometheus-Configuration`**.
   c. To select the target instances, you have two options.
      i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.
      ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)
5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on Amazon CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-with-prometheus-config-1.0.0.json.

> **Note**
>
> After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:
>
> 1. If the Systems Manager parameter is deleted, the agent will stop.
> 2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.
> 3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in Step 1: Ensure the target EC2 instances have the required IAM permissions.
- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in ???.

If everything is set up correctly, then you should see the NGINX metrics being published to CloudWatch. You can check the CloudWatch console to verify they are being published.

To verify that NGINX metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Metrics**, **All metrics**.

3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for metrics such as `nginx_http_requests_total`. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the NGINX solution dashboard

The dashboard provided by this solution presents NGINX workload metrics by aggregating and presenting metrics across all instances. The dashboard shows a breakdown of the top contributors (top 10 per metric widget) for each metric. This helps you to quickly identify outliers or instances that significantly contribute to the observed metrics.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use Amazon CloudFormation console to deploy the dashboard.
- Download the Amazon CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with Amazon CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the Amazon CloudFormation stack in the Region where your NGINX metrics are published.
> If you've specified a custom namespace other than `CWAgent` in the CloudWatch agent configuration, you'll have to change the CloudFormation template for the dashboard to replace `CWAgent` with the customized namespace you are using.

To create the dashboard via CloudWatch Console

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=NginxOnEc2&referrer=os-catalog .

2. Verify that the selected Region on the console is the Region where the NGINX workload is running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`NGINXDashboard-us-east-1`**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via Amazon CloudFormation

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/NGINX_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json .
2. Verify that the selected Region on the console is the Region where the NGINX workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`NGINXDashboardStack`**.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.
5. To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`NGINXDashboard-us-east-1`**.
6. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that CloudFormation doesn't add any IAM resources.
7. Review the settings, then choose **Create stack**.
8. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on Amazon CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/NGINX_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.

Get started with the NGINX dashboard

Here are a few tasks that you can try out with the new NGINX dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor a NGINX workload. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Review connection metrics

In the **Connections** section, you can find several key metrics that provide insights into the client connection handling of your NGINX server. Monitoring these connection metrics can help you identify potential bottlenecks, connection issues, or unexpected connection patterns.

- Accepted client connections
- Active client connections
- Handled client connections
- Connections reading requests
- Idle client connections
- Connections writing responses

Analyze HTTP request volume

The `request` metric in the **HTTP Requests** section shows the total number of HTTP requests handled by the NGINX server. Tracking this metric over time can help you understand the overall traffic load on your NGINX infrastructure and plan for resource allocation and scaling accordingly.

CloudWatch solution: NVIDIA GPU workload on Amazon EC2

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for NVIDIA GPU workloads running on EC2 instances. Additionally, it helps you set up a pre-configured CloudWatch dashboard. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions.

Topics

- Requirements

- Benefits
- CloudWatch agent configuration for this solution
- Deploy the agent for your solution
- Create the NVIDIA GPU solution dashboard

Requirements

This solution is relevant for the following conditions:

- Compute: Amazon EC2
- Supports up to 500 GPUs across all EC2 instances in a given Amazon Web Services Region
- Latest version of CloudWatch agent
- SSM agent installed on EC2 instance
- The EC2 instance must have an NVIDIA driver installed. NVIDIA drivers are pre-installed on some Amazon Machine Images (AMIs). Otherwise, you can manually install the driver. For more information, see Install NVIDIA drivers on Linux instances.

> **Note**
>
> Amazon Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by Amazon and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
> - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
> - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

The solution delivers NVIDIA monitoring, providing valuable insights for the following use cases:

- Analyze GPU and memory usage for performance bottlenecks or the need for additional resources.
- Monitor temperature and power draw to ensure GPUs operate within safe limits.

- Evaluate encoder performance for GPU video workloads.
- Verify PCIe connectivity for expected generation and width.
- Monitor GPU clock speeds to detect scaling and throttling issues.

Below are the key advantages of the solution:

- Automates metric collection for NVIDIA using CloudWatch agent configuration, eliminating manual instrumentation.
- Provides a pre-configured, consolidated CloudWatch dashboard for NVIDIA metrics. The dashboard will automatically handle metrics from new NVIDIA EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard.

The following image is an example of the dashboard for this solution.

Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.
  - Each EC2 host configured for the solution publishes a total of 17 metrics per GPU.
- One custom dashboard.
- API operations requested by the CloudWatch agent to publish the metrics. With the default configuration for this solution, the CloudWatch agent calls the **PutMetricData** once every minute for each EC2 host. This means the **PutMetricData** API will be called `30*24*60=43,200` in a 30-day month for each EC2 host.

For more information about CloudWatch pricing, see [Amazon CloudWatch Pricing](https://aws.amazon.com/cloudwatch/pricing/).

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the [Amazon CloudWatch pricing calculator](https://calculator.aws/#/createCalculator/CloudWatch).
2. For **Choose a Region**, select the Region where you would like to deploy the solution.
3. In the **Metrics** section, for **Number of metrics**, enter **`17 * average number of GPUs per EC2 host * number of EC2 instances configured for this solution`**.
4. In the **APIs** section, for **Number of API requests**, enter **`43200 * number of EC2 instances configured for this solution`**.
5. By default, the CloudWatch agent performs one **PutMetricData** operation each minute for each EC2 host.
6. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
7. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces with the CloudWatch agent.

The agent configuration in this solution collects a set of metrics to help you get started monitoring and observing your NVIDIA GPU. The CloudWatch agent can be configured to collect more NVIDIA GPU metrics than the dashboard displays by default. For a list of all NVIDIA GPU metrics that you can collect, see Collect NVIDIA GPU metrics.

Agent configuration for this solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard.

Use the following CloudWatch agent configuration on EC2 instances with NVIDIA GPUs. Configuration will be stored as a parameter in SSM's Parameter Store, as detailed later in Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store.

```
{
    "metrics": {
        "namespace": "CWAgent",
        "append_dimensions": {
            "InstanceId": "${aws:InstanceId}"
        },
        "metrics_collected": {
            "nvidia_gpu": {
                "measurement": [
                    "utilization_gpu",
                    "temperature_gpu",
                    "power_draw",
                    "utilization_memory",
                    "fan_speed",
                    "memory_total",
                    "memory_used",
                    "memory_free",
                    "pcie_link_gen_current",
                    "pcie_link_width_current",
                    "encoder_stats_session_count",
                    "encoder_stats_average_fps",
                    "encoder_stats_average_latency",
                    "clocks_current_graphics",
                    "clocks_current_sm",
```

```
                    "clocks_current_memory",
                    "clocks_current_video"
                ],
                "metrics_collection_interval": 60
            }
        }
    },
    "force_flush_interval": 60
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single Amazon account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts where the workload is deployed and managing agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge the agent configuration of NVIDIA GPU with your existing agent configuration, and then deploy the merged configuration. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances. You can modify this configuration to suit your unique environment or use case. The metrics defined in configuration are the minimum required for the dashboard provided the solution.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.

- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an Amazon CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must also grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** and **AmazonSSMManagedInstanceCore** IAM policies attached.

- To create a role, see [Create IAM roles to use with the CloudWatch agent on Amazon EC2 instances](#).
- After the role is created, attach the role to your EC2 instances. To attach a role to an EC2 instance, follow the steps in [Attach an IAM role to an instance](#).

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. Verify that the selected Region on the console is the Region where the NVIDIA GPU workload is running.
3. From the navigation pane, choose **Application Management**, **Parameter Store**.

4. Follow these steps to create a new parameter for the configuration.

   a. Choose **Create parameter**.

   b. In the **Name** box, enter a name that you'll use to reference the CloudWatch agent configuration file in later steps. For example, **`AmazonCloudWatch-NVIDIA-GPU-Configuration`**.

   c. (Optional) In the **Description** box, type a description for the parameter.

   d. For **Parameter tier**, choose **Standard**.

   e. For **Type**, choose **String**.

   f. For **Data type**, choose **text**.

   g. In the **Value** box, paste the corresponding JSON block that was listed in Agent configuration for this solution.

   h. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an Amazon CloudFormation template

You can use Amazon CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json.

2. Verify that the selected Region on the console is the Region where the NVIDIA GPU workload is running.

3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.

4. In the **Parameters** section, specify the following:

   a. For **CloudWatchAgentConfigSSM**, enter the name of the Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-NVIDIA-GPU-Configuration`**.

   b. To select the target instances, you have two options.

i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.

ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)

5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see [Creating a stack on Amazon CloudFormation console].

> **Note**
>
> After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:
>
> 1. If the Systems Manager parameter is deleted, the agent will stop.
> 2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.
> 3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see [Working with associations in Systems Manager].

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in [Verify that the CloudWatch agent is running]. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in [Step 1: Ensure the target EC2 instances have the required IAM permissions].

- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in ???.

If everything is set up correctly, then you should see the NVIDIA GPU metrics being published to CloudWatch. You can check the CloudWatch console to verify they are being published.

To verify that NVIDIA GPU metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Metrics**, **All metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for the metrics mentioned in Agent configuration for this solution, such as `nvidia_smi_utilization_gpu`. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the NVIDIA GPU solution dashboard

The dashboard provided by this solution presents NVIDIA GPUs metrics by aggregating and presenting metrics across all instances. The dashboard shows a breakdown of the top contributors (top 10 per metric widget) for each metric. This helps you to quickly identify outliers or instances that significantly contribute to the observed metrics.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use Amazon CloudFormation console to deploy the dashboard.
- Download the Amazon CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with Amazon CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the Amazon CloudFormation stack in the Region where your NVIDIA GPU metrics are published.
> If you've specified a custom namespace other than CWAgent in the CloudWatch agent configuration, you'll have to change the Amazon CloudFormation template for the dashboard to replace CWAgent with the customized namespace you are using.

To create the dashboard via CloudWatch Console

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=NvidiaGpuOnEc2&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the NVIDIA GPU workload is running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`NVIDIA-GPU-Dashboard-us-east-1`**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via Amazon CloudFormation

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/NVIDIA_GPU_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the NVIDIA GPU workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`NVIDIA-GPU-DashboardStack`**.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.

5. To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`NVIDIA-GPU-Dashboard-us-east-1`**.
6. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that Amazon CloudFormation doesn't add any IAM resources.
7. Review the settings, then choose **Create stack**.
8. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file to customize it for any purpose, you can use **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on Amazon CloudFormation console. You can use this link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/NVIDIA_GPU_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json .

Get started with the NVIDIA GPU dashboard

Here are a few tasks that you can try out with the new NVIDIA GPU dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor your NVIDIA GPUs. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Review GPU utilization

From the **Utilization** section, find the **GPU Utilization** and **Memory Utilization** widgets. These show the percentage of time the GPU is being actively used for computations and the percentage of global memory being read or written, respectively. High utilization could indicate potential performance bottlenecks or the need for additional GPU resources.

Analyze GPU memory usage

In the **Memory** section, find the **Total Memory**, **Used Memory**, and **Free Memory** widgets. These provide insights into the overall memory capacity of the GPUs and how much memory is currently being consumed or available. Memory pressure could lead to performance issues or out-of-memory errors, so it's important to monitor these metrics and ensure sufficient memory is available for your workloads.

Monitor temperature and power draw

In the **Temperature / Power** section, find the **GPU Temperature** and **Power Draw** widgets. These metrics are essential for ensuring that your GPUs are operating within safe thermal and power limits.

Identify encoder performance

In the **Encoder** section, find the **Encoder Session Count**, **Average FPS**, and **Average Latency** widgets. These metrics are relevant if you're running video encoding workloads on your GPUs. Monitor these metrics to ensure that your encoders are performing optimally and identify any potential bottlenecks or performance issues.

Check PCIe link status

In the **PCIe** section, find the **PCIe Link Generation** and **PCIe Link Width** widgets. These metrics provide information about the PCIe link connecting the GPU to the host system. Ensure that the link is operating at the expected generation and width to avoid potential performance limitations due to PCIe bottlenecks.

Review GPU clocks

In the **Clock** section, find the **Graphics Clock**, **SM Clock**, **Memory Clock**, and **Video Clock** widgets. These metrics show the current operating frequencies of various GPU components. Monitoring these clocks can help identify potential issues with GPU clock scaling or frequency throttling, which could impact performance.

CloudWatch solution: Kafka workload on Amazon EC2

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for Kafka workloads (brokers, producers, and consumers) running on EC2 instances. Additionally, it helps you set up a pre-configured CloudWatch dashboard. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions.

Topics

Requirements

This solution is relevant for the following conditions:

- Workload: Kafka v0.8.2.x and later
- Compute: Amazon EC2
- Supports up to 500 EC2 instances across all Kafka workloads in a given Amazon Web Services Region
- Latest version of CloudWatch agent
- SSM agent installed on EC2 instance

> **Note**
>
> Amazon Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by Amazon and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
> - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
> - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

The solution delivers Kafka server monitoring, providing valuable insights for the following use cases:

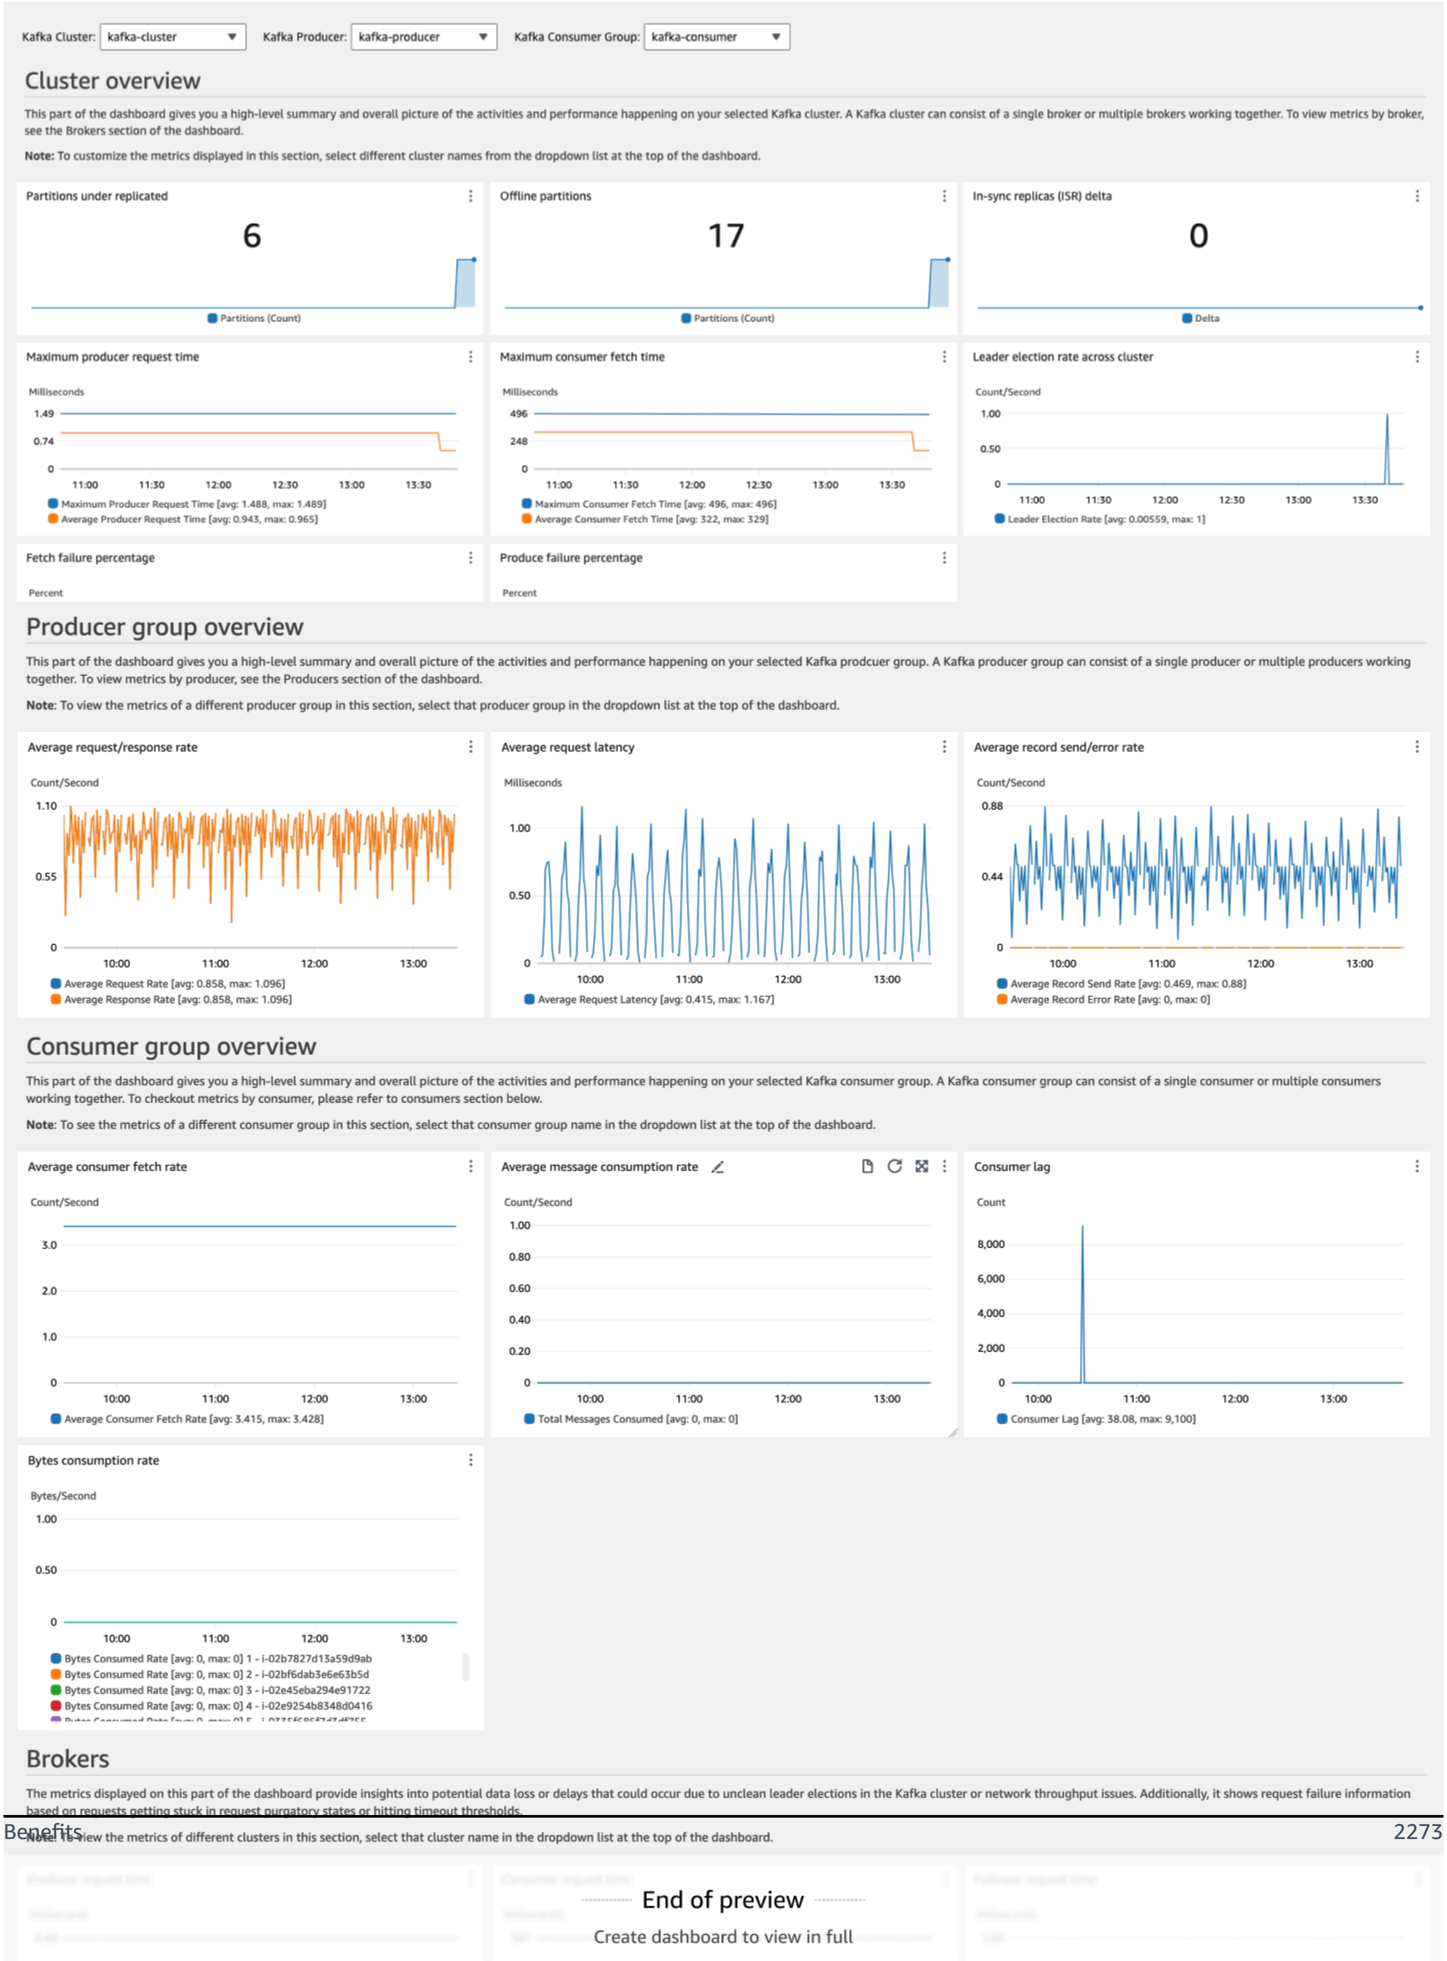
- Monitor Kafka cluster health via replication and sync metrics.
- Track broker performance through request failures and latencies along with network traffic.
- Monitor producer/consumer errors, latencies, and consumer lag.

- Analyze underlying JVM performance for Kafka clusters.
- Switch between multiple Kafka clusters, producers, and consumers configured via the solution under the same account.

Below are the key advantages of the solution:

- Automates metric collection for Kafka and the underlying JVM using CloudWatch agent configuration, eliminating manual instrumentation.
- Provides a pre-configured, consolidated CloudWatch dashboard for Kafka and JVM metrics. The dashboard will automatically handle metrics from new Kafka EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard. It also allows you to group the metrics into logical applications for easier focus and management.

The following image is an example of the dashboard for this solution.



Kafka Cluster: kafka-cluster
Kafka Producer: kafka-producer
Kafka Consumer Group: kafka-consumer
Cluster overview
This part of the dashboard gives you a high-level summary and overall picture of the activities and performance happening on your selected Kafka cluster. A Kafka cluster can consist of a single broker or multiple brokers working together. To view metrics by broker, see the Brokers section of the dashboard.
Note: To customize the metrics displayed in this section, select different cluster names from the dropdown list at the top of the dashboard.
Partitions under replicated
6
Partitions (Count)
Offline partitions
17
Partitions (Count)
In-sync replicas (ISR) delta
0
Delta
Maximum producer request time
Milliseconds
Maximum Producer Request Time [avg: 1.488, max: 1.489]
Average Producer Request Time [avg: 0.943, max: 0.965]
Maximum consumer fetch time
Milliseconds
Maximum Consumer Fetch Time [avg: 496, max: 496]
Average Consumer Fetch Time [avg: 322, max: 329]
Leader election rate across cluster
Count/Second
Leader Election Rate [avg: 0.00559, max: 1]
Fetch failure percentage
Percent
Produce failure percentage
Percent
Producer group overview
This part of the dashboard gives you a high-level summary and overall picture of the activities and performance happening on your selected Kafka prodcuer group. A Kafka producer group can consist of a single producer or multiple producers working together. To view metrics by producer, see the Producers section of the dashboard.
Note: To view the metrics of a different producer group in this section, select that producer group in the dropdown list at the top of the dashboard.
Average request/response rate
Count/Second
Average Request Rate [avg: 0.858, max: 1.096]
Average Response Rate [avg: 0.858, max: 1.096]
Average request latency
Milliseconds
Average Request Latency [avg: 0.415, max: 1.167]
Average record send/error rate
Count/Second
Average Record Send Rate [avg: 0.469, max: 0.88]
Average Record Error Rate [avg: 0, max: 0]
Consumer group overview
This part of the dashboard gives you a high-level summary and overall picture of the activities and performance happening on your selected Kafka consumer group. A Kafka consumer group can consist of a single consumer or multiple consumers working together. To checkout metrics by consumer, please refer to consumers section below.
Note: To see the metrics of a different consumer group in this section, select that consumer group name in the dropdown list at the top of the dashboard.
Average consumer fetch rate
Count/Second
Average Consumer Fetch Rate [avg: 3.415, max: 3.428]
Average message consumption rate
Count/Second
Total Messages Consumed [avg: 0, max: 0]
Consumer lag
Count
Consumer Lag [avg: 38.08, max: 9,100]
Bytes consumption rate
Bytes/Second
Bytes Consumed Rate [avg: 0, max: 0] 1 - i-02b7827d13a59d9ab
Bytes Consumed Rate [avg: 0, max: 0] 2 - i-02bf6dab3e6e63b5d
Bytes Consumed Rate [avg: 0, max: 0] 3 - i-02e45eba294e91722
Bytes Consumed Rate [avg: 0, max: 0] 4 - i-02e9254b8348d0416
Brokers
The metrics displayed on this part of the dashboard provide insights into potential data loss or delays that could occur due to unclean leader elections in the Kafka cluster or network throughput issues. Additionally, it shows request failure information based on requests getting stuck in request purgatory states or hitting timeout thresholds.
Note: To view the metrics of different clusters in this section, select that cluster name in the dropdown list at the top of the dashboard.

Create dashboard to view in full

Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.
  - Each broker host configured for the solution publishes 33 metrics plus one metric (`disk_used_percent`) for which the metric count for each EC2 host depends on the number of disk paths for that host.
  - Each producer host configured for the solution publishes three metrics with the `topic` dimension and three metrics without the `topic` dimension. For the metrics with the `topic` dimension, each topic counts as a separate metric.
  - Each consumer host configured for the solution publishes two metrics with `topic` dimensions and three metrics without `topic` dimensions. For the metrics with topic dimensions, each topic counts as a separate metric.
- One custom dashboard.
- API operations requested by the CloudWatch agent to publish the metrics. With the default configuration for this solution, the CloudWatch agent calls the **PutMetricData** once every minute for each EC2 host. This means the **PutMetricData** API will be called `30*24*60=43,200` in a 30-day month for each EC2 host.

For more information about CloudWatch pricing, see [Amazon CloudWatch Pricing]().

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the [Amazon CloudWatch pricing calculator]().
2. In the **Metrics** section, for **Number of metrics**, enter **`broker_metrics_count + producer_metrics_count + consumer_metrics_count`**. Calculate these as follows:
   - `broker_metrics_count` = (33 + average number of disk paths per EC2 host) * number_of_ec2_broker_hosts
   - `producer_metrics_count` = (3 * average_number_of_topics_per_producer_host + 3) * number_of_ec2_producer_hosts

- `consumer_metrics_count` = (2 * average_number_of_topics_per_consumer_host + 3) * number_of_ec2_consumer_hosts

3. In the **APIs** section, for **Number of API requests**, enter **`43200 * number of EC2 instances configured for this solution`**.

   By default, the CloudWatch agent performs one **PutMetricData** operation each minute for each EC2 host.

4. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
5. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces with the CloudWatch agent.

The agent configuration in this solution collects the foundational metrics for Kafka, JVM, and EC2. The CloudWatch agent can be configured to collect more Kafka and JVM metrics than the dashboard displays by default. For a list of all Kafka metrics that you can collect, see Collect Kafka metrics. For a list of all JVM metrics that you can collect, see Collect JVM metrics. For a list of EC2 metrics, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

Expose JMX ports for the Kafka broker, producer, and consumer roles

The CloudWatch agent relies on JMX to collect the metrics related to the Kafka brokers, producers, and consumers. To make this possible, you must expose the JMX port on your servers and applications.

For Kafka brokers, you must use the `JMX_PORT` environment variable to set the port. You'll have to restart the brokers after you set this environment variable. Review the starting scripts and configuration files of your application to find the best place to add these arguments.

For example, for Linux and macOS systems, you can use the following command to set the JMX port. Be sure to specify an unused port number.

```
export JMX_PORT=port-number
```

For Kafka producers and consumers, instructions for exposing the JMX port depend on the workload type you are using for your producer or consumer JVM application. See the documentation for your application to find these instructions.

In general, to enable a JMX port for monitoring and management, you would set the following system properties for your JVM application. The following example sets up unauthenticated JMX. If your security policies/requirements require you to enable JMX with password authentication or SSL for remote access, refer to the JMX documentation to set the required property.

```
-Dcom.sun.management.jmxremote
-Dcom.sun.management.jmxremote.port=port-number
-Dcom.sun.management.jmxremote.authenticate=false
-Dcom.sun.management.jmxremote.ssl=false
```

To verify the JMX port, run `ps aux | grep jmxremote.port`. The results should show that the JMX port was set on the JVM processes.

Agent configuration for this solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard. Each Kafka role, such as broker, producer, or consumer, has its own agent configuration that enables the collection of Kafka metrics and underlying JVM and EC2 metrics.

The steps for deploying the solution are described later in Deploy the agent for your solution. The following information is intended to help you understand how to customize the agent configuration for your environment.

You must customize some parts of the following agent configuration for your environment:

- The JMX port number is the port number that you configured in the previous section of this documentation. The port number is in the `endpoint` line in the configuration.
- `ClusterName`– This is used as a dimension for broker metrics collected. Provide a meaningful name that represents the cluster grouping for the instances that run the Kafka broker.
- `ProcessGroupName`– This is used as a dimension for JVM metrics collected for brokers. Provide the same value as you provide for `ClusterName`. This enables viewing the JVM metrics of the same Kafka broker group as the broker metrics in the solution dashboard.

- `ProducerGroupName`– This is used as a dimension for producer metrics collected. Provide a meaningful name that represents the group of producer instances. For this value, you can specify your producer application or service that you want to use for a combined view of producer metrics in the solution dashboard.
- `ConsumerGroupName`– This is used as a dimension for consumer metrics collected. Provide a meaningful name that represents the group of consumer instances This is not the same as the consumer group concept in Kafka. This is just a grouping dimension where you can specify your consumer application or service that you want to use for a combined view of consumer metrics in the solution dashboard

For example, if you have two Kafka clusters running in the same account, one for the `order-processing` application and another for the `inventory-management` application, you should set the `ClusterName` and `ProcessGroupName` dimensions accordingly in the agent configuration of the broker instance.

- For the `order-processing` cluster broker instances, set `ClusterName=order-processing` and `ProcessGroupName=order-processing`.
- For the `inventory-management` cluster broker instances, set `ClusterName=inventory-management` and `ProcessGroupName=inventory-management`.
- Similarly, set the `ProducerGroupName` for producer instances and `ConsumerGroupName` for consumer instances based on their respective applications.

When you correctly set the above dimensions, the solution dashboard will automatically group the metrics based on the `ClusterName`, `ProducerGroupName`, and `ConsumerGroupName` dimensions. The dashboard will include dropdown options to select and view metrics for specific clusters and groups, allowing you to monitor the performance of individual clusters and groups separately.

Be sure to deploy the relevant agent configuration to the correct EC2 instances. Each configuration will be stored as a separate Parameter in SSM's Parameter Store, as detailed later in [Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store](#).

The following instructions describe the situation where the producer, consumer, and broker roles are deployed to separate EC2 instances, without any overlap. If you are running multiple Kafka roles on the same EC2 instances, see [Configure the agent for multiple Kafka roles on the same instance](#) for more information.

Agent configuration for Kafka broker agents

Use the following CloudWatch agent configuration on EC2 instances where Kafka broker agents are deployed. Replace *ClusterName* with the name of the cluster to use to group these metrics for a unified view. The value you specify for *ClusterName* is used as both the `ClusterName` dimension and the `ProcessGroupName` dimension. Replace *port-number* with the JMX port of your Kafka server. If JMX was enabled with password authentication or SSL for remote access, see Collect Java Management Extensions (JMX) metrics for information about setting up TLS or authorization as required.

The EC2 metrics shown in this configuration (configuration shown outside the JMX block) only work for Linux and macOS instances. If you are using Windows instances, you can choose to omit these metrics in the configuration. For information about metrics collected on Windows instances, see Metrics collected by the CloudWatch agent on Windows Server instances.

```
{
  "metrics": {
    "namespace": "CWAgent",
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "kafka": {
            "measurement": [
              "kafka.request.time.avg",
              "kafka.request.failed",
              "kafka.request.count",
              "kafka.purgatory.size",
              "kafka.partition.under_replicated",
              "kafka.partition.offline",
              "kafka.network.io",
              "kafka.leader.election.rate",
              "kafka.isr.operation.count"
            ]
          },
          "append_dimensions": {
            "ClusterName": "ClusterName"
          }
        },
```

```
        {
          "endpoint": "localhost:port-number",
          "jvm": {
            "measurement": [
              "jvm.classes.loaded",
              "jvm.gc.collections.count",
              "jvm.gc.collections.elapsed",
              "jvm.memory.heap.committed",
              "jvm.memory.heap.max",
              "jvm.memory.heap.used",
              "jvm.memory.nonheap.committed",
              "jvm.memory.nonheap.max",
              "jvm.memory.nonheap.used",
              "jvm.threads.count"
            ]
          },
          "append_dimensions": {
            "ProcessGroupName": "ClusterName"
          }
        }
      ],
      "disk": {
        "measurement": [
          "used_percent"
        ]
      },
      "mem": {
        "measurement": [
          "used_percent"
        ]
      },
      "swap": {
        "measurement": [
          "used_percent"
        ]
      },
      "netstat": {
        "measurement": [
          "tcp_established",
          "tcp_time_wait"
        ]
      }
    }
  }
```

```
}
```

Agent configuration for Kafka producers

Use the following CloudWatch agent configuration on Amazon EC2 instances where Kafka producers are deployed. Replace *ProducerGroupName* with the name of the application or group that you want to use to group your metrics for a unified view. Replace *port-number* with the JMX port of your Kafka producer application.

The solution doesn't enable JVM metrics for Kafka producers because the solution dashboard doesn't display JVM metrics related to JVM for producers. You can customize the agent configuration to emit JVM metrics as well, however, JVM metrics related to producers are not visible on the solution dashboard.

```
{
  "metrics": {
    "namespace": "CWAgent",
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "kafka-producer": {
            "measurement": [
              "kafka.producer.request-rate",
              "kafka.producer.byte-rate",
              "kafka.producer.request-latency-avg",
              "kafka.producer.response-rate",
              "kafka.producer.record-error-rate",
              "kafka.producer.record-send-rate"
            ]
          },
          "append_dimensions": {
            "ProducerGroupName": "ProducerGroupName"
          }
        }
      ]
    }
  }
}
```

Agent configuration for Kafka consumers

Use the following CloudWatch agent configuration on EC2 instances where Kafka consumers are running. Replace *ConsumerGroupName* with the name of the application or group to use to group these metrics for a unified view. Replace *port-number* with the JMX port of your Kafka consumer application.

The solution doesn't enable JVM metrics for Kafka consumers because the solution dashboard doesn't display JVM metrics related to JVM for consumers. You can customize the agent configuration to emit JVM metrics as well, however JVM metrics related to consumer are not visible on the solution dashboard.

```
{
  "metrics": {
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "kafka-consumer": {
            "measurement": [
              "kafka.consumer.fetch-rate",
              "kafka.consumer.total.bytes-consumed-rate",
              "kafka.consumer.records-consumed-rate",
              "kafka.consumer.bytes-consumed-rate",
              "kafka.consumer.records-lag-max"
            ]
          },
          "append_dimensions": {
            "ConsumerGroupName": "ConsumerGroupName"
          }
        }
      ]
    }
  }
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single Amazon account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts where the workload is deployed and managing the agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge the agent configuration according to the role (broker, producer, or consumer) with your existing agent configuration, and then deploy the merged configuration. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances. You can modify this configuration to suit your unique environment or use case. The metrics defined in this solution are the minimum required for the recommended dashboard.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.
- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an Amazon CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

You must repeat these steps based on whether your broker, producer, and consumer are deployed on the same EC2 instance or different instances. For example, if the Kafka broker, producer, and consumers are getting deployed on separate instances without overlap, you must repeat these steps three times with the appropriate agent configurations for broker, producer, and consumer EC2 instances.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must also grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** and **AmazonSSMManagedInstanceCore** IAM policies attached.

- To create a role, see Create IAM roles to use with the CloudWatch agent on Amazon EC2 instances.
- After the role is created, attach the role to your EC2 instances. Follow the steps in Launch an instance with an IAM role to attach a role while launching a new EC2 instance. To attach a role to an existing EC2 instance, follow the steps in Attach an IAM role to an instance.

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. From the navigation pane, choose **Application Management**, **Parameter Store**.
3. Follow these steps to create a new parameter for the configuration.

    a. Choose **Create parameter**.
    b. Provide a name for the parameter that will store your CloudWatch agent configuration, such as **`AmazonCloudWatch-Kafka-Producer-Configuration`** for producers,

AmazonCloudWatch-Kafka-Consumer-Configuration for consumers, or **AmazonCloudWatch-Kafka-Broker-Configuration** for brokers. If you have multiple Kafka roles on a single EC2, name the roles accordingly for easier identification. This value will later be used to distribute this configuration to the agent running on your EC2 instance.

c. For **Parameter tier**, choose **Standard**.

d. For **Type**, choose **String**.

e. For **Data type**, choose **text**.

f. In the **Value** box, paste the full text of the CloudWatch agent configuration. Be sure to select the JSON block for the Kafka role that this instance is hosting. Refer to the configuration provided in Agent configuration for Kafka broker agents, Agent configuration for Kafka producers, and Agent configuration for Kafka consumers when storing the configuration for broker, producer, and consumer respectively. If you are running multiple Kafka roles on the same EC2 instance, be sure to merge the configuration if required as described in Configure the agent for multiple Kafka roles on the same instance on the same instance

g. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an Amazon CloudFormation template

You can use Amazon CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.amazonaws.cn/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the Kafka workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **CWAgentInstallationStack**.
4. In the **Parameters** section, specify the following:

a. For **CloudWatchAgentConfigSSM**, enter the name of the Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-Kafka-Broker-Configuration`** for brokers, **`AmazonCloudWatch-Kafka-Producer-Configuration`** for producers, and **`AmazonCloudWatch-Kafka-Consumer-Configuration`** for consumers.

b. To select the target instances, you have two options.

   i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.

   ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)

   If you specify both the **InstanceIds** and the **TagKeys** parameters, the **InstanceIds** will take precedence and the tags will be ignored.

5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on Amazon CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json.

> **Note**
>
> After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:
>
> 1. If the Systems Manager parameter is deleted, the agent will stop.
> 2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.

3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in Step 1: Ensure the target EC2 instances have the required IAM permissions.
- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in ???.

If everything is set up correctly, then you should see the Kafka metrics being published to CloudWatch. You can check the CloudWatch console to verify they are being published.

To verify that Kafka metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Metrics**, **All metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for the metrics mentioned in the agent configuration section of this document, such as `kafka.partition.offline` for brokers, `kafka.consumer.fetch.rate` for consumers, or `kafka.producer.request-rate` for producers. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the Kafka solution dashboard

This dashboard displays the newly emitted metrics for both Kafka and the underlying JVM. This dashboard provides a top contributor view for the health of your Kafka workload, across producers, brokers, and consumers. The top contributor view displays the top 10 per metric widget. This allows you to identify outliers at a glance.

The solution dashboard doesn't display EC2 metrics. To view EC2 metrics, you'll need to use the EC2 automatic dashboard to see EC2 vended metrics and use the EC2 console dashboard to see EC2 metrics that are collected by the CloudWatch agent. For more information about automatic dashboards for Amazon services, see Viewing a CloudWatch dashboard for a single Amazon service.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use Amazon CloudFormation console to deploy the dashboard.
- Download the Amazon CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with Amazon CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the Amazon CloudFormation stack in the Region where your JVM and Kafka metrics are published.
> If you've specified a custom namespace other than `CWAgent` in the CloudWatch agent configuration, you'll have to change the Amazon CloudFormation template for the dashboard to replace `CWAgent` with the customized namespace you are using.

To create the dashboard via CloudWatch Console

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young`**

Generation\" to **name=\"Parallel GC\"** of the garbage collection count metric jvm.gc.collections.count.

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=ApacheKafkaOnEc2&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the Kafka workload is running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **KafkaDashboard-us-east-1**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via Amazon CloudFormation

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.amazonaws.cn/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/Kafka_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the Kafka workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **KafkaDashboardStack**.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **KafkaDashboard-us-east-1**.
5. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that CloudFormation doesn't add any IAM resources.
6. Review the settings, then choose **Create stack**.

7. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file to customize it for any purpose, you can use **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see [Creating a stack on Amazon CloudFormation console](). You can use this link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/Kafka_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

Get started with the Kafka dashboard

Here are a few tasks that you can try out with the new Kafka dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor a Kafka cluster. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Using the dropdown lists

The dashboard provides dropdown lists at the top that you can use to filter and select the specific Kafka cluster, producer, and consumer groups that you want to monitor.

- To display metrics for a specific Kafka cluster, select that cluster name in the **Kafka Cluster** dropdown list.

- To display metrics for a specific Kafka producer group, select that producer group name in the **Kafka Producer** dropdown list.
- To display metrics for a specific Kafka consumer group, select that consumer group name in the **Kafka Consumer Group** dropdown list.

Verify cluster health

From the **Cluster Overview** section, find the **Partitions Under Replicated** and **In-Sync Replicas** widgets. These should ideally be zero or a small number. A large value for any of these metrics could indicate issues with the Kafka cluster that need investigation.

Investigate broker performance

In the **Brokers** section, find the **Failed Fetch Requests** and **Failed Producer Requests** widgets. These show the number of failed requests for fetch and produce operations, respectively. High failure rates could indicate issues with the brokers or network connectivity that require further investigation.

Monitor producer performance

In the **Producer Group Overview** section, find the **Average Request Rate**, **Average Request Latency**, and **Average Record Send/Error Rate** widgets. These will give you an overview of how the producers in the selected group are performing. You can also drill down to view metrics for specific producers and topics in the **Producers** section.

Monitor consumer lag

In the **Consumer Group Overview** section, find the **Consumer Lag** widget. This shows how far behind the consumers are in processing messages from the latest offsets in the partitions they are subscribed to. Ideally, the consumer lag should be low or zero. A high consumer lag could indicate that the consumers are unable to keep up with the rate of data production, leading to potential data loss or delays in processing. You can also drill down to view metrics for specific consumers and topics in the **Consumers** section.

Configure the agent for multiple Kafka roles on the same instance

The individual configurations for Kafka roles listed in [CloudWatch agent configuration for this solution](#) apply only when the producer, consumer, and broker roles are deployed on separate EC2 instances, without any overlap. If you are running multiple Kafka roles on the same Amazon EC2 instances, you have two options:

- Create a single agent configuration file which lists and configures all metrics for all the Kafka roles deployed on that instance. If you are going to use Systems Manager to manage agent configuration, this is the preferred option.

  If you choose this option and the multiple Kafka roles are part of the same JVM process, you must specify the same endpoint for each Kafka role in the agent configuration. If the multiple Kafka roles are part of different JVM processes, the endpoint for each role can be different depending on the JMX port set for that process.
- Create separate agent configuration files for each Kafka role, and configure the agent to apply both configuration files. For instructions for applying multiple configuration files, see Multiple CloudWatch agent configuration files.

The following example shows a CloudWatch agent configuration where the producer and consumer roles are running on one instance as part of the same JVM process. In this case, the port number must be the same in both the producer and consumer parts of the configuration below. If instead the two roles were running as part of different JVM processes, you could specify different port numbers for each, according to the JMX port of each individual JVM process.

```
{
  "metrics": {
    "namespace": "CWAgent",
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "kafka-producer": {
            "measurement": [
              "kafka.producer.request-rate",
              "kafka.producer.byte-rate",
              "kafka.producer.request-latency-avg",
              "kafka.producer.response-rate",
              "kafka.producer.record-error-rate",
              "kafka.producer.record-send-rate"
            ]
```

```
          },
          "append_dimensions": {
            "ProducerGroupName": "ProducerGroupName"
          }
        },
        {
          "endpoint": "localhost:port-number",
          "kafka-consumer": {
            "measurement": [
              "kafka.consumer.fetch-rate",
              "kafka.consumer.total.bytes-consumed-rate",
              "kafka.consumer.records-consumed-rate",
              "kafka.consumer.bytes-consumed-rate",
              "kafka.consumer.records-lag-max"
            ]
          },
          "append_dimensions": {
            "ConsumerGroupName": "ConsumerGroupName"
          }
        }
      ]
    }
  }
}
```

CloudWatch solution: Tomcat workload on Amazon EC2

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for Tomcat server running on EC2 instances. Additionally, it helps you set up a pre-configured CloudWatch dashboard. For general information about all CloudWatch observability solutions, see CloudWatch observability solutions.

Topics

Requirements

This solution is relevant for the following conditions:

- Supported versions: Tomcat versions 9, 10.1, and 11 (beta)
- Compute: Amazon EC2
- Supports up to 500 EC2 instances across all Tomcat workloads in a given Amazon Web Services Region
- Latest version of CloudWatch agent
- SSM agent installed on EC2 instance

> **Note**
>
> Amazon Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by Amazon and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux
> - Manually installing and uninstalling SSM Agent on EC2 instances for macOS
> - Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server

Benefits

The solution delivers Tomcat server monitoring, providing valuable insights for the following use cases:

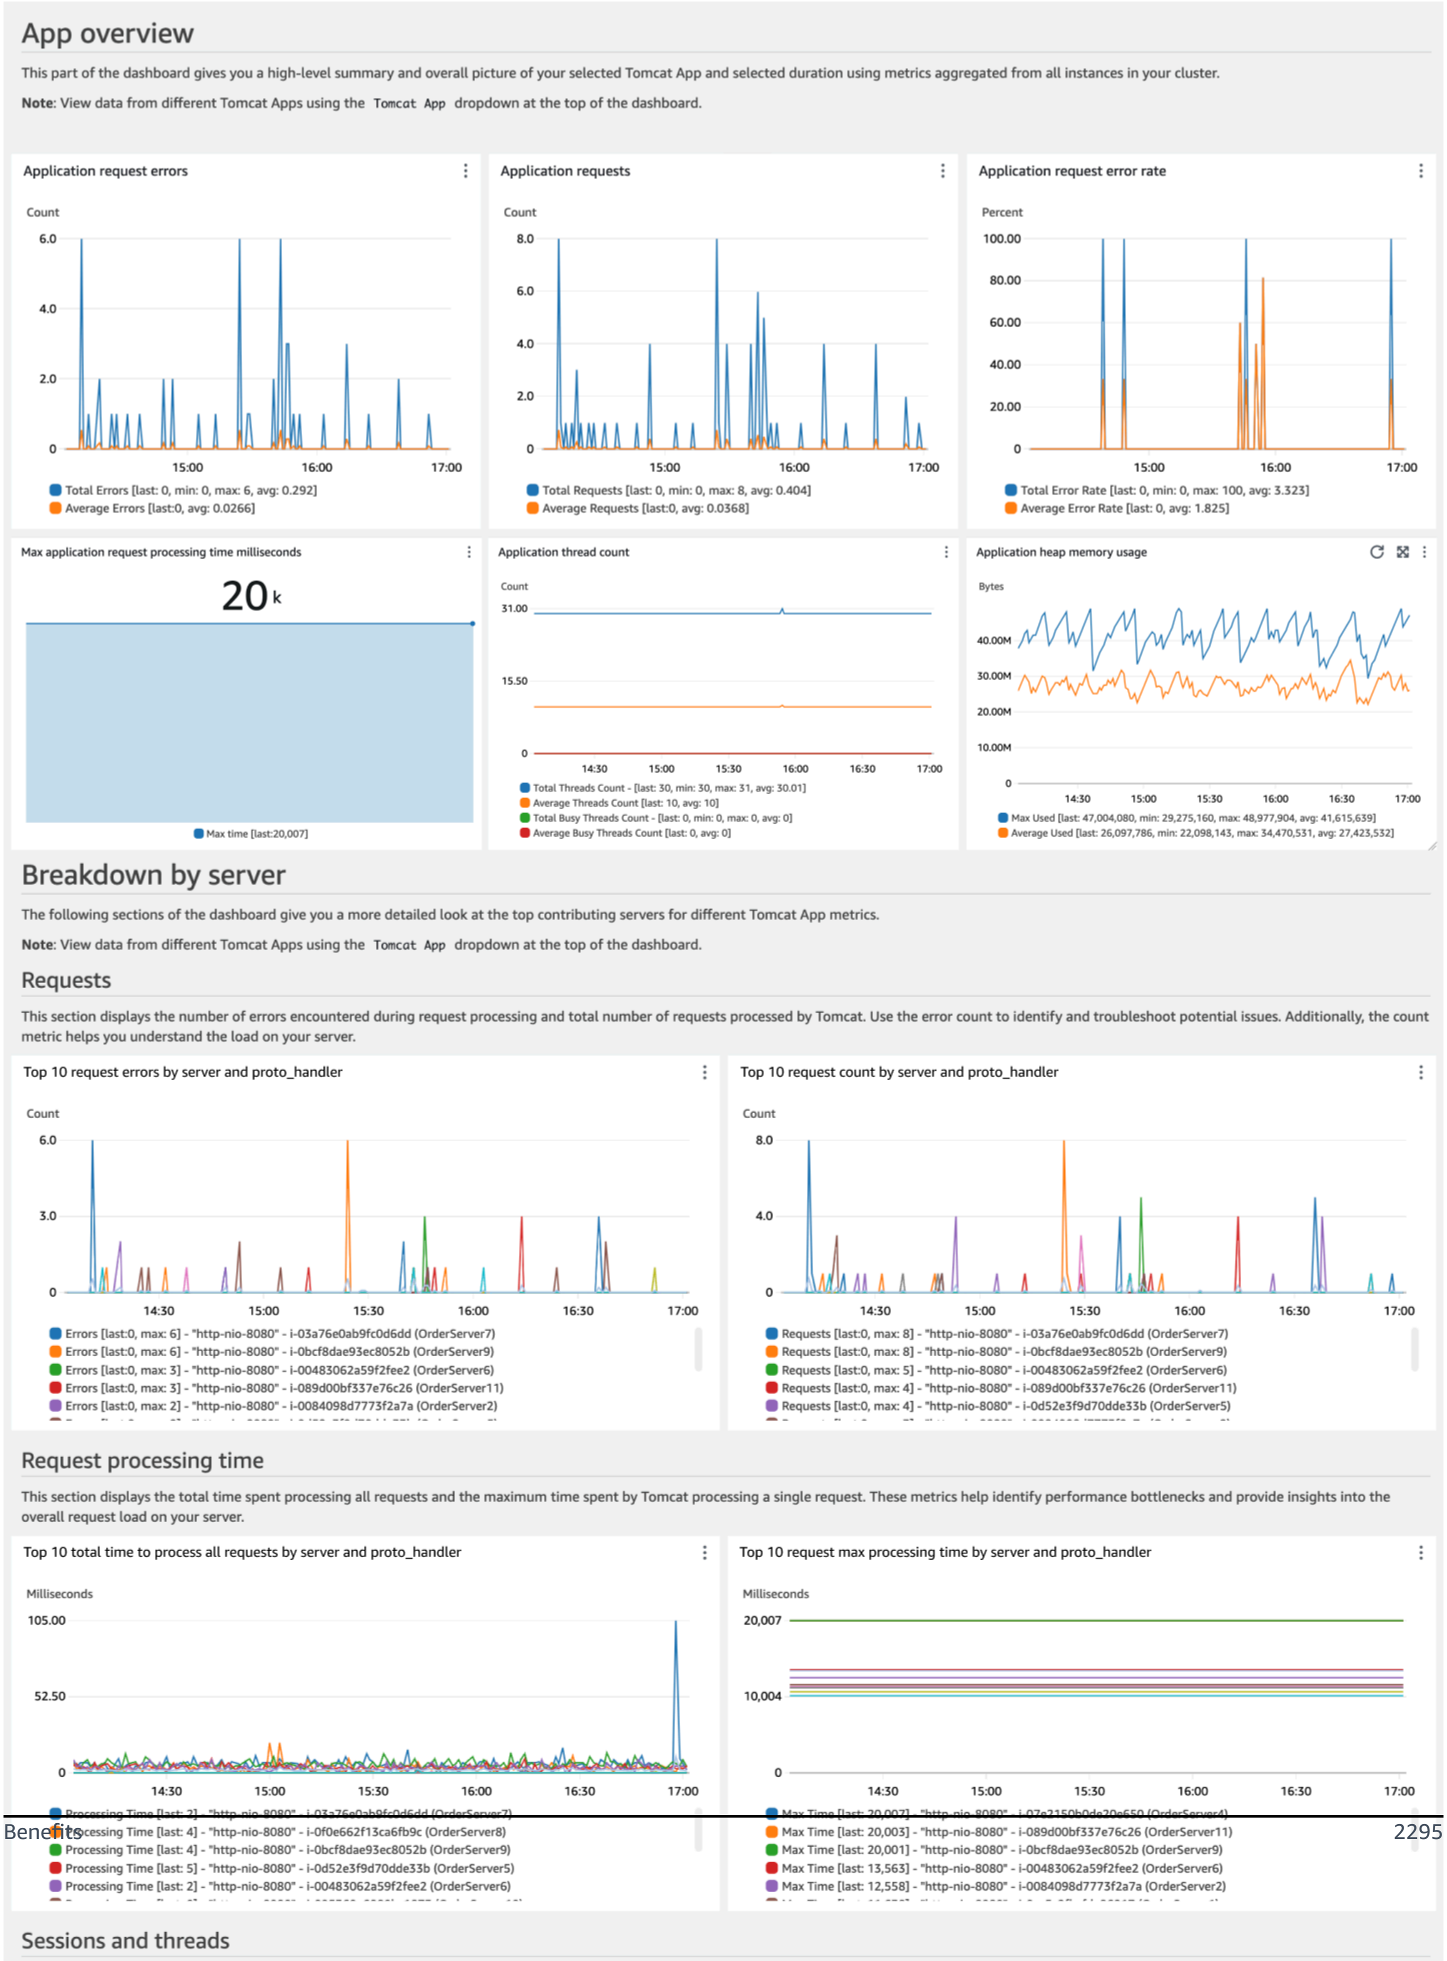
- Detect Tomcat server errors and performance issues.
- Monitor network traffic for data transfer problems.
- Track thread usage and active user sessions.
- Analyze underlying JVM performance for Tomcat server.

Below are the key advantages of the solution:

- Automates metric collection for Apache Tomcat and the underlying JVM using CloudWatch agent configuration, eliminating manual instrumentation.

- Provides a pre-configured, consolidated CloudWatch dashboard for Apache Tomcat and JVM metrics. The dashboard will automatically handle metrics from new Tomcat EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard. It also allows you to group the metrics into logical applications for easier focus and management.

The following image is an example of the dashboard for this solution.



App overview
This part of the dashboard gives you a high-level summary and overall picture of your selected Tomcat App and selected duration using metrics aggregated from all instances in your cluster.
Note: View data from different Tomcat Apps using the Tomcat App dropdown at the top of the dashboard.
Application request errors
Total Errors [last: 0, min: 0, max: 6, avg: 0.292]
Average Errors [last:0, avg: 0.0266]
Application requests
Total Requests [last: 0, min: 0, max: 8, avg: 0.404]
Average Requests [last:0, avg: 0.0368]
Application request error rate
Total Error Rate [last: 0, min: 0, max: 100, avg: 3.323]
Average Error Rate [last: 0, avg: 1.825]
Max application request processing time milliseconds
20k
Max time [last:20,007]
Application thread count
Total Threads Count - [last: 30, min: 30, max: 31, avg: 30.01]
Average Threads Count [last: 10, avg: 10]
Total Busy Threads Count - [last: 0, min: 0, max: 0, avg: 0]
Average Busy Threads Count [last: 0, avg: 0]
Application heap memory usage
Max Used [last: 47,004,080, min: 29,275,160, max: 48,977,904, avg: 41,615,639]
Average Used [last: 26,097,786, min: 22,098,143, max: 34,470,531, avg: 27,423,532]
Breakdown by server
The following sections of the dashboard give you a more detailed look at the top contributing servers for different Tomcat App metrics.
Note: View data from different Tomcat Apps using the Tomcat App dropdown at the top of the dashboard.
Requests
This section displays the number of errors encountered during request processing and total number of requests processed by Tomcat. Use the error count to identify and troubleshoot potential issues. Additionally, the count metric helps you understand the load on your server.
Top 10 request errors by server and proto_handler
Errors [last:0, max: 6] - "http-nio-8080" - i-03a76e0ab9fc0d6dd (OrderServer7)
Errors [last:0, max: 6] - "http-nio-8080" - i-0bcf8dae93ec8052b (OrderServer9)
Errors [last:0, max: 3] - "http-nio-8080" - i-00483062a59f2fee2 (OrderServer6)
Errors [last:0, max: 3] - "http-nio-8080" - i-089d00bf337e76c26 (OrderServer11)
Errors [last:0, max: 2] - "http-nio-8080" - i-0084098d7773f2a7a (OrderServer2)
Top 10 request count by server and proto_handler
Requests [last:0, max: 8] - "http-nio-8080" - i-03a76e0ab9fc0d6dd (OrderServer7)
Requests [last:0, max: 8] - "http-nio-8080" - i-0bcf8dae93ec8052b (OrderServer9)
Requests [last:0, max: 5] - "http-nio-8080" - i-00483062a59f2fee2 (OrderServer6)
Requests [last:0, max: 4] - "http-nio-8080" - i-089d00bf337e76c26 (OrderServer11)
Requests [last:0, max: 4] - "http-nio-8080" - i-0d52e3f9d70dde33b (OrderServer5)
Request processing time
This section displays the total time spent processing all requests and the maximum time spent by Tomcat processing a single request. These metrics help identify performance bottlenecks and provide insights into the overall request load on your server.
Top 10 total time to process all requests by server and proto_handler
Processing Time [last: 4] - "http-nio-8080" - i-0f0e662f13ca6fb9c (OrderServer8)
Processing Time [last: 4] - "http-nio-8080" - i-0bcf8dae93ec8052b (OrderServer9)
Processing Time [last: 5] - "http-nio-8080" - i-0d52e3f9d70dde33b (OrderServer5)
Processing Time [last: 2] - "http-nio-8080" - i-00483062a59f2fee2 (OrderServer6)
Top 10 request max processing time by server and proto_handler
Max Time [last: 20,003] - "http-nio-8080" - i-089d00bf337e76c26 (OrderServer11)

Max Time [last: 13,563] - "http-nio-8080" - i-00483062a59f2fee2 (OrderServer6)
Max Time [last: 12,558] - "http-nio-8080" - i-0084098d7773f2a7a (OrderServer2)
Sessions and threads

Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.
  - Each Tomcat host configured for the solution publishes a total of 27 metrics plus one metric (`disk_used_percent`) for which the metric count depends on number of disk paths for that host.
- One custom dashboard.
- API operations requested by the CloudWatch agent to publish the metrics. With the default configuration for this solution, the CloudWatch agent calls the **PutMetricData** once every minute. This means the **PutMetricData** API will be called `30*24*60=43,200` in a 30-day month for each EC2 host.

For more information about CloudWatch pricing, see [Amazon CloudWatch Pricing](https://aws.amazon.com/cloudwatch/pricing/).

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the [Amazon CloudWatch pricing calculator](https://calculator.aws/#/createCalculator/CloudWatch).
2. In the **Metrics** section, for **Number of metrics**, enter **`(27 + average number of disk paths per EC2 host) * number of EC2 instances configured for this solution`**.
3. In the **APIs** section, for **Number of API requests**, enter **`43200 * number of EC2 instances configured for this solution`**.

   By default, the solution performs one **PutMetricData** operation each minute for each EC2 host.
4. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
5. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces with the CloudWatch agent.

The agent configuration in this solution collects the foundational metrics for Tomcat, JVM, and EC2. The CloudWatch agent can be configured to collect more JVM metrics than the dashboard displays by default. For a list of all Tomcat metrics that you can collect, see Collect Tomcat metrics. For a list of all JVM metrics that you can collect, see Collect JVM metrics. For a list of Amazon EC2 metrics, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

Expose JMX ports for the Tomcat server

The CloudWatch agent relies on JMX to collect the metrics related to the Tomcat server and JVM process. To make this possible, you must expose the JMX port from your servers. To enable a JMX port for monitoring and management, you would set system properties for your Tomcat servers. You can use the environment variable `CATALINA_OPTS` to set the required system properties for Tomcat. Review the startup scripts and configuration files of your Tomcat server on the best place to set the environment variable. Be sure that you specify an unused port number. You will need to restart the server after the change.

```
export CATALINA_OPTS="-Dcom.sun.management.jmxremote -
Dcom.sun.management.jmxremote.port=<<port-number>> -
Dcom.sun.management.jmxremote.ssl=false -
Dcom.sun.management.jmxremote.authenticate=false"
```

This example sets up unauthenticated JMX. If your security policies/requirements require you to enable JMX with password authentication or SSL for remote access, refer to the JMX documentation to set the required property.

To verify the JMX port, run `ps aux | grep jmxremote.port`. The results should show that the JMX port was set on the JVM processes.

Agent configuration for Tomcat solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard.

The steps for deploying the solution are described later in Deploy the agent for your solution. The following information is intended to help you understand how to customize the agent configuration for your environment.

You must customize some parts of the following agent configuration for your environment:

- The JMX port number is the port number that you configured in the previous section of this documentation. The port number is in the `endpoint` line in the configuration.
- `AppName` – This is used as a dimension for the Tomcat application metrics collected. Provide a meaningful name that represents the grouping for the instances that run the Tomcat application.
- `ProcessGroupName` – This is used as a dimension for JVM metrics collected for Tomcat hosts. Provide the value which is the same as `AppName` above. This is to enable viewing the JVM metrics of the same Tomcat app group as server metrics under the solution dashboard.

For example, if you have two Tomcat apps running in the same Amazon Web Services account, one for the `billing-system` application and another for the `order-system` application, you can set the `AppName` and `ProcessGroupName` dimensions accordingly in the agent configuration of each instance.

- For the `billing-system` application instances, set `AppName=billing-system` and `ProcessGroupName=billing-system`.
- For the `order-system` application instances, set `AppName=order-system` and `ProcessGroupName=order-system`.

When you follow these guidelines, the solution will automatically group the metrics based on the `AppName` and `ProcessGroupName` dimensions. The dashboard will include dropdown options to select and view metrics for a specific Tomcat application, allowing you to monitor the performance of individual applications separately.

Agent configuration for Tomcat hosts

Use the following CloudWatch agent configuration on EC2 instances where your Tomcat applications are deployed. Configuration will be stored as a parameter in SSM's Parameter Store, as detailed later in Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store.

Replace *AppName* with a meaningful name that represents the Tomcat application the instances are part of. Replace *port-number* with the JMX port of your Tomcat server. If JMX was enabled with password authentication or SSL for remote access, see Collect Java Management Extensions (JMX) metrics for information about setting up TLS or authorization in agent configuration as required.

The EC2 metrics shown in this configuration (configuration shown outside the JMX block) only work for Linux and macOS instances. If you are using Windows instances, you can choose to omit these metrics in the configuration. For information about metrics collected on Windows instances, see Metrics collected by the CloudWatch agent on Windows Server instances.

```
{
  "metrics": {
    "namespace": "CWAgent",
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "localhost:port-number",
          "tomcat": {
            "measurement": [
              "tomcat.sessions",
              "tomcat.errors",
              "tomcat.processing_time",
              "tomcat.traffic",
              "tomcat.max_time",
              "tomcat.request_count",
              "tomcat.threads"
            ]
          },
          "append_dimensions": {
            "AppName": "AppName"
          }
        },
```

```
        {
          "endpoint": "localhost:port-number",
          "jvm": {
            "measurement": [
              "jvm.classes.loaded",
              "jvm.gc.collections.count",

```
}
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single Amazon account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts where the JVM application is deployed and managing the agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge the agent configuration of JVM with your existing agent configuration, and then deploy the merged configuration. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances. You can modify this configuration to suit your unique environment or use case. The metrics defined in this solution are the minimum required for the recommended dashboard.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.
- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an Amazon CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must also grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** and **AmazonSSMManagedInstanceCore** IAM policies attached.

- To create a role, see Create IAM roles to use with the CloudWatch agent on Amazon EC2 instances.
- After the role is created, attach the role to your EC2 instances. Follow the steps in Launch an instance with an IAM role to attach a role while launching a new EC2 instance. To attach a role to an existing EC2 instance, follow the steps in Attach an IAM role to an instance.

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the Amazon Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. From the navigation pane, choose **Application Management**, **Parameter Store**.
3. Follow these steps to create a new parameter for the configuration.

    a. Choose **Create parameter**.

    b. In the **Name** box, enter a name that you'll use to reference the CloudWatch agent configuration file in later steps. For example, **`AmazonCloudWatch-Tomcat-Configuration`**.

    c. (Optional) In the **Description** box, type a description for the parameter.

    d. For **Parameter tier**, choose **Standard**.

e. For **Type**, choose **String**.

f. For **Data type**, choose **text**.

g. In the **Value** box, paste the corresponding JSON block that was listed in [Agent configuration for Tomcat hosts](). Be sure to customize the grouping dimension value and port number as described.

h. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an Amazon CloudFormation template

You can use Amazon CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.amazonaws.cn/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the Tomcat workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.
4. In the **Parameters** section, specify the following:

    a. For **CloudWatchAgentConfigSSM**, enter the name of the Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-Tomcat-Configuration`**.

    b. To select the target instances, you have two options.

        i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.

        ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify

aws:autoscaling:groupName for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)

If you specify both the **InstanceIds** and the **TagKeys** parameters, the **InstanceIds** will take precedence and the tags will be ignored.

5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on Amazon CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json.

Note

After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:

1. If the Systems Manager parameter is deleted, the agent will stop.
2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.
3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in Step 1: Ensure the target EC2 instances have the required IAM permissions.
- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in ???.

If everything is set up correctly, then you should see the Tomcat metrics being published to CloudWatch. You can check the CloudWatch console to verify they are being published.

To verify that Tomcat metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. Choose **Metrics**, **All metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for the metrics mentioned in the agent configuration section of this document, such as `tomcat.errors`. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the Tomcat solution dashboard

This dashboard displays the newly emitted metrics, showing both the Tomcat application server and the underlying JVM. This dashboard provides a top contributor view for the health of your Tomcat workload. The top contributor view displays the top 10 per metric widget. This allows you to identify outliers at a glance. The dashboard also includes an overview of the cluster by aggregating and presenting metrics across all instances, providing a high-level summary of the overall health and operational state of the cluster.

The solution dashboard doesn't display EC2 metrics. To view EC2 metrics, you'll need to use the EC2 automatic dashboard to see EC2 vended metrics and use the EC2 console dashboard to see EC2 metrics that are collected by the CloudWatch agent. For more information about automatic dashboards for Amazon Web Services services, see Viewing a CloudWatch dashboard for a single Amazon service.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use Amazon CloudFormation console to deploy the dashboard.
- Download the Amazon CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with Amazon CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the Amazon CloudFormation stack in the Region where your Tomcat metrics are published.
>
> If you've specified a custom namespace other than `CWAgent` in the CloudWatch agent configuration, you'll have to change the Amazon CloudFormation template for the dashboard to replace `CWAgent` with the customized namespace you are using.

To create the dashboard via CloudWatch Console

> **Note**
>
> Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=ApacheTomcatOnEc2&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the Tomcat workload is running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`TomcatDashboard-us-east-1`**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via Amazon CloudFormation

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.amazonaws.cn/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/Tomcat_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.
2. Verify that the selected Region on the console is the Region where the Tomcat workload is running.
3. For **Stack name**, enter a name to identity this stack, such as **`TomcatDashboard-us-east-1`**.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.
5. To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`TomcatDashboard-us-east-1`**.
6. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that CloudFormation doesn't add any IAM resources.
7. Review the settings, then choose **Create stack**.
8. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file to customize it for any purpose, you can use **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on Amazon CloudFormation console. You can use this link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/Tomcat_EC2/CloudWatch/CFN/v1.0.0/dashboard-template-1.0.0.json.

Note

Solution dashboards currently display garbage collection-related metrics only for the G1 Garbage Collector, which is the default collector for the latest Java versions. If you are using a different garbage collection algorithm, the widgets pertaining to garbage collection are empty. However, you can customize these widgets by changing the dashboard CloudFormation template and applying the appropriate garbage collection type to the name dimension of the garbage collection-related metrics. For example, if you are using parallel garbage collection, change the **`name=\"G1 Young Generation\"`** to **`name=\"Parallel GC\"`** of the garbage collection count metric `jvm.gc.collections.count`.

Get started with the Tomcat monitoring dashboard

Here are a few tasks that you can try out with the new Tomcat dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor a Tomcat application. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Using the dropdown list

The dashboard provides a dropdown list at the top that you can use to filter and select the specific Tomcat application that you want to monitor. To display metrics for a specific Tomcat application, select that application name in the **Tomcat App** dropdown list.

Verify application health

From the **App Overview** section, find the **Requests**, **Errors**, and **Error Rate** widgets. These provide a high-level summary of the application's request handling performance. Look for any abnormally high error counts or rates, which could indicate issues that need investigation.

Monitor request processing

In the **Request Processing Time** section, find the **Max Time** and **Total Time to Process All Requests** widgets. These metrics help you identify potential performance bottlenecks in request processing. Look for any servers with significantly higher max processing times compared to others.

Analyze network traffic

In the **Network Traffic** section, find the **Sent Traffic** and **Received Traffic** widgets. These show the amount of data being sent and received by the application over the network. Unexpectedly high traffic levels could indicate potential issues with network saturation or inefficient data transfer.

Investigate thread usage

In the **Sessions and Threads** section, find the **Busy Threads Count**, **Threads Count**, and **Sessions** widgets. These metrics provide insights into the application's thread management and active user sessions. Look for any servers with an abnormally high number of busy threads or sessions, which could indicate potential resource constraints.

CloudWatch solution: Amazon EC2 health

This solution helps you configure out-of-the-box metric collection using CloudWatch agents for workloads running on EC2 instances. Additionally, it helps you set up a pre-configured CloudWatch dashboard.

Topics

Requirements

This solution is relevant for the following conditions:

- Compute: Amazon EC2
- Platform: Linux and macOS
- Supports up to 500 EC2 instances in a given Amazon Web Services Region
- Latest version of CloudWatch agent
- SSM agent installed on EC2 instance

> **Note**
>
> Amazon Systems Manager (SSM agent) is pre-installed on some Amazon Machine Images (AMIs) provided by Amazon and trusted third-parties. If the agent isn't installed, you can install it manually using the procedure for your operating system type.
>
> - Manually installing and uninstalling SSM Agent on EC2 instances for Linux

- [Manually installing and uninstalling SSM Agent on EC2 instances for macOS]
- [Manually installing and uninstalling SSM Agent on EC2 instances for Windows Server]

Benefits

The solution delivers EC2 server monitoring using the CloudWatch Agent, providing additional system-level metrics on top of the standard EC2 namespace metrics for the following use cases:

- Detect CPU performance issues and resource constraints.
- Monitor disk utilization and storage capacity across different disks throughout your EC2 instances.
- Track memory usage patterns and potential memory leaks.
- Analyze I/O operations and their impact on overall performance.
- Observe network traffic patterns and potential anomalies.

Below are the key advantages of the solution:

- Automates metric collection for EC2 instances eliminating manual instrumentation.
- Provides a pre-configured, consolidated CloudWatch dashboard for EC2 instance metrics. The dashboard will automatically handle metrics from new EC2 instances configured using the solution, even if those metrics don't exist when you first create the dashboard. It also allows you to observe EC2 instances managed via Auto Scaling groups.

The following image is an example of the dashboard for this solution.

AWS/EC2 Vended Metrics

Costs

This solution creates and uses resources in your account. You are charged for standard usage, including the following:

- All metrics collected by the CloudWatch agent are charged as custom metrics. The number of metrics used by this solution depends on the number of EC2 hosts.

  The total number of CloudWatch agent metrics depends on the configuration of disks. Excluding disk and diskio metrics, the solution publishes six metrics. The number of disk metrics (`disk_used_percent`, `disk_inodes_free`) depend on the count of `device/fstype/path` dimensions. The diskio metric (`diskio_io_time`) depends on the count of `name` dimensions. For example, a single t2.micro with default settings as per EC2 console experience, produces a total of 22 CloudWatch agent metrics (4 CPU, 12 disk, 4 diskio, 1 memory, and 1 swap). Vended metrics like `AWS/EC2` are provided free of charge.
- One custom dashboard.
- API operations requested by the CloudWatch agent to publish the metrics. With the default configuration for this solution, the CloudWatch agent calls the **PutMetricData** once every minute. This means the **PutMetricData** API will be called `30*24*60=43,200` in a 30-day month for each EC2 host.

For more information about CloudWatch pricing, see [Amazon CloudWatch Pricing](#).

The pricing calculator can help you estimate approximate monthly costs for using this solution.

To use the pricing calculator to estimate your monthly solution costs

1. Open the [Amazon CloudWatch pricing calculator](#).
2. In the **Metrics** section, for **Number of metrics**, enter **`(6 + total count of disk and diskio metrics per EC2 host as described above) * number of EC2 instances configured for this solution`**.
3. In the **APIs** section, for **Number of API requests**, enter **`43200 * number of EC2 instances configured for this solution`**.
4. By default, the solution performs one **PutMetricData** operation each minute for each EC2 host.
5. In the **Dashboards and Alarms** section, for **Number of Dashboards**, enter **1**.
6. You can see your monthly estimated costs at the bottom of the pricing calculator.

CloudWatch agent configuration for this solution

The CloudWatch agent is software that runs continuously and autonomously on your servers and in containerized environments. It collects metrics, logs, and traces from your infrastructure and applications and sends them to CloudWatch and X-Ray.

For more information about the CloudWatch agent, see Collect metrics, logs, and traces with the CloudWatch agent.

The agent configuration in this solution collects a set of metrics to help you get started monitoring and observing your EC2 instances. The CloudWatch agent can be configured to collect more EC2 metrics than the dashboard displays by default. For a list of Amazon EC2 metrics, see Metrics collected by the CloudWatch agent on Linux and macOS instances. For information about metrics collected on Windows instances, see Metrics collected by the CloudWatch agent on Windows Server instances.

Agent configuration for EC2 Health solution

The metrics collected by the agent are defined in the agent configuration. The solution provides agent configurations to collect the recommended metrics with suitable dimensions for the solution's dashboard.

The steps for deploying the solution are described later in the section called "Deploy the agent for your solution". The following information is intended to help you understand how to customize the agent configuration for your environment.

> **Note**
>
> If an EC2 instance is not part of an Auto Scaling group, the CloudWatch agent drops the `AutoScalingGroupName` dimension entirely. This behavior helps to prevent dimension names with null/empty values. Each metric widget included in the solution dashboard searches for metrics which include and exclude the `AutoScalingGroup` dimension. This helps to ensure that all EC2 instances where the solution is applied are supported by the same dashboard.

If you wish to make any modifications to the agent configuration, you must apply the same changes to the solution's accompanying dashboard. For example, if you decide to omit the ImageId dimension, the same dimension must be removed from the metric search expression used in the dashboard widgets.

Agent configuration for EC2 Instances

Use the following CloudWatch agent configuration on Amazon EC2 instances where your workloads are deployed.

```
{
    "agent": {
      "metrics_collection_interval": 60,
      "run_as_user": "cwagent"
    },
    "metrics": {
      "append_dimensions": {
        "InstanceId": "${aws:InstanceId}",
        "InstanceType": "${aws:InstanceType}",
        "ImageId": "${aws:ImageId}",
        "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
      },
      "metrics_collected": {
        "cpu": {
          "measurement": [
            "cpu_usage_idle",
             "cpu_usage_iowait",
             "cpu_usage_user",
             "cpu_usage_system"
          ],
          "totalcpu": true
        },
        "disk": {
          "measurement": [
            "used_percent",
            "inodes_free"
          ],
          "resources": [
            "*"
          ],
          "dimensions": [
            ["device", "fstype", "path"]
          ]
        },
        "diskio": {
```

```
            "measurement": [
              "io_time"
            ],
            "resources": [
              "*"
            ]
          },
        "mem": {
          "measurement": [
            "used_percent"
          ]
        },
        "swap": {
          "measurement": [
            "used_percent"
          ]
        }
      }
    }
  }
```

Deploy the agent for your solution

There are several approaches for installing the CloudWatch agent, depending on the use case. We recommend using Systems Manager for this solution. It provides a console experience and makes it simpler to manage a fleet of managed servers within a single Amazon account. The instructions in this section use Systems Manager and are intended for when you don't have the CloudWatch agent running with existing configurations. You can check whether the CloudWatch agent is running by following the steps in Verify that the CloudWatch agent is running.

If you are already running the CloudWatch agent on the EC2 hosts and managing the agent configurations, you can skip the instructions in this section and follow your existing deployment mechanism to update the configuration. Be sure to merge the EC2 Health agent configuration with your existing agent configuration, and then deploy the merged configuration. If you are using Systems Manager to store and manage the configuration for the CloudWatch agent, you can merge the configuration to the existing parameter value. For more information, see Managing CloudWatch agent configuration files.

> **Note**
>
> Using Systems Manager to deploy the following CloudWatch agent configurations will replace or overwrite any existing CloudWatch agent configuration on your EC2 instances. You can modify this configuration to suit your unique environment or use case. The metrics defined in configuration are the minimum required for the dashboard provided the solution.

The deployment process includes the following steps:

- Step 1: Ensure that the target EC2 instances have the required IAM permissions.
- Step 2: Store the recommended agent configuration file in the Systems Manager Parameter Store.
- Step 3: Install the CloudWatch agent on one or more EC2 instances using an Amazon CloudFormation stack.
- Step 4: Verify the agent setup is configured properly.

Step 1: Ensure the target EC2 instances have the required IAM permissions

You must grant permission for Systems Manager to install and configure the CloudWatch agent. You must also grant permission for the CloudWatch agent to publish telemetry from your EC2 instance to CloudWatch. Make sure that the IAM role attached to the instance has the **CloudWatchAgentServerPolicy** and **AmazonSSMManagedInstanceCore** IAM policies attached.

- To create a role, see Create IAM roles to use with the CloudWatch agent on Amazon EC2 instances.
- After the role is created, attach the role to your EC2 instances. To attach a role to an EC2 instance, follow the steps in Attach an IAM role to an instance.

Step 2: Store the recommended CloudWatch agent configuration file in Systems Manager Parameter Store

Parameter Store simplifies the installation of the CloudWatch agent on an EC2 instance by securely storing and managing configuration parameters, eliminating the need for hard-coded values. This ensures a more secure and flexible deployment process, enabling centralized management and easier updates to configurations across multiple instances.

Use the following steps to store the recommended CloudWatch agent configuration file as a parameter in Parameter Store.

To create the CloudWatch agent configuration file as a parameter

1. Open the Amazon Systems Manager console at https://console.aws.amazon.com/systems-manager/.
2. Verify that the selected Region on the console is the Region where the EC2 instances are running.
3. From the navigation pane, choose **Application Management**, **Parameter Store**.
4. Follow these steps to create a new parameter for the configuration.

    a. Choose **Create parameter**.

    b. In the **Name** box, enter a name that you'll use to reference the CloudWatch agent configuration file in later steps. For example, **`AmazonCloudWatch-EC2Health-Configuration`**.

    c. (Optional) In the **Description** box, type a description for the parameter.

    d. For **Parameter tier**, choose **Standard**.

    e. For **Type**, choose **String**.

    f. For **Data type**, choose **text**.

    g. In the **Value** box, paste the agent configuration JSON provided earlier in this document.

    h. Choose **Create parameter**.

Step 3: Install the CloudWatch agent and apply the configuration using an Amazon CloudFormation template

You can use Amazon CloudFormation to install the agent and configure it to use the CloudWatch agent configuration that you created in the previous steps.

To install and configure the CloudWatch agent for this solution

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https:// console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://

aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json .

2. Verify that the selected Region on the console is the Region where the EC2 instances are running.
3. For **Stack name**, enter a name to identity this stack, such as **`CWAgentInstallationStack`**.
4. In the **Parameters** section, specify the following:

   a. For **CloudWatchAgentConfigSSM**, enter the name of the Systems Manager parameter for the agent configuration that you created earlier, such as **`AmazonCloudWatch-EC2Health-Configuration`**.

   b. To select the target instances, you have two options.

      i. For **InstanceIds**, specify a comma-delimited list of instance IDs list of instance IDs where you want to install the CloudWatch agent with this configuration. You can list a single instance or several instances.

      ii. If you are deploying at scale, you can specify the **TagKey** and the corresponding **TagValue** to target all EC2 instances with this tag and value. If you specify a **TagKey**, you must specify a corresponding **TagValue**. (For an Auto Scaling group, specify **`aws:autoscaling:groupName`** for the **TagKey** and specify the Auto Scaling group name for the **TagValue** to deploy to all instances within the Auto Scaling group.)

   If you specify both the **InstanceIds** and the **TagKeys** parameters, the **InstanceIds** will take precedence and the tags will be ignored.

5. Review the settings, then choose **Create stack**.

If you want to edit the template file first to customize it, choose the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on Amazon CloudFormation console. You can use the following link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/CloudWatchAgent/CFN/v1.0.0/cw-agent-installation-template-1.0.0.json .

> **Note**
>
> After this step is completed, this Systems Manager parameter will be associated with the CloudWatch agents running in the targeted instances. This means that:

1. If the Systems Manager parameter is deleted, the agent will stop.
2. If the Systems Manager parameter is edited, the configuration changes will automatically apply to the agent at the scheduled frequency which is 30 days by default.
3. If you want to immediately apply changes to this Systems Manager parameter, you must run this step again. For more information about associations, see Working with associations in Amazon Systems Manager.

Step 4: Verify the agent setup is configured properly

You can verify whether the CloudWatch agent is installed by following the steps in Verify that the CloudWatch agent is running. If the CloudWatch agent is not installed and running, make sure you have set up everything correctly.

- Be sure you have attached a role with correct permissions for the EC2 instance as described in the section called "Step 1: Ensure the target EC2 instances have the required IAM permissions".
- Be sure you have correctly configured the JSON for the Systems Manager parameter. Follow the steps in Troubleshooting installation of the CloudWatch agent with Amazon CloudFormation.

To verify that EC2 health metrics are being published to CloudWatch

1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/.
2. Choose **Metrics**, **All metrics**.
3. Make sure you've selected the Region where you deployed the solution, and choose **Custom namespaces**, **CWAgent**.
4. Search for the metrics mentioned in the agent configuration section of this document, such as `mem_used_percent`. If you see results for these metrics, then the metrics are being published to CloudWatch.

Create the EC2 Health solution dashboard

This dashboard displays the newly emitted metrics, showing the EC2 Health metrics. This dashboard provides a top contributor view for the health of your EC2 instances in a single region. The top contributor view displays the top 10 per metric widget. This allows you to identify outliers at a glance.

To create the dashboard, you can use the following options:

- Use CloudWatch console to create the dashboard.
- Use Amazon CloudFormation console to deploy the dashboard.
- Download the Amazon CloudFormation infrastructure as code and integrate it as part of your continuous integration (CI) automation.

By using the CloudWatch console to create a dashboard, you can preview the dashboard before actually creating and being charged.

> **Note**
>
> The dashboard created with Amazon CloudFormation in this solution displays metrics from the Region where the solution is deployed. Be sure to create the Amazon CloudFormation stack in the Region where your EC2 metrics are published.
> If you've specified a custom namespace other than `CWAgent` in the CloudWatch agent configuration, you'll have to change the Amazon CloudFormation template for the dashboard to replace `CWAgent` with the customized namespace you are using.

To create the dashboard via CloudWatch Console

1. Open the CloudWatch Console **Create Dashboard** using this link: https://console.aws.amazon.com/cloudwatch/home?#dashboards?dashboardTemplate=Ec2LinuxMacOsHealth&referrer=os-catalog .
2. Verify that the selected Region on the console is the Region where the EC2 instances are running.
3. Enter the name of the dashboard, then choose **Create Dashboard**.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`EC2HealthDashboard-us-east-1`**.
4. Preview the dashboard and choose **Save** to create the dashboard.

To create the dashboard via Amazon CloudFormation

1. Open the Amazon CloudFormation **Quick create stack** wizard using this link: https://console.aws.amazon.com/cloudformation/home?#/stacks/quickcreate?templateURL=https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/EC2_Health/CloudWatch/CFN/v1.0.0/dashboard-template-linux-macos-1.0.0.json .
2. Verify that the selected Region on the console is the Region where the EC2 instances are running.
3. For **Stack name**, enter a name to identity this stack, such as `EC2HealthDashboardStack`.
4. In the **Parameters** section, specify the name of the dashboard under the **DashboardName** parameter.

   To easily differentiate this dashboard from similar dashboards in other Regions, we recommend including the Region name in the dashboard name, such as **`EC2HealthDashboard-us-east-1`**.
5. Acknowledge access capabilities for transforms under **Capabilities and transforms**. Note that Amazon CloudFormation doesn't add any IAM resources.
6. Review the settings, then choose **Create stack**.
7. After the stack status is **CREATE_COMPLETE**, choose the **Resources** tab under the created stack and then choose the link under **Physical ID** to go to the dashboard. You can also access the dashboard in the CloudWatch console by choosing **Dashboards** in the left navigation pane of the console, and finding the dashboard name under **Custom Dashboards**.

If you want to edit the template file to customize it for any purpose, you can use the **Upload a template file** option under **Create Stack Wizard** to upload the edited template. For more information, see Creating a stack on Amazon CloudFormation console. You can use this link to download the template: https://aws-observability-solutions-prod-us-east-1.s3.us-east-1.amazonaws.com/EC2_Health/CloudWatch/CFN/v1.0.0/dashboard-template-linux-macos-1.0.0.json

Get started with the EC2 Health solution dashboard

Here are a few tasks that you can try out with the new EC2 monitoring dashboard. These tasks allow you to validate that the dashboard is working correctly and provide you some hands-on experience using it to monitor EC2 instances. As you try these out, you'll get familiar with navigating the dashboard and interpreting the visualized metrics.

Monitor the various CPU utilization metrics

In the **CPU** section, examine the array of CPU usage metrics. These provide insight into how CPU resources are being utilized across different activities like user processes, system tasks, and I/O operations. Look for instances with consistently high utilization or unusual patterns, which might indicate the need for scaling or optimization.

Analyze disk utilization across different devices

Navigate to the **Disk** section to find the storage usage and inode availability metrics. These help you identify instances that are running low on storage space or file system resources. Pay attention to any instances approaching high disk usage levels, as this could lead to performance issues or service disruptions.

Investigate memory utilization patterns

In the **Memory** section, observe the graph which plots memory utilization over time. This shows how much of the available memory is being used by each instance. Look for patterns or spikes in memory usage that might correlate with specific times or events. High memory utilization could indicate the need for instance resizing or application optimization.

Correlate patterns across core utilization metrics

Compare and watch out for related utilization patterns. For example, a workload running a log rotation process could present regular increases in **CPU** and **memory** utilization, followed by a decrease in **disk** utilization.

Inspect network activity

In the **Network** section, examine the inbound and outbound network traffic metrics, both in terms of data volume and packet count. These give you insight into the network activity for your EC2 instances. Look out for both regular or anomalous spikes in network traffic, or imbalances between inbound and outbound data.

Monitor across accounts and Regions

To enable unified monitoring across accounts, CloudWatch offers the following features:

- **CloudWatch cross-account observability**– facilitate observability within a single Region with the Observability Access Manager (OAM) service. You can link accounts and easily view metrics, logs, traces, and other telemetry between accounts. This helps you to unify observability in central monitoring accounts that view telemetry shared from source accounts, and operate on this shared telemetry as if it were native to the monitoring account.
- **Cross-account cross-Region CloudWatch console**– delivers a console experience that allows you to view dashboards, metrics, and alarms consoles of other accounts across Regions by toggling between accounts. After you set up the necessary permissions, you use an account selector integrated into the alarms, dashboards, and metrics consoles to view metrics, dashboards, and alarms in other accounts without having to log in and out of the accounts. By enabling this feature, you can also set up dashboards that contain cross-account cross-Region metrics for centralized visibility within an account.

These two features are complementary to each other and can be used independently or together. See the following table for a comparison of the two features. We recommend that you use CloudWatch cross-account observability for the richest cross-account observability and discovery experience within a Region for your metrics, logs, and traces.

	CloudWatch cross-account observability	Cross-account cross-Region CloudWatch console
What is it?	Unified access to underlying telemetry and other observabi lity resources across multiple accounts. After this is configure d, observability resources are seamlessly viewable between accounts, eliminating the need for role assumptions. The central monitoring account gains direct access to the telemetry data and resources from source accounts,	A designated monitoring account assume a **CrossAccountSharin gRole** defined in source accounts from the CloudWatch console. By assuming this role, the monitorin g account can invoke operation s such as dashboard viewing on behalf of source accounts, directly from its console.

	[CloudWatch cross-account observability]()	[Cross-account cross-Region CloudWatch console]()
	streamlining the monitoring and observability process.	
How does it work?	A monitoring account, using the Observability Access Monitorin g service, creates a *sink* and attaches a sink policy to it. The sink policy defines which resources they would like to view and which source accounts should share them. Then source accounts can create a link to the monitoring account sink, establish ing what they actually want to share. After the link is created, the specified resources are visible in the monitoring account.	A source account initiates the configuration by setting up a **CrossAccountSharingRole**, allowing a monitoring account to run operations in the source account. Then, a monitoring account enables the cross-acc ount cross-Region selector in the console by specifying the source account ID. This enables the monitoring account to be able to switch into the source account. When switching, the CloudWatch console checks for the existence of a service-linked role that allows CloudWatch to assume the **CrossAccountSharin gRole** that was created in the source account.
What telemetry is supported?	• Metrics • Traces • Logs .	• Metrics • Traces

	CloudWatch cross-account observability	Cross-account cross-Region CloudWatch console
What functionality is supported?	• Dashboarding • Alarms • Metrics Insights • Anomaly Detection • CloudWatch Logs insights • Application Insights • Other functionalities. For more details see CloudWatch cross-account observability. .	• Console switching between accounts and Regions in metrics, alarms, and traces consoles. • Custom dashboards with metrics and alarms from other accounts and Regions For more details, see Cross-account cross-Region CloudWatch console.
How many accounts can I use it with?	A monitoring account can see resources from as many as 100,000 source accounts at the same time. A source account can share their resources with as many as five different monitoring accounts.	By using the cross-account cross-Region selector in the console, a monitoring account can switch to one other account at a time but there is no limit on the number of accounts that can be linked. When defining cross-account dashboards and alarms, many source accounts can be reference d.
Does it move telemetry data?	No. Resources are shared between accounts with the exception of copied traces.	No. An IAM policy is configure d to allow embedded account switching for cross-account cross-Region resource visibilty.

	CloudWatch cross-account observability	Cross-account cross-Region CloudWatch console
How much does it cost?	No extra charges for shared logs and metrics, and the first trace copy is free. For more informati on about pricing, see Amazon CloudWatch pricing.	No additional charges for cross-account or cross-Region actions.
Does it support observability across Regions?	No	Yes
Does it support programmatic access?	Yes. the Amazon CLI, Amazon Cloud Development Kit (Amazon CDK), and APIs are supported.	No.
Does it support programmatic setup?	Yes	Yes
Does it support Amazon Organizat ions?	Yes	Yes

Topics

- CloudWatch cross-account observability
- Cross-account cross-Region CloudWatch console

CloudWatch cross-account observability

With Amazon CloudWatch cross-account observability, you can monitor and troubleshoot applications that span multiple accounts within a Region. Seamlessly search, visualize, and analyze your metrics, logs, traces, Application Signals services and service level objectives (SLOs), Application Insights applications, and internet monitors in any of the linked accounts without account boundaries.

Set up one or more Amazon accounts as *monitoring accounts* and link them with multiple *source accounts*. A monitoring account is a central Amazon account that can view and interact with observability data generated from source accounts. A source account is an individual Amazon account that generates observability data for the resources that reside in it. Source accounts share their observability data with the monitoring account. The shared observability data can include the following types of telemetry:

- Metrics in Amazon CloudWatch. You can choose to share the metrics from all namespaces with the monitoring account, or filter to a subset of namespaces.
- Log groups in Amazon CloudWatch Logs. You can choose to share all log groups with the monitoring account, or filter to a subset of log groups.
- Traces in Amazon X-Ray
- Services and Service level objectives (SLOs) in Application Signals
- Applications in Amazon CloudWatch Application Insights
- Monitors in CloudWatch Internet Monitor

To create links between monitoring accounts and source accounts, you can use the CloudWatch console. Alternatively, use the *Observability Access Manager* commands in the Amazon CLI and API. For more information, see Observability Access Manager API Reference.

A *sink* is a resource that represents an attachment point in a monitoring account. Source accounts can link to the sink to share observability data. Each account can have one sink per Region. Each sink is managed by the monitoring account where it is located. An *observability link* is a resource that represents the link established between a source account and a monitoring account. Links are managed by the source account.

The next topic explains how to set up CloudWatch cross-account observability in both monitoring accounts and source accounts. For information about the cross-account cross-Region CloudWatch dashboard, see Cross-account cross-Region CloudWatch console.

Use Organizations for source accounts

There are two options for linking source accounts to your monitoring account. You can use one or both options.

- Use Amazon Organizations to link accounts in an organization or organizational unit to the monitoring account.

- Connect individual Amazon accounts to the monitoring account.

We recommend that you use Organizations so that new Amazon accounts created later in the organization are automatically onboarded to cross-account observability as source accounts.

Details about linking monitoring accounts and source accounts

- Each monitoring account can be linked to as many as 100,000 source accounts.
- Each source account can share data with as many as five monitoring accounts.
- You can set up a single account as both a monitoring account and a source account. If you do, this account sends only the observability data from itself to its linked monitoring account. It does not relay the data from its source accounts.
- A monitoring account specifies which telemetry types can be shared with it. A source account specifies which telemetry types it wants to share.
  - If there are more telemetry types selected in the *monitoring account* than in the source account, the accounts are linked. Only the data types that are selected in both accounts are shared.
  - If there are more telemetry types selected in the *source account* than in the monitoring account, the link creation fails and nothing is shared.
  - A metric name doesn't appear in the monitoring account console until that metric emits new data points after the link is created.
- To remove a link between accounts, do so from the source account.
- To delete a sink in a monitoring account, you must first remove all links to that sink the monitoring account.

Pricing

Cross-account observability in CloudWatch comes with no extra cost for logs and metrics, Application Signals, and the first trace copy is free. For more information about pricing, see [Amazon CloudWatch Pricing](#).

Contents

Link monitoring accounts with source accounts

The topics in this section explain how to set up links between monitoring accounts and source accounts.

We recommend that you create a new Amazon account to serve as the monitoring account for your organization.

Contents

- Use a URL to set up individual source accounts

Necessary permissions

Permissions needed to create links

To create links between a monitoring account and a source account, you must be signed in with certain permissions.

- **To set up a monitoring account –** You must have either full administrator access in the monitoring account, or you must sign in to that account with the following permissions:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowSinkModification",
            "Effect": "Allow",
            "Action": [
                "oam:CreateSink",
                "oam:DeleteSink",
                "oam:PutSinkPolicy",
                "oam:TagResource"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AllowReadOnly",
            "Effect": "Allow",
            "Action": ["oam:Get*", "oam:List*"],
            "Resource": "*"
        }
    ]
}
```

- **Source account, scoped to a specific monitoring account –** To create, update, and manage links for just one specified monitoring account, you must sign in to account with at least the following permissions. In this example, the monitoring account is 999999999999.

  If the link isn't going to share all seven resource types (metrics, logs, traces, Application Insights applications, Application Signals services and service level objectives (SLOs), and

Internet Monitor monitors), you can omit `cloudwatch:Link`, `logs:Link`, `xray:Link`, `applicationinsights:Link`, `application-signals:Link`, or `internetmonitor:Link` as needed.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "oam:CreateLink",
                "oam:UpdateLink",
                "oam:DeleteLink",
                "oam:GetLink",
                "oam:TagResource"
            ],
            "Effect": "Allow",
            "Resource": "arn:*:oam:*:*:link/*"
        },
        {
            "Action": [
                "oam:CreateLink",
                "oam:UpdateLink"
            ],
            "Effect": "Allow",
            "Resource": "arn:*:oam:*:*:sink/*",
            "Condition": {
                "StringEquals": {
                    "aws:ResourceAccount": [
                        "999999999999"
                    ]
                }
            }
        },
        {
            "Action": "oam:ListLinks",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "cloudwatch:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
```

```
        {
            "Action": "logs:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "xray:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
             "Action": "applicationinsights:Link",
             "Effect": "Allow",
             "Resource": "*"
         },
        {
             "Action": "internetmonitor:Link",
             "Effect": "Allow",
             "Resource": "*"
        },
        {
             "Action": "application-signals:Link",
             "Effect": "Allow",
             "Resource": "*"
        }
    ]
}
```

- **Source account, with permissions to link to any monitoring account** – To create a link to any existing monitoring account sink and share metrics, log groups, traces, Application Insights applications, and Internet Monitor monitors, you must sign in to the source account with full administrator permissions or sign in there with the following permissions

  If the link isn't going to share all seven resource types (metrics, logs, traces, Application Insights applications, Application Signals services and service level objectives (SLOs), and Internet Monitor monitors), you can omit `cloudwatch:Link`, `logs:Link`, `xray:Link`, `applicationinsights:Link`, `application-signals:Link`, or `internetmonitor:Link` as needed.

```
{
    "Version": "2012-10-17",
    "Statement": [{
```

```
            "Effect": "Allow",
            "Action": [
                "oam:CreateLink",
                "oam:UpdateLink"
            ],
            "Resource": [
                "arn:aws:oam:*:*:link/*",
                "arn:aws:oam:*:*:sink/*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "oam:List*",
                "oam:Get*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "oam:DeleteLink",
                "oam:GetLink",
                "oam:TagResource"
            ],
            "Resource": "arn:aws:oam:*:*:link/*"
        },
        {
            "Action": "cloudwatch:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "xray:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
            "Action": "logs:Link",
            "Effect": "Allow",
            "Resource": "*"
        },
        {
             "Action": "applicationinsights:Link",
```

```
                "Effect": "Allow",
                "Resource": "*"
            },
            {
                "Action": "internetmonitor:Link",
                "Effect": "Allow",
                "Resource": "*"
            },
            {
                "Action": "application-signals:Link",
                "Effect": "Allow",
                "Resource": "*"
            }
        ]
}
```

Permissions needed to monitor across accounts

After a link has been created, to view source account information from a monitoring account, you must be signed in to an account with one of the following:

- Full administrator access in the monitoring account
- The following cross-account permissions, in addition to permissions to view the specific types of resources that you will be monitoring

```
{
   "Sid": "AllowReadOnly",
   "Effect": "Allow",
   "Action": [
     "oam:Get*",
     "oam:List*"
   ],
   "Resource": "*"
 }
```

Setup overview

The following high-level steps show you how to set up CloudWatch cross-account observability.

> **Note**
>
> We recommend creating a new Amazon account to use as your organization's monitoring account.

1. Set up a dedicated monitoring account.
2. (Optional) Download an Amazon CloudFormation template or copy a URL to link source accounts.
3. Link source accounts to the monitoring account.

After completing these steps, you can use the monitoring account to view the observability data of the source accounts.

Step 1: Set up a monitoring account

Follow the steps in this section to set up an Amazon account as a monitoring account for CloudWatch cross-account observability.

Prerequisites

- **If you're setting up accounts in an Amazon Organizations organization as the source accounts** – Get the organization path or organization ID.
- **If you're not using Organizations for the source accounts** – Get the account IDs of the source accounts.

To set up an account as a monitoring account, you must have certain permissions. For more information, see Necessary permissions.

To set up a monitoring account

1. Sign in to the account that you want to use as a monitoring account.
2. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
3. In the left navigation pane, choose **Settings**.
4. By **Monitoring account configuration**, choose **Configure**.
5. For **Select data**, choose whether this monitoring account will be able to view **Logs**, **Metrics**, **Traces**, **Application Insights - Applications**, **Internet Monitor - Monitors**, and **Application**

Signals - Services, Service Level Objectives (SLOs) data from the source accounts it is linked to.

6. For **List source accounts**, enter the source accounts that this monitoring account will view. To identify the source accounts, enter individual account IDs, organization paths, or organization IDs. If you enter an organization path or organization ID, this monitoring account is allowed to view observability data from all linked accounts in that organization.

   Separate the entries in this list with commas.

   > **Important**
   >
   > When you enter an organization path, follow the exact format. The ou-id must end with a / (a slash character). For example: `o-a1b2c3d4e5/r-f6g7h8i9j0example/ou-def0-awsbbbb/`

7. For **Define a label to use to identify your source account**, you can define alabel that is used to create a Amazon CloudFormation template. The label is then applied to source accounts when that template is used to link the source accounts to this monitoring account.

   You can specify whether to use account names or email addresses in this label, and also use variables such as `$AccountName`, `$AcccountEmail`, and `$AcccountEmailNoDomain`.

   > **Note**
   >
   > In the Amazon GovCloud (US-East) and Amazon GovCloud (US-West) Regions, the only supported option is to use custom labels, and the `$AccountName`, `$AcccountEmail`, and `$AcccountEmailNoDomain` variables all resolve as *`account-id`* instead of the specified variable.

8. Choose **Configure**.

> **Important**
>
> The link between the monitoring and source accounts is not complete until you configure the source accounts. For more information, see the following sections.

Step 2: (Optional) Download an Amazon CloudFormation template or URL

To link source accounts to a monitoring account, we recommend using an Amazon CloudFormation template or a URL.

- **If you are linking an entire organization –** CloudWatch provides an Amazon CloudFormation template.
- **If you are linking individual accounts –** Use either an Amazon CloudFormation template or a URL that CloudWatch provides.

To use an Amazon CloudFormation template, you must download it during these steps. After you link the monitoring account with at least one source account, the Amazon CloudFormation template is no longer available to download.

To download an Amazon CloudFormation template or copy a URL for linking source accounts to the monitoring account

1. Sign in to the account that you want to use as a monitoring account.
2. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
3. In the left navigation pane, choose **Settings**.
4. By **Monitoring account configuration**, choose **Resources to link accounts**.
5. Do one of the following:
   - Choose **Amazon organization** to get a template to use to link accounts in an organization to this monitoring account.
   - Choose **Any account** to get a template or URL for setting up individual accounts as source accounts.
6. Do one of the following:
   - If you chose **Amazon organization**, choose **Download CloudFormation template**.
   - If you chose **Any account**, choose either **Download CloudFormation template** or **Copy URL**.
7. (Optional) Repeat steps 5-6 to download both the Amazon CloudFormation template and the URL.

Step 3: Link the source accounts

Use the steps in these sections to link source accounts to a monitoring account.

To link monitoring accounts with source accounts, you must have certain permissions. For more information, see Necessary permissions.

Use an Amazon CloudFormation template to set up all accounts in an organization or an organizational unit as source accounts

These steps assume that you already downloaded the necessary Amazon CloudFormation template by performing the steps in Step 2: (Optional) Download an Amazon CloudFormation template or URL.

To use an Amazon CloudFormation template to link accounts in an organization or organizational unit to the monitoring account

1. Sign in to the organization's management account.
2. Open the Amazon CloudFormation console at https://console.amazonaws.cn/cloudformation.
3. In the left navigation bar, choose **StackSets**.
4. Check that you are signed in to the Region that you want, then choose **Create StackSet**.
5. Choose **Next**.
6. Choose **Template is ready** and choose **Upload a template file**.
7. Choose **Choose file**, choose the template that you downloaded from the monitoring account, and choose **Open**.
8. Choose **Next**.
9. For **Specify StackSet details**, enter a name for the StackSet and choose **Next**.
10. For **Add stacks to stack set**, choose **Deploy new stacks**.
11. For **Deployment targets**, choose whether to deploy to the entire organization or to specified organizational units.
12. For **Specify regions**, choose which Regions to deploy CloudWatch cross-account observability to.
13. Choose **Next**.
14. On the **Review** page, confirm your selected options and choose **Submit**.
15. In the **Stack instances** tab, refresh the screen until you see that your stack instances have the status **CREATE_COMPLETE**.

Use an Amazon CloudFormation template to set up individual source accounts

These steps assume that you already downloaded the necessary Amazon CloudFormation template by performing the steps in Step 2: (Optional) Download an Amazon CloudFormation template or URL.

To use an Amazon CloudFormation template to set up individual source accounts for CloudWatch cross-account observability

1. Sign in to the source account.
2. Open the Amazon CloudFormation console at https://console.amazonaws.cn/cloudformation.
3. In the left navigation bar, choose **Stacks**.
4. Check that you are signed in to the Region that you want, then choose **Create stack**, **With new resources (standard)**.
5. Choose **Next**.
6. Choose **Upload a template file**.
7. Choose **Choose file**, choose the template that you downloaded from the monitoring account, and choose **Open**.
8. Choose **Next**.
9. For **Specify stack details**, enter a name for the stack and choose **Next**.
10. On the **Configure stack options** page, choose **Next**.
11. On the **Review** page, choose **Submit**.
12. On the status page for your stack, refresh the screen until you see that your stack has the status **CREATE_COMPLETE**.
13. To use this same template to link more source accounts to this monitoring account, sign out of this account and sign in to the next source account. Then repeat steps 2-12.

Use a URL to set up individual source accounts

These steps assume that you already copied the necessary URL by performing the steps in Step 2: (Optional) Download an Amazon CloudFormation template or URL.

To use a URL to link individual source accounts to the monitoring account

1. Sign in to the account that you want to use as a source account.
2. Enter the URL that you copied from the monitoring account.

You see the CloudWatch settings page, with some information filled in.

3. For **Select data**, choose whether this source account will share **Logs**, **Metrics**, **Traces**, **Application Insights - Applications**, and **Internet Monitor - Monitors** data to this monitoring account.

   For both **Logs** and **Metrics**, you can choose whether to share all resources or a subset with the monitoring account.

   a. (Optional) To share a subset of this account's log groups with the monitoring account, select **Logs** and choose **Filter Logs**. Then use the **Filter Logs** box to construct a query to find the log groups that you want to share. The query will use the term `LogGroupName` and one or more of the following operands.

      - `=` and `!=`
      - `AND`
      - `OR`
      - `^` indicates LIKE and `!^` indicates NOT LIKE. These can be used only as prefix searches. Include a `%` at the end of the string that you want to search for and include.
      - `IN` and `NOT IN`, using parentheses `( )`

      The complete query must be no more than 2000 characters and is limited to five conditional operands. Conditional operands are `AND` and `OR`. There isn't a limit on the number of other operands.

      > **Tip**
      >
      > Choose **View sample queries** to see the correct syntax for common query formats.

   b. (Optional) To share a subset of this account's metric namespaces with the monitoring account, select **Metrics** and choose **Filter Metrics**. Then use the **Filter Metrics** box to construct a query to find the metric namespaces that you want to share. Use the term `Namespace` and one or more of the following operands.

      - `=` and `!=`
      - `AND`
      - `OR`

- `LIKE` and `NOT LIKE`. These can be used only as prefix searches. Include a `%` at the end of the string that you want to search for and include.
- `IN` and `NOT IN`, using parentheses `( )`

The complete query must be no more than 2000 characters and is limited to five conditional operands. Conditional operands are `AND` and `OR`. There isn't a limit on the number of other operands.

> **Tip**
>
> Choose **View sample queries** to see the correct syntax for common query formats.

4. Do not change the ARN in **Enter monitoring account configuration ARN**.
5. The **Define a label to identify your source account** section is pre-filled with the label choice from the monitoring account, if there is one. Optionally, choose **Edit** to change it.

> **Note**
>
> In the Amazon GovCloud (US-East) and Amazon GovCloud (US-West) Regions, the only supported option is to use custom labels, and the `$AccountName`, `$AcccountEmail`, and `$AcccountEmailNoDomain` variables all resolve as *`account-id`* instead of the specified variable.

6. Choose **Link**.
7. Enter **`Confirm`** in the box and choose **Confirm**.
8. To use this same URL to link more source accounts to this monitoring account, sign out of this account and sign in to the next source account. Then repeat steps 2-7.

Manage monitoring accounts and source accounts

After you set up your monitoring accounts and source accounts, you can use the steps in these sections to manage them.

Contents

- Remove the link between a monitoring account and source account
- View information about a monitoring account

Link more source accounts to an existing monitoring account

Follow the steps in this section to add links from additional source accounts to an existing monitoring account.

Each source account can be linked to as many as five monitoring accounts. Each monitoring account can be linked to as many as 100,000 source accounts.

To manage a source account, you must have certain permissions. For more information, see Necessary permissions.

To add more source accounts to a monitoring account

1. Sign in to the monitoring account.
2. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
3. In the left navigation pane, choose **Settings**.
4. By **Monitoring account configuration**, choose **Manage source accounts**.
5. Choose the **Configuration policy** tab.
6. In the **Configuration policy** box, add the new source account ID in the **Principal** line.

   For example, suppose the **Principal** line is currently the following:

   ```
   "Principal": {"AWS": ["111111111111", "222222222222"]}
   ```

   To add 999999999999 as a third source account, edit the line to the following:

   ```
   "Principal": {"AWS": ["111111111111", "222222222222", "999999999999"]}
   ```
7. Choose **Update**.
8. Choose the **Configuration details** tab.
9. Choose the copy icon that is next to the monitoring account's sink ARN.
10. Sign in to the account that you want to use as a new source account.
11. Paste the monitoring account's sink ARN that you copied in Step 9.

You see the CloudWatch settings page, with some information filled in.

12. For **Select data**, choose whether this source account will send **Logs**, **Metrics**, **Traces**, and **Application Insights - Applications**, **Internet Monitor - Monitors**, and **Application Signals - Services, Service Level Objectives (SLOs)** data to the monitoring accounts it is linked to.
13. Do not change the ARN in **Enter monitoring account configuration ARN**.
14. The **Define a label to identify your source account** section is pre-filled with the label choice from the monitoring account, if there is one. Optionally, choose **Edit** to change it.

> **Note**
>
> In the Amazon GovCloud (US-East) and Amazon GovCloud (US-West) Regions, the only supported option is to use custom labels, and the `$AccountName`, `$AcccountEmail`, and `$AcccountEmailNoDomain` variables all resolve as *`account-id`* instead of the specified variable.

15. Choose **Link**.
16. Enter **`Confirm`** in the box and choose **Confirm**.

Remove the link between a monitoring account and source account

Follow the steps in this section to stop sending data from one source account to a monitoring account.

You must have the permissions required to manage a source account to complete this task. For more information, see Necessary permissions.

To remove the link between a source account and a monitoring account

1. Sign in to the source account.
2. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
3. In the left navigation pane, choose **Settings**.
4. By **Source account information**, choose **View monitoring accounts**.
5. Select the check box next to the monitoring account that you want to stop sharing data with.
6. Choose **Stop sharing data**, **Confirm**.
7. Sign in to the monitoring account.

8. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
9. Choose **Settings**.
10. By **Monitoring account information**, choose **View configuration**.
11. In the **Policy** box, delete the source account ID from the **Principal** line and choose **Update**.

View information about a monitoring account

Follow the steps in this section to view the cross-account settings for a monitoring account.

To manage a monitoring account, you must have certain permissions. For more information, see Necessary permissions.

To manage a monitoring account

1. Sign in to the monitoring account.
2. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
3. In the left navigation pane, choose **Settings**.
4. By **Monitoring account configuration**, choose **Manage source accounts**.
5. To view the Observability Access Manager policy that enables this account to be a monitoring account, choose the **Configuration policy** tab.
6. To view the source accounts that are linked to this monitoring account, choose the **Linked source accounts** tab.
7. To view the monitoring account sink ARN, and the types of data that this monitoring account can view in linked source accounts, choose the **Linked source accounts** tab.

Cross-account cross-Region CloudWatch console

> **Note**
>
> We recommend that you use CloudWatch cross-account observability to get the richest cross-account observability and discovery experience for your metrics, logs, and traces within a Region. For more information, see CloudWatch cross-account observability.

The cross-account, cross-Region CloudWatch console allows you to easily switch between different accounts and Region by using selectors in the console to view the dashboards, alarms, and metrics in other accounts and Regions. This feature also allows you to create cross-account, cross-Region dashboards which summarize your CloudWatch metrics from multiple Amazon accounts and multiple Regions into a single dashboard, making them accessible without having to switch accounts or Regions.

Many organizations have their Amazon resources deployed in multiple accounts, to provide billing and security boundaries. In this case, we recommend that you designate one or more of your accounts as your *monitoring accounts*, and build your cross-account cross-Region dashboards in these accounts. Cross-account cross-Region console functionality is integrated with Amazon Organizations, to help you efficiently build your cross-account cross-Region dashboards.

The cross-account, cross-region CloudWatch console experience does not provide cross-account cross-Region visibility for logs. Additionally, it does not support the creation of alarms on metrics in other accounts or Regions from within a monitoring account.

Topics

- Enabling cross-account cross-Region functionality in CloudWatch
- (Optional) Integrate with Amazon Organizations
- Troubleshooting your CloudWatch cross-account setup
- Disabling and cleaning up after using cross-account

Enabling cross-account cross-Region functionality in CloudWatch

To set up cross-account cross-Region functionality in your CloudWatch console, use the CloudWatch console to set up your sharing accounts and monitoring accounts.

Set up a sharing account

You must enable sharing in each account that will make data available to the monitoring account.

This will grant the read-only permissions that you choose in step 5 to all users that view a cross account dashboard in the account that you share with, if the user has corresponding permissions in the account that you share with.

To enable your account to share CloudWatch data with other accounts

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**.

3. For **Share your CloudWatch data**, choose **Configure**.
4. For **Sharing**, choose **Specific accounts** and enter the IDs of the accounts that you want to share data with.

   Any accounts that you specify here can view your account's CloudWatch data. Specify the IDs only of accounts that you know and trust.
5. For **Permissions**, specify how to share your data with one of the following options:
   - **Provide read-only access to your CloudWatch metrics, dashboards, and alarms**. This option enables the monitoring accounts to create cross-account dashboards that include widgets that contain CloudWatch data from your account.
   - **Include CloudWatch automatic dashboards**. If you select this option, users in the monitoring account can also view the information in this account's automatic dashboards. For more information, see [Getting started with CloudWatch automatic dashboards](#).
   - **Include X-Ray read-only access for the X-Ray Trace Map**. If you select this option, users in the monitoring account can also view the X-Ray trace map and X-Ray trace information in this account. For more information, see [Using the X-Ray Trace Map](#).
   - **Full read-only access to everything in your account**. This option enables the accounts that you use for sharing to create cross-account dashboards that include widgets that contain CloudWatch data from your account. It also enables those accounts to look deeper into your account and view your account's data in the consoles of other Amazon services.
6. Choose **Launch CloudFormation template**.

   In the confirmation screen, type **`Confirm`**, and choose **Launch template**.
7. Select the **I acknowledge...** check box, and choose **Create stack**.

Sharing with an entire organization

Completing the preceding procedure creates an IAM role which enables your account to share data with one account. You can create or edit an IAM role that shares your data with all accounts in an organization. Do this only if you know and trust all accounts in the organization.

This will grant the read-only permissions listed in the policies shown in step 5 of the previous procedure to all users that view a cross-account dashboard in the account that you share with, if the user has corresponding permissions in the account that you share with.

To share your CloudWatch account data with all accounts in an organization

1. If you haven't already, complete the preceding procedure to share your data with one Amazon account.
2. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
3. In the navigation pane, choose **Roles**.
4. In the list of roles, choose **CloudWatch-CrossAccountSharingRole**.
5. Choose **Trust relationships**, **Edit trust relationship**.

   You see a policy like this:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:root"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

6. Change the policy to the following, replacing *org-id* with the ID of your organization.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "*"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:PrincipalOrgID": "org-id"
        }
      }
```

```
    }
  ]
}
```

7. Choose **Update Trust Policy**.

Set up a monitoring account

Enable each monitoring account if you want to view cross-account CloudWatch data.

When you complete the following procedure, CloudWatch creates a service-linked role that CloudWatch uses in the monitoring account to access data shared from your other accounts. This service-linked role is called **AWSServiceRoleForCloudWatchCrossAccount**. For more information, see Using service-linked roles for CloudWatch.

To enable your account to view cross-account CloudWatch data

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**, and then, in the **Cross-account cross-region** section, choose **Configure**.
3. Under the **View cross-account cross-region** section, choose **Enable**, and then select the **Show selector in the console** checkbox to enable an account selector to appear in the CloudWatch console when you're graphing a metric or creating an alarm.
4. Under **View cross-account cross-region**, choose one of the following options:

   - **Account Id Input**. This option prompts you to manually input an account ID each time that you want to switch accounts when you view cross-account data.
   - **Amazon Organization account selector**. This option causes the accounts that you specified when you completed your cross-account integration with Organizations to appear. When you next use the console, CloudWatch displays a dropdown list of these accounts for you to select from when you are viewing cross-account data.

     To do this, you must have first used your organization management account to allow CloudWatch to see a list of accounts in your organization. For more information, see (Optional) Integrate with Amazon Organizations.

- **Custom account selector**. This option prompts you to enter a list of account IDs. When you next use the console, CloudWatch displays a dropdown list of these accounts for you to select from when you are viewing cross-account data.

  You can also enter a label for each of these accounts to help you identify them when choosing accounts to view.

  The account selector settings that a user makes here are retained only for that user, not for all other users in the monitoring account.

5. Choose **Enable**.

After you complete this setup, you can create cross-account dashboards. For more information, see [Creating a customized CloudWatch dashboard](#).

Cross-Region functionality

Cross-Region functionality is built in to this feature automatically. You do not need to take any extra steps to be able to display metrics from different Regions in a single account on the same graph or the same dashboard. Cross-Region functionality is not supported for alarms, so you can't create an alarm in one Region that watches a metric in a different Region.

(Optional) Integrate with Amazon Organizations

If you want to integrate cross-account functionality with Amazon Organizations, you must make a list of all accounts in the organization available to the monitoring accounts.

To enable cross-account CloudWatch functionality to access a list of all accounts in your organization

1. Sign in to your organization's management account.
2. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
3. In the navigation pane, choose **Settings**, then choose **Configure**.
4. For **Grant permission to view the list of accounts in the organization**, choose **Specific accounts** to be prompted to enter a list of account IDs. The list of accounts in your organization are shared with only the accounts that you specify here.
5. Choose **Share organization account list**.
6. Choose **Launch CloudFormation template**.

In the confirmation screen, type **`Confirm`**, and choose **Launch template**.

Troubleshooting your CloudWatch cross-account setup

This section contains troubleshooting tips for cross-account, console deployment in CloudWatch.

I am getting access denied errors displaying cross-account data

Check the following:

- Your monitoring account should have a role named **AWSServiceRoleForCloudWatchCrossAccount**. If it does not, you need to create this role. For more information, see Set Up a Monitoring Account.
- Each sharing account should have a role named **CloudWatch-CrossAccountSharingRole**. If it does not, you need to create this role. For more information, see Set Up A Sharing Account.
- The sharing role must trust the monitoring account.

To confirm that your roles are set up properly for the CloudWatch cross-account console

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Roles**.
3. In the list of roles, make sure the needed role exists. In a sharing account, look for **CloudWatch-CrossAccountSharingRole**. In a monitoring account, look for **AWSServiceRoleForCloudWatchCrossAccount**.
4. If you are in a sharing account and **CloudWatch-CrossAccountSharingRole** already exists, choose **CloudWatch-CrossAccountSharingRole**.
5. Choose **Trust relationships**, **Edit trust relationship**.
6. Confirm that the policy lists either the account ID of the monitoring account, or the organization ID of an organization that contains the monitoring account.

I don't see an account dropdown in the console

First, check that you have created the correct IAM roles, as discussed in the preceding troubleshooting section. If those are set up correctly, make sure that you have enabled this account to view cross-account data, as described in Enable Your Account to View Cross-Account Data.

Disabling and cleaning up after using cross-account

To disable cross-account functionality for CloudWatch, follow these steps.

Step 1: Remove the cross-account stacks or roles

The best method is to remove the Amazon CloudFormation stacks that were used to enable cross-account functionality.

- In each of the sharing accounts, remove the **CloudWatch-CrossAccountSharingRole** stack.
- If you used Amazon Organizations to enable cross-account functionality with all accounts in an organization, remove the **CloudWatch-CrossAccountListAccountsRole** stack in the organization's management account.

If you didn't use the Amazon CloudFormation stacks to enable cross-account functionality, do the following:

- In each of the sharing accounts, delete the **CloudWatch-CrossAccountSharingRole** IAM role.
- If you used Amazon Organizations to enable cross-account functionality with all accounts in an organization, delete the **CloudWatch-CrossAccountSharing-ListAccountsRole** IAM role in the organization's management account.

Step 2: Remove the service-linked role

In the monitoring account, delete the **AWSServiceRoleForCloudWatchCrossAccount** service-linked IAM role.

Explore related telemetry

Computer systems can generate a large amount of telemetry, including both metrics and logs, and complex systems even more so. When looking at a specific set of telemetry, it can be a challenge to find other telemetry related to your initial set. It can take advanced training to gain the skills needed to find issues and troubleshoot them. Because systems are complex, understanding what is going on can involve viewing metrics and logs from many different services and resources, requiring context switching and navigating between systems.

The Amazon CloudWatch **Explore related** feature offers access to Amazon resource relationships, related metrics, and logs across service consoles, enhancing observability and efficiency for operators of all skill levels. When viewing alarms or anomalies in CloudWatch dashboards, or metrics in Amazon, users can quickly find and view metrics and logs for related resources in your system.

CloudWatch provides visibility into metrics and logs tied to specific resources, and the **Explore related** pane extends that by allowing you to correlate your infrastructure resources to your workloads with all of their associated telemetry. This gives you quick access to the information you need to troubleshoot infrastructure-related issues. You view the relationship between resources, and their related telemetry in the **Explore related** pane. The **Explore related** pane is accessed from CloudWatch or from other Amazon consoles showing resources or telemetry.

> **Note**
>
> **Explore related** is currently limited in accounts set up as monitoring accounts in CloudWatch cross-account observability. You should access **Explore related** from the source accounts where the resources are originally created and managed. In source accounts, you can navigate between connected resources, and view related logs and metrics.

The following topics discuss the details of exploring related telemetry.

Topics

What is related telemetry?

Related telemetry is metrics and log data from resources that are related to the current resource or service. Traditionally, you might look at the metrics and logs that are related to a single load balancer, or all telemetry related to Amazon EC2. The **Explore related** feature in Amazon CloudWatch adds an interactive *topology map*. The map is a resource-centric view where you can find metrics and logs for a specific resource, but you can also see how that resource is connected to other resources.

For example, if you are looking at the telemetry for a load balancer in the **Explore related** pane, besides the metrics and logs associated with that load balancer, the maps shows you the target groups for that load balancer. Selecting one of the target groups will then show you the Amazon EC2 instances associated with that target group. At each step in this process, the telemetry, including metrics and logs, for the selected resources are shown, making it easy to quickly find the telemetry you are looking for, or to explore the telemetry, looking for the cause of a specific issue.

How to access the Explore related pane

Within the CloudWatch console, there are multiple ways to access telemetry related to your current view. For example, if you are looking at a graph on a dashboard, and you want to view telemetry related to that graph or an aspect of the graph, you can choose to explore related data directly from that graph. From many places in the console, you can choose an **Explore related** menu item, or select a compass icon ( ) to show the **Explore related** pane.

You can access the exploring experience from entry points throughout the CloudWatch console (and other Amazon consoles), including:

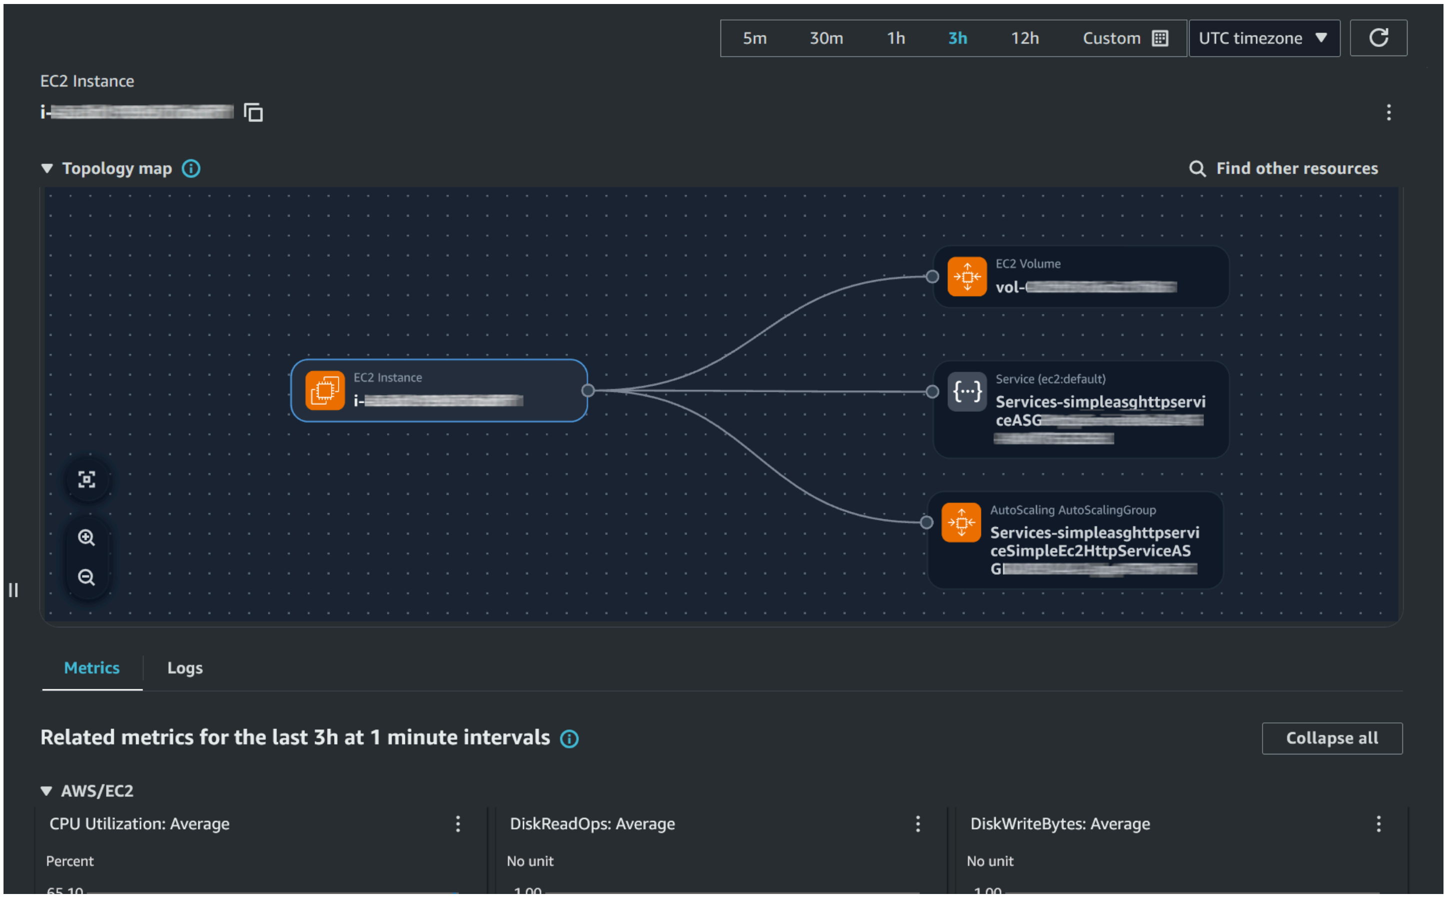
- **Metrics navigation –** When you choose **Metrics** then **All metrics** from the CloudWatch console left hand menu, the tile for any supported service or metric source will show the compass icon that brings up related telemetry in the bottom right corner.
- **Metric legend –** When viewing any metric graph (in CloudWatch or other Amazon consoles), hovering over the legend of the graph shows information about the data, as well as an **Explore related** button that brings up the related telemetry.
- **Metric datapoints –** When viewing any metric graph, hovering over a datapoint in the graph shows information about the metric, as well as a compass icon, to bring up the related telemetry.
- **Metric search –** When searching for metrics in CloudWatch, if you choose a found metric name, you can select **Explore related** from the menu that pops up, which will bring up the related telemetry.
- **Console toolbar –** In many Amazon console pages, the console toolbar (usually in the upper right of the console) includes a CloudWatch service icon, which will bring up CloudWatch tools, including the **Explore related** pane.

Depending on where you access the pane from, the default context of the pane will show an appropriate filter, if possible.

Navigating related telemetry

When you select any of the entry points to the **Explore related** pane, it appears on the right side of the CloudWatch console. This pane gives you access to view and find telemetry related to *entities*, in your system. An entity is a resource, such as an Amazon EC2 instance, or a service, such as an application that you have built. You can work within this pane without interrupting your current workflow, because it opens to the side of your initial page.

The following image shows the **Explore related** pane focused on a single Amazon EC2 instance, and the associated entities.



The top of the **Explore related** pane is a visual *topology map* (map) of the current entity and other related entities. The currently selected entity sets the focus for the pane. There are two ways to select an entity.

- Topology map – The *map* is a visual display of the current entity with focus. It also displays any related entities, allowing you to navigate around the set of resources and services that are related to each other.
- Find other resources – You can use the **Find other resources** button to filter and search for entities to use as the focus.

The bottom part of the pane shows you an automated search of metrics and logs for the current focal entity.

By default, the focus is set to an entity matching the location from which you accessed the **Explore related** pane. For example, if you accessed it by clicking the compass icon associated with a metric from a specific Amazon EC2 instance, then the focus will be set to that Amazon EC2 instance.

When you select an Amazon resource for the focus in the **Explore related** pane, you can navigate to the resource-specific console for the selected resource. For example, if you have selected an Amazon EC2 instance, you can select the **View in EC2 console** link to open the Amazon EC2 console with that instance selected.

When you set a focus, the metrics and logs are automatically filtered to show the telemetry related to your focus.

- **Metrics –** Each metric is shown as a graph for the time period that you have chosen.

  Much like any dashboard graph in CloudWatch, you can hover over or select a graph to get more information about the metric graph, and to see options including viewing in CloudWatch metrics. Choosing to view in CloudWatch will open the metrics view with the same viewing context as the **Explore related** pane, including resource and time range.
- **Log patterns –** CloudWatch analyzes the log groups associated with the focal resource and shows common patterns in those logs. For more information about log patterns, see Pattern analysis in the *Amazon CloudWatch Logs User Guide*.

  You can select **Compare timerange** to choose another time range and compare logs across the two time ranges.

  You can select **View in Logs Insights** to analyze the logs in CloudWatch Logs Insights with the same options as your current view, including resource, log group, and time range. For more information, see Analyzing log data with CloudWatch Logs Insights in the *Amazon CloudWatch Logs User Guide*.
- **Log groups –** The log groups that contain the logs are shown.

  You can select the log groups and then perform one of the following actions:

  - Choose **Start tailing in Live Tail** to view a streaming list of new log events as they are ingested for the selected log groups. The Live Tail session is started in the CloudWatch console. For more information on Live Tail, see Troubleshoot with CloudWatch Logs LiveTail in the *Amazon CloudWatch Logs User Guide*.
  - Choose **Query in Logs Insights** to open Logs Insights with a query scoped to just those log groups, applying your current context, including resources and time range.

Using the topology map

The *topology map* (map) is a visual display of the current focal entity and its related resources or services. You can use this interactive visualization to see the connections between different resources and services, and explore the relationships between components in your system. For example, if you are viewing *load balancer* resource, the map will show connected *target group* resources. Selecting a target group will display the associated instances. The visualization of connectivity helps operators understand and explore the relationships between different resources and services in your system.

You can drag the map, and zoom in and out, to see more of the associated entities, or to focus on fewer entities.

When you select an associated entity, like a target group, the pane's focus shifts to show telemetry for that entity. The map updates to center on the selected target group, displaying its connections to other entities, such as the load balancer and and any Amazon EC2 instances that are specified in that target group. As you navigate through different entities in the map, the metrics and logs at the bottom of the pane dynamically update, providing you with relevant telemetry for the newly selected resources.

Finding a specific resource

If a resource doesn't appear on the topology map, you can use the **Find other resources** feature to locate it. You can filter resources by tag or type, then select the ones you are looking for. After you have found resources to focus on, you are returned to the topology map, with those resources selected, to browse associated entities and telemetry.

> **Note**
>
> There are many reasons why you might not see your resources on the topology map. For example:
>
> - It's not related to the current focal entity.
> - You don't have permissions to access associated entities or telemetry.
> - The resource or service may not support telemetry or associated entities.

By using **Find other resources**, you can discover and visualize resources that may not be directly connected or visible in the current map. This ensures that you can access and analyze all relevant components of your infrastructure.

Select a resource with Find resources.

1. Open the **Explore related** pane from any of the entry points in the CloudWatch console.
2. Choose **Find resources**.
3. Choose the time frame for which you want to view logs or metrics.
4. Choose **Resource types**, then select the type of the resource you want to focus on from the drop down list, for example, **EC2 instances**.
5. Optionally, filter the set of resources by providing a tag to filter on. You can do this by selecting the **Filter resources by tags** filter, or by choosing the label that says **5 tags found** (the number will depend on the tags in your system). This gives you a list of tags to choose from.

   After you have selected the tags, the list of resources is automatically filtered to only those that are associated with those tags.
6. Optionally, choose one or more specific resources from the ones found that match your filters.
7. Choose **Show on map** to return to the **Topology map** with your resources selected.

Your list of **Metrics** and **Logs** is now filtered to just logs and metrics that are associated with that resource type. You can choose the **Metrics** or **Logs** tab to view the kind of telemetry that you want to view.

Permissions and prerequisites needed to view and explore related telemetry

To explore related telemetry, you must be getting entity information with the telemetry from your workloads, and you must have the proper permissions to view that data.

Many services send entity information automatically. For workloads that use the CloudWatch agent, you must have at least version `1.300049.1` of the agent, and you must configure it correctly. For information about configuring the agent, see How to add related information to custom telemetry sent to CloudWatch. For workloads running on Amazon EKS, you must have at least version `v2.3.1-eksbuild.1` of the Amazon CloudWatch Observability EKS add-on. For more information about this add-on, see Quick start with the Amazon CloudWatch Observability EKS add-on.

To explore related telemetry you must be signed in with certain permissions. Exploring related telemetry is a read-only activity, and requires at least read-only access to CloudWatch.

The permissions needed for viewing associations between telemetry and entities are: `logs:ListLogGroupsForEntity`, `logs:ListEntitiesForLogGroup`, `cloudwatch:ListEntitiesForMetric`, and `application-signals:ListObservedEntities`.

Each of the following Amazon managed policies will provide the CloudWatch permissions needed to access related telemetry in the CloudWatch console:

- CloudWatchFullAccessV2 – Provides full access to CloudWatch.
- CloudWatchReadOnlyAccess – Provides read-only access to CloudWatch.
- ReadOnlyAccess – Provides read-only access to Amazon services and resources.

Additionally, you must have at least read-only access (`Describe*` and `Get*`) to any resources in the topology map, in order for CloudWatch to discover and display relationships.

For more details about using policies to control access, see Managing access using policies.

How does CloudWatch find related telemetry?

The CloudWatch **Explore related** pane shows you metrics and logs that are related to each other, but how does that work?

Metrics and logs that are sent to CloudWatch can include an optional *entity* to which they are related. Typically, the entity will be a representation of what the telemetry is about. For example, a metric about CPU usage is about an Amazon EC2 instance, and will use that instance as its entity. When you view that metric in the **Explore related** pane, it shows you other telemetry for that same instance.

The *topology map* (map) in the **Explore related** pane displays the currently selected resource, along with *related resources*. For Amazon resources, CloudWatch automatically displays other resources that it knows are related. For example, if you are viewing an Amazon EC2 instance, the map will also display any Amazon EBS volumes that are attached to the instance. Selecting a volume shows telemetry for the volume, and the map is updated to display resources related to the volume. It also displays resources that are part of the same *service*.

The entity information associated with your telemetry defines the resource that the telemetry is associated with, such as the Amazon EC2 instance. However, it can also include contextual data about the resource. For example, if you have a website application that includes resources such as an Amazon EC2 instance and a database, the entity information can include the website application as a service. In this case, the topology map shows the service as a related entity, and when you select it, it displays the instances and database. This can make finding all the telemetry for a service simpler.

> **Note**
>
> CloudWatch must have received telemetry with entity information within the last three hours in order to find related resources and telemetry.

Where does the entity data come from?

There are different ways that CloudWatch gets entities for telemetry:

- Most telemetry sent to CloudWatch from Amazon services are associated with resources automatically. For a complete list of supported resources, see Amazon services that support related telemetry.
- The CloudWatch agent automatically adds entity information to the telemetry that it sends to CloudWatch.

  > **Note**
  >
  > You may need to update your CloudWatch agent to the latest version to include entity data. For more information, see Collect metrics, logs, and traces with the CloudWatch agent, and Configure CloudWatch agent service and environment names for related entities.

- When you are submitting your own telemetry, you can add entity information to the data. For more information, see How to add related information to custom telemetry sent to CloudWatch.

- CloudWatch makes a best effort to recognize the entity information associated with other telemetry (for example, custom telemetry that you send to CloudWatch without any entity information).

Where does service data come from?

Besides recognizing the natural connections between resources, such as an instance resource and an attached volume resource, CloudWatch can also group resources by *service*. For example, a service might be a website application. An Amazon EC2 instance with a web server, and another with a database might both be part of the same service, and are connected on the topology map based on that service.

There are different ways that CloudWatch gets a service name for telemetry, including:

- Application signals or otel instrumented telemetry use the `OTEL_SERVICE_NAME` environment variable used by supported OpenTelemetry instrumentation libraries to set the service name.
- The CloudWatch agent configuration allows configuring a service name. For more information, see Configure CloudWatch agent service and environment names for related entities.
- Kubernetes workloads use a corresponding name from the cluster, such as the Deployment, ReplicaSet, Pod, or Container, for the service name.
- For Amazon EC2 workloads, the service can come from tags (the `service`, `application`, or `app` tags).

> **Note**
>
> To use tags to generate service names, you must first set up instance metadata for the Amazon EC2 instance.

- When you are submitting your own telemetry, you can add service information to the data. For more information, see How to add related information to custom telemetry sent to CloudWatch.
- When it cannot use the above, CloudWatch uses the name of the IAM role that sends the metrics as the service name. This, for example, can provide a service name for Amazon ECS telemetry.

Amazon services that support related telemetry

The following table lists the Amazon services that support related entity information in their CloudWatch telemetry. Services or resources that are not listed in the table do not have related entity information exposed in CloudWatch.

> **Note**
>
> For services that use the CloudWatch agent, you may need to update the agent to the latest version to get related telemetry. For information about sending related entity information with your own custom metrics, see How to add related information to custom telemetry sent to CloudWatch.

Amazon Service	Resource	Metrics	Logs

How to add related information to custom telemetry sent to CloudWatch

When you publish your own metrics and logs to CloudWatch, the entity information needed for related telemetry is not there by default. When you send metrics to CloudWatch or logs to CloudWatch Logs (with the PutMetricData or PutLogEvents operations), you can add entity information to those logs or metrics. The entity information is associated with the telemetry, and used in the **Explore related** feature to find related telemetry that is associated with the same entity.

The entity sent with telemetry represents a resource or service that the telemetry is associated with. For example, a metric about a service, or that comes from an Amazon resource. To identify the entity associated in your code, you create a set of `KeyAttributes` and optional `Attributes` of the entity.

> **Note**
>
> CloudWatch can only find related resources for entities that have had telemetry sent within the previous three hours. If your resource only emits sparse telemetry (less than once every 3 hours), you may want to send additional *heartbeat* telemetry, to keep the entity active within CloudWatch.

The following sections describe how to create the `KeyAttributes` and `Attributes` so that CloudWatch can identify the resources and services associated with the telemetry.

Identifying the entity with the KeyAttributes object

The `KeyAttributes` property of the Entity objects (in CloudWatch or in CloudWatch logs) uniquely identifies the entity for CloudWatch. It is a list of key-value pairs. Entities with the same `KeyAttributes` are considered to be the same entity. Telemetry associated with the same entity are considered related, and can be easily found in the **Explore related** pane.

> **Note**
>
> In the CloudWatch API, the property is called `KeyAttributes`. In the CloudWatch Logs API, the property is called `keyAttributes`. Here they are treated as the same property.

There are five possible types of object that an `Entity` can represent.

- **AWS::Resource** – The entity represents an Amazon resource, such as a DynamoDB table or Amazon EC2 instance.

- **AWS::Service –** The entity represent an Amazon service, such as Amazon S3. This might be used, for example, when calling the `ListBuckets` operation, which is not associated with a specific Amazon S3 resource.
- **Service –** The entity represents a workload running in your account. For example, an application or service that you manage.
- **Resource –** The entity represents a resource that is not managed by Amazon, for example, operating system resources, such as processes or file volumes.
- **RemoteService –** The entity represents an external service in a remote call. For example, a remote call to a database, external cache, or an external endpoint.

Depending on which of the above types you are trying to represent, you must provide the correct key-value pairs for the `KeyAttributes`. The following describes each type.

AWS::Resource

To specify an Amazon Resource, you must include the following three key value pairs:

- `"Type": "AWS::Resource"` – This key-value pair identifies the entity as an Amazon resource.
- `"ResourceType": "<resource-type>"` – The string value of the `ResourceType` is the Amazon CloudFormation resource type string. For example, `AWS::DynamoDB::Table`.
- `"Identifier": "<resource-id>"` – The primary identifier for the resource. For more information, see primaryIdentifier in the *Extension Development for CloudFormation User Guide*.

AWS::Service

To specify an Amazon Service, you must include the following two key value pairs:

- `"Type": "AWS::Service"` – This key-value pair identifies the entity as an Amazon service.
- `"Name": "<service-name>"` – The value of the `Name` is the Amazon CloudFormation service name string. For example, `AWS::DynamoDB`.

Service

To specify a service that is not operated by Amazon, you must include the following three key value pairs:

- `"Type": "Service"` – This key-value pair identifies the entity as a service.
- `"Name": "<service-name>"` – This represents the name of the service that is sending the metrics. For example, `my-service-frontend` or `api.myservice.com`.
- `"Environment": "<environment-name>"` – This attribute specifies where the service is hosted, or the environment to which it belongs. For example `us-west-2`, or `myservice.production`.

Resource

To specify a resource that is not provided by Amazon, you must include the following three key value pairs:

- `"Type": "Resource"` – This key-value pair identifies the entity as a resource.
- `"ResourceType": "<resource-type>"` – A string specifying the type of resource. For example, `K8s::Pod` for a Kubernetes Pod.
- `"Identifier": "<resource-id>"` – A string identifier for the resource. Can contain multiple names, separated by pipes. For example, a Kubernetes Pod might be represented by it's cluster name, namespace, and pod name, such as `MyCluster|MyNamespace|MyPod`.

RemoteService

To specify a remote service, you must include the following two key value pairs:

- `"Type": "RemoteService"` – This key-value pair identifies the entity as a remote service.
- `"Name": "<remote-service-name>"` – Specifies how the application refers to the external service in a remote call. For example, `api.test.myservice.com`.

Providing additional details about the entity with the Attributes object

You can provide additional details about the `Entity` that you provide with your telemetry. This can include details about the platform, resource, application, or telemetry provider. The following tables describes the key words that you can use for each of these types of data.

> **Note**
>
> In the CloudWatch API, the property is called `Attributes`. In the CloudWatch Logs API, the property is called `attributes`. Here they are treated as the same property.

Platform details

Keyword	Usage	Domain of Values	Examples
`PlatformType`	Defines the hosted-in platform.	AWS::EKS, AWS::ECS, AWS::EC2, AWS::Lambda, K8s, Generic	`AWS::EC2`
`EKS.Cluster`	Name of the Amazon EKS cluster.	Alphanumeric string with basic delimiters.	`FlyingSquad`
`K8s.Cluster`	Name of the self-hosted Kubernetes cluster.	Alphanumeric string with basic delimiters.	`minicube`
`K8s.Namespace`	Name of Kubernetes namespace in Amazon EKS or K8s clusters.	Alphanumeric string with basic delimiters.	`default`, `pet-clinic`
`K8s.Workload`	Name of Kubernetes workload in Amazon EKS and K8s clusters.	Alphanumeric string with basic delimiters.	`frontend`
`K8s.Node`	Identity of Kubernetes node in Amazon EKS and K8s clusters.	K8s node name (for example, Amazon EC2 instance DNS name).	`ip-11-22-33-44.ec2.internal`

Keyword	Usage	Domain of Values	Examples
`K8s.Pod`	Identity of Kubernetes pod in Amazon EKS and K8s clusters.	K8s pod identifier.	`frontend-1234abcd56-ef7890`
`EC2.AutoScalingGroup`	Name of the Amazon EC2 AutoScaling Group.	Alphanumeric string with basic delimiters.	`my-asg-name-1`
`EC2.InstanceId`	Identity of the Amazon EC2 instance.	Amazon EC2 instance identifier.	`i-1234abcd5678ef90`
`ECS.Cluster`	Identity of the Amazon ECS cluster.	Amazon ECS cluster name.	`MyCluster`
`ECS.Service`	Identity of the Amazon ECS service.	Amazon ECS service name.	`MyService`
`ECS.Task`	Identity of the Amazon ECS task.	Amazon ECS task ID.	`task-123abc`
`Lambda.Function`	Identity of the Lambda function.	Lambda function name.	`MyFunction`
`Host`	Name of the host for all platform types.	Sub-domain format.	`ip-111-22-33-44.example.com`

Resource details

Keyword	Usage	Domain of Values	Examples
`AWS.Resource.ARN`	ARN for the Amazon resource.	Alphanumeric string with basic delimiters.	`arn:aws:dynamodb:us-east-1:123456789`

Keyword	Usage	Domain of Values	Examples
			012:table/ myDynamoDBTable

Application details

Keyword	Usage	Domain of Values	Examples
AWS.Application	Name of the application in AppRegistry.	Alphanumeric string with basic delimiters.	PetClinicApp
AWS.Application.ARN	ARN of the application in AppRegistry.	Alphanumeric string with basic delimiters.	arn:aws:servicecatalog:us-east-1:1234567890:/applications/...

Telemetry provider details

Keyword	Usage	Domain of Values	Examples
Telemetry.SDK	The fingerprint of OTEL SDK version for instrumented services.	Alphanumeric string with basic delimiters.	opentelemetry,1.32.0-aws-SNAPSHOT,java,Auto
Telemetry.Agent	The fingerprint of the Agent used to collect and send telemetry data.	Alphanumeric string with basic delimiters.	CWAgent/1.300026.3, ADOTCollector/1.x
Telemetry.Source	Specifies the point of application where	ServerSpan, ClientSpan,	ClientSpan, JMX

Keyword	Usage	Domain of Values	Examples
	the telemetry was collected or what was used for the source of telemetry data.	ProducerSpan, ConsumerSpan, LocalRoot Span, JMX, OS.	

Query metrics from other data sources

You can use CloudWatch to query, visualize, and create alarms for metrics from other data sources. To do so, you connect CloudWatch to the other data sources. This gives you a single, consolidated monitoring experience within the CloudWatch console. You can have a unified view of your infrastructure and application metrics regardless of where the data is stored, helping you identify and resolve issues faster.

After you connect to a data source using a CloudWatch wizard, CloudWatch creates an Amazon CloudFormation stack that deploys and configures an Amazon Lambda function. This Lambda function runs on demand every time you query the data source. The CloudWatch query builder shows you in real time a list of elements that can be queried, such as metrics, tables, fields, or labels. As you make choices, the query builder pre-populates a query in the native language of the selected source.

CloudWatch provides guided wizards for you to connect to the following data sources. For these data sources, you provide basic information to identify the data source and credentials. You can also manually create connectors to other data sources by creating your own Lambda functions.

- Amazon OpenSearch Service– Derive metrics from your OpenSearch Service logs and traces.
- Amazon Managed Service for Prometheus– Query these metrics using PromQL.
- Amazon RDS for MySQL – Use SQL to convert data stored in your Amazon RDS tables into metrics.
- Amazon RDS for PostgreSQL– Use SQL to convert data stored in your Amazon RDS tables into metrics.
- Amazon S3 CSV files– Display metrics data from a CSV file stored in an Amazon S3 bucket.
- Microsoft Azure Monitor– Query metrics from your Microsoft Azure Monitor account.
- Prometheus– Query these metrics using PromQL.

After you create connectors to data sources, see Creating a graph of metrics from another data source for information about graphing a metric from a data source. For information about setting an alarm on a metric from a data source, see Create an alarm based on a connected data source.

Topics

- Connect to a prebuilt data source with a wizard
- Create a custom connector to a data source
- Use your custom data source
- Delete a connector to a data source

Managing access to data sources

CloudWatch uses Amazon CloudFormation to create the required resources in your account. We recommend that you use the `cloudformation:TemplateUrl` condition to control access to Amazon CloudFormation templates when you grant `CreateStack` permissions to IAM users.

Warning

Any user that you grant data source invoke permission to can query metrics from that data source even if that user does not have direct IAM permissions to the data source. For example, if you grant `lambda:InvokeFunction` permissions on a Amazon Managed Service for Prometheus data source Lambda function to a user, that user will be able to query metrics from the corresponding Amazon Managed Service for Prometheus workspace even if you didn't grant them direct IAM access to that workspace.

You can find template URLs for data sources on the **Create stack** page in the CloudWatch Settings Console.

```
{
  "Version":"2012-10-17",
  "Statement":[
    {
      "Effect" : "Allow",
      "Action" : [ "cloudformation:CreateStack" ],
      "Resource" : "*",
      "Condition" : {
        "StringEquals" : {
          "cloudformation:TemplateUrl" : [ data-source-template-url ]
        }
      }
    }
  ]
```

```
}
```

For more information about controlling Amazon CloudFormation access, see Controlling access with Amazon Identity and Access Management

Connect to a prebuilt data source with a wizard

This topic provides instructions for using the wizard to connect CloudWatch to the following data sources.

- Amazon OpenSearch Service
- Amazon Managed Service for Prometheus
- Amazon RDS for MySQL
- Amazon RDS for PostgreSQL
- Amazon S3 CSV files
- Microsoft Azure Monitor
- Prometheus

The subsections in this topic include notes about managing and querying with each of these data sources.

To create a connector to a data source

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Metrics data sources** tab.
4. Choose **Create data source**.
5. Select the source that you want, then choose **Next**.
6. Enter a name for the data source.
7. Enter the other required information, depending on the data source that you chose. This can include credentials to access the data source and data source identifying information such as Prometheus workspace name, database name, or Amazon S3 bucket name. For Amazon services, the wizard discovers the resources and populates them into the selection dropdown.

   For more notes about the data source you are using, see the sections after this procedure.

8. To have CloudWatch connect to the data source in a VPC, choose **Use a VPC** and select the VPC to use. Then select the subnet and security group.
9. Choose **I acknowledge that Amazon CloudFormation will create IAM resources**. This resource is the Lambda function execution role.
10. Choose **Create data source**.

    The new source that you just added doesn't appear until the Amazon CloudFormation stack is done creating it. To check progress, you can choose **View the status of my CloudFormation stack**. Or you can choose the refresh icon to update this list.

    When your new data source appears in this list, it is ready to use. You can choose **Query from CloudWatch metrics** to begin querying with it. For more information, see Creating a graph of metrics from another data source.

Amazon Managed Service for Prometheus

Updating the data source configuration

- You can update your data source manually by doing the following:
  - To update the Amazon Managed Service for Prometheus workspace ID, update the `AMAZON_PROMETHEUS_WORKSPACE_ID` environment variable for the data source connector Lambda function.
  - To update the VPC configuration, see Configuring VPC access (console) for more information.

Querying the data source

- When querying Amazon Managed Service for Prometheus, after you select the data source in the **Multi source query** tab and select an Amazon Managed Service for Prometheus connector, you can use the **Query helper** to discover metrics and labels and provide simple PromQL queries. You can also use the PromQL query editor to build a PromQL query.
- Multi-line queries are not supported by the CloudWatch data source connectors. Every line feed is replaced with a space when the query is executed, or when you create an alarm or a dashboard widget with the query. In some cases, this might make your query not valid. For example, if your query contains a single line comment it will not be valid. If you try to create a dashboard or alarm with a multi-line query from the command line or Infrastructure as Code, the API will reject the action with a parse error.

Amazon OpenSearch Service

Creating the data source

If the OpenSearch domain is enabled for FGAC, you must map the execution role of the connector Lambda function to a user in OpenSearch Service. For more information, see the **Mapping users to roles** section in Managing permissions in the OpenSearch Service documentation.

If your OpenSearch domain is only accessible within a Virtual Private Cloud (VPC), you need to manually include a new environment variable in the Lambda function called `AMAZON_OPENSEARCH_ENDPOINT`. The value for this variable should be the root domain of the OpenSearch endpoint. You can obtain this root domain by removing `https://` and `<region>.es.amazonaws.com` from the domain endpoint listed in the OpenSearch Service console. For example, if your domain endpoint is `https://sample-domain.us-east-1.es.amazonaws.com`, the root domain would be `sample-domain`.

Updating the data source

- You can update your data source manually by doing the following:
  - To update the OpenSearch Service domain, update the `AMAZON_OPENSEARCH_DOMAIN_NAME` environment variable for the data source connector Lambda function.
  - To update the VPC configuration, see Configuring VPC access (console) for more information.

Querying the data source

- When querying OpenSearch Service, after you select the data source in the **Multi source query** tab, do the following:
  - Select the Index to query.
  - Select the Metric name (Any numeric field in the document) and Stat.
  - Select the Time axis (Any date field in the document).
  - Select Filters to apply (Any String field in the document).
  - Choose **Graph query**.

Amazon RDS for PostgreSQL and Amazon RDS for MySQL

Creating the data source

- If your data source is only accessible in a VPC, you must include the VPC configuration for the connector, as described in Connect to a prebuilt data source with a wizard. If the data source is to connect to the VPC for credentials, the endpoint must be configured in the VPC. For more information, see Using an Amazon Secrets Manager VPC endpoint.

  Additionally, you must create a VPC endpoint for the Amazon RDS service. For more information, see Amazon RDS API and interface VPC endpoints (Amazon PrivateLink).

Updating the data source

- You can update your data source manually by doing the following:
  - To update the database instance, update the `RDS_INSTANCE` environment variable for the data source connector Lambda function.
  - To update the username and password used to connect to Amazon RDS, use Amazon Secrets Manager. You can find the ARN of the secret used for the data source in the environment variable `RDS_SECRET` on the data source Lambda function. For more information about updating the secret in Amazon Secrets Manager, see Modify an Amazon Secrets Manager secret.
  - To update the VPC configuration, see Configuring VPC access (console) for more information.

Querying the data source

- When querying Amazon RDS, after you select the data source in the **Multi source query** tab and select an Amazon RDS connector, you can use the database discoverer to view available databases, tables, and columns. You can also use the SQL editor to create an SQL query.

  You can use the following variables in the query:
  - `$start.iso` – The start time in ISO date format
  - `$end.iso` – The end time in ISO date format
  - `$period` – The selected period in seconds

  For example, you can query `SELECT value, timestamp FROM table WHERE timestamp BETWEEN $start.iso and $end.iso`
- Multi-line queries are not supported by the CloudWatch data source connectors. Every line feed is replaced with a space when the query is executed, or when you create an alarm or a dashboard widget with the query. In some cases, this might make your query not valid. For example, if

your query contains a single line comment it will not be valid. If you try to create a dashboard or alarm with a multi-line query from the command line or Infrastructure as Code, the API will reject the action with a parse error.

> **Note**
>
> If no date field is found in the results, the values for each numeric field are summed to single values and plotted across the provided time range. If the timestamps don't align with the selected period in CloudWatch, the data is automatically aggregated using `SUM` and aligned with the period in CloudWatch.

Amazon S3 CSV files

Querying the data source

- When querying Amazon S3 CSV files, after you select the data source in the **Multi source query** tab and select an Amazon S3 connector, you select the Amazon S3 bucket and key.

  The CSV file must be formatted in the following ways:

  - The time stamp must be the first column.
  - The table must have a header row. The headers are used to name your metrics. The title of the time stamp column will be ignored, only the titles of the metrics columns are used.
  - The time stamps must be in ISO date format.
  - The metrics must be numeric fields.

  ```
  Timestamp, Metric-1, Metric-2, ...
  ```

  The following is an example:

timestamp	CPU (%)	Memory (%)	Storage (%)
2023-11-23T17:09:41+00:00	1	2	3

timestamp	CPU (%)	Memory (%)	Storage (%)
2023-11-23T17:04:41+00:00	4	5	6
2023-11-23T16:59:41+00:00	7	8	9
2023-11-23T16:54:41+00:00	10	11	12

Note

If no timestamp is provided, the values for each metric are summed to single values and plotted across the provided time range. If the timestamps don't align with the selected period in CloudWatch, the data is automatically aggregated using `SUM` and aligned with the period in CloudWatch.

Microsoft Azure Monitor

Creating the data source

- You must provide your tenant ID, client ID, and client secret to connect to Microsoft Azure Monitor. The credentials will be stored in Amazon Secrets Manager. For more information, see [Create a Microsoft Entra application and service principal that can access resources] in the Microsoft documentation.

Updating the data source

- You can update your data source manually by doing the following:
  - To update the tenant ID, client ID, and client secret used to connect to Azure Monitor, you can find the ARN of the secret used for the data source as the `AZURE_CLIENT_SECRET` environment variable on the data source Lambda function. For more information about updating the secret in Amazon Secrets Manager, see [Modify an Amazon Secrets Manager secret].

Querying the data source

- When querying Azure Monitor, after you select the data source in the **Multi source query** tab and select an Azure Monitor connector, you specify the Azure subscription, and the resource group and resource. You can then select the metric namespace, metric, and aggregation, and filter by dimensions.

Prometheus

Creating the data source

- You must provide the Prometheus endpoint and the user and password required to query Prometheus. The credentials will be stored in Amazon Secrets Manager.
- If your data source is only accessible in a VPC, you must include the VPC configuration for the connector, as described in Connect to a prebuilt data source with a wizard. If the data source is to connect to for credentials, the endpoint must be configured in the VPC. For more information, see Using an Amazon Secrets Manager VPC endpoint.

Updating data source configuration

- You can update your data source manually by doing the following:
  - To update the Prometheus endpoint, specify the new endpoint as the `PROMETHEUS_API_ENDPOINT` environment variable on the data source Lambda function.
  - To update the username and password used to connect to Prometheus, you can find the ARN of the secret used for the data source as the `PROMETHEUS_API_SECRET` environment variable on the data source Lambda function. For more information about updating the secret in Amazon Secrets Manager, see Modify an Amazon Secrets Manager secret.
  - To update the VPC configuration, see Configuring VPC access (console) for more information.

Querying the data source

> **Important**
>
> Prometheus metric types are different than CloudWatch metrics and many metrics available through Prometheus are cumulative by design. When you query Prometheus metrics, CloudWatch doesn't apply any additional transformation to the data: if you

specify only the metric name or label, the displayed value will be cumulative. For more information, see Metric types in the Prometheus documentation.

To see Prometheus metrics data as discrete values, like CloudWatch metrics, you need to edit the query before you run it. For example, you might need to add a call to the rate function over your Prometheus metric name. For documentation about the rate function and other Prometheus functions, see rate() in the Prometheus documentation.

Multi-line queries are not supported by the CloudWatch data source connectors. Every line feed is replaced with a space when the query is executed, or when you create an alarm or a dashboard widget with the query. In some cases, this might make your query not valid. For example, if your query contains a single line comment it will not be valid. If you try to create a dashboard or alarm with a multi-line query from the command line or Infrastructure as Code, the API will reject the action with a parse error.

Notification of Available Updates

From time to time, Amazon might notify you that we recommend that you update your connectors with a newer available version and will provide instructions for how to do so.

Create a custom connector to a data source

This topic describes how to connect a custom data source to CloudWatch. You can connect a custom data source to CloudWatch in two ways:

- Using a sample template that CloudWatch provides. You can use either JavaScript or Python with this template. These templates include sample Lambda code that will be useful to you when you create your Lambda function. You can then modify the Lambda function from the template to connect to your custom data source.
- Creating an Amazon Lambda function from scratch that implements the data source connector, the data query, and the preparation of the time series for use by CloudWatch. This function must pre-aggregate or merge datapoints if needed, and also align the period and timestamps to be compatible with CloudWatch.

Contents

Use a template

Using a template creates a sample Lambda function, and can help you get your custom connector built faster. These sample functions provide sample code for many common scenarios involved with building a custom connector. You can examine the Lambda code after you create a connector with a template, then modify it to use to connect to your data source.

Additionally, if you use the template, CloudWatch takes care of creating the Lambda permissions policy and attaching resource tags to the Lambda function.

To use the template to create a connector to a custom data source

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Metrics data sources** tab.
4. Choose **Create data source**.
5. Choose the radio button for **Custom - getting started template** and then choose **Next**.
6. Enter a name for the data source.
7. Select the one of the listed templates.
8. Select either Node.js or Python.
9. Choose **Create data source**.

   The new custom source that you just added doesn't appear until the Amazon CloudFormation stack finishes creating it. To check progress, you can choose **View the status of my CloudFormation stack**. Or you can choose the refresh icon to update this list.

When your new data source appears in this list, it is ready for you to test in the console and modify.

10. (Optional) To query the test data from this source in the console, follow the instructions in Creating a graph of metrics from another data source.
11. Modify the Lambda function for your needs.

    a. In the navigation pane, choose **Settings**.
    b. Choose the **Metrics data sources** tab.
    c. Choose **View in Lambda console** for the source that you want to modify.

    You can now modify the function to access your data source. For more information, see Step 1: Create the function.

> **Note**
>
> By using the template, when you write your Lambda function you don't need to follow the instructions in Step 2: Create a Lambda permissions policy or Step 3: Attach a resource tag to the Lambda function. These steps were performed by CloudWatch because you used the template.

Create a custom data source from scratch

Follow the steps in this section to create a Lambda function that connects CloudWatch to a data source.

Step 1: Create the function

A custom data source connector must support `GetMetricData` events from CloudWatch. Optionally, you can also implement a `DescribeGetMetricData` event to provide documentation to users in the CloudWatch console for how to use the connector. The `DescribeGetMetricData` response can also be used to set defaults that are used in the CloudWatch custom query builder.

CloudWatch provides code snippets as samples to help you get started. For more information, see the samples repository at https://github.com/aws-samples/cloudwatch-data-source-samples.

Constraints

- The response from Lambda must be smaller than 6 Mb. If the response exceeds 6 Mb, the `GetMetricData` response marks the Lambda function as `InternalError` and no data is returned.
- The Lambda function must complete its execution within 10 seconds for visualization and dashboarding purposes, or within 4.5 seconds for alarms usage. If the execution time exceeds that time, the `GetMetricData` response marks the Lambda function as `InternalError` and no data is returned.
- The Lambda function must send its output using epoch timestamps in seconds.
- If the Lambda function doesn't resample the data and instead returns data that doesn't correspond to the start time and period length that was requested by the CloudWatch user, that data is ignored by CloudWatch. The extra data is discarded from any visualization or alarming. Any data that is not between the start time and end time is also discarded.

  For example, if a user asks for data from 10:00 to 11:00 with a period of 5 min, then "10:00:00 to 10:04:59" and "10:05:00 to 10:09:59" are the valid time ranges for data to be returned. You must return a time series that includes `10:00 value1`, `10:05 value2`, and so on. If the function returns `10:03 valueX`, for example, it gets dropped because 10:03 does not correspond to the requested start time and period.
- Multi-line queries are not supported by the CloudWatch data source connectors. Every line feed is replaced with a space when the query is executed, or when you create an alarm or a dashboard widget with the query. In some cases, this might make your query not valid.

GetMetricData event

Request payload

The following is an example of a `GetMetricData` request payload sent as input to the Lambda function.

```
{
  "EventType": "GetMetricData",
  "GetMetricDataRequest": {
    "StartTime": 1697060700,
    "EndTime": 1697061600,
    "Period": 300,
    "Arguments": ["serviceregistry_external_http_requests{host_cluster!=\"prod\"}"]
  }
}
```

- **StartTime–** The timestamp specifying the earliest data to return. The **Type** is timestamp epoch seconds.
- **EndTime–** The timestamp specifying the latest data to return. The **Type** is timestamp epoch seconds.
- **Period–** The number of seconds that each aggregation of the metrics data represents. The minimum is 60 seconds. The **Type** is Seconds.
- **Arguments–** An array of arguments to pass to the Lambda metric math expression. For more information about passing arguments, see [How to pass arguments to your Lambda function].

Response payload

The following is an example of a `GetMetricData` response payload returned by the Lambda function.

```
{
   "MetricDataResults": [
      {
         "StatusCode": "Complete",
         "Label": "CPUUtilization",
         "Timestamps": [ 1697060700, 1697061000, 1697061300 ],
         "Values": [ 15000, 14000, 16000 ]
      }
   ]
}
```

The response payload will contain either a `MetricDataResults` field or an `Error` field, but not both.

A `MetricDataResults` field is a list of time-series fields of type `MetricDataResult`. Each of those time-series fields can include the following fields.

- **StatusCode–** (Optional) `Complete` indicates that all data points in the requested time range were returned. `PartialData` means that an incomplete set of data points were returned. If this is omitted, the default is `Complete`.

  Valid Values: `Complete` | `InternalError` | `PartialData` | `Forbidden`
- **Messages–** Optional list of messages with additional information about the data returned.

  Type: Array of [MessageData] objects with `Code` and `Value` strings.

- **Label**– The human-readable label associated with the data.

  Type: String

- **Timestamps**– The timestamps for the data points, formatted in epoch time. The number of timestamps always matches the number of values and the value for `Timestamps[x]` is `Values[x]`.

  Type: Array of timestamps

- **Values**– The data point values for the metric, corresponding to `Timestamps`. The number of values always matches the number of timestamps and the value for `Timestamps[x]` is `Values[x]`.

  Type: Array of doubles

For more information about `Error` objects, see the following sections.

Error response formats

You can optionally use the error response to provide more information about errors. We recommend that you return an error with Code Validation when a validation error occurs, such as when a parameter is missing or is the wrong type.

The following is an example of the response when the Lambda function wants to raise a `GetMetricData` validation exception.

```
{
   "Error": {
      "Code": "Validation",
      "Value": "Invalid Prometheus cluster"
   }
}
```

The following is an example of the response when the Lambda function indicates that it's unable to return data because of an access issue. The response is translated into a single time series with a status code of `Forbidden`.

```
{
   "Error": {
      "Code": "Forbidden",
```

```
        "Value": "Unable to access ..."
    }
}
```

The following is an example of when the Lambda function raises an overall `InternalError` exception, which is translated into a single time series with a status code of `InternalError` and a message. Whenever an error code has a value other than `Validation` or `Forbidden`, CloudWatch assumes that it's a generic internal error.

```
{
   "Error": {
      "Code": "PrometheusClusterUnreachable",
      "Value": "Unable to communicate with the cluster"
   }
}
```

DescribeGetMetricData event

Request payload

The following is an example of a `DescribeGetMetricData` request payload.

```
{
  "EventType": "DescribeGetMetricData"
}
```

Response payload

The following is an example of a `DescribeGetMetricData` response payload.

```
{
    "Description": "Data source connector",
    "ArgumentDefaults": [{
        Value: "default value"
     }]
}
```

- **Description–** A description of how to use the data source connector. This description will appear in the CloudWatch console. Markdown is supported.

  Type: String

- **ArgumentDefaults**– Optional array of argument default values used pre-populate the custom data source builder.

  If `[{ Value: "default value 1"}, { Value: 10}]`, is returned, the query builder in the CloudWatch console displays two inputs, the first with “default value 1” and the second with 10.

  If `ArgumentDefaults` is not provided, a single input is displayed with type default set to `String`.

  Type: Array of objects containing Value and Type.
- **Error**– (Optional) An error field can be included in any response. You can see examples in GetMetricData event.

Important considerations for CloudWatch alarms

If you are going to use the data source to set CloudWatch alarms, you should set it up to report data with timestamps every minute to CloudWatch. For more information and other considerations for creating alarms on metrics from connected data sources, see Create an alarm based on a connected data source.

(Optional) Use Amazon Secrets Manager to store credentials

If your Lambda function needs to use credentials to access the data source, we recommend using Amazon Secrets Manager to store these credentials instead of hardcoding them into your Lambda function. For more information about using Amazon Secrets Manager with Lambda, see Use Amazon Secrets Manager secrets in Amazon Lambda functions.

(Optional) Connect to a data source in a VPC

If your data source is in a VPC managed by Amazon Virtual Private Cloud, you must configure your Lambda function to access it. For more information, see Connecting outbound networking to resources in a VPC.

You might also need to configure VPC service endpoints to access services such as Amazon Secrets Manager. For more information, see Access an Amazon service using an interface VPC endpoint.

Step 2: Create a Lambda permissions policy

You must use create a policy statement that grants CloudWatch permission to use the Lambda function that you created. You can use the Amazon CLI or the Lambda console to create the policy statement.

To use the Amazon CLI to create the policy statement

- Enter the following command. Replace *123456789012* with your account ID, replace *my-data-source-function* with the name of your Lambda function, and replace *MyDataSource-DataSourcePermission1234* with an arbitrary unique value.

```
aws lambda add-permission --function-name my-data-source-function --statement-id MyDataSource-DataSourcePermission1234 --action lambda:InvokeFunction --principal lambda.datasource.cloudwatch.amazonaws.com --source-account 123456789012
```

Step 3: Attach a resource tag to the Lambda function

The CloudWatch console determines which of your Lambda functions are data source connectors by using a tag. When you create a data source using one of the wizards, the tag is automatically applied by the Amazon CloudFormation stack that configures it. When you create a data source yourself, you can use the following tag for your Lambda function. This makes your connector appear in the **Data source** dropdown in the CloudWatch console when you query metrics.

- A tag with `cloudwatch:datasource` as the key and `custom` as the value.

Use your custom data source

After you create a data source, you can use it to query and visualize data from that source, as well as to set alarms. If you used a template to create your custom data source connector or you added the tag listed in Step 3: Attach a resource tag to the Lambda function, you can follow the steps in Creating a graph of metrics from another data source to query it. You can also use the metric math function `LAMBDA` to query it, as explained in the following section. For information about creating alarms on metrics from your data source, see Create an alarm based on a connected data source. This topic describes how to pass arguments to your Lambda function to your custom data source.

How to pass arguments to your Lambda function

The recommended way for you to pass arguments to your custom data source is to use the query builder in the CloudWatch console when you query the data source.

You can also use your Lambda function to retrieve data from your data source by using the new LAMBDA expression in CloudWatch metric math.

```
LAMBDA("LambdaFunctionName" [, optional-arg]*)
```

`optional-arg` is up to 20 strings, numbers, or Booleans. For example, `param`, `3.14`, or `true`.

> **Note**
>
> Multi-line strings are not supported by the CloudWatch data source connectors. Every line feed is replaced with a space when the query is executed, or when you create an alarm or a dashboard widget with the query. In some cases, this might make your query not valid.

When you use the LAMBDA metric math function, you can provide the function name (`"MyFunction"`). If your resource policy allows, you can also use a specific version of the function (`"MyFunction:22"`), or a Lambda function alias (`"MyFunction:MyAlias"`). You can't use *

The following are some examples of calling the LAMBDA function.

```
LAMBDA("AmazonOpenSearchDataSource", "MyDomain", "some-query")
```

```
LAMBDA("MyCustomDataSource", true, "fuzzy", 99.9)
```

The LAMBDA metric math function returns a list of time series that can be returned to the requester or combined with other metric math functions. The following is an example of combining LAMBDA with other metric math functions.

```
FILL(LAMBDA("AmazonOpenSearchDataSource", "MyDomain", "some-query"), 0)
```

Delete a connector to a data source

The instructions in this section describe how to delete a connector to a data source.

To delete a connector to a data source

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Settings**.
3. Choose the **Metrics data sources** tab.
4. Choose **Manage in CloudFormation** in the row of the data source that you want to delete.

   You are taken to the Amazon CloudFormation console.
5. In the section with the name of your data source, choose **Delete**.
6. In the confirmation pop-up, choose **Delete**.

Collect metrics, logs, and traces with the CloudWatch agent

The unified CloudWatch agent enables you to do the following:

- Collect internal system-level metrics from Amazon EC2 instances across operating systems. The metrics can include in-guest metrics, in addition to the metrics for EC2 instances. The additional metrics that can be collected are listed in Metrics collected by the CloudWatch agent.
- Collect system-level metrics from on-premises servers. These can include servers in a hybrid environment as well as servers not managed by Amazon.
- Retrieve custom metrics from your applications or services using the `StatsD` and `collectd` protocols. `StatsD` is supported on both Linux servers and servers running Windows Server. `collectd` is supported only on Linux servers.
- Collect logs from Amazon EC2 instances and on-premises servers, running either Linux or Windows Server.

> **Note**
>
> The CloudWatch agent does not support collecting logs from FIFO pipes.

- Send the metrics to either CloudWatch or Amazon Managed Service for Prometheus, or to both. The CloudWatch agent configuration file contains a `metrics_destinations` parameter in the `metrics` section. You can specify `cloudwatch`, `amp`, or both in this parameter.
- Version 1.300031.0 and later can be used to enable CloudWatch Application Signals. For more information, see Application Signals.
- Version 1.300025.0 and later can collect traces from OpenTelemetry or X-Ray client SDKs, and send them to X-Ray.

  Using the CloudWatch agent allows you to collect traces without needing to run a separate trace collection daemon, helping to reduce the number of agents that you run and manage.

Metrics sent to CloudWatch can be viewed in CloudWatch just as any other CloudWatch metrics. The default CloudWatch namespace for metrics collected by the CloudWatch agent is `CWAgent`, although you can specify a different namespace when you configure the agent.

The logs collected by the unified CloudWatch agent are processed and stored in Amazon CloudWatch Logs, just like logs collected by the older CloudWatch Logs agent. For information about CloudWatch Logs pricing, see Amazon CloudWatch Pricing.

Metrics collected by the CloudWatch agent are billed as custom metrics. For more information about CloudWatch metrics pricing, see Amazon CloudWatch Pricing.

The CloudWatch agent is open-source under the MIT license, and is hosted on GitHub. If you would like to build, customize or contribute to the CloudWatch agent, see the GitHub repository for the latest instructions. If you think you've found a potential security issue, do not post it on GitHub or any public forum. Instead, please follow the instructions at Vulnerability Reporting or email Amazon security directly.

The steps in this section explain how to install the unified CloudWatch agent on Amazon EC2 instances and on-premises servers. For more information about the metrics that the CloudWatch agent can collect, see Metrics collected by the CloudWatch agent.

Supported operating systems

The CloudWatch agent is supported on x86-64 architecture on the following operating systems. It is also supported on all minor version updates for each of the major versions listed here.

- Amazon Linux 2023
- Amazon Linux 2
- Ubuntu Server versions 24.04, 23.10, 22.04, 20.04, 18.04, 16.04, and 14.04
- CentOS versions 9, 8, and 7
- Red Hat Enterprise Linux (RHEL) versions 9, 8, and 7
- Debian versions 12, 11 and 10
- SUSE Linux Enterprise Server (SLES) versions 15 and 12
- Oracle Linux versions 9, 8 and 7
- AlmaLinux versions 9 and 8
- Rocky Linux versions 9 and 8
- The following macOS computers: EC2 M1 Mac1 instances, and computers running macOS 14 (Sonoma), macOS 13 (Ventura), and macOS 12 (Monterey)
- Windows Server 2025, Windows Server 2022, Windows Server 2019, and Windows Server 2016

- Windows 11
- 64-bit Windows 10

The agent is supported on ARM64 architecture on the following operating systems. It is also supported on all minor version updates for each of the major versions listed here.

- Amazon Linux 2023
- Amazon Linux 2
- Ubuntu Server versions 23.10, 22.04, 20.04, 18.04, and 16.04
- CentOS versions 9 and 8
- Red Hat Enterprise Linux (RHEL) versions 9, 8, and 7
- Debian versions 12, 11 and 10
- SUSE Linux Enterprise Server 15
- The following macOS computers: macOS 14 (Sonoma), macOS 13 (Ventura), and macOS 12 (Monterey)

Installation process overview

You can download and install the CloudWatch agent manually using the command line, or you can integrate it with SSM. The general flow of installing the CloudWatch agent using either method is as follows:

1. Create IAM roles or users that enable the agent to collect metrics from the server and optionally to integrate with Amazon Systems Manager.
2. Download the agent package.
3. Modify the CloudWatch agent configuration file and specify the metrics that you want to collect.
4. Install and start the agent on your servers. As you install the agent on an EC2 instance, you attach the IAM role that you created in step 1. As you install the agent on an on-premises server, you specify a named profile that contains the credentials of the IAM user that you created in step 1.

Contents

- CloudWatch agent credentials preference
- Verifying the signature of the CloudWatch agent package
- Create the CloudWatch agent configuration file
- Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart
- Metrics collected by the CloudWatch agent
- Using the CloudWatch agent with related telemetry
- Common scenarios with the CloudWatch agent
- Troubleshooting the CloudWatch agent

Install the CloudWatch agent

You can download and install the CloudWatch agent using either the command line with an Amazon S3 download link, using SSM, or using an Amazon CloudFormation template.

Contents

- Install the CloudWatch agent using the command line
- Install the CloudWatch agent using Amazon Systems Manager
- Install the CloudWatch agent on on-premises servers

Install the CloudWatch agent using the command line

Use the following topics to download, configure, and install the CloudWatch agent package.

Topics

- Download and configure the CloudWatch agent using the command line
- Create IAM roles and users for use with CloudWatch agent
- Install and run the CloudWatch agent on your servers

Download and configure the CloudWatch agent using the command line

You can use the following steps to download the CloudWatch agent package, create IAM roles or users, and optionally modify the common configuration file.

Download the CloudWatch agent package

Note

To download the CloudWatch agent, your connection must use TLS 1.2 or later.

You can use an Amazon S3 download link to download the CloudWatch agent package. Choose the download link from this table, depending on your architecture and platform.

Architecture	Platform	Download link	Signature file link
amd64	Amazon Linux 2023 and Amazon Linux 2	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm.sig
amd64	Centos	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/centos/amd64/latest/amazon-cloudwatch-agent.rpm	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/centos/amd64/latest/amazon-cloudwatch-agent.rpm.sig

amd64	Windows	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/windows/amd64/latest/amazon-cloudwatch-agent.msi	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/windows/amd64/latest/amazon-cloudwatch-agent.msi.sig
ARM64	Amazon Linux 2023 and Amazon Linux 2	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/amazon_linux/arm64/latest/amazon-cloudwatch-agent.rpm	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/amazon_linux/arm64/latest/amazon-cloudwatch-agent.rpm.sig
ARM64	Redhat	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/redhat/arm64/latest/amazon-cloudwatch-agent.rpm	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/redhat/arm64/latest/amazon-cloudwatch-agent.rpm.sig
ARM64	Ubuntu	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/ubuntu/arm64/latest/amazon-cloudwatch-agent.deb	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/ubuntu/arm64/latest/amazon-cloudwatch-agent.deb.sig

To use the command line to download and install the CloudWatch agent package

1. Download the CloudWatch agent.

   On a Linux server, enter the following. For *download-link*, use the appropriate download link from the previous table.

   ```
   wget download-link
   ```

   On a server running Windows Server, download the following file:

2. After you have downloaded the package, you can optionally verify the package signature. For more information, see Verifying the signature of the CloudWatch agent package.

3. Install the package. If you downloaded an RPM package on a Linux server, change to the directory containing the package and enter the following:

   ```
   sudo rpm -U ./amazon-cloudwatch-agent.rpm
   ```

   If you downloaded a DEB package on a Linux server, change to the directory containing the package and enter the following:

   ```
   sudo dpkg -i -E ./amazon-cloudwatch-agent.deb
   ```

   If you downloaded an MSI package on a server running Windows Server, change to the directory containing the package and enter the following:

   ```
   msiexec /i amazon-cloudwatch-agent.msi
   ```

   This command also works from within PowerShell. For more information about MSI command options, see Command-Line Options in the Microsoft Windows documentation.

   If you downloaded a PKG package on a macOS server, change to the directory containing the package and enter the following:

   ```
   sudo installer -pkg ./amazon-cloudwatch-agent.pkg -target /
   ```

Create and modify the agent configuration file

After you have downloaded the CloudWatch agent, you must create the configuration file before you start the agent on any servers. For more information, see Create the CloudWatch agent configuration file.

Create IAM roles and users for use with CloudWatch agent

Access to Amazon resources requires permissions. You create an IAM role, an IAM user, or both to grant permissions that the CloudWatch agent needs to write metrics to CloudWatch. If you're going to use the agent on Amazon EC2 instances, you must create an IAM role. If you're going to use the agent on on-premises servers, you must create an IAM user.

> **Note**
>
> We recently modified the following procedures by using new `CloudWatchAgentServerPolicy` and `CloudWatchAgentAdminPolicy` policies created by Amazon, instead of requiring customers to create these policies themselves. For writing files to and downloading files from the Parameter Store, the policies created by Amazon support only files with names that start with `AmazonCloudWatch-`. If you have a CloudWatch agent configuration file with a file name that doesn't start with `AmazonCloudWatch-`, these policies can't be used to write the file to Parameter Store or download it from Parameter Store.

If you're going to run the CloudWatch agent on Amazon EC2 instances, use the following steps to create the necessary IAM role. This role provides permissions for reading information from the instance and writing it to CloudWatch.

To create the IAM role necessary to run the CloudWatch agent on EC2 instances

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane on the left, choose **Roles** and then **Create role**.
3. Make sure that **Amazon service** is selected under **Trusted entity type**.
4. For **Use case**, choose **EC2** under **Common use cases**,
5. Choose **Next**.

6. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find the policy.
7. (Optional) If the agent is sending traces to X-Ray you need to also give the role the **AWSXRayDaemonWriteAccess** policy. To do so, find that policy in the list and select the check box next to it.
8. Choose **Next**.
9. In **Role name**, enter a name for the role, such as *`CloudWatchAgentServerRole`*. Optionally give it a description. Then choose **Create role**.

   The role is now created.
10. (Optional) If the agent is going to send logs to CloudWatch Logs and you want the agent to be able to set retention policies for these log groups, you need to add the `logs:PutRetentionPolicy` permission to the role. For more information, see Allowing the CloudWatch agent to set log retention policy.

If you're going to run the CloudWatch agent on on-premises servers, use the following steps to create the necessary IAM user.

> **Warning**
>
> This scenario requires IAM users with programmatic access and long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed. Access keys can be updated if necessary. For more information, see Update access keys in the *IAM User Guide*.

To create the IAM user necessary for the CloudWatch agent to run on on-premises servers

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane on the left, choose **Users** and then **Add users**.
3. Enter the user name for the new user.
4. Select **Access key - Programmatic access** and choose **Next: Permissions**.
5. Choose **Attach existing policies directly**.

6. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find the policy.
7. (Optional) If the agent is going to traces to X-Ray you need to also give the role the **AWSXRayDaemonWriteAccess** policy. To do so, find that policy in the list and select the check box next to it.
8. Choose **Next: Tags**.
9. Optionally create tags for the new IAM user, and then choose **Next:Review**.
10. Confirm that the correct policy is listed, and choose **Create user**.
11. Next to the name of the new user, choose **Show**. Copy the access key and secret key to a file so that you can use them when installing the agent. Choose **Close**.

Allowing the CloudWatch agent to set log retention policy

You can configure the CloudWatch agent to set the retention policy for log groups that it sends log events to. If you do this, you must grant the `logs:PutRetentionPolicy` to the IAM role or user that the agent uses. The agent uses an IAM role to run on Amazon EC2 instances, and uses an IAM user for on-premises servers.

To grant the CloudWatch agent's IAM role permission to set log retention policies

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the left navigation pane, choose **Roles**.
3. In the search box, Type the beginning of the name of the CloudWatch agent's IAM role. You chose this name when you created the role. It might be named `CloudWatchAgentServerRole`.

   When you see the role, choose the name of the role.
4. In the **Permissions** tab, choose **Add permissions**, **Create inline policy**.
5. Choose the **JSON** tab and copy the following policy into the box, replacing the default JSON in the box:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
      "Effect": "Allow",
      "Action": "logs:PutRetentionPolicy",
      "Resource": "*"
    }
  ]
}
```

6. Choose **Review policy**.
7. For **Name**, enter **`CloudWatchAgentPutLogsRetention`** or something similar, and choose **Create policy**.

To grant the CloudWatch agent's IAM user permission to set log retention policies

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the left navigation pane, choose **Users**.
3. In the search box, Type the beginning of the name of the CloudWatch agent's IAM user. You chose this name when you created the user.

   When you see the user, choose the name of the user.
4. In the **Permissions** tab, choose **Add inline policy**.
5. Choose the **JSON** tab and copy the following policy into the box, replacing the default JSON in the box:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "logs:PutRetentionPolicy",
      "Resource": "*"
    }
  ]
}
```

6. Choose **Review policy**.
7. For **Name**, enter **`CloudWatchAgentPutLogsRetention`** or something similar, and choose **Create policy**.

Install and run the CloudWatch agent on your servers

After you create your agent configuration file for an IAM role or IAM user, use the following steps to install and run the CloudWatch agent on your servers with that configuration. First, attach an IAM role or IAM user to the server that will run the agent. Then, on that server, download the agent package and start it using the agent configuration you created.

Download the CloudWatch agent package using an S3 download link

> **Note**
>
> To download the CloudWatch agent, your connection must use TLS 1.2 or later.

On each server where you will run the agent, download the agent package. Choose the download link from this table, depending on your architecture and platform.

Architecture	Platform	Download link	Signature file link
amd64	Amazon Linux 2023 and Amazon Linux 2	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm.sig
amd64	Centos	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/centos/amd64/latest/amazon-cloudwatch-agent.rpm	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/centos/amd64/latest/amazon-cloudwatch-agent.rpm.sig
amd64	Redhat	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/redhat/amd64/latest/amazon-cloudwatch-agent.rpm	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/redhat/amd64/latest/amazon-cloudwatch-agent.rpm.sig

Architecture	Platform	Download link	Signature file link
ARM64	Ubuntu	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/ubuntu/arm64/latest/amazon-cloudwatch-agent.deb	https://s3.cn-north-1.amazonaws.com.cn/amazoncloudwatch-agent/ubuntu/arm64/latest/amazon-cloudwatch-agent.deb.sig

To use the command line to install the CloudWatch agent on an Amazon EC2 instance

1. Download the CloudWatch agent. For a Linux server, enter the following. For *download-link*, use the appropriate download link from the previous table.

```
wget download-link
```

   For a server running Windows Server, download the following file:

2. After you have downloaded the package, you can optionally verify the package signature. For more information, see Verifying the signature of the CloudWatch agent package.

3. Install the package. If you downloaded an RPM package on a Linux server, change to the directory containing the package and enter the following:

```
sudo rpm -U ./amazon-cloudwatch-agent.rpm
```

   If you downloaded a DEB package on a Linux server, change to the directory containing the package and enter the following:

```
sudo dpkg -i -E ./amazon-cloudwatch-agent.deb
```

   If you downloaded an MSI package on a server running Windows Server, change to the directory containing the package and enter the following:

```
msiexec /i amazon-cloudwatch-agent.msi
```

   This command also works from within PowerShell. For more information about MSI command options, see Command-Line Options in the Microsoft Windows documentation.

(Installing on an EC2 instance) Attaching an IAM role

To enable the CloudWatch agent to send data from the instance, you must attach an IAM role to the instance. The role to attach is **CloudWatchAgentServerRole**. You should have created this role previously. For more information see Create IAM roles and users for use with CloudWatch agent.

For more information on attaching an IAM role to an instance, see Attaching an IAM Role to an Instance in the *Amazon EC2 User Guide*.

(Installing on an on-premises server) Specify IAM credentials and Amazon Region

To enable the CloudWatch agent to send data from an on-premises server, you must specify the access key and secret key of the IAM user that you created earlier. For more information about creating this user, see Create IAM roles and users for use with CloudWatch agent.

You also must specify the Amazon Region to send the metrics to, using the `region` field in the `[AmazonCloudWatchAgent]` section of the Amazon config file, as in the following example.

```
[profile AmazonCloudWatchAgent]
region = us-west-1
```

The following is an example of using the `aws configure` command to create a named profile for the CloudWatch agent. This example assumes that you are using the default profile name of `AmazonCloudWatchAgent`.

To create the AmazonCloudWatchAgent profile for the CloudWatch agent

1. If you haven't already done so, install the Amazon Command Line Interface on the server. For more information, see Installing the Amazon CLI.
2. On Linux servers, enter the following command and follow the prompts:

   ```
   sudo aws configure --profile AmazonCloudWatchAgent
   ```

   On Windows Server, open PowerShell as an administrator, enter the following command, and follow the prompts.

   ```
   aws configure --profile AmazonCloudWatchAgent
   ```

Verify internet access

Your Amazon EC2 instances must have outbound internet access to send data to CloudWatch or CloudWatch Logs. For more information about how to configure internet access, see Internet Gateways in the *Amazon VPC User Guide*.

The endpoints and ports to configure on your proxy are as follows:

- If you're using the agent to collect metrics, you must add the CloudWatch endpoints for the appropriate Regions to the allow list. These endpoints are listed in Amazon CloudWatch endpoints and quotas.
- If you're using the agent to collect logs, you must add the CloudWatch Logs endpoints for the appropriate Regions to the allow list. These endpoints are listed in Amazon CloudWatch Logs endpoints and quotas.
- If you're using Systems Manager to install the agent or Parameter Store to store your configuration file, you must add the Systems Manager endpoints for the appropriate Regions to the allow list. These endpoints are listed in Amazon Systems Manager endpoints and quotas.

(Optional) Modify the common configuration for proxy or Region information

The CloudWatch agent includes a configuration file called `common-config.toml`. You can optionally use this file to specify proxy and Region information.

On a server running Linux, this file is in the `/opt/aws/amazon-cloudwatch-agent/etc` directory. On a server running Windows Server, this file is in the `C:\ProgramData\Amazon\AmazonCloudWatchAgent` directory.

> **Note**
>
> We recommend that you use the `common-config.toml` file to provide shared configuration and credentials when you run the CloudWatch agent in an on-premise mode, and it can also be useful when you are running on Amazon EC2 and you want to reuse existing shared credential profiles and files. Enabling it via the `common-config.toml` has the added advantage that if your shared credentials file gets rotated with renewed credentials after they expire, the new credentials are automatically picked up by the agent without requiring a restart.

The default `common-config.toml` is as follows.

```
# This common-config is used to configure items used for both ssm and cloudwatch access

## Configuration for shared credential.
## Default credential strategy will be used if it is absent here:
##            Instance role is used for EC2 case by default.
##            AmazonCloudWatchAgent profile is used for the on-premises case by
 default.
# [credentials]
#    shared_credential_profile = "{profile_name}"
#    shared_credential_file= "{file_name}"

## Configuration for proxy.
## System-wide environment-variable will be read if it is absent here.
## i.e. HTTP_PROXY/http_proxy; HTTPS_PROXY/https_proxy; NO_PROXY/no_proxy
## Note: system-wide environment-variable is not accessible when using ssm run-command.
## Absent in both here and environment-variable means no proxy will be used.
# [proxy]
#    http_proxy = "{http_url}"
#    https_proxy = "{https_url}"
#    no_proxy = "{domain}"
```

All lines are commented out initially. To set the credential profile or proxy settings, remove the # from that line and specify a value. You can edit this file manually or by using the `RunShellScript` Run Command in Systems Manager:

- `shared_credential_profile` – For on-premises servers, this line specifies the IAM user credential profile to use to send data to CloudWatch. If you keep this line commented out, `AmazonCloudWatchAgent` is used. For more information about creating this profile, see [(Installing on an on-premises server) Specify IAM credentials and Amazon Region](#).

  On an EC2 instance, you can use this line to have the CloudWatch agent send data from this instance to CloudWatch in a different Amazon Region. To do so, specify a named profile that includes a `region` field specifying the name of the Region to send to.

  If you specify a `shared_credential_profile`, you must also remove the # from the beginning of the `[credentials]` line.

- `shared_credential_file` – To have the agent look for credentials in a file located in a path other than the default path, specify that complete path and file name here. The default path is `/root/.aws` on Linux and is `C:\\Users\\Administrator\\.aws` on Windows Server.

  The first example below shows the syntax of a valid `shared_credential_file` line for Linux servers, and the second example is valid for Windows Server. On Windows Server, you must escape the \ characters.

  ```
  shared_credential_file= "/usr/username/credentials"
  ```

  ```
  shared_credential_file= "C:\\Documents and Settings\\username\\.aws\\credentials"
  ```

  If you specify a `shared_credential_file`, you must also remove the # from the beginning of the `[credentials]` line.

- Proxy settings – If your servers use HTTP or HTTPS proxies to contact Amazon services, specify those proxies in the `http_proxy` and `https_proxy` fields. If there are URLs that should be excluded from proxying, specify them in the `no_proxy` field, separated by commas.

Start the CloudWatch agent using the command line

Follow these steps to use the command line to start the CloudWatch agent on a server.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

To use the command line to start the CloudWatch agent on a server

1. Copy the agent configuration file that you want to use to the server where you're going to run the agent. Note the pathname where you copy it to.
2. In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

   Enter one of the following commands. Replace *`configuration-file-path`* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

   On an EC2 instance running Linux, enter the following command.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m ec2 -s -c file:configuration-file-path
```

On an on-premises server running Linux, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m onPremise -s -c file:configuration-file-path
```

On an EC2 instance running Windows Server, enter the following from the PowerShell console:

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
a fetch-config -m ec2 -s -c file:configuration-file-path
```

On an on-premises server running Windows Server, enter the following from the PowerShell console:

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -
a fetch-config -m onPremise -s -c file:configuration-file-path
```

Install the CloudWatch agent using Amazon Systems Manager

Using Amazon Systems Manager makes it easier to install the CloudWatch agent on a fleet of Amazon EC2 instances. You can download the agent into one server and create your CloudWatch agent configuration file for all servers in the fleet. Then you can use Systems Manager to install the agent on the other servers, using the configuration file that you created. Use the following topics to install and run the CloudWatch agent using Amazon Systems Manager.

Topics

Create IAM roles and users for use with the CloudWatch agent

Access to Amazon resources requires permissions. You can create IAM roles and users that include the permissions that you need for the CloudWatch agent to write metrics to CloudWatch and for the CloudWatch agent to communicate with Amazon EC2 and Amazon Systems Manager. You use IAM roles on Amazon EC2 instances, and you use IAM users with on-premises servers.

One role or user enables CloudWatch agent to be installed on a server and send metrics to CloudWatch. The other role or user is needed to store your CloudWatch agent configuration in Systems Manager Parameter Store. Parameter Store enables multiple servers to use one CloudWatch agent configuration.

The ability to write to Parameter Store is a broad and powerful permission. You should use it only when you need it, and it shouldn't be attached to multiple instances in your deployment. If you store your CloudWatch agent configuration in Parameter Store, we recommend the following:

- Set up one instance where you perform this configuration.
- Use the IAM role with permissions to write to Parameter Store only on this instance.
- Use the IAM role with permissions to write to Parameter Store only while you are working with and saving the CloudWatch agent configuration file.

> **Note**
>
> We recently modified the following procedures by using new `CloudWatchAgentServerPolicy` and `CloudWatchAgentAdminPolicy` policies created by Amazon, instead of requiring customers to create these policies themselves. To use these policies to write the agent configuration file to Parameter Store and then download it from Parameter Store, your agent configuration file must have a name that starts with `AmazonCloudWatch-`. If you have a CloudWatch agent configuration file with a file name that doesn't start with `AmazonCloudWatch-`, these policies can't be used to write the file to Parameter Store or to download the file from Parameter Store.

Create IAM roles to use with the CloudWatch agent on Amazon EC2 instances

The first procedure creates the IAM role that you must attach to each Amazon EC2 instance that runs the CloudWatch agent. This role provides permissions for reading information from the instance and writing it to CloudWatch.

The second procedure creates the IAM role that you must attach to the Amazon EC2 instance being used to create the CloudWatch agent configuration file. This step is necessary if you're going to store this file in Systems Manager Parameter Store so that other servers can use it. This role provides permissions for writing to Parameter Store, in addition to the permissions for reading information from the instance and writing it to CloudWatch. This role includes permissions sufficient to run the CloudWatch agent as well as to write to Parameter Store.

> **Note**
>
> Parameter Store supports parameters in Standard and Advanced tiers. These parameter tiers are not related to the Basic, Standard, and Advanced levels of details available with the CloudWatch Agent predefined metric sets.

To create the IAM role necessary for each server to run the CloudWatch agent

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Roles** and then choose **Create role**.
3. Under **Select type of trusted entity**, choose **Amazon service**.
4. Immediately under **Common use cases**, choose **EC2**,and then choose **Next: Permissions**.
5. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find the policy.
6. To use Systems Manager to install or configure the CloudWatch agent, select the box next to **AmazonSSMManagedInstanceCore**. This Amazon managed policy enables an instance to use Systems Manager service core functionality. If necessary, use the search box to find the policy. This policy isn't necessary if you start and configure the agent only through the command line.
7. Choose **Next: Tags**.
8. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this role, and then choose **Next: Review**.
9. For **Role name**, enter a name for your new role, such as `CloudWatchAgentServerRole` or another name that you prefer.
10. (Optional) For **Role description**, enter a description.
11. Confirm that **CloudWatchAgentServerPolicy** and optionally **AmazonSSMManagedInstanceCore** appear next to **Policies**.
12. Choose **Create role**.

The role is now created.

The following procedure creates the IAM role that can also write to Parameter Store. You can use this role to store the agent configuration file in Parameter Store so that other servers can retrieve it.

The permissions for writing to Parameter Store provide broad access. This role shouldn't be attached to all your servers, and only administrators should use it. After you create the agent configuration file and copy it to Parameter Store, you should detach this role from the instance and use `CloudWatchAgentServerRole` instead.

To create the IAM role for an administrator to write to Parameter Store

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Roles** and then choose **Create role**.
3. Under **Select type of trusted entity**, choose **Amazon service**.
4. Immediately under **Choose the service that will use this role**, choose **EC2**, and then choose **Next: Permissions**.
5. In the list of policies, select the check box next to **CloudWatchAgentAdminPolicy**. If necessary, use the search box to find the policy.
6. To use Systems Manager to install or configure the CloudWatch agent, select the box next to **AmazonSSMManagedInstanceCore**. This Amazon managed policy enables an instance to use Systems Manager service core functionality. If necessary, use the search box to find the policy. This policy isn't necessary if you start and configure the agent only through the command line.
7. Choose **Next: Tags**.
8. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this role, and then choose **Next: Review**.
9. For **Role name**, enter a name for your new role, such as **`CloudWatchAgentAdminRole`** or another name that you prefer.
10. (Optional) For **Role description**, enter a description.
11. Confirm that **CloudWatchAgentAdminPolicy** and optionally **AmazonSSMManagedInstanceCore** appear next to **Policies**.
12. Choose **Create role**.

The role is now created.

Create IAM users to use with the CloudWatch agent on on-premises servers

The first procedure creates the IAM user that you need to run the CloudWatch agent. This user provides permissions to send data to CloudWatch.

The second procedure creates the IAM user that you can use when creating the CloudWatch agent configuration file. Use this procedure to store this file in Systems Manager Parameter Store so that other servers can use it. This user provides permissions to write to Parameter Store, in addition to the permissions to write data to CloudWatch.

> **Note**
>
> Parameter Store supports parameters in Standard and Advanced tiers. These parameter tiers are not related to the Basic, Standard, and Advanced levels of details available with the CloudWatch Agent predefined metric sets.

To create the IAM user necessary for the CloudWatch agent to write data to CloudWatch

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Users**, and then choose **Add user**.
3. Enter the user name for the new user.
4. For **Access type**, select **Programmatic access**, and then choose **Next: Permissions**.
5. For **Set permissions**, choose **Attach existing policies directly**.
6. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find the policy.
7. To use Systems Manager to install or configure the CloudWatch agent, select the box next to **AmazonSSMManagedInstanceCore**. This Amazon managed policy enables an instance to use Systems Manager service core functionality. (If necessary, use the search box to find the policy. This policy isn't necessary if you start and configure the agent only through the command line.)
8. Choose **Next: Tags**.

9. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this role, and then choose **Next: Review**.
10. Confirm that the correct policies are listed, and then choose **Create user**.
11. In the row for the new user, choose **Show**. Copy the access key and secret key to a file so that you can use them when installing the agent. Choose **Close**.

The following procedure creates the IAM user that can also write to Parameter Store. If you're going to store the agent configuration file in Parameter Store so that other servers can use it, you need to use this IAM user. This IAM user provides permissions for writing to Parameter Store. This user also provides the permissions for reading information from the instance and writing it to CloudWatch. The permissions for writing to Systems Manager Parameter Store provide broad access. This IAM user shouldn't be attached to all your servers, and only administrators should use it. You should use this IAM user only when you are storing the agent configuration file in Parameter Store.

To create the IAM user necessary to store the configuration file in Parameter Store and send information to CloudWatch

1. Sign in to the Amazon Web Services Management Console and open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Users**, and then choose **Add user**.
3. Enter the user name for the new user.
4. For **Access type**, select **Programmatic access**, and then choose **Next: Permissions**.
5. For **Set permissions**, choose **Attach existing policies directly**.
6. In the list of policies, select the check box next to **CloudWatchAgentAdminPolicy**. If necessary, use the search box to find the policy.
7. To use Systems Manager to install or configure the CloudWatch agent, select the check box next to **AmazonSSMManagedInstanceCore**. This Amazon managed policy enables an instance to use Systems Manager service core functionality. (If necessary, use the search box to find the policy. This policy isn't necessary if you start and configure the agent only through the command line.)
8. Choose **Next: Tags**.
9. (Optional) Add one or more tag-key value pairs to organize, track, or control access for this role, and then choose **Next: Review**.
10. Confirm that the correct policies are listed, and then choose **Create user**.

11. In the row for the new user, choose **Show**. Copy the access key and secret key to a file so that you can use them when installing the agent. Choose **Close**.

Download, configure, and run the CloudWatch agent using SSM

This section explains how to use Systems Manager to download the agent and then how to create your agent configuration file. Before you can use Systems Manager to download the agent, you must make sure that the instance is configured correctly for Systems Manager.

Install or update the SSM Agent

On an Amazon EC2 instance, the CloudWatch agent requires that the instance is running version 2.2.93.0 or later of the SSM Agent. Before you install the CloudWatch agent, update or install SSM Agent on the instance if you haven't already done so.

For information about installing or updating SSM Agent on an instance running Linux, see Installing and Configuring SSM Agent on Linux Instances in the *Amazon Systems Manager User Guide*.

For information about installing or updating the SSM Agent, see Working with SSM Agent in the *Amazon Systems Manager User Guide*.

Verify Systems Manager prerequisites

Before you use Systems Manager Run Command to install and configure the CloudWatch agent, verify that your instances meet the minimum Systems Manager requirements. For more information, see Systems Manager Prerequisites in the *Amazon Systems Manager User Guide*.

Verify internet access

Your Amazon EC2 instances must be able to connect to CloudWatch endpoints. This can be by Internet Gateway, NAT gateway, or CloudWatch Interface VPC endpoints. For more information about how to configure internet access, see Internet Gateways in the *Amazon VPC User Guide*.

The endpoints and ports to configure on your proxy are as follows:

- If you're using the agent to collect metrics, you must allow list the CloudWatch endpoints for the appropriate Regions. These endpoints are listed in Amazon CloudWatch in the *Amazon Web Services General Reference*.

- If you're using the agent to collect logs, you must allow list the CloudWatch Logs endpoints for the appropriate Regions. These endpoints are listed in Amazon CloudWatch Logs in the *Amazon Web Services General Reference*.
- If you're using Systems Manager to install the agent or Parameter Store to store your configuration file, you must allow list the Systems Manager endpoints for the appropriate Regions. These endpoints are listed in Amazon Systems Manager in the *Amazon Web Services General Reference*.

Download the CloudWatch agent package to your first instance

Use the following steps to download the CloudWatch agent package using Systems Manager.

To download the CloudWatch agent using Systems Manager

1. Open the Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the Amazon Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **AWS-ConfigureAWSPackage**.
5. In the **Targets** area, choose the instance to install the CloudWatch agent on. If you don't see a specific instance, it might not be configured as a managed instance for use with Systems Manager. For more information, see Setting Up Amazon Systems Manager for Hybrid Environments in the *Amazon Systems Manager User Guide*.
6. In the **Action** list, choose **Install**.
7. In the **Name** field, enter *`AmazonCloudWatchAgent`*.
8. Keep **Version** set to **latest** to install the latest version of the agent.
9. Choose **Run**.
10. Optionally, in the **Targets and outputs** areas, select the button next to an instance name and choose **View output**. Systems Manager should show that the agent was successfully installed.

Create and modify the agent configuration file

After you have downloaded the CloudWatch agent, you must create the configuration file before you start the agent on any servers.

If you're going to save your agent configuration file in the Systems Manager Parameter Store, you must use an EC2 instance to save to the Parameter Store. Additionally, you must first attach to that instance the `CloudWatchAgentAdminRole` IAM role. For more information about attaching roles, see Attaching an IAM Role to an Instance in the *Amazon EC2 User Guide*.

For more information about creating the CloudWatch agent configuration file, see Create the CloudWatch agent configuration file.

Install and start the CloudWatch agent on additional EC2 instances using your agent configuration

After you have a CloudWatch agent configuration saved in Parameter Store, you can use it when you install the agent on other servers.

For each of these servers, follow the steps listed previously in this section to verify the Systems Manager prerequisites, the version of the SSM Agent, and internet access. Then use the following instructions to install the CloudWatch agent on the additional instances, using the CloudWatch agent configuration file that you have created.

Step 1: Download and install the CloudWatch agent

To be able to send the CloudWatch data to a different Region, make sure that the IAM role that you attached to this instance has permissions to write the CloudWatch data in that Region.

Following is an example of using the `aws configure` command to create a named profile for the CloudWatch agent. This example assumes that you are using the default profile name of `AmazonCloudWatchAgent`.

To create the AmazonCloudWatchAgent profile for the CloudWatch agent

- On Linux servers, type the following command and follow the prompts:

  ```
  sudo aws configure --profile AmazonCloudWatchAgent
  ```

  On Windows Server, open PowerShell as an administrator, type the following command and follow the prompts.

```
aws configure --profile AmazonCloudWatchAgent
```

Install the CloudWatch agent on additional EC2 instances using your agent configuration

After you have a CloudWatch agent configuration saved in Parameter Store, you can use it when you install the agent on other servers.

For each of these servers, follow the steps listed previously in this section to verify the Systems Manager prerequisites, the version of the SSM Agent, and internet access. Then use the following instructions to install the CloudWatch agent on the additional instances, using the CloudWatch agent configuration file that you have created.

Step 1: Download and install the CloudWatch agent

> **Note**
>
> When you install or update the CloudWatch agent, only the **Uninstall and reinstall** option is supported. You can't use the **In-place update** option.

You can download the CloudWatch agent package using either Systems Manager Run Command or an Amazon S3 download link. For information about using an Amazon S3 download link, see Download the CloudWatch agent package.

Systems Manager Run Command enables you to manage the configuration of your instances. You specify a Systems Manager document, specify parameters, and execute the command on one or more instances. SSM Agent on the instance processes the command and configures the instance as specified.

To download the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the Amazon Systems Manager home page opens, scroll down and choose **Explore Run Command**.

3. Choose **Run command**.
4. In the **Command document** list, choose **AWS-ConfigureAWSPackage**.
5. In the **Targets** area, choose the instance on which to install the CloudWatch agent. If you do not see a specific instance, it might not be configured for Run Command. For more information, see Setting Up Amazon Systems Manager for Hybrid Environments in the *Amazon Systems Manager User Guide*.
6. In the **Action** list, choose **Install**.
7. In the **Name** box, enter *AmazonCloudWatchAgent*.
8. Keep **Version** set to **latest** to install the latest version of the agent.
9. Choose **Run**.
10. Optionally, in the **Targets and outputs** areas, select the button next to an instance name and choose **View output**. Systems Manager should show that the agent was successfully installed.

Step 2: Start the CloudWatch agent using your agent configuration file

Follow these steps to start the agent using Systems Manager Run Command.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

To start the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the Amazon Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, choose the instance where you installed the CloudWatch agent.
6. In the **Action** list, choose **configure**.
7. In the **Optional Configuration Source** list, choose **ssm**.

8. In the **Optional Configuration Location** box, enter the name of the Systems Manager parameter name of the agent configuration file that you created and saved to Systems Manager Parameter Store, as explained in [Create the CloudWatch agent configuration file](#).
9. In the **Optional Restart** list, choose **yes** to start the agent after you have finished these steps.
10. Choose **Run**.
11. Optionally, in the **Targets and outputs** areas, select the button next to an instance name and choose **View output**. Systems Manager should show that the agent was successfully started.

(Optional) Modify the common configuration and named profile for CloudWatch agent

The CloudWatch agent includes a configuration file called `common-config.toml`. You can use this file to optionally specify proxy and Region information.

On a server running Linux, this file is in the `/opt/aws/amazon-cloudwatch-agent/etc` directory. On a server running Windows Server, this file is in the `C:\ProgramData\Amazon\AmazonCloudWatchAgent` directory.

The default `common-config.toml` is as follows:

```
# This common-config is used to configure items used for both ssm and cloudwatch access

## Configuration for shared credential.
## Default credential strategy will be used if it is absent here:
##            Instance role is used for EC2 case by default.
##            AmazonCloudWatchAgent profile is used for onPremise case by default.
# [credentials]
#    shared_credential_profile = "{profile_name}"
#    shared_credential_file= "{file_name}"

## Configuration for proxy.
## System-wide environment-variable will be read if it is absent here.
## i.e. HTTP_PROXY/http_proxy; HTTPS_PROXY/https_proxy; NO_PROXY/no_proxy
## Note: system-wide environment-variable is not accessible when using ssm run-command.
## Absent in both here and environment-variable means no proxy will be used.
# [proxy]
#    http_proxy = "{http_url}"
#    https_proxy = "{https_url}"
#    no_proxy = "{domain}"
```

All lines are commented out initially. To set the credential profile or proxy settings, remove the # from that line and specify a value. You can edit this file manually, or by using the `RunShellScript` Run Command in Systems Manager:

- `shared_credential_profile` – For on-premises servers, this line specifies the IAM user credential profile to use to send data to CloudWatch. If you keep this line commented out, `AmazonCloudWatchAgent` is used.

  On an EC2 instance, you can use this line to have the CloudWatch agent send data from this instance to CloudWatch in a different Amazon Region. To do so, specify a named profile that includes a `region` field specifying the name of the Region to send to.

  If you specify a `shared_credential_profile`, you must also remove the # from the beginning of the `[credentials]` line.
- `shared_credential_file` – To have the agent look for credentials in a file located in a path other than the default path, specify that complete path and file name here. The default path is `/root/.aws` on Linux and is `C:\\Users\\Administrator\\.aws` on Windows Server.

  The first example below shows the syntax of a valid `shared_credential_file` line for Linux servers, and the second example is valid for Windows Server. On Windows Server, you must escape the \ characters.

  ```
  shared_credential_file= "/usr/username/credentials"
  ```

  ```
  shared_credential_file= "C:\\Documents and Settings\\username\\.aws\\credentials"
  ```

  If you specify a `shared_credential_file`, you must also remove the # from the beginning of the `[credentials]` line.
- Proxy settings – If your servers use HTTP or HTTPS proxies to contact Amazon services, specify those proxies in the `http_proxy` and `https_proxy` fields. If there are URLs that should be excluded from proxying, specify them in the `no_proxy` field, separated by commas.

Install the CloudWatch agent on on-premises servers

If you downloaded the CloudWatch agent on a computer and created your agent configuration file, you can use that configuration file to install the agent in other on-premises servers.

Download the CloudWatch agent on an on-premises server

You can download the CloudWatch agent package using either Systems Manager Run Command or an Amazon S3 download link. For information about using an Amazon S3 download link, see Download the CloudWatch agent package.

Download using Systems Manager

To use Systems Manager Run Command, you must register your on-premises server with Amazon EC2 Systems Manager. For more information, see Setting Up Systems Manager in Hybrid Environments in the *Amazon Systems Manager User Guide*.

If you have already registered your server, update SSM Agent to the latest version.

For information about updating SSM Agent on a server running Linux, see Install SSM Agent for a Hybrid Environment (Linux) in the *Amazon Systems Manager User Guide*.

For information about updating the SSM Agent on a server running Windows Server, see Install SSM Agent for a Hybrid Environment (Windows) in the *Amazon Systems Manager User Guide*.

To use the SSM Agent to download the CloudWatch agent package on an on-premises server

1. Open the Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the Amazon Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, select the button next to **AWS-ConfigureAWSPackage**.
5. In the **Targets** area, select the server to install the CloudWatch agent on. If you don't see a specific server, it might not be configured for Run Command. For more information, see Setting Up Amazon Systems Manager for Hybrid Environments in the *Amazon Systems Manager User Guide*.
6. In the **Action** list, choose **Install**.
7. In the **Name** box, enter *`AmazonCloudWatchAgent`*.
8. Keep **Version** blank to install the latest version of the agent.
9. Choose **Run**.

The agent package is downloaded, and the next steps are to configure and start it.

(Installing on an on-premises server) Specify IAM credentials and Amazon Region

To enable the CloudWatch agent to send data from an on-premises server, you must specify the access key and secret key of the IAM user that you created earlier. For more information about creating this user, see Create IAM roles and users for use with the CloudWatch agent.

You also must specify the Amazon Region to send the metrics to, using the `region` field.

Following is an example of this file.

```
[AmazonCloudWatchAgent]
aws_access_key_id=my_access_key
aws_secret_access_key=my_secret_key
region = us-west-1
```

For *`my_access_key`* and *`my_secret_key`*, use the keys from the IAM user that doesn't have the permissions to write to Systems Manager Parameter Store. For more information about the IAM users needed for CloudWatch agent, see Create IAM users to use with the CloudWatch agent on on-premises servers.

If you name this profile `AmazonCloudWatchAgent`, you don't need to do anything more. Optionally, you can give it a different name and specify that name as the value for `shared_credential_profile` in the `common-config.toml` file, which is explained in the following section.

Following is an example of using the **aws configure** command to create a named profile for the CloudWatch agent. This example assumes that you're using the default profile name of `AmazonCloudWatchAgent`.

To create the AmazonCloudWatchAgent profile for the CloudWatch agent

1. If you haven't already done so, install the Amazon Command Line Interface on the server. For more information, see Installing the Amazon CLI.
2. On Linux servers, enter the following command and follow the prompts:

   ```
   sudo aws configure --profile AmazonCloudWatchAgent
   ```

On Windows Server, open PowerShell as an administrator, enter the following command, and follow the prompts.

```
aws configure --profile AmazonCloudWatchAgent
```

(Optional) Modifying the common configuration and named profile for CloudWatch agent

The CloudWatch agent includes a configuration file called `common-config.toml`. You can optionally use this file to specify proxy and Region information.

On a server running Linux, this file is in the `/opt/aws/amazon-cloudwatch-agent/etc` directory. On a server running Windows Server, this file is in the `C:\ProgramData\Amazon\AmazonCloudWatchAgent` directory.

The default `common-config.toml` is as follows:

```
# This common-config is used to configure items used for both ssm and cloudwatch access

## Configuration for shared credential.
## Default credential strategy will be used if it is absent here:
##            Instance role is used for EC2 case by default.
##            AmazonCloudWatchAgent profile is used for onPremise case by default.
# [credentials]
#    shared_credential_profile = "{profile_name}"
#    shared_credential_file= "{file_name}"

## Configuration for proxy.
## System-wide environment-variable will be read if it is absent here.
## i.e. HTTP_PROXY/http_proxy; HTTPS_PROXY/https_proxy; NO_PROXY/no_proxy
## Note: system-wide environment-variable is not accessible when using ssm run-command.
## Absent in both here and environment-variable means no proxy will be used.
# [proxy]
#    http_proxy = "{http_url}"
#    https_proxy = "{https_url}"
#    no_proxy = "{domain}"
```

All lines are commented out initially. To set the credential profile or proxy settings, remove the # from that line and specify a value. You can edit this file manually, or by using the `RunShellScript` Run Command in Systems Manager:

- `shared_credential_profile` – For on-premises servers, this line specifies the IAM user credential profile to use to send data to CloudWatch. If you keep this line commented out, `AmazonCloudWatchAgent` is used. For more information about creating this profile, see [(Installing on an on-premises server) Specify IAM credentials and Amazon Region](#).

  On an EC2 instance, you can use this line to have the CloudWatch agent send data from this instance to CloudWatch in a different Amazon Region. To do so, specify a named profile that includes a `region` field specifying the name of the Region to send to.

  If you specify a `shared_credential_profile`, you must also remove the # from the beginning of the `[credentials]` line.
- `shared_credential_file` – To have the agent look for credentials in a file located in a path other than the default path, specify that complete path and file name here. The default path is `/root/.aws` on Linux and is `C:\\Users\\Administrator\\.aws` on Windows Server.

  The first example below shows the syntax of a valid `shared_credential_file` line for Linux servers, and the second example is valid for Windows Server. On Windows Server, you must escape the \ characters.

  ```
  shared_credential_file= "/usr/username/credentials"
  ```

  ```
  shared_credential_file= "C:\\Documents and Settings\\username\\.aws\\credentials"
  ```

  If you specify a `shared_credential_file`, you must also remove the # from the beginning of the `[credentials]` line.
- Proxy settings – If your servers use HTTP or HTTPS proxies to contact Amazon services, specify those proxies in the `http_proxy` and `https_proxy` fields. If there are URLs that should be excluded from proxying, specify them in the `no_proxy` field, separated by commas.

Starting the CloudWatch agent

You can start the CloudWatch agent using either Systems Manager Run Command or the command line.

For information about setting up the agent on a system that has security-enhanced Linux (SELinux) enabled, see Set up the CloudWatch agent with security-enhanced Linux (SELinux).

To use SSM Agent to start the CloudWatch agent on an on-premises server

1. Open the Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the Amazon Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, select the button next to **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, select the instance where you installed the agent.
6. In the **Action** list, choose **configure**.
7. In the **Mode** list, choose **onPremise**.
8. In the **Optional Configuration Location** box, enter the name of the agent configuration file that you created with the wizard and stored in the Parameter Store.
9. Choose **Run**.

   The agent starts with the configuration you specified in the configuration file.

To use the command line to start the CloudWatch agent on an on-premises server

- In this command, `-a fetch-config` causes the agent to load the latest version of the CloudWatch agent configuration file, and `-s` starts the agent.

  Linux: If you saved the configuration file in the Systems Manager Parameter Store, enter the following:

  ```
  sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m onPremise -s -c ssm:configuration-parameter-store-name
  ```

  Linux: If you saved the configuration file on the local computer, enter the following command. Replace *`configuration-file-path`* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m onPremise -s -c file:configuration-file-path
```

Windows Server: If you saved the agent configuration file in Systems Manager Parameter Store, enter the following from the PowerShell console:

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -a fetch-config -m onPremise -s -c ssm:configuration-parameter-store-name
```

Windows Server: If you saved the agent configuration file on the local computer, enter the following from the PowerShell console. Replace *`configuration-file-path`* with the path to the agent configuration file. This file is called `config.json` if you created it with the wizard, and might be called `amazon-cloudwatch-agent.json` if you created it manually.

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1" -a fetch-config -m onPremise -s -c file:configuration-file-path
```

Set up the CloudWatch agent with security-enhanced Linux (SELinux)

If your system has security-enhanced Linux (SELinux) enabled, you must apply the appropriate security policies to ensure that the CloudWatch agent runs in a confined domain.

Prerequisites

Before you can configure SELinux for the agent, check the following **prerequisites**:

To complete the prerequisites for using the CloudWatch agent with SELinux

1. If you haven't done so, install the following SELinux policy development packages:

```
sudo yum update
sudo yum install -y selinux-policy-devel policycoreutils-devel rpm-build git
```

2. Run the following command to check your system's SELinux status:

```
sestatus
```

Example output:

```
SELinux status:                 enabled
SELinuxfs mount:                /sys/fs/selinux
SELinux root directory:         /etc/selinux
Loaded policy name:             targeted
Current mode:                   permissive
Mode from config file:          permissive
Policy MLS status:              enabled
Policy deny_unknown status:     allowed
Memory protection checking:     actual (secure)
Max kernel policy version:      33
```

If you find that SELinux is currently disabled, do the following:

a. Open the SELinux file by entering the following command:

```
sudo vi /etc/selinux/config
```

b. Set the `SELINUX` parameter to either `permissive` or `enforcing`. For example:

```
SELINUX=enforcing
```

c. Save the file and reboot the system to apply the changes.

```
sudo reboot
```

3. Ensure that the CloudWatch agent is running as a `systemd` service. This is required to use it within a confined SELinux domain.

```
sudo systemctl status amazon-cloudwatch-agent
```

If the agent is correctly configured, the output should indicate that it is `active (running)` and `enabled` at startup.

Configure SELinux for the agent

After you complete the prerequisites, you can configure SELinux.

To configure SELinux for the CloudWatch agent

1. Clone the SELinux policy for the CloudWatch agent by entering the following command:

```
git clone https://github.com/aws/amazon-cloudwatch-agent-selinux.git
```

2. Navigate to the cloned repository and then update the script permissions by entering the following commands:

```
cd amazon-cloudwatch-agent-selinux
chmod +x amazon_cloudwatch_agent.sh
```

3. Use `sudo` to run the SELinux policy installation script by entering the following command. During execution, the script prompts you to enter `y` or `n` to allow automatic restart. This restart ensures that the agent transitions into the correct SELinux domain.

```
sudo ./amazon_cloudwatch_agent.sh
```

4. If the CloudWatch agent hasn't been restarted yet, restart it to ensure that it transitions to the correct SELinux domain:

```
sudo systemctl restart amazon-cloudwatch-agent
```

5. Verify that CloudWatch Agent is running in the confined domain by entering the following command:

```
ps -efZ | grep amazon-cloudwatch-agent
```

   If the agent is correctly confined, the output should indicate a SELinux-confined domain instead of `unconfined_service_t`.

   The following is an example of output when the agent is correctly confined.

```
system_u:system_r:confined_t:s0 root 1234 1 0 12:00 ? 00:00:10 /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent
```

After SELinux is configured, you can proceed to configure the agent to collect metrics, logs, and traces. For more information, see Manually create or edit the CloudWatch agent configuration file.

CloudWatch agent credentials preference

This section outlines the credentials provider chain the CloudWatch agent uses to obtain credentials when communicating with other Amazon services and APIs. The ordering is as follows:

> **Note**
>
> The preferences listed in numbers two through five are the same preference order as defined in the Amazon SDK. For more information, see Specifying Credentials in the SDK documentation.

1. Shared config and credentials files as defined in the CloudWatch agent's `common-config.toml` file. For more information, see (Optional) Modify the common configuration for proxy or Region information.
2. Amazon SDK environment variables

   > **Important**
   >
   > On Linux, if you run the CloudWatch agent using the `amazon-cloudwatch-agent-ctl` script, the script starts the agent as a `systemd` service. In this case, environment variables such as `HOME`, `AWS_ACCESS_KEY_ID`, and `AWS_SECRET_ACCESS_KEY` are not accessible by the agent.

3. Shared configuration and credentials files found in `$HOME/%USERPROFILE%`

   > **Note**
   >
   > The CloudWatch agent looks for `.aws/credentials` in `$HOME` for Linux and MacOS and looks in `%USERPROFILE%` for Windows. Unlike the Amazon SDK, the CloudWatch agent does not have fallback methods to determine the home directory if the environment variables are inaccessible. This difference in behavior is to maintain backwards compatibility with earlier implementations of the Amazon SDK.
   >
   > Furthermore, unlike with the shared credentials found in `common-config.toml`, if the Amazon SDK-derived shared credentials expire and are rotated, the renewed credentials

are not automatically picked up by the CloudWatch agent and require a restart of the agent to do so.

4. An Amazon Identity and Access Management role for tasks if an application is present that uses an Amazon Elastic Container Service task definition or a RunTask API operation.
5. An instance profile attached to an Amazon EC2 instance.

As a best practice, we recommend that you specify credentials in the following order when you use the CloudWatch agent.

1. Use IAM roles for tasks if your application uses an Amazon Elastic Container Service task definition or a RunTask API operation.
2. Use IAM roles if your application runs on an Amazon EC2 instance.
3. Use the CloudWatch agent `common-config.toml` file to specify the credentials file. This credentials file is the same one used by other Amazon SDKs and the Amazon CLI. If you're already using a shared credentials file, you can also use it for this purpose. If you provide it by using the CloudWatch agent's `common-config.toml` file, you ensure that the agent will consume rotated credentials when they expire and get replaced without requiring you to restart the agent.
4. Use environment variables. Setting environment variables is useful if you're doing development work on a computer other than an Amazon EC2 instance.

Note

If you send telemetry to a different account as explained in [Sending metrics, logs, and traces to a different account](), the CloudWatch agent uses the credentials provider chain described in this section to obtain the initial set of credentials. It then uses those credentials when assuming the IAM role specified by `role_arn` in the CloudWatch agent configuration file.

Verifying the signature of the CloudWatch agent package

GPG signature files are included for CloudWatch agent packages on Linux servers. You can use a public key to verify the agent download file is original and unmodified.

For Windows Server, you can use the MSI to verify the signature. For macOS computers, the signature is included in the agent download package.

To find the correct signature file, use the following table. For each architecture and operating system, you can see a general link and links for each Region. For example, for Amazon Linux 2023 and Amazon Linux 2 and the x86-64 architecture, three of the valid links are:

- `https://amazoncloudwatch-agent.s3.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm.sig`
- `https://amazoncloudwatch-agent-us-east-1.s3.us-east-1.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`
- `https://amazoncloudwatch-agent-eu-central-1.s3.eu-central-1.amazonaws.com/amazon_linux/amd64/latest/amazon-cloudwatch-agent.rpm`

> **Note**
>
> To download the CloudWatch agent, your connection must use TLS 1.2 or later.

To verify the CloudWatch agent package on a Linux server

1. Download the public key.
2. Import the public key into your keyring.

```
shell$  gpg --import amazon-cloudwatch-agent.gpg
gpg: key 3B789C72: public key "Amazon CloudWatch Agent" imported
gpg: Total number processed: 1
gpg: imported: 1 (RSA: 1)
```

   Make a note of the key value, as you need it in the next step. In the preceding example, the key value is 3B789C72.

3. Verify the fingerprint by running the following command, replacing *key-value* with the value from the preceding step:

```
shell$  gpg --fingerprint key-value
pub   2048R/3B789C72 2017-11-14
      Key fingerprint = 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
```

```
uid                     Amazon CloudWatch Agent
```

The fingerprint string should be equal to the following:

`9376 16F3 450B 7D80 6CBD 9725 D581 6730 3B78 9C72`

If the fingerprint string doesn't match, don't install the agent. Contact Amazon Web Services.

After you have verified the fingerprint, you can use it to verify the signature of the CloudWatch agent package.

4. Download the package signature file using **wget**. To determine the correct signature file, see the preceding table.

```
wget Signature File Link
```

5. To verify the signature, run **gpg --verify**.

```
shell$ gpg --verify signature-filename agent-download-filename
gpg: Signature made Wed 29 Nov 2017 03:00:59 PM PST using RSA key ID 3B789C72
gpg: Good signature from "Amazon CloudWatch Agent"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 9376 16F3 450B 7D80 6CBD  9725 D581 6730 3B78 9C72
```

If the output includes the phrase `BAD signature`, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and avoid using the downloaded file.

Note the warning about trust. A key is trusted only if you or someone who you trust has signed it. This doesn't mean that the signature is invalid, only that you have not verified the public key.

Create the CloudWatch agent configuration file

Before running the CloudWatch agent on any servers, you must create one or more CloudWatch agent configuration files.

The agent configuration file is a JSON file that specifies the metrics, logs, and traces that the agent is to collect, including custom metrics. You can create it by using the wizard or by creating it yourself from scratch. You could also use the wizard to initially create the configuration file and then modify it manually. If you create or modify the file manually, the process is more complex, but you have more control over the metrics collected and can specify metrics not available through the wizard.

Any time you change the agent configuration file, you must then restart the agent to have the changes take effect. To restart the agent, follow the instructions in [(Optional) Modify the common configuration and named profile for CloudWatch agent](#).

After you have created a configuration file, you can save it manually as a JSON file and then use this file when installing the agent on your servers. Alternatively, you can store it in Systems Manager Parameter Store if you're going to use Systems Manager when you install the agent on servers.

The CloudWatch agent supports using multiple configuration files. For more information, see [Multiple CloudWatch agent configuration files](#).

Metrics, logs, and traces collected by the CloudWatch agent incur charges. For more information about pricing, see [Amazon CloudWatch Pricing](#).

Contents

Create the CloudWatch agent configuration file with the wizard

The agent configuration file wizard, `amazon-cloudwatch-agent-config-wizard`, asks a series of questions to help you configure the CloudWatch agent for your needs. This section describes the credentials required for the configuration file. It describes how to run the CloudWatch agent configuration wizard. It also describes the metrics that are predefined in the wizard.

Required credentials

The wizard can autodetect the credentials and Amazon Region to use if you have the Amazon credentials and configuration files in place before you start the wizard. For more information about these files, see [Configuration and Credential Files](#) in the *Amazon Systems Manager User Guide*.

In the Amazon credentials file, the wizard checks for default credentials and also looks for an `AmazonCloudWatchAgent` section such as the following:

```
[AmazonCloudWatchAgent]
aws_access_key_id = my_access_key
aws_secret_access_key = my_secret_key
```

The wizard displays the default credentials, the credentials from the `AmazonCloudWatchAgent`, and an `Others` option. You can select which credentials to use. If you choose `Others`, you can input credentials.

In the Amazon configuration file, you can specify the Region that the agent sends metrics to if it's different than the `[default]` section. The default is to publish the metrics to the Region where the Amazon EC2 instance is located. If the metrics should be published to a different Region, specify the Region here. In the following example, the metrics are published to the `us-west-1` Region.

```
[AmazonCloudWatchAgent]
region = us-west-1
```

Run the CloudWatch agent configuration wizard

To create the CloudWatch agent configuration file

1. Start the CloudWatch agent configuration wizard by entering the following:

   ```
   sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-config-wizard
   ```

   On a server running Windows Server, run the following commands to launch the wizard:

   ```
   cd "C:\Program Files\Amazon\AmazonCloudWatchAgent"
   ```

   ```
   .\amazon-cloudwatch-agent-config-wizard.exe
   ```

2. Answer the questions to customize the configuration file for your server.
3. If you're storing the configuration file locally, the configuration file `config.json` is stored in `/opt/aws/amazon-cloudwatch-agent/bin/` on Linux servers, and is stored in `C:\Program Files\Amazon\AmazonCloudWatchAgent` on Windows Server. You can then copy this file to other servers where you want to install the agent.

If you're going to use Systems Manager to install and configure the agent, be sure to answer **Yes** when prompted whether to store the file in Systems Manager Parameter Store. You can also choose to store the file in Parameter Store even if you aren't using the SSM Agent to install the CloudWatch agent. To be able to store the file in Parameter Store, you must use an IAM role with sufficient permissions. For more information, see [Create IAM roles and users for use with the CloudWatch agent](#).

CloudWatch agent predefined metric sets

The wizard is configured with predefined sets of metrics, with different detail levels. These sets of metrics are shown in the following tables. For more information about these metrics, see [Metrics collected by the CloudWatch agent](#).

> **Note**
>
> Parameter Store supports parameters in Standard and Advanced tiers. These parameter tiers are not related to the Basic, Standard, and Advanced levels of metric details that are described in these tables.

Amazon EC2 instances running Linux

Detail level	Metrics included
Basic	**Mem:** mem_used_percent **Disk:** disk_used_percent The `disk` metrics such as `disk_used_percent` have a dimension for `Partition`, which means that the number of custom metrics generated is dependent on the number of partitions associated with your instance. The number of disk partitions you have depends on which AMI you are using and the number of Amazon EBS volumes you attach to the server.
Standard	**CPU:** `cpu_usage_idle`, `cpu_usage_iowait`, `cpu_usage_user`, `cpu_usage_system` **Disk:** `disk_used_percent`, `disk_inodes_free`

Detail level	Metrics included
	Diskio: diskio_io_time **Mem:** mem_used_percent **Swap:** swap_used_percent
Advanced	**CPU:** cpu_usage_idle , cpu_usage_iowait , cpu_usage_user , cpu_usage_system **Disk:** disk_used_percent , disk_inodes_free **Diskio:** diskio_io_time , diskio_write_bytes , diskio_read_bytes , diskio_writes , diskio_reads **Mem:** mem_used_percent **Netstat:** netstat_tcp_established , netstat_tcp_time_wait **Swap:** swap_used_percent

On-premises servers running Linux

Detail level	Metrics included
Basic	**Disk:** disk_used_percent **Diskio:** diskio_write_bytes , diskio_read_bytes , diskio_writes , diskio_reads **Mem:** mem_used_percent **Net:** net_bytes_sent , net_bytes_recv , net_packets_sent , net_packets_recv **Swap:** swap_used_percent
Standard	**CPU:** cpu_usage_idle , cpu_usage_iowait **Disk:** disk_used_percent , disk_inodes_free

Detail level	Metrics included
	Diskio: diskio_io_time , diskio_write_bytes , diskio_read_bytes , diskio_writes , diskio_reads **Mem:** mem_used_percent **Net:** net_bytes_sent , net_bytes_recv , net_packets_sent , net_packets_recv **Swap:** swap_used_percent
Advanced	**CPU:** cpu_usage_guest , cpu_usage_idle , cpu_usage_iowait , cpu_usage_steal , cpu_usage_user , cpu_usage_system **Disk:** disk_used_percent , disk_inodes_free **Diskio:** diskio_io_time , diskio_write_bytes , diskio_read_bytes , diskio_writes , diskio_reads **Mem:** mem_used_percent **Net:** net_bytes_sent , net_bytes_recv , net_packets_sent , net_packets_recv **Netstat:** netstat_tcp_established , netstat_tcp_time_wait **Swap:** swap_used_percent

Amazon EC2 instances running Windows Server

> **Note**
>
> The metric names listed in this table display how the metric appears when viewed in the console. The actual metric name might not include the first word. For example, the actual metric name for `LogicalDisk % Free Space` is just `% Free Space`.

Detail level	Metrics included
Basic	**Memory:** `Memory % Committed Bytes In Use` **LogicalDisk:** `LogicalDisk % Free Space`
Standard	**Memory:** `Memory % Committed Bytes In Use` **Paging:** `Paging File % Usage` **Processor:** `Processor % Idle Time`, `Processor % Interrupt Time`, `Processor % User Time` **PhysicalDisk:** `PhysicalDisk % Disk Time` **LogicalDisk:** `LogicalDisk % Free Space`
Advanced	**Memory:** `Memory % Committed Bytes In Use` **Paging:** `Paging File % Usage` **Processor:** `Processor % Idle Time`, `Processor % Interrupt Time`, `Processor % User Time` **LogicalDisk:** `LogicalDisk % Free Space` **PhysicalDisk:** `PhysicalDisk % Disk Time` , `PhysicalDisk Disk Write Bytes/sec` , `PhysicalDisk Disk Read Bytes/sec` , `PhysicalDisk Disk Writes/sec` , `PhysicalDisk Disk Reads/sec` **TCP:** `TCPv4 Connections Established` , `TCPv6 Connections Established`

On-premises server running Windows Server

Note

The metric names listed in this table display how the metric appears when viewed in the console. The actual metric name might not include the first word. For example, the actual metric name for `LogicalDisk % Free Space` is just `% Free Space`.

Detail level	Metrics included
Basic	**Paging:** `Paging File % Usage` **Processor:** `Processor % Processor Time` **LogicalDisk:**`LogicalDisk % Free Space` **PhysicalDisk:** `PhysicalDisk Disk Write Bytes/sec` , `PhysicalDisk Disk Read Bytes/sec` , `PhysicalDisk Disk Writes/sec` , `PhysicalDisk Disk Reads/sec` **Memory:** `Memory % Committed Bytes In Use` **Network Interface:** `Network Interface Bytes Sent/sec`, `Network Interface Bytes Received/sec` , `Network Interface Packets Sent/sec`, `Network Interface Packets Received/sec`
Standard	**Paging:** `Paging File % Usage` **Processor:** `Processor % Processor Time`, `Processor % Idle Time`, `Processor % Interrupt Time` **LogicalDisk:** `LogicalDisk % Free Space` **PhysicalDisk:** `PhysicalDisk % Disk Time` , `PhysicalDisk Disk Write Bytes/sec` , `PhysicalDisk Disk Read Bytes/sec` , `PhysicalDisk Disk Writes/sec` , `PhysicalDisk Disk Reads/sec` **Memory:** `Memory % Committed Bytes In Use`

Detail level	Metrics included
	Network Interface: `Network Interface Bytes Sent/sec`, `Network Interface Bytes Received/sec` , `Network Interface Packets Sent/sec`, `Network Interface Packets Received/sec`
Advanced	**Paging:** `Paging File % Usage` **Processor:** `Processor % Processor Time`, `Processor % Idle Time`, `Processor % Interrupt Time`, `Processor % User Time` **LogicalDisk:** `LogicalDisk % Free Space` **PhysicalDisk:** `PhysicalDisk % Disk Time` , `PhysicalDisk Disk Write Bytes/sec` , `PhysicalDisk Disk Read Bytes/sec` , `PhysicalDisk Disk Writes/sec` , `PhysicalDisk Disk Reads/sec` **Memory:** `Memory % Committed Bytes In Use` **Network Interface:** `Network Interface Bytes Sent/sec`, `Network Interface Bytes Received/sec` , `Network Interface Packets Sent/sec`, `Network Interface Packets Received/sec` **TCP:** `TCPv4 Connections Established` , `TCPv6 Connections Established`

Manually create or edit the CloudWatch agent configuration file

The CloudWatch agent configuration file is a JSON file with four sections: `agent`, `metrics`, `logs`, and `traces`.

- The `agent` section includes fields for the overall configuration of the agent.
- The `metrics` section specifies the custom metrics for collection and publishing to CloudWatch. If you're using the agent only to collect logs, you can omit the `metrics` section from the file.
- The `logs` section specifies what log files are published to CloudWatch Logs. This can include events from the Windows Event Log if the server runs Windows Server.
- The `traces` section specifies the sources for traces that are collected and sent to Amazon X-Ray.

This section explains the structure and fields of the CloudWatch agent configuration file. You can view the schema definition for this configuration file. The schema definition is located at *installation-directory*/doc/amazon-cloudwatch-agent-schema.json on Linux servers and at *installation-directory*/amazon-cloudwatch-agent-schema.json on servers running Windows Server.

If you create or edit the agent configuration file manually, you can give it any name. For simplicity in troubleshooting, we recommend that you name it /opt/aws/amazon-cloudwatch-agent/etc/cloudwatch-agent.json on a Linux server and $Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.json on servers running Windows Server. After you have created the file, you can copy it to other servers where you want to install the agent.

When the agent is started, it creates a copy of each configuration file in /opt/aws/amazon-cloudwatch/etc/amazon-cloudwatch-agent.d directory, with the filename prefixed with either file_ (for local file sources) or ssm_ (for Systems Manager parameter store sources) to indicate the configuration origin.

> **Note**
>
> Metrics, logs, and traces collected by the CloudWatch agent incur charges. For more information about pricing, see Amazon CloudWatch Pricing.

CloudWatch agent configuration file: Agent section

The agent section can include the following fields. The wizard doesn't create an agent section. Instead, the wizard omits it and uses the default values for all fields in this section.

- metrics_collection_interval – Optional. Specifies how often all metrics specified in this configuration file are to be collected. You can override this value for specific types of metrics.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.

  The default value is 60.

- `region` – Specifies the Region to use for the CloudWatch endpoint when an Amazon EC2 instance is being monitored. The metrics collected are sent to this Region, such as `us-west-1`. If you omit this field, the agent sends metrics to the Region where the Amazon EC2 instance is located.

  If you are monitoring an on-premises server, this field isn't used, and the agent reads the Region from the `AmazonCloudWatchAgent` profile of the Amazon configuration file.
- `credentials` – Specifies an IAM role to use when sending metrics, logs, and traces to a different Amazon account. If specified, this field contains one parameter, `role_arn`.
  - `role_arn` – Specifies the Amazon Resource Name (ARN) of an IAM role to use for authentication when sending metrics, logs, and traces to a different Amazon account. For more information, see Sending metrics, logs, and traces to a different account.
- `debug` – Optional. Specifies running the CloudWatch agent with debug log messages. The default value is `false`.
- `aws_sdk_log_level` – Optional. Supported only in versions 1.247350.0 and later of the CloudWatch agent.

  You can specify this field to have the agent perform logging for Amazon SDK endpoints. The value for this field can include one or more of the following options. Separate multiple options with the `|` character.
  - `LogDebug`
  - `LogDebugWithSigning`
  - `LogDebugWithHTTPBody`
  - `LogDebugRequestRetries`
  - `LogDebugWithEventStreamBody`

  For more information about these options, see LogLevelType.
- `logfile` – Specifies the location where the CloudWatch agent writes log messages. If you specify an empty string, the log goes to stderr. If you don't specify this option, the default locations are the following:
  - Linux: `/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log`
  - Windows Server: `c:\\ProgramData\\Amazon\\CloudWatchAgent\\Logs\\amazon-cloudwatch-agent.log`

The CloudWatch agent automatically rotates the log file that it creates. A log file is rotated out when it reaches 100 MB in size. The agent keeps the rotated log files for up to seven days, and it keeps as many as five backup log files that have been rotated out. Backup log files have a timestamp appended to their filename. The timestamp shows the date and time that the file was rotated out: for example, `amazon-cloudwatch-agent-2018-06-08T21-01-50.247.log.gz`.

- `omit_hostname` – Optional. By default, the hostname is published as a dimension of metrics that are collected by the agent, unless you are using the `append_dimensions` field in the `metrics` section. Set `omit_hostname` to `true` to prevent the hostname from being published as a dimension even if you are not using `append_dimensions`. The default value is `false`.
- `run_as_user` – Optional. Specifies a user to use to run the CloudWatch agent. If you don't specify this parameter, the root user is used. This option is valid only on Linux servers.

  If you specify this option, the user must exist before you start the CloudWatch agent. For more information, see Running the CloudWatch agent as a different user.
- `user_agent` – Optional. Specifies the `user-agent` string that is used by the CloudWatch agent when it makes API calls to the CloudWatch backend. The default value is a string consisting of the agent version, the version of the Go programming language that was used to compile the agent, the runtime operating system and architecture, the build time, and the plugins enabled.
- `usage_data` – Optional. By default, the CloudWatch agent sends health and performance data about itself to CloudWatch whenever it publishes metrics or logs to CloudWatch. This data incurs no costs to you. You can prevent the agent from sending this data by specifying `false` for `usage_data`. If you omit this parameter, the default of `true` is used and the agent sends the health and performance data.

  If you set this value to `false`, you must stop and restart the agent for it to take effect.
- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.
- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.

The following is an example of an `agent` section.

```
"agent": {
   "metrics_collection_interval": 60,
```

```
    "region": "us-west-1",
    "logfile": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log",
    "debug": false,
    "run_as_user": "cwagent"
  }
```

CloudWatch agent configuration file: Metrics section

Fields common to Linux and Windows

On servers running either Linux or Windows Server, the `metrics` section includes the following fields:

- `namespace` – Optional. The namespace to use for the metrics collected by the agent. The default value is `CWAgent`. The maximum length is 255 characters. The following is an example:

  ```
  {
    "metrics": {
      "namespace": "Development/Product1Metrics",
     ......
     },
  }
  ```

- `append_dimensions` – Optional. Adds Amazon EC2 metric dimensions to all metrics collected by the agent. This also causes the agent to not publish the hostname as a dimension.

  The only supported key-value pairs for `append_dimensions` are shown in the following list. Any other key-value pairs are ignored. The agent supports these key-value pairs exactly as they are shown in the following list. You can't change the key values to publish different dimension names for them.

  - `"ImageId":"${aws:ImageId}"` sets the instance's AMI ID as the value of the `ImageId` dimension.
  - `"InstanceId":"${aws:InstanceId}"` sets the instance's instance ID as the value of the `InstanceId` dimension.
  - `"InstanceType":"${aws:InstanceType}"` sets the instance's instance type as the value of the `InstanceType` dimension.
  - `"AutoScalingGroupName":"${aws:AutoScalingGroupName}"` sets the instance's Auto Scaling group name as the value of the `AutoScalingGroupName` dimension.

If you want to append dimensions to metrics with arbitrary key-value pairs, use the `append_dimensions` parameter in the field for that particular type of metric.

If you specify a value that depends on Amazon EC2 metadata and you use proxies, you must make sure that the server can access the endpoint for Amazon EC2. For more information about these endpoints, see Amazon Elastic Compute Cloud (Amazon EC2) in the *Amazon Web Services General Reference*.

- `aggregation_dimensions` – Optional. Specifies the dimensions that collected metrics are to be aggregated on. For example, if you roll up metrics on the `AutoScalingGroupName` dimension, the metrics from all instances in each Auto Scaling group are aggregated and can be viewed as a whole.

  You can roll up metrics along single or multiple dimensions. For example, specifying `[["InstanceId"], ["InstanceType"], ["InstanceId","InstanceType"]]` aggregates metrics for instance ID singly, instance type singly, and for the combination of the two dimensions.

  You can also specify `[]` to roll up all metrics into one collection, disregarding all dimensions.

- `endpoint_override` – Specifies a FIPS endpoint or private link to use as the endpoint where the agent sends metrics. Specifying this and setting a private link enables you to send the metrics to an Amazon VPC endpoint. For more information, see What Is Amazon VPC?.

  The value of `endpoint_override` must be a string that is a URL.

  For example, the following part of the metrics section of the configuration file sets the agent to use a VPC Endpoint when sending metrics.

```
{
  "metrics": {
    "endpoint_override": "vpce-XXXXXXXXXXXXXXXXXXXXXXXXX.monitoring.us-
east-1.vpce.amazonaws.com",
   ......
   },
}
```

- `metrics_collected` – Required. Specifies which metrics are to be collected, including custom metrics collected through `StatsD` or `collectd`. This section includes several subsections.

The contents of the `metrics_collected` section depend on whether this configuration file is for a server running Linux or Windows Server.

- `metrics_destinations` – Optional. Specifies one or more destinations for all metrics defined in `metrics_collected`. If specified here, it overrides the default destination of `cloudwatch`.
  - `cloudwatch` – Amazon CloudWatch.
  - amp – Amazon Managed Service for Prometheus.
    - `workspace_id` – The ID corresponding to the Amazon Managed Service for Prometheus workspace.

```
{
  "metrics": {
    "metrics_destinations": {
      "cloudwatch": {},
      "amp": {
        "workspace_id": "ws-abcd1234-ef56-7890-ab12-example"
      }
    }
  }
}
```

- `force_flush_interval` – Specifies in seconds the maximum amount of time that metrics remain in the memory buffer before being sent to the server. No matter the setting for this, if the size of the metrics in the buffer reaches 1 MB or 1000 different metrics, the metrics are immediately sent to the server.

  The default value is 60.
- `credentials` – Specifies an IAM role to use when sending metrics to a different account. If specified, this field contains one parameter, `role_arn`.
  - `role_arn` – Specifies the ARN of an IAM role to use for authentication when sending metrics to a different account. For more information, see [Sending metrics, logs, and traces to a different account](). If specified here, this value overrides the `role_arn` specified in the `agent` section of the configuration file, if any.
  - `service.name` – Optional. Specifies the service name to be used to populate the entity for [finding related telemetry]().
  - `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for [finding related telemetry]().

Linux section

On servers running Linux, the `metrics_collected` section of the configuration file can also contain the following fields.

Many of these fields can include a `measurement` sections that lists the metrics you want to collect for that resource. These `measurement` sections can either specify the complete metric name such as `swap_used`, or just the part of the metric name that will be appended to the type of resource. For example, specifying `reads` in the `measurement` section of the `diskio` section causes the `diskio_reads` metric to be collected.

- `collectd` – Optional. Specifies that you want to retrieve custom metrics using the `collectd` protocol. You use `collectd` software to send the metrics to the CloudWatch agent. For more information about the configuration options available for collectd, see [Retrieve custom metrics with collectd](#).
- `cpu` – Optional. Specifies that CPU metrics are to be collected. This section is valid only for Linux instances. You must include at least one of the `resources` and `totalcpu` fields for any CPU metrics to be collected. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
  - `resources` – Optional. Specify this field with a value of `*` to cause per-cpu metrics to be collected. The only allowed value is `*`.
  - `totalcpu` – Optional. Specifies whether to report cpu metrics aggregated across all cpu cores. The default is true.
  - `measurement` – Specifies the array of cpu metrics to be collected. Possible values are `time_active`, `time_guest`, `time_guest_nice`, `time_idle`, `time_iowait`, `time_irq`, `time_nice`, `time_softirq`, `time_steal`, `time_system`, `time_user`, `usage_active`, `usage_guest`, `usage_guest_nice`, `usage_idle`, `usage_iowait`, `usage_irq`, `usage_nice`, `usage_softirq`, `usage_steal`, `usage_system`, and `usage_user`. This field is required if you include `cpu`.

By default, the unit for `cpu_usage_*` metrics is `Percent`, and `cpu_time_*` metrics don't have a unit.

Within the entry for each individual metric, you might optionally specify one or both of the following:

- `rename` – Specifies a different name for this metric.
- `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in [MetricDatum](https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/API_MetricDatum.html).

- `metrics_collection_interval` – Optional. Specifies how often to collect the cpu metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see [High-resolution metrics](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/publishingMetrics.html#high-resolution-metrics).
- `append_dimensions` – Optional. Additional dimensions to use for only the cpu metrics. If you specify this field, it's used in addition to dimensions specified in the global `append_dimensions` field that is used for all types of metrics that the agent collects.

- `disk` – Optional. Specifies that disk metrics are to be collected. Collects metrics only for mounted volumes. This section is valid only for Linux instances. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
  - `resources` – Optional. Specifies an array of disk mount points. This field limits CloudWatch to collect metrics from only the listed mount points. You can specify `*` as the value to collect metrics from all mount points. The default value is to collect metrics from all mount points.

- `measurement` – Specifies the array of disk metrics to be collected. Possible values are `free`, `total`, `used`, `used_percent`, `inodes_free`, `inodes_used`, and `inodes_total`. This field is required if you include `disk`.

> **Note**
>
> The `disk` metrics have a dimension for `Partition`, which means that the number of custom metrics generated is dependent on the number of partitions associated with your instance. The number of disk partitions you have depends on which AMI you are using and the number of Amazon EBS volumes you attach to the server.

  To see the default units for each `disk` metric, see [Metrics collected by the CloudWatch agent on Linux and macOS instances](#).

  Within the entry for each individual metric, you might optionally specify one or both of the following:

  - `rename` – Specifies a different name for this metric.
  - `unit` – Specifies the unit to use for this metric, overriding the default unit of None of None for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in [MetricDatum](#).
- `ignore_file_system_types` – Specifies file system types to exclude when collecting disk metrics. Valid values include `sysfs`, `devtmpfs`, and so on.
- `drop_device` – Setting this to `true` causes `Device` to not be included as a dimension for disk metrics.

  Preventing `Device` from being used as a dimension can be useful on instances that use the Nitro system because on those instances the device names change for each disk mount when the instance is rebooted. This can cause inconsistent data in your metrics and cause alarms based on these metrics to go to `INSUFFICIENT DATA` state.

  The default is `false`.
- `metrics_collection_interval` – Optional. Specifies how often to collect the disk metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.

- `append_dimensions` – Optional. Specify key-value pairs to use as additional dimensions for only the disk metrics. If you specify this field, it is used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

  One key-value pair that you can use is the following. You can also specify other custom key-value pairs.

  - `"VolumeId":"${aws:VolumeId}"` adds a `VolumeId` dimension to your block device disk metrics. For Amazon EBS volumes, this will be the Amazon EBS Volume ID. For EC2 instance store, this will be the device serial. Using this requires the `drop_device` parameter to be set to `false`.

- `diskio` – Optional. Specifies that disk i/o metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

  - `resources` – Optional. If you specify an array of devices, CloudWatch collects metrics from only those devices. Otherwise, metrics for all devices are collected. You can also specify * as the value to collect metrics from all devices.

  - `measurement` – Specifies the array of diskio metrics to be collected. Possible values are `reads`, `writes`, `read_bytes`, `write_bytes`, `read_time`, `write_time`, `io_time`, and `iops_in_progress`. This field is required if you include `diskio`.

    Within the entry for each individual metric, you might optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.

    - `unit` – Specifies the unit to use for this metric, overriding the default unit of None of None for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

  - `metrics_collection_interval` – Optional. Specifies how often to collect the diskio metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

    This value is specified in seconds.

    If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.
  - `append_dimensions` – Optional. Additional dimensions to use for only the diskio metrics. If you specify this field, it is used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.
- `swap` – Optional. Specifies that swap memory metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
  - `measurement` – Specifies the array of swap metrics to be collected. Possible values are `free`, `used`, and `used_percent`. This field is required if you include `swap`.

    To see the default units for each `swap` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

    Within the entry for each individual metric, you might optionally specify one or both of the following:
    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit of None of None for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
  - `metrics_collection_interval` – Optional. Specifies how often to collect the swap metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

This value is specified in seconds.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.

- `append_dimensions` – Optional. Additional dimensions to use for only the swap metrics. If you specify this field, it is used in addition to dimensions specified in the global `append_dimensions` field that is used for all types of metrics collected by the agent. It's collected as a high-resolution metric.

- `mem` – Optional. Specifies that memory metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
  - `measurement` – Specifies the array of memory metrics to be collected. Possible values are `active`, `available`, `available_percent`, `buffered`, `cached`, `free`, `inactive`, `total`, `used`, and `used_percent`. This field is required if you include `mem`.

    To see the default units for each `mem` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

    Within the entry for each individual metric, you might optionally specify one or both of the following:
    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
  - `metrics_collection_interval` – Optional. Specifies how often to collect the mem metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

    This value is specified in seconds.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.

  - `append_dimensions` – Optional. Additional dimensions to use for only the mem metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics that the agent collects.
- `net` – Optional. Specifies that networking metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
  - `resources` – Optional. If you specify an array of network interfaces, CloudWatch collects metrics from only those interfaces. Otherwise, metrics for all devices are collected. You can also specify `*` as the value to collect metrics from all interfaces.
  - `measurement` – Specifies the array of networking metrics to be collected. Possible values are `bytes_sent`, `bytes_recv`, `drop_in`, `drop_out`, `err_in`, `err_out`, `packets_sent`, and `packets_recv`. This field is required if you include `net`.

    To see the default units for each `net` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

    Within the entry for each individual metric, you might optionally specify one or both of the following:
    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit of None for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
  - `metrics_collection_interval` – Optional. Specifies how often to collect the net metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.

  - `append_dimensions` – Optional. Additional dimensions to use for only the net metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `netstat` – Optional. Specifies that TCP connection state and UDP connection metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
  - `measurement` – Specifies the array of netstat metrics to be collected. Possible values are `tcp_close`, `tcp_close_wait`, `tcp_closing`, `tcp_established`, `tcp_fin_wait1`, `tcp_fin_wait2`, `tcp_last_ack`, `tcp_listen`, `tcp_none`, `tcp_syn_sent`, `tcp_syn_recv`, `tcp_time_wait`, and `udp_socket`. This field is required if you include `netstat`.

    To see the default units for each `netstat` metric, see Metrics collected by the CloudWatch agent on Linux and macOS instances.

    Within the entry for each individual metric, you might optionally specify one or both of the following:
    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

  - `metrics_collection_interval` – Optional. Specifies how often to collect the netstat metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

    This value is specified in seconds.

    If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information about high-resolution metrics, see High-resolution metrics.
  - `append_dimensions` – Optional. Additional dimensions to use for only the netstat metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.
- `processes` – Optional. Specifies that process metrics are to be collected. This section is valid only for Linux instances. This section can include the following fields:
  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.
  - `measurement` – Specifies the array of processes metrics to be collected. Possible values are `blocked`, `dead`, `idle`, `paging`, `running`, `sleeping`, `stopped`, `total`, `total_threads`, `wait`, and `zombies`. This field is required if you include `processes`.

    For all `processes` metrics, the default unit is `None`.

    Within the entry for each individual metric, you might optionally specify one or both of the following:
    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.
  - `metrics_collection_interval` – Optional. Specifies how often to collect the processes metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.

- `append_dimensions` – Optional. Additional dimensions to use for only the process metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

- `nvidia_gpu` – Optional. Specifies that NVIDIA GPU metrics are to be collected. This section is valid only for Linux instances on hosts that are configured with a NVIDIA GPU accelerator and have the NVIDIA System Management Interface (nvidia-smi) installed.

  The NVIDIA GPU metrics that are collected are prefixed with the string `nvidia_smi_` to distinguish them from the metrics collected for other accelerator types. This section can include the following fields:

  - `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

  - `measurement` – Specifies the array of NVIDIA GPU metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect NVIDIA GPU metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit of `None` for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

  - `metrics_collection_interval` – Optional. Specifies how often to collect the NVIDIA GPU metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

- `jmx` – Optional. Specifies that you want to retrieve Java Management Extensions (JMX) metrics from the instance. For more information about the parameters that you can use in this section and the metrics that you can collect, see Collect Java Management Extensions (JMX) metrics.
- `otlp` – Optional. Specifies that you want to collect metrics from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry.
- `procstat` – Optional. Specifies that you want to retrieve metrics from individual processes. For more information about the configuration options available for procstat, see Collect process metrics with the procstat plugin.
- `statsd` – Optional. Specifies that you want to retrieve custom metrics using the `StatsD` protocol. The CloudWatch agent acts as a daemon for the protocol. You use any standard `StatsD` client to send the metrics to the CloudWatch agent. For more information about the configuration options available for StatsD, see Retrieve custom metrics with StatsD.
- `ethtool` – Optional. Specifies that you want to retrieve network metrics using the `ethtool` plugin. This plugin can import both the metrics collected by the standard ethtool utility, as well as network performance metrics from Amazon EC2 instances. For more information about the configuration options available for ethtool, see Collect network performance metrics.

The following is an example of a `metrics` section for a Linux server. In this example, three CPU metrics, three netstat metrics, three process metrics, and one disk metric are collected, and the agent is set up to receive additional metrics from a `collectd` client.

```
"metrics": {
    "aggregation_dimensions" : [["AutoScalingGroupName"], ["InstanceId",
 "InstanceType"],[]],
    "metrics_collected": {
      "collectd": {},
      "cpu": {
        "resources": [
          "*"
        ],
        "measurement": [
          {"name": "cpu_usage_idle", "rename": "CPU_USAGE_IDLE", "unit": "Percent"},
          {"name": "cpu_usage_nice", "unit": "Percent"},
          "cpu_usage_guest"
        ],
        "totalcpu": false,
        "drop_original_metrics": [ "cpu_usage_guest" ],
```

```
        "metrics_collection_interval": 10,
        "append_dimensions": {
          "test": "test1",
          "date": "2017-10-01"
        }
      },
      "netstat": {
        "measurement": [
          "tcp_established",
          "tcp_syn_sent",
          "tcp_close"
        ],
        "metrics_collection_interval": 60
      },
       "disk": {
        "measurement": [
          "used_percent"
        ],
        "resources": [
          "*"
        ],
        "drop_device": true
      },
      "processes": {
        "measurement": [
          "running",
          "sleeping",
          "dead"
        ]
      }
    },
    "append_dimensions": {
      "ImageId": "${aws:ImageId}",
      "InstanceId": "${aws:InstanceId}",
      "InstanceType": "${aws:InstanceType}",
      "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
    }
  }
```

Windows Server

In the `metrics_collected` section for Windows Server, you can have subsections for each Windows performance object, such as `Memory`, `Processor`, and `LogicalDisk`. For information about what objects and counters are available, see Performance Counters in the Microsoft Windows documentation.

Within the subsection for each object, you specify a `measurement` array of the counters to collect. The `measurement` array is required for each object that you specify in the configuration file. You can also specify a `resources` field to name the instances to collect metrics from. You can also specify `*` for `resources` to collect separate metrics for every instance. If you omit `resources` for counters that have instances, the data for all instances is aggregated into one set. If you omit `resources` for counters that don't have instances, the counters are not collected by the CloudWatch agent. To determine whether counters have instances, you can use one of the following commands.

Powershell:

```
Get-Counter -ListSet *
```

Command line (not Powershell):

```
TypePerf.exe -q
```

Within each object section, you can also specify the following optional fields:

- `metrics_collection_interval` – Optional. Specifies how often to collect the metrics for this object, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see High-resolution metrics.
- `append_dimensions` – Optional. Specifies additional dimensions to use for only the metrics for this object. If you specify this field, it's used in addition to dimensions specified in the global `append_dimensions` field that is used for all types of metrics collected by the agent.
- `drop_original_metrics` – Optional. If you are using the `aggregation_dimensions` field in the `metrics` section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify

this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

Within each counter section, you can also specify the following optional fields:

- `rename` – Specifies a different name to be used in CloudWatch for this metric.
- `unit` – Specifies the unit to use for this metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

There are other optional sections that you can include in `metrics_collected`:

- `statsd` – Enables you to retrieve custom metrics using the `StatsD` protocol. The CloudWatch agent acts as a daemon for the protocol. You use any standard `StatsD` client to send the metrics to the CloudWatch agent. For more information, see Retrieve custom metrics with StatsD.
- `procstat` – Enables you to retrieve metrics from individual processes. For more information, see Collect process metrics with the procstat plugin.
- `jmx` – Optional. Specifies that you want to retrieve Java Management Extensions (JMX) metrics from the instance. For more information about the fields that you can use in this section and the metrics that you can collect, see Collect Java Management Extensions (JMX) metrics.
- `otlp` – Optional. Specifies that you want to collect metrics from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry.

The following is an example `metrics` section for use on Windows Server. In this example, many Windows metrics are collected, and the computer is also set to receive additional metrics from a `StatsD` client.

```
"metrics": {
    "metrics_collected": {
      "statsd": {},
      "Processor": {
        "measurement": [
          {"name": "% Idle Time", "rename": "CPU_IDLE", "unit": "Percent"},
          "% Interrupt Time",
          "% User Time",
          "% Processor Time"
```

```
        ],
        "resources": [
          "*"
        ],
        "append_dimensions": {
          "d1": "win_foo",
          "d2": "win_bar"
        }
      },
      "LogicalDisk": {
        "measurement": [
          {"name": "% Idle Time", "unit": "Percent"},
          {"name": "% Disk Read Time", "rename": "DISK_READ"},
          "% Disk Write Time"
        ],
        "resources": [
          "*"
        ]
      },
      "Memory": {
        "metrics_collection_interval": 5,
        "measurement": [
          "Available Bytes",
          "Cache Faults/sec",
          "Page Faults/sec",
          "Pages/sec"
        ],
        "append_dimensions": {
          "d3": "win_bo"
        }
      },
      "Network Interface": {
        "metrics_collection_interval": 5,
        "measurement": [
          "Bytes Received/sec",
          "Bytes Sent/sec",
          "Packets Received/sec",
          "Packets Sent/sec"
        ],
        "resources": [
          "*"
        ],
        "append_dimensions": {
          "d3": "win_bo"
```

```
        }
      },
      "System": {
        "measurement": [
          "Context Switches/sec",
          "System Calls/sec",
          "Processor Queue Length"
        ],
        "append_dimensions": {
          "d1": "win_foo",
          "d2": "win_bar"
        }
      }
    },
    "append_dimensions": {
      "ImageId": "${aws:ImageId}",
      "InstanceId": "${aws:InstanceId}",
      "InstanceType": "${aws:InstanceType}",
      "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
    },
    "aggregation_dimensions" : [["ImageId"], ["InstanceId", "InstanceType"], ["d1"],[]]
    }
  }
```

CloudWatch agent configuration file: Logs section

The `logs` section includes the following fields:

- `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.
- `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.
- `logs_collected` – Required if the `logs` section is included. Specifies which log files and Windows event logs are to be collected from the server. It can include two fields, `files` and `windows_events`.
  - `files` – Specifies which regular log files the CloudWatch agent is to collect. It contains one field, `collect_list`, which further defines these files.
    - `collect_list` – Required if `files` is included. Contains an array of entries, each of which specifies one log file to collect. Each of these entries can include the following fields:

- `file_path` – Specifies the path of the log file to upload to CloudWatch Logs. Standard Unix glob matching rules are accepted, with the addition of `**` as a *super asterisk*. For example, specifying `/var/log/**.log` causes all `.log` files in the `/var/log` directory tree to be collected. For more examples, see Glob Library.

  You can also use the standard asterisk as a standard wildcard. For example, `/var/log/system.log*` matches files such as `system.log_1111`, `system.log_2222`, and so on in `/var/log`.

  Only the latest file is pushed to CloudWatch Logs based on file modification time. We recommend that you use wildcards to specify a series of files of the same type, such as `access_log.2018-06-01-01` and `access_log.2018-06-01-02`, but not multiple kinds of files, such as `access_log_80` and `access_log_443`. To specify multiple kinds of files, add another log stream entry to the agent configuration file so that each kind of log file goes to a different log stream.
- `auto_removal` – Optional. If this is `true`, the CloudWatch agent automatically deletes this log file after reading it and it has been rotated. Usually the log files are deleted after their entire contents are uploaded to CloudWatch Logs, but if the agent reaches the EOF (end of file) and also detects another newer log file that matches the same `file_path`, the agent deletes the OLD file, so you must make sure that you are done writing to the OLD file before creating the NEW file. The RUST tracing library has a known incompatibility because it will potentially create a NEW log file and then still attempt to write to the OLD log file.

  The agent only removes complete files from logs that create multiple files, such as logs that create separate files for each date. If a log continuously writes to a single file, it is not removed.

  If you already have a log file rotation or removal method in place, we recommend that you omit this field or set it to `false`.

  If you omit this field, the default value of `false` is used.
- `log_group_name` – Optional. Specifies what to use as the log group name in CloudWatch Logs.

  We recommend that you use this field to specify a log group name to prevent confusion. If you omit `log_group_name`, the value of `file_path` up to the final dot is used as the log group name. For example, if the file path is `/tmp/TestLogFile.log.2017-07-11-14`, the log group name is `/tmp/TestLogFile.log`.

If you specify a log group name, you can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. `{hostname}` retrieves the hostname from the EC2 metadata, and `{local_hostname}` uses the hostname from the network configuration file.

If you use these variables to create many different log groups, keep in mind the limit of 1,000,000 log groups per Region per account.

Allowed characters include a–z, A–Z, 0–9, '_' (underscore), '-' (hyphen), '/' (forward slash), and '.' (period).

- `log_group_class` – Optional. Specifies which log group class to use for the new log group. For more information about log group classes, see [Log classes](#).

  Valid values are `STANDARD` and `INFREQUENT_ACCESS`. If you omit this field, the default of `STANDARD` is used.

  > **Important**
  >
  > After a log group is created, its class can't be changed.

- `log_stream_name` – Optional. Specifies what to use as the log stream name in CloudWatch Logs. As part of the name, you can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. `{hostname}` retrieves the hostname from the EC2 metadata, and `{local_hostname}` uses the hostname from the network configuration file.

  If you omit this field, the value of the `log_stream_name` parameter in the global `logs` section is used. If that is also omitted, the default value of `{instance_id}` is used.

  If a log stream doesn't already exist, it's created automatically.

- `retention_in_days` – Optional. Specifies the number of days to retain the log events in the specified log group.
  - If the agent is creating this log group now, and you omit this field, the retention of this new log group is set to never expire.

- If this log group already exists and you specify this field, the new retention that you specify is used. If you omit this field for a log group that already exists, the log group's retention is not changed.

  The CloudWatch agent wizard uses `-1` as the default value for this field when it is used to create the agent configuration file and you don't specify a value for log retention. This `-1` value set by the wizard specifies that the events in the log group will never expire. However, manually editing this value to `-1` has no effect.

Valid values are 1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365, 400, 545, 731, 1827, 2192, 2557, 2922, 3288, and 3653.

If you configure the agent to write multiple log streams to the same log group, specifying the `retention_in_days` in one place will set the log retention for the entire log group. If you specify `retention_in_days` for the same log group in multiple places, the retention is set if all of those values are equal. However, if different `retention_in_days` values are specified for the same log group in multiple places, the log retention will not be set and the agent will stop, returning an error.

> **Note**
>
> The agent's IAM role or IAM user must have the `logs:PutRetentionPolicy` for it to be able to set retention policies. For more information, see Allowing the CloudWatch agent to set log retention policy.

> **Warning**
>
> If you set `retention_in_days` for a log group that already exists, all logs in that log group that were published before the number of days that you specify are deleted. For example, setting it to 3 would cause all logs from 3 days ago and before to be deleted.

- `filters` – Optional. Can contain an array of entries, each of which specifies a regular expression and a filter type to specify whether to publish or drop log entries that match the filter. If you omit this field, all logs in the log file are published to CloudWatch Logs. If you include this field, the agent processes each log message with all of the filters that you specify, and only the log events that pass all of the filters are published to CloudWatch

Logs. The log entries that don’t pass all of the filters will still remain in the host's log file, but will not be sent to CloudWatch Logs.

Each entry in the filters array can include the following fields:

- `type`– Denotes the type of filter. Valid values are `include` and `exclude`. With `include`, the log entry must match the expression to be published to CloudWatch Logs. With `exclude`, each log entry that matches the filter is not sent to CloudWatch Logs.
- `expression`– A regular expression string that follows the RE2 Syntax.

> **Note**
>
> The CloudWatch agent doesn't check the performance of any regular expression that you supply, or restrict the run time of the evaluation of the regular expressions. We recommend that you are careful not to write an expression that is expensive to evaluate. For more information about possible issues, see Regular expression Denial of Service - ReDoS

For example, the following excerpt of the CloudWatch agent configuration file publishes logs that are PUT and POST requests to CloudWatch Logs, but excluding logs that come from Firefox.

```
"collect_list": [
  {
    "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/test.log",
    "log_group_name": "test.log",
    "log_stream_name": "test.log",
    "filters": [
      {
        "type": "exclude",
        "expression": "Firefox"
      },
      {
        "type": "include",
        "expression": "P(UT|OST)"
      }
    ]
  },
  .....
]
```

> **Note**
>
> The order of the filters in the configuration file matters for performance. In the preceding example, the agent drops all the logs that match `Firefox` before it starts evaluating the second filter. To cause fewer log entries to be evaluated by more than one filter, put the filter that you expect to rule out more logs first in the configuration file.

- `timezone` – Optional. Specifies the time zone to use when putting timestamps on log events. The valid values are `UTC` and `Local`. The default value is `Local`.

  This parameter is ignored if you don't specify a value for `timestamp_format`.

- `timestamp_format` – Optional. Specifies the timestamp format, using plaintext and special symbols that start with %. If you omit this field, the current time is used. If you use this field, you can use the symbols in the following list as part of the format.

  > **Note**
  >
  > This parameter is not considered when the `file_path` is set to `amazon-cloudwatch-agent.log`

  If a single log entry contains two time stamps that match the format, the first time stamp is used.

  This list of symbols is different than the list used by the older CloudWatch Logs agent. For a summary of these differences, see [Timestamp differences between the unified CloudWatch agent and the earlier CloudWatch Logs agent]

  `%y`

  Year without century as a zero-padded decimal number. For example, `19` to represent 2019.

  `%Y`

  Year with century as a decimal number. For example, `2019`.

`%b`

Month as the locale's abbreviated name

`%B`

Month as the locale's full name

`%m`

Month as a zero-padded decimal number

`%-m`

Month as a decimal number (not zero-padded)

`%d`

Day of the month as a zero-padded decimal number

`%-d`

Day of the month as a decimal number (not zero-padded)

`%A`

Full name of weekday, such as `Monday`

`%a`

Abbreviation of weekday, such as `Mon`

`%H`

Hour (in a 24-hour clock) as a zero-padded decimal number

`%I`

Hour (in a 12-hour clock) as a zero-padded decimal number

`%-I`

Hour (in a 12-hour clock) as a decimal number (not zero-padded)

`%p`

AM or PM

`%M`

Minutes as a zero-padded decimal number

`%-M`

Minutes as a decimal number (not zero-padded)

`%S`

Seconds as a zero-padded decimal number

`%-S`

Seconds as a decimal number (not zero padded)

`%f`

Fractional seconds as a decimal number (1-9 digits), zero-padded on the left.

`%Z`

Time zone, for example PST

`%z`

Time zone, expressed as the offset between the local time zone and UTC. For example, `-0700`. Only this format is supported. For example, `-07:00` isn't a valid format.

- `multi_line_start_pattern` – Specifies the pattern for identifying the start of a log message. A log message is made of a line that matches the pattern and any subsequent lines that don't match the pattern.

  If you omit this field, multi-line mode is disabled, and any line that begins with a non-whitespace character closes the previous log message and starts a new log message.

  If you include this field, you can specify `{timestamp_format}` to use the same regular expression as your timestamp format. Otherwise, you can specify a different regular expression for CloudWatch Logs to use to determine the start lines of multi-line entries.
- `encoding` – Specified the encoding of the log file so that it can be read correctly. If you specify an incorrect coding, there might be data loss because characters that can't be decoded are replaced with other characters.

  The default value is `utf-8`. The following are all possible values:

    ascii, big5, euc-jp, euc-kr, gbk, gb18030, ibm866, iso2022-jp, iso8859-2, iso8859-3, iso8859-4, iso8859-5, iso8859-6, iso8859-7, iso8859-8, iso8859-8-i, iso8859-10, iso8859-13, iso8859-14, iso8859-15, iso8859-16, koi8-r, koi8-u, macintosh, shift_jis, utf-8, utf-16, utf-16le, UTF-16, UTF-16LE, windows-874, windows-1250, windows-1251, windows-1252, windows-1253, windows-1254, windows-1255, windows-1256, windows-1257, windows-1258, x-mac-cyrillic

    - `service.name` – Optional. Specifies the service name to be used to populate the entity for finding related telemetry.
    - `deployment.environment` – Optional. Specifies the environment name to be used to populate the entity for finding related telemetry.

- The `windows_events` section specifies the type of Windows events to collect from servers running Windows Server. It includes the following fields:
  - `collect_list` – Required if `windows_events` is included. Specifies the types and levels of Windows events to be collected. Each log to be collected has an entry in this section, which can include the following fields:
    - `event_name` – Specifies the type of Windows events to log. This is equivalent to the Windows event log channel name: for example, `System`, `Security`, `Application`, and so on. This field is required for each type of Windows event to log.

      Note

      When CloudWatch retrieves messages from a Windows log channel, it looks up the log channel based on its `Full Name` property. Meanwhile, the Windows Event Viewer navigation pane displays the `Log Name` property of log channels. The `Full Name` and `Log Name` do not always match. To confirm the `Full Name` of a channel, right-click on it in the Windows Event viewer and open **Properties**.

    - `event_levels` – Specifies the levels of event to log. You must specify each level to log. Possible values include `INFORMATION`, `WARNING`, `ERROR`, `CRITICAL`, and `VERBOSE`. This field is required for each type of Windows event to log.
    - `log_group_name` – Required. Specifies what to use as the log group name in CloudWatch Logs.

- `log_stream_name` – Optional. Specifies what to use as the log stream name in CloudWatch Logs. As part of the name, you can use `{instance_id}`, `{hostname}`, `{local_hostname}`, and `{ip_address}` as variables within the name. `{hostname}` retrieves the hostname from the EC2 metadata, and `{local_hostname}` uses the hostname from the network configuration file.

  If you omit this field, the value of the `log_stream_name` parameter in the global `logs` section is used. If that is also omitted, the default value of `{instance_id}` is used.

  If a log stream doesn't already exist, it's created automatically.
- `event_format` – Optional. Specifies the format to use when storing Windows events in CloudWatch Logs. `xml` uses the XML format as in Windows Event Viewer. `text` uses the legacy CloudWatch Logs agent format.
- `retention_in_days` – Optional. Specifies the number of days to retain the Windows events in the specified log group.
  - If the agent is creating this log group now, and you omit this field, the retention of this new log group is set to never expire.
  - If this log group already exists and you specify this field, the new retention that you specify is used. If you omit this field for a log group that already exists, the log group's retention is not changed.

    The CloudWatch agent wizard uses `-1` as the default value for this field when it is used to create the agent configuration file and you don't specify a value for log retention. This `-1` value specifies set by the wizard specifies that the events in the log group don't expire. However, manually editing this value to `-1` has no effect.

  Valid values are 1, 3, 5, 7, 14, 30, 60, 90, 120, 150, 180, 365, 400, 545, 731, 1827, 2192, 2557, 2922, 3288, and 3653.

  If you configure the agent to write multiple log streams to the same log group, specifying the `retention_in_days` in one place will set the log retention for the entire log group. If you specify `retention_in_days` for the same log group in multiple places, the retention is set if all of those values are equal. However, if different `retention_in_days` values are specified for the same log group in multiple places, the log retention will not be set and the agent will stop, returning an error.

> **Note**
>
> The agent's IAM role or IAM user must have the `logs:PutRetentionPolicy` for it to be able to set retention policies. For more information, see [Allowing the CloudWatch agent to set log retention policy]().

> **Warning**
>
> If you set `retention_in_days` for a log group that already exists, all logs in that log group that were published before the number of days that you specify are deleted. For example, setting it to 3 would cause all logs from 3 days ago and before to be deleted.

- `log_stream_name` – Optional. Specifies the default log stream name to be used for any logs or Windows events that don't have individual log stream names defined in the `log_stream_name` parameter within their entry in `collect_list`.
- `endpoint_override` – Specifies a FIPS endpoint or private link to use as the endpoint where the agent sends logs. Specifying this field and setting a private link enables you to send the logs to an Amazon VPC endpoint. For more information, see [What Is Amazon VPC?]().

  The value of `endpoint_override` must be a string that is a URL.

  For example, the following part of the logs section of the configuration file sets the agent to use a VPC Endpoint when sending logs.

```
{
  "logs": {
    "endpoint_override": "vpce-XXXXXXXXXXXXXXXXXXXXXXXXX.logs.us-
east-1.vpce.amazonaws.com",
   ......
   },
}
```

- `force_flush_interval` – Specifies in seconds the maximum amount of time that logs remain in the memory buffer before being sent to the server. No matter the setting for this field, if the size of the logs in the buffer reaches 1 MB, the logs are immediately sent to the server. The default value is 5.

If you are using the agent to report high-resolution metrics in embedded metric format, and you are setting alarms on those metrics, keep this parameter set to the default value of 5. Otherwise, the metrics are reported with a delay that can cause alarming on partial or incomplete data.

- `credentials` – Specifies an IAM role to use when sending logs to a different Amazon account. If specified, this field contains one parameter, `role_arn`.
  - `role_arn` – Specifies the ARN of an IAM role to use for authentication when sending logs to a different Amazon account. For more information, see Sending metrics, logs, and traces to a different account. If specified here, this overrides the `role_arn` specified in the `agent` section of the configuration file, if any.
- `metrics_collected` – This field can contain sections to specify that the agent is to collect logs to enable use cases such as CloudWatch Application Signals and Container Insights with enhanced observability for Amazon EKS.
  - `application_signals` (Optional) Specifies that you want to enable CloudWatch Application Signals For more information about this configuration, see Enable CloudWatch Application Signals.
  - `kubernetes` – This field can contain an `enhanced_container_insights` parameter, which you can use to enable Container Insights with enhanced observability for Amazon EKS.
    - `enhanced_container_insights` – Set this to `true` to enable Container Insights with enhanced observability for Amazon EKS. For more information, see Container Insights with enhanced observability for Amazon EKS.
    - `accelerated_compute_metrics` – Set this to `false` to opt out of collecting Nvidia GPU metrics on Amazon EKS clusters. For more information, see NVIDIA GPU metrics.
  - `emf` – To collect metrics embedded in logs, it is no longer necessary to add this `emf` field. This is a legacy field that specified that the agent is to collect logs that are in embedded metric format. You can generate metric data from these logs. For more information, see Embedding metrics within logs.
  - `otlp` – Optional. Specifies that you want to collect metrics from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry.

The following is an example of a `logs` section.

```
"logs":
   {
```

```
        "logs_collected": {
            "files": {
                "collect_list": [
                    {
                        "file_path": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\Logs\\amazon-cloudwatch-agent.log",
                        "log_group_name": "amazon-cloudwatch-agent.log",
                        "log_stream_name": "my_log_stream_name_1"
                    },
                    {
                        "file_path": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\Logs\\test.log",
                        "log_group_name": "test.log",
                        "log_stream_name": "my_log_stream_name_2"
                    }
                ]
            },
            "windows_events": {
                "collect_list": [
                    {
                        "event_name": "System",
                        "event_levels": [
                            "INFORMATION",
                            "ERROR"
                        ],
                        "log_group_name": "System",
                        "log_stream_name": "System"
                    },
                    {
                        "event_name": "CustomizedName",
                        "event_levels": [
                            "INFORMATION",
                            "ERROR"
                        ],
                        "log_group_name": "CustomizedLogGroup",
                        "log_stream_name": "CustomizedLogStream"
                    }
                ]
            }
        },
        "log_stream_name": "my_log_stream_name",
        "metrics_collected": {
            "kubernetes": {
                 "enhanced_container_insights": true
```

```
      }
    }
  }
```

CloudWatch agent configuration file: Traces section

By adding a `traces` section to the CloudWatch agent configuration file, you can enable CloudWatch Application Signals or collect traces from X-Ray and from the OpenTelemetry instrumentation SDK and send them to X-Ray.

> **Important**
>
> The agent's IAM role or IAM user must have the **AWSXrayWriteOnlyAccess** policy to send trace data to X-Ray. For more information, see [Create IAM roles and users for use with CloudWatch agent](#).

For a quick start for collecting traces, you can add just the following to the CloudWatch agent configuration file.

```
"traces_collected": {
        "xray": {
        },
        "otlp": {
        }
      }
```

If you add the previous section to the CloudWatch agent configuration file and restart the agent, this causes the agent to start collecting traces using the following default options and values. For more information about these parameters, see the parameter definitions later in this section.

```
"traces_collected": {
        "xray": {
            "bind_address": "127.0.0.1:2000",
            "tcp_proxy": {
              "bind_address": "127.0.0.1:2000"
            }
        },
        "otlp": {
            "grpc_endpoint": "127.0.0.1:4317",
            "http_endpoint": "127.0.0.1:4318"
```

```
        }
      }
```

The `traces` section can include the following fields:

- `traces_collected` – Required if the `traces` section is included. Specifies which SDKs to collect traces from. It can include the following fields:
  - `application_signals` – Optional. Specifies that you want to enable CloudWatch Application Signals For more information about this configuration, see Enable CloudWatch Application Signals.
  - `xray` – Optional. Specifies that you want to collect traces from the X-Ray SDK. This section can include the following fields:
    - `bind_address` – Optional. Specifies the UDP address for the CloudWatch agent to use to listen for X-Ray traces. The format is `ip:port`. This address must match the address set in the X-Ray SDK.

      If you omit this field, the default of `127.0.0.1:2000` is used.
    - `tcp_proxy` – Optional. Configures the address for a proxy used to support X-Ray remote sampling. For more information, see Configuring sampling rules in the X-Ray documentation.

      This section can contain the following field.
      - `bind_address` – Optional. Specifies the TCP address to which the CloudWatch agent should set up the proxy. The format is `ip:port`. This address must match the address set in the X-Ray SDK.

        If you omit this field, the default of `127.0.0.1:2000` is used.
  - `otlp` – Optional. Specifies that you want to collect traces from the OpenTelemetry SDK. For more information about the fields that you can use in this section, see Collect metrics and traces with OpenTelemetry). For more information about the Amazon Distro for OpenTelemetry, see Amazon Distro for OpenTelemetry. For more information about the Amazon Distro for OpenTelemetry SDKs, see Introduction.

    This section can include the following fields:
    - `grpc_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry traces sent using gRPC Remote Procedure Calls. The format is `ip:port`. This address must match the address set for the gRPC exporter in the OpenTelemetry SDK.

If you omit this field, the default of 127.0.0.1:4317 is used.

- http_endpoint – Optional. Specifies the address for the CloudWatch agent to use to listen for OTLP traces sent over HTTP. The format is ip:port. This address must match the address set for the HTTP exporter in the OpenTelemetry SDK.

  If you omit this field, the default of 127.0.0.1:4318 is used.

- concurrency – Optional. Specifies the maximum number of concurrent calls to X-Ray that can be used to upload traces. The default value is 8
- local_mode – Optional. If true, the agent doesn't collect Amazon EC2 instance metadata. The default is false
- endpoint_override – Optional. Specifies a FIPS endpoint or private link to use as the endpoint where the CloudWatch agent sends traces. Specifying this field and setting a private link enables you to send the traces to an Amazon VPC endpoint. For more information, see What is Amazon VPC

  The value of endpoint_override must be a string that is a URL.

- region_override – Optional. Specifies the Region to use for the X-Ray endpoint. The CloudWatch agent sends the traces to X-Ray in the specified Region. If you omit this field, the agent sends the traces to the Region where the Amazon EC2 instance is located.

  If you specify a Region here, it takes precedence over the setting of the region parameter in the agent section of the configuration file.

- proxy_override – Optional. Specifies the proxy server address for the CloudWatch agent to use when sending requests to X-Ray. The proxy server's protocol must be specified as part of this address.
- credentials – Specifies an IAM role to use when sending traces to a different Amazon account. If specified, this field contains one parameter, role_arn.
  - role_arn – Specifies the ARN of an IAM role to use for authentication when sending traces to a different Amazon account. For more information, see Sending metrics, logs, and traces to a different account. If specified here, this overrides the role_arn specified in the agent section of the configuration file, if any.
- transit_spans_in_otlp_format – Optional. If true, sends traces to X-Ray in the OpenTelemetry Protocol format, which supports span events in Transaction Search. For more information, see Adding custom attributes. The default is false.

CloudWatch agent configuration file: Complete examples

The following is an example of a complete CloudWatch agent configuration file for a Linux server.

The items listed in the `measurement` sections for the metrics you want to collect can either specify the complete metric name such or just the part of the metric name that will be appended to the type of resource. For example, specifying either `reads` or `diskio_reads` in the `measurement` section of the `diskio` section will cause the `diskio_reads` metric to be collected.

This example includes both ways of specifying metrics in the `measurement` section.

```
    {
      "agent": {
        "metrics_collection_interval": 10,
        "logfile": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log"
      },
      "metrics": {
        "namespace": "MyCustomNamespace",
        "metrics_collected": {
          "cpu": {
            "resources": [
              "*"
            ],
            "measurement": [
              {"name": "cpu_usage_idle", "rename": "CPU_USAGE_IDLE", "unit":
  "Percent"},
              {"name": "cpu_usage_nice", "unit": "Percent"},
              "cpu_usage_guest"
            ],
            "totalcpu": false,
            "metrics_collection_interval": 10,
            "append_dimensions": {
              "customized_dimension_key_1": "customized_dimension_value_1",
              "customized_dimension_key_2": "customized_dimension_value_2"
            }
          },
          "disk": {
            "resources": [
              "/",
              "/tmp"
            ],
            "measurement": [
              {"name": "free", "rename": "DISK_FREE", "unit": "Gigabytes"},
```

```
          "total",
          "used"
        ],
         "ignore_file_system_types": [
          "sysfs", "devtmpfs"
        ],
        "metrics_collection_interval": 60,
        "append_dimensions": {
          "customized_dimension_key_3": "customized_dimension_value_3",
          "customized_dimension_key_4": "customized_dimension_value_4"
        }
      },
      "diskio": {
        "resources": [
          "*"
        ],
        "measurement": [
          "reads",
          "writes",
          "read_time",
          "write_time",
          "io_time"
        ],
        "metrics_collection_interval": 60
      },
      "swap": {
        "measurement": [
          "swap_used",
          "swap_free",
          "swap_used_percent"
        ]
      },
      "mem": {
        "measurement": [
          "mem_used",
          "mem_cached",
          "mem_total"
        ],
        "metrics_collection_interval": 1
      },
      "net": {
        "resources": [
          "eth0"
        ],
```

```
          "measurement": [
            "bytes_sent",
            "bytes_recv",
            "drop_in",
            "drop_out"
          ]
        },
        "netstat": {
          "measurement": [
            "tcp_established",
            "tcp_syn_sent",
            "tcp_close"
          ],
          "metrics_collection_interval": 60
        },
        "processes": {
          "measurement": [
            "running",
            "sleeping",
            "dead"
          ]
        }
      },
      "append_dimensions": {
        "ImageId": "${aws:ImageId}",
        "InstanceId": "${aws:InstanceId}",
        "InstanceType": "${aws:InstanceType}",
        "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
      },
      "aggregation_dimensions" : [["ImageId"], ["InstanceId", "InstanceType"],
 ["d1"],[]],
      "force_flush_interval" : 30
    },
    "logs": {
      "logs_collected": {
        "files": {
          "collect_list": [
            {
              "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-
agent.log",
              "log_group_name": "amazon-cloudwatch-agent.log",
              "log_stream_name": "amazon-cloudwatch-agent.log",
              "timezone": "UTC"
            },
```

```
              {
                "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/test.log",
                "log_group_name": "test.log",
                "log_stream_name": "test.log",
                "timezone": "Local"
              }
            ]
          }
        },
        "log_stream_name": "my_log_stream_name",
        "force_flush_interval" : 15,
        "metrics_collected": {
           "kubernetes": {
                "enhanced_container_insights": true
      }
    }
  }
}
```

The following is an example of a complete CloudWatch agent configuration file for a server running Windows Server.

```
{
      "agent": {
        "metrics_collection_interval": 60,
        "logfile": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\Logs\\amazon-
cloudwatch-agent.log"
      },
      "metrics": {
        "namespace": "MyCustomNamespace",
        "metrics_collected": {
          "Processor": {
            "measurement": [
              {"name": "% Idle Time", "rename": "CPU_IDLE", "unit": "Percent"},
              "% Interrupt Time",
              "% User Time",
              "% Processor Time"
            ],
            "resources": [
              "*"
            ],
            "append_dimensions": {
              "customized_dimension_key_1": "customized_dimension_value_1",
```

```
            "customized_dimension_key_2": "customized_dimension_value_2"
          }
        },
        "LogicalDisk": {
          "measurement": [
            {"name": "% Idle Time", "unit": "Percent"},

            "measurement": [
              "Context Switches/sec",
              "System Calls/sec",
              "Processor Queue Length"
            ]
          }
        },
        "append_dimensions": {
          "ImageId": "${aws:ImageId}",
          "InstanceId": "${aws:InstanceId}",
          "InstanceType": "${aws:InstanceType}",
          "AutoScalingGroupName": "${aws:AutoScalingGroupName}"
        },
        "aggregation_dimensions" : [["ImageId"], ["InstanceId", "InstanceType"],
 ["d1"],[]]
      },
      "logs": {
        "logs_collected": {
          "files": {
            "collect_list": [
              {
                "file_path": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\Logs\
\amazon-cloudwatch-agent.log",
                "log_group_name": "amazon-cloudwatch-agent.log",
                "timezone": "UTC"
              },
              {
                "file_path": "c:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\Logs\
\test.log",
                "log_group_name": "test.log",
                "timezone": "Local"
              }
            ]
          },
          "windows_events": {
            "collect_list": [
              {
                "event_name": "System",
                "event_levels": [
                  "INFORMATION",
```

```
                "ERROR"
              ],
              "log_group_name": "System",
              "log_stream_name": "System",
              "event_format": "xml"
            },
            {
              "event_name": "CustomizedName",
              "event_levels": [
                "WARNING",
                "ERROR"
              ],
              "log_group_name": "CustomizedLogGroup",
              "log_stream_name": "CustomizedLogStream",
              "event_format": "xml"
            }
          ]
        }
      },
      "log_stream_name": "example_log_stream_name"
    }
  }
```

Save the CloudWatch agent configuration file manually

If you create or edit the CloudWatch agent configuration file manually, you can give it any name. After you have created the file, you can copy it to other servers where you want to run the agent.

Uploading the CloudWatch agent configuration file to Systems Manager Parameter Store

If you plan to use the SSM Agent to install the CloudWatch agent on servers, after you manually edit the CloudWatch agent configuration file, you can upload it to Systems Manager Parameter Store. To do so, use the Systems Manager `put-parameter` command.

To be able to store the file in Parameter Store, you must use an IAM role with sufficient permissions. For more information, see [Create IAM roles and users for use with the CloudWatch agent](#).

Use the following command, where *`parameter name`* is the name to be used for this file in Parameter Store and *`configuration_file_pathname`* is the path and file name of the configuration file that you edited.

```
aws ssm put-parameter --name "parameter name" --type "String" --value
 file://configuration_file_pathname
```

Enable CloudWatch Application Signals

Use CloudWatch Application Signals to automatically instrument your applications on Amazon so that you can track application performance against your business objectives. Application Signals provides you a unified, application-centric view of your Java applications, their dependencies, and their edges. For more information, see Application Signals.

CloudWatch Application Signals leverages the CloudWatch agent to receive metrics and traces from your auto-instrumented applications, optionally apply rules to reduce high cardinality, and then publish the processed telemetry to CloudWatch. You can provide custom configuration to the CloudWatch agent specifically for Application Signals using the agent configuration file. To start with, the presence of an `application_signals` section under the `metrics_collected` section within the `logs` section of the agent configuration file specifies that the CloudWatch agent will receive metrics from your auto-instrumented applications. Similarly, the presence of an `application_signals` section under the `traces_collected` section within the `traces` section of the agent configuration file specifies that the CloudWatch agent is enabled to receive traces from your auto-instrumented applications. In addition, you can optionally pass in custom configuration rules to reduce publishing high-cardinality telemetry as outlined in this section.

- For Amazon EKS clusters, when you install the Amazon CloudWatch Observability EKS add-on, the CloudWatch agent is by default enabled to receive both metrics and traces from your auto-instrumented applications. If you would like to optionally pass in custom configuration rules, you can do so by passing in a custom agent configuration to the Amazon EKS add-on when you create or update it by using additional configuration, as outlined in (Optional) Additional configuration.
- For RedHat for OpenShift on Amazon (ROSA), when you install the CloudWatch agent operator using helm charts, the CloudWatch agent is by default enabled to receive both metrics and traces from your auto-instrumented applications. If you would like to optionally pass in custom configuration rules, you can do so by passing in a custom agent configuration by using the Helm chart, as outlined in (Optional) [Additional configuration], as outlined in (Optional) Additional configuration.
- For other supported platforms including Amazon EC2, you must start the CloudWatch agent with an agent configuration that enables Application Signals by specifying the

`application_signals` sections and optionally any custom configuration rules as outlined later in this section.

The following is an overview of the fields in the CloudWatch agent configuration file that are related to CloudWatch Application Signals.

- `logs`
  - `metrics_collected` – This field can contain sections to specify that the agent is to collect logs to enable use cases such as CloudWatch Application Signals and Container Insights with enhanced observability for Amazon EKS.

    > **Note**
    >
    > Previously this section was also used to specify that the agent is to collect logs that are in embedded metric format. Those settings are no longer needed.

    - `application_signals` (Optional) Specifies that you want to enable CloudWatch Application Signals to receive metrics from your auto-instrumented applications to facilitate CloudWatch Application Signals.
      - `rules` (Optional) An array of rules to conditionally select metrics and traces and apply actions to handle high-cardinality scenarios. Each rule can contain the following fields:
        - `rule_name` (Optional) The name of the rule.
        - `selectors` (Optional) An array of metrics and traces dimension matchers. Each selector must provide the following fields:
          - `dimension` Required if `selectors` is not empty. This specifies the dimension of metrics and traces to use as a filter.
          - `match` Required if `selectors` is not empty. A wildcard pattern used for matching values of the specified dimension.
        - `action` (Optional) The action to be applied to metrics and traces that match the specified selectors. The value of `action` must be one of the following keywords:
          - `keep` Specifies to send only the metrics and traces to CloudWatch if matched by the `selectors`.
          - `drop` Specifies to drop the metric and traces that match the `selectors`.

    - `replace` Specifies to replace the dimensions of the metrics and traces that match `selectors`. They are replaced according to the `replacements` section.
  - `replacements` Required if `action` is `replace`. An array of dimension and value pairs that will be applied to metrics and traces that match the specified `selectors` when the `action` is `replace`. Each replacement must provide the following fields:
    - `target_dimension` Required if `replacements` is not empty. Specifies the dimension that needs to be replace.
    - `value` Required if `replacements` is not empty. The value to replace the original value of `target_dimension` with.
- `limiter` (Optional) Use this section to limit how many metrics and dimensions Application Signals sends to CloudWatch, to optimize your costs.
  - `disabled` (Optional) If `true`, the metric limiting feature is disabled. The default is `false`
  - `drop_threshold` (Optional) The maximum number of distinct metrics per service in one rotation interval that can be exported by one CloudWatch agent. The default is 500.
  - `rotation_interval` (Optional) The interval at which the limiter resets the metric records for distinction counting. This is expressed as a string with a sequence of numbers and a unit suffix. Fractions are supported. The supported unit suffixes are `s`, `m`, `h`, `ms`, `us`, and `ns`

    The default is `1h` for one hour.
  - `log_dropped_metrics` (Optional) Specifies whether the agent should write logs to the CloudWatch agent logs when Application Signals metrics are dropped. The default is `false`.

    > **Note**
    >
    > To activate this logging, the `debug` parameter in the `agent` section must also be set to `true`.

- `traces`
  - `traces_collected`
    - `application_signals` Optional. Specify this to enable the CloudWatch agent to receive traces from your auto-instrumented applications for facilitating CloudWatch Application Signals.

> **Note**
>
> Even though the custom `application_signals` rules are specified under the `metrics_collected` section that is contained in the `logs` section, they also implicitly apply to the `traces_collected` section as well. The same set of rules will apply to both metrics and traces.

When there are multiple rules with different actions, they apply in the following sequence: `keep`, then `drop`, then `replace`.

The following is an example of a full CloudWatch agent configuration file that applies custom rules.

```
{
  "logs": {
    "metrics_collected": {
      "application_signals": {
        "rules": [
          {
            "rule_name": "keep01",
            "selectors": [
              {
                "dimension": "Service",
                "match": "pet-clinic-frontend"
              },
              {
                "dimension": "RemoteService",
                "match": "customers-service"
              }
            ],
            "action": "keep"
          },
          {
            "rule_name": "drop01",
            "selectors": [
              {
                "dimension": "Operation",
                "match": "GET /api/customer/owners/*"
              }
            ],
            "action": "drop"
```

```
          },
          {
            "rule_name": "replace01",
            "selectors": [
              {
                "dimension": "Operation",
                "match": "PUT /api/customer/owners/*/pets/*"
              },
              {
                "dimension": "RemoteOperation",
                "match": "PUT /owners"
              }
            ],
            "replacements": [
              {
                "target_dimension": "Operation",
                "value": "PUT /api/customer/owners/{ownerId}/pets{petId}"
              }
            ],
            "action": "replace"
          }
        ]
      }
    }
  },
  "traces": {
    "traces_collected": {
      "application_signals": {}
    }
  }
}
```

For the previous example configuration file, the `rules` are processed as follows:

1. Rule `keep01` ensures that any metrics and traces with the dimension `Service` as `pet-clinic-frontend` and the dimension `RemoteService` as `customers-service` are kept.
2. For the processed metrics and traces after applying `keep01`, the `drop01` rule ensures that metrics and traces with the dimension `Operation` as `GET /api/customer/owners/*` are dropped.
3. For the processed metrics and traces after applying `drop01`, the `replace01` rule updates metrics and traces that have the dimension `Operation` as `PUT /api/customer/owners/*/`

pets/* and the dimension RemoteOperation as PUT /owners such that their Operation dimension is now replaced to be PUT /api/customer/owners/{ownerId}/pets{petId}.

The following is a complete example of a CloudWatch configuration file that manages cardinality in Application Signals by changing the metric limit to 100, enabling the logging of dropped metrics, and setting the rotation interval to two hours.

```
{
    "logs": {
        "metrics_collected": {
            "application_signals": {
                "limiter": {
                    "disabled": false,
                    "drop_threshold": 100,
                    "rotation_interval": "2h",
                    "log_dropped_metrics": true
                }
            }
        },
        "traces": {
            "traces_collected": {
                "application_signals": {}
            }
        }
    }
}
```

Collect network performance metrics

EC2 instances running on Linux that use the Elastic Network Adapter (ENA) publish network performance metrics. Version 1.246396.0 and later of the CloudWatch agent enable you to import these network performance metrics into CloudWatch. When you import these network performance metrics into CloudWatch, they are charged as CloudWatch custom metrics.

For more information about the ENA driver, see Enabling enhanced networking with the Elastic Network Adapter (ENA) on Linux instances and Enabling enhanced networking with the Elastic Network Adapter (ENA) on Windows instances.

How you set up the collection of network performance metrics differs on Linux servers and Windows servers.

The following table lists these network performance metrics enabled by the ENA adapter. When the CloudWatch agent imports these metrics into CloudWatch from Linux instances, it prepends `ethtool_` at the beginning of each of these metric names.

Metric	Description
Name on Linux servers: **`bw_in_allowance_exceeded`** Name on Windows servers: **`Aggregate inbound BW allowance exceeded`**	The number of packets queued and/or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers: **`bw_out_allowance_exceeded`** Name on Windows servers: **`Aggregate outbound BW allowance exceeded`**	The number of packets queued and/or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
Name on Linux servers:**`conntrack_allowance_available`** Name on Windows servers: **`Available connection tracking allowance`**	Reports the number of tracked connections that can be established by the instance before hitting the Connections Tracked allowance of that instance type. This metric is available only on Nitro-based EC2 instances using the Linux driver for Elastic Network Adapter (ENA) starting from version 2.8.1, and on computers using the Windows driver for Elastic Network Adapter (ENA) starting from version 2.6.0.

Metric	Description
	This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see [Collect network performance metrics](#) Unit: None
Name on Linux servers:**`ena_srd_mode`** Name on Windows servers: **`ena srd mode`**	Describes which ENA Express features are enabled. For more information about ENA Express, see [Improve network performance with ENA Express on Linux instances](#) Values are as follows: • `0` = ENA Express off, UDP off • 1 = ENA Express on, UDP off • 2 = ENA Express off, UDP on **Note** This happens only when ENA Express was originally enabled, and UDP was configured to use it. The prior value is retained for UDP traffic. • 3 = ENA Express on, UDP on

Metric	Description
Name on Linux servers:**ena_srd_eligible_tx_pkts** Name on Windows servers: **ena srd eligible tx pkts**	The number of network packets sent within a given time period that meet Amazon Scalable Reliable Datagram (SRD) requirements for eligibility, as follows: • Both sending and receiving instance types are supported. • Both sending and receiving instances must have ENA Express configured. • The sending and receiving instances must be on the same subnet. • The network path between the instances must not include middleware boxes. ENA Express doesn't currently support middleware boxes.
Name on Linux servers:**ena_srd_tx_pkts** Name on Windows servers: **ena srd tx pkts**	The number of SRD packets transmitted within a given time period.
Name on Linux servers:**ena_srd_rx_pkts** Name on Windows servers: **ena srd rx pkts**	The number of SRD packets received within a given time period.
Name on Linux servers:**ena_srd_resource_utilization** Name on Windows servers: **ena srd resource utilization**	The percentage of the maximum allowed memory utilization for concurrent SRD connections that the instance has consumed.

Metric	Description
Name on Linux servers: **linklocal_allowance_exceeded** Name on Windows servers: **Link local packet rate allowance exceeded**	The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service, but does not impact traffic to custom DNS resolvers. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see [Collect network performance metrics] Unit: None
Name on Linux servers: **pps_allowance_exceeded** Name on Windows servers: **PPS allowance exceeded**	The number of packets queued and/or dropped because the bidirectional PPS exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see [Collect network performance metrics] Unit: None

Linux setup

On Linux servers, the *ethtool plugin* enables you to import the network performance metrics into CloudWatch.

ethtool is a standard Linux utility that can collect statistics about Ethernet devices on Linux servers. The statistics it collects depend on the network device and driver. Examples of these statistics include `tx_cnt`, `rx_bytes`, `tx_errors`, and `align_errors`. When you use the ethtool plugin with the CloudWatch agent, you can also import these statistics into CloudWatch, along with the EC2 network performance metrics listed earlier in this section.

> **Tip**
>
> To find the statistics available on our operating system and network device, use the `ethtool -S` command.

When the CloudWatch agent imports metrics into CloudWatch, it adds an `ethtool_` prefix to the names of all imported metrics. So the standard ethtool statistic `rx_bytes` is called `ethtool_rx_bytes` in CloudWatch, and the EC2 network performance metric `bw_in_allowance_exceeded` is called `ethtool_bw_in_allowance_exceeded` in CloudWatch.

On Linux servers, to import ethtool metrics, add an `ethtool` section to the `metrics_collected` section of the CloudWatch agent configuration file. The `ethtool` section can include the following subsections:

- **interface_include**— Including this section causes the agent to collect metrics from only the interfaces that have names listed in this section. If you omit this section, metrics are collected from all Ethernet interfaces that aren't listed in `interface_exclude`.

  The default ethernet interface is `eth0`.
- **interface_exclude**— If you include this section, list the Ethernet interfaces that you don't want to collect metrics from.

  The ethtool plugin always ignores loopback interfaces.
- **metrics_include**— This section lists the metrics to import into CloudWatch. It can include both standard statistics collected by ethtool and Amazon EC2 high-resolution network metrics.

The following example displays part of the CloudWatch agent configuration file. This configuration collects the standard ethtool metrics `rx_packets` and `tx_packets`, and the Amazon EC2 network performance metrics from only the `eth1` interface.

For more information about the CloudWatch agent configuration file, see Manually create or edit the CloudWatch agent configuration file.

```
"metrics": {
```

```
    "append_dimensions": {
      "InstanceId": "${aws:InstanceId}"
    },
    "metrics_collected": {
      "ethtool": {
        "interface_include": [
          "eth1"
        ],
        "metrics_include": [
          "bw_in_allowance_exceeded",
          "bw_out_allowance_exceeded",
          "conntrack_allowance_exceeded",
          "linklocal_allowance_exceeded",
          "pps_allowance_exceeded"
         ]
      }
   }
}
```

Windows setup

On Windows servers, the network performance metrics are available through Windows Performance Counters, which the CloudWatch agent already collects metrics from. So you do not need a plugin to collect these metrics from Windows servers.

The following is a sample configuration file to collect network performance metrics from Windows. For more information about editing the CloudWatch agent configuration file, see Manually create or edit the CloudWatch agent configuration file.

```
{
    "metrics": {
        "append_dimensions": {
            "InstanceId": "${aws:InstanceId}"
        },
        "metrics_collected": {
            "ENA Packets Shaping": {
                "measurement": [
                    "Aggregate inbound BW allowance exceeded",
                    "Aggregate outbound BW allowance exceeded",
                    "Connection tracking allowance exceeded",
                    "Link local packet rate allowance exceeded",
                    "PPS allowance exceeded"
                ],
```

```
                "metrics_collection_interval": 60,
                "resources": [
                    "*"
                ]
            }
        }
    }
}
```

Viewing network performance metrics

After importing network performance metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view ethtool metrics as a time series graph. For more information about setting alarms, see [Using Amazon CloudWatch alarms](#).

Because all of these metrics are aggregate counters, you can use CloudWatch metric math functions such as `RATE(METRICS())` to calculate the rate for these metrics in graphs or use them to set alarms. For more information about metric math functions, see [Using math expressions with CloudWatch metrics](#).

To view network performance metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

    b. To sort the table, use the column heading.

    c. To filter by resource, choose the resource ID, and then choose **Add to search**.

    d. To filter by metric, choose the metric name, and then choose **Add to search**.

6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, and then choose **Add to dashboard**.

Collect NVIDIA GPU metrics

You can use the CloudWatch agent to collect NVIDIA GPU metrics from Linux servers. To set this up, add a `nvidia_gpu` section inside the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Linux section.

Additionally, the instance must have an NVIDIA driver installed. NVIDIA drivers on pre-installed on some Amazon Machine Images (AMIs). Otherwise, you can manually install the driver. For more information, see Install NVIDIA drivers on Linux instances.

The following metrics can be collected. All of these metrics are collected with no CloudWatch `Unit`, but you can specify a unit for each metric by adding a parameter to the CloudWatch agent configuration file. For more information, see Linux section.

Metric	Metric name in CloudWatch	Description
`utilization_gpu`	`nvidia_smi_utilization_gpu`	The percentage of time over the past sample period during which one or more kernals on the GPU was running.
`temperature_gpu`	`nvidia_smi_temperature_gpu`	The core GPU temperature in degrees Celsius.
`power_draw`	`nvidia_smi_power_draw`	The last measured power draw for the entire board, in watts.
`utilization_memory`	`nvidia_smi_utilization_memory`	The percentage of time over the past sample period during which global (device) memory was being read or written.
`fan_speed`	`nvidia_smi_fan_speed`	The percentage of maximum fan speed that the device's fan is currently intended to run at.
`memory_total`	`nvidia_smi_memory_total`	Reported total memory, in MB.
`memory_used`	`nvidia_smi_memory_used`	Memory used, in MB.

Metric	Metric name in CloudWatch	Description
memory_free	nvidia_smi_memory_free	Memory free, in MB.
pcie_link_gen_current	nvidia_smi_pcie_link_gen_current	The current link generation.
pcie_link_width_current	nvidia_smi_pcie_link_width_current	The current link width.
encoder_stats_session_count	nvidia_smi_encoder_stats_session_count	Current number of encoder sessions.
encoder_stats_average_fps	nvidia_smi_encoder_stats_average_fps	The moving average of the encode frames per second.
encoder_stats_average_latency	nvidia_smi_encoder_stats_average_latency	The moving average of the encode latency in microseconds.
clocks_current_graphics	nvidia_smi_clocks_current_graphics	The current frequency of the graphics (shader) clock.
clocks_current_sm	nvidia_smi_clocks_current_sm	The current frequency of the Streaming Multiprocessor (SM) clock.
clocks_current_memory	nvidia_smi_clocks_current_memory	The current frequency of the memory clock.

Metric	Metric name in CloudWatch	Description
clocks_current_video	nvidia_smi_clocks_current_video	The current frequency of the video (encoder plus decoder) clocks.

All of these metrics are collected with the following dimensions:

Dimension	Description
index	A unique identifier for the GPU on this server. Represents the NVIDIA Management Library (NVML) index of the device.
name	The type of GPU. For example, `NVIDIA Tesla A100`
arch	The server architecture.

Collect Java Management Extensions (JMX) metrics

You can use the CloudWatch agent to collect Java Management Extensions (JMX) metrics from your Java applications.

The CloudWatch agent supports collecting these metrics from the following versions:

- JVM 8 and later
- Kafka 0.8.2.x and later
- Tomcat 9, 10.1, and 11 (beta)

Amazon EC2

To enable JMX in your JVM instance

For the CloudWatch agent to be able to collect JMX metrics, your application's JVM must bind to a port using the `com.sun.management.jmxremote.port` system property.

```
java -Dcom.sun.management.jmxremote.port=port-number -jar example.jar
```

For more information and other configurations, see the JMX documentation.

Amazon EKS

To enable JMX on your Java application pods

When using the CloudWatch Observability EKS add-on, you can manage how JMX metrics are enabled with annotations. For more information, see Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart. To enable JMX metrics collection from a workload, add the following annotations to the workload manifest file under the `PodTemplate` section:

- `instrumentation.opentelemetry.io/inject-java: "true"`
- One or more of the following:
  - For JVM metrics: `cloudwatch.aws.amazon.com/inject-jmx-jvm: "true"`
  - For Kafka broker metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka: "true"`
  - For Kafka consumer metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka-consumer: "true"`
  - For Kafka producer metrics: `cloudwatch.aws.amazon.com/inject-jmx-kafka-producer: "true"`
  - For Tomcat metrics: `cloudwatch.aws.amazon.com/inject-jmx-tomcat: "true"`

To start collecting JMX metrics, add a `jmx` section inside the `metrics_collected` section of the CloudWatch agent configuration file. The `jmx` section can contain the following fields.

- `jvm` – Optional. Specifies that you want to retrieve Java Virtual Machine (JVM) metrics from the instance. For more information, see Collect JVM metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of JVM metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect JVM metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `kafka` – Optional. Specifies that you want to retrieve Apache Kafka broker metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Kafka broker metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the first table in Collect Kafka metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `kafka-consumer` – Optional. Specifies that you want to retrieve Apache Kafka consumer metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Kafka broker metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the second metrics table in Collect Kafka metrics.

Within the entry for each individual metric, you can optionally specify one or both of the following:

- `rename` – Specifies a different name for this metric.
- `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `kafka-producer` – Optional. Specifies that you want to retrieve Apache Kafka producer metrics from the instance. For more information, see Collect Kafka metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Kafka broker metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the third metrics table in Collect Kafka metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

- `tomcat` – Optional. Specifies that you want to retrieve Tomcat metrics from the instance. For more information, see Collect Tomcat metrics.

  This section can include the following fields:

  - `measurement` – Specifies the array of Tomcat metrics to be collected. For a list of the possible values to use here, see the **Metric** column in the table in Collect Tomcat metrics.

    Within the entry for each individual metric, you can optionally specify one or both of the following:

    - `rename` – Specifies a different name for this metric.
    - `unit` – Specifies the unit to use for this metric, overriding the default unit for the metric. The unit that you specify must be a valid CloudWatch metric unit, as listed in the `Unit` description in MetricDatum.

The `jmx` section can also include the optional `append_dimensions` field:

- `append_dimensions` – Optional. Additional dimensions to use for only the process metrics. If you specify this field, it's used in addition to dimensions specified in the `append_dimensions` field that is used for all types of metrics collected by the agent.

The following fields are for Amazon EC2 only.

- `endpoint` – The address for the JMX client to connect to. The format is `ip:port`. If the endpoint is not the localhost, and password authentication and SSL must be enabled.
- `metrics_collection_interval` – Optional. Specifies how often to collect the processes metrics, overriding the global `metrics_collection_interval` specified in the `agent` section of the configuration file.

  This value is specified in seconds. For example, specifying 10 causes metrics to be collected every 10 seconds, and setting it to 300 specifies metrics to be collected every 5 minutes.

  If you set this value below 60 seconds, each metric is collected as a high-resolution metric. For more information, see [High-resolution metrics](#).

If JMX was enabled with password authentication or SSL for remote access, you can use the following fields.

- `password_file` – Optional. Specifies a Java properties file of keys to passwords. The file must be read-only and restricted to the user running the CloudWatch agent. If password authentication is enabled, this requires the same username and password pair as the entry in the JMX password file provided in the `com.sun.management.jmxremote.password.file` property. If SSL is enabled, it requires entries for `keystore` and `truststore` and corresponds to the `javax.net.ssl.keyStorePassword` and `javax.net.ssl.trustStorePassword` respectively.
- `username` – If password authentication is enabled, specify the username that matches the username in the provided password file.
- `keystore_path` – If SSL is enabled, specify the full path to the Java keystore, which consists of a private key and a certificate to the public key. Corresponds to the `javax.net.ssl.keyStore` property.
- `keystore_type` – If SSL is enabled, specify the type of keystore being used. Corresponds to the `javax.net.ssl.keyStoreType` property.

- `truststore_path` – If SSL is enabled, specify the full path to the Java truststore, which must contain the remote JMX server's public certificate. Corresponds to the `javax.net.ssl.trustStore` property.
- `truststore_type` – If SSL is enabled, specify the type of truststore being used. Corresponds to the `javax.net.ssl.trustStoreType` property.
- `remote_profile` – Optional. Supported JMX remote profiles are TLS in combination with SASL profiles: `SASL/PLAIN`, `SASL/DIGEST-MD5`, and `SASL/CRAM-MD5`. Should be one of:`SASL/PLAIN`, `SASL/DIGEST-MD5`, `SASL/CRAM-MD5`, `TLS SASL/PLAIN`, `TLS SASL/DIGEST-MD5`, or `TLS SASL/CRAM-MD5`
- `realm` – Optional. The realm as required by the remote profile `SASL/DIGEST-MD5`.
- `registry_ssl_enabled` – If RMI registry authentication is enabled. Set to true if the JVM was configured with `com.sun.management.jmxremote.registry.ssl=true`.
- `insecure` Set to `true` to opt out of the validation required if the agent is configured for a non-localhost endpoint.

The following is an example of the `jmx` section of the CloudWatch agent configuration file.

```
{
  "metrics": {
    "metrics_collected": {
      "jmx": [
        {
          "endpoint": "remotehost:1314",
          "jvm": {
            "measurement": [
              "jvm.memory.heap.init",
              "jvm.memory.nonheap.used"
            ]
          },
          "kafka": {
            "measurement": [
              "kafka.request.count",
              {
                "name": "kafka.message.count",
                "rename": "KAFKA_MESSAGE_COUNT",
                "unit": "Count"
              }
            ]
          },
```

```
          "username": "cwagent",
          "keystore_path": "/path/to/keystore",
          "keystore_type": "PKCS12",
          "truststore_path": "/path/to/truststore",
          "truststore_type": "PKCS12"
        },
        {
          "endpoint": "localhost:1315",
          "kafka-producer": {
            "measurement": [
              "kafka.producer.request-rate"
            ]
          },
          "append_dimensions": {
            "service.name": "kafka/1"
          }
        }
      ]
    }
  }
}
```

Collect JVM metrics

You can use the CloudWatch agent to collect Java Virtual Machine (JVM) metrics. To set this up, add a `jvm` section inside the `jmx`section of the CloudWatch agent configuration file.

The following metrics can be collected.

Metric	Dimensions	Description	
`jvm.classes.loaded`	[DEFAULT]	The total number of loaded classes. **Unit:** None **Meaningful statistics:** Minimum,	

Metric	Dimensions	Description
		Maximum, Average
`jvm.gc.collections.count`	[DEFAULT], name	The total number of garbage collections that have occurred. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`jvm.gc.collections.elapsed`	[DEFAULT], name	The approximate accumulated garbage collection elapsed time. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`jvm.memory.heap.init`	[DEFAULT]	The initial amount of memory that the JVM requests from the operating system for the heap. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`jvm.memory.heap.max`	[DEFAULT]	The maximum amount of memory that can be used for the heap. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
`jvm.memory.heap.used`	[DEFAULT]	The current heap memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`jvm.memory.heap.committed`	[DEFAULT]	The amount of memory that is guaranteed to be available for the heap. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`jvm.memory.nonheap.init`	[DEFAULT]	The initial amount of memory that the JVM requests from the operating system for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`jvm.memory.nonheap.max`	[DEFAULT]	The maximum amount of memory that can be used for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
`jvm.memory.nonheap.used`	[DEFAULT]	The current non-heap memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`jvm.memory.nonheap.committed`	[DEFAULT]	The amount of memory that is guaranteed to be available for non-heap purposes. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`jvm.memory.pool.init`	[DEFAULT], `name`	The initial amount of memory that the JVM requests from the operating system for the memory pool. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`jvm.memory.pool.max`	[DEFAULT], `name`	The maximum amount of memory that can be used for the memory pool. **Unit:** Bytes **Meaningful statistics:** Maximum

Metric	Dimensions	Description
`jvm.memory.pool.used`	[DEFAULT], name	The current memory pool memory usage. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`jvm.memory.pool.committed`	[DEFAULT], name	The amount of memory that is guaranteed to be available for the memory pool. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`jvm.threads.count`	[DEFAULT]	The current number of threads. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

The JVM metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of [Manually create or edit the CloudWatch agent configuration file](#) for more information. On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.

Dimension	Description
`name`	For `jvm.gc.collections` metrics, the value is the garbage collector name. For `jvm.memory.pool` metrics, the value is the memory pool name.

Collect Kafka metrics

You can use the CloudWatch agent to collect Apache Kafka metrics. To set this up, add one or more of the following subsections inside the `jmx` section of the CloudWatch agent configuration file.

- Use a `kafka` section to collect Kafka broker metrics.
- Use a `kafka-consumer` section to collect Kafka consumer metrics.
- Use a `kafka-producer` section to collect Kafka producer metrics.

Kafka broker metrics

The following metrics can be collected for Kafka brokers.

Metric	Dimensions	Description	
`kafka.message.count`	[DEFAULT]	The number of messages received by the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average	

Metric	Dimensions	Description
`kafka.request.count`	[DEFAULT], `type`	The number of requests received by the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.failed`	[DEFAULT], `type`	The number of requests to the Kafka broker that resulted in a failure. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.request.time.total`	[DEFAULT], `type`	The total time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.time.50p`	[DEFAULT], `type`	The 50th percentile time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.request.time.99p`	[DEFAULT], `type`	The 99th percentile time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.time.avg`	[DEFAULT], `type`	The average time that the Kafka broker has taken to service requests. **Unit:** Milliseconds **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.network.io`	[DEFAULT], `state`	The number of bytes received by or sent by the Kafka broker. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`kafka.purgatory.size`	[DEFAULT], `type`	The number of requests waiting in purgatory. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
kafka.partition.count	[DEFAULT]	The number of partitions on the Kafka broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.partition.offline	[DEFAULT]	The number of partitions that are offline. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
kafka.partition.under_replicated	[DEFAULT]	The number of under-replicated partitions. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.isr.operation.count`	[DEFAULT], `operation`	The number of in-sync replica shrink and expand operations. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.max.lag`	[DEFAULT]	The maximum lag in messages between follower and leader replicas. **Unit:** None **Meaningful statistics:** Maximum

Metric	Dimensions	Description
`kafka.controller.active.count`	[DEFAULT]	The number of active controllers on the broker. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.leader.election.rate`	[DEFAULT]	Leader election rate. If this increases, it indicates broker failures. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.unclean.election.rate`	[DEFAULT]	Unclean leader election rate. If this increases, it indicates broker failures. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.request.queue`	[DEFAULT]	The size of the request queue. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.logs.flush.time.count`	[DEFAULT]	The logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
`kafka.logs.flush.time.median`	[DEFAULT]	The 50th percentile value of the logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
`kafka.logs.flush.time.99p`	[DEFAULT]	The 99th percentile value of the logs flush count. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average

The Kafka broker metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are

Dimension	Description
	collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of [Manually create or edit the CloudWatch agent configuration file](#) for more information. On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`type`	The request type. Possible values are `produce`, `fetch`, `fetchconsumer` , and `fetchfollower` .
`state`	The direction of network traffic. Possible values are `in` and `out`.
`operation`	The operation type for the in-sync replica. Possible values are `shrink` and `expand`.

Kafka consumer metrics

The following metrics can be collected for Kafka consumers.

Metric	Dimensions	Description
`kafka.consumer.fetch-rate`	[DEFAULT], `client-id`	The number of fetch requests

Metric	Dimensions	Description
		for all topics per second. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.records-lag-max`	[DEFAULT], `client-id`	The number of messages that the consumer lags behind the producer. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.total.bytes-consumed-rate`	[DEFAULT], `client-id`	The average number of bytes consumed for all topics per second. **Unit:** Bytes **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.consumer.total.fetch-size-avg`	[DEFAULT], `client-id`	The number of bytes fetched per request for all topics. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
`kafka.consumer.total.records-consumed-rate`	[DEFAULT], `client-id`	The average number of records consumed for all topics per second. **Unit:** None **Meaningful statistics:** Average
`kafka.consumer.bytes-consumed-rate`	[DEFAULT], `client-id` , `topic`	The average number of bytes consumed per second. **Unit:** Bytes **Meaningful statistics:** Average

Metric	Dimensions	Description
kafka.consumer.fetch-size-avg	[DEFAULT], client-id , topic	The number of bytes fetched per request. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
kafka.consumer.records-consumed-rate	[DEFAULT], client-id , topic	The average number of records consumed per second. **Unit:** None **Meaningful statistics:** Average

The Kafka consumer metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of [Manually create or edit the CloudWatch agent configuration file](#) for more information.

Dimension	Description
	On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`client-id`	The ID of the client.
`topic`	The Kafka topic.

Kafka producer metrics

The following metrics can be collected for Kafka producers.

Metric	Dimensions	Description
`kafka.producer.io-wait-time-ns-avg`	[DEFAULT], `client-id`	The average length of time the I/O thread spent waiting for a socket ready for reads or writes. **Unit:** None **Meaningful statistics:** Average
`kafka.producer.out`	[DEFAULT], `client-id`	The average number of

Metric	Dimensions	Description
going-byte-rate		outgoing bytes sent per second to all servers. **Unit:** Bytes **Meaningful statistics:** Average
kafka.producer.request-latency-avg	[DEFAULT], client-id	The average request latency. **Unit:** Milliseconds **Meaningful statistics:** Average
kafka.producer.request-rate	[DEFAULT], client-id	The average number of requests sent per second. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.producer.response-rate`	[DEFAULT], `client-id`	The number of responses received per second. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`kafka.producer.byte-rate`	[DEFAULT], `client-id` , `topic`	The average number of bytes sent per second for a topic. **Unit:** Bytes **Meaningful statistics:** Average
`kafka.producer.compression-rate`	[DEFAULT], `client-id` , `topic`	The average compression rate of record batches for a topic. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
kafka.producer.record-error-rate	[DEFAULT], client-id , topic	The average per-second number of record sends that resulted in errors for a topic. **Unit:** None **Meaningful statistics:** Average
kafka.producer.record-retry-rate	[DEFAULT], client-id , topic	The average per-second number of retried record sends for a topic. **Unit:** None **Meaningful statistics:** Average

Metric	Dimensions	Description
`kafka.producer.record-send-rate`	[DEFAULT], `client-id` , `topic`	The average number of records sent per second for a topic. **Unit:** None **Meaningful statistics:** Average

Kafka producer metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of [Manually create or edit the CloudWatch agent configuration file]() for more information. On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.

Dimension	Description
client-id	The ID of the client.
topic	The Kafka topic.

Collect Tomcat metrics

You can use the CloudWatch agent to collect Apache Tomcat metrics. To set this up, add a `tomcat` section inside the `metrics_collected` section of the CloudWatch agent configuration file.

The following metrics can be collected.

Metric	Dimensions	Description
`tomcat.sessions`	[DEFAULT]	The number of active sessions. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average
`tomcat.errors`	[DEFAULT], `proto_handler`	The number of errors encountered. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
tomcat.processing_time	[DEFAULT], proto_handler	The total processing time. **Unit:** Milliseconds **Meaningful statistics:** Minimum, Maximum, Average
tomcat.traffic	[DEFAULT], proto_handler	The number of bytes received and sent. **Unit:** Bytes **Meaningful statistics:** Minimum, Maximum, Average
tomcat.threads	[DEFAULT], proto_handler	The number of threads. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Metric	Dimensions	Description
tomcat.max_time	[DEFAULT], proto_handler , direction	Maximum time to process a request. **Unit:** Milliseconds **Meaningful statistics:** Maximum
tomcat.request_count	[DEFAULT], proto_handler	The total requests. **Unit:** None **Meaningful statistics:** Minimum, Maximum, Average

Tomcat metrics are collected with the following dimensions:

Dimension	Description
[DEFAULT]	On Amazon EC2 by default, the host is also published as a dimension of metrics that are collected by the CloudWatch agent, unless you are using the `append_dimensions` field in the `metrics` section. See `omit_hostname` in the agent section of [Manually create or edit the CloudWatch agent configuration file](#) for more information.

Dimension	Description
	On Amazon EKS by default, k8s related context is also published as dimensions of metrics (`k8s.container.name` , `k8s.deployment.name` , `k8s.namespace.name` , `k8s.node.name` , `k8s.pod.name` , and `k8s.replicaset.name`). These can be filtered down using the `aggregation_dimensions` field.
`proto_handler`	The `proto_handler` is an identifier for a connector, which is provided in the `<protocol>-<type>-<port>` format (for example, `http-nio-8080`).
`direction`	The traffic direction. Possible values are `received` and `sent`.

Collect metrics and traces with OpenTelemetry

You can collect metrics and traces from your applications or services using the CloudWatch agent with the OpenTelemetry Protocol (OTLP), which is a popular open source solution. You can use any OpenTelemetry SDK to send metrics and traces to the CloudWatch agent. For more information about the available OpenTelemetry SDKs, see [OpenTelemetry Supported Language APIs & SDKs.](#).

To collect OpenTelemetry metrics and traces, add an `otlp` section to the CloudWatch agent configuration file. The section has the following fields:

- `grpc_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry metrics or traces sent using gRPC Remote Procedure Calls. The format is `ip:port`. This address must match the address set for the gRPC exporter in the OpenTelemetry SDK. If you omit this field, the default of `127.0.0.1:4317` is used.
- `http_endpoint` – Optional. Specifies the address for the CloudWatch agent to use to listen for OpenTelemetry metrics or traces sent over HTTP. The format is `ip:port`. This address must

match the address set for the HTTP exporter in the OpenTelemetry SDK. If you omit this field, the default of `127.0.0.1:4318` is used.

- `tls` – Optional. Specifies that the server should be configured with TLS.
  - `cert_file` – Path to the TLS certificate to use for TLS required connections.
  - `key_file` – Path to the TLS key to use for TLS required connections.

The `otlp` section can be placed in multiple sections within the CloudWatch agent configuration file depending on how and where you want to send the metrics and traces. Each `otlp` section requires a unique endpoint. For detailed information about splitting the metrics and traces endpoints, see OTLP Exporter Configuration in the OpenTelemetry SDK documentation.

To send metrics to CloudWatch or Amazon Managed Service for Prometheus, add the `otlp` section under `metrics_collected` within the `metrics` section. For more information about sending metrics to different destinations, see Manually create or edit the CloudWatch agent configuration file. The following example shows a configuration that sends metrics to CloudWatch:

```
{
  "metrics": {
    "metrics_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

To send metrics to Amazon CloudWatch Logs using the Embedded metric format (EMF), add the `otlp` section under `metrics_collected` within the `logs` section. This sends the EMF logs by default to the `/aws/cwagent` log group and a generated log stream. The metrics are extracted into the `CWAgent` namespace by default. The following example shows a configuration that sends metrics as EMF logs to CloudWatch Logs:

```
{
  "logs": {
    "metrics_collected": {
      "otlp": {
```

```
          "grpc_endpoint": "127.0.0.1:4317",
          "http_endpoint": "127.0.0.1:4318"
        }
      }
    }
}
```

To send traces to Amazon X-Ray, add the `otlp` section under `traces_collected` within the `traces` section. The following example shows a configuration that sends traces to X-Ray:

```
{
  "traces": {
    "traces_collected": {
      "otlp": {
        "grpc_endpoint": "127.0.0.1:4317",
        "http_endpoint": "127.0.0.1:4318"
      }
    }
  }
}
```

Collect process metrics with the procstat plugin

The *procstat* plugin enables you to collect metrics from individual processes. The plugin is supported on Linux servers and on servers running supported version of Windows Server. This section describes how to configure the CloudWatch agent for procstat and view metrics the CloudWatch agent imports. It also lists the metrics that procstat collects.

> **Note**
>
> The `procstat` plugin is not supported for the Fargate launch type in Amazon ECS environments.

Topics

- Viewing process metrics imported by the CloudWatch agent

Configure the CloudWatch agent for procstat

To use the procstat plugin, add a `procstat` section in the `metrics_collected` section of the CloudWatch agent configuration file. There are three ways to specify the processes to monitor. You can use only one of these methods, but you can use that method to specify one or more processes to monitor.

- `pid_file`: Selects processes by the names of the process identification number (PID) files they create.
- `exe`: Selects the processes that have process names that match the string that you specify, using regular expression matching rules. The match is a "contains" match, meaning that if you specify `agent` as the term to match, processes with names like `cloudwatchagent` match the term. For more information, see Syntax.
- `pattern`: Selects processes by the command lines used to start the processes. All processes are selected that have command lines matching the specified string using regular expression matching rules. The entire command line is checked, including parameters and options used with the command.

  The match is a "contains" match, meaning that if you specify `-c` as the term to match, processes with parameters like `-config` match the term.

The CloudWatch agent uses only one of these methods, even if you include more than one of the above sections. If you specify more than one section, the CloudWatch agent uses the `pid_file` section if it is present. If not, it uses the `exe` section.

On Linux servers, the strings that you specify in an `exe` or `pattern` section are evaluated as regular expressions. On servers running Windows Server, these strings are evaluated as WMI queries. An example would be `pattern: "%apache%"`. For more information, see LIKE Operator.

Whichever method you use, you can include an optional `metrics_collection_interval` parameter, which specifies how often in seconds to collect those metrics. If you omit this parameter, the default value of 60 seconds is used.

In the examples in the following sections, the `procstat` section is the only section included in the `metrics_collected` section of the agent configuration file. Actual configuration files can also include other sections in `metrics_collected`. For more information, see [Manually create or edit the CloudWatch agent configuration file](#).

Configure with pid_file

The following example `procstat` section monitors the processes that create the PID files `example1.pid` and `example2.pid`. Different metrics are collected from each process. Metrics collected from the process that creates `example2.pid` are collected every 10 seconds, and the metrics collected from the `example1.pid` process are collected every 60 seconds, the default value.

```
{
    "metrics": {
        "metrics_collected": {
            "procstat": [
                {
                    "pid_file": "/var/run/example1.pid",
                    "measurement": [
                        "cpu_usage",
                        "memory_rss"
                    ]
                },
                {
                    "pid_file": "/var/run/example2.pid",
                    "measurement": [
                        "read_bytes",
                        "read_count",
                        "write_bytes"
                    ],
                    "metrics_collection_interval": 10
                }
            ]
        }
    }
}
```

Configuring with exe

The following example `procstat` section monitors all processes with names that match the strings `agent` or `plugin`. The same metrics are collected from each process.

```
{
```

```
    "metrics": {
        "metrics_collected": {
            "procstat": [
                {
                    "exe": "agent",
                    "measurement": [
                        "cpu_time",
                        "cpu_time_system",
                        "cpu_time_user"
                    ]
                },
                {
                    "exe": "plugin",
                    "measurement": [
                        "cpu_time",
                        "cpu_time_system",
                        "cpu_time_user"
                    ]
                }
            ]
        }
    }
}
```

Configuring with pattern

The following example `procstat` section monitors all processes with command lines that match the strings `config` or `-c`. The same metrics are collected from each process.

```
{
    "metrics": {
        "metrics_collected": {
            "procstat": [
                {
                    "pattern": "config",
                    "measurement": [
                        "rlimit_memory_data_hard",
                        "rlimit_memory_data_soft",
                        "rlimit_memory_stack_hard",
                        "rlimit_memory_stack_soft"
                    ]
                },
                {
```

```
                    "pattern": "-c",
                    "measurement": [
                        "rlimit_memory_data_hard",
                        "rlimit_memory_data_soft",
                        "rlimit_memory_stack_hard",
                        "rlimit_memory_stack_soft"
                    ]
                }
            ]
        }
    }
}
```

Metrics collected by procstat

The following table lists the metrics that you can collect with the `procstat` plugin.

The CloudWatch agent adds `procstat` to the beginning of the following metric names. There is a different syntax depending on whether it was collected from a Linux server or a server running Windows Server. For example, the `cpu_time` metric appears as `procstat_cpu_time` when collected from Linux and as `procstat cpu_time` when collected from Windows Server.

Metric name	Available on	Description
`cpu_time`	Linux	The amount of time that the process uses the CPU. This metric is measured in hundredths of a second. Unit: Count
`cpu_time_guest`	Linux	The amount of time that the process is in guest mode. This metric is

Metric name	Available on	Description
		measured in hundredths of a second. Type: Float Unit: None
`cpu_time_guest_nice`	Linux	The amount of time that the process is running in a nice guest. This metric is measured in hundredths of a second. Type: Float Unit: None
`cpu_time_idle`	Linux	The amount of time that the process is in idle mode. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
cpu_time_iowait	Linux	The amount of time that the process is waiting for I/O operations to complete. This metric is measured in hundredths of a second. Type: Float Unit: None
cpu_time_irq	Linux	The amount of time that the process is servicing interrupts. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
`cpu_time_nice`	Linux	The amount of time that the process is in nice mode. This metric is measured in hundredths of a second. Type: Float Unit: None
`cpu_time_soft_irq`	Linux	The amount of time that the process is servicing software interrupts. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
`cpu_time_steal`	Linux	The amount of time spent running in other operating systems when running in a virtualized environment. This metric is measured in hundredths of a second. Type: Float Unit: None
`cpu_time_stolen`	Linux, Windows Server	The amount of time that the process is in *stolen time*, which is time spent in other operating systems in a virtualized environment. This metric is measured in hundredths of a second. Type: Float Unit: None

Metric name	Available on	Description
`cpu_time_system`	Linux, Windows Server, macOS	The amount of time that the process is in system mode. This metric is measured in hundredths of a second. Type: Float Unit: Count
`cpu_time_user`	Linux, Windows Server, macOS	The amount of time that the process is in user mode. This metric is measured in hundredths of a second. Unit: Count
`cpu_usage`	Linux, Windows Server, macOS	The percentage of time that the process is active in any capacity. Unit: Percent

Metric name	Available on	Description
`memory_data`	Linux, macOS	The amount of memory that the process uses for data. Unit: Bytes
`memory_locked`	Linux, macOS	The amount of memory that the process has locked. Unit: Bytes
`memory_rss`	Linux, Windows Server, macOS	The amount of real memory (resident set) that the process is using. Unit: Bytes
`memory_stack`	Linux, macOS	The amount of stack memory that the process is using. Unit: Bytes

Metric name	Available on	Description
`memory_swap`	Linux, macOS	The amount of swap memory that the process is using. Unit: Bytes
`memory_vms`	Linux, Windows Server, macOS	The amount of virtual memory that the process is using. Unit: Bytes
`num_fds`	Linux	The number of file descripto rs that this process has open. Unit: None
`num_threads`	Linux, Windows, macOS	The number of threads in this process. Unit: None
`pid`	Linux, Windows Server, macOS	Process identifier (ID). Unit: None

Metric name	Available on	Description
`pid_count`	Linux, Windows Server. macOS	The number of process IDs associated with the process. On Linux servers and macOS computers the full name of this metric is `procstat_lookup_pid_count` and on Windows Server it is `procstat_lookup pid_count` . Unit: None
`read_bytes`	Linux, Windows Server	The number of bytes that the process has read from disks. Unit: Bytes

Metric name	Available on	Description
`write_bytes`	Linux, Windows Server	The number of bytes that the process has written to disks. Unit: Bytes
`read_count`	Linux, Windows Server	The number of disk read operation s that the process has executed. Unit: None
`rlimit_realtime_pr iority_hard`	Linux	The hard limit on the real-time priority that can be set for this process. Unit: None
`rlimit_realtime_pr iority_soft`	Linux	The soft limit on the real-time priority that can be set for this process. Unit: None

Metric name	Available on	Description
rlimit_signals_pending_hard	Linux	The hard limit on maximum number of signals that can be queued by this process. Unit: None
rlimit_signals_pending_soft	Linux	The soft limit on maximum number of signals that can be queued by this process. Unit: None
rlimit_nice_priority_hard	Linux	The hard limit on the maximum nice priority that can be set by this process. Unit: None

Metric name	Available on	Description
`rlimit_nice_priority_soft`	Linux	The soft limit on the maximum nice priority that can be set by this process. Unit: None
`rlimit_num_fds_hard`	Linux	The hard limit on the maximum number of file descriptors that this process can have open. Unit: None
`rlimit_num_fds_soft`	Linux	The soft limit on the maximum number of file descriptors that this process can have open. Unit: None

Metric name	Available on	Description
`write_count`	Linux, Windows Server	The number of disk write operations that the process has executed. Unit: None
`involuntary_context_switches`	Linux	The number of times that the process was involuntarily context-switched. Unit: None
`voluntary_context_switches`	Linux	The number of times that the process was context-switched voluntarily. Unit: None
`realtime_priority`	Linux	The current usage of real-time priority for the process. Unit: None

Metric name	Available on	Description
nice_priority	Linux	The current usage of nice priority for the process. Unit: None
signals_pending	Linux	The number of signals pending to be handled by the process. Unit: None
rlimit_cpu_time_hard	Linux	The hard CPU time resource limit for the process. Unit: None
rlimit_cpu_time_soft	Linux	The soft CPU time resource limit for the process. Unit: None
rlimit_file_locks_hard	Linux	The hard file locks resource limit for the process. Unit: None

Metric name	Available on	Description
`rlimit_file_locks_soft`	Linux	The soft file locks resource limit for the process. Unit: None
`rlimit_memory_data_hard`	Linux	The hard resource limit on the process for memory used for data. Unit: Bytes
`rlimit_memory_data_soft`	Linux	The soft resource limit on the process for memory used for data. Unit: Bytes
`rlimit_memory_lock ed_hard`	Linux	The hard resource limit on the process for locked memory. Unit: Bytes

Metric name	Available on	Description
rlimit_memory_locked_soft	Linux	The soft resource limit on the process for locked memory. Unit: Bytes
rlimit_memory_rss_hard	Linux	The hard resource limit on the process for physical memory. Unit: Bytes
rlimit_memory_rss_soft	Linux	The soft resource limit on the process for physical memory. Unit: Bytes
rlimit_memory_stack_hard	Linux	The hard resource limit on the process stack. Unit: Bytes
rlimit_memory_stack_soft	Linux	The soft resource limit on the process stack. Unit: Bytes

Metric name	Available on	Description
`rlimit_memory_vms_hard`	Linux	The hard resource limit on the process for virtual memory. Unit: Bytes
`rlimit_memory_vms_soft`	Linux	The soft resource limit on the process for virtual memory. Unit: Bytes

Viewing process metrics imported by the CloudWatch agent

After importing process metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view process metrics as a time series graph. For more information about setting alarms, see [Using Amazon CloudWatch alarms](#).

To view process metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:

    a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.

b. To sort the table, use the column heading.

c. To filter by resource, choose the resource ID and then choose **Add to search**.

d. To filter by metric, choose the metric name and then choose **Add to search**.

6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Retrieve custom metrics with StatsD

You can retrieve additional custom metrics from your applications or services using the CloudWatch agent with the `StatsD` protocol. StatsD is a popular open-source solution that can gather metrics from a wide variety of applications. StatsD is especially useful for instrumenting your own metrics. For an example of using the CloudWatch agent and StatsD together, see [How to better monitor your custom application metrics using Amazon CloudWatch Agent]().

`StatsD` is supported on both Linux servers and servers running Windows Server. CloudWatch supports the following `StatsD` format:

```
MetricName:value|type|@sample_rate|#tag1:
  value,tag1...
```

- `MetricName` – A string with no colons, bars, # characters, or @ characters.
- `value` – This can be either integer or float.
- `type` – Specify `c` for counter, `g` for gauge, `ms` for timer, `h` for histogram, or `s` for set.
- `sample_rate` – (Optional) A float between 0 and 1, inclusive. Use only for counter, histogram, and timer metrics. The default value is 1 (sampling 100% of the time).
- `tags` – (Optional) A comma-separated list of tags. `StatsD` tags are similar to dimensions in CloudWatch. Use colons for key/value tags, such as `env:prod`.

You can use any `StatsD` client that follows this format to send the metrics to the CloudWatch agent. For more information about some of the available `StatsD` clients, see the StatsD client page on GitHub.

To collect these custom metrics, add a `"statsd": {}` line to the `metrics_collected` section of the agent configuration file. You can add this line manually. If you use the wizard to create the configuration file, it's done for you. For more information, see Create the CloudWatch agent configuration file.

The StatsD default configuration works for most users. There are optional fields that you can add to the **statsd** section of the agent configuration file as needed:

- service_address – The service address to which the CloudWatch agent should listen. The format is *ip*:*port*. If you omit the IP address, the agent listens on all available interfaces. Only the UDP format is supported, so you don't need to specify a UDP prefix.

  The default value is :8125.
- metrics_collection_interval – How often in seconds that the StatsD plugin runs and collects metrics. The default value is 10 seconds. The range is 1–172,000.
- metrics_aggregation_interval – How often in seconds CloudWatch aggregates metrics into single data points. The default value is 60 seconds.

  For example, if metrics_collection_interval is 10 and metrics_aggregation_interval is 60, CloudWatch collects data every 10 seconds. After each minute, the six data readings from that minute are aggregated into a single data point, which is sent to CloudWatch.

  The range is 0–172,000. Setting metrics_aggregation_interval to 0 disables the aggregation of StatsD metrics.
- allowed_pending_messages – The number of UDP messages that are allowed to queue up. When the queue is full, the StatsD server starts dropping packets. The default value is 10000.
- drop_original_metrics – Optional. If you are using the aggregation_dimensions field in the metrics section to roll up metrics into aggregated results, then by default the agent sends both the aggregated metrics and the original metrics that are separated for each value of the dimension. If you don't want the original metrics to be sent to CloudWatch, you can specify this parameter with a list of metrics. The metrics specified along with this parameter don't have their metrics by dimension reported to CloudWatch. Instead, only the aggregated metrics are reported. This reduces the number of metrics that the agent collects, reducing your costs.

The following is an example of the **statsd** section of the agent configuration file, using the default port and custom collection and aggregation intervals.

```
{
   "metrics":{
      "metrics_collected":{
         "statsd":{
```

```
                "service_address":":8125",
                "metrics_collection_interval":60,
                "metrics_aggregation_interval":300
            }
        }
    }
}
```

Viewing StatsD metrics imported by the CloudWatch agent

After importing StatsD metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view StatsD metrics as a time series graph. For more information about setting alarms, see Using Amazon CloudWatch alarms.

To view StatsD metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:
   a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.
   b. To sort the table, use the column heading.
   c. To filter by resource, choose the resource ID and then choose **Add to search**.
   d. To filter by metric, choose the metric name and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Retrieve custom metrics with collectd

You can retrieve additional metrics from your applications or services using the CloudWatch agent with the collectd protocol, which is supported only on Linux servers. collectd is a popular open-source solution with plugins that can gather system statistics for a wide variety of applications. By combining the system metrics that the CloudWatch agent can already collect with the additional metrics from collectd, you can better monitor, analyze, and troubleshoot your systems and applications. For more information about collectd, see [collectd - The system statistics collection daemon](#).

You use the collectd software to send the metrics to the CloudWatch agent. For the collectd metrics, the CloudWatch agent acts as the server while the collectd plugin acts as the client.

The collectd software is not installed automatically on every server. On a server running Amazon Linux 2, follow these steps to install collectd

```
sudo amazon-linux-extras install collectd
```

For information about installing collectd on other systems, see the [Download page for collectd.](#)

To collect these custom metrics, add a **"collectd": {}** line to the **metrics_collected** section of the agent configuration file. You can add this line manually. If you use the wizard to create the configuration file, it is done for you. For more information, see [Create the CloudWatch agent configuration file](#).

Optional parameters are also available. If you are using collectd and you do not use `/etc/collectd/auth_file` as your **collectd_auth_file**, you must set some of these options.

- **service_address:** The service address to which the CloudWatch agent should listen. The format is `"udp://ip:port`. The default is `udp://127.0.0.1:25826`.
- **name_prefix:** A prefix to attach to the beginning of the name of each collectd metric. The default is `collectd_`. The maximum length is 255 characters.
- **collectd_security_level:** Sets the security level for network communication. The default is **encrypt**.

  encrypt specifies that only encrypted data is accepted. **sign** specifies that only signed and encrypted data is accepted. **none** specifies that all data is accepted. If you specify a value for **collectd_auth_file**, encrypted data is decrypted if possible.

  For more information, see [Client setup](#) and [Possible interactions](#) in the collectd Wiki.
- **collectd_auth_file** Sets a file in which user names are mapped to passwords. These passwords are used to verify signatures and to decrypt encrypted network packets. If given, signed data is verified and encrypted packets are decrypted. Otherwise, signed data is accepted without checking the signature and encrypted data cannot be decrypted.

The default is `/etc/collectd/auth_file`.

If **collectd_security_level** is set to **none**, this is optional. If you set **collectd_security_level** to `encrypt` or **sign**, you must specify **collectd_auth_file**.

For the format of the auth file, each line is a user name followed by a colon and any number of spaces followed by the password. For example:

`user1: user1_password`

`user2: user2_password`

- **collectd_typesdb:** A list of one or more files that contain the dataset descriptions. The list must be surrounded by brackets, even if there is just one entry in the list. Each entry in the list must be surrounded by double quotes. If there are multiple entries, separate them with commas. The default on Linux servers is `["/usr/share/collectd/types.db"]`. The default on macOs computers depends on the version of collectd. For example, `["/usr/local/Cellar/collectd/5.12.0/share/collectd/types.db"]`.

  For more information, see https://www.collectd.org/documentation/manpages/types.db.html.
- **metrics_aggregation_interval:** How often in seconds CloudWatch aggregates metrics into single data points. The default is 60 seconds. The range is 0 to 172,000. Setting it to 0 disables the aggregation of collectd metrics.

The following is an example of the collectd section of the agent configuration file.

```
{
   "metrics":{
      "metrics_collected":{
         "collectd":{
            "name_prefix":"My_collectd_metrics_",
            "metrics_aggregation_interval":120
         }
      }
   }
}
```

Viewing collectd metrics imported by the CloudWatch agent

After importing collectd metrics into CloudWatch, you can view these metrics as time series graphs, and create alarms that can watch these metrics and notify you if they breach a threshold that you specify. The following procedure shows how to view collectd metrics as a time series graph. For more information about setting alarms, see [Using Amazon CloudWatch alarms](#).

To view collectd metrics in the CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Choose the namespace for the metrics collected by the agent. By default, this is **CWAgent**, but you may have specified a different namespace in the CloudWatch agent configuration file.
4. Choose a metric dimension (for example, **Per-Instance Metrics**).
5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:

   a. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.
   b. To sort the table, use the column heading.
   c. To filter by resource, choose the resource ID and then choose **Add to search**.
   d. To filter by metric, choose the metric name and then choose **Add to search**.
6. (Optional) To add this graph to a CloudWatch dashboard, choose **Actions**, **Add to dashboard**.

Set up and configure Prometheus metrics collection on Amazon EC2 instances

The following sections explain how to install the CloudWatch agent with Prometheus monitoring on EC2 instances, and how to configure the agent to scrape additional targets. It also provides tutorials for setting up sample workloads to use testing with Prometheus monitoring.

Both Linux and Windows instances are supported.

For information about the operating systems supported by the CloudWatch agent, see [Collect metrics, logs, and traces with the CloudWatch agent](#)

VPC security group requirements

If you are using a VPC, the following requirements apply.

- The ingress rules of the security groups for the Prometheus workloads must open the Prometheus ports to the CloudWatch agent for scraping the Prometheus metrics by the private IP.
- The egress rules of the security group for the CloudWatch agent must allow the CloudWatch agent to connect to the Prometheus workloads' port by private IP.

Topics

Step 1: Install the CloudWatch agent

The first step is to install the CloudWatch agent on the EC2 instance. For instructions, see Install the CloudWatch agent.

Step 2: Scrape Prometheus sources and import metrics

The CloudWatch agent with Prometheus monitoring needs two configurations to scrape the Prometheus metrics. One is for the standard Prometheus configurations as documented in <scrape_config>in the Prometheus documentation. The other is for the CloudWatch agent configuration.

Prometheus scrape configuration

The CloudWatch agent supports the standard Prometheus scrape configurations as documented in <scrape_config> in the Prometheus documentation. You can edit this section to update the configurations that are already in this file, and add additional Prometheus scraping targets. A sample configuration file contains the following global configuration lines:

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
- job_name: MY_JOB
  sample_limit: 10000
  file_sd_configs:
```

```
    - files: ["C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\prometheus_sd_1.yaml",
 "C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\\prometheus_sd_2.yaml"]
```

The `global` section specifies parameters that are valid in all configuration contexts. They also serve as defaults for other configuration sections. It contains the following parameters:

- `scrape_interval`— Defines how frequently to scrape targets.
- `scrape_timeout`— Defines how long to wait before a scrape request times out.

The `scrape_configs` section specifies a set of targets and parameters that define how to scrape them. It contains the following parameters:

- `job_name`— The job name assigned to scraped metrics by default.
- `sample_limit`— Per-scrape limit on the number of scraped samples that will be accepted.
- `file_sd_configs`— List of file service discovery configurations. It reads a set of files containing a list of zero or more static configs. The `file_sd_configs` section contains a `files` parameter which defines patterns for files from which target groups are extracted.

The CloudWatch agent supports the following service discovery configuration types.

`static_config` Allows specifying a list of targets and a common label set for them. It is the canonical way to specify static targets in a scrape configuration.

The following is a sample static config to scrape Prometheus metrics from a local host. Metrics can also be scraped from other servers if the Prometheus port is open to the server where the agent runs.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_sd_1.yaml
- targets:
    - 127.0.0.1:9404
  labels:
    key1: value1
    key2: value2
```

This example contains the following parameters:

- `targets`— The targets scraped by the static config.
- `labels`— Labels assigned to all metrics that are scraped from the targets.

`ec2_sd_config` Allows retrieving scrape targets from Amazon EC2 instances. The following is a sample `ec2_sd_config` to scrape Prometheus metrics from a list of EC2 instances. The Prometheus ports of these instances have to open to the server where the CloudWatch agent runs. The IAM role for the EC2 instance where the CloudWatch agent runs must include the `ec2:DescribeInstance` permission. For example, you could attach the managed policy **AmazonEC2ReadOnlyAccess** to the instance running the CloudWatch agent.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: MY_JOB
    sample_limit: 10000
    ec2_sd_configs:
      - region: us-east-1
        port: 9404
        filters:
          - name: instance-id
            values:
              - i-98765432109876543
              - i-12345678901234567
```

This example contains the following parameters:

- `region`— The Amazon Region where the target EC2 instance is. If you leave this blank, the Region from the instance metadata is used.
- `port`— The port to scrape metrics from.
- `filters`— Optional filters to use to filter the instance list. This example filters based on EC2 instance IDs. For more criteria that you can filter on, see [DescribeInstances](#).

CloudWatch agent configuration for Prometheus

The CloudWatch agent configuration file includes `prometheus` sections under both `logs` and `metrics_collected`. It includes the following parameters.

- **cluster_name**— specifies the cluster name to be added as a label in the log event. This field is optional.
- **log_group_name**— specifies the log group name for the scraped Prometheus metrics.

- **prometheus_config_path**— specifies the Prometheus scrape configuration file path.
- **emf_processor**— specifies the embedded metric format processor configuration. For more information about embedded metric format, see Embedding metrics within logs.

  The `emf_processor` section can contain the following parameters:

  - **metric_declaration_dedup**— It set to true, the de-duplication function for the embedded metric format metrics is enabled.
  - **metric_namespace**— Specifies the metric namespace for the emitted CloudWatch metrics.
  - **metric_unit**— Specifies the metric name:metric unit map. For information about supported metric units, see MetricDatum.
  - **metric_declaration**— are sections that specify the array of logs with embedded metric format to be generated. There are `metric_declaration` sections for each Prometheus source that the CloudWatch agent imports from by default. These sections each include the following fields:
    - `source_labels` specifies the value of the labels that are checked by the `label_matcher` line.
    - `label_matcher` is a regular expression that checks the value of the labels listed in `source_labels`. The metrics that match are enabled for inclusion in the embedded metric format sent to CloudWatch.
    - `metric_selectors` is a regular expression that specifies the metrics to be collected and sent to CloudWatch.
    - `dimensions` is the list of labels to be used as CloudWatch dimensions for each selected metric.

The following is an example CloudWatch agent configuration for Prometheus.

```
{
   "logs":{
      "metrics_collected":{
         "prometheus":{
            "cluster_name":"prometheus-cluster",
            "log_group_name":"Prometheus",
            "prometheus_config_path":"C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\prometheus.yaml",
            "emf_processor":{
               "metric_declaration_dedup":true,
               "metric_namespace":"CWAgent-Prometheus",
```

```
                "metric_unit":{
                   "jvm_threads_current": "Count",
                   "jvm_gc_collection_seconds_sum": "Milliseconds"
                },
                "metric_declaration":[
                   {
                      "source_labels":[
                         "job", "key2"
                      ],
                      "label_matcher":"MY_JOB;^value2",
                      "dimensions":[
                         [
                            "key1", "key2"
                         ],
                         [
                            "key2"
                         ]
                      ],
                      "metric_selectors":[
                         "^jvm_threads_current$",
                         "^jvm_gc_collection_seconds_sum$"
                      ]
                   }
                ]
             }
          }
       }
    }
}
```

The previous example configures an embedded metric format section to be sent as a log event if the following conditions are met:

- The value of the label `job` is `MY_JOB`
- The value of the label `key2` is `value2`
- The Prometheus metrics `jvm_threads_current` and `jvm_gc_collection_seconds_sum` contains both `job` and `key2` labels.

The log event that is sent includes the following highlighted section.

```
{
```

```
    "CloudWatchMetrics": [
        {
            "Metrics": [
                {
                    "Unit": "Count",
                    "Name": "jvm_threads_current"
                },
                {
                    "Unit": "Milliseconds",
                    "Name": "jvm_gc_collection_seconds_sum"
                }
            ],
            "Dimensions": [
                [
                    "key1",
                    "key2"
                ],
                [
                    "key2"
                ]
            ],
            "Namespace": "CWAgent-Prometheus"
        }
    ],
    "ClusterName": "prometheus-cluster",
    "InstanceId": "i-0e45bd06f196096c8",
    "Timestamp": "1607966368109",
    "Version": "0",
    "host": "EC2AMAZ-PDDOIUM",
    "instance": "127.0.0.1:9404",
    "jvm_threads_current": 2,
    "jvm_gc_collection_seconds_sum": 0.006000000000000002,
    "prom_metric_type": "gauge",
    ...
}
```

Example: Set up Java/JMX sample workloads for Prometheus metric testing

JMX Exporter is an official Prometheus exporter that can scrape and expose JMX mBeans as Prometheus metrics. For more information, see prometheus/jmx_exporter.

The CloudWatch agent can collect predefined Prometheus metrics from Java Virtual Machine (JVM), Hjava, and Tomcat (Catalina), from a JMX exporter on EC2 instances.

Step 1: Install the CloudWatch agent

The first step is to install the CloudWatch agent on the EC2 instance. For instructions, see Install the CloudWatch agent.

Step 2: Start the Java/JMX workload

The next step is to start the Java/JMX workload.

First, download the latest JMX exporter jar file from the following location: prometheus/jmx_exporter.

Use the jar for your sample application

The example commands in the following sections use `SampleJavaApplication-1.0-SNAPSHOT.jar` as the jar file. Replace these parts of the commands with the jar for your application.

Prepare the JMX exporter configuration

The `config.yaml` file is the JMX exporter configuration file. For more information, see Configuration in the JMX exporter documentation.

Here is a sample configuration for Java and Tomcat.

```
---
lowercaseOutputName: true
lowercaseOutputLabelNames: true

- pattern: ".*"
```

Start the Java application with the Prometheus exporter

Start the sample application. This will emit Prometheus metrics to port 9404. Be sure to replace the entry point `com.gubupt.sample.app.App` with the correct information for your sample java application.

On Linux, enter the following command.

```
$ nohup java -javaagent:./jmx_prometheus_javaagent-0.14.0.jar=9404:./config.yaml -cp
  ./SampleJavaApplication-1.0-SNAPSHOT.jar com.gubupt.sample.app.App &
```

On Windows, enter the following command.

```
PS C:\> java -javaagent:.\jmx_prometheus_javaagent-0.14.0.jar=9404:.\config.yaml -cp  .
\SampleJavaApplication-1.0-SNAPSHOT.jar com.gubupt.sample.app.App
```

Verify the Prometheus metrics emission

Verify that Prometheus metrics are being emitted.

On Linux, enter the following command.

```
$ curl localhost:9404
```

On Windows, enter the following command.

```
PS C:\> curl  http://localhost:9404
```

Sample output on Linux:

```
StatusCode        : 200

```

Step 3: Configure the CloudWatch agent to scrape Prometheus metrics

Next, set up the Prometheus scrape configuration in the CloudWatch agent configuration file.

To set up the Prometheus scrape configuration for the Java/JMX example

1. Set up the configuration for `file_sd_config` and `static_config`.

   On Linux, enter the following command.

```
$ cat /opt/aws/amazon-cloudwatch-agent/var/prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: jmx
    sample_limit: 10000
    file_sd_configs:
      - files: [ "/opt/aws/amazon-cloudwatch-agent/var/prometheus_file_sd.yaml" ]
```

   On Windows, enter the following command.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: jmx
    sample_limit: 10000
    file_sd_configs:
      - files: [ "C:\\ProgramData\\Amazon\\AmazonCloudWatchAgent\
\prometheus_file_sd.yaml" ]
```

2. Set up the scrape targets configuration.

   On Linux, enter the following command.

```
$ cat /opt/aws/amazon-cloudwatch-agent/var/prometheus_file_sd.yaml
```

```
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
    os: linux
```

On Windows, enter the following command.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_file_sd.yaml
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
    os: windows
```

3. Set up the Prometheus scrape configuration by `ec2_sc_config`. Replace *`your-ec2-instance-id`* with the correct EC2 instance ID.

   On Linux, enter the following command.

```
$ cat .\prometheus.yaml
global:
  scrape_interval: 1m
  scrape_timeout: 10s
scrape_configs:
  - job_name: jmx
    sample_limit: 10000
    ec2_sd_configs:
      - region: us-east-1
        port: 9404
        filters:
          - name: instance-id
            values:
              - your-ec2-instance-id
```

   On Windows, enter the following command.

```
PS C:\ProgramData\Amazon\AmazonCloudWatchAgent> cat prometheus_file_sd.yaml
- targets:
  - 127.0.0.1:9404
  labels:
    application: sample_java_app
```

```
    os: windows
```

4. Set up the CloudWatch agent configuration. First, navigate to the correct directory. On Linux, it is `/opt/aws/amazon-cloudwatch-agent/var/cwagent-config.json`. On Windows, it is `C:\ProgramData\Amazon\AmazonCloudWatchAgent\cwagent-config.json`.

   The following is a sample configuration with Java/JHX Prometheus metrics defined. Be sure to replace *`path-to-Prometheus-Scrape-Configuration-file`* with the correct path.

```
{
  "agent": {
    "region": "us-east-1"
  },
  "logs": {
    "metrics_collected": {
      "prometheus": {
        "cluster_name": "my-cluster",
        "log_group_name": "prometheus-test",
        "prometheus_config_path": "path-to-Prometheus-Scrape-Configuration-file",
        "emf_processor": {
          "metric_declaration_dedup": true,
          "metric_namespace": "PrometheusTest",
          "metric_unit":{
            "jvm_threads_current": "Count",
            "jvm_classes_loaded": "Count",
            "java_lang_operatingsystem_freephysicalmemorysize": "Bytes",
            "catalina_manager_activesessions": "Count",
            "jvm_gc_collection_seconds_sum": "Seconds",
            "catalina_globalrequestprocessor_bytesreceived": "Bytes",
            "jvm_memory_bytes_used": "Bytes",
            "jvm_memory_pool_bytes_used": "Bytes"
          },
          "metric_declaration": [
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["instance"]],
              "metric_selectors": [
                "^jvm_threads_current$",
                "^jvm_classes_loaded$",
                "^java_lang_operatingsystem_freephysicalmemorysize$",
                "^catalina_manager_activesessions$",
                "^jvm_gc_collection_seconds_sum$",
```

```
                "^catalina_globalrequestprocessor_bytesreceived$"
              ]
            },
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["area"]],
              "metric_selectors": [
                "^jvm_memory_bytes_used$"
              ]
            },
            {
              "source_labels": ["job"],
              "label_matcher": "^jmx$",
              "dimensions": [["pool"]],
              "metric_selectors": [
                "^jvm_memory_pool_bytes_used$"
              ]
            }
          ]
        }
      }
    },
    "force_flush_interval": 5
  }
}
```

5. Restart the CloudWatch agent by entering one of the following commands.

   On Linux, enter the following command.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m ec2 -s -c file:/opt/aws/amazon-cloudwatch-agent/var/cwagent-config.json
```

   On Windows, enter the following command.

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1"
 -a fetch-config -m ec2 -s -c file:C:\ProgramData\Amazon\AmazonCloudWatchAgent
\cwagent-config.json
```

Viewing the Prometheus metrics and logs

You can now view the Java/JMX metrics being collected.

To view the metrics for your sample Java/JMX workload

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the Region where your cluster is running, choose **Metrics** in the left navigation pane. Find the **PrometheusTest** namespace to see the metrics.
3. To see the CloudWatch Logs events, choose **Log groups** in the navigation pane. The events are in the log group **prometheus-test**.

Configure CloudWatch agent service and environment names for related entities

The CloudWatch agent can send metrics and logs with entity data to support the Explore related pane in the CloudWatch console. The service name or environment name can be configured by the CloudWatch Agent JSON configuration.

> **Note**
>
> The agent configuration may be overridden. For details about how the agent decides what data to send for related entities, see Using the CloudWatch agent with related telemetry.

For metrics, it can be configured at the agent, metrics, or plugin level. For logs it can be configured at the agent, logs, or file level. The most specific configuration is always used. For example if the configuration exists at the agent level and metrics level, then metrics will use the metric configuration, and anything else (logs) will use the agent configuration. The following example shows different ways to configure the service name and environment name.

```
{
  "agent": {
    "service.name": "agent-level-service",
    "deployment.environment": "agent-level-environment"
  },

  "metrics": {
    "service.name": "metric-level-service",
     "deployment.environment": "metric-level-environment",
```

```
    "metrics_collected": {
      "statsd": {
        "service.name": "statsd-level-service",
        "deployment.environment": "statsd-level-environment",
      },
      "collectd": {
        "service.name": "collectdd-level-service",
        "deployment.environment": "collectd-level-environment",
      }
    }

  },

  "logs": {
    "service.name": "log-level-service",
    "deployment.environment": "log-level-environment",

    "logs_collected": {
      "files": {
        "collect_list": [
          {
            "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-
agent.log",
            "log_group_name": "amazon-cloudwatch-agent.log",
            "log_stream_name": "amazon-cloudwatch-agent.log",

            "service.name": "file-level-service",
            "deployment.environment": "file-level-environment"
          }
        ]
      }
    }

  }
}
```

Install the CloudWatch agent with the Amazon CloudWatch Observability EKS add-on or the Helm chart

You can use either the Amazon CloudWatch Observability EKS add-on or the Amazon CloudWatch Observability Helm chart to install the CloudWatch Agent and the Fluent-bit agent on an Amazon

EKS cluster. You can also use the Helm chart to install the CloudWatch Agent and the Fluent-bit agent on a Kubernetes cluster that is not hosted on Amazon EKS.

Using either method on an Amazon EKS cluster enables both Container Insights with enhanced observability for Amazon EKS and CloudWatch Application Signals by default. Both features help you to collect infrastructure metrics, application performance telemetry, and container logs from the cluster.

With Container Insights with enhanced observability for Amazon EKS, Container Insights metrics are charged per observation instead of being charged per metric stored or log ingested. For Application Signals, billing is based on inbound requests to your applications, outbound requests from your applications, and each configured service level objective (SLO). Each inbound request received generates one application signal, and each outbound request made generates one application signal. Every SLO creates two application signals per measurement period. For more information about CloudWatch pricing, see Amazon CloudWatch Pricing.

Both methods enable Container Insights on both Linux and Windows worker nodes in the Amazon EKS cluster. To enable Container Insights on Windows, you must use version 1.5.0 or later of the Amazon EKS add-on or the Helm chart. Currently, Application Signals is not supported on Windows in Amazon EKS clusters.

The Amazon CloudWatch Observability EKS add-on is supported on Amazon EKS clusters running with Kubernetes version 1.23 or later.

When you install the add-on or the Helm chart, you must also grant IAM permissions to enable the CloudWatch agent to send metrics, logs, and traces to CloudWatch. There are two ways to do this:

- Attach a policy to the IAM role of your worker nodes. This option grants permissions to worker nodes to send telemetry to CloudWatch.
- Use an IAM role for service accounts for the agent pods, and attach the policy to this role. This works only for Amazon EKS clusters. This option gives CloudWatch access only to the appropriate agent pods.

Option 1: Install using EKS Pod Identity

If you use version 3.1.0 or later of the add-on, you can use EKS Pod Identity to grant the required permissions to the add-on. EKS Pod Identity is the recommended option and provides benefits such as least privilege, credential rotation, and auditability. Additionally, using EKS Pod Identity allows you to install the EKS add-on as part of the cluster creation itself.

To use this method, first follow the EKS Pod Identity association steps to create the IAM role and set up the EKS Pod Identity agent.

Then install the Amazon CloudWatch Observability EKS add-on. To install the add-on, you can use the Amazon CLI, the Amazon EKS console, Amazon CloudFormation, or Terraform.

Amazon CLI

To use the Amazon CLI to install the Amazon CloudWatch Observability EKS add-on

Enter the following commands. Replace *my-cluster-name* with the name of your cluster and replace *111122223333* with your account ID. Replace *my-role* with the IAM role that you created in the EKS Pod Identity association step.

```
aws iam attach-role-policy \
--role-name my-role \
--policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy

aws eks create-addon \
--addon-name amazon-cloudwatch-observability \
--cluster-name my-cluster-name \
--pod-identity-associations serviceAccount=cloudwatch-
agent,roleArn=arn:aws:iam::111122223333:role/my-role
```

Amazon EKS console

To use the Amazon EKS console to add the Amazon CloudWatch Observability EKS add-on

1. Open the Amazon EKS console at https://console.amazonaws.cn/eks/home#/clusters.
2. In the left navigation pane, choose **Clusters**.
3. Choose the name of the cluster that you want to configure the Amazon CloudWatch Observability EKS add-on for.
4. Choose the **Add-ons** tab.
5. Choose **Get more add-ons**.
6. On the **Select add-ons** page, do the following:
    a. In the **Amazon EKS-addons** section, select the **Amazon CloudWatch Observability** check box.
    b. Choose **Next**.

7. On the **Configure selected add-ons settings** page, do the following:

   a. Select the **Version** you'd like to use.

   b. For **Add-on access**, select **EKS Pod Identity**

   c. If you don't have an IAM role configured, choose **Create recommended role**, then choose **Next** until you are at **Step 3 Name, review, and create**. You can change your role name if desired, otherwise, choose **Create Role**, and then return to the Add-on page and select the IAM role that you just created.

   d. (Optional) You can expand the **Optional configuration settings**. If you select **Override** for the **Conflict resolution method**, one or more of the settings for the existing add-on can be overwritten with the Amazon EKS add-on settings. If you don't enable this option and there's a conflict with your existing settings, the operation fails. You can use the resulting error message to troubleshoot the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage.

   e. Choose **Next**.

8. On the **Review and add** page, choose **Create**. After the add-on installation is complete, you see your installed add-on.

Amazon CloudFormation

To use Amazon CloudFormation to install the Amazon CloudWatch Observability EKS add-on

1. First, run the following Amazon CLI command to attach the necessary IAM policy to your IAM role. Replace *my-role* with the role that you created in the EKS Pod Identity association step.

```
aws iam attach-role-policy \
--role-name my-role \
--policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

2. Then create the following resource. Replace *my-cluster-name* with the name of your cluster, replace *111122223333* with your account ID, and replace *my-role* with the IAM role created in EKS Pod Identity association step. For more information, see AWS::EKS::Addon.

```
{
    "Resources": {
        "EKSAddOn": {
            "Type": "AWS::EKS::Addon",
            "Properties": {
                "AddonName": "amazon-cloudwatch-observability",
                "ClusterName": "my-cluster-name",
                "PodIdentityAssociations": [
                    {
                        "ServiceAccount": "cloudwatch-agent",
                        "RoleArn": "arn:aws:iam::111122223333:role/my-role"
                    }
                ]
            }
        }
    }
}
```

Terraform

To use Terraform to install the Amazon CloudWatch Observability EKS add-on

1. Use the following. Replace *my-cluster-name* with the name of your cluster, replace *111122223333* with your account ID, and replace *my-service-account-role* with the IAM role created in EKS Pod Identity association step.

   For more information, see [Resource: aws_eks_addon](#) in the Terraform documentation.

2.
```
resource "aws_iam_role_policy_attachment" "CloudWatchAgentServerPolicy" {
  policy_arn = "arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy"
  role       = "my-role"
}

resource "aws_eks_addon" "example" {
  cluster_name = "my-cluster-name"
  addon_name   = "amazon-cloudwatch-observability"
  pod_identity_associations {
      roleArn = "arn:aws:iam::111122223333:role/my-role"
      serviceAccount = "cloudwatch-agent"
  }
}
```

Option 2: Install with IAM permissions on worker nodes

To use this method, first attach the **CloudWatchAgentServerPolicy** IAM policy to your worker nodes by entering the following command. In this command, replace *my-worker-node-role* with the IAM role used by your Kubernetes worker nodes.

```
aws iam attach-role-policy \
--role-name my-worker-node-role \
--policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
```

Then install the Amazon CloudWatch Observability EKS add-on. To install the add-on, you can use the Amazon CLI, the console, Amazon CloudFormation, or Terraform.

Amazon CLI

To use the Amazon CLI to install the Amazon CloudWatch Observability EKS add-on

Enter the following command. Replace *my-cluster-name* with the name of your cluster.

```
aws eks create-addon --addon-name amazon-cloudwatch-observability --cluster-name my-cluster-name
```

Amazon EKS console

To use the Amazon EKS console to add the Amazon CloudWatch Observability EKS add-on

1. Open the Amazon EKS console at https://console.amazonaws.cn/eks/home#/clusters.
2. In the left navigation pane, choose **Clusters**.
3. Choose the name of the cluster that you want to configure the Amazon CloudWatch Observability EKS add-on for.
4. Choose the **Add-ons** tab.
5. Choose **Get more add-ons**.
6. On the **Select add-ons** page, do the following:
   a. In the **Amazon EKS-addons** section, select the **Amazon CloudWatch Observability** check box.
   b. Choose **Next**.
7. On the **Configure selected add-ons settings** page, do the following:

   a. Select the **Version** you'd like to use.
   b. (Optional) You can expand the **Optional configuration settings**. If you select **Override** for the **Conflict resolution method**, one or more of the settings for the existing add-on can be overwritten with the Amazon EKS add-on settings. If you don't enable this option and there's a conflict with your existing settings, the operation fails. You can use the resulting error message to troubleshoot the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage.
   c. Choose **Next**.

8. On the **Review and add** page, choose **Create**. After the add-on installation is complete, you see your installed add-on.

Amazon CloudFormation

To use Amazon CloudFormation to install the Amazon CloudWatch Observability EKS add-on

Replace *my-cluster-name* with the name of your cluster. For more information, see AWS::EKS::Addon.

```
{
    "Resources": {
        "EKSAddOn": {
            "Type": "AWS::EKS::Addon",
            "Properties": {
                "AddonName": "amazon-cloudwatch-observability",
                "ClusterName": "my-cluster-name"
            }
        }
    }
}
```

Helm chart

To use the `amazon-cloudwatch-observability` Helm chart

1. You must have Helm installed to use this chart. For more information about installing Helm, see the Helm documentation.

2. After you have installed Helm, enter the following commands. Replace *my-cluster-name* with the name of your cluster, and replace *my-cluster-region* with the Region that the cluster runs in.

```
helm repo add aws-observability https://aws-observability.github.io/helm-charts
helm repo update aws-observability
helm install --wait --create-namespace --namespace amazon-cloudwatch amazon-
cloudwatch-observability aws-observability/amazon-cloudwatch-observability --set
 clusterName=my-cluster-name --set region=my-cluster-region
```

Terraform

To use Terraform to install the Amazon CloudWatch Observability EKS add-on

Replace *my-cluster-name* with the name of your cluster. For more information, see [Resource: aws_eks_addon](#).

```
resource "aws_eks_addon" "example" {
  addon_name   = "amazon-cloudwatch-observability"
  cluster_name = "my-cluster-name"
}
```

Option 3: Install using IAM service account role (applies only to using the add-on)

This method is valid only if you are using the Amazon CloudWatch Observability EKS add-on. Before using this method, verify the following prerequisites:

- You have a functional Amazon EKS cluster with nodes attached in one of the Amazon Web Services Regions that supports Container Insights. For the list of supported Regions, see Container Insights.
- You have `kubectl` installed and configured for the cluster. For more information, see Installing `kubectl` in the *Amazon EKS User Guide*.
- You have `eksctl` installed. For more information, see Installing or updating `eksctl` in the *Amazon EKS User Guide*.

Amazon CLI

To use the Amazon CLI to install the Amazon CloudWatch Observability EKS add-on using the IAM service account role

1. Enter the following command to create an OpenID Connect (OIDC) provider, if the cluster doesn't have one already. For more information, see Configuring a Kubernetes service account to assume an IAM role in the *Amazon EKS User Guide*.

```
eksctl utils associate-iam-oidc-provider --cluster my-cluster-name --approve
```

2. Enter the following command to create the IAM role with the **CloudWatchAgentServerPolicy** policy attached, and configure the agent service account to assume that role using OIDC. Replace *my-cluster-name* with the name of your cluster, and replace *my-service-account-role* with the name of the role that you want to associate the service account with. If the role doesn't already exist, `eksctl` creates it for you.

```
eksctl create iamserviceaccount \
  --name cloudwatch-agent \
  --namespace amazon-cloudwatch --cluster my-cluster-name \
  --role-name my-service-account-role \
  --attach-policy-arn arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy \
  --role-only \
  --approve
```

3. Install the add-on by entering the following command. Replace *my-cluster-name* with the name of your cluster, replace *111122223333* with your account ID, and replace *my-service-account-role* with the IAM role created in the previous step.

```
aws eks create-addon --addon-name amazon-cloudwatch-observability
 --cluster-name my-cluster-name --service-account-role-arn
 arn:aws:iam::111122223333:role/my-service-account-role
```

Amazon EKS console

To use the console to install the Amazon CloudWatch Observability EKS add-on using the IAM service account role

1. Open the Amazon EKS console at https://console.amazonaws.cn/eks/home#/clusters.
2. In the left navigation pane, choose **Clusters**.
3. Choose the name of the cluster that you want to configure the Amazon CloudWatch Observability EKS add-on for.
4. Choose the **Add-ons** tab.
5. Choose **Get more add-ons**.
6. On the **Select add-ons** page, do the following:

   a. In the **Amazon EKS-addons** section, select the **Amazon CloudWatch Observability** check box.

   b. Choose **Next**.
7. On the **Configure selected add-ons settings** page, do the following:

   a. Select the **Version** you'd like to use.

   b. For **Add-on access**, select **IAM roles for service accounts (IRSA)**

   c. Select the IAM role in the **Add-on access** box.

   d. (Optional) You can expand the **Optional configuration settings**. If you select **Override** for the **Conflict resolution method**, one or more of the settings for the existing add-on can be overwritten with the Amazon EKS add-on settings. If you don't enable this option and there's a conflict with your existing settings, the operation fails. You can use the resulting error message to troubleshoot the conflict. Before selecting this option, make sure that the Amazon EKS add-on doesn't manage settings that you need to self-manage.

   e. Choose **Next**.
8. On the **Review and add** page, choose **Create**. After the add-on installation is complete, you see your installed add-on.

Considerations for Amazon EKS Hybrid Nodes

Node-level metrics aren't available for hybrid nodes because Container Insights depends on the availability of the EC2 Instance Metadata Service (IMDS) for node-level metrics. Cluster, workload, Pod, and container-level metrics are available for hybrid nodes.

After you install the add-on by following the steps in the previous sections, you must update the add-on manifest so that the agent can run successfully on hybrid nodes. Edit the `amazoncloudwatchagents` resource in the cluster to add the `RUN_WITH_IRSA` environment variable to match the following.

```
kubectl edit amazoncloudwatchagents -n amazon-cloudwatch cloudwatch-agent
```

```
apiVersion: v1
       items:
       - apiVersion: cloudwatch.aws.amazon.com/v1alpha1
         kind: AmazonCloudWatchAgent
         metadata:
           ...
           name: cloudwatch-agent
           namespace: amazon-cloudwatch
           ...
         spec:
           ...
           env:
           - name: RUN_WITH_IRSA # <-- Add this
             value: "True" # <-- Add this
           - name: K8S_NODE_NAME
             valueFrom:
               fieldRef:
                 fieldPath: spec.nodeName
                 ...
```

(Optional) Additional configuration

Topics

- Opt out of collecting container logs
- Use a custom Fluent Bit configuration
- Manage Kubernetes tolerations for the installed pod workloads

- Opt out of accelerated compute metrics collection
- Use a custom CloudWatch agent configuration
- Manage admission webhook TLS certificates
- Collect Amazon EBS volume IDs

Opt out of collecting container logs

By default, the add-on uses Fluent Bit to collect container logs from all pods and then sends the logs to CloudWatch Logs. For information about which logs are collected, see Setting up Fluent Bit.

> **Note**
>
> Neither the add-on or the Helm chart manage existing Fluentd or Fluent Bit resources in a cluster. You can delete the existing Fluentd or Fluent Bit resources before installing the add-on or Helm chart. Alternatively, to keep your existing setup and avoid having the add-on or the Helm chart from also installing Fluent Bit, you can disable it by following the instructions in this section.

To opt out of the collection of container logs if you are using the Amazon CloudWatch Observability EKS add-on, pass the following option when you create or update the add-on:

```
--configuration-values '{ "containerLogs": { "enabled": false } }'
```

To opt out of the collection of container logs if you are using the Helm chart, pass the following option when you create or update the add-on:

```
--set containerLogs.enabled=false
```

Use a custom Fluent Bit configuration

Starting with version 1.7.0 of the Amazon CloudWatch Observability EKS add-on, you can modify the Fluent Bit configuration when you create or update the add-on or Helm chart. You supply the custom Fluent Bit configuration in the `containerLogs` root level section of the advanced configuration of the add-on or the value overrides in the Helm chart. Within this section, you supply the custom Fluent Bit configuration in the `config` section (for Linux) or `configWindows` section (for Windows). The `config` is further broken down into the following sub-sections:

- `service`– This section represents the `SERVICE` config to define the global behavior of the Fluent Bit engine.
- `customParsers`– This section represents any global `PARSER`s that you want to include that are capable of taking unstructured log entries and giving them a structure to make it easier for processing and further filtering.
- `extraFiles`– This section can be used to provide additional Fluent Bit `conf` files to be included. By default, the following 3 `conf` files are included:.
  - `application-log.conf`– A `conf` file for sending application logs from your cluster to the log group `/aws/containerinsights/my-cluster-name/application` in CloudWatch Logs.
  - `dataplane-log.conf`– A `conf` file for sending logs corresponding to your cluster's data plane components including the CRI logs, kubelet logs, kube-proxy logs and Amazon VPC CNI logs to the log group `/aws/containerinsights/my-cluster-name/dataplane` in CloudWatch Logs.
  - `host-log.conf`– A `conf` for sending logs from `/var/log/dmesg`, `/var/log/messages`, and `/var/log/secure` on Linux, and System `winlogs` on Windows, to the log group `/aws/containerinsights/my-cluster-name/host` in CloudWatch.

Note

Provide the full configuration for each of these individual sections even if you are modifying only one field within a sub-section. We recommend that you use the default configuration provided below as a baseline and then modify it accordingly so that you don't disable functionality that is enabled by default. You can use the following YAML configuration when modifying the advanced config for the Amazon EKS add-on or when you supply value overrides for the Helm chart.

To find the `config` section for your cluster, see aws-observability / helm-charts on GitHub and find the release corresponding to the version of the add-on or Helm chart that you are installing. Then navigate to `/charts/amazon-cloudwatch-observability/values.yaml` to find the `config` section (for Linux) and `configWindows` section (for Windows) within the `fluentBit` section under `containerLogs`.

As an example, the default Fluent Bit configuration for version 1.7.0 can be found here.

We recommend that you provide the `config` as YAML when you supply it using the Amazon EKS add-on's advanced config or when you supply it as value overrides for your Helm installation. Be sure that the YAML conforms to the following structure.

```
containerLogs:
  fluentBit:
    config:
      service: |
        ...
      customParsers: |
        ...
      extraFiles:
        application-log.conf: |
          ...
        dataplane-log.conf: |
          ...
        host-log.conf: |
          ...
```

The following example `config` changes the global setting for the flush interval to be 45 seconds. Even though the only modification is to the `Flush` field, you must still provide the full `SERVICE` definition for the service sub-section. Because this example didn't specify overrides for the other sub-sections, the defaults are used for them.

```
containerLogs:
  fluentBit:
    config:
      service: |
        [SERVICE]
          Flush                     45
          Grace                     30
          Log_Level                 error
          Daemon                    off
          Parsers_File              parsers.conf
          storage.path              /var/fluent-bit/state/flb-storage/
          storage.sync              normal
          storage.checksum          off
          storage.backlog.mem_limit 5M
```

The following example configuration includes an extra Fluent bit `conf` file. In this example, we are adding a custom `my-service.conf` under `extraFiles` and it will be included in addition to the three default `extraFiles`.

```
containerLogs:
  fluentBit:
    config:
      extraFiles:
        my-service.conf: |
          [INPUT]
            Name                tail
            Tag                 myservice.*
            Path                /var/log/containers/*myservice*.log
            DB                  /var/fluent-bit/state/flb_myservice.db
            Mem_Buf_Limit       5MB
            Skip_Long_Lines     On
            Ignore_Older        1d
            Refresh_Interval    10

          [OUTPUT]
            Name                  cloudwatch_logs
            Match                 myservice.*
            region                ${AWS_REGION}
            log_group_name        /aws/containerinsights/${CLUSTER_NAME}/myservice
            log_stream_prefix     ${HOST_NAME}-
            auto_create_group     true
```

The next example removes an existing `conf` file entirely from `extraFiles`. This excludes the `application-log.conf` entirely by overriding it with an empty string. Simply omitting `application-log.conf` from `extraFiles` would instead imply to use the default, which is not what we are trying to achieve in this example. The same applies to removing any custom `conf` file that you might have previously added to `extraFiles`.

```
containerLogs:
  fluentBit:
    config:
      extraFiles:
        application-log.conf: ""
```

Manage Kubernetes tolerations for the installed pod workloads

Starting with version 1.7.0 of the Amazon CloudWatch Observability EKS add-on, the add-on and the Helm chart by default set Kubernetes *tolerations* to tolerate all taints on the pod workloads that are installed by the add-on or the Helm chart. This ensures that daemonsets such as the CloudWatch agent and Fluent Bit can schedule pods on all nodes in your cluster by default. For more information about tolerations and taints, see Taints and Tolerations in the Kubernetes documentation.

The default tolerations set by the add-on or the Helm chart are as follows:

```
tolerations:
- operator: Exists
```

You can override the default tolerations by setting the `tolerations` field at the root level when using the add-on advanced config or when you install or upgrade the Helm chart with value overrides. An example would look like the following:

```
tolerations:
- key: "key1"
  operator: "Exists"
  effect: "NoSchedule"
```

To omit tolerations completely, you can use a config that looks like the following:

```
tolerations: []
```

Any changes to tolerations apply to all pod workloads that are installed by the add-on or the Helm chart.

Opt out of accelerated compute metrics collection

By default, Container Insights with enhanced observability collects metrics for Accelerated Compute monitoring, including NVIDIA GPU metrics, Amazon Neuron metrics for Amazon Trainium and Amazon Inferentia, and Amazon Elastic Fabric Adapter (EFA) metrics.

NVIDIA GPU metrics from Amazon EKS workloads are collected by default beginning with version `v1.3.0-eksbuild.1` of the EKS add-on or the Helm chart and version `1.300034.0` of the CloudWatch agent. For a list of metrics collected and prerequisites, see NVIDIA GPU metrics.

Amazon Neuron metrics for Amazon Trainium and Amazon Inferentia accelerators are collected by default beginning with version `v1.5.0-eksbuild.1` of the EKS add-on or the Helm chart, and version `1.300036.0` of the CloudWatch agent. For a list of metrics collected and prerequisites, see Amazon Neuron metrics for Amazon Trainium and Amazon Inferentia .

Amazon Elastic Fabric Adapter (EFA) metrics from Linux nodes on Amazon EKS clusters are collected by default beginning with version `v1.5.2-eksbuild.1` of the EKS add-on or the Helm chart and version `1.300037.0` of the CloudWatch agent. For a list of metrics collected and prerequisites, see Amazon Elastic Fabric Adapter (EFA) metrics .

You can opt out of collecting these metrics by setting the `accelerated_compute_metrics` field in the CloudWatch agent configuration file to `false`. This field is in the `kubernetes` section of the `metrics_collected` section in the CloudWatch configuration file. The following is an example of an opt-out configuration. For more information about how to use custom CloudWatch agent configurations, see the following section, Use a custom CloudWatch agent configuration.

```
{
  "logs": {
    "metrics_collected": {
      "kubernetes": {
        "enhanced_container_insights": true,
        "accelerated_compute_metrics": false
      }
    }
  }
}
```

Use a custom CloudWatch agent configuration

To collect other metrics, logs or traces using the CloudWatch agent, you can specify a custom configuration while also keeping Container Insights and CloudWatch Application Signals enabled. To do so, embed the CloudWatch agent configuration file within the config key under the agent key of the advanced configuration that you can use when creating or updating the EKS add-on or the Helm chart. The following represents the default agent configuration when you do not provide any additional configuration.

> **Important**
>
> Any custom configuration that you provide using additional configuration settings overrides the default configuration used by the agent. Be cautious not to unintentionally

disable functionality that is enabled by default, such as Container Insights with enhanced observability and CloudWatch Application Signals. In the scenario that you are required to provide a custom agent configuration, we recommend using the following default configuration as a baseline and then modifying it accordingly.

- For using the Amazon CloudWatch observability EKS add-on

```
--configuration-values '{
  "agent": {
    "config": {
      "logs": {
        "metrics_collected": {
          "application_signals": {},
          "kubernetes": {
            "enhanced_container_insights": true
          }
        }
      },
      "traces": {
        "traces_collected": {
          "application_signals": {}
        }
      }
    }

}'
```

- For using the Helm chart

```
--set agent.config='{
  "logs": {
    "metrics_collected": {
      "application_signals": {},
      "kubernetes": {
        "enhanced_container_insights": true
      }
    }
  },
  "traces": {
    "traces_collected": {
      "application_signals": {}
```

```
    }
  }
}'
```

The following example shows the default agent configuration for the CloudWatch agent on Windows. The CloudWatch agent on Windows does not support custom configuration.

```
{
  "logs": {
    "metrics_collected": {
      "kubernetes": {
        "enhanced_container_insights": true
      },
    }
  }
}
```

Manage admission webhook TLS certificates

The Amazon CloudWatch Observability EKS add-on and the Helm chart leverage Kubernetes admission webhooks to validate and mutate `AmazonCloudWatchAgent` and `Instrumentation` custom resource (CR) requests, and optionally Kubernetes pod requests on the cluster if CloudWatch Application Signals is enabled. In Kubernetes, webhooks require a TLS certificate that the API server is configured to trust in order to ensure secure communication.

By default, the Amazon CloudWatch Observability EKS add-on and the Helm chart auto-generate a self-signed CA and a TLS certificate signed by this CA for securing the communication between the API server and the webhook server. This auto-generated certificate has a default expiry of 10 years and is not auto-renewed upon expiry. In addition, the CA bundle and the certificate are re-generated every time the add-on or Helm chart is upgraded or re-installed, thus resetting the expiry. If you want to change the default expiry of the auto-generated certificate, you can use the following additional configurations when creating or updating the add-on. Replace *`expiry-in-days`* with your desired expiry duration in days.

- Use this for the Amazon CloudWatch Observability EKS add-on

```
--configuration-values '{ "admissionWebhooks": { "autoGenerateCert":
 { "expiryDays": expiry-in-days } } }'
```

- Use this for the Helm chart

```
--set admissionWebhooks.autoGenerateCert.expiryDays=expiry-in-days
```

For a more secure and feature-rich certificate authority solution, the add-on has opt-in support for cert-manager, a widely-adopted solution for TLS certificate management in Kubernetes that simplifies the process of obtaining, renewing, managing and using those certificates. It ensures that certificates are valid and up to date, and attempts to renew certificates at a configured time before expiry. cert-manager also facilitates issuing certificates from a variety of supported sources, including Amazon Certificate Manager Private Certificate Authority.

We recommend that you review best practices for management of TLS certificates on your clusters and advise you to opt in to cert-manager for production environments. Note that if you opt-in to enabling cert-manager for managing the admission webhook TLS certificates, you are required to pre-install cert-manager on your Amazon EKS cluster before you install the Amazon CloudWatch Observability EKS add-on or the Helm chart. For more information about available installation options, see cert-manager documentation. After you install it, you can opt in to using cert-manager for managing the admission webhook TLS certificates using the following additional configuration.

- If you are using the Amazon CloudWatch Observability EKS add-on

  ```
  --configuration-values '{ "admissionWebhooks": { "certManager": { "enabled":
   true } } }'
  ```

- If you are using the Helm chart

  ```
  --set admissionWebhooks.certManager.enabled=true
  ```

```
--configuration-values '{ "admissionWebhooks": { "certManager": { "enabled":
 true } } }'
```

The advanced configuration discussed in this section will by default use a SelfSigned issuer.

Collect Amazon EBS volume IDs

If you want to collect Amazon EBS volume IDs in the performance logs, you must add another policy to the IAM role that is attached to the worker nodes or to the service account. Add the following as an inline policy. For more information, see [Adding and Removing IAM Identity Permissions](#).

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ec2:DescribeVolumes"
            ],
            "Resource": "*",
            "Effect": "Allow"
        }
    ]
}
```

Troubleshooting the Amazon CloudWatch Observability EKS add-on or the Helm chart

Use the following information to help troubleshoot problems with the Amazon CloudWatch Observability EKS add-on or the Helm chart

Topics

Updating and deleting the Amazon CloudWatch Observability EKS add-on or the Helm chart

For instructions about updating or deleting the Amazon CloudWatch Observability EKS add-on, see Managing Amazon EKS add-ons. Use `amazon-cloudwatch-observability` as the name of the add-on.

To delete the Helm chart in a cluster, enter the following command.

```
helm delete amazon-cloudwatch-observability -n amazon-cloudwatch --wait
```

Verify the version of the CloudWatch agent used by the Amazon CloudWatch Observability EKS add-on or the Helm chart

The Amazon CloudWatch Observability EKS add-on and the Helm chart installs a custom resource of kind `AmazonCloudWatchAgent` that controls the behavior of the CloudWatch agent daemonset on the cluster, including the version of the CloudWatch agent being used. You can get a list of all the `AmazonCloudWatchAgent` custom resources installed on your cluster u by entering the following command:

```
kubectl get amazoncloudwatchagent -A
```

In the output of this command, you should be able to check the version of the CloudWatch agent. Alternatively, you can also describe the `amazoncloudwatchagent` resource or one of the `cloudwatch-agent-*` pods running on your cluster to inspect the image being used.

Handling a ConfigurationConflict when managing the add-on or the Helm chart

When you install or update the Amazon CloudWatch Observability EKS add-on or the Helm chart, if you notice a failure caused by existing resources, it is likely because you already have the CloudWatch agent and its associated components such as the ServiceAccount, the ClusterRole and the ClusterRoleBinding installed on the cluster.

The error displayed by the add-on will include `Conflicts found when trying to apply. Will not continue due to resolve conflicts mode`,

The error displayed by the Helm chart will be similar to `Error: INSTALLATION FAILED: Unable to continue with install and invalid ownership metadata.`.

When the add-on or the Helm chart tries to install the CloudWatch agent and its associated components, if it detects any change in the contents, it by default fails the installation or update to avoid overwriting the state of the resources on the cluster.

If you are trying to onboard to the Amazon CloudWatch Observability EKS add-on and you see this failure, we recommend deleting an existing CloudWatch agent setup that you had previously installed on the cluster and then installing the EKS add-on or Helm chart. Be sure to back up any customizations you might have made to the original CloudWatch agent setup such as a custom agent configuration, and provide these to the add-on or Helm chart when you next install or update it. If you had previously installed the CloudWatch agent for onboarding to Container Insights, see Deleting the CloudWatch agent and Fluent Bit for Container Insights for more information.

Alternatively, the add-on supports a conflict resolution configuration option that has the capability to specify `OVERWRITE`. You can use this option to proceed with installing or updating the add-on by overwriting the conflicts on the cluster. If you are using the Amazon EKS console, you'll find the **Conflict resolution method** when you choose the **Optional configuration settings** when you create or update the add-on. If you are using the Amazon CLI, you can supply the `--resolve-conflicts OVERWRITE` to your command to create or update the add-on.

Collect Java Management Extensions (JMX) metrics

The CloudWatch agent supports Java Management Extensions (JMX) metrics collection on Amazon EKS. This allows you to collect additional metrics from Java applications running on Amazon EKS clusters enabling insight into performance, memory usage, traffic, and other critical metrics. For more information, see Collect Java Management Extensions (JMX) metrics.

Enable Kueue metrics

Beginning with version `v2.4.0-eksbuild.1` of the the CloudWatch Observability EKS add-on, Container Insights for Amazon EKS supports collecting Kueue metrics from Amazon EKS clusters. For more information about these metrics, see Kueue metrics .

If you are using the Amazon SageMaker AI Hyperpod Task Governance EKS add-on, you can skip the steps in the **Prerequisites** section and just follow the steps in Enable the configuration flag.

Prerequisites

Before you install Kueue in your Amazon EKS cluster, make the following updates in the manifest file:

1. Enable the optional cluster queue resource metrics for Kueue. To do this, modify the in-line `controller_manager_config.yaml` in the `kueue-system` ConfigMap. In the `metrics` section, add or uncomment the line `enableClusterQueueResources: true`.

```
apiVersion: v1
data:
  controller_manager_config.yaml: |
    apiVersion: config.kueue.x-k8s.io/v1beta1
```

```
    kind: Configuration
    health:
      healthProbeBindAddress: :8081
    metrics:
      bindAddress: :8080
      enableClusterQueueResources: true  <-- ADD/UNCOMMENT THIS LINE
```

2. By default, all `k8s` services are available cluster-wide. Kueue creates a service `kueue-controller-manager-metrics-service` for exposing metrics. To prevent duplicate observations for metrics, modify this service to allow access only to the metrics service from the same node. To do this, add the line `internalTrafficPolicy: Local` to the `kueue-controller-manager-metrics-service` definition.

```
apiVersion: v1
kind: Service
metadata:
  labels:
    ...
  name: kueue-controller-manager-metrics-service
  namespace: kueue-system
spec:
  ports:
  - name: https
    port: 8443
    protocol: TCP
    targetPort: https
  internalTrafficPolicy: Local   <-- ADD THIS LINE
  selector:
    control-plane: controller-manager
```

3. Lastly, the `kueue-controller-manager` pod creates a `kube-rbac-proxy` container. This container currently has a high level of logging verbosity, which causes the cluster's bearer token to be logged by that container when the metrics scraper accesses the `kueue-controller-manager-metrics-service`. We recommend that you decrease this logging verbosity. The default value in the manifest distributed by Kueue is 10, we recommend to change it to 0.

```
apiVersion: apps/v1
kind: Deployment
metadata:
  labels:
    ...
  name: kueue-controller-manager
```

```
  namespace: kueue-system
spec:
  ...
  template:
    ...
    spec:
      containers:
      ...
      - args:
        - --secure-listen-address=0.0.0.0:8443
        - --upstream=http://127.0.0.1:8080/
        - --logtostderr=true
        - --v=0  <-- CHANGE v=10 TO v=0
        image: gcr.io/kubebuilder/kube-rbac-proxy:v0.8.0
        name: kube-rbac-proxy
        ...
```

Enable the configuration flag

To enable the Kueue metrics, you must enable `kueue_container_insights` in the add-on additional configuration. You can do this either by using the Amazon CLI to set up the EKS Observability add-on, or by using the Amazon EKS console.

After you have successfully installed the EKS Observability add-on with one of the following methods, you can view your Amazon EKS cluster metrics under the HyperPod console **Dashboard** tab.

Amazon CLI

To enable Kueue metrics using the Amazon CLI

- Enter the following Amazon CLI command to install the add-on.

  ```
  aws eks create-addon --cluster-name cluster-name --addon-name amazon-cloudwatch-observability --configuration-values "configuration_json_file"
  ```

  The following is an example of the JSON file with the configuration values.

  ```
  {
      "agent": {
          "config": {
  ```

```
            "logs": {
                "metrics_collected": {
                    "kubernetes": {
                        "kueue_container_insights": true,
                        "enhanced_container_insights": true
                    },
                    "application_signals": { }
                }
            },
            "traces": {
                "traces_collected": {
                    "application_signals": { }
                }
            }
        },
    },
}
```

Amazon EKS console

To enable Kueue metrics using the Amazon EKS console

1. Open the Amazon EKS console at https://console.amazonaws.cn/eks/home#/clusters.
2. Choose the name of your cluster.
3. Choose **Add-ons**.
4. Find the **Amazon CloudWatch Observability** add-on in the list, and install it. When you do so, choose **Optional configuration** and include the following JSON configuration values.

```
{
    "agent": {
        "config": {
            "logs": {
                "metrics_collected": {
                    "kubernetes": {
                        "kueue_container_insights": true,
                        "enhanced_container_insights": true
                    },
                    "application_signals": { }
                }
            },
            "traces": {
```

```
                "traces_collected": {
                    "application_signals": { }
                }
            }
        },
    },
}
```

Appending OpenTelemetry collector configuration files

The CloudWatch agent supports supplemental OpenTelemetry collector configuration files alongside its own configuration files. This feature allows you to use CloudWatch agent features such as CloudWatch Application Signals or Container Insights through the CloudWatch agent configuration and bring in your existing OpenTelemetry collector configuration with a single agent.

To prevent merge conflicts with pipelines automatically created by CloudWatch agent, we recommend that you add a custom suffix to each of the components and pipelines in your OpenTelemetry collector configuration. This will prevent clashing and merge conflicts.

- If you are using the Amazon CloudWatch Observability EKS add-on

  ```
  --configuration-values file://values.yaml
  ```

  or

  ```
  --configuration-values '
    agent:
      otelConfig:
        receivers:
          otlp/custom-suffix:
            protocols:
              http: {}
        exporters:
          awscloudwatchlogs/custom-suffix:
            log_group_name: "test-group"
            log_stream_name: "test-stream"
        service:
          pipelines:
            logs/custom-suffix:
              receivers: [otlp/custom-suffix]
  ```

```
            exporters: [awscloudwatchlogs/custom-suffix]
'
```

- If you are using the Helm chart

```
--set agent.otelConfig='
  receivers:
    otlp/custom-suffix:
      protocols:
        http: {}
  exporters:
    awscloudwatchlogs/custom-suffix:
      log_group_name: "test-group"
      log_stream_name: "test-stream"
  service:
    pipelines:
      logs/custom-suffix:
        receivers: [otlp/custom-suffix]
        exporters: [awscloudwatchlogs/custom-suffix]
'
```

Metrics collected by the CloudWatch agent

You can collect metrics from servers by installing the CloudWatch agent on the server. You can install the agent on both Amazon EC2 instances and on-premises servers. You can also install the agent on computers running Linux, Windows Server, or macOS. If you install the agent on an Amazon EC2 instance, the metrics the agent collects are in addition to the metrics enabled by default on Amazon EC2 instances. For information about installing the CloudWatch agent on an instance, see Collect metrics, logs, and traces with the CloudWatch agent. You can use this section to learn about metrics the CloudWatch agent collects.

Metrics collected by the CloudWatch agent on Windows Server instances

On a server running Windows Server, installing the CloudWatch agent enables you to collect the metrics associated with the counters in Windows Performance Monitor. The CloudWatch metric names for these counters are created by putting a space between the object name and the counter name. For example, the `% Interrupt Time` counter of the `Processor` object is given the metric name `Processor % Interrupt Time` in CloudWatch. For more information about Windows Performance Monitor counters, see the Microsoft Windows Server documentation.

The default namespace for metrics collected by the CloudWatch agent is `CWAgent`, although you can specify a different namespace when you configure the agent.

Metrics collected by the CloudWatch agent on Linux and macOS instances

The following table lists the metrics that you can collect with the CloudWatch agent on Linux servers and macOS computers.

Metric	Description
`cpu_time_active`	The amount of time that the CPU is active in any capacity. This metric is measured in hundredths of a second. Unit: None
`cpu_time_guest`	The amount of time that the CPU is running a virtual CPU for a guest operating system. This metric is measured in hundredths of a second. Unit: None
`cpu_time_guest_nice`	The amount of time that the CPU is running a virtual CPU for a guest operating system, which is low-priority and can be interrupted by other processes. This metric is measured in hundredths of a second. Unit: None
`cpu_time_idle`	The amount of time that the CPU is idle. This metric is measured in hundredths of a second. Unit: None

Metric	Description
`cpu_time_iowait`	The amount of time that the CPU is waiting for I/O operations to complete. This metric is measured in hundredths of a second. Unit: None
`cpu_time_irq`	The amount of time that the CPU is servicing interrupts. This metric is measured in hundredths of a second. Unit: None
`cpu_time_nice`	The amount of time that the CPU is in user mode with low-priority processes, which can easily be interrupted by higher-priority processes. This metric is measured in hundredths of a second. Unit: None
`cpu_time_softirq`	The amount of time that the CPU is servicing software interrupts. This metric is measured in hundredths of a second. Unit: None
`cpu_time_steal`	The amount of time that the CPU is in *stolen time*, which is time spent in other operating systems in a virtualized environment. This metric is measured in hundredths of a second. Unit: None
`cpu_time_system`	The amount of time that the CPU is in system mode. This metric is measured in hundredths of a second. Unit: None

Metric	Description
`cpu_time_user`	The amount of time that the CPU is in user mode. This metric is measured in hundredths of a second. Unit: None
`cpu_usage_active`	The percentage of time that the CPU is active in any capacity. Unit: Percent
`cpu_usage_guest`	The percentage of time that the CPU is running a virtual CPU for a guest operating system. Unit: Percent
`cpu_usage_guest_nice`	The percentage of time that the CPU is running a virtual CPU for a guest operating system, which is low-priority and can be interrupted by other processes. Unit: Percent
`cpu_usage_idle`	The percentage of time that the CPU is idle. Unit: Percent
`cpu_usage_iowait`	The percentage of time that the CPU is waiting for I/O operations to complete. Unit: Percent
`cpu_usage_irq`	The percentage of time that the CPU is servicing interrupts. Unit: Percent

Metric	Description
cpu_usage_nice	The percentage of time that the CPU is in user mode with low-priority processes, which higher-pr iority processes can easily interrupt. Unit: Percent
cpu_usage_softirq	The percentage of time that the CPU is servicing software interrupts. Unit: Percent
cpu_usage_steal	The percentage of time that the CPU is in *stolen time*, or time spent in other operating systems in a virtualized environment. Unit: Percent
cpu_usage_system	The percentage of time that the CPU is in system mode. Unit: Percent
cpu_usage_user	The percentage of time that the CPU is in user mode. Unit: Percent
disk_free	Free space on the disks. Unit: Bytes
disk_inodes_free	The number of available index nodes on the disk. Unit: Count
disk_inodes_total	The total number of index nodes reserved on the disk. Unit: Count

Metric	Description
`disk_inodes_used`	The number of used index nodes on the disk. Unit: Count
`disk_total`	Total space on the disks, including used and free. Unit: Bytes
`disk_used`	Used space on the disks. Unit: Bytes
`disk_used_percent`	The percentage of total disk space that is used. Unit: Percent
`diskio_iops_in_progress`	The number of I/O requests that have been issued to the device driver but have not yet completed. Unit: Count
`diskio_io_time`	The amount of time that the disk has had I/O requests queued. Unit: Milliseconds The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`diskio_reads`	The number of disk read operations. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.

Metric	Description
`diskio_read_bytes`	The number of bytes read from the disks. Unit: Bytes The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`diskio_read_time`	The amount of time that read requests have waited on the disks. Multiple read requests waiting at the same time increase the number. For example, if 5 requests all wait for an average of 100 milliseconds, 500 is reported. Unit: Milliseconds The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`diskio_writes`	The number disk write operations. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`diskio_write_bytes`	The number of bytes written to the disks. Unit: Bytes The only statistic that should be used for this metric is `Sum`. Do not use `Average`.

Metric	Description
diskio_write_time	The amount of time that write requests have waited on the disks. Multiple write requests waiting at the same time increase the number. For example, if 8 requests all wait for an average of 1000 milliseco nds, 8000 is reported. Unit: Milliseconds The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
ethtool_bw_in_allowance_exc eeded	The number of packets queued and/or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_c ollected` section of the CloudWatch agent configuration file. For more information, see [Collect network performance metrics] Unit: None
ethtool_bw_out_allowance_ex ceeded	The number of packets queued and/or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_c ollected` section of the CloudWatch agent configuration file. For more information, see [Collect network performance metrics] Unit: None

Metric	Description
`ethtool_conntrack_allowance_exceeded`	The number of packets dropped because connection tracking exceeded the maximum for the instance and new connections could not be established. This can result in packet loss for traffic to or from the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None
`ethtool_linklocal_allowance_exceeded`	The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see Collect network performance metrics Unit: None

Metric	Description
`ethtool_pps_allowance_exceeded`	The number of packets queued and/or dropped because the bidirectional PPS exceeded the maximum for the instance. This metric is collected only if you have listed it in the `ethtool` subsection of the `metrics_collected` section of the CloudWatch agent configuration file. For more information, see [Collect network performance metrics](). Unit: None
`mem_active`	The amount of memory that has been used in some way during the last sample period. Unit: Bytes
`mem_available`	The amount of memory that is available and can be given instantly to processes. Unit: Bytes
`mem_available_percent`	The percentage of memory that is available and can be given instantly to processes. Unit: Percent
`mem_buffered`	The amount of memory that is being used for buffers. Unit: Bytes
`mem_cached`	The amount of memory that is being used for file caches. Unit: Bytes

Metric	Description
mem_free	The amount of memory that isn't being used. Unit: Bytes
mem_inactive	The amount of memory that hasn't been used in some way during the last sample period Unit: Bytes
mem_total	The total amount of memory. Unit: Bytes
mem_used	The amount of memory currently in use. Unit: Bytes
mem_used_percent	The percentage of memory currently in use. Unit: Percent
net_bytes_recv	The number of bytes received by the network interface. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.
net_bytes_sent	The number of bytes sent by the network interface. Unit: Bytes The only statistic that should be used for this metric is Sum. Do not use Average.

Metric	Description
`net_drop_in`	The number of packets received by this network interface that were dropped. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`net_drop_out`	The number of packets transmitted by this network interface that were dropped. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`net_err_in`	The number of receive errors detected by this network interface. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`net_err_out`	The number of transmit errors detected by this network interface. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`net_packets_sent`	The number of packets sent by this network interface. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.

Metric	Description
`net_packets_recv`	The number of packets received by this network interface. Unit: Count The only statistic that should be used for this metric is `Sum`. Do not use `Average`.
`netstat_tcp_close`	The number of TCP connections with no state. Unit: Count
`netstat_tcp_close_wait`	The number of TCP connections waiting for a termination request from the client. Unit: Count
`netstat_tcp_closing`	The number of TCP connections that are waiting for a termination request with acknowledgment from the client. Unit: Count
`netstat_tcp_established`	The number of TCP connections established. Unit: Count
`netstat_tcp_fin_wait1`	The number of TCP connections in the `FIN_WAIT1` state during the process of closing a connection. Unit: Count
`netstat_tcp_fin_wait2`	The number of TCP connections in the `FIN_WAIT2` state during the process of closing a connection. Unit: Count

Metric	Description
`netstat_tcp_last_ack`	The number of TCP connections waiting for the client to send acknowledgment of the connectio n termination message. This is the last state right before the connection is closed down. Unit: Count
`netstat_tcp_listen`	The number of TCP ports currently listening for a connection request. Unit: Count
`netstat_tcp_none`	The number of TCP connections with inactive clients. Unit: Count
`netstat_tcp_syn_sent`	The number of TCP connections waiting for a matching connection request after having sent a connection request. Unit: Count
`netstat_tcp_syn_recv`	The number of TCP connections waiting for connection request acknowledgment after having sent and received a connection request. Unit: Count
`netstat_tcp_time_wait`	The number of TCP connections currently waiting to ensure that the client received the acknowledgment of its connection termination request. Unit: Count
`netstat_udp_socket`	The number of current UDP connections. Unit: Count

Metric	Description
processes_blocked	The number of processes that are blocked. Unit: Count
processes_dead	The number of processes that are dead, indicated by the X state code on Linux. This metric is not collected on macOS computers. Unit: Count
processes_idle	The number of processes that are idle (sleeping for more than 20 seconds). Available only on FreeBSD instances. Unit: Count
processes_paging	The number of processes that are paging, indicated by the W state code on Linux. This metric is not collected on macOS computers. Unit: Count
processes_running	The number of processes that are running, indicated by the R state code. Unit: Count
processes_sleeping	The number of processes that are sleeping, indicated by the S state code. Unit: Count
processes_stopped	The number of processes that are stopped, indicated by the T state code. Unit: Count

Metric	Description
`processes_total`	The total number of processes on the instance. Unit: Count
`processes_total_threads`	The total number of threads making up the processes. This metric is available only on Linux instances. This metric is not collected on macOS computers. Unit: Count
`processes_wait`	The number of processes that are paging, indicated by the `W` state code on FreeBSD instances. This metric is available only on FreeBSD instances, and is not available on Linux, Windows Server, or macOS instances. Unit: Count
`processes_zombies`	The number of zombie processes, indicated by the `Z` state code. Unit: Count
`swap_free`	The amount of swap space that isn't being used. Unit: Bytes
`swap_used`	The amount of swap space currently in use. Unit: Bytes
`swap_used_percent`	The percentage of swap space currently in use. Unit: Percent

Definitions of memory metrics collected by the CloudWatch agent

When the CloudWatch agent collects memory metrics, the source is the host's memory management subsystem. For example, the Linux kernel exposes OS-maintained data in `/proc`. For memory, the data is in `/proc/meminfo`.

Each different operating system and architecture has different calculations of the resources that are used by processes. For more information, see the following sections.

During each collection interval, the CloudWatch agent on each instance collects the instance resources and calculates the resources being used by all processes which are running in that instance. This information is reported back to CloudWatch metrics. You can configure the length of the collection interval in the CloudWatch agent configuration file. For more information, see CloudWatch agent configuration file: Agent section.

The following list explains how the memory metrics that the CloudWatch agent collects are defined.

- **Active Memory**– Memory that is being used by a process. In other words, the memory used by current running apps.
- **Available Memory**– The memory that can be instantly given to the processes without the system going into swap (also known as virtual memory).
- **Buffer Memory**– The data area shared by hardware devices or program processes that operate at different speeds and priorities.
- **Cached Memory**– Stores program instructions and data that are used repeatedly in the operation of programs that the CPU is likely to need next.
- **Free Memory**– Memory that is not being used at all and is readily available. It is completely free for the system to be used when needed.
- **Inactive Memory**– Pages that have not been accessed "recently".
- **Total Memory**– The size of the actual physical memory RAM.
- **Used Memory**– Memory that is currently in use by programs and processes.

- [Windows: Metrics collected]
- [Example: Calculating memory metrics on Linux]

Linux: Metrics collected and calculations used

Metrics collected and units:

- Active (Bytes)
- Available (Bytes)
- Available Percent (Percent)
- Buffered (Bytes)
- Cached (Bytes)
- Free (Bytes)
- Inactive (Bytes)
- Total (Bytes)
- Used (Bytes)
- Used Percent (Percent)

Used memory = Total Memory - Free Memory - Cached memory - Buffer memory

Total memory = Used Memory + Free Memory + Cached memory + Buffer memory

macOS: Metrics collected and calculations used

Metrics collected and units:

- Active (Bytes)
- Available (Bytes)
- Available Percent (Percent)
- Free (Bytes)
- Inactive (Bytes)
- Total (Bytes)
- Used (Bytes)
- Used Percent (Percent)

Available memory = Free Memory + Inactive memory

Used memory = Total Memory - Available memory

Total memory = Available Memory + Used Memory

Windows: Metrics collected

The metrics collected on Windows hosts are listed below. All of these metrics have None for `Unit`.

- Available bytes
- Cache Faults/sec
- Page Faults/sec
- Pages/sec

There are no calculations used for Windows metrics because the CloudWatch agent parses events from performance counters.

Example: Calculating memory metrics on Linux

As an example, suppose that entering the **`cat /proc/meminfo`** command on a Linux host shows the following results:

```
MemTotal:       3824388 kB
MemFree:         462704 kB
MemAvailable:   2157328 kB
Buffers:         126268 kB
Cached:         1560520 kB
SReclaimable:    289080 kB>
```

In this example, the CloudWatch agent will collect the following values. All the values that the CloudWatch agent collects and reports are in bytes.

- `mem_total`: 3916173312 bytes
- `mem_available`: 2209103872 bytes (MemFree + Cached)
- `mem_free`: 473808896 bytes
- `mem_cached`: 1893990400 bytes (`cached` + `SReclaimable`
- `mem_used`: 1419075584 bytes (`MemTotal` – (`MemFree` + `Buffers` + (`Cached` + `SReclaimable`)))

- `mem_buffered`: 129667072 bytes
- `mem_available_percent`: 56.41%
- `mem_used_percent`: 36.24% (`mem_used` / `mem_total`) * 100

Using the CloudWatch agent with related telemetry

Metrics and logs that are sent to CloudWatch can include an optional entity to correlate telemetry. Entities are used in the Explore related pane. The CloudWatch agent sends entities with a service name and environment name included.

The agent chooses the service name and environment name from the following data.

Service name

The agent chooses the service name from the following options, in priority order:

- **Application Signals instrumentation** – The agent sends the service name used by Application Signals. This can be overwritten by changing the `OTEL_SERVICE_NAME` environment variable used by supported OpenTelemetry instrumentation libraries.
- **CloudWatch agent configuration** – You can configure the agent to use a specific service name. This can be configured at the agent, plugin, metrics, logs, or log file level.
- **Kubernetes workload name** – For Kubernetes workloads, the agent sends the name of the workload for the corresponding pod, in the following priority order.
  - Deployment name
  - ReplicaSet name
  - StatefulSet name
  - DaemonSet name
  - CronJob name
  - Job name
  - Pod name
  - Container name
- **Resource tags from instance metadata** – For Amazon EC2 workloads, the agent sends the a name from tags, in the following order.
  - service

  - application
  - app

  You must setup instance metadata for the agent to be able to access tags.

- **Default** – If no other service name is found, the agent will send the name `Unknown`.

Environment name

The agent chooses the environment name from the following options, in priority order:

- **Application Signals instrumentation** – The agent sends the environment name used by Application Signals. This can be overwritten by setting a `deployment.environment` environment variable used by supported OpenTelemetry instrumentation libraries. For example, applications may set the environment variable `OTEL_RESOURCE_ATTRIBUTES=deployment.environment=MyEnvironment`.
- **CloudWatch agent configuration** – You can configure the agent to use a specific environment name. This can be configured at the agent, plugin, metrics, logs, or log file level.
- **Cluster name and workspace** – For Amazon EKS, `eks:`*`cluster-name`*`/`*`Namespace`*. For native Kubernetes running on Amazon EC2, `k8s:`*`cluster-name`*`/`*`Namespace`*.
- **Resource tags from instance metadata** – For Amazon EC2 workloads, the agent can will use the `AutoScalingGroup` tag.

  You must setup instance metadata for the agent to be able to access tags.

- By default, Amazon EC2 instances that aren't running Kubernetes will get the environment name `ec2:default`.

Common scenarios with the CloudWatch agent

This section provides you with different scenarios that outline how to complete common configuration and customization tasks for the CloudWatch agent.

Topics

- Multiple CloudWatch agent configuration files
- Aggregating or rolling up metrics collected by the CloudWatch agent
- Collecting high-resolution metrics with the CloudWatch agent
- Sending metrics, logs, and traces to a different account
- Timestamp differences between the unified CloudWatch agent and the earlier CloudWatch Logs agent
- Appending OpenTelemetry collector configuration files

Running the CloudWatch agent as a different user

On Linux servers, the CloudWatch runs as the root user by default. To have the agent run as a different user, use the `run_as_user` parameter in the `agent` section in the CloudWatch agent configuration file. This option is available only on Linux servers.

If you're already running the agent with the root user and want to change to using a different user, use one of the following procedures.

To run the CloudWatch agent as a different user on an EC2 instance running Linux

1. Download and install a new CloudWatch agent package. For more information, see Download the CloudWatch agent package.
2. Create a new Linux user or use the default user named `cwagent` that the RPM or DEB file created.
3. Provide credentials for this user in one of these ways:
   - If the file `.aws/credentials` exists in the home directory of the root user, you must create a credentials file for the user you are going to use to run the CloudWatch agent. This credentials file will be `/home/`*`username`*`/.aws/credentials`. Then set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see (Optional) Modify the common configuration for proxy or Region information.
   - If the file `.aws/credentials` does not exist in the home directory of the root user, you can do one of the following:
     - Create a credentials file for the user you are going to use to run the CloudWatch agent. This credentials file will be `/home/`*`username`*`/.aws/credentials`. Then set the value of the `shared_credential_file` parameter in `common-config.toml`

to the pathname of the credential file. For more information, see (Optional) Modify the common configuration for proxy or Region information.

- Instead of creating a credentials file, attach an IAM role to the instance. The agent uses this role as the credential provider.

4. In the CloudWatch agent configuration file, add the following line in the `agent` section:

```
"run_as_user": "username"
```

Make other modifications to the configuration file as needed. For more information, see Create the CloudWatch agent configuration file

5. Give the user the required permissions. The user must have Read (r) permissions for the log files to be collected, and must have Execute (x) permission on every directory in the log files' path.

6. Start the agent with the configuration file that you just modified.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -s -c file:configuration-file-path
```

To run the CloudWatch agent as a different user on an on-premises server running Linux

1. Download and install a new CloudWatch agent package. For more information, see Download the CloudWatch agent package.

2. Create a new Linux user or use the default user named `cwagent` that the RPM or DEB file created.

3. Store the credentials of this user to a path that the user can access, such as `/home/username/.aws/credentials`.

4. Set the value of the `shared_credential_file` parameter in `common-config.toml` to the pathname of the credential file. For more information, see (Optional) Modify the common configuration for proxy or Region information.

5. In the CloudWatch agent configuration file, add the following line in the `agent` section:

```
"run_as_user": "username"
```

Make other modifications to the configuration file as needed. For more information, see Create the CloudWatch agent configuration file

6. Give the user required permissions. The user must have Read (r) permissions for the log files to be collected, and must have Execute (x) permission on every directory in the log files' path.
7. Start the agent with the configuration file that you just modified.

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -s -c file:configuration-file-path
```

How the CloudWatch agent handles sparse log files

Sparse files are files with both empty blocks and real contents. A sparse file uses disk space more efficiently by writing brief information representing the empty blocks to disk instead of the actual null bytes which makes up the block. This makes the actual size of a sparse file usually much smaller than its apparent size.

However, the CloudWatch agent doesn’t treat sparse files differently than it treats normal files. When the agent reads a sparse file, the empty blocks are treated as "real" blocks filled with null bytes. Because of this, the CloudWatch agent publishes as many bytes as the apparent size of a sparse file to CloudWatch.

Configuring the CloudWatch agent to publish a sparse file can cause higher than expected CloudWatch costs, so we recommend not to do so. For example, `/var/logs/lastlog` in Linux is usually a very sparse file, and we recommend that you don't publish it to CloudWatch.

Adding custom dimensions to metrics collected by the CloudWatch agent

To add custom dimensions such as tags to metrics collected by the agent, add the `append_dimensions` field to the section of the agent configuration file that lists those metrics.

For example, the following example section of the configuration file adds a custom dimension named `stackName` with a value of `Prod` to the `cpu` and `disk` metrics collected by the agent.

```
"cpu":{
  "resources":[
    "*"
  ],
  "measurement":[
    "cpu_usage_guest",
```

```
      "cpu_usage_nice",
      "cpu_usage_idle"
    ],
    "totalcpu":false,
    "append_dimensions":{
      "stackName":"Prod"
    }
  },
  "disk":{
    "resources":[
      "/",
      "/tmp"
    ],
    "measurement":[
      "total",
      "used"
    ],
    "append_dimensions":{
      "stackName":"Prod"
    }
  }
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Multiple CloudWatch agent configuration files

On both Linux servers and Windows servers, you can set up the CloudWatch agent to use multiple configuration files. For example, you can use a common configuration file that collects a set of metrics, logs, and traces that you always want to collect from all servers in your infrastructure. You can then use additional configuration files that collect metrics from certain applications or in certain situations.

To set this up, first create the configuration files that you want to use. Any configuration files that will be used together on the same server must have different file names. You can store the configuration files on servers or in Parameter Store.

Start the CloudWatch agent using the `fetch-config` option and specify the first configuration file. To append the second configuration file to the running agent, use the same command but with the `append-config` option. All metrics, logs, and traces listed in either configuration file are collected. The following example commands illustrate this scenario using configurations stores as files. The first line starts the agent using the `infrastructure.json` configuration file, and the second line appends the `app.json` configuration file.

The following example commands are for Linux.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2
 -s -c file:/tmp/infrastructure.json
```

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a append-config -m
 ec2 -s -c file:/tmp/app.json
```

The following example commands are for Windows Server.

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1"
 -a fetch-config -m ec2 -s -c file:"C:\Program Files\Amazon\AmazonCloudWatchAgent
\infrastructure.json"
```

```
& "C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1"
 -a append-config -m ec2 -s -c file:"C:\Program Files\Amazon\AmazonCloudWatchAgent
\app.json"
```

The following example configuration files illustrate a use for this feature. The first configuration file is used for all servers in the infrastructure, and the second collects only logs from a certain application and is appended to servers running that application.

infrastructure.json

```
{
  "metrics": {
    "metrics_collected": {
      "cpu": {
        "resources": [
          "*"
        ],
        "measurement": [
          "usage_active"
        ],
        "totalcpu": true
      },
      "mem": {
         "measurement": [
```

```
            "used_percent"
          ]
        }
      }
    },
    "logs": {
      "logs_collected": {
        "files": {
          "collect_list": [
            {
              "file_path": "/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-
agent.log",
              "log_group_name": "amazon-cloudwatch-agent.log"
            },
            {
              "file_path": "/var/log/messages",
              "log_group_name": "/var/log/messages"
            }
          ]
        }
      }
    }
}
```

app.json

```
{
    "logs": {
        "logs_collected": {
            "files": {
                "collect_list": [
                    {
                        "file_path": "/app/app.log*",
                        "log_group_name": "/app/app.log"
                    }
                ]
            }
        }
    }
}
```

Any configuration files appended to the configuration must have different file names from each other and from the initial configuration file. If you use `append-config` with a configuration file with the same file name as a configuration file that the agent is already using, the append command overwrites the information from the first configuration file instead of appending to it. This is true even if the two configuration files with the same file name are on different file paths.

The preceding example shows the use of two configuration files, but there is no limit to the number of configuration files that you can append to the agent configuration. You can also mix the use of configuration files located on servers and configurations located in Parameter Store.

Aggregating or rolling up metrics collected by the CloudWatch agent

To aggregate or roll up metrics collected by the agent, add an `aggregation_dimensions` field to the section for that metric in the agent configuration file.

For example, the following configuration file snippet rolls up metrics on the `AutoScalingGroupName` dimension. The metrics from all instances in each Auto Scaling group are aggregated and can be viewed as a whole.

```
"metrics": {
  "cpu":{...}
  "disk":{...}
  "aggregation_dimensions" : [["AutoScalingGroupName"]]
}
```

To roll up along the combination of each `InstanceId` and `InstanceType` dimensions in addition to rolling up on the Auto Scaling group name, add the following.

```
"metrics": {
  "cpu":{...}
  "disk":{...}
  "aggregation_dimensions" : [["AutoScalingGroupName"], ["InstanceId", "InstanceType"]]
}
```

To roll up metrics into one collection instead, use `[]`.

```
"metrics": {
  "cpu":{...}
  "disk":{...}
  "aggregation_dimensions" : [[]]
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Collecting high-resolution metrics with the CloudWatch agent

The `metrics_collection_interval` field specifies the time interval for the metrics collected, in seconds. By specifying a value of less than 60 for this field, the metrics are collected as high-resolution metrics.

For example, if your metrics should all be high-resolution and collected every 10 seconds, specify 10 as the value for `metrics_collection_interval` under the `agent` section as a global metrics collection interval.

```
"agent": {
  "metrics_collection_interval": 10
}
```

Alternatively, the following example sets the `cpu` metrics to be collected every second, and all other metrics are collected every minute.

```
"agent":{
  "metrics_collection_interval": 60
},
"metrics":{
  "metrics_collected":{
    "cpu":{
      "resources":[
        "*"
      ],
      "measurement":[
        "cpu_usage_guest"
      ],
      "totalcpu":false,
      "metrics_collection_interval": 1
    },
    "disk":{
      "resources":[
        "/",
        "/tmp"
      ],
      "measurement":[
        "total",
```

```
        "used"
      ]
    }
  }
}
```

Remember that any time you change the agent configuration file, you must restart the agent to have the changes take effect.

Sending metrics, logs, and traces to a different account

To have the CloudWatch agent send the metrics, logs, or traces to a different account, specify a `role_arn` parameter in the agent configuration file on the sending server. The `role_arn` value specifies an IAM role in the target account that the agent uses when sending data to the target account. This role enables the sending account to assume a corresponding role in the target account when delivering the metrics or logs to the target account.

You can also specify separate `role_arn` strings in the agent configuration file: one to use when sending metrics, another for sending logs, and another for sending traces.

The following example of part of the `agent` section of the configuration file sets the agent to use `CrossAccountAgentRole` when sending data to a different account.

```
{
  "agent": {
    "credentials": {
      "role_arn": "arn:aws:iam::123456789012:role/CrossAccountAgentRole"
    }
  },
  .....
}
```

Alternatively, the following example sets different roles for the sending account to use for sending metrics, logs, and traces:

```

"metrics": {
    "credentials": {
     "role_arn": "RoleToSendMetrics"
    },
    "metrics_collected": {....
```

```
"logs": {
    "credentials": {
    "role_arn": "RoleToSendLogs"
    },
    ....
```

Policies needed

When you specify a `role_arn` in the agent configuration file, you must also make sure the IAM roles of the sending and target accounts have certain policies. The roles in both the sending and target accounts should have `CloudWatchAgentServerPolicy`. For more information about assigning this policy to a role, see [Create IAM roles to use with the CloudWatch agent on Amazon EC2 instances](#).

The role in the sending account also must include the following policy. You add this policy on the **Permissions** tab in the IAM console when you edit the role.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "sts:AssumeRole"
            ],
            "Resource": [
                "arn:aws:iam::target-account-ID:role/agent-role-in-target-account"
            ]
        }
    ]
}
```

The role in the target account must include the following policy so that it recognizes the IAM role used by the sending account. You add this policy on the **Trust relationships** tab in the IAM console when you edit the role. The role in the target account where you add this policy is the role you created in [Create IAM roles and users for use with CloudWatch agent](#). This role is the role specified in *`agent-role-in-target-account`* in the policy used by the sending account.

```
{
  "Version": "2012-10-17",
```

```
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws:iam::sending-account-ID:role/role-in-sender-account"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

Timestamp differences between the unified CloudWatch agent and the earlier CloudWatch Logs agent

The CloudWatch agent supports a different set of symbols for timestamp formats, compared to the earlier CloudWatch Logs agent. These differences are shown in the following table.

Symbols supported by both agents	Symbols supported only by unified CloudWatch agent	Symbols supported only by earlier CloudWatch Logs agent
%A, %a, %b, %B, %d, %f, %H, %l, %m, %M, %p, %S, %y, %Y, %Z, %z	%-d, %-l, %-m, %-M, %-S	%c,%j, %U, %W, %w

For more information about the meanings of the symbols supported by the new CloudWatch agent, see CloudWatch Agent Configuration File: Logs Section in the *Amazon CloudWatch User Guide*. For information about symbols supported by the CloudWatch Logs agent, see Agent Configuration File in the *Amazon CloudWatch Logs User Guide*.

Appending OpenTelemetry collector configuration files

The CloudWatch agent supports supplemental OpenTelemetry collector configuration files alongside its own configuration files. This feature allows you to use CloudWatch agent features such as CloudWatch Application Signals or Container Insights through the CloudWatch agent configuration and bring in your existing OpenTelemetry collector configuration with a single agent.

To prevent merge conflicts with pipelines automatically created by CloudWatch agent, we recommend that you add a custom suffix to each of the components and pipelines in your OpenTelemetry collector configuration.

```
receivers:
  otlp/custom-suffix:
    protocols:
      http:

exporters:
  awscloudwatchlogs/custom-suffix:
    log_group_name: "test-group"
    log_stream_name: "test-stream"

service:
  pipelines:
    logs/custom-suffix:
      receivers: [otlp/custom-suffix]
      exporters: [awscloudwatchlogs/custom-suffix]
```

To configure the CloudWatch agent, start the CloudWatch agent using the `fetch-config` option and specify the CloudWatch agent's configuration file. CloudWatch agent requires at least one CloudWatch agent configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -c
 file:/tmp/agent.json -s
```

Next, use the `append-config` option while specifying the OpenTelemetry collector configuration file.

```
/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a append-config -c
 file:/tmp/otel.yaml -s
```

The agent merges the two configuration files on start up and logs the resolved configuration.

Troubleshooting the CloudWatch agent

You can use the information in this section to troubleshoot issues you might encounter with the CloudWatch agent.

Topics

CloudWatch agent command line parameters

To see the full list of parameters supported by the CloudWatch agent, enter the following at the command line at a computer where you have it installed:

```
amazon-cloudwatch-agent-ctl -help
```

Install the CloudWatch agent using Run Command fails

To install the CloudWatch agent using Systems Manager Run Command, the SSM Agent on the target server must be version 2.2.93.0 or later of the SSM Agent agent. If your SSM Agent isn't the correct version, you might see errors that include the following messages:

```
no latest version found for package AmazonCloudWatchAgent on platform linux
```

```
failed to download installation package reliably
```

For information about updating your SSM Agent version, see Installing and Configuring SSM Agent in the *Amazon Systems Manager User Guide*.

The CloudWatch agent won't start

If the CloudWatch agent fails to start, there might be an issue in your configuration. Configuration information is logged in the `configuration-validation.log` file. This file is located in `/opt/aws/amazon-cloudwatch-agent/logs/configuration-validation.log` on Linux servers and in `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\configuration-validation.log` on servers running Windows Server.

Verify that the CloudWatch agent is running

You can query the CloudWatch agent to find whether it's running or stopped. You can use Amazon Systems Manager to do this remotely. You can also use the command line, but only to check the local server.

To query the status of the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

   If the Amazon Systems Manager home page opens, scroll down and choose **Explore Run Command**.
3. Choose **Run command**.
4. In the **Command document** list, choose the button next to **AmazonCloudWatch-ManageAgent**.
5. In the **Action** list, choose **status**.
6. For **Optional Configuration Source** choose **default** and keep **Optional Configuration Location** blank.
7. In the **Target** area, choose the instance to check.
8. Choose **Run**.

If the agent is running, the output resembles the following.

```
{
       "status": "running",
       "starttime": "2017-12-12T18:41:18",
       "version": "1.73.4"
```

```
}
```

If the agent is stopped, the "status" field displays "stopped".

To query the status of the CloudWatch agent locally using the command line

- On a Linux server, enter the following:

  ```
  sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -m ec2 -a
   status
  ```

  On a server running Windows Server, enter the following in PowerShell as an administrator:

  ```
  & $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m
   ec2 -a status
  ```

The CloudWatch agent won't start, and the error mentions an Amazon EC2 Region

If the agent doesn't start and the error message mentions an Amazon EC2 Region endpoint, you might have configured the agent to need access to the Amazon EC2 endpoint without granting that access.

For example, if you specify a value for the append_dimensions parameter in the agent configuration file that depends on Amazon EC2 metadata and you use proxies, you must make sure that the server can access the endpoint for Amazon EC2. For more information about these endpoints, see Amazon Elastic Compute Cloud (Amazon EC2) in the *Amazon Web Services General Reference*.

The CloudWatch agent won't start on Windows Server

On Windows Server, you might see the following error:

```
Start-Service : Service 'Amazon CloudWatch Agent (AmazonCloudWatchAgent)' cannot be
 started due to the following
error: Cannot start service AmazonCloudWatchAgent on computer '.'.
At C:\Program Files\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1:113
 char:12
+     $svc | Start-Service
```

```
+             ~~~~~~~~~~~~~
    + CategoryInfo          : OpenError:
 (System.ServiceProcess.ServiceController:ServiceController) [Start-Service],
   ServiceCommandException
    + FullyQualifiedErrorId :
 CouldNotStartService,Microsoft.PowerShell.Commands.StartServiceCommand
```

To fix this, first make sure that the server service is running. This error can be seen if the agent tries to start when the server service isn't running.

If the server service is already running, the following may be the issue. On some Windows Server installations, the CloudWatch agent takes more than 30 seconds to start. Because Windows Server, by default, allows only 30 seconds for services to start, this causes the agent to fail with an error similar to the following:

To fix this issue, increase the service timeout value. For more information, see [A service does not start, and events 7000 and 7011 are logged in the Windows event log].

Where are the metrics?

If the CloudWatch agent has been running but you can't find metrics collected by it in the Amazon Web Services Management Console or the Amazon CLI, confirm that you're using the correct namespace. By default, the namespace for metrics collected by the agent is `CWAgent`. You can customize this namespace using the `namespace` field in the `metrics` section of the agent configuration file. If you don't see the metrics that you expect, check the configuration file to confirm the namespace being used.

When you first download the CloudWatch agent package, the agent configuration file is `amazon-cloudwatch-agent.json`. This file is in the directory where you ran the configuration wizard, or you might have moved it to a different directory. If you use the configuration wizard, the agent configuration file output from the wizard is named `config.json`. For more information about the configuration file, including the `namespace` field, see [CloudWatch agent configuration file: Metrics section].

The CloudWatch agent takes a long time to run in a container or logs a hop limit error

When you run the CloudWatch agent as a container service and want to add Amazon EC2 metric dimensions to all metrics collected by the agent, you might see the following errors in version v1.247354.0 of the agent:

```
2022-06-07T03:36:11Z E! [processors.ec2tagger] ec2tagger: Unable to retrieve Instance
 Metadata Tags. This plugin must only be used on an EC2 instance.
2022-06-07T03:36:11Z E! [processors.ec2tagger] ec2tagger: Please increase hop limit
 to 2 by following this document https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/
configuring-instance-metadata-options.html#configuring-IMDS-existing-instances.
2022-06-07T03:36:11Z E! [telegraf] Error running agent: could not initialize processor
 ec2tagger: EC2MetadataRequestError: failed to get EC2 instance identity document
caused by: EC2MetadataError: failed to make EC2Metadata request
        status code: 401, request id:
caused by:
```

You might see this error if the agent tries to get metadata from IMDSv2 inside a container without an appropriate hop limit. In versions of the agent earlier than v1.247354.0, you can experience this issue without seeing the log message.

To solve this, increase the hop limit to 2 by following the instructions in [Configure the instance metadata options](#).

I updated my agent configuration but don’t see the new metrics or logs in the CloudWatch console

If you update your CloudWatch agent configuration file, the next time that you start the agent, you need to use the **`fetch-config`** option. For example, if you stored the updated file on the local computer, enter the following command:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -
s -m ec2 -c file:configuration-file-path
```

CloudWatch agent files and locations

The following table lists the files installed by and used with the CloudWatch agent, along with their locations on servers running Linux or Windows Server.

File	Linux location	Windows Server location
The control script that controls starting, stopping, and restarting the agent.	`/opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl` or `/usr/bin/`	`$Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-`

File	Linux location	Windows Server location
	`amazon-cloudwatch-agent-ctl`	`cloudwatch-agent-ctl.ps1`
The log file the agent writes to. You might need to attach this when contacting Amazon Web Services Support.	`/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log` or `/var/log/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.log`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\amazon-cloudwatch-agent.log`
Agent configuration validation file.	`/opt/aws/amazon-cloudwatch-agent/logs/configuration-validation.log` or `/var/log/amazon/amazon-cloudwatch-agent/configuration-validation.log`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\configuration-validation.log`
The JSON file used to configure the agent immediately after the wizard creates it. For more information, see [Create the CloudWatch agent configuration file]().	`/opt/aws/amazon-cloudwatch-agent/bin/config.json`	`$Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\config.json`
The JSON file used to configure the agent if this configuration file has been downloaded from Parameter Store.	`/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.json` or `/etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.json`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.json`

File	Linux location	Windows Server location
The TOML file used to specify Region and credential information to be used by the agent, overriding system defaults.	`/opt/aws/amazon-cloudwatch-agent/etc/common-config.toml` or `/etc/amazon/amazon-cloudwatch-agent/common-config.toml`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\common-config.toml`
The TOML file that contains the converted contents of the JSON configuration file. The `amazon-cloudwatch-agent-ctl` script generates this file. Users should not directly modify this file. It can be useful for verifying that JSON to TOML translation was successful.	`/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.toml` or `/etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.toml`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.toml`
The YAML file that contains the converted contents of the JSON configuration file. The `amazon-cloudwatch-agent-ctl` script generates this file. You should not directly modify this file. This file can be useful for verifying that the JSON to YAML translation was successful.	`/opt/aws/amazon-cloudwatch-agent/etc/amazon-cloudwatch-agent.yaml or /etc/amazon/amazon-cloudwatch-agent/amazon-cloudwatch-agent.yaml`	`$Env:ProgramData\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent.yaml`

Logs generated by the CloudWatch agent

The agent generates a log while it runs. This log includes troubleshooting information. This log is the `amazon-cloudwatch-agent.log` file. This file is located in `/opt/aws/amazon-cloudwatch-agent/logs/amazon-cloudwatch-agent.log` on Linux servers and in `$Env:ProgramData\Amazon\AmazonCloudWatchAgent\Logs\amazon-cloudwatch-agent.log` on servers running Windows Server.

You can configure the agent to log additional details in the `amazon-cloudwatch-agent.log` file. In the agent configuration file, in the `agent` section, set the `debug` field to `true`, then reconfigure and restart the CloudWatch agent. To disable the logging of this extra information, set the `debug` field to `false`. Then, reconfigure and restart the agent. For more information, see [Manually create or edit the CloudWatch agent configuration file](#).

In versions 1.247350.0 and later of the CloudWatch agent, you can optionally set the `aws_sdk_log_level` field in the `agent` section of the agent configuration file to one or more of the following options. Separate multiple options with the `|` character.

- `LogDebug`
- `LogDebugWithSigning`
- `LogDebugWithHTTPBody`
- `LogDebugRequestRetries`
- `LogDebugWithEventStreamBody`

For more information about these options, see [LogLevelType](#).

Stopping and restarting the CloudWatch agent

You can manually stop the CloudWatch agent using either Amazon Systems Manager or the command line.

To stop the CloudWatch agent using Run Command

1. Open the Systems Manager console at https://console.amazonaws.cn/systems-manager/.
2. In the navigation pane, choose **Run Command**.

   -or-

If the Amazon Systems Manager home page opens, scroll down and choose **Explore Run Command**.

3. Choose **Run command**.
4. In the **Command document** list, choose **AmazonCloudWatch-ManageAgent**.
5. In the **Targets** area, choose the instance where you installed the CloudWatch agent.
6. In the **Action** list, choose **stop**.
7. Keep **Optional Configuration Source** and **Optional Configuration Location** blank.
8. Choose **Run**.

To stop the CloudWatch agent locally using the command line

- On a Linux server, enter the following:

```
sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -m ec2 -a
 stop
```

On a server running Windows Server, enter the following in PowerShell as an administrator:

```
& $Env:ProgramFiles\Amazon\AmazonCloudWatchAgent\amazon-cloudwatch-agent-ctl.ps1 -m
 ec2 -a stop
```

To restart the agent, follow the instructions in (Optional) Modify the common configuration and named profile for CloudWatch agent.

Embedding metrics within logs

The CloudWatch embedded metric format allows you to generate custom metrics asynchronously in the form of logs written to CloudWatch Logs. You can embed custom metrics alongside detailed log event data, and CloudWatch automatically extracts the custom metrics so that you can visualize and alarm on them, for real-time incident detection. Additionally, the detailed log events associated with the extracted metrics can be queried using CloudWatch Logs Insights to provide deep insights into the root causes of operational events.

Embedded metric format helps you generate actionable custom metrics from ephemeral resources such as Lambda functions and containers. By using the embedded metric format to send logs from these ephemeral resources, you can now easily create custom metrics without having to instrument or maintain separate code, while gaining powerful analytical capabilities on your log data.

No setup is required to use the embedded metric format. Either structure your logs by following the Embedded metric format specification, or generate them using our client libraries and send them to CloudWatch Logs using the PutLogEvents API or the CloudWatch agent.

To generate metrics from logs with embedded metric format, you need the `logs:PutLogEvents` permission but you don't need to also have the `cloudwatch:PutMetricData` permission.

Charges are incurred for logs ingestion and archival, and custom metrics that are generated. For more information, see Amazon CloudWatch Pricing.

> **Note**
>
> Be careful when configuring your metric extraction as it impacts your custom metric usage and corresponding bill. If you unintentionally create metrics based on high-cardinality dimensions (such as `requestId`), the embedded metric format will by design create a custom metric corresponding to each unique dimension combination. For more information, see Dimensions.

The following topics describe how to publish logs using the embedded metric format, view your metrics and logs in the console, and set alarms on metrics created with the embedded metric format.

Topics

Publishing logs with the embedded metric format

You can generate embedded metric format logs using the following methods:

- Generate and send the logs by using the open-sourced client libraries.
- Manually generate the logs using the embedded metric format specification, and then use the CloudWatch agent or the PutLogEvents API to send the logs.

The following topics provide more information about embedded metrics.

Topics

Creating logs in embedded metric format using the client libraries

You can use the open-sourced client libraries that Amazon provides to create embedded metric format logs. Currently, these libraries are available for the languages in the following list. Full examples for different setups can be found in our client libraries under **/examples**. The libraries and the instructions for how to use them are located on Github. Use the following links.

- Node.Js

> **Note**
>
> For Node.js, versions 4.1.1+, 3.0.2+, 2.0.7+ are required for use with the Lambda JSON log format. Using previous versions in such Lambda environments will lead to metric loss. For more information, see Accessing Amazon CloudWatch logs for Amazon Lambda.

- Python
- Java
- C#

Client libraries are meant to work out of the box with the CloudWatch agent. Generated embedded metric format logs are sent to the CloudWatch agent, which then aggregates and publishes them to CloudWatch Logs for you.

> **Note**
>
> When using Lambda, no agent is required to send the logs to CloudWatch. Anything logged to STDOUT is sent to CloudWatch Logs via the Lambda Logging Agent.

Specification: Embedded metric format

The CloudWatch embedded metric format is a JSON specification used to instruct CloudWatch Logs to automatically extract metric values embedded in structured log events. You can use CloudWatch to graph and create alarms on the extracted metric values. This section describes embedded metric format specification conventions and the embedded metric format document structure.

Embedded metric format specification conventions

The key words “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”, “SHOULD”, “SHOULD NOT”, “RECOMMENDED”, “MAY”, and “OPTIONAL” in this format specification are to be interpreted as described in Key Words RFC2119.

The terms "JSON", "JSON text", "JSON value", "member", "element", "object", "array", "number", "string", "boolean", "true", "false", and "null" in this format specification are to be interpreted as defined in JavaScript Object Notation RFC8259.

> **Note**
>
> If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

Embedded metric format document structure

This section describes the structure of an embedded metric format document. Embedded metric format documents are defined in JavaScript Object Notation RFC8259.

Unless otherwise noted, objects defined by this specification MUST NOT contain any additional members. Members not recognized by this specification MUST be ignored. Members defined in this specification are case-sensitive.

The embedded metric format is subject to the same limits as standard CloudWatch Logs events and are limited to a maximum size of 1 MB.

With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the `Amazon/Logs` namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Root node

The LogEvent message MUST be a valid JSON object with no additional data at the beginning or end of the LogEvent message string. For more information about the LogEvent structure, see InputLogEvent.

Embedded metric format documents MUST contain the following top-level member on the root node. This is a Metadata object object.

```
{
 "_aws": {
    "CloudWatchMetrics": [ ... ]
  }
}
```

The root node MUST contain all Target members members defined by the references in the MetricDirective object.

The root node MAY contain any other members that are not included in the above requirements. The values of these members MUST be valid JSON types.

Metadata object

The _aws member can be used to represent metadata about the payload that informs downstream services how they should process the LogEvent. The value MUST be an object and MUST contain the following members:

- **CloudWatchMetrics**— An array of MetricDirective object used to instruct CloudWatch to extract metrics from the root node of the LogEvent.

```
{
  "_aws": {
    "CloudWatchMetrics": [ ... ]
  }
}
```

- **Timestamp**— A number representing the time stamp used for metrics extracted from the event. Values MUST be expressed as the number of milliseconds after Jan 1, 1970 00:00:00 UTC.

```
{
  "_aws": {
    "Timestamp": 1559748430481
  }
}
```

MetricDirective object

The MetricDirective object instructs downstream services that the LogEvent contains metrics that will be extracted and published to CloudWatch. MetricDirectives MUST contain the following members:

- **Namespace**— A string representing the CloudWatch namespace for the metric.
- **Dimensions**— A DimensionSet array.
- **Metrics**— An array of MetricDefinition objects. This array MUST NOT contain more than 100 MetricDefinition objects.

DimensionSet array

A DimensionSet is an array of strings containing the dimension keys that will be applied to all metrics in the document. The values within this array MUST also be members on the root-node— referred to as the Target members

A DimensionSet MUST NOT contain more than 30 dimension keys. A DimensionSet MAY be empty.

The target member MUST have a string value. This value MUST NOT contain more than 1024 characters. The target member defines a dimension that will be published as part of the metric identity. Every DimensionSet used creates a new metric in CloudWatch. For more information about dimensions, see Dimension and Dimensions.

```
{
 "_aws": {
   "CloudWatchMetrics": [
     {
       "Dimensions": [ [ "functionVersion" ] ],
       ...
     }
   ]
 },
 "functionVersion": "$LATEST"
}
```

> **Note**
>
> Be careful when configuring your metric extraction as it impacts your custom metric usage and corresponding bill. If you unintentionally create metrics based on high-cardinality dimensions (such as `requestId`), the embedded metric format will by design create a custom metric corresponding to each unique dimension combination. For more information, see Dimensions.

MetricDefinition object

A MetricDefinition is an object that MUST contain the following member:

- **Name**— A string Reference values to a metric Target members. Metric targets MUST be either a numeric value or an array of numeric values.

A MetricDefinition object MAY contain the following members:

- **Unit**— An OPTIONAL string value representing the unit of measure for the corresponding metric. Values SHOULD be valid CloudWatch metric units. For information about valid units, see MetricDatum. If a value is not provided, then a default value of NONE is assumed.
- **StorageResolution**— An OPTIONAL integer value representing the storage resolution for the corresponding metric. Setting this to 1 specifies this metric as a high-resolution metric, so that CloudWatch stores the metric with sub-minute resolution down to one second. Setting this to 60 specifies this metric as standard-resolution, which CloudWatch stores at 1-minute resolution. Values SHOULD be valid CloudWatch supported resolutions, 1 or 60. If a value is not provided, then a default value of 60 is assumed.

  For more information about high-resolution metrics, see High-resolution metrics.

> **Note**
>
> If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

```
{
  "_aws": {
    "CloudWatchMetrics": [
      {
        "Metrics": [
          {
            "Name": "Time",
            "Unit": "Milliseconds",
            "StorageResolution": 60
          }
        ],
        ...
      }
    ]
  },
  "Time": 1
}
```

Reference values

Reference values are string values that reference Target members members on the root node. These references should NOT be confused with the JSON Pointers described in RFC6901. Target values cannot be nested.

Target members

Valid targets MUST be members on the root node and cannot be nested objects. For example, a _reference_ value of "A.a" MUST match the following member:

```
{ "A.a" }
```

It MUST NOT match the nested member:

```
{ "A": { "a" } }
```

Valid values of target members depend on what is referencing them. A metric target MUST be a numeric value or an array of numeric values. Numeric array metric targets MUST NOT have more than 100 members. A dimension target MUST have a string value.

Embedded metric format example and JSON schema

The following is a valid example of embedded metric format.

```
{
  "_aws": {
    "Timestamp": 1574109732004,
    "CloudWatchMetrics": [
      {
        "Namespace": "lambda-function-metrics",
        "Dimensions": [["functionVersion"]],
        "Metrics": [
          {
            "Name": "time",
            "Unit": "Milliseconds",
            "StorageResolution": 60
          }
        ]
      }
    ]
```

```
  },
  "functionVersion": "$LATEST",
  "time": 100,
  "requestId": "989ffbf8-9ace-4817-a57c-e4dd734019ee"
}
```

You can use the following schema to validate embedded metric format documents.

```
{
    "type": "object",
    "title": "Root Node",
    "required": [
        "_aws"
    ],
    "properties": {
        "_aws": {
            "$id": "#/properties/_aws",
            "type": "object",
            "title": "Metadata",
            "required": [
                "Timestamp",
                "CloudWatchMetrics"
            ],
            "properties": {
                "Timestamp": {
                    "$id": "#/properties/_aws/properties/Timestamp",
                    "type": "integer",
                    "title": "The Timestamp Schema",
                    "examples": [
                        1565375354953
                    ]
                },
                "CloudWatchMetrics": {
                    "$id": "#/properties/_aws/properties/CloudWatchMetrics",
                    "type": "array",
                    "title": "MetricDirectives",
                    "items": {
                        "$id": "#/properties/_aws/properties/CloudWatchMetrics/items",
                        "type": "object",
                        "title": "MetricDirective",
                        "required": [
                            "Namespace",
                            "Dimensions",
```

```
                                "Metrics"
                            ],
                            "properties": {
                                "Namespace": {
                                    "$id": "#/properties/_aws/properties/CloudWatchMetrics/
items/properties/Namespace",
                                    "type": "string",
                                    "title": "CloudWatch Metrics Namespace",
                                    "examples": [
                                        "MyApp"
                                    ],
                                    "pattern": "^(.*)$",
                                    "minLength": 1,
                                    "maxLength": 1024
                                },
                                "Dimensions": {
                                    "$id": "#/properties/_aws/properties/CloudWatchMetrics/
items/properties/Dimensions",
                                    "type": "array",
                                    "title": "The Dimensions Schema",
                                    "minItems": 1,
                                    "items": {
                                        "$id": "#/properties/_aws/properties/
CloudWatchMetrics/items/properties/Dimensions/items",
                                        "type": "array",
                                        "title": "DimensionSet",
                                        "minItems": 0,
                                        "maxItems": 30,
                                        "items": {
                                            "$id": "#/properties/_aws/properties/
CloudWatchMetrics/items/properties/Dimensions/items/items",
                                            "type": "string",
                                            "title": "DimensionReference",
                                            "examples": [
                                                "Operation"
                                            ],
                                            "pattern": "^(.*)$",
                                            "minLength": 1,
                                            "maxLength": 250
}
                                    }
                                },
                                "Metrics": {
```

```
                                "$id": "#/properties/_aws/properties/CloudWatchMetrics/
items/properties/Metrics",
                                "type": "array",
                                "title": "MetricDefinitions",
                                "items": {
                                    "$id": "#/properties/_aws/properties/
CloudWatchMetrics/items/properties/Metrics/items",
                                    "type": "object",
                                    "title": "MetricDefinition",
                                    "required": [
                                        "Name"
                                    ],
                                    "properties": {
                                        "Name": {
                                            "$id": "#/properties/_aws/properties/
CloudWatchMetrics/items/properties/Metrics/items/properties/Name",
                                            "type": "string",
                                            "title": "MetricName",
                                            "examples": [
                                                "ProcessingLatency"
                                            ],
                                            "pattern": "^(.*)$",
                                            "minLength": 1,
                                            "maxLength": 1024
                                        },
                                        "Unit": {
                                            "$id": "#/properties/_aws/properties/
CloudWatchMetrics/items/properties/Metrics/items/properties/Unit",
                                            "type": "string",
                                            "title": "MetricUnit",
                                            "examples": [
                                                "Milliseconds"
                                            ],
                                            "pattern": "^(Seconds|Microseconds|
Milliseconds|Bytes|Kilobytes|Megabytes|Gigabytes|Terabytes|Bits|Kilobits|Megabits|
Gigabits|Terabits|Percent|Count|Bytes\\/Second|Kilobytes\\/Second|Megabytes\\/Second|
Gigabytes\\/Second|Terabytes\\/Second|Bits\\/Second|Kilobits\\/Second|Megabits\\/
Second|Gigabits\\/Second|Terabits\\/Second|Count\\/Second|None)$"
                                         },
                                         "StorageResolution": {
                                            "$id": "#/properties/_aws/properties/
CloudWatchMetrics/items/properties/Metrics/items/properties/StorageResolution",
                                            "type": "integer",
                                            "title": "StorageResolution",
```

```
                                            "examples": [
                                                60
                                            ]
                                        }
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
    }
}
```

Using the PutLogEvents API to send manually-created embedded metric format logs

You can send embedded metric format logs to CloudWatch Logs using the CloudWatch Logs PutLogEvents API. When calling PutLogEvents, you have the option to include the following HTTP header, which tells CloudWatch Logs the metrics should be extracted, but it's not required.

```
x-amzn-logs-format: json/emf
```

The following is a full example using the Amazon SDK for Java 2.x:

```
package org.example.basicapp;

import software.amazon.awssdk.regions.Region;
import software.amazon.awssdk.services.cloudwatchlogs.CloudWatchLogsClient;
import software.amazon.awssdk.services.cloudwatchlogs.model.DescribeLogStreamsRequest;
import software.amazon.awssdk.services.cloudwatchlogs.model.DescribeLogStreamsResponse;
import software.amazon.awssdk.services.cloudwatchlogs.model.InputLogEvent;
import software.amazon.awssdk.services.cloudwatchlogs.model.PutLogEventsRequest;

import java.util.Collections;

public class EmbeddedMetricsExample {
        public static void main(String[] args) {

                final String usage = "To run this example, supply a Region code (eg.
 us-east-1), log group, and stream name as command line arguments"
```

```
                                + "Ex: PutLogEvents <region-id> <log-group-name>
 <stream-name>";

                if (args.length != 3) {
                        System.out.println(usage);
                        System.exit(1);
                }

                String regionId = args[0];
                String logGroupName = args[1];
                String logStreamName = args[2];

                CloudWatchLogsClient logsClient =
 CloudWatchLogsClient.builder().region(Region.of(regionId)).build();

                // Build a JSON log using the EmbeddedMetricFormat.
                long timestamp = System.currentTimeMillis();
                String message = "{" +
                                "  \"_aws\": {" +
                                "    \"Timestamp\": " + timestamp  + "," +
                                "    \"CloudWatchMetrics\": [" +
                                "      {" +
                                "        \"Namespace\": \"MyApp\"," +
                                "        \"Dimensions\": [[\"Operation\"], [\"Operation
\", \"Cell\"]]," +
                                "        \"Metrics\": [{ \"Name\": \"ProcessingLatency
\", \"Unit\": \"Milliseconds\", \"StorageResolution\": 60 }]" +
                                "      }" +
                                "    ]" +
                                "  }," +
                                "  \"Operation\": \"Aggregator\"," +
                                "  \"Cell\": \"001\"," +
                                "  \"ProcessingLatency\": 100" +
                                "}";
                InputLogEvent inputLogEvent = InputLogEvent.builder()
                        .message(message)
                        .timestamp(timestamp)
                        .build();

                // Specify the request parameters.
                PutLogEventsRequest putLogEventsRequest = PutLogEventsRequest.builder()
                        .logEvents(Collections.singletonList(inputLogEvent))
                        .logGroupName(logGroupName)
                        .logStreamName(logStreamName)
```

```
                        .build();

                logsClient.putLogEvents(putLogEventsRequest);

                System.out.println("Successfully put CloudWatch log event");
        }

}
```

> **Note**
>
> With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the `Amazon/Logs` namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Using the CloudWatch agent to send embedded metric format logs

This section describes how to install and use the CloudWatch agent. The first part of this section describes how to install the CloudWatch agent. The the second part of this section describes how to use the CloudWatch agent to send embedded metric format logs. If you want to use this method, you must install the CloudWatch agent for the Amazon Web Services services you want to send embedded metric format logs from. Then you can begin sending the events. The CloudWatch agent must be version 1.230621.0 or later.

> **Note**
>
> You do not need to install the CloudWatch agent to send logs from Lambda functions. Lambda function timeouts are not handled automatically. This means that if your function times out before the metrics get flushed, then the metrics for that invocation will not be captured.

Installing the CloudWatch agent

Install the CloudWatch agent for each service which is to send embedded metric format logs.

Installing the CloudWatch agent on EC2

First, install the CloudWatch agent on the instance. For more information, see Install the CloudWatch agent.

Once you have installed the agent, configure the agent to listen on a UDP or TCP port for the embedded metric format logs. The following is an example of this configuration that listens on the default socket `tcp:25888`. For more information about agent configuration, see Manually create or edit the CloudWatch agent configuration file.

```
{
  "logs": {
    "metrics_collected": {
      "emf": { }
    }
  }
}
```

Installing the CloudWatch agent on Amazon ECS

The easiest way to deploy the CloudWatch agent on Amazon ECS is to run it as a sidecar, defining it in the same task definition as your application.

Create agent configuration file

Create your CloudWatch agent configuration file locally. In this example, the relative file path will be `amazon-cloudwatch-agent.json`.

For more information about agent configuration, see Manually create or edit the CloudWatch agent configuration file.

```
{
  "logs": {
    "metrics_collected": {
      "emf": { }
    }
  }
}
```

Push configuration to SSM Parameter Store

Enter the following command to push the CloudWatch agent configuration file to the Amazon Systems Manager (SSM) Parameter Store.

```
aws ssm put-parameter \
    --name "cwagentconfig" \
    --type "String" \
    --value "`cat amazon-cloudwatch-agent.json`" \
    --region "{{region}}"
```

Configure the task definition

Configure your task definition to use the CloudWatch Agent and expose the TCP or UDP port. The sample task definition that you should use depends on your networking mode.

Notice that the `webapp` specifies the `AWS_EMF_AGENT_ENDPOINT` environment variable. This is used by the library and should point to the endpoint that the agent is listening on. Additionally, the `cwagent` specifies the `CW_CONFIG_CONTENT` as a “valueFrom” parameter that points to the SSM configuration that you created in the previous step.

This section contains one example for bridge mode and one example for host or awsvpc mode. For more examples of how you can configure the CloudWatch agent on Amazon ECS, see the [Github samples repository]

The following is an example for bridge mode. When bridge mode networking is enabled, the agent needs to be linked to your application using the `links` parameter and must be addressed using the container name.

```
{
  "containerDefinitions": [
          {
              "name": "webapp",
              "links": [ "cwagent" ],
              "image": "my-org/web-app:latest",
              "memory": 256,
              "cpu": 256,
              "environment": [{
                "name": "AWS_EMF_AGENT_ENDPOINT",
                "value": "tcp://cwagent:25888"
              }],
          },
          {
```

```
                "name": "cwagent",
                "mountPoints": [],
                "image": "public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest",
                "memory": 256,
                "cpu": 256,
                "portMappings": [{
                    "protocol": "tcp",
                    "containerPort": 25888
                }],
                "environment": [{
                  "name": "CW_CONFIG_CONTENT",
                  "valueFrom": "cwagentconfig"
                }],
            }
        ],
}
```

The following is an example for host mode or awsvpc mode. When running on these network modes, the agent can be addressed over `localhost`.

```
{
  "containerDefinitions": [
            {
                "name": "webapp",
                "image": "my-org/web-app:latest",
                "memory": 256,
                "cpu": 256,
                "environment": [{
                  "name": "AWS_EMF_AGENT_ENDPOINT",
                  "value": "tcp://127.0.0.1:25888"
                }],
            },
            {
                "name": "cwagent",
                "mountPoints": [],
                "image": "public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest",
                "memory": 256,
                "cpu": 256,
                "portMappings": [{
                    "protocol": "tcp",
                    "containerPort": 25888
                }],
                "environment": [{
```

```
                "name": "CW_CONFIG_CONTENT",
                "valueFrom": "cwagentconfig"
              }],
          }
      ],
}
```

> **Note**
>
> In awsvpc mode, you must either give a public IP address to the VPC (Fargate only), set up a NAT gateway, or set up a CloudWatch Logs VPC endpoint. For more information about setting up a NAT, see [NAT Gateways](). For more information about setting up a CloudWatch Logs VPC endpoint, see [Using CloudWatch Logs with Interface VPC Endpoints]().
> The following is an example of how to assign a public IP address to a task that uses the Fargate launch type.
>
> ```
> aws ecs run-task \
> --cluster {{cluster-name}} \
> --task-definition cwagent-fargate \
> --region {{region}} \
> --launch-type FARGATE \
> --network-configuration
>  "awsvpcConfiguration={subnets=[{{subnetId}}],securityGroups=[{{sgId}}],assignPublicIp=ENA
> ```

Ensure permissions

Ensure the IAM role executing your tasks has permission to read from the SSM Parameter Store. You can add this permission by attaching the **AmazonSSMReadOnlyAccess** policy. To do so, enter the following command.

```
aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/AmazonSSMReadOnlyAccess
 \
--role-name CWAgentECSExecutionRole
```

Installing the CloudWatch agent on Amazon EKS

Parts of this process can be skipped if you have already installed CloudWatch Container Insights on this cluster.

Permissions

If you have not already installed Container Insights, then first ensure that your Amazon EKS nodes have the appropriate IAM permissions. They should have the **CloudWatchAgentServerPolicy** attached. For more information, see Verifying prerequisites for Container Insights in CloudWatch.

Create ConfigMap

Create a ConfigMap for the agent. The ConfigMap also tells the agent to listen on a TCP or UDP port. Use the following ConfigMap.

```
# cwagent-emf-configmap.yaml
apiVersion: v1
data:
  # Any changes here must not break the JSON format
  cwagentconfig.json: |
    {
      "agent": {
        "omit_hostname": true
      },
      "logs": {
        "metrics_collected": {
          "emf": { }
        }
      }
    }
kind: ConfigMap
metadata:
  name: cwagentemfconfig
  namespace: default
```

If you have already installed Container Insights, add the following `"emf": { }` line to your existing ConfigMap.

Apply the ConfigMap

Enter the following command to apply the ConfigMap.

```
kubectl apply -f cwagent-emf-configmap.yaml
```

Deploy the agent

To deploy the CloudWatch agent as a sidecar, add the agent to your pod definition, as in the following example.

```
apiVersion: v1
kind: Pod
metadata:
  name: myapp
  namespace: default
spec:
  containers:
    # Your container definitions go here
    - name: web-app
      image: my-org/web-app:latest
    # CloudWatch Agent configuration
    - name: cloudwatch-agent
      image: public.ecr.aws/cloudwatch-agent/cloudwatch-agent:latest
      imagePullPolicy: Always
      resources:
        limits:
          cpu: 200m
          memory: 100Mi
        requests:
          cpu: 200m
          memory: 100Mi
      volumeMounts:
        - name: cwagentconfig
          mountPath: /etc/cwagentconfig
      ports:
  # this should match the port configured in the ConfigMap
        - protocol: TCP
          hostPort: 25888
          containerPort: 25888
  volumes:
    - name: cwagentconfig
      configMap:
        name: cwagentemfconfig
```

Using the CloudWatch agent to send embedded metric format logs

When you have the CloudWatch agent installed and running, you can send the embedded metric format logs over TCP or UDP. There are two requirements when sending the logs over the agent:

- The logs must contain a `LogGroupName` key that tells the agent which log group to use.

- Each log event must be on a single line. In other words, a log event cannot contain the newline (\n) character.

The log events must also follow the embedded metric format specification. For more information, see Specification: Embedded metric format.

If you plan to create alarms on metrics created using embedded metric format, see Setting alarms on metrics created with the embedded metric format for recommendations.

The following is an example of sending log events manually from a Linux bash shell. You can instead use the UDP socket interfaces provided by your programming language of choice.

```
echo '{"_aws":{"Timestamp":1574109732004,"LogGroupName":"Foo","CloudWatchMetrics":
[{"Namespace":"MyApp","Dimensions":[["Operation"]],"Metrics":
[{"Name":"ProcessingLatency","Unit":"Milliseconds","StorageResolution":60}]}]},"Operation":"Agg
 \
> /dev/udp/0.0.0.0/25888
```

> **Note**
>
> With the embedded metric format, you can track the processing of your EMF logs by metrics that are published in the `Amazon/Logs` namespace of your account. These can be used to track failed metric generation from EMF, as well as whether failures happen due to parsing or validation. For more details see Monitoring with CloudWatch metrics.

Using the embedded metric format with Amazon Distro for OpenTelemetry

OpenTelemetry is an open-source initiative that removes boundaries and restrictions between vendor-specific formats for tracing, logs, and metrics by offering a single set of specifications and APIs. For more information, see OpenTelemetry. You can use the embedded metric format as a part of the OpenTelemetry project. Using the embedded metric format with OpenTelemetry requires two components: an OpenTelemetry-compliant data source and the Amazon Distro for OpenTelemetry Collector enabled for use with CloudWatch embedded metric format logs.

We have preconfigured redistributions of the OpenTelemetry components, which Amazon maintains, to make onboarding as easy as possible. For more information about using

OpenTelemetry with the embedded metric format, in addition to other Amazon services, see Amazon Distro for OpenTelemetry. For additional information regarding language support and usage, see Amazon Observability on Github.

Viewing your metrics and logs in the console

After you generate embedded metric format logs that extract metrics, you can use the CloudWatch console to view the metrics. Embedded metrics have the dimensions that you specified when you generated the logs. Also, the embedded metrics that you generated using the client libraries have the following default dimensions:

- ServiceType
- ServiceName
- LogGroup

This section describes how to view these metrics in the CloudWatch console and query your extracted metrics using CloudWatch Logs Insights.

To view metrics that were generated from embedded metric format logs

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. Select a namespace that you specified for your embedded metrics when you generated them. If you used the client libraries to generate the metrics and did not specify a namespace, then select **aws-embedded-metrics**. This is the default namespace for embedded metrics generated using the client libraries.
4. Select a metric dimension (for example, **ServiceName**).
5. The **All metrics** tab displays all metrics for that dimension in the namespace. You can do the following:
    a. To sort the table, use the column heading.
    b. To graph a metric, select the check box next to the metric. To select all metrics, select the check box in the heading row of the table.
    c. To filter by resource, choose the resource ID and then choose **Add to search**.
    d. To filter by metric, choose the metric name and then choose **Add to search**.

Querying logs using CloudWatch Logs Insights

You can query the detailed log events associated with the extracted metrics by using CloudWatch Logs Insights to provide deep insights into the root causes of operational events. One of the benefits of extracting metrics from your logs is that you can filter your logs later by the unique metric (metric name plus unique dimension set) and metric values, to get context on the events that contributed to the aggregated metric value

For example, to get an impacted request id or x-ray trace id, you could run the following query in CloudWatch Logs Insights.

```
filter Latency > 1000 and Operation = "Aggregator"
| fields RequestId, TraceId
```

You can also perform query-time aggregation on high-cardinality keys, such as finding the customers impacted by an event. The following example illustrates this.

```
filter Latency > 1000 and Operation = "Aggregator"
| stats count() by CustomerId

For more information, see [Analyzing Log Data with CloudWatch Logs Insights]

Setting alarms on metrics created with the embedded metric format

In general, creating alarms on metrics generated by the embedded metric format follows the same pattern as creating alarms on any other metrics. For more information, see [Using Amazon CloudWatch alarms]. Embedded metric format metric generation depends on your log publishing flow because CloudWatch Logs needs to process logs so they can be transformed into metrics. It's important to publish logs in a timely manner, so that metric datapoints are created within the period of time that alarms are evaluated.

If you plan on using the embedded metric format to send high-resolution metrics and create alarms on these metrics, we recommended that you flush logs to CloudWatch Logs at an interval of 5 seconds or less to avoid introducing an additional delay, which can cause alarming on partial or missing data. If you are using the CloudWatch agent, you can adjust the flush interval by setting the `force_flush_interval` parameter in the CloudWatch agent configuration file. This value defaults to 5 seconds. If you are using Lambda on other platforms where you can't control the log flush interval, consider using “M out of N” alarms to control the number of datapoints used to alarm. For more information, see Evaluating an alarm.

Amazon services that publish CloudWatch metrics

You can use the following table to learn which Amazon services publish metrics to CloudWatch. For information about the metrics and dimensions, see the specified documentation.

Service	Namespace	Documentation
Amazon Amplify	AWS/AmplifyHosting	Monitoring
Amazon API Gateway	AWS/ApiGateway	Monitor API Execution with Amazon CloudWatch
Amazon AppFlow	AWS/AppFlow	Monitoring Amazon AppFlow with Amazon CloudWatch
Amazon Application Migration Service	AWS/MGN	Monitoring Application Migration Service with Amazon CloudWatch
Amazon App Runner	AWS/AppRunner	Viewing App Runner service metrics reported to CloudWatch
AppStream 2.0	AWS/AppStream	Monitoring Amazon AppStream 2.0 Resources
Amazon AppSync	AWS/AppSync	CloudWatch Metrics
Amazon Athena	AWS/Athena	Monitoring Athena Queries with CloudWatch Metrics
Amazon Aurora	AWS/RDS	Amazon Aurora metrics
Amazon Backup	AWS/Backup	Monitoring Amazon Backup Metrics with CloudWatch
Amazon Bedrock Guardrails	AWS/Bedrock/Guardrails	Monitoring Amazon Bedrock Guardrails using CloudWatch Metrics

Service	Namespace	Documentation
Amazon Billing and Cost Management	AWS/Billing	Monitoring Charges with Alerts and Notifications
Amazon Braket	AWS/Braket/By Device	Monitoring Amazon Braket with Amazon CloudWatch
Amazon Certificate Manager	AWS/CertificateManager	Supported CloudWatch Metrics
Amazon Private CA	AWS/ACMPrivateCA	Supported CloudWatch Metrics
Amazon Q Developer in chat applications	AWS/Chatbot	Monitoring Amazon Q Developer in chat applications with Amazon CloudWatch
Amazon Chime	AWS/ChimeVoiceConnector	Monitoring Amazon Chime with Amazon CloudWatch
Amazon Chime SDK	AWS/ChimeSDK	Service metrics
Amazon Client VPN	AWS/ClientVPN	Monitoring with Amazon CloudWatch
Amazon CloudFront	AWS/CloudFront	Monitoring CloudFront Activity Using CloudWatch
Amazon CloudHSM	AWS/CloudHSM	Getting CloudWatch Metrics
Amazon CloudSearch	AWS/CloudSearch	Monitoring an Amazon CloudSearch Domain with Amazon CloudWatch

Service	Namespace	Documentation
Amazon CloudTrail	AWS/CloudTrail	Supported CloudWatch metrics
CloudWatch agent	CWAgent or a custom namespace	Metrics collected by the CloudWatch agent
CloudWatch Application Signals	ApplicationSignals	Metrics collected by Application Signals
CloudWatch metric streams	AWS/CloudWatch/MetricStreams	Monitoring your metric streams with CloudWatch metrics
CloudWatch RUM	AWS/RUM	CloudWatch metrics that you can collect with CloudWatch RUM
CloudWatch Synthetics	CloudWatchSynthetics	CloudWatch metrics published by canaries
Amazon CloudWatch Logs	AWS/Logs	Monitoring Usage with CloudWatch Metrics
Amazon CodeBuild	AWS/CodeBuild	Monitoring Amazon CodeBuild
Amazon CodeGuru Reviewer		Monitoring CodeGuru Reviewer with Amazon CloudWatch
Amazon CodePipeline		Amazon CodePipeline CloudWatch metrics
Amazon Kendra		Monitoring Amazon Kendra with Amazon CloudWatch

Service	Namespace	Documentation
Amazon Cognito	AWS/Cognito	Monitoring Amazon Cognito
Amazon Comprehend	AWS/Comprehend	Monitoring Amazon Comprehend endpoints
Amazon Config	AWS/Config	Amazon Config Usage and Success Metrics
Amazon Connect	AWS/Connect	Monitoring Amazon Connect in Amazon CloudWatch Metrics
Amazon Data Lifecycle Manager	AWS/DataLifecycleManager	Monitor your policies using Amazon CloudWatch
Amazon DataSync	AWS/DataSync	Monitoring Your Task
Amazon DataZone		Monitoring Amazon DataZone with Amazon CloudWatch
Amazon DevOps Guru	AWS/DevOps-Guru	Monitoring Amazon DevOps Guru with Amazon CloudWatch
Amazon Database Migration Service	AWS/DMS	Monitoring Amazon DMS Tasks
Amazon Direct Connect	AWS/DX	Monitoring with Amazon CloudWatch
Amazon Directory Service	AWS/DirectoryService	Use Amazon CloudWatch metrics to determine when to add domain controllers
Amazon DocumentDB	AWS/DocDB	Monitoring Amazon DocumentDB with CloudWatch

Service	Namespace	Documentation
Amazon DynamoDB	AWS/DynamoDB	DynamoDB Metrics and Dimensions
DynamoDB Accelerator (DAX)	AWS/DAX	Viewing DAX Metrics and Dimensions
Amazon EC2	AWS/EC2	Monitoring Your Instances Using CloudWatch
Amazon EC2 Elastic Graphics	AWS/ElasticGPUs	Using CloudWatch metrics to monitor Elastic Graphics
Amazon EC2 Spot Fleet	AWS/EC2Spot	CloudWatch Metrics for Spot Fleet
Amazon EC2 Auto Scaling	AWS/AutoScaling	Monitoring Your Auto Scaling Groups and Instances Using CloudWatch
Amazon Elastic Beanstalk	AWS/ElasticBeanstalk	Publishing Amazon CloudWatch Custom Metrics for an Environment
Amazon Elastic Block Store	AWS/EBS	Amazon CloudWatch Metrics for Amazon EBS
Amazon Elastic Container Registry	AWS/ECR	Amazon ECR repository metrics
Amazon Elastic Container Service	AWS/ECS	Amazon ECS CloudWatch Metrics

Service	Namespace	Documentation
Amazon ECS through CloudWatch Container Insights	ECS/ContainerInsights	Amazon ECS Container Insights metrics
Amazon ECS Cluster auto scaling	AWS/ECS/ManagedScaling	Amazon ECS cluster auto scaling
Amazon Elastic Disaster Recovery		CloudWatch Metrics for DRS
Amazon Elastic File System	AWS/EFS	Monitoring with CloudWatch
Amazon Elastic Inference	AWS/ElasticInference	Using CloudWatch Metrics to Monitor Amazon Elastic Inference
Amazon EKS	AWS/EKS	Basic metrics in Amazon CloudWatch
Amazon EKS through CloudWatch Container Insights	ContainerInsights	Amazon EKS and Kubernetes Container Insights metrics
Elastic Load Balancing	AWS/ApplicationELB	CloudWatch Metrics for your Application Load Balancer
Elastic Load Balancing	AWS/NetworkELB	CloudWatch Metrics for your Network Load Balancer
Elastic Load Balancing	AWS/GatewayELB	CloudWatch Metrics for your Gateway Load Balancer

Service	Namespace	Documentation
Elastic Load Balancing	AWS/ELB	CloudWatch Metrics for your Classic Load Balancer
Amazon Elastic Transcoder	AWS/ElasticTranscoder	Monitoring with Amazon CloudWatch
Amazon ElastiCache (Memcached)	AWS/ElastiCache	Monitoring Use with CloudWatch Metrics
Amazon ElastiCache (Redis OSS)	AWS/ElastiCache	Monitoring Use with CloudWatch Metrics
Amazon OpenSearch Service	AWS/ES	Monitoring OpenSearch cluster metrics with Amazon CloudWatch
Amazon EMR	AWS/ElasticMapReduce	Monitor Metrics with CloudWatch
AWS Elemental MediaConnect	AWS/MediaConnect	Monitoring MediaConnect with Amazon CloudWatch
AWS Elemental MediaConvert	AWS/MediaConvert	Using CloudWatch Metrics to View Metrics for AWS Elemental MediaConvert Resources
AWS Elemental MediaLive	AWS/MediaLive	Monitoring activity using Amazon CloudWatch metrics
AWS Elemental MediaPackage	AWS/MediaPackage	Monitoring AWS Elemental MediaPackage with Amazon CloudWatch Metrics
AWS Elemental MediaStore	AWS/MediaStore	Monitoring AWS Elemental MediaStore with Amazon CloudWatch Metrics

Service	Namespace	Documentation
AWS Elemental MediaTailor	AWS/MediaTailor	Monitoring AWS Elemental MediaTailor with Amazon CloudWatch
Amazon End User Messaging SMS	AWS/SMSVoice	Monitoring Amazon End User Messaging SMS with Amazon CloudWatch
Amazon End User Messaging Social	AWS/SocialMessaging	Monitoring Amazon End User Messaging Social with Amazon CloudWatch
Amazon EventBridge	AWS/Events	Monitoring Amazon EventBridge
Amazon FinSpace		Logging and monitoring
Amazon Forecast		CloudWatch Metrics for Amazon Forecast
Amazon Fraud Detector		Monitoring Amazon Fraud Detector with Amazon CloudWatch
Amazon FSx for Lustre	AWS/FSx	Monitoring Amazon FSx for Lustre
Amazon FSx for OpenZFS	AWS/FSx	Monitoring with Amazon CloudWatch
Amazon FSx for Windows File Server	AWS/FSx	Monitoring Amazon FSx for Windows File Server
Amazon FSx for NetApp ONTAP	AWS/FSx	Monitoring with Amazon CloudWatch

Service	Namespace	Documentation
Amazon FSx for OpenZFS	AWS/FSx	Monitoring with Amazon CloudWatch
Amazon GameLift Servers	AWS/GameLift	Monitor Amazon GameLift Servers with CloudWatch
Amazon Global Accelerator	AWS/GlobalAccelerator	Using Amazon CloudWatch with Amazon Global Accelerator
Amazon Glue	Glue	Monitoring Amazon Glue Using CloudWatch Metrics
Amazon Ground Station	AWS/GroundStation	Metrics Using Amazon CloudWatch
Amazon HealthLake	AWS/HealthLake	Monitoring HealthLake with CloudWatch
Amazon Inspector	AWS/Inspector	Monitoring Amazon Inspector Using CloudWatch
Amazon Interactive Video Service	AWS/IVS	Monitoring Amazon IVS with Amazon CloudWatch
Amazon Interactive Video Service Chat	AWS/IVSChat	Monitoring Amazon IVS with Amazon CloudWatch
Amazon IoT	AWS/IoT	Amazon IoT Metrics and Dimensions
Amazon IoT Analytics	AWS/IoTAnalytics	Namespace, Metrics, and Dimensions
Amazon IoT FleetWise	AWS/IoTFleetWise	Monitoring Amazon IoT FleetWise with Amazon CloudWatch

Service	Namespace	Documentation
Amazon IoT SiteWise	AWS/IoTSiteWise	Monitoring Amazon IoT SiteWise with Amazon CloudWatch metrics
Amazon IoT TwinMaker	AWS/IoTTwinMaker	Monitoring Amazon IoT TwinMaker with Amazon CloudWatch metrics
Amazon Key Management Service	AWS/KMS	Monitoring with CloudWatch
Amazon Keyspaces (for Apache Cassandra)	AWS/Cassandra	Amazon Keyspaces Metrics and Dimensions
Amazon Kendra		Monitoring Amazon Kendra with Amazon CloudWatch
Amazon Managed Service for Apache Flink	AWS/KinesisAnalytics	*Managed Service for Apache Flink for SQL Applications*: Monitoring with CloudWatch *Managed Service for Apache Flink for Apache Flink*: Viewing Amazon Managed Service for Apache Flink Metrics and Dimensions
Amazon Data Firehose	AWS/Firehose	Monitoring Firehose Using CloudWatch Metrics
Amazon Kinesis Data Streams	AWS/Kinesis	Monitoring Amazon Kinesis Data Streams with Amazon CloudWatch
Amazon Kinesis Video Streams	AWS/KinesisVideo	Monitoring Kinesis Video Streams Metrics with CloudWatch
Amazon Lambda	AWS/Lambda	Amazon Lambda Metrics
Amazon Lex	AWS/Lex	Monitoring Amazon Lex with Amazon CloudWatch

Service	Namespace	Documentation
Amazon License Manager	AWSLicenseManager/licenseUsage AWS/LicenseManager/LinuxSubscriptions	Monitoring license usage with Amazon CloudWatch Usage metrics and Amazon CloudWatch alarms for Linux subscriptions
Amazon Location Service	AWS/Location	Amazon Location Service metrics exported to Amazon CloudWatch
Amazon Lookout for Equipment	AWS/lookoutequipment	Monitoring Lookout for Equipment with Amazon CloudWatch

Amazon Translate	AWS/Translate	CloudWatch Metrics and Dimensions for Amazon Translate
Amazon Trusted Advisor	AWS/TrustedAdvisor	Creating Trusted Advisor Alarms Using CloudWatch
Amazon VPC	AWS/NATGateway	Monitoring Your NAT Gateway with CloudWatch
Amazon VPC	AWS/TransitGateway	CloudWatch Metrics for Your Transit Gateways

Service	Namespace	Documentation
Amazon VPC	AWS/VPN	Monitoring with CloudWatch
Amazon VPC IP Address Manager	AWS/IPAM	Create alarms with Amazon CloudWatch
Amazon WAF	AWS/WAFV2 for Amazon WAF resources WAF for Amazon WAF classic resources	Monitoring with CloudWatch
Amazon WorkMail	AWS/WorkMail	Monitoring Amazon WorkMail with Amazon CloudWatch
Amazon WorkSpaces	AWS/WorkSpaces	Monitor Your WorkSpaces Using CloudWatch Metrics
Amazon WorkSpaces Web	AWS/WorkSpacesWeb	Monitoring Amazon WorkSpaces Web with Amazon CloudWatch

Amazon usage metrics

CloudWatch collects metrics that track the usage of some Amazon resources and APIs. These metrics are published in the `AWS/Usage` namespace. Usage metrics in CloudWatch allow you to proactively manage usage by visualizing metrics in the CloudWatch console, creating custom dashboards, detecting changes in activity with CloudWatch anomaly detection, and configuring alarms that alert you when usage approaches a threshold.

Some Amazon services integrate these usage metrics with Service Quotas. For these services, you can use CloudWatch to manage your account's use of your service quotas. For more information, see Visualizing your service quotas and setting alarms.

Topics

Visualizing your service quotas and setting alarms

For some Amazon services, you can use the usage metrics to visualize your current service usage on CloudWatch graphs and dashboards. You can use a CloudWatch metric math function to display the service quotas for those resources on your graphs. You can also configure alarms that alert you when your usage approaches a service quota. For more information about service quotas, see What Is Service Quotas in the *Service Quotas User Guide*.

If you are signed in to an account that is set up as a monitoring account in CloudWatch cross-account observability, you can use that monitoring account to visualize service quotas and set alarms for metrics in the source accounts that are linked to that monitoring account. For more information, see CloudWatch cross-account observability.

Currently, the following services integrate their usage metrics with Service Quotas:

- Amazon CloudHSM
- Amazon Chime SDK
- Amazon CloudWatch

- Amazon CloudWatch Logs
- Amazon DynamoDB
- Amazon EC2
- Amazon Elastic Container Registry
- Elastic Load Balancing
- Amazon Fargate
- Amazon Fault Injection Service
- Amazon Interactive Video Service
- Amazon Key Management Service
- Amazon Data Firehose
- Amazon Location Service
- Amazon Managed Blockchain (AMB) Query
- Amazon RoboMaker
- Amazon SageMaker AI

To visualize a service quota and optionally set an alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. On the **All metrics** tab, choose **Usage**, and then choose **By Amazon Resource**.

   The list of service quota usage metrics appears.
4. Select the check box next to one of the metrics.

   The graph displays your current usage of that Amazon resource.
5. To add your service quota to the graph, do the following:

   a. Choose the **Graphed metrics** tab.

   b. Choose **Math expression**, **Start with an empty expression**. In the new row, under **Details**, enter **`SERVICE_QUOTA(m1)`**.

      A new line is added to the graph, displaying the service quota for the resource represented in the metric.

6. To see your current usage as a percentage of the quota, add a new expression or change the current **SERVICE_QUOTA** expression. The new expression to use is **`m1/SERVICE_QUOTA(m1)*100`**.
7. (Optional) To set an alarm that notifies you if you approach the service quota, do the following:

   a. On the row with **`m1/SERVICE_QUOTA(m1)*100`**, under **Actions**, choose the alarm icon. It looks like a bell.

      The alarm creation page appears.
   b. Under **Conditions**, ensure that **Threshold type** is **Static** and **Whenever Expression1 is** is set to **Greater**. Under **than**, enter **`80`**. This creates an alarm that goes into ALARM state when your usage exceeds 80 percent of the quota.
   c. Choose **Next**.
   d. On the next page, select an Amazon SNS topic or create a new one, and then choose **Next**. The topic you select is notified when the alarm goes to ALARM state.
   e. On the next page, enter a name and description for the alarm, and then choose **Next**.
   f. Choose **Create alarm**.

Amazon API usage metrics

Most APIs that support Amazon CloudTrail logging also report usage metrics to CloudWatch. API usage metrics in CloudWatch allow you to proactively manage API usage by visualizing metrics in the CloudWatch console, creating custom dashboards, detecting changes in activity with CloudWatch Anomaly Detection, and configuring alarms that alert when usage approaches a threshold.

You can use the he following table to learn about services that report API usage metrics to CloudWatch. The table lists the values to use for the `Service` dimension, so you can see the usage metrics from that service. You can use the procedure in this section to view the list of a service's APIs that report usage metrics to CloudWatch.

Service	Value for the `Service` dimension
Amazon Identity and Access Management Access Analyzer	`Access Analyzer`

Service	Value for the Service dimension
Amazon Account Management	Account Management
Alexa for Business	A4B
Amazon API Gateway	API Gateway
Amazon App Mesh	App Mesh
Amazon AppConfig	AWS AppConfig
Amazon AppFlow	AppFlow
Application Auto Scaling	Application Auto Scaling
Application Discovery Service	Application Discovery Service
Amazon AppStream	AppStream
AppStream 2.0 Image Builder	Image Builder
Amazon Athena	Athena
Amazon Audit Manager	Audit Manager
Amazon Backup	Backup
Amazon Batch	Batch
Amazon Braket	Braket
Amazon Budgets	Budgets
Amazon Certificate Manager	Certificate Manager
Amazon Chime SDK	ChimeSDK
Amazon Cloud Directory	Cloud Directory
Amazon Cloud Map	Cloud Map

Service	Value for the Service dimension
Amazon CloudFormation	CloudFormation
Amazon CloudHSM	CloudHSM
Amazon CloudSearch	CloudSearch
Amazon CloudShell	CloudShell
Amazon CloudTrail	CloudTrail
Amazon CloudWatch	CloudWatch
Amazon CloudWatch Application Signals	CloudWatch Application Signals
Amazon CloudWatch Logs	Logs
Amazon CloudWatch Application Insights	CloudWatch Application Insights
Amazon CodeBuild	CodeBuild
Amazon CodeCommit	CodeCommit
Amazon CodeGuru Profiler	CodeGuru Profiler
Amazon CodePipeline	CodePipeline
AWS CodeStar	CodeStar
AWS CodeStar Notifications	CodeStar Notifications
AWS CodeStar Connections	CodeStar Connections
Amazon Cognito Identity pools	Cognito Identity Pools
Amazon Cognito Sync	Cognito Sync
Amazon Comprehend	Comprehend
Amazon Comprehend Medical	Comprehend Medical

Service	Value for the Service dimension
Amazon Compute Optimizer	ComputeOptimzier
Amazon Connect	Connect
Amazon Connect Customer Profiles	Customer Profiles
Amazon Cost and Usage Reports	Cost and Usage Report
Amazon Cost Explorer	Cost Explorer
Amazon Data Exchange	Data Exchange
Amazon Data Lifecycle Manager	Data Lifecycle Manager
Amazon Database Migration Service	Database Migration Service
Amazon DataSync	DataSync
Amazon Detective	Detective
Device Advisor	Device Advisor
Amazon Direct Connect	Direct Connect
Amazon Directory Service	Directory Service
DynamoDB Accelerator	DynamoDBAccelerator
Amazon EC2	EC2
EC2 Auto Scaling	EC2 Auto Scaling
Amazon Elastic Container Registry	ECR Public
Amazon Elastic Container Service	ECS
Amazon Elastic File System	EFS
Amazon Elastic Kubernetes Service	EKS

Service	Value for the Service dimension
Amazon Elastic Beanstalk	Elastic Beanstalk
Amazon Elastic Inference	Elastic Inference
Elastic Load Balancing	Elastic Load Balancing
Amazon EMR	EMR Containers
Amazon Firewall Manager	Firewall Manager
Amazon FSx	FSx
Amazon GameLift Servers	GameLift
Amazon Glue DataBrew	DataBrew
Amazon Managed Grafana	Grafana
Amazon IoT Greengrass	Greengrass
Amazon Ground Station	Ground Station
Amazon Health APIs And Notifications	Amazon Health APIs And Notifications
Amazon Interactive Video Service	IVS
Amazon IoT Core	IoT
Amazon IoT Events	IoT Events
Amazon IoT RoboRunner	IoT RoboRunner
Amazon IoT SiteWise	IoT Sitewise
Amazon IoT Wireless	IoT Wireless
Amazon Kendra	Kendra
Amazon Keyspaces (for Apache Cassandra)	Keyspaces

Service	Value for the Service dimension
Amazon Managed Service for Apache Flink	Kinesis Analytics
Amazon Data Firehose	Firehose
Kinesis Video Streams	Kinesis Video Streams
Amazon Key Management Service	KMS
Amazon Lambda	Lambda
Amazon Launch Wizard	Launch Wizard
Amazon Lex	Amazon Lex
Amazon Lightsail	Lightsail
Amazon Location Service	Location
Amazon Lookout for Vision	Lookout for Vision
Amazon Machine Learning	Amazon Machine Learning
Amazon Macie	Macie
Amazon Managed Blockchain (AMB) Query	Amazon Managed Blockchain Query
Amazon Managed Services	AWS Managed Services
Amazon Marketplace Commerce Analytics	Marketplace Analytics Service
AWS Elemental MediaConnect	MediaConnect
AWS Elemental MediaConvert	MediaConvert
AWS Elemental MediaLive	MediaLive
AWS Elemental MediaStore	Mediastore
AWS Elemental MediaTailor	MediaTailor

Service	Value for the `Service` dimension
Amazon Mobile Hub	`Mobile Hub`
Amazon Network Firewall	`Network Firewall`
Amazon OpsWorks	`OpsWorks`
Amazon OpsWorks for Configuration Management	`OPsWorks CM`
Amazon Outposts	`Outposts`
Amazon Organizations	`Organizations`
Amazon RDS Performance Insights	`Performance Insights`
Amazon Pinpoint	`Pinpoint`
Amazon Private Certificate Authority	`Private Certificate Authority`
Amazon Managed Service for Prometheus	`Prometheus`
Amazon Proton	`Proton`
Amazon Quantum Ledger Database (Amazon QLDB)	`QLDB`
Amazon RDS	`RDS`
Amazon Redshift	`Redshift Data API`
Amazon Rekognition	`Rekognition`
Amazon Resource Access Manager	`Resource Access Manager`
Amazon Resource Groups	`Resource Groups`
Amazon Resource Groups Tagging API	`Resource Groups Tagging API`
Amazon RoboMaker	`RoboMaker`

Service	Value for the Service dimension
Amazon Route 53 Domains	`Route 53 Domains`
Amazon Route 53 Resolver	`Route 53 Resolver`
Amazon S3	`S3`
Amazon S3 Glacier	`Amazon S3 Glacier`
Amazon SageMaker Runtime	`Sagemaker`
Savings Plans	`Savings Plans`
Amazon Secrets Manager	`Secrets Manager`
Amazon Security Hub	`Security Hub`
Amazon Server Migration Service	`Amazon Server Migration Service`
Amazon Service Catalog AppRegistry	`Service Catalog AppRegistry`
Service Quotas	`Service Quotas`
Amazon Shield	`Shield`
Amazon Signer	`Signer`
Amazon Simple Notification Service	`SNS`
Amazon Simple Email Service	`SES`
Amazon Simple Queue Service	`SQS`
Identity Store	`Identity Store`
Storage Gateway	`Storage Gateway`
Amazon Web Services Support	`Support`
Amazon Simple Workflow Service	`SWF`

Service	Value for the Service dimension
Amazon Textract	Textract
Amazon IoT Things Graph	ThingsGraph
Amazon Timestream	Timestream
Amazon Transcribe	Transcribe
Amazon Translate	Translate
Amazon Transcribe streaming transcription	Transcribe Streaming
Amazon Transfer Family	Transfer
Amazon WAF	WAF
Amazon WorkDocs	Amazon WorkDocs
Amazon WorkLink	WorkLink
Amazon WorkMail	Amazon WorkMail
Amazon WorkSpaces	Workspaces
Amazon X-Ray	X-Ray

Some services report usage metrics for additional APIs as well. To see whether an API reports usage metrics to CloudWatch, use the CloudWatch console to see the metrics reported by that service in the AWS/Usage namespace.

To see the list of a service's APIs that report usage metrics to CloudWatch

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Metrics**.
3. On the **All metrics** tab, choose **Usage**, and then choose **By Amazon Resource**.
4. In the search box near the list of metrics, enter the name of the service. The metrics are filtered by the service you entered.

CloudWatch usage metrics

CloudWatch collects metrics that track the usage of some Amazon resources. These metrics correspond to Amazon service quotas. Tracking these metrics can help you proactively manage your quotas. For more information, see Visualizing your service quotas and setting alarms. Service quota usage metrics are in the AWS/Usage namespace and are collected every minute.

The metrics that can be published in this namespace include CallCount, ResourceCount, and ThrottleCount. These metrics are published with the dimensions Resource, Service, and Type. The Resource dimension specifies the name of the API operation being tracked. For example, the CallCount metric with the dimensions "Service": "CloudWatch", "Type": "API" and "Resource": "PutMetricData" indicates the number of times the CloudWatch PutMetricData API operation has been called in your account.

The CallCount metric does not have a specified unit. The most useful statistic for the metric is SUM, which represents the total operation count for the 1-minute period.

Metrics

Metric	Description
CallCount	The number of specified operations performed in your account.

Dimensions

Dimension	Description
Service	The name of the Amazon service containing the resource. For CloudWatch usage metrics, the value for this dimension is CloudWatch .
Class	The class of resource being tracked. CloudWatch API usage metrics use this dimension with a value of None.
Type	The type of resource being tracked. Currently, when the Service dimension is CloudWatch , the only valid value for Type is API.
Resource	The name of the API operation. Valid values include the following:

Dimension	Description
	DeleteAlarms ,DeleteDashboards ,DescribeAlarmHisto ry ,DescribeAlarms ,GetDashboard ,GetMetricData , GetMetricStatistics ,ListMetrics ,PutDashboard ,and PutMetricData

Amazon CloudWatch tutorials

The following scenarios illustrate how you can use Amazon CloudWatch. In the first scenario, you use the CloudWatch console to create a billing alarm that tracks your Amazon usage and lets you know when you have exceeded a certain spending threshold. In the second scenario, you use the Amazon Command Line Interface (Amazon CLI) to publish a single metric for a hypothetical application named *GetStarted*.

Scenarios

- Monitor your estimated charges
- Publish metrics

Scenario: Monitor your estimated charges using CloudWatch

In this scenario, you create an Amazon CloudWatch alarm to monitor your estimated charges. When you enable the monitoring of estimated charges for your Amazon account, the estimated charges are calculated and sent several times daily to CloudWatch as metric data.

Billing metric data is stored in the US East (N. Virginia) Region and reflects worldwide charges. This data includes the estimated charges for every service in Amazon that you use, as well as the estimated overall total of your Amazon charges.

You can choose to receive alerts by email when charges have exceeded a certain threshold. These alerts are triggered by CloudWatch and messages are sent using Amazon Simple Notification Service (Amazon SNS).

> **Note**
>
> For information about analyzing CloudWatch charges that you have already been billed for, see Analyzing, optimizing, and reducing CloudWatch costs.

Tasks

- Step 1: Enable billing alerts
- Step 2: Create a billing alarm

- Step 3: Check the alarm status
- Step 4: Edit a billing alarm
- Step 5: Delete a billing alarm

Step 1: Enable billing alerts

Before you can create an alarm for your estimated charges, you must enable billing alerts, so that you can monitor your estimated Amazon charges and create an alarm using billing metric data. After you enable billing alerts, you cannot disable data collection, but you can delete any billing alarms that you created.

After you enable billing alerts for the first time, it takes about 15 minutes before you can view billing data and set billing alarms.

Requirements

- You must be signed in using root user credentials or as a user who has been given permission to view billing information.
- For consolidated billing accounts, billing data for each linked account can be found by logging in as the paying account. You can view billing data for total estimated charges and estimated charges by service for each linked account, in addition to the consolidated account.
- In a consolidated billing account, member linked account metrics are captured only if the payer account enables the **Receive Billing Alerts** preference. If you change which account is your management/payer account, you must enable the billing alerts in the new management/payer account.
- The account must not be part of the Amazon Partner Network (APN) because billing metrics are not published to CloudWatch for APN accounts. For more information, see Amazon Partner Network.

To enable the monitoring of estimated charges

1. Open the Amazon Billing and Cost Management console at https://console.amazonaws.cn/costmanagement/.
2. In the navigation pane, choose **Billing Preferences**.
3. By **Alert preferences** choose **Edit**.

4. Choose **Receive CloudWatch Billing Alerts**.
5. Choose **Save preferences**.

Step 2: Create a billing alarm

> **Important**
>
> Before you create a billing alarm, you must set your Region to US East (N. Virginia). Billing metric data is stored in this Region and represents worldwide charges. You also must enable billing alerts for your account or in the management/payer account (if you are using consolidated billing). For more information, see Step 1: Enable billing alerts.

In this procedure, you create an alarm that sends a notification when your estimated charges for Amazon exceed a defined threshold.

To create a billing alarm using the CloudWatch console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the navigation pane, choose **Alarms**, and then choose **All alarms**.
3. Choose **Create alarm**.
4. Choose **Select metric**. In the **Browse** tab, choose **Billing**, and then choose **Total Estimated Charge**.

    > **Note**
    >
    > If you don't see the **Billing/Total Estimated Charge** metric, enable billing alerts, and change your Region to US East (N. Virginia). For more information, see Enabling billing alerts.

5. Select the checkbox for the **EstimatedCharges** metric, and then choose **Select metric**.
6. For **Statistic**, choose **Maximum**.
7. For **Period**, choose **6 hours**.
8. For **Threshold type**, choose **Static**.
9. For **Whenever EstimatedCharges is . . .**, choose **Greater**.

10. For **than . . .**, define the value that you want to cause your alarm to trigger. For example, **200** USD.

    The **EstimatedCharges** metric values are only in US dollars (USD), and the currency conversion is provided by Amazon Services LLC. For more information, see What is Amazon Billing?.

11. Choose **Additional Configuration** and do the following:

    - For **Datapoints to alarm**, specify **1 out of 1**.
    - For **Missing data treatment**, choose **Treat missing data as missing**.

12. Choose **Next**.

13. Under **Notification**, ensure that **In alarm** is selected. Then specify an Amazon SNS topic to be notified when your alarm is in the `ALARM` state. The Amazon SNS topic can include your email address so that you recieve email when the billing amount crosses the threshold that you specified.

    You can select an existing Amazon SNS topic, create a new Amazon SNS topic, or use a topic ARN to notify other account. If you want your alarm to send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**.

14. Choose **Next**.

15. Under **Name and description**, enter a name for your alarm.

    - (Optional) Enter a description of your alarm.

16. Choose **Next**.

17. Under **Preview and create**, make sure that your configuration is correct, and then choose **Create alarm**.

Step 3: Check the alarm status

Now, check the status of the billing alarm that you just created.

To check the alarm status

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**, **All alarms**.

4. Find the row in the table for your new alarm. Until the subscription is confirmed, it is shown as "Pending confirmation". After the subscription is confirmed, refresh the console to show the updated status.

Step 4: Edit a billing alarm

For example, you may want to increase the amount of money you spend with Amazon each month from $200 to $400. You can edit your existing billing alarm and increase the monetary amount that must be exceeded before the alarm is triggered.

To edit a billing alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**, **All alarms**.
4. Select the checkbox next to the alarm and choose **Actions**, **Edit**.
5. For **than...**, specify the new amount that must be exceeded to trigger the alarm and send an email notification.
6. Choose **Save Changes**.

Step 5: Delete a billing alarm

If you no longer need your billing alarm, you can delete it.

To delete a billing alarm

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. If necessary, change the Region to US East (N. Virginia). Billing metric data is stored in this Region and reflects worldwide charges.
3. In the navigation pane, choose **Alarms**, **All alarms**.
4. Select the checkbox next to the alarm and choose **Actions**, **Delete**.
5. When prompted for confirmation, choose **Yes, Delete**.

Scenario: Publish metrics to CloudWatch

In this scenario, you use the Amazon Command Line Interface (Amazon CLI) to publish a single metric for a hypothetical application named *GetStarted*. If you haven't already installed and configured the Amazon CLI, see Getting Set Up with the Amazon Command Line Interface in the *Amazon Command Line Interface User Guide*.

Tasks

Step 1: Define the data configuration

In this scenario, you publish data points that track the request latency for the application. Choose names for your metric and namespace that make sense to you. For this example, name the metric *RequestLatency* and place all of the data points into the *GetStarted* namespace.

You publish several data points that collectively represent three hours of latency data. The raw data comprises 15 request latency readings distributed over three hours. Each reading is in milliseconds:

- Hour one: 87, 51, 125, 235
- Hour two: 121, 113, 189, 65, 89
- Hour three: 100, 47, 133, 98, 100, 328

You can publish data to CloudWatch as single data points or as an aggregated set of data points called a *statistic set*. You can aggregate metrics to a granularity as low as one minute. You can publish the aggregated data points to CloudWatch as a set of statistics with four predefined keys: `Sum`, `Minimum`, `Maximum`, and `SampleCount`.

You publish the data points from hour one as single data points. For the data from hours two and three, you aggregate the data points and publish a statistic set for each hour. The key values are shown in the following table.

Hour	Raw data	Sum	Minimum	Maximum	SampleCount
1	87				
1	51				
1	125				
1	235				
2	121, 113, 189, 65, 89	577	65	189	5
3	100, 47, 133, 98, 100, 328	806	47	328	6

Step 2: Add metrics to CloudWatch

After you have defined your data configuration, you are ready to add data.

To publish data points to CloudWatch

1. At a command prompt, run the following put-metric-data commands to add data for the first hour. Replace the example timestamp with a timestamp that is two hours in the past, in Universal Coordinated Time (UTC).

```
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 87 --unit Milliseconds
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 51 --unit Milliseconds
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 125 --unit Milliseconds
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T20:30:00Z --value 235 --unit Milliseconds
```

2. Add data for the second hour, using a timestamp that is one hour later than the first hour.

```
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--timestamp 2016-10-14T21:30:00Z --statistic-values
 Sum=577,Minimum=65,Maximum=189,SampleCount=5 --unit Milliseconds
```

3. Add data for the third hour, omitting the timestamp to default to the current time.

```
aws cloudwatch put-metric-data --metric-name RequestLatency --namespace GetStarted
 \
--statistic-values Sum=806,Minimum=47,Maximum=328,SampleCount=6 --unit Milliseconds
```

Step 3: Get statistics from CloudWatch

Now that you have published metrics to CloudWatch, you can retrieve statistics based on those metrics using the get-metric-statistics command as follows. Be sure to specify `--start-time` and `--end-time` far enough in the past to cover the earliest timestamp that you published.

```
aws cloudwatch get-metric-statistics --namespace GetStarted --metric-name
 RequestLatency --statistics Average \
--start-time 2016-10-14T00:00:00Z --end-time 2016-10-15T00:00:00Z --period 60
```

The following is example output:

```
{
 "Datapoints": [],
 "Label": "Request:Latency"
}
```

Step 4: View graphs with the console

After you have published metrics to CloudWatch, you can use the CloudWatch console to view statistical graphs.

To view graphs of your statistics on the console

1. Open the CloudWatch console at https://console.amazonaws.cn/cloudwatch/.
2. In the **Navigation** pane, choose **Metrics**.
3. On the **All metrics** tab, in the search box, type **RequestLatency** and press Enter.

4. Select the check box for the **RequestLatency** metric. A graph of the metric data is displayed in the upper pane.

For more information, see Graphing metrics.

Using CloudWatch with an Amazon SDK

Amazon software development kits (SDKs) are available for many popular programming languages. Each SDK provides an API, code examples, and documentation that make it easier for developers to build applications in their preferred language.

SDK documentation
Amazon CLI
Amazon SDK for Java
Amazon SDK for JavaScript
Amazon SDK for .NET
Amazon SDK for PHP
Amazon Tools for PowerShell
Amazon SDK for Python (Boto3)
Amazon SDK for Ruby
Amazon SDK for SAP ABAP

For examples specific to CloudWatch, see Code examples for CloudWatch using Amazon SDKs.

Code examples for CloudWatch using Amazon SDKs

The following code examples show how to use CloudWatch with an Amazon software development kit (SDK).

Basics are code examples that show you how to perform the essential operations within a service.

Actions are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios.

Scenarios are code examples that show you how to accomplish specific tasks by calling multiple functions within a service or combined with other Amazon Web Services services.

For a complete list of Amazon SDK developer guides and code examples, see Using CloudWatch with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello CloudWatch

The following code examples show how to get started using CloudWatch.

.NET

Amazon SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
using Amazon.CloudWatch;
using Amazon.CloudWatch.Model;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;

namespace CloudWatchActions;
```

```
public static class HelloCloudWatch
{
    static async Task Main(string[] args)
    {
        // Use the AWS .NET Core Setup package to set up dependency injection for
 the Amazon CloudWatch service.
        // Use your AWS profile name, or leave it blank to use the default
 profile.
        using var host = Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonCloudWatch>()
            ).Build();

        // Now the client is available for injection.
        var cloudWatchClient =
 host.Services.GetRequiredService<IAmazonCloudWatch>();

        // You can use await and any of the async methods to get a response.
        var metricNamespace = "AWS/Billing";
        var response = await cloudWatchClient.ListMetricsAsync(new
 ListMetricsRequest
        {
            Namespace = metricNamespace
        });
        Console.WriteLine($"Hello Amazon CloudWatch! Following are some metrics
 available in the {metricNamespace} namespace:");
        Console.WriteLine();
        foreach (var metric in response.Metrics.Take(5))
        {
            Console.WriteLine($"\tMetric: {metric.MetricName}");
            Console.WriteLine($"\tNamespace: {metric.Namespace}");
            Console.WriteLine($"\tDimensions: {string.Join(", ",
 metric.Dimensions.Select(m => $"{m.Name}:{m.Value}"))}");
            Console.WriteLine();
        }
    }
}
```

- For API details, see ListMetrics in *Amazon SDK for .NET API Reference*.

Java

SDK for Java 2.x

> **Note**

Code examples

Basic examples for CloudWatch using Amazon SDKs

The following code examples show how to use the basics of Amazon CloudWatch with Amazon SDKs.

Examples

Hello CloudWatch

The following code examples show how to get started using CloudWatch.

.NET

Amazon SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](https://github.com/awsdocs/aws-doc-sdk-examples/tree/main/dotnetv3/CloudWatch#code-examples).

```
using Amazon.CloudWatch;
using Amazon.CloudWatch.Model;
using Microsoft.Extensions.DependencyInjection;
using Microsoft.Extensions.Hosting;

namespace CloudWatchActions;

public static class HelloCloudWatch
{
    static async Task Main(string[] args)
    {
        // Use the AWS .NET Core Setup package to set up dependency injection for
 the Amazon CloudWatch service.
        // Use your AWS profile name, or leave it blank to use the default
 profile.
        using var host = Host.CreateDefaultBuilder(args)
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonCloudWatch>()
            ).Build();

        // Now the client is available for injection.
        var cloudWatchClient =
 host.Services.GetRequiredService<IAmazonCloudWatch>();

        // You can use await and any of the async methods to get a response.
        var metricNamespace = "AWS/Billing";
        var response = await cloudWatchClient.ListMetricsAsync(new
 ListMetricsRequest
        {
            Namespace = metricNamespace
        });
```

```
        Console.WriteLine($"Hello Amazon CloudWatch! Following are some metrics
 available in the {metricNamespace} namespace:");
        Console.WriteLine();
        foreach (var metric in response.Metrics.Take(5))
        {
            Console.WriteLine($"\tMetric: {metric.MetricName}");
            Console.WriteLine($"\tNamespace: {metric.Namespace}");
            Console.WriteLine($"\tDimensions: {string.Join(", ",
 metric.Dimensions.Select(m => $"{m.Name}:{m.Value}"))}");
            Console.WriteLine();
        }
    }
}
```

- For API details, see ListMetrics in *Amazon SDK for .NET API Reference*.

Learn core operations for CloudWatch using an Amazon SDK

The following code examples show how to:

- List CloudWatch namespaces and metrics.
- Get statistics for a metric and for estimated billing.
- Create and update a dashboard.
- Create and add data to a metric.
- Create and trigger an alarm, then view alarm history.
- Add an anomaly detector.
- Get a metric image, then clean up resources.

.NET

Amazon SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

Run an interactive scenario at a command prompt.

```
public class CloudWatchScenario
{
    /*
    Before running this .NET code example, set up your development environment,
 including your credentials.

    To enable billing metrics and statistics for this example, make sure billing
 alerts are enabled for your account:
    https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
monitor_estimated_charges_with_cloudwatch.html#turning_on_billing_metrics

    This .NET example performs the following tasks:
        1. List and select a CloudWatch namespace.
        2. List and select a CloudWatch metric.
        3. Get statistics for a CloudWatch metric.
        4. Get estimated billing statistics for the last week.
        5. Create a new CloudWatch dashboard with two metrics.
        6. List current CloudWatch dashboards.
        7. Create a CloudWatch custom metric and add metric data.
        8. Add the custom metric to the dashboard.
        9. Create a CloudWatch alarm for the custom metric.
       10. Describe current CloudWatch alarms.
       11. Get recent data for the custom metric.
       12. Add data to the custom metric to trigger the alarm.
       13. Wait for an alarm state.
       14. Get history for the CloudWatch alarm.
       15. Add an anomaly detector.
       16. Describe current anomaly detectors.
       17. Get and display a metric image.
       18. Clean up resources.
    */
```

/**
 * Before running this Java V2 code example, set up your development
 * environment, including your credentials.
 *
 * For more information, see the following documentation topic:
 *
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-
started.html
 *
 * To enable billing metrics and statistics for this example, make sure billing
 * alerts are enabled for your account:
 * https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
monitor_estimated_charges_with_cloudwatch.html#turning_on_billing_metrics
 *
 * This Java code example performs the following tasks:
 *
 * 1. List available namespaces from Amazon CloudWatch.
 * 2. List available metrics within the selected Namespace.
 * 3. Get statistics for the selected metric over the last day.
 * 4. Get CloudWatch estimated billing for the last week.
 * 5. Create a new CloudWatch dashboard with metrics.
 * 6. List dashboards using a paginator.
 * 7. Create a new custom metric by adding data for it.
```

```
 * 8. Add the custom metric to the dashboard.
 * 9. Create an alarm for the custom metric.
 * 10. Describe current alarms.
 * 11. Get current data for the new custom metric.
 * 12. Push data into the custom metric to trigger the alarm.
 * 13. Check the alarm state using the action DescribeAlarmsForMetric.
 * 14. Get alarm history for the new alarm.
 * 15. Add an anomaly detector for the custom metric.
 * 16. Describe current anomaly detectors.
 * 17. Get a metric image for the custom metric.
 * 18. Clean up the Amazon CloudWatch resources.

            Amazon CloudWatch is a comprehensive monitoring and observability
 service
            provided by Amazon Web Services (AWS). It is designed to help you
 monitor your
            AWS resources, applications, and services, as well as on-premises
 resources,
            in real-time.

            CloudWatch collects and tracks various types of data, including
 metrics,
            logs, and events, from your AWS and on-premises resources. It allows
 you to set
            alarms and automatically respond to changes in your environment,
            enabling you to quickly identify and address issues before they
 impact your
            applications or services.

            With CloudWatch, you can gain visibility into your entire
 infrastructure, from the cloud
            to the edge, and use this information to make informed decisions and
 optimize your
            resource utilization.

            This scenario guides you through how to perform Amazon CloudWatch
 tasks by using the
            AWS SDK for Java v2. Let's get started...

Kotlin

SDK for Kotlin

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](https://github.com/awsdocs/aws-doc-sdk-examples/tree/main/kotlin/services/cloudwatch#code-examples).

Run an interactive scenario demonstrating CloudWatch features.

```
/**
 Before running this Kotlin code example, set up your development environment,
 including your credentials.

 For more information, see the following documentation topic:
 https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html

 To enable billing metrics and statistics for this example, make sure billing
 alerts are enabled for your account:
 https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
monitor_estimated_charges_with_cloudwatch.html#turning_on_billing_metrics

 This Kotlin code example performs the following tasks:

 1. List available namespaces from Amazon CloudWatch. Select a namespace from the
 list.
 2. List available metrics within the selected namespace.
 3. Get statistics for the selected metric over the last day.
 4. Get CloudWatch estimated billing for the last week.
 5. Create a new CloudWatch dashboard with metrics.
 6. List dashboards using a paginator.
 7. Create a new custom metric by adding data for it.
 8. Add the custom metric to the dashboard.
 9. Create an alarm for the custom metric.
 10. Describe current alarms.
 11. Get current data for the new custom metric.
 12. Push data into the custom metric to trigger the alarm.
 13. Check the alarm state using the action DescribeAlarmsForMetric.
 14. Get alarm history for the new alarm.
 15. Add an anomaly detector for the custom metric.
```

```
 16. Describe current anomaly detectors.
 17. Get a metric image for the custom metric.
 18. Clean up the Amazon CloudWatch resources.

Actions for CloudWatch using Amazon SDKs

The following code examples demonstrate how to perform individual CloudWatch actions with Amazon SDKs. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

These excerpts call the CloudWatch API and are code excerpts from larger programs that must be run in context. You can see actions in context in Scenarios for CloudWatch using Amazon SDKs .

The following examples include only the most commonly used actions. For a complete list, see the Amazon CloudWatch API Reference.

Examples

- Use DeleteAlarms with an Amazon SDK or CLI
- Use DeleteAnomalyDetector with an Amazon SDK or CLI
- Use DeleteDashboards with an Amazon SDK or CLI
- Use DescribeAlarmHistory with an Amazon SDK or CLI
- Use DescribeAlarms with an Amazon SDK or CLI
- Use DescribeAlarmsForMetric with an Amazon SDK or CLI
- Use DescribeAnomalyDetectors with an Amazon SDK or CLI
- Use DisableAlarmActions with an Amazon SDK or CLI
- Use EnableAlarmActions with an Amazon SDK or CLI
- Use GetDashboard with an Amazon SDK or CLI
- Use GetMetricData with an Amazon SDK or CLI
- Use GetMetricStatistics with an Amazon SDK or CLI
- Use GetMetricWidgetImage with an Amazon SDK or CLI
- Use ListDashboards with an Amazon SDK or CLI
- Use ListMetrics with an Amazon SDK or CLI
- Use PutAnomalyDetector with an Amazon SDK or CLI
- Use PutDashboard with an Amazon SDK or CLI
- Use PutMetricAlarm with an Amazon SDK or CLI
- Use PutMetricData with an Amazon SDK or CLI

Use `DeleteAlarms` with an Amazon SDK or CLI

The following code examples show how to use `DeleteAlarms`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Learn the basics
- Get started with alarms

- Manage metrics and alarms

.NET

Amazon SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
/// <summary>
/// Delete a list of alarms from CloudWatch.
/// </summary>
/// <param name="alarmNames">A list of names of alarms to delete.</param>
/// <returns>True if successful.</returns>
public async Task<bool> DeleteAlarms(List<string> alarmNames)
{
    var deleteAlarmsResult = await _amazonCloudWatch.DeleteAlarmsAsync(
        new DeleteAlarmsRequest()
        {
            AlarmNames = alarmNames
        });

    return deleteAlarmsResult.HttpStatusCode == HttpStatusCode.OK;
}
```

- For API details, see DeleteAlarms in *Amazon SDK for .NET API Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/DeleteAlarmsRequest.h>
#include <iostream>
```

Delete the alarm.

```
        Aws::CloudWatch::CloudWatchClient cw;
        Aws::CloudWatch::Model::DeleteAlarmsRequest request;
        request.AddAlarmNames(alarm_name);

        auto outcome = cw.DeleteAlarms(request);
        if (!outcome.IsSuccess())
        {
            std::cout << "Failed to delete CloudWatch alarm:" <<
                outcome.GetError().GetMessage() << std::endl;
        }
        else
        {
            std::cout << "Successfully deleted CloudWatch alarm " << alarm_name
                << std::endl;
        }
```

- For API details, see [DeleteAlarms] in *Amazon SDK for C++ API Reference*.

CLI

Amazon CLI

To delete an alarm

The following example uses the `delete-alarms` command to delete the Amazon CloudWatch alarm named "myalarm":

```
aws cloudwatch delete-alarms --alarm-names myalarm
```

Output:

```
This command returns to the prompt if successful.
```

- For API details, see DeleteAlarms in *Amazon CLI Command Reference*.

Java

SDK for Java 2.x

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /**
     * Deletes a CloudWatch alarm.
     *
     * @param alarmName the name of the alarm to be deleted
     * @return a {@link CompletableFuture} representing the asynchronous
 operation to delete the alarm
     * the {@link DeleteAlarmsResponse} is returned when the operation completes
 successfully,
     * or a {@link RuntimeException} is thrown if the operation fails
     */
    public CompletableFuture<DeleteAlarmsResponse> deleteCWAlarmAsync(String
 alarmName) {
        DeleteAlarmsRequest request = DeleteAlarmsRequest.builder()
            .alarmNames(alarmName)
            .build();

        return getAsyncClient().deleteAlarms(request)
            .whenComplete((response, exception) -> {
                if (exception != null) {

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { DeleteAlarmsCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  const command = new DeleteAlarmsCommand({
    AlarmNames: [process.env.CLOUDWATCH_ALARM_NAME], // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see Amazon SDK for JavaScript Developer Guide.
- For API details, see DeleteAlarms in *Amazon SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Import the SDK and client modules and call the API.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

var params = {
  AlarmNames: ["Web_Server_CPU_Utilization"],
};

cw.deleteAlarms(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", data);
  }
});
```

- For more information, see Amazon SDK for JavaScript Developer Guide.
- For API details, see DeleteAlarms in *Amazon SDK for JavaScript API Reference*.

Kotlin

SDK for Kotlin

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
suspend fun deleteAlarm(alarmNameVal: String) {
    val request =
        DeleteAlarmsRequest {
            alarmNames = listOf(alarmNameVal)
        }

    CloudWatchClient { region = "us-east-1" }.use { cwClient ->
        cwClient.deleteAlarms(request)
        println("Successfully deleted alarm $alarmNameVal")
    }
}
```

- For API details, see DeleteAlarms in *Amazon SDK for Kotlin API reference*.

Python

SDK for Python (Boto3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
class CloudWatchWrapper:
    """Encapsulates Amazon CloudWatch functions."""

    def __init__(self, cloudwatch_resource):
        """
```

```
        :param cloudwatch_resource: A Boto3 CloudWatch resource.
        """

SAP ABAP

SDK for SAP ABAP

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
TRY.
    lo_cwt->deletealarms(
      it_alarmnames = it_alarm_names ).
    MESSAGE 'Alarms deleted.' TYPE 'I'.
  CATCH /aws1/cx_cwtresourcenotfound.
    MESSAGE 'Resource being accessed is not found.' TYPE 'E'.
ENDTRY.
```

- For API details, see DeleteAlarms in *Amazon SDK for SAP ABAP API reference*.

For a complete list of Amazon SDK developer guides and code examples, see Using CloudWatch with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Use `DeleteAnomalyDetector` with an Amazon SDK or CLI

The following code examples show how to use `DeleteAnomalyDetector`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

Amazon SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
/// <summary>
/// Delete a single metric anomaly detector.
/// </summary>
/// <param name="anomalyDetector">The anomaly detector to delete.</param>
/// <returns>True if successful.</returns>
```

```
    public async Task<bool> DeleteAnomalyDetector(SingleMetricAnomalyDetector
 anomalyDetector)
    {
        var deleteAnomalyDetectorResponse = await
 _amazonCloudWatch.DeleteAnomalyDetectorAsync(
            new DeleteAnomalyDetectorRequest()
            {
                SingleMetricAnomalyDetector = anomalyDetector
            });

        return deleteAnomalyDetectorResponse.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see [DeleteAnomalyDetector](#) in *Amazon SDK for .NET API Reference*.

CLI

Amazon CLI

To delete a specified anomaly detection model

The following `delete-anomaly-detector` example deletes an anomaly detector model in the specified account.

```
aws cloudwatch delete-anomaly-detector \
    --namespace AWS/Logs \
    --metric-name IncomingBytes \
    --stat SampleCount
```

This command produces no output.

For more information, see [Deleting an anomaly detection model](#) in the *Amazon CloudWatch User Guide*.

- For API details, see [DeleteAnomalyDetector](#) in *Amazon CLI Command Reference*.

Use `DeleteDashboards` with an Amazon SDK or CLI

The following code examples show how to use `DeleteDashboards`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

Amazon SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /// <summary>
    /// Delete a list of CloudWatch dashboards.
    /// </summary>
    /// <param name="dashboardNames">List of dashboard names to delete.</param>
    /// <returns>True if successful.</returns>
    public async Task<bool> DeleteDashboards(List<string> dashboardNames)
    {
        var deleteDashboardsResponse = await
 _amazonCloudWatch.DeleteDashboardsAsync(
            new DeleteDashboardsRequest()
            {
                DashboardNames = dashboardNames
            });

        return deleteDashboardsResponse.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see DeleteDashboards in *Amazon SDK for .NET API Reference*.

CLI

Amazon CLI

To delete specified dashboards

The following `delete-dashboards` example deletes two dashboards named `Dashboard-A` and `Dashboard-B` in the specified account.

```
aws cloudwatch delete-dashboards \
    --dashboard-names Dashboard-A Dashboard-B
```

This command produces no output.

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see DeleteDashboards in *Amazon CLI Command Reference*.

```
suspend fun deleteDashboard(dashboardName: String) {
    val dashboardsRequest =
        DeleteDashboardsRequest {
            dashboardNames = listOf(dashboardName)
        }
    CloudWatchClient { region = "us-east-1" }.use { cwClient ->
        cwClient.deleteDashboards(dashboardsRequest)
        println("$dashboardName was successfully deleted.")
    }
}
```

- For API details, see DeleteDashboards in *Amazon SDK for Kotlin API reference*.

PowerShell

Tools for PowerShell

Example 1: Deletes the specified dashboard, promoting for confirmation before proceeding. To bypass confirmation add the -Force switch to the command.

```
Remove-CWDashboard -DashboardName Dashboard1
```

- For API details, see DeleteDashboards in *Amazon Tools for PowerShell Cmdlet Reference*.

For a complete list of Amazon SDK developer guides and code examples, see [Using CloudWatch with an Amazon SDK](). This topic also includes information about getting started and details about previous SDK versions.

Use `DescribeAlarmHistory` with an Amazon SDK or CLI

The following code examples show how to use `DescribeAlarmHistory`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Learn the basics]()

.NET

Amazon SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository]().

```
    /// <summary>
    /// Describe the history of an alarm for a number of days in the past.
    /// </summary>
    /// <param name="alarmName">The name of the alarm.</param>
    /// <param name="historyDays">The number of days in the past.</param>
    /// <returns>The list of alarm history data.</returns>
    public async Task<List<AlarmHistoryItem>> DescribeAlarmHistory(string
 alarmName, int historyDays)
    {
        List<AlarmHistoryItem> alarmHistory = new List<AlarmHistoryItem>();
        var paginatedAlarmHistory =
 _amazonCloudWatch.Paginators.DescribeAlarmHistory(
            new DescribeAlarmHistoryRequest()
            {
                AlarmName = alarmName,
                EndDateUtc = DateTime.UtcNow,
                HistoryItemType = HistoryItemType.StateUpdate,
                StartDateUtc = DateTime.UtcNow.AddDays(-historyDays)
```

```
            });

        await foreach (var data in paginatedAlarmHistory.AlarmHistoryItems)
        {
            alarmHistory.Add(data);
        }
        return alarmHistory;
    }
```

- For API details, see DescribeAlarmHistory in *Amazon SDK for .NET API Reference*.

CLI

Amazon CLI

To retrieve history for an alarm

The following example uses the `describe-alarm-history` command to retrieve history for the Amazon CloudWatch alarm named "myalarm":

```
aws cloudwatch describe-alarm-history --alarm-name "myalarm" --history-item-type StateUpdate
```

Output:

```
{
    "AlarmHistoryItems": [
        {
            "Timestamp": "2014-04-09T18:59:06.442Z",
            "HistoryItemType": "StateUpdate",
            "AlarmName": "myalarm",
            "HistoryData": "{\"version\":\"1.0\",\"oldState\":{\"stateValue

CLI

Amazon CLI

To display information about alarms associated with a metric

The following example uses the `describe-alarms-for-metric` command to display information about any alarms associated with the Amazon EC2 CPUUtilization metric and the instance with the ID i-0c986c72.:

```
aws cloudwatch describe-alarms-for-metric --metric-name CPUUtilization --
namespace AWS/EC2 --dimensions Name=InstanceId,Value=i-0c986c72
```

Output:

```
{
    "MetricAlarms": [
        {
            "EvaluationPeriods": 10,
            "AlarmArn": "arn:aws:cloudwatch:us-

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository].

Import the SDK and client modules and call the API.

```
import { DescribeAlarmsCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  const command = new DescribeAlarmsCommand({
    AlarmNames: [process.env.CLOUDWATCH_ALARM_NAME], // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see Amazon SDK for JavaScript Developer Guide.
- For API details, see DescribeAlarmsForMetric in *Amazon SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

cw.describeAlarms({ StateValue: "INSUFFICIENT_DATA" }, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    // List the names of all current alarms in the console
    data.MetricAlarms.forEach(function (item, index, array) {
      console.log(item.AlarmName);
    });
  }
});
```

CLI

Amazon CLI

To retrieve a list of anomaly detection models

The following `describe-anomaly-detectors` example displays information about anomaly detector models that are associated with the `AWS/Logs` namespace in the specified account.

```
aws cloudwatch describe-anomaly-detectors \
```

```
    --namespace AWS/Logs
```

Output:

```
{
    "AnomalyDetectors": [
        {
            "Namespace": "AWS/Logs",
            "MetricName": "IncomingBytes",

Use DisableAlarmActions with an Amazon SDK or CLI

The following code examples show how to use DisableAlarmActions.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code examples:

- Get started with alarms
- Manage metrics and alarms

.NET

Amazon SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /// <summary>
    /// Disable the actions for a list of alarms from CloudWatch.
    /// </summary>
    /// <param name="alarmNames">A list of names of alarms.</param>
    /// <returns>True if successful.</returns>
    public async Task<bool> DisableAlarmActions(List<string> alarmNames)
    {
        var disableAlarmActionsResult = await
 _amazonCloudWatch.DisableAlarmActionsAsync(
            new DisableAlarmActionsRequest()
            {
                AlarmNames = alarmNames
            });

        return disableAlarmActionsResult.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see [DisableAlarmActions](#) in *Amazon SDK for .NET API Reference*.

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/DisableAlarmActionsRequest.h>
#include <iostream>
```

Disable the alarm actions.

```
        Aws::CloudWatch::CloudWatchClient cw;

        Aws::CloudWatch::Model::DisableAlarmActionsRequest
 disableAlarmActionsRequest;
        disableAlarmActionsRequest.AddAlarmNames(alarm_name);

        auto disableAlarmActionsOutcome =
 cw.DisableAlarmActions(disableAlarmActionsRequest);
        if (!disableAlarmActionsOutcome.IsSuccess())
        {
            std::cout << "Failed to disable actions for alarm " << alarm_name <<
                ": " << disableAlarmActionsOutcome.GetError().GetMessage() <<
                std::endl;
        }
        else
        {
            std::cout << "Successfully disabled actions for alarm " <<
```

```
                alarm_name << std::endl;
        }
```

- For API details, see DisableAlarmActions in *Amazon SDK for C++ API Reference*.

CLI

Amazon CLI

To disable actions for an alarm

The following example uses the `disable-alarm-actions` command to disable all actions for the alarm named myalarm.:

```
aws cloudwatch disable-alarm-actions --alarm-names myalarm
```

This command returns to the prompt if successful.

- For API details, see DisableAlarmActions in *Amazon CLI Command Reference*.

```
    /// <summary>
    /// Enable the actions for a list of alarms from CloudWatch.
    /// </summary>
    /// <param name="alarmNames">A list of names of alarms.</param>
    /// <returns>True if successful.</returns>
    public async Task<bool> EnableAlarmActions(List<string> alarmNames)
    {
        var enableAlarmActionsResult = await
 _amazonCloudWatch.EnableAlarmActionsAsync(
            new EnableAlarmActionsRequest()
            {
                AlarmNames = alarmNames
            });

        return enableAlarmActionsResult.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see EnableAlarmActions in *Amazon SDK for .NET API Reference*.

C++

SDK for C++

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/EnableAlarmActionsRequest.h>
#include <aws/monitoring/model/PutMetricAlarmRequest.h>
#include <iostream>
```

Enable the alarm actions.

```
    Aws::CloudWatch::CloudWatchClient cw;
    Aws::CloudWatch::Model::PutMetricAlarmRequest request;
    request.SetAlarmName(alarm_name);
    request.SetComparisonOperator(
        Aws::CloudWatch::Model::ComparisonOperator::GreaterThanThreshold);
    request.SetEvaluationPeriods(1);
    request.SetMetricName("CPUUtilization");
    request.SetNamespace("AWS/EC2");
    request.SetPeriod(60);
    request.SetStatistic(Aws::CloudWatch::Model::Statistic::Average);
    request.SetThreshold(70.0);
    request.SetActionsEnabled(false);
    request.SetAlarmDescription("Alarm when server CPU exceeds 70%");
    request.SetUnit(Aws::CloudWatch::Model::StandardUnit::Seconds);
    request.AddAlarmActions(actionArn);

    Aws::CloudWatch::Model::Dimension dimension;
    dimension.SetName("InstanceId");
    dimension.SetValue(instanceId);
    request.AddDimensions(dimension);
```

```
    auto outcome = cw.PutMetricAlarm(request);
    if (!outcome.IsSuccess())
    {
        std::cout << "Failed to create CloudWatch alarm:" <<
            outcome.GetError().GetMessage() << std::endl;
        return;
    }

    Aws::CloudWatch::Model::EnableAlarmActionsRequest enable_request;
    enable_request.AddAlarmNames(alarm_name);

    auto enable_outcome = cw.EnableAlarmActions(enable_request);
    if (!enable_outcome.IsSuccess())
    {
        std::cout << "Failed to enable alarm actions:" <<
            enable_outcome.GetError().GetMessage() << std::endl;
        return;
    }

    std::cout << "Successfully created alarm " << alarm_name <<
        " and enabled actions on it." << std::endl;
```

- For API details, see EnableAlarmActions in *Amazon SDK for C++ API Reference*.

CLI

Amazon CLI

To enable all actions for an alarm

The following example uses the `enable-alarm-actions` command to enable all actions for the alarm named myalarm.:

```
aws cloudwatch enable-alarm-actions --alarm-names myalarm
```

This command returns to the prompt if successful.

- For API details, see EnableAlarmActions in *Amazon CLI Command Reference*.

Use `GetDashboard` with an Amazon SDK or CLI

The following code examples show how to use `GetDashboard`.

.NET

Amazon SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](https://github.com/awsdocs/aws-doc-sdk-examples/tree/main/dotnetv3/CloudWatch#code-examples).

```
/// <summary>
/// Get information on a dashboard.
/// </summary>
/// <param name="dashboardName">The name of the dashboard.</param>
/// <returns>A JSON object with dashboard information.</returns>
public async Task<string> GetDashboard(string dashboardName)
{
    var dashboardResponse = await _amazonCloudWatch.GetDashboardAsync(
        new GetDashboardRequest()
        {
            DashboardName = dashboardName
        });

    return dashboardResponse.DashboardBody;
}
```

- For API details, see [GetDashboard](https://docs.aws.amazon.com/goto/DotNetSDKV3/monitoring-2010-08-01/GetDashboard) in *Amazon SDK for .NET API Reference*.

CLI

Amazon CLI

To retrieve information about a Dashboard

The following `get-dashboard` example displays information about the dashboard named `Dashboard-A` in the specified account.

```
aws cloudwatch get-dashboard \
    --dashboard-name Dashboard-A
```

Output:

```
{
    "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/Dashboard-A",
    "DashboardBody": "{\"widgets\":[{\"type\":\"metric\",\"x\":0,\"y\":0,\"width
\":6,\"height\":6,\"properties\":{\"view\":\"timeSeries\",\"stacked\":false,
\"metrics\":[[\"AWS/EC2\",\"NetworkIn\",\"InstanceId\",\"i-0131f062232ade043\"],
[\".\",\"NetworkOut\",\".\",\".\"]],\"region\":\"us-east-1\"}}]}",
    "DashboardName": "Dashboard-A"
}
```

For more information, see Amazon CloudWatch dashboards in the *Amazon CloudWatch User Guide*.

- For API details, see GetDashboard in *Amazon CLI Command Reference*.

PowerShell

Tools for PowerShell

Example 1: Returns the arn the body of the specified dashboard.

```
Get-CWDashboard -DashboardName Dashboard1
```

Output:

```
DashboardArn                                          DashboardBody
------------                                          -------------
arn:aws:cloudwatch::123456789012:dashboard/Dashboard1 {...
```

- For API details, see GetDashboard in *Amazon Tools for PowerShell Cmdlet Reference*.

            });

        await foreach (var data in paginatedMetricData.MetricDataResults)
        {
            metricData.Add(data);
        }
        return metricData;
    }
```

- For API details, see GetMetricData in *Amazon SDK for .NET API Reference*.

CLI

Amazon CLI

Example 1: To get the Average Total IOPS for the specified EC2 using math expression

The following `get-metric-data` example retrieves CloudWatch metric values for the EC2 instance with InstanceID `i-abcdef` using metric math exprssion that combines `EBSReadOps` and `EBSWriteOps` metrics.

```
aws cloudwatch get-metric-data \
    --metric-data-queries file://file.json \
    --start-time 2024-09-29T22:10:00Z \
    --end-time 2024-09-29T22:15:00Z
```

Contents of `file.json`:

```
[
    {
        "Id": "m3",
        "Expression": "(m1+m2)/300",
```

```
            "Label": "Avg Total IOPS"
        },
        {
            "Id": "m1",
            "MetricStat": {
                "Metric": {
                    "Namespace": "AWS/EC2",
                    "MetricName": "EBSReadOps",
                    "Dimensions": [
                        {
                            "Name": "InstanceId",
                            "Value": "i-abcdef"
                        }
                    ]
                },
                "Period": 300,
                "Stat": "Sum",
                "Unit": "Count"
            },
            "ReturnData": false
        },
        {
            "Id": "m2",
            "MetricStat": {
                "Metric": {
                    "Namespace": "AWS/EC2",
                    "MetricName": "EBSWriteOps",
                    "Dimensions": [
                        {
                            "Name": "InstanceId",
                            "Value": "i-abcdef"
                        }
                    ]
                },
                "Period": 300,
                "Stat": "Sum",
                "Unit": "Count"
            },
            "ReturnData": false
        }
    ]
```

Output:

```
{
    "MetricDataResults": [
        {
            "Id": "m3",
            "Label": "Avg Total IOPS",
            "Timestamps": [
                "2024-09-29T22:10:00+00:00"
            ],
            "Values": [
                96.85
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
}
```

Example 2: To monitor the estimated Amazon charges using CloudWatch billing metrics

The following `get-metric-data` example retrieves `EstimatedCharges` CloudWatch metric from Amazon/Billing namespace.

```
aws cloudwatch get-metric-data \
    --metric-data-queries '[{"Id":"m1","MetricStat":{"Metric":
{"Namespace":"AWS/Billing","MetricName":"EstimatedCharges","Dimensions":
[{"Name":"Currency","Value":"USD"}]},"Period":21600,"Stat":"Maximum"}}]' \
    --start-time 2024-09-26T12:00:00Z \
    --end-time 2024-09-26T18:00:00Z \
    --region us-east-1
```

Output:

```
{
    "MetricDataResults": [
        {
            "Id": "m1",
            "Label": "EstimatedCharges",
            "Timestamps": [
                "2024-09-26T12:00:00+00:00"
            ],
            "Values": [
                542.38
```

```
            ],
            "StatusCode": "Complete"
        }
    ],
    "Messages": []
}
```

CLI

Amazon CLI

To get the CPU utilization per EC2 instance

The following example uses the `get-metric-statistics` command to get the CPU utilization for an EC2 instance with the ID i-abcdef.

```
aws cloudwatch get-metric-statistics --metric-name CPUUtilization --start-time 2014-04-08T23:18:00Z --end-time 2014-04-09T23:18:00Z --period 3600 --namespace AWS/EC2 --statistics Maximum --dimensions Name=InstanceId,Value=i-abcdef
```

Output:

```
{
    "Datapoints": [
        {
            "Timestamp": "2014-04-09T11:18:00Z",
            "Maximum": 44.79,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T20:18:00Z",
            "Maximum": 47.92,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T19:18:00Z",
```

```
            "Maximum": 50.85,
            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T09:18:00Z",

            "Unit": "Percent"
        },
        {
            "Timestamp": "2014-04-09T01:18:00Z",
            "Maximum": 49.18,
            "Unit": "Percent"
        }
    ],
    "Label": "CPUUtilization"
}
```

Specifying multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name/Value pair, with a comma between the name and the value. Multiple dimensions are separated by a space. If a single metric includes multiple dimensions, you must specify a value for every defined dimension.

For more examples using the `get-metric-statistics` command, see Get Statistics for a Metric in the *Amazon CloudWatch Developer Guide*.

```
aws cloudwatch get-metric-statistics --metric-name Buffers --
namespace MyNameSpace --dimensions Name=InstanceID,Value=i-
abcdef Name=InstanceType,Value=m1.small --start-time 2016-10-15T04:00:00Z --end-
time 2016-10-19T07:00:00Z --statistics Average --period 60
```

- For API details, see GetMetricStatistics in *Amazon CLI Command Reference*.

    def get_metric_statistics(self, namespace, name, start, end, period,
 stat_types):
        """
        Gets statistics for a metric within a specified time span. Metrics are
 grouped
        into the specified period.

        :param namespace: The namespace of the metric.
        :param name: The name of the metric.
        :param start: The UTC start time of the time span to retrieve.
        :param end: The UTC end time of the time span to retrieve.
        :param period: The period, in seconds, in which to group metrics. The
 period
                       must match the granularity of the metric, which depends on
                       the metric's age. For example, metrics that are older than
                       three hours have a one-minute granularity, so the period
 must
                       be at least 60 and must be a multiple of 60.
        :param stat_types: The type of statistics to retrieve, such as average
 value
                           or maximum value.
        :return: The retrieved statistics for the metric.
```

```
        """

        return filePath;
    }
```

- For API details, see GetMetricWidgetImage in *Amazon SDK for .NET API Reference*.

CLI

Amazon CLI

To retrieve a snapshot graph of CPUUtilization

The following `get-metric-widget-image` example retrieves snapshot graph for the metric `CPUUtilization` of the EC2 instance with the ID `i-abcde` and saves the retrieved image as a file named "image.png" on your local machine.

```
aws cloudwatch get-metric-widget-image \
    --metric-widget '{"metrics":[["AWS/EC2","CPUUtilization","InstanceId","i-
abcde"]]}' \
    --output-format png \
    --output text | base64 --decode > image.png
```

This command produces no output.

- For API details, see GetMetricWidgetImage in *Amazon CLI Command Reference*.

Use `ListDashboards` with an Amazon SDK or CLI

The following code examples show how to use `ListDashboards`.

.NET

Amazon SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](https://github.com/awsdocs/aws-doc-sdk-examples/tree/main/dotnetv3/CloudWatch#code-examples).

```
/// <summary>
/// Get a list of dashboards.
/// </summary>
/// <returns>A list of DashboardEntry objects.</returns>
public async Task<List<DashboardEntry>> ListDashboards()
{
    var results = new List<DashboardEntry>();
    var paginateDashboards = _amazonCloudWatch.Paginators.ListDashboards(
        new ListDashboardsRequest());
    // Get the entire list using the paginator.
    await foreach (var data in paginateDashboards.DashboardEntries)
    {
        results.Add(data);
    }

    return results;
}
```

- For API details, see ListDashboards in *Amazon SDK for .NET API Reference*.

CLI

Amazon CLI

To retrieve a list of Dashboards

The following `list-dashboards` example lists all the Dashboards in the specified account.

```
aws cloudwatch list-dashboards
```

Output:

```
{
    "DashboardEntries": [
        {
            "DashboardName": "Dashboard-A",
            "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/
Dashboard-A",
            "LastModified": "2024-10-11T18:40:11+00:00",
            "Size": 271
        },
        {
            "DashboardName": "Dashboard-B",
            "DashboardArn": "arn:aws:cloudwatch::123456789012:dashboard/
Dashboard-B",
            "LastModified": "2024-10-11T18:44:41+00:00",
            "Size": 522
        }
    ]
}
```

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Import the SDK and client modules and call the API.

```
import {
  CloudWatchServiceException,
  ListMetricsCommand,
} from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

export const main = async () => {
  // Use the AWS console to see available namespaces and metric names. Custom
 metrics can also be created.
  // https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
viewing_metrics_with_cloudwatch.html
  const command = new ListMetricsCommand({
```

```
    Dimensions: [
      {
        Name: "LogGroupName",
      },
    ],
    MetricName: "IncomingLogEvents",
    Namespace: "AWS/Logs",
  });

  try {
    const response = await client.send(command);
    console.log(`Metrics count: ${response.Metrics?.length}`);
    return response;
  } catch (caught) {
    if (caught instanceof CloudWatchServiceException) {
      console.error(`Error from CloudWatch. ${caught.name}: ${caught.message}`);
    } else {
      throw caught;
    }
  }
};
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see Amazon SDK for JavaScript Developer Guide.
- For API details, see ListMetrics in *Amazon SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
// Load the AWS SDK for Node.js
```

```
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

var params = {
  Dimensions: [
    {
      Name: "LogGroupName" /* required */,
    },
  ],
  MetricName: "IncomingLogEvents",
  Namespace: "AWS/Logs",
};

cw.listMetrics(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Metrics", JSON.stringify(data.Metrics));
  }
});
```

Use `PutAnomalyDetector` with an Amazon SDK or CLI

The following code examples show how to use `PutAnomalyDetector`.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Learn the basics

.NET

Amazon SDK for .NET

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
    /// <summary>
    /// Add an anomaly detector for a single metric.
    /// </summary>
    /// <param name="anomalyDetector">A single metric anomaly detector.</param>
    /// <returns>True if successful.</returns>
```

```
    public async Task<bool> PutAnomalyDetector(SingleMetricAnomalyDetector
 anomalyDetector)
    {
        var putAlarmDetectorResult = await
 _amazonCloudWatch.PutAnomalyDetectorAsync(
            new PutAnomalyDetectorRequest()
            {
                SingleMetricAnomalyDetector = anomalyDetector
            });

        return putAlarmDetectorResult.HttpStatusCode == HttpStatusCode.OK;
    }
```

- For API details, see PutAnomalyDetector in *Amazon SDK for .NET API Reference*.

CLI

Amazon CLI

To create an anomaly detection model

The following `put-anomaly-detector` example creates an anomaly detection model for a CloudWatch metric.

```
aws cloudwatch put-anomaly-detector \
    --namespace AWS/Logs \
    --metric-name IncomingBytes \
    --stat SampleCount
```

This command produces no output.

For more information, see Using CloudWatch anomaly detection in the *Amazon CloudWatch User Guide*.

- For API details, see PutAnomalyDetector in *Amazon CLI Command Reference*.

    /// <returns>A list of validation messages for the dashboard.</returns>
    public async Task<List<DashboardValidationMessage>> PutDashboard(string
 dashboardName,
        string dashboardBody)
    {
        // Updating a dashboard replaces all contents.
        // Best practice is to include a text widget indicating this dashboard
 was created programmatically.
        var dashboardResponse = await _amazonCloudWatch.PutDashboardAsync(
            new PutDashboardRequest()
            {
                DashboardName = dashboardName,
                DashboardBody = dashboardBody
            });

        return dashboardResponse.DashboardValidationMessages;
    }
```

- For API details, see PutDashboard in *Amazon SDK for .NET API Reference*.

CLI

Amazon CLI

To create a dashboard

The following `put-dashboard` example creates a dashboard named `Dashboard-A` in the specified account.

```
aws cloudwatch put-dashboard \
    --dashboard-name Dashboard-A \
    --dashboard-body '{"widgets":
[{"height":6,"width":6,"y":0,"x":0,"type":"metric","properties":
{"view":"timeSeries","stacked":false,"metrics":
[["Namespace","CPUUtilization","Environment","Prod","Type","App"]],"region":"us-
east-1"}}]}'
```

Output:

```
{
    "DashboardValidationMessages": []
}
```

For more information, see Creating a CloudWatch dashboard in the *Amazon CloudWatch User Guide*.

- For API details, see PutDashboard in *Amazon CLI Command Reference*.

Java

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the [Amazon Code Examples Repository](#).

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/PutMetricAlarmRequest.h>
#include <iostream>
```

Create the alarm to watch the metric.

```
        Aws::CloudWatch::CloudWatchClient cw;
        Aws::CloudWatch::Model::PutMetricAlarmRequest request;
        request.SetAlarmName(alarm_name);
        request.SetComparisonOperator(
            Aws::CloudWatch::Model::ComparisonOperator::GreaterThanThreshold);
        request.SetEvaluationPeriods(1);
        request.SetMetricName("CPUUtilization");
        request.SetNamespace("AWS/EC2");
        request.SetPeriod(60);
        request.SetStatistic(Aws::CloudWatch::Model::Statistic::Average);
        request.SetThreshold(70.0);
        request.SetActionsEnabled(false);
        request.SetAlarmDescription("Alarm when server CPU exceeds 70%");
        request.SetUnit(Aws::CloudWatch::Model::StandardUnit::Seconds);

        Aws::CloudWatch::Model::Dimension dimension;
        dimension.SetName("InstanceId");
        dimension.SetValue(instanceId);

        request.AddDimensions(dimension);

        auto outcome = cw.PutMetricAlarm(request);
```

```
        if (!outcome.IsSuccess())
        {
            std::cout << "Failed to create CloudWatch alarm:" <<
                outcome.GetError().GetMessage() << std::endl;
        }
        else
        {
            std::cout << "Successfully created CloudWatch alarm " << alarm_name
                << std::endl;
        }
```

- For API details, see PutMetricAlarm in *Amazon SDK for C++ API Reference*.

CLI

Amazon CLI

To send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent

The following example uses the `put-metric-alarm` command to send an Amazon Simple Notification Service email message when CPU utilization exceeds 70 percent:

```
aws cloudwatch put-metric-alarm --alarm-name cpu-mon --alarm-description "Alarm
 when CPU exceeds 70 percent" --metric-name CPUUtilization --namespace AWS/
EC2 --statistic Average --period 300 --threshold 70 --comparison-
operator GreaterThanThreshold  --dimensions "Name=InstanceId,Value=i-12345678" --
evaluation-periods 2 --alarm-actions arn:aws:sns:us-east-1:111122223333:MyTopic
 --unit Percent
```

This command returns to the prompt if successful. If an alarm with the same name already exists, it will be overwritten by the new alarm.

To specify multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name/Value pair, with a comma between the name and the value. Multiple dimensions are separated by a space:

```
aws cloudwatch put-metric-alarm --alarm-name "Default_Test_Alarm3" --alarm-
description "The default example alarm" --namespace "CW EXAMPLE METRICS"
```

```
--metric-name Default_Test --statistic Average --period 60 --evaluation-
periods 3 --threshold 50 --comparison-operator GreaterThanOrEqualToThreshold --
dimensions Name=key1,Value=value1 Name=key2,Value=value2
```

- For API details, see PutMetricAlarm in *Amazon CLI Command Reference*.

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { PutMetricAlarmCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  // This alarm triggers when CPUUtilization exceeds 70% for one minute.
  const command = new PutMetricAlarmCommand({
    AlarmName: process.env.CLOUDWATCH_ALARM_NAME, // Set the value of
 CLOUDWATCH_ALARM_NAME to the name of an existing alarm.
    ComparisonOperator: "GreaterThanThreshold",
    EvaluationPeriods: 1,
    MetricName: "CPUUtilization",
    Namespace: "AWS/EC2",
    Period: 60,
    Statistic: "Average",
    Threshold: 70.0,
    ActionsEnabled: false,
    AlarmDescription: "Alarm when server CPU exceeds 70%",
    Dimensions: [
      {
        Name: "InstanceId",
        Value: process.env.EC2_INSTANCE_ID, // Set the value of EC_INSTANCE_ID to
 the Id of an existing Amazon EC2 instance.
      },
    ],
    Unit: "Percent",
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
```

```
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

```
# Creates or updates an alarm in Amazon CloudWatch.
#
# @param cloudwatch_client [Aws::CloudWatch::Client]
#   An initialized CloudWatch client.
# @param alarm_name [String] The name of the alarm.
# @param alarm_description [String] A description about the alarm.
# @param metric_name [String] The name of the metric associated with the alarm.
```

```
# @param alarm_actions [Array] A list of Strings representing the
#   Amazon Resource Names (ARNs) to execute when the alarm transitions to the
#   ALARM state.
# @param namespace [String] The namespace for the metric to alarm on.
# @param statistic [String] The statistic for the metric.
# @param dimensions [Array] A list of dimensions for the metric, specified as
#   Aws::CloudWatch::Types::Dimension.
# @param period [Integer] The number of seconds before re-evaluating the metric.
# @param unit [String] The unit of measure for the statistic.
# @param evaluation_periods [Integer] The number of periods over which data is
#   compared to the specified threshold.
# @param theshold [Float] The value against which the specified statistic is
 compared.
# @param comparison_operator [String] The arithmetic operation to use when
#   comparing the specified statistic and threshold.
# @return [Boolean] true if the alarm was created or updated; otherwise, false.
# @example
#   exit 1 unless alarm_created_or_updated?(
#     Aws::CloudWatch::Client.new(region: 'us-east-1'),

C++

SDK for C++

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Include the required files.

```
#include <aws/core/Aws.h>
#include <aws/monitoring/CloudWatchClient.h>
#include <aws/monitoring/model/PutMetricDataRequest.h>
#include <iostream>
```

Put data into the metric.

```
        Aws::CloudWatch::CloudWatchClient cw;

        Aws::CloudWatch::Model::Dimension dimension;
        dimension.SetName("UNIQUE_PAGES");
        dimension.SetValue("URLS");

        Aws::CloudWatch::Model::MetricDatum datum;
        datum.SetMetricName("PAGES_VISITED");
        datum.SetUnit(Aws::CloudWatch::Model::StandardUnit::None);
        datum.SetValue(data_point);
        datum.AddDimensions(dimension);

        Aws::CloudWatch::Model::PutMetricDataRequest request;
        request.SetNamespace("SITE/TRAFFIC");
        request.AddMetricData(datum);

        auto outcome = cw.PutMetricData(request);
        if (!outcome.IsSuccess())
        {
            std::cout << "Failed to put sample metric data:" <<
                outcome.GetError().GetMessage() << std::endl;
        }
        else
        {
            std::cout << "Successfully put sample metric data" << std::endl;
        }
```

- For API details, see PutMetricData in *Amazon SDK for C++ API Reference*.

CLI

Amazon CLI

To publish a custom metric to Amazon CloudWatch

The following example uses the `put-metric-data` command to publish a custom metric to Amazon CloudWatch:

```
aws cloudwatch put-metric-data --namespace "Usage Metrics" --metric-data file://
metric.json
```

The values for the metric itself are stored in the JSON file, `metric.json`.

Here are the contents of that file:

```
[
  {
    "MetricName": "New Posts",
    "Timestamp": "Wednesday, June 12, 2013 8:28:20 PM",
    "Value": 0.50,
    "Unit": "Count"
  }
]
```

For more information, see Publishing Custom Metrics in the *Amazon CloudWatch Developer Guide*.

To specify multiple dimensions

The following example illustrates how to specify multiple dimensions. Each dimension is specified as a Name=Value pair. Multiple dimensions are separated by a comma.:

```
aws cloudwatch put-metric-data --metric-name Buffers --
namespace MyNameSpace --unit Bytes --value 231434333 --
dimensions InstanceID=1-23456789,InstanceType=m1.small
```

- For API details, see [PutMetricData](#) in *Amazon CLI Command Reference*.

Java

JavaScript

SDK for JavaScript (v3)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

Import the SDK and client modules and call the API.

```
import { PutMetricDataCommand } from "@aws-sdk/client-cloudwatch";
import { client } from "../libs/client.js";

const run = async () => {
  // See https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/
API_PutMetricData.html#API_PutMetricData_RequestParameters
  // and https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/
publishingMetrics.html
  // for more information about the parameters in this command.
  const command = new PutMetricDataCommand({
    MetricData: [
      {
        MetricName: "PAGES_VISITED",
        Dimensions: [
          {
            Name: "UNIQUE_PAGES",
            Value: "URLS",
          },
        ],
        Unit: "None",
        Value: 1.0,
      },
    ],
    Namespace: "SITE/TRAFFIC",
```

```
  });

  try {
    return await client.send(command);
  } catch (err) {
    console.error(err);
  }
};

export default run();
```

Create the client in a separate module and export it.

```
import { CloudWatchClient } from "@aws-sdk/client-cloudwatch";

export const client = new CloudWatchClient({});
```

- For more information, see Amazon SDK for JavaScript Developer Guide.
- For API details, see PutMetricData in *Amazon SDK for JavaScript API Reference*.

SDK for JavaScript (v2)

> **Note**
>
> There's more on GitHub. Find the complete example and learn how to set up and run in the Amazon Code Examples Repository.

```
// Load the AWS SDK for Node.js
var AWS = require("aws-sdk");
// Set the region
AWS.config.update({ region: "REGION" });

// Create CloudWatch service object
var cw = new AWS.CloudWatch({ apiVersion: "2010-08-01" });

// Create parameters JSON for putMetricData
var params = {
  MetricData: [
```

```
    {
      MetricName: "PAGES_VISITED",
      Dimensions: [
        {
          Name: "UNIQUE_PAGES",
          Value: "URLS",
        },
      ],
      Unit: "None",
      Value: 1.0,
    },
  ],
  Namespace: "SITE/TRAFFIC",
};

cw.putMetricData(params, function (err, data) {
  if (err) {
    console.log("Error", err);
  } else {
    console.log("Success", JSON.stringify(data));
  }
});
```

- For more information, see Amazon SDK for JavaScript Developer Guide.
- For API details, see PutMetricData in *Amazon SDK for JavaScript API Reference*.

Scenarios for CloudWatch using Amazon SDKs

The following code examples show you how to implement common scenarios in CloudWatch with Amazon SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within CloudWatch or combined with other Amazon Web Services services. Each scenario includes a link to the complete source code, where you can find instructions on how to set up and run the code.

Scenarios target an intermediate level of experience to help you understand service actions in context.

Examples

- Get started with CloudWatch alarms using an Amazon SDK
- Manage CloudWatch metrics and alarms using an Amazon SDK
- Monitor performance of Amazon DynamoDB using an Amazon SDK

Get started with CloudWatch alarms using an Amazon SDK

The following code example shows how to:

- Create an alarm.
- Disable alarm actions.
- Describe an alarm.
- Delete an alarm.

SAP ABAP

SDK for SAP ABAP

    pprint(sorted(stats["Datapoints"], key=lambda x: x["Timestamp"]))

    print(f"Getting alarms for metric {metric_name}.")
    alarms = cw_wrapper.get_metric_alarms(metric_namespace, metric_name)
    for alarm in alarms:
        print(f"Alarm {alarm.name} is currently in state {alarm.state_value}.")

    print(f"Deleting alarms for metric {metric_name}.")
    cw_wrapper.delete_metric_alarms(metric_namespace, metric_name)

    print("Thanks for watching!")
    print("-" * 88)
```

  - DeleteAlarms
  - DescribeAlarmsForMetric
  - DisableAlarmActions
  - EnableAlarmActions
  - GetMetricStatistics
  - ListMetrics
  - PutMetricAlarm
  - PutMetricData

For a complete list of Amazon SDK developer guides and code examples, see Using CloudWatch with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Monitor performance of Amazon DynamoDB using an Amazon SDK

The following code example shows how to configure an application's use of DynamoDB to monitor performance.

Java

SDK for Java 2.x

This example shows how to configure a Java application to monitor the performance of DynamoDB. The application sends metric data to CloudWatch where you can monitor the performance.

For complete source code and instructions on how to set up and run, see the full example on GitHub.

Services used in this example

- CloudWatch
- DynamoDB

For a complete list of Amazon SDK developer guides and code examples, see Using CloudWatch with an Amazon SDK. This topic also includes information about getting started and details about previous SDK versions.

Security in Amazon CloudWatch

Cloud security at Amazon is the highest priority. As an Amazon customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between Amazon and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – Amazon is responsible for protecting the infrastructure that runs Amazon services in the Amazon Cloud. Amazon also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the Amazon Compliance Programs. To learn about the compliance programs that apply to CloudWatch, see Amazon Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility is determined by the Amazon service that you use. You are also responsible for other factors including the sensitivity of your data, your company's requirements, and applicable laws and regulations

This documentation helps you understand how to apply the shared responsibility model when using Amazon CloudWatch. It shows you how to configure Amazon CloudWatch to meet your security and compliance objectives. You also learn how to use other Amazon services that help you to monitor and secure your CloudWatch resources.

Contents

Data protection in Amazon CloudWatch

The Amazon shared responsibility model applies to data protection in Amazon CloudWatch. As described in this model, Amazon is responsible for protecting the global infrastructure that runs all of the Amazon Web Services Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the Amazon Web Services services that you use. For more information about data privacy, see the Data Privacy FAQ.

For data protection purposes, we recommend that you protect Amazon Web Services account credentials and set up individual users with Amazon IAM Identity Center or Amazon Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with Amazon resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with Amazon CloudTrail. For information about using CloudTrail trails to capture Amazon activities, see Working with CloudTrail trails in the *Amazon CloudTrail User Guide*.
- Use Amazon encryption solutions, along with all default security controls within Amazon Web Services services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-3 validated cryptographic modules when accessing Amazon through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-3.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a **Name** field. This includes when you work with CloudWatch or other Amazon Web Services services using the console, API, Amazon CLI, or Amazon SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Encryption in transit

CloudWatch uses end-to-end encryption of data in transit. For more information, see Encryption of data in transit.

Identity and access management for Amazon CloudWatch

Amazon Identity and Access Management (IAM) is an Amazon Web Services service that helps an administrator securely control access to Amazon resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use CloudWatch resources. IAM is an Amazon Web Services service that you can use with no additional charge.

Topics

Audience

How you use Amazon Identity and Access Management (IAM) differs, depending on the work that you do in CloudWatch.

Service user – If you use the CloudWatch service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more CloudWatch features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in CloudWatch, see Troubleshooting Amazon CloudWatch identity and access.

Service administrator – If you're in charge of CloudWatch resources at your company, you probably have full access to CloudWatch. It's your job to determine which CloudWatch features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with CloudWatch, see How Amazon CloudWatch works with IAM.

IAM administrator – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to CloudWatch. To view example CloudWatch identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon CloudWatch.

Authenticating with identities

Authentication is how you sign in to Amazon using your identity credentials. You must be *authenticated* (signed in to Amazon) as the Amazon Web Services account root user, as an IAM user, or by assuming an IAM role.

If you access Amazon programmatically, Amazon provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use Amazon tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Amazon Signature Version 4 for API requests in the *IAM User Guide*.

Regardless of the authentication method that you use, you might be required to provide additional security information. For example, Amazon recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Amazon Multi-factor authentication in IAM in the *IAM User Guide*.

Amazon Web Services account root user

When you create an Amazon Web Services account, you begin with one sign-in identity that has complete access to all Amazon Web Services services and resources in the account. This identity is called the Amazon Web Services account *root user* and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the *IAM User Guide*.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access Amazon Web Services services by using temporary credentials.

A *federated identity* is a user from your enterprise user directory, a web identity provider, the Amazon Directory Service, or any user that accesses Amazon Web Services services by using credentials provided through an identity source. When federated identities access Amazon Web Services accounts, they assume roles, and the roles provide temporary credentials.

IAM users and groups

An *IAM user* is an identity within your Amazon Web Services account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the *IAM User Guide*.

An *IAM group* is an identity that specifies a collection of IAM users. You can't sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named *IAMAdmins* and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see Use cases for IAM users in the *IAM User Guide*.

IAM roles

An *IAM role* is an identity within your Amazon Web Services account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. To temporarily assume an IAM role in the Amazon Web Services Management Console, you can switch from a user to an IAM role (console). You can assume a role by calling an Amazon CLI or Amazon API operation or by using a custom URL. For more information about methods for using roles, see Methods to assume a role in the *IAM User Guide*.

IAM roles with temporary credentials are useful in the following situations:

- **Federated user access** – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Create a role for a third-party identity provider (federation) in the *IAM User Guide*.
- **Temporary IAM user permissions** – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.
- **Cross-account access** – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some Amazon Web Services services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.
- **Cross-service access** – Some Amazon Web Services services use features in other Amazon Web Services services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.
  - **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in Amazon, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an Amazon Web Services service, combined with the requesting Amazon Web Services service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other Amazon Web Services services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

  - **Service role –** A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an Amazon Web Services service in the *IAM User Guide*.
  - **Service-linked role –** A service-linked role is a type of service role that is linked to an Amazon Web Services service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your Amazon Web Services account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.
- **Applications running on Amazon EC2 –** You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making Amazon CLI or Amazon API requests. This is preferable to storing access keys within the EC2 instance. To assign an Amazon role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see Use an IAM role to grant permissions to applications running on Amazon EC2 instances in the *IAM User Guide*.

Managing access using policies

You control access in Amazon by creating policies and attaching them to Amazon identities or resources. A policy is an object in Amazon that, when associated with an identity or resource, defines their permissions. Amazon evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most policies are stored in Amazon as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the *IAM User Guide*.

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action.

A user with that policy can get role information from the Amazon Web Services Management Console, the Amazon CLI, or the Amazon API.

Identity-based policies

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

Identity-based policies can be further categorized as *inline policies* or *managed policies*. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your Amazon Web Services account. Managed policies include Amazon managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choose between managed policies and inline policies in the *IAM User Guide*.

Resource-based policies

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or Amazon Web Services services.

Resource-based policies are inline policies that are located in that service. You can't use Amazon managed policies from IAM in a resource-based policy.

Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, Amazon WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the *Amazon Simple Storage Service Developer Guide*.

Other policy types

Amazon supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries –** A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the `Principal` field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the *IAM User Guide*.
- **Service control policies (SCPs) –** SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in Amazon Organizations. Amazon Organizations is a service for grouping and centrally managing multiple Amazon Web Services accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each Amazon Web Services account root user. For more information about Organizations and SCPs, see Service control policies in the *Amazon Organizations User Guide*.
- **Resource control policies (RCPs) –** RCPs are JSON policies that you can use to set the maximum available permissions for resources in your accounts without updating the IAM policies attached to each resource that you own. The RCP limits permissions for resources in member accounts and can impact the effective permissions for identities, including the Amazon Web Services account root user, regardless of whether they belong to your organization. For more information about Organizations and RCPs, including a list of Amazon Web Services services that support RCPs, see Resource control policies (RCPs) in the *Amazon Organizations User Guide*.
- **Session policies –** Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the *IAM User Guide*.

Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how Amazon determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the *IAM User Guide*.

How Amazon CloudWatch works with IAM

Before you use IAM to manage access to CloudWatch, learn what IAM features are available to use with CloudWatch.

The following tables list the IAM features that you can use with Amazon CloudWatch.

IAM feature	CloudWatch support
Identity-based policies	Yes
Resource-based policies	No
Policy actions	Yes
Policy resources	Yes
Policy condition keys (service-specific)	Yes
ACLs	No
ABAC (tags in policies)	Partial
Temporary credentials	Yes
Principal permissions	Yes
Service roles	Yes
Service-linked roles	No

To get a high-level view of how CloudWatch and other Amazon services work with most IAM features, see Amazon services that work with IAM in the *IAM User Guide*.

Identity-based policies for CloudWatch

Supports identity-based policies: Yes

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Define custom IAM permissions with customer managed policies in the *IAM User Guide*.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the *IAM User Guide*.

Identity-based policy examples for CloudWatch

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Resource-based policies within CloudWatch

Supports resource-based policies: No

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM *role trust policies* and Amazon S3 *bucket policies*. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or Amazon Web Services services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different Amazon Web Services accounts, an IAM administrator in the trusted account must also grant the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see Cross account resource access in IAM in the *IAM User Guide*.

Policy actions for CloudWatch

Supports policy actions: Yes

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Action` element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated Amazon API operation. There are some exceptions, such as *permission-only actions* that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called *dependent actions*.

Include actions in a policy to grant permissions to perform the associated operation.

To see a list of CloudWatch actions, see Actions defined by Amazon CloudWatch in the *Service Authorization Reference*.

Policy actions in CloudWatch use the following prefix before the action:

```
cloudwatch
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
      "cloudwatch:action1",
      "cloudwatch:action2"
         ]
```

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Policy resources for CloudWatch

Supports policy resources: Yes

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Resource` JSON policy element specifies the object or objects to which the action applies. Statements must include either a `Resource` or a `NotResource` element. As a best practice, specify a resource using its Amazon Resource Name (ARN). You can do this for actions that support a specific resource type, known as *resource-level permissions*.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

To see a list of CloudWatch resource types and their ARNs, see Resources defined by Amazon CloudWatch in the *Service Authorization Reference*. To learn with which actions you can specify the ARN of each resource, see Actions defined by Amazon CloudWatch.

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

Policy condition keys for CloudWatch

Supports service-specific policy condition keys: Yes

Administrators can use Amazon JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The `Condition` element (or `Condition` *block*) lets you specify conditions in which a statement is in effect. The `Condition` element is optional. You can create conditional expressions that use condition operators, such as equals or less than, to match the condition in the policy with values in the request.

If you specify multiple `Condition` elements in a statement, or multiple keys in a single `Condition` element, Amazon evaluates them using a logical `AND` operation. If you specify multiple values for a single condition key, Amazon evaluates the condition using a logical `OR` operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the *IAM User Guide*.

Amazon supports global condition keys and service-specific condition keys. To see all Amazon global condition keys, see Amazon global condition context keys in the *IAM User Guide*.

To see a list of CloudWatch condition keys, see Condition keys for Amazon CloudWatch in the *Service Authorization Reference*. To learn with which actions and resources you can use a condition key, see Actions defined by Amazon CloudWatch.

To view examples of CloudWatch identity-based policies, see Identity-based policy examples for Amazon CloudWatch.

ACLs in CloudWatch

Supports ACLs: No

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

ABAC with CloudWatch

Supports ABAC (tags in policies): Partial

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In Amazon, these attributes are called *tags*. You can attach tags to IAM entities (users or roles) and to many Amazon resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the `aws:ResourceTag/key-name`, `aws:RequestTag/key-name`, or `aws:TagKeys` condition keys.

If a service supports all three condition keys for every resource type, then the value is **Yes** for the service. If a service supports all three condition keys for only some resource types, then the value is **Partial**.

For more information about ABAC, see Define permissions with ABAC authorization in the *IAM User Guide*. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the *IAM User Guide*.

Using temporary credentials with CloudWatch

Supports temporary credentials: Yes

Some Amazon Web Services services don't work when you sign in using temporary credentials. For additional information, including which Amazon Web Services services work with temporary credentials, see Amazon Web Services services that work with IAM in the *IAM User Guide*.

You are using temporary credentials if you sign in to the Amazon Web Services Management Console using any method except a user name and password. For example, when you access Amazon using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see Switch from a user to an IAM role (console) in the *IAM User Guide*.

You can manually create temporary credentials using the Amazon CLI or Amazon API. You can then use those temporary credentials to access Amazon. Amazon recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see Temporary security credentials in IAM.

Cross-service principal permissions for CloudWatch

Supports forward access sessions (FAS): Yes

When you use an IAM user or role to perform actions in Amazon, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an Amazon Web Services service, combined with the requesting Amazon Web Services service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other Amazon Web Services services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see Forward access sessions.

Service roles for CloudWatch

Supports service roles: Yes

A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Create a role to delegate permissions to an Amazon Web Services service in the *IAM User Guide*.

> **Warning**
>
> Changing the permissions for a service role might break CloudWatch functionality. Edit service roles only when CloudWatch provides guidance to do so.

Identity-based policy examples for Amazon CloudWatch

By default, users and roles don't have permission to create or modify CloudWatch resources. They also can't perform tasks by using the Amazon Web Services Management Console, Amazon Command Line Interface (Amazon CLI), or Amazon API. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Create IAM policies (console) in the *IAM User Guide*.

For details about actions and resource types defined by CloudWatch, including the format of the ARNs for each of the resource types, see Actions, resources, and condition keys for Amazon CloudWatch in the *Service Authorization Reference*.

Topics

- Policy best practices
- Using the CloudWatch console

Policy best practices

Identity-based policies determine whether someone can create, access, or delete CloudWatch resources in your account. These actions can incur costs for your Amazon Web Services account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with Amazon managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *Amazon managed policies* that grant permissions for many common use cases. They are available in your Amazon Web Services account. We recommend that you reduce permissions further by defining Amazon customer managed policies that are specific to your use cases. For more information, see Amazon managed policies or Amazon managed policies for job functions in the *IAM User Guide*.

- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see Policies and permissions in IAM in the *IAM User Guide*.
- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to service actions if they are used through a specific Amazon Web Services service, such as Amazon CloudFormation. For more information, see IAM JSON policy elements: Condition in the *IAM User Guide*.
- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see Validate policies with IAM Access Analyzer in the *IAM User Guide*.
- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your Amazon Web Services account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Secure API access with MFA in the *IAM User Guide*.

For more information about best practices in IAM, see Security best practices in IAM in the *IAM User Guide*.

Using the CloudWatch console

To access the Amazon CloudWatch console, you must have a minimum set of permissions. These permissions must allow you to list and view details about the CloudWatch resources in your Amazon Web Services account. If you create an identity-based policy that is more restrictive than the minimum required permissions, the console won't function as intended for entities (users or roles) with that policy.

You don't need to allow minimum console permissions for users that are making calls only to the Amazon CLI or the Amazon API. Instead, allow access to only the actions that match the API operation that they're trying to perform.

To ensure that users and roles can still use the CloudWatch console, also attach the CloudWatch `ConsoleAccess` or `ReadOnly` Amazon managed policy to the entities. For more information, see [Adding permissions to a user](#) in the *IAM User Guide*.

Permissions needed for CloudWatch console

The full set of permissions required to work with the CloudWatch console are listed below. These permissions provide full write and read access to the CloudWatch console.

- application-autoscaling:DescribeScalingPolicies
- autoscaling:DescribeAutoScalingGroups
- autoscaling:DescribePolicies
- cloudtrail:DescribeTrails
- cloudwatch:DeleteAlarms

Additionally, to view the X-Ray Trace Map, you need `AWSXrayReadOnlyAccess`

Troubleshooting Amazon CloudWatch identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with CloudWatch and IAM.

Topics

I am not authorized to perform an action in CloudWatch

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.

The following example error occurs when the `mateojackson` IAM user tries to use the console to view details about a fictional *`my-example-widget`* resource but doesn't have the fictional `cloudwatch:`*`GetWidget`* permissions.

```
User: arn:aws-cn:iam::123456789012:user/mateojackson is not authorized to perform:
 cloudwatch:GetWidget on resource: my-example-widget
```

In this case, the policy for the `mateojackson` user must be updated to allow access to the *`my-example-widget`* resource by using the `cloudwatch:`*`GetWidget`* action.

If you need help, contact your Amazon administrator. Your administrator is the person who provided you with your sign-in credentials.

I am not authorized to perform iam:PassRole

If you receive an error that you're not authorized to perform the `iam:PassRole` action, your policies must be updated to allow you to pass a role to CloudWatch.

Some Amazon Web Services services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named `marymajor` tries to use the console to perform an action in CloudWatch. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws-cn:iam::123456789012:user/marymajor is not authorized to perform:
 iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the `iam:PassRole` action.

If you need help, contact your Amazon administrator. Your administrator is the person who provided you with your sign-in credentials.

I want to allow people outside of my Amazon Web Services account to access my CloudWatch resources

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether CloudWatch supports these features, see How Amazon CloudWatch works with IAM.
- To learn how to provide access to your resources across Amazon Web Services accounts that you own, see Providing access to an IAM user in another Amazon Web Services account that you own in the *IAM User Guide*.
- To learn how to provide access to your resources to third-party Amazon Web Services accounts, see Providing access to Amazon Web Services accounts owned by third parties in the *IAM User Guide*.
- To learn how to provide access through identity federation, see Providing access to externally authenticated users (identity federation) in the *IAM User Guide*.
- To learn the difference between using roles and resource-based policies for cross-account access, see Cross account resource access in IAM in the *IAM User Guide*.

CloudWatch dashboard permissions update

On May 1, 2018, Amazon changed the permissions required to access CloudWatch dashboards. Dashboard access in the CloudWatch console now requires permissions that were introduced in 2017 to support dashboard API operations:

- **cloudwatch:GetDashboard**
- **cloudwatch:ListDashboards**
- **cloudwatch:PutDashboard**
- **cloudwatch:DeleteDashboards**

To access CloudWatch dashboards, you need one of the following:

- The **AdministratorAccess** policy.
- The **CloudWatchFullAccess** policy.
- A custom policy that includes one or more of these specific permissions:
  - `cloudwatch:GetDashboard` and `cloudwatch:ListDashboards` to be able to view dashboards
  - `cloudwatch:PutDashboard` to be able to create or modify dashboards
  - `cloudwatch:DeleteDashboards` to be able to delete dashboards

For more information about using policies to change permissions for an IAM user, see Changing Permissions for an IAM user.

For more information about CloudWatch permissions, see Amazon CloudWatch permissions reference.

For more information about dashboard API operations, see PutDashboard in the Amazon CloudWatch API Reference.

Amazon managed (predefined) policies for CloudWatch

Amazon addresses many common use cases by providing standalone IAM policies that are created and administered by Amazon. These Amazon managed policies grant necessary permissions for common use cases so that you can avoid having to investigate what permissions are needed. For more information, see Amazon managed policies in the *IAM User Guide*.

The following Amazon managed policies, which you can attach to users in your account, are specific to CloudWatch.

Topics

CloudWatchFullAccessV2

Amazon recently added the **CloudWatchFullAccessV2** managed IAM policy. This policy grants full access to CloudWatch actions and resources and also more properly scopes the permissions granted for other services such as Amazon SNS and Amazon EC2 Auto Scaling. We recommend that you begin using this policy instead of using **CloudWatchFullAccess**. Amazon plans to deprecate **CloudWatchFullAccess** in the near future.

It includes `application-signals:` permissions so that users can access all the functionality from the CloudWatch console under Application Signals. It includes some `autoscaling:Describe` permissions so that users with this policy can see the Auto Scaling actions that are associated with CloudWatch alarms. It includes some `sns` permissions so that users with this policy can retrieve create Amazon SNS topics and associate them with CloudWatch alarms. It includes IAM permissions so that users with this policy can view information about service-linked roles associated with CloudWatch. It includes the `oam:ListSinks` and `oam:ListAttachedLinks` permissions so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability.

It includes Amazon OpenSearch Service permissions to support vended logs dashboards in CloudWatch Logs, which are created with Amazon OpenSearch Service analytics.

It includes `rum`, `synthetics`, and `xray` permissions so that users can have full access to CloudWatch Synthetics, Amazon X-Ray, and CloudWatch RUM, all of which are under the CloudWatch service.

```

CloudWatchFullAccess

The **CloudWatchFullAccess** policy is on the path to deprecation. We recommend that you stop using it, and use CloudWatchFullAccessV2 instead.

The contents of **CloudWatchFullAccess** are as follows:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",

CloudWatchReadOnlyAccess

The **CloudWatchReadOnlyAccess** policy grants read-only access to CloudWatch.

The policy includes some `logs:` permissions, so that users with this policy can use the console to view CloudWatch Logs information and CloudWatch Logs Insights queries. It includes `autoscaling:Describe*`, so that users with this policy can see the Auto Scaling actions that are associated with CloudWatch alarms. It includes the `application-signals:` permissions so that users can use Application Signals to monitor the health of their services. It includes `application-autoscaling:DescribeScalingPolicies`, so that users with this policy can access information about Application Auto Scaling policies. It includes `sns:Get*` and `sns:List*`, so that users with this policy can retrieve information about the Amazon SNS topics that receive notifications about CloudWatch alarms. It includes the `oam:ListSinks` and `oam:ListAttachedLinks` permissions, so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability. It includes the `iam:GetRole` permissions so that users can check if CloudWatch Application Signals have been set up.

It includes `rum`, `synthetics`, and `xray` permissions so that users can have read-only access to CloudWatch Synthetics, Amazon X-Ray, and CloudWatch RUM, all of which are under the CloudWatch service.

The following is the content of the **CloudWatchReadOnlyAccess** policy.

```
{
"Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CloudWatchReadOnlyAccessPermissions",
            "Effect": "Allow",
            "Action": [
                "application-autoscaling:DescribeScalingPolicies",
                "application-signals:BatchGet*",

                "synthetics:List*",
                "xray:BatchGet*",
                "xray:Get*",
                "xray:List*",
                "xray:StartTraceRetrieval",
                "xray:CancelTraceRetrieval"
            ],
            "Resource": "*"
        },
        {
            "Sid": "OAMReadPermissions",
            "Effect": "Allow",
            "Action": [
                "oam:ListAttachedLinks"
            ],
            "Resource": "arn:aws:oam:*:*:sink/*"
        },
        {
            "Sid": "CloudWatchReadOnlyGetRolePermissions",
            "Effect": "Allow",
            "Action": "iam:GetRole",
            "Resource": "arn:aws:iam::*:role/aws-service-role/application-
signals.cloudwatch.amazonaws.com/AWSServiceRoleForCloudWatchApplicationSignals"
```

```
        }
      ]
}
```

CloudWatchActionsEC2Access

The **CloudWatchActionsEC2Access** policy grants read-only access to CloudWatch alarms and metrics in addition to Amazon EC2 metadata. It also grants access to the Stop, Terminate, and Reboot API actions for EC2 instances.

The following is the content of the **CloudWatchActionsEC2Access** policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudwatch:Describe*",
        "ec2:Describe*",
        "ec2:RebootInstances",
        "ec2:StopInstances",
        "ec2:TerminateInstances"
      ],
      "Resource": "*"
    }
  ]
}
```

CloudWatch-CrossAccountAccess

The **CloudWatch-CrossAccountAccess** managed policy is used by the **CloudWatch-CrossAccountSharingRole** IAM role. This role and policy enable users of cross-account dashboards to view automatic dashboards in each account that is sharing dashboards.

The following is the content of **CloudWatch-CrossAccountAccess**:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Action": [
                "sts:AssumeRole"
            ],
            "Resource": [
                "arn:aws:iam::*:role/CloudWatch-CrossAccountSharing*"
            ],
            "Effect": "Allow"
        }
    ]
}
```

CloudWatchAutomaticDashboardsAccess

The **CloudWatchAutomaticDashboardsAccess** managed policy grants access to CloudWatch for non-CloudWatch APIs, so that resources such as Lambda functions can be displayed on CloudWatch automatic dashboards.

The following is the content of **CloudWatchAutomaticDashboardsAccess**:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {

CloudWatchAgentServerPolicy

The **CloudWatchAgentServerPolicy** policy can be used in IAM roles that are attached to Amazon EC2 instances to allow the CloudWatch agent to read information from the instance and write it to CloudWatch. Its contents are as follows.

CloudWatchAgentAdminPolicy

The **CloudWatchAgentAdminPolicy** policy can be used in IAM roles that are attached to Amazon EC2 instances. This policy allows the CloudWatch agent to read information from the instance and write it to CloudWatch, and also to write information to Parameter Store. Its contents are as follows.

> **Note**
>
> You can review these permissions policies by signing in to the IAM console and searching for specific policies there.

You can also create your own custom IAM policies to allow permissions for CloudWatch actions and resources. You can attach these custom policies to the IAM users or groups that require those permissions.

Amazon managed (predefined) policies for CloudWatch cross-account observability

The policies in this section grant permissions related to CloudWatch cross-account observability. For more information, see CloudWatch cross-account observability.

CloudWatchCrossAccountSharingConfiguration

The **CloudWatchCrossAccountSharingConfiguration** policy grants access to create, manage, and view Observability Access Manager links for sharing CloudWatch resources between accounts. For more information, see CloudWatch cross-account observability. The contents are as follows:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudwatch:Link",
                "oam:ListLinks"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "oam:DeleteLink",
                "oam:GetLink",
                "oam:TagResource"
            ],
            "Resource": "arn:aws:oam:*:*:link/*"
```

```
        },
        {
            "Effect": "Allow",
            "Action": [
                "oam:CreateLink",
                "oam:UpdateLink"
            ],
            "Resource": [
                "arn:aws:oam:*:*:link/*",
                "arn:aws:oam:*:*:sink/*"
            ]
        }
    ]
}
```

OAMFullAccess

The **OAMFullAccess** policy grants access to create, manage, and view Observability Access Manager sinks and links, which are used for CloudWatch cross-account observability.

The **OAMFullAccess** policy by itself does not permit you to share observability data across links. To create a link to share CloudWatch metrics, you also need either **CloudWatchFullAccess** or **CloudWatchCrossAccountSharingConfiguration**. To create a link to share CloudWatch Logs log groups, you also need either **CloudWatchLogsFullAccess** or **CloudWatchLogsCrossAccountSharingConfiguration**. To create a link to share X-Ray traces, you also need either **AWSXRayFullAccess** or **AWSXRayCrossAccountSharingConfiguration**.

For more information, see CloudWatch cross-account observability. The contents are as follows:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "oam:*"
            ],
            "Resource": "*"
        }
    ]
}
```

OAMReadOnlyAccess

The **OAMReadOnlyAccess** policy grants read-only access to Observability Access Manager resources, which are used for CloudWatch cross-account observability. For more information, see CloudWatch cross-account observability. The contents are as follows:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "oam:Get*",
                "oam:List*"
            ],
            "Resource": "*"
        }
    ]
}
```

Amazon managed (predefined) policies for Amazon Q Developer operational investigations

The policies in this section grant permissions related to Amazon Q Developer operational investigations. For more information, see Amazon Q Developer operational investigations (Preview).

AIOpsConsoleAdminPolicy

The **AIOpsConsoleAdminPolicy** policy grants full access to all Amazon Q Developer operational investigations actions and their required permissions via the Amazon console. This policy also grants limited access to other service's APIs required for Amazon Q Developer operational investigations functionality.

- The `aiops` permissions grant access to all Amazon Q Developer operational investigations actions.
- The `organizations`, `sso`, `identitystore`, and `sts` permissions allow actions needed for IAM Identity Center management which facilitate identity-aware sessions.
- The `ssm` permissions are required for SSM Ops Item integration with third-party issue management.

- The `iam` permissions are needed so that administrators can pass IAM roles to the `aiops` and `ssm.integrations` services, and the role is later used by the assistant to analyze Amazon resources

> **Important**
>
> These permissions allow users with this policy to pass any IAM role to the `aiops` and `ssm.integrations` services.

- It allows APIs from services outside Amazon Q Developer operational investigations, which are required for investigation feature functionality. These include actions to configure Amazon Q Developer in chat applications, Amazon KMS, CloudTrail trails, and SSM third-party issue management.

The following are the contents of the **AIOpsConsoleAdminPolicy** policy.

```

}
```

AIOpsOperatorAccess

The **AIOpsOperatorAccess** policy grants access to a limited set of Amazon Q Developer operational investigations APIs which include creating, updating, and deleting investigations, investigation events, and investigation resources.

This policy only provides access to investigations. You should be sure that IAM principals with this policy also have permissions to read CloudWatch observability data such as metrics, SLOs, and CloudWatch Logs query results.

- The `aiops` permissions allow access to Amazon Q Developer operational investigations APIs to create, update, and delete investigations.
- The `sso`, `identitystore`, and `sts` permssions allow actions needed for IAM Identity Center management which facilitate identity-aware sessions.
- The `ssm` permissions are required for SSM Ops Item integration with third-party issue management.

The following are the contents of the **AIOpsOperatorAccess** policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AIOpsOperatorAccess",
            "Effect": "Allow",
            "Action": [
                "aiops:CreateInvestigation",
                "aiops:CreateInvestigationEvent",
                "aiops:CreateInvestigationResource",
                "aiops:DeleteInvestigation",
                "aiops:Get*",
                "aiops:List*",
                "aiops:UpdateInvestigation",
                "aiops:UpdateInvestigationEvent"
            ],
            "Resource": "*"
        },
        {

}
```

AIOpsReadOnlyAccess

The **AIOpsReadOnlyAccess** policy grants read-only permissions for Amazon Q investigations and other related services.

The following are the contents of the **AIOpsReadOnlyAccess** policy.

```
{
```

```
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AIOpsReadOnlyAccess",
      "Effect": "Allow",
      "Action": [
        "aiops:Get*",
        "aiops:List*"
      ],
      "Resource": "*"
    },
    {
      "Sid": "SSOManagementAccess",
      "Effect": "Allow",
      "Action": [
        "identitystore:DescribeUser",
        "sso:DescribeInstance",

IAM policy for Amazon Q Developer operational investigations (AIOpsAssistantPolicy)

The **AIOpsAssistantPolicy** policy in this section is not to be assigned to users or administrators. Instead, you assign **AIOpsAssistantPolicy** to Amazon Q Developer to enable it to analyze your Amazon resources during investigations of operational events. This policy is scoped based on the resources that Amazon Q Developer supports during investigations, and will be updated as more resources are supported.

You can also choose to assign the general Amazon ReadOnlyAccess to the assistant in addition to assigning it **AIOpsAssistantPolicy**. The reason to do this is that **ReadOnlyAccess** will be updated more frequently by Amazon with permissions for new Amazon services and actions that are released. The **AIOpsAssistantPolicy** will also be updated for new actions, but not as frequently.

The following are the contents of the **AIOpsAssistantPolicy** policy.

```

Amazon managed (predefined) policies for CloudWatch Application Signals

The policies in this section grant permissions related to CloudWatch Application Signals. For more information, see Application Signals.

CloudWatchApplicationSignalsReadOnlyAccess

Amazon has added the **CloudWatchApplicationSignalsReadOnlyAccess** managed IAM policy. This policy grants read only access to actions and resources available to users in the CloudWatch console under Application Signals. It includes `application-signals:` policies so that users can use CloudWatch Application signals to view, investigate and monitor the health of their services. It includes an `iam:GetRole` policy to allow users to retrieve information about an IAM role. It includes `logs:` policies to start and stop queries, retrieve the configuration for a metruc filter, and obtain query results. It includes `cloudwatch:` policies so that users can obtain information about a CloudWatch alarm or metrics. It includes `synthetics:` policies so that users can retrieve information about synthetics canary runs. It includes `rum:` policies to run batch operations, retrieve data, and update metrics definitions for RUM clients. It includes an `xray:` policy to retrieve trace summaries.

The following are the contents of the **CloudWatchApplicationSignalsReadOnlyAccess** policy.

```
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Sid": "CloudWatchApplicationSignalsReadOnlyAccessPermissions",
   "Effect": "Allow",
   "Action": [
    "application-signals:BatchGetServiceLevelObjectiveBudgetReport",
    "application-signals:GetService",
    "application-signals:GetServiceLevelObjective",
    "application-signals:ListServiceLevelObjectives",
    "application-signals:ListServiceDependencies",
    "application-signals:ListServiceDependents",
    "application-signals:ListServiceOperations",
    "application-signals:ListServices",
    "application-signals:ListTagsForResource"
   ],
   "Resource": "*"
  },
  {
   "Sid": "CloudWatchApplicationSignalsGetRolePermissions",
```

```
    "Effect": "Allow",

    ],
    "Resource": "*"
   }
  ]
}
```

CloudWatchApplicationSignalsFullAccess

Amazon has added the **CloudWatchApplicationSignalsFullAccess** managed IAM policy. This policy grants access to all actions and resources available to users in the CloudWatch console. It includes `application-signals:` policies so that users can use CloudWatch Application signals to view, investigate and monitor the health of their services. It uses `cloudwatch:` policies to retrieve data from metrics and alarms. It uses `logs:` policies to manage queries and filters. It uses `synthetics:` policies so that users can retrieve information about synthetics canary runs. It includes `rum:` policies to run batch operations, retrieve data and update metrics definitions for RUM clients. It includes an `xray:` policy to retrieve trace summaries. It includes `arn:aws:cloudwatch:*:*:alarm:` policies so that users can retrieve information about a service level objective (SLO) alarm. It includes `iam:` policies to manage IAM roles. It uses `sns:` policies to create, list, and subscribe to an Amazon SNS topic.

The following are the contents of the **CloudWatchApplicationSignalsFullAccess** policy.

```
{
 "Version": "2012-10-17",
 "Statement": [
    {
        "Sid": "CloudWatchApplicationSignalsFullAccessPermissions",
        "Effect": "Allow",
        "Action": "application-signals:*",
        "Resource": "*"
    },
    {
        "Sid": "CloudWatchApplicationSignalsAlarmsPermissions",
        "Effect": "Allow",
        "Action": "cloudwatch:DescribeAlarms",
        "Resource": "*"
    },
    {
        "Sid": "CloudWatchApplicationSignalsMetricsPermissions",
        "Effect": "Allow",
        "Action": [
            "cloudwatch:GetMetricData",
            "cloudwatch:ListMetrics"
        ],
        "Resource": "*"
    },
    {
        "Sid": "CloudWatchApplicationSignalsLogGroupPermissions",
        "Effect": "Allow",
        "Action": [
            "logs:StartQuery"
        ],
        "Resource": "arn:aws:logs:*:*:log-group:/aws/application-signals/data:*"
    },
    {

        "Resource": "*"
    }
 ]
}
```

CloudWatchLambdaApplicationSignalsExecutionRolePolicy

This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.

The following are the contents of the **CloudWatchLambdaApplicationSignalsExecutionRolePolicy** policy.

```
{
 "Version": "2012-10-17",
```

```
  "Statement": [
   {
    "Sid": "CloudWatchApplicationSignalsXrayWritePermissions",
    "Effect": "Allow",
    "Action": [
     "xray:PutTraceSegments"
    ],
    "Resource": [
     "*"
    ],
    "Condition": {
     "StringEquals": {
      "aws:ResourceAccount": "${aws:PrincipalAccount}"
     }
    }
   },
   {
    "Sid": "CloudWatchApplicationSignalsLogGroupWritePermissions",
    "Effect": "Allow",
    "Action": [
     "logs:CreateLogGroup",
     "logs:CreateLogStream",
     "logs:PutLogEvents"
    ],
    "Resource": "arn:aws:logs:*:*:log-group:/aws/application-signals/data:*",
    "Condition": {
     "StringEquals": {
      "aws:ResourceAccount": "${aws:PrincipalAccount}"
     }
    }
   }
  ]
}
```

Amazon managed (predefined) policies for CloudWatch Synthetics

The **CloudWatchSyntheticsFullAccess** and **CloudWatchSyntheticsReadOnlyAccess** Amazon managed policies are available for you to assign to users who will manage or use CloudWatch Synthetics. The following additional policies are also relevant:

- **AmazonS3ReadOnlyAccess** and **CloudWatchReadOnlyAccess –** These are necessary to read all Synthetics data in the CloudWatch console.

- **AWSLambdaReadOnlyAccess –** Required to view the source code used by canaries.
- **CloudWatchSyntheticsFullAccess –** Allows you to create canaries. Additionally, to create and delete canaries that have a new IAM role created for them, you need the following inline policy statement:

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":[
            "synthetics:*"
         ],
         "Resource":"*"
      },
      {
         "Effect":"Allow",
         "Action":[
            "s3:CreateBucket",
            "s3:PutEncryptionConfiguration"
         ],
         "Resource":[
            "arn:aws:s3:::cw-syn-results-*"
         ]
      },
      {
         "Effect":"Allow",
         "Action":[
            "iam:ListRoles",
            "s3:ListAllMyBuckets",
            "s3:GetBucketLocation",
            "xray:GetTraceSummaries",
            "xray:BatchGetTraces",
            "apigateway:GET"
         ],
         "Resource":"*"
      },
      {
         "Effect":"Allow",
         "Action":[
            "s3:GetObject",
            "s3:ListBucket"
         ],
```

```
            "Resource":"arn:aws:s3:::cw-syn-*"
         },
         {
            "Effect":"Allow",
            "Action":[
               "s3:GetObjectVersion"
            ],
            "Resource":"arn:aws:s3:::aws-synthetics-library-*"
         },
         {
            "Effect":"Allow",

}
```

Important

Granting a user the `iam:CreateRole`, `iam:DeleteRole`, `iam:CreatePolicy`, `iam:DeletePolicy`, `iam:AttachRolePolicy`, and `iam:DetachRolePolicy` permissions gives that user full administrative access to create, attach, and delete roles and policies that have ARNs that match `arn:aws:iam::*:role/service-role/CloudWatchSyntheticsRole*` and `arn:aws:iam::*:policy/service-role/`

CloudWatchSyntheticsPolicy*. For example, a user with these permissions can create a policy that has full permissions for all resources, and attach that policy to any role that matches that ARN pattern. Be careful to whom you grant these permissions.

For information about attaching policies and granting permissions to users, see Changing Permissions for an IAM User and To embed an inline policy for a user or role.

CloudWatchSyntheticsFullAccess

The following is the content of the **CloudWatchSyntheticsFullAccess** policy.

```
{
    "Version": "2012-10-17",

                "logs:CreateLogStream"
            ],
            "Resource": "arn:aws:logs:*:*:log-group:*RUMService*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "logs:CreateLogDelivery",
                "logs:GetLogDelivery",
                "logs:UpdateLogDelivery",
                "logs:DeleteLogDelivery",
                "logs:ListLogDeliveries",
                "logs:DescribeResourcePolicies"
            ],
            "Resource": "*"
        },
        {
```

```
            "Effect": "Allow",
            "Action": [
                "logs:DescribeLogGroups"
            ],
            "Resource": "arn:aws:logs:*:*:log-group::log-stream:*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "synthetics:describeCanaries",
                "synthetics:describeCanariesLastRun"
            ],
            "Resource": "arn:aws:synthetics:*:*:canary:*"
        }
    ]
}
```

AmazonCloudWatchRUMReadOnlyAccess

The **AmazonCloudWatchRUMReadOnlyAccess** allows read-only administrative access to CloudWatch RUM.

The following are the contents of the **AmazonCloudWatchRUMReadOnlyAccess** policy.

```
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "rum:GetAppMonitor",
    "rum:GetAppMonitorData",
    "rum:ListAppMonitors",
    "rum:ListRumMetricsDestinations",
    "rum:BatchGetRumMetricDefinitions",
    "rum:GetResourcePolicy"
   ],
   "Resource": "*"
  }
 ]
}
```

AmazonCloudWatchRUMServiceRolePolicy

You can't attach **AmazonCloudWatchRUMServiceRolePolicy** to your IAM entities. This policy is attached to a service-linked role that allows CloudWatch RUM to publish monitoring data to other relevant Amazon services. For more information about this service linked role, see Using service-linked roles for CloudWatch RUM.

The complete contents of **AmazonCloudWatchRUMServiceRolePolicy** are as follows.

```
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "xray:PutTraceSegments"
   ],
   "Resource": [
    "*"
   ]
  },
  {
   "Effect": "Allow",
   "Action": "cloudwatch:PutMetricData",
   "Resource": "*",
   "Condition": {
    "StringLike": {
     "cloudwatch:namespace": [
      "RUM/CustomMetrics/*",
      "AWS/RUM"
     ]
    }
   }
  }
 ]
}
```

Amazon managed (predefined) policies for CloudWatch Evidently

The **CloudWatchEvidentlyFullAccess** and **CloudWatchEvidentlyReadOnlyAccess** Amazon managed policies are available for you to assign to users who will manage or use CloudWatch Evidently.

CloudWatchEvidentlyFullAccess

The following are the contents of the **CloudWatchEvidentlyFullAccess** policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "evidently:*"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:ListRoles"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "iam:GetRole"
            ],
            "Resource": [
                "arn:aws:iam::*:role/service-role/CloudWatchRUMEvidentlyRole-*"

                "cloudwatch:PutMetricAlarm"
            ],
            "Resource": [
                "arn:aws:cloudwatch:*:*:alarm:Evidently-Alarm-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "sns:ListTopics"
            ],
            "Resource": [
                "*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
```

```
                "sns:CreateTopic",
                "sns:Subscribe",
                "sns:ListSubscriptionsByTopic"
            ],
            "Resource": [
                "arn:*:sns:*:*:Evidently-*"
            ]
        },
        {
            "Effect": "Allow",
            "Action": [
                "logs:DescribeLogGroups"
            ],
            "Resource": [
                "*"
            ]
        }
    ]
}
```

CloudWatchEvidentlyReadOnlyAccess

The following are the contents of the **CloudWatchEvidentlyReadOnlyAccess** policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "evidently:GetExperiment",
                "evidently:GetFeature",
                "evidently:GetLaunch",
                "evidently:GetProject",
                "evidently:GetSegment",
                "evidently:ListExperiments",
                "evidently:ListFeatures",
                "evidently:ListLaunches",
                "evidently:ListProjects",
                "evidently:ListSegments",
                "evidently:ListSegmentReferencs"
            ],
            "Resource": "*"
        }
```

```
    ]
}
```

Amazon managed policy for Amazon Systems Manager Incident Manager

The **AWSCloudWatchAlarms_ActionSSMIncidentsServiceRolePolicy** policy is attached to a service-linked role that allows CloudWatch to start incidents in Amazon Systems Manager Incident Manager on your behalf. For more information, see Service-linked role permissions for CloudWatch alarms Systems Manager Incident Manager actions.

The policy has the following permission:

- ssm-incidents:StartIncident

Customer managed policy examples

In this section, you can find example user policies that grant permissions for various CloudWatch actions. These policies work when you are using the CloudWatch API, Amazon SDKs, or the Amazon CLI.

Examples

- Example 1: Allow user full access to CloudWatch
- Example 2: Allow read-only access to CloudWatch
- Example 3: Stop or terminate an Amazon EC2 instance

Example 1: Allow user full access to CloudWatch

To grant a user full access to CloudWatch, you can use grant them the **CloudWatchFullAccess** managed policy instead of creating a customer-managed policy. The contents of the **CloudWatchFullAccess** are listed in CloudWatchFullAccess.

Example 2: Allow read-only access to CloudWatch

The following policy allows a user read-only access to CloudWatch and view Amazon EC2 Auto Scaling actions, CloudWatch metrics, CloudWatch Logs data, and alarm-related Amazon SNS data.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
    {
      "Action": [
        "autoscaling:Describe*",
        "cloudwatch:Describe*",
        "cloudwatch:Get*",
        "cloudwatch:List*",
        "logs:Get*",
        "logs:Describe*",
        "logs:StartQuery",
        "logs:StopQuery",
        "logs:TestMetricFilter",
        "logs:FilterLogEvents",
        "logs:StartLiveTail",
        "logs:StopLiveTail",
        "sns:Get*",
        "sns:List*"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

Example 3: Stop or terminate an Amazon EC2 instance

The following policy allows an CloudWatch alarm action to stop or terminate an EC2 instance. In the sample below, the GetMetricData, ListMetrics, and DescribeAlarms actions are optional. It is recommended that you include these actions to ensure that you have correctly stopped or terminated the instance.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "cloudwatch:PutMetricAlarm",
        "cloudwatch:GetMetricData",
        "cloudwatch:ListMetrics",
        "cloudwatch:DescribeAlarms"
      ],
      "Resource": [
        "*"
      ],
```

```
      "Effect": "Allow"
    },
    {
      "Action": [
        "ec2:DescribeInstanceStatus",
        "ec2:DescribeInstances",
        "ec2:StopInstances",
        "ec2:TerminateInstances"
      ],
      "Resource": [
        "*"
      ],
      "Effect": "Allow"
    }
  ]
}
```

CloudWatch updates to Amazon managed policies

View details about updates to Amazon managed policies for CloudWatch since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the CloudWatch Document history page.

Change	Description	Date
AmazonCloudWatchRUMReadOnlyAccess – Updated policy	CloudWatch added a permission to the **AmazonCloudWatchRUMReadOnlyAccess** policy. The `rum:GetResourcePolicy` permission was added so that CloudWatch RUM can view the resource policy attached to the RUM application monitor.	April 28, 2025
AIOpsConsoleAdminPolicy – New policy	CloudWatch created a new policy named **AIOpsConsoleAdminPolicy**.	December 3, 2024

Change	Description	Date
	This policy grants users full administrative access for managing Amazon Q Developer operational investigations, including the management of trusted identity propagation, and the management of IAM Identity Center and organizational access.	
AIOpOperatorAccess – New policy	CloudWatch created a new policy named **AIOpsOperatorAccess**. This policy grants users access to Amazon Q Developer operational investigations actions, and to additional Amazon actions that are necessary for accessing investigation events.	December 3, 2024
AIOpsReadOnlyAccess – New policy	CloudWatch created a new policy named **AIOpsReadOnlyAccess**. This policy grants a user read-only permissions for Amazon AI Operations and other related services.	December 3, 2024

Change	Description	Date
AIOpsAssistantPolicy – New policy	CloudWatch created a new policy named **AIOpsAssistantPolicy**. You don't assign this policy to a user. You assign this policy to the Amazon AI Operations assistant to enable Amazon Q operational investigations to analyze your Amazon resources during the investigation of operational events.	December 3, 2024
CloudWatchFullAccessV2 – Updates to existing policies	CloudWatch updated both **CloudWatchFullAccessV2** and **CloudWatchFullAccess**. Permissions for Amazon OpenSearch Service were added to to enable CloudWatch Logs integration with OpenSearch Service for some features.	December 1, 2024

Change	Description	Date
[CloudWatchNetworkFlowMonitorServiceRolePolicy](#) – New policy	CloudWatch added a new policy **CloudWatchNetworkFlowMonitorServiceRolePolicy**. The **CloudWatchNetworkFlowMonitorServiceRolePolicy** grants permissions for Network Flow Monitor to publish metrics to CloudWatch. It also allows the service to use Amazon Organizations to get information for multi-account scenarios.	December 1, 2024
[CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy](#) – New policy	CloudWatch added a new policy **CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy**. The **CloudWatchNetworkFlowMonitorTopologyServiceRolePolicy** grants permissions for Network Flow Monitor to generate topology snapshots of resources used in your account.	December 1, 2024

Change	Description	Date
[CloudWatchNetworkFlowMonitorAgentPublishPolicy]() – New policy	CloudWatch added a new policy **CloudWatchNetworkFlowMonitorAgentPublishPolicy**. The **CloudWatchNetworkFlowMonitorAgentPublishPolicy** grants permissions for resources, such as Amazon EC2 and Amazon EKS instances, to send telemetry reports (metrics) to a Network Flow Monitor endpoint.	December 1, 2024

Change	Description	Date
[CloudWatchSyntheticsFullAccess]() – Update to an existing policy	CloudWatch updated the policy named **CloudWatchSyntheticsFullAccess**. The following CloudWatch Logs actions have been added to allow CloudWatch Synthetics to get and use canary log data in Lambda log groups. The `lambda:GetFunction` permission has also been added to allow Synthetics to get information about a specific function. • `logs:GetLogRecord` – Required to expand a log entry in CloudWatch Logs Insights. (Required to view logs in the Synthetics console.) • `logs:DescribeLogStreams` – Required to list all log streams on a log group. • `logs:StartQuery` – Required to start a Logs Insights query (required in the Synthetics console to view logs). • `logs:GetLogEvents` – Required to list log events from the specified log stream. Used for querying	November 20, 2024

Change	Description	Date
	a specific log stream on a log group. • `logs:FilterLogEvents` – Required to view logs in a canary's log group. • `logs:GetLogGroupFields` – Required for running a Logs Insights query in the console. (The Synthetics console links to the Logs Insights query. Without this permission, Logs Insights queries on a log group fail.) Additionally, Lambda layer version actions now apply to all CloudWatch Synthetics layer ARNs.	

Change	Description	Date
[CloudWatchInternetMonitorReadOnlyAccess]() – New **CloudWatchInternetMonitorReadOnlyAccess**. This policy grants read only access to resources and actions available in the CloudWatch console for Internet Monitor. The scope of this policy includes `internetmonitor:` so that users can use read-only Internet Monitor actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch metrics. It includes some `logs:` policies to manage log queries.	November 14, 2024	

Change	Description	Date
CloudWatchInternetMonitorFullAccess – New policy	CloudWatch created a new policy named **CloudWatchInternetMonitorFullAccess**. This policy grants full access to resources and actions available in the CloudWatch console for Internet Monitor. The scope of this policy includes `internetmonitor:` so that users can use Internet Monitor actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `logs:` policies to manage log queries. It includes some `ec2:`, `cloudfront:` , `elasticloadbalancing:` , and `workspaces:` policies to work with resources that you add to monitors so that Internet Monitor can create a traffic profile for your application. It contains some `iam:` policies to manage IAM roles.	October 23, 2024

Change	Description	Date
[CloudWatchLambdaApplicationSignalsExecutionRolePolicy]() – New **CloudWatchLambdaApplicationSignalsExecutionRolePolicy**. This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.	October 16, 2024	
[CloudWatchSyntheticsFullAccess]() – Update to an existing policy	CloudWatch updated the policy named **CloudWatchSyntheticsFullAccess**. The `lambda:ListTags` , `lambda:TagResource` , and `lambda:UntagResource` permissions were added so that when you apply or change tags on a canary, you can choose to have Synthetics also apply those same tags or changes to the Lambda function that the canary uses.	October 11, 2024

Change	Description	Date
CloudWatchApplicationSignalsReadOnlyAccess – New policy	CloudWatch created a new policy named **CloudWatchApplicationSignalsReadOnlyAccess**. This policy grants read only access to resources and actions available in the CloudWatch console for Application Signals. The scope of this policy includes `application-signals:` policies so that users can use read only actions and resources available in the CloudWatch console under Application Signals. It contains an `iam:` policy to manage IAM roles. It includes some `logs:` policies to manage log queries and filters. It includes `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `synthetics:` policies to retrive information about synthetics canaries. It includes `rum:` policies to manage RUM clients and jobs. It contains an `xray:` policy to obtain trace summaries.	June 7, 2024

Change	Description	Date
CloudWatchApplicationSignalsFullAccess – New policy	CloudWatch created a new policy named **CloudWatchApplicationSignalsFullAccess**. This policy grants full access to resources and actions available in the CloudWatch console for Application Signals. The scope of this policy includes `application-signals:` so that users can use Application Signals actions and resources. It includes some `cloudwatch:` policies to retrieve information on CloudWatch alarms and metrics. It includes some `logs:` policies to manage log queries. It includes some `synthetics:` policies to write and retrieve information about synthetics canaries. It includes `rum:` policies to manage RUM clients and jobs. It contains an `xray:` policy to obtain trace summaries. It includes some `cloudwatch:` policies to manage CloudWatch alarms. It contains some `iam:` policies to manage IAM roles. It includes some `sns:` policies to manage Amazon Simple	June 7, 2024

Change	Description	Date
	Notification Service notificat ions.	
[CloudWatchFullAccessV2](#) – Update to an existing policy	CloudWatch updated the policy named **CloudWatchFullAccessV2**. The scope of the `CloudWatchFullAccessPermissions` policy was updated to add `application-signals:*` so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services.	May 20, 2024

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch updated the policy named **CloudWatchReadOnlyAccess**. The scope of the `CloudWatchReadOnlyAccessPermissions` policy was updated to add `application-signals:BatchGet*` , `application-signals:List*` , and `application-signals:Get*` so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services. The scope of `CloudWatchReadOnlyGetRolePermissions` was updated to add the `iam:GetRole` action so that users can check if CloudWatch Application Signals is set up.	May 20, 2024

Change	Description	Date
CloudWatchApplicationSignalsServiceRolePolicy – Update to an existing policy	CloudWatch updated the policy named **CloudWatchApplicationSignalsServiceRolePolicy**. The scoping of the `logs:StartQuery` and `logs:GetQueryResults` permissions was changed to add the `arn:aws:logs:*:*:log-group:/aws/appsignals/*:*` and `arn:aws:logs:*:*:log-group:/aws/application-signals/data:*` ARNs to enable Application Signals on more architectures.	April 18, 2024
CloudWatchApplicationSignalsServiceRolePolicy – Update to an existing policy	CloudWatch changed the scope of a permission in **CloudWatchApplicationSignalsServiceRolePolicy**. The scope of the `cloudwatch:GetMetricData` permission was changed to * so that Application Signals can retrieve metrics from sources in linked accounts.	April 08, 2024

Change	Description	Date
CloudWatchFullAccessV2 – Update to an existing policy	CloudWatch added permissions to **CloudWatchFullAccessV2**. Existing permissions for CloudWatch Synthetics, X-Ray, and CloudWatch RUM actions and new permissions for CloudWatch Application Signals were added so that users with this policy can manage CloudWatch Application Signals. The permission to create the CloudWatch Application Signals service-linked role was added to allow CloudWatch Application Signals to discover telemetry data in logs, metrics, traces, and tags.	December 5, 2023

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. Existing read-only permissions for CloudWatch Synthetics, X-Ray, and CloudWatch RUM actions and new read-only permissions for CloudWatch Application Signals were added so that users with this policy can triage and dignose their service health issues as reported by CloudWatch Application Signals. The `cloudwatch:GenerateQuery` permission was added so that users with this policy can generate a CloudWatch Metrics Insights query string from a natural language prompt.	December 5, 2023
CloudWatchReadOnlyAccess – Update to an existing policy.	CloudWatch added a permission to **CloudWatchReadOnlyAccess**. The `cloudwatch:GenerateQuery` permission was added, so that users with this policy can generate a CloudWatch Metrics Insights query string from a natural language prompt.	December 01, 2023

Change	Description	Date
[CloudWatchApplicationSignalsServiceRolePolicy](#) – New policy	CloudWatch added a new policy **CloudWatchApplicationSignalsServiceRolePolicy**. The **CloudWatchApplicationSignalsServiceRolePolicy** grants an upcoming feature permissions to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data.	November 9, 2023
[AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy](#) – New policy	CloudWatch added a new policy **AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy**. The **AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy** grants permission to CloudWatch to fetch Performance Insights metrics from databases on your behalf.	September 20, 2023

Change	Description	Date
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added a permission to **CloudWatchReadOnlyAccess**. The `application-autoscaling:DescribeScalingPolicies` permission was added so that users with this policy can access information about Application Auto Scaling policies.	September 14, 2023
CloudWatchFullAccessV2 – New policy	CloudWatch added a new policy **CloudWatchFullAccessV2**. The **CloudWatchFullAccessV2** grants full access to CloudWatch actions and resources while better scoping the permissions granted to other services such as Amazon SNS and Amazon EC2 Auto Scaling. For more information, see CloudWatchFullAccessV2.	August 1, 2023

Change	Description	Date
AWSServiceRoleForInternetMonitor – Update to an existing policy	Amazon CloudWatch Internet Monitor added new permissions to monitor Network Load Balancer resources. The `elasticloadbalancing:DescribeLoadBalancers` and `ec2:DescribeNetworkInterfaces` permissions are required so that Internet Monitor can monitor customers' Network Load Balancer traffic by analyzing flow logs for NLB resources. For more information, see Using Internet Monitor.	July 15, 2023
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. The `logs:StartLiveTail` and `logs:StopLiveTail` permissions were added so that users with this policy can use the console to start and stop CloudWatch Logs live tail sessions. For more information, see Use live tail to view logs in near real time.	June 6, 2023

Change	Description	Date
CloudWatchCrossAccountSharingConfiguration – New policy	CloudWatch added a new policy to enable you to manage CloudWatch cross-account observability links that share CloudWatch metrics. For more information, see CloudWatch cross-account observability.	November 27, 2022
OAMFullAccess – New policy	CloudWatch added a new policy to enable you to fully manage CloudWatch cross-account observability links and sinks. For more information, see CloudWatch cross-account observability.	November 27, 2022
OAMReadOnlyAccess – New policy	CloudWatch added a new policy to enable you to view information about CloudWatch cross-account observability links and sinks. For more information, see CloudWatch cross-account observability.	November 27, 2022

Change	Description	Date
CloudWatchFullAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchFullAccess**. The `oam:ListSinks` and `oam:ListAttachedLinks` permissions were added so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability.	November 27, 2022
CloudWatchReadOnlyAccess – Update to an existing policy	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. The `oam:ListSinks` and `oam:ListAttachedLinks` permissions were added so that users with this policy can use the console to view data shared from source accounts in CloudWatch cross-account observability.	November 27, 2022

Change	Description	Date
AmazonCloudWatchRUMServiceRolePolicy – Update to an existing policy	CloudWatch RUM updated a condition key in **AmazonCloudWatchRUMServiceRolePolicy**. The `"Condition": { "StringEquals": { "cloudwatch:namespace": "AWS/RUM" } }` condition key was changed to the following so that CloudWatch RUM can send custom metrics to custom metric namespaces. `"Condition": { "StringLike": { "cloudwatch:namespace": [ "RUM/CustomMetrics/*", "AWS/RUM" ] } }`	February 2, 2023

Change	Description	Date
AmazonCloudWatchRUMReadOnlyAccess – Updated policy	CloudWatch added permissions the **AmazonCloudWatchRUMReadOnlyAccess** policy. The `rum:ListRumMetricsDestinations` and `rum:BatchGetRumMetricsDefinitions` permissions were added so that CloudWatch RUM can send extended metrics to CloudWatch and Evidently.	October 27, 2022
AmazonCloudWatchRUMServiceRolePolicy – Update to an existing policy	CloudWatch RUM added permissions to **AmazonCloudWatchRUMServiceRolePolicy**. The `cloudwatch:PutMetricData` permission was added so that CloudWatch RUM can send extended metrics to CloudWatch.	October 26, 2022

Change	Description	Date
CloudWatchEvidentlyReadOnlyAccess – Update to an existing policy	CloudWatch Evidently added permissions to **CloudWatchEvidentlyReadOnlyAccess**. The `evidently:GetSegment`, `evidently:ListSegments`, and `evidently:ListSegmentReferences` permissions were added so that users with this policy can see Evidently audience segments that have been created.	August 12, 2022
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch Synthetics added permissions to **CloudWatchSyntheticsFullAccess**. The `lambda:DeleteFunction` and `lambda:DeleteLayerVersion` permissions were added so that CloudWatch Synthetics can delete related resources when a canary is deleted. The `iam:ListAttachedRolePolicies` was added so that customers can view the policies that are attached to a canary's IAM role.	May 6, 2022

Change	Description	Date
AmazonCloudWatchRUMFullAccess – New policy	CloudWatch added a new policy to enable full management of CloudWatch RUM. CloudWatch RUM allows you to perform real user monitoring of your web application. For more information, see CloudWatch RUM.	November 29, 2021
AmazonCloudWatchRUMReadOnlyAccess – New policy	CloudWatch added a new policy to enable read-only access to CloudWatch RUM. CloudWatch RUM allows you to perform real user monitoring of your web application. For more information, see CloudWatch RUM.	November 29, 2021
CloudWatchEvidentlyFullAccess – New policy	CloudWatch added a new policy to enable full management of CloudWatch Evidently. CloudWatch Evidently allows you to perform A/B experiments of your web applications, and to roll them out gradually. For more information, see Perform launches and A/B experiments with CloudWatch Evidently.	November 29, 2021

Change	Description	Date
CloudWatchEvidentlyReadOnlyAccess – New policy	CloudWatch added a new policy to enable read-only access to CloudWatch Evidently. CloudWatch Evidently allows you to perform A/B experiments of your web applications, and to roll them out gradually. For more information, see Perform launches and A/B experiments with CloudWatch Evidently.	November 29, 2021
AWSServiceRoleForCloudWatchRUM – New managed policy	CloudWatch added a policy for a new service-linked role to allow CloudWatch RUM to pubish monitoring data to other relevant Amazon services.	November 29, 2021

Change	Description	Date
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch Synthetics added permissions to **CloudWatchSyntheticsFullAccess**, and also changed the scope of one permission. The `kms:ListAliases` permission was added so that users can list available Amazon KMS keys that can be used to encrypt canary artifacts. The `kms:DescribeKey` permission was added so that users can see the details of keys that will be used to encrypt for canary artifacts. And the `kms:Decrypt` permission was added to enable users to decrypt canary artifacts. This decryption ability is limited to use on resources within Amazon S3 buckets. The `Resource` scope of the `s3:GetBucketLocation` permission was changed from `*` to `arn:aws:s3:::*` .	September 29, 2021

Change	Description	Date
CloudWatchSyntheticsFullAccess – Update to an existing policy	CloudWatch Synthetics added a permission to **CloudWatchSyntheticsFullAccess**. The `lambda:UpdateFunctionCode` permission was added so that users with this policy can change the runtime version of canaries.	July 20, 2021
AWSCloudWatchAlarms_ActionSSMIncidentsServiceRolePolicy – New managed policy	CloudWatch added a new managed IAM policy to allow CloudWatch to create incidents in Amazon Systems Manager Incident Manager.	May 10, 2021
CloudWatchAutomaticDashboardsAccess – Update to an existing policy	CloudWatch added a permission to the **CloudWatchAutomaticDashboardsAccess** managed policy. The `synthetics:DescribeCanariesLastRun` permission was added to this policy to enable cross-account dashboard users to see details about CloudWatch Synthetics canary runs.	April 20, 2021
CloudWatch started tracking changes	CloudWatch started tracking changes for its Amazon managed policies.	April 14, 2021

Using condition keys to limit access to CloudWatch namespaces

Use IAM condition keys to limit users to publishing metrics only in the CloudWatch namespaces that you specify. This section provides examples that describe how to allow and exclude users from publishing metrics in a namespace.

Allowing publishing in one namespace only

The following policy limits the user to publishing metrics only in the namespace named `MyCustomNamespace`.

```
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Resource": "*",
        "Action": "cloudwatch:PutMetricData",
        "Condition": {
            "StringEquals": {
                "cloudwatch:namespace": "MyCustomNamespace"
            }
        }
    }
}
```

Excluding publishing from a namespace

The following policy allows the user to publish metrics in any namespace except for `CustomNamespace2`.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Resource": "*",
            "Action": "cloudwatch:PutMetricData"
        },
        {
            "Effect": "Deny",
            "Resource": "*",
```

```
            "Action": "cloudwatch:PutMetricData",
            "Condition": {
                "StringEquals": {
                    "cloudwatch:namespace": "CustomNamespace2"
                }
            }
        }
    ]
}
```

Using condition keys to limit Contributor Insights users' access to log groups

To create a rule in Contributor Insights and see its results, a user must have the `cloudwatch:PutInsightRule` permission. By default, a user with this permission can create a Contributor Insights rule that evaluates any log group in CloudWatch Logs and then see the results. The results can contain contributor data for those log groups.

You can create IAM policies with condition keys to grant users the permission to write Contributor Insights rules for some log groups while preventing them from writing rules for and seeing this data from other log groups.

For more information about the `Condition` element in IAM policies, see [IAM JSON policy elements: Condition](#).

Allow access to write rules and view results for only certain log groups

The following policy allows the user access to write rules and view results for the log group named `AllowedLogGroup` and all log groups that have names that start with `AllowedWildCard`. It does not grant access to write rules or view rule results for any other log groups.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowCertainLogGroups",
            "Effect": "Allow",
            "Action": "cloudwatch:PutInsightRule",
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/*",
            "Condition": {
```

```
                "ForAllValues:StringEqualsIgnoreCase": {
                    "cloudwatch:requestInsightRuleLogGroups": [
                        "AllowedLogGroup",
                        "AllowedWildcard*"
                    ]
                }
            }
        }
    ]
}
```

Deny writing rules for specific log groups but allow writing rules for all other log groups

The following policy explicitly denies the user access to write rules and view rule results for the log group named `ExplicitlyDeniedLogGroup`, but allows writing rules and viewing rule results for all other log groups.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowInsightRulesOnLogGroupsByDefault",
            "Effect": "Allow",
            "Action": "cloudwatch:PutInsightRule",
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/*"

        },
        {
            "Sid": "ExplicitDenySomeLogGroups",
            "Effect": "Deny",
            "Action": "cloudwatch:PutInsightRule",
            "Resource": "arn:aws:cloudwatch:*:*:insight-rule/*",
            "Condition": {
                "ForAllValues:StringEqualsIgnoreCase": {
                    "cloudwatch:requestInsightRuleLogGroups": [
                        "/test/alpine/ExplicitlyDeniedLogGroup"
                    ]
                }
            }
        }
    ]
}
```

Using condition keys to limit alarm actions

When CloudWatch alarms change state, they can perform different actions such as stopping and terminating EC2 instances and performing Systems Manager actions. These actions can be initiated when the alarm changes to any state, including ALARM, OK, or INSUFFICIENT_DATA.

Use the `cloudwatch:AlarmActions` condition key to allow a user to create alarms that can only perform the actions you specify when the alarm state changes. For example, you can allow a user to create alarms that can only perform actions which are not EC2 actions.

Allow a user to create alarms that can only send Amazon SNS notifications or perform Systems Manager actions

The following policy limits the user to creating alarms that can only send Amazon SNS notifications and perform Systems Manager actions. The user can't create alarms that perform EC2 actions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateAlarmsThatCanPerformOnlySNSandSSMActions",
            "Effect": "Allow",
            "Action": "cloudwatch:PutMetricAlarm",
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringLike": {
                    "cloudwatch:AlarmActions": [
                        "arn:aws:sns:*",
                        "arn:aws:ssm:*"
                    ]
                }
            }
        }
    ]
}
```

Using service-linked roles for CloudWatch

Amazon CloudWatch uses Amazon Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch. Service-linked roles are predefined by CloudWatch and include all the permissions that the service requires to call other Amazon services on your behalf.

One service-linked role in CloudWatch makes setting up CloudWatch alarms that can terminate, stop, or reboot an Amazon EC2 instance without requiring you to manually add the necessary permissions. Another service-linked role enables a monitoring account to access CloudWatch data from other accounts that you specify, to build cross-account cross-Region dashboards.

CloudWatch defines the permissions of these service-linked roles, and unless defined otherwise, only CloudWatch can assume the role. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the roles only after first deleting their related resources. This restriction protects your CloudWatch resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see Amazon Services That Work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for CloudWatch alarms EC2 actions

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchEvents** – CloudWatch uses this service-linked role to perform Amazon EC2 alarm actions.

The AWSServiceRoleForCloudWatchEvents service-linked role trusts the CloudWatch Events service to assume the role. CloudWatch Events invokes the terminate, stop, or reboot instance actions when called upon by the alarm.

The AWSServiceRoleForCloudWatchEvents service-linked role permissions policy allows CloudWatch Events to complete the following actions on Amazon EC2 instances:

- `ec2:StopInstances`
- `ec2:TerminateInstances`
- `ec2:RecoverInstances`
- `ec2:DescribeInstanceRecoveryAttribute`
- `ec2:DescribeInstances`
- `ec2:DescribeInstanceStatus`

The **AWSServiceRoleForCloudWatchCrossAccount** service-linked role permissions policy allows CloudWatch to complete the following actions:

- `sts:AssumeRole`

Service-linked role permissions for CloudWatch telemetry config

CloudWatch observability admin creates and uses a service-linked role named **AWSServiceRoleForObservabilityAdmin –** CloudWatch uses this service-linked role to support resource and telemetry config discovery for Amazon Organizations. The role is created in all member accounts of the Organization.

The **AWSServiceRoleForObservabilityAdmin** service-linked role trusts Observability Admin to assume the role. Observability Admin manages Amazon Config Service Linked Configuration Recorders and Service Linked Configuration Aggregator in your Organizations accounts.

The **AWSServiceRoleForObservabilityAdmin** service-linked role has a policy, called AWSObservabilityAdminServiceRolePolicy, attached and this policy grants permission to CloudWatch Observability Admin to complete the following actions:

- `organizations:ListAccounts`
- `organizations:ListAccountsForParent`
- `organizations:ListChildren`
- `organizations:ListParents`
- `organizations:DescribeOrganization`
- `organizations:DescribeOrganizationalUnit`
- `organizations:EnableAWSServiceAccess`
- `organizations:ListDelegatedAdministrators`
- `config:PutServiceLinkedConfigurationRecorder`
- `config:DeleteServiceLinkedConfigurationRecorder`
- `config:PutConfigurationAggregator`
- `config:DeleteConfigurationAggregator`
- `config:SelectAggregateResourceConfig`
- `iam:CreateServiceLinkedRole`
- `iam:PassRole`

The complete contents of the AWSObservabilityAdminServiceRolePolicy policy are as follows:

```
 {
 "Version": "2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "organizations:ListAccounts",
    "organizations:ListAccountsForParent",
    "organizations:ListChildren",
    "organizations:ListParents",
    "organizations:DescribeOrganization",
    "organizations:DescribeOrganizationalUnit"
   ],
   "Resource": "*"
  },

```
    "Effect": "Allow",
    "Action": [
     "organizations:ListDelegatedAdministrators"
    ],
    "Resource": "*",
    "Condition": {
     "StringEquals": {
      "organizations:ServicePrincipal": [
       "observabilityadmin.amazonaws.com",
       "config.amazonaws.com"
      ]
     }
    }
   }
  ]
 }
```

Service-linked role permissions for CloudWatch Application Signals

CloudWatch Application Signals uses the service-linked role named **AWSServiceRoleForCloudWatchApplicationSignals** – CloudWatch uses this service-linked role to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data from applications that you have enabled for CloudWatch Application Signals.

The **AWSServiceRoleForCloudWatchApplicationSignals** service-linked role trusts CloudWatch Application Signals to assume the role. Application Signals collects the logs, traces, metrics, and tags data from your account.

The **AWSServiceRoleForCloudWatchApplicationSignals** has an IAM policy attached, and this policy is named **CloudWatchApplicationSignalsServiceRolePolicy**. This policy grants permission to CloudWatch Application Signals to collect monitoring and tagging data from other relevant Amazon services. It includes permissions for Application Signals to complete the following actions:

- `xray` – Retrieve X-Ray traces.
- `logs` – Retrieve the current CloudWatch logs information.
- `cloudwatch` – Retrieve the current CloudWatch metric information.
- `tags` – Retrieve the current tags.
- `application-signals` – Retrieve information on SLOs and their associated time exclusion windows.

- `autoscaling` – Retrieve application tags from Amazon EC2 Autoscaling group.

The complete contents of **CloudWatchApplicationSignalsServiceRolePolicy** are as follows:

```
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Sid": "XRayPermission",
   "Effect": "Allow",
   "Action": [
    "xray:GetServiceGraph"
   ],
   "Resource": [
    "*"
   ],
   "Condition": {
    "StringEquals": {
     "aws:ResourceAccount": "${aws:PrincipalAccount}"
    }
   }
  },
  {
   "Sid": "CWLogsPermission",
   "Effect": "Allow",
   "Action": [
    "logs:StartQuery",
    "logs:GetQueryResults"
   ],
   "Resource": [
    "arn:aws:logs:*:*:log-group:/aws/appsignals/*:*",
    "arn:aws:logs:*:*:log-group:/aws/application-signals/data:*"
   ],
   "Condition": {
    "StringEquals": {
     "aws:ResourceAccount": "${aws:PrincipalAccount}"
    }
   }
  },
  {
   "Sid": "CWListMetricsPermission",
   "Effect": "Allow",
   "Action": [
```

```
      "cloudwatch:ListMetrics"
    ],
    "Resource": [
      "*"
    ],

    ],
    "Condition": {
     "StringEquals": {
      "aws:ResourceAccount": "${aws:PrincipalAccount}"
     }
    }
   }
  ]
}
```

Service-linked role permissions for CloudWatch alarms Systems Manager OpsCenter actions

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchAlarms_ActionSSM** – CloudWatch uses this service-linked role to perform Systems Manager OpsCenter actions when a CloudWatch alarm goes into ALARM state.

The AWSServiceRoleForCloudWatchAlarms_ActionSSM service-linked role trusts the CloudWatch service to assume the role. CloudWatch alarms invoke the Systems Manager OpsCenter actions when called upon by the alarm.

The **AWSServiceRoleForCloudWatchAlarms_ActionSSM** service-linked role permissions policy allows Systems Manager to complete the following actions:

- `ssm:CreateOpsItem`

Service-linked role permissions for CloudWatch alarms Systems Manager Incident Manager actions

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents** – CloudWatch uses this service-linked role to start Incident Manager incidents when a CloudWatch alarm goes into ALARM state.

The **AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents** service-linked role trusts the CloudWatch service to assume the role. CloudWatch alarms invoke the Systems Manager Incident Manager action when called upon by the alarm.

The **AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents** service-linked role permissions policy allows Systems Manager to complete the following actions:

- `ssm-incidents:StartIncident`

Service-linked role permissions for CloudWatch cross-account cross-Region

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchCrossAccount** – CloudWatch uses this role to access CloudWatch data in other Amazon accounts that you specify. The SLR only provides the assume role permission to allow the CloudWatch service to assume the role in the sharing account. It is the sharing role that provides access to data.

The **AWSServiceRoleForCloudWatchCrossAccount** service-linked role permissions policy allows CloudWatch to complete the following actions:

- `sts:AssumeRole`

The **AWSServiceRoleForCloudWatchCrossAccount** service-linked role trusts the CloudWatch service to assume the role.

Service-linked role permissions for CloudWatch database Performance Insights

CloudWatch uses the service-linked role named **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights**. – CloudWatch uses this role to retrieve Performance Insights metrics for creating alarms and snapshotting.

The **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** service-linked role has the `AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy` IAM policy attached. The contents of that policy are as follows:

```
{
 "Version": "2012-10-17",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "pi:GetResourceMetrics"
   ],
   "Resource": "*",
   "Condition": {
    "StringEquals": {
     "aws:ResourceAccount": "${aws:PrincipalAccount}"
    }
   }
  }
 ]
}
```

The **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** service-linked role trusts the CloudWatch service to assume the role.

Creating a service-linked role for CloudWatch

You do not need to manually create any of these service-linked roles. The first time you create an alarm in the Amazon Web Services Management Console, the IAM CLI, or the IAM API, CloudWatch creates AWSServiceRoleForCloudWatchEvents and **AWSServiceRoleForCloudWatchAlarms_ActionSSM** for you.

The first time that you enable service and topology discovery, Application Signals creates **AWSServiceRoleForCloudWatchApplicationSignals** for you.

When you first enable an account to be a monitoring account for cross-account cross-Region functionality, CloudWatch creates **AWSServiceRoleForCloudWatchCrossAccount** for you.

When you first create an alarm that uses the `DB_PERF_INSIGHTS` metric math function, CloudWatch creates **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** for you.

For more information, see Creating a Service-Linked Role in the *IAM User Guide*.

Editing a service-linked role for CloudWatch

CloudWatch does not allow you to edit the **AWSServiceRoleForCloudWatchEvents**, **AWSServiceRoleForCloudWatchAlarms_ActionSSM**, **AWSServiceRoleForCloudWatchCrossAccount**, or **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** roles. After you create these roles, you cannot change their names because various entities might reference these roles. However, you can edit the description of these roles using IAM.

Editing a service-linked role description (IAM console)

You can use the IAM console to edit the description of a service-linked role.

To edit the description of a service-linked role (console)

1. In the navigation pane of the IAM console, choose **Roles**.
2. Choose the name of the role to modify.
3. To the far right of **Role description**, choose **Edit**.
4. Type a new description in the box, and choose **Save**.

Editing a service-linked role description (Amazon CLI)

You can use IAM commands from the Amazon Command Line Interface to edit the description of a service-linked role.

To change the description of a service-linked role (Amazon CLI)

1. (Optional) To view the current description for a role, use the following commands:

   ```
   $ aws iam get-role --role-name role-name
   ```

   Use the role name, not the ARN, to refer to roles with the Amazon CLI commands. For example, if a role has the following ARN: `arn:aws-cn:iam::123456789012:role/myrole`, you refer to the role as **`myrole`**.

2. To update a service-linked role's description, use the following command:

   ```
   $ aws iam update-role-description --role-name role-name --description description
   ```

Editing a service-linked role description (IAM API)

You can use the IAM API to edit the description of a service-linked role.

To change the description of a service-linked role (API)

1. (Optional) To view the current description for a role, use the following command:

   GetRole
2. To update a role's description, use the following command:

   UpdateRoleDescription

Deleting a service-linked role for CloudWatch

If you no longer have alarms that automatically stop, terminate, or reboot EC2 instances, we recommend that you delete the AWSServiceRoleForCloudWatchEvents role.

If you not longer have alarms that perform Systems Manager OpsCenter actions, we recommend that you delete the AWSServiceRoleForCloudWatchAlarms_ActionSSM role.

If you delete all alarms that use the `DB_PERF_INSIGHTS` metric math function, we recommend that you delete the **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights** service-linked role.

That way you don’t have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Roles**. Choose the name (not the check box) of the AWSServiceRoleForCloudWatchEvents role.
3. On the **Summary** page for the selected role, choose **Access Advisor** and review the recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether CloudWatch is using the AWSServiceRoleForCloudWatchEvents role, try to delete the role. If the service is using the role, then the deletion fails and you can view the Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

Deleting a service-linked role (IAM console)

You can use the IAM console to delete a service-linked role.

To delete a service-linked role (console)

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Roles**. Select the check box next to the name of the role you want to delete, not the name or row itself.
3. For **Role actions**, choose **Delete role**.
4. In the confirmation dialog box, review the service last accessed data, which shows when each of the selected roles last accessed an Amazon service. This helps you to confirm whether the role is currently active. To proceed, choose **Yes, Delete**.
5. Watch the IAM console notifications to monitor the progress of the service-linked role deletion. Because the IAM service-linked role deletion is asynchronous, the deletion task can succeed or fail after you submit the role for deletion. If the task fails, choose **View details** or **View Resources** from the notifications to learn why the deletion failed. If the deletion fails because there are resources in the service that are being used by the role, then the reason for the failure includes a list of resources.

Deleting a service-linked role (Amazon CLI)

You can use IAM commands from the Amazon Command Line Interface to delete a service-linked role.

To delete a service-linked role (Amazon CLI)

1. Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `deletion-task-id` from the response to check the status of the deletion task. Type the following command to submit a service-linked role deletion request:

```
$ aws iam delete-service-linked-role --role-name service-linked-role-name
```

2. Type the following command to check the status of the deletion task:

```
$ aws iam get-service-linked-role-deletion-status --deletion-task-id deletion-task-id
```

   The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

Deleting a service-linked role (IAM API)

You can use the IAM API to delete a service-linked role.

To delete a service-linked role (API)

1. To submit a deletion request for a service-linked role, call [DeleteServiceLinkedRole](). In the request, specify the role name that you want to delete.

   Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `DeletionTaskId` from the response to check the status of the deletion task.

2. To check the status of the deletion, call [GetServiceLinkedRoleDeletionStatus](). In the request, specify the `DeletionTaskId`.

   The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

CloudWatch updates to Amazon service-linked roles

View details about updates to Amazon managed policies for CloudWatch since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the CloudWatch Document history page.

Change	Description	Date
AWSServiceRoleForCloudWatchApplicationSignals – Update to permissions of service-linked role policy	Updated the CloudWatchApplicationSignalsServiceRolePolicy to exclude time windows from impacting the SLO attainment rate, error budget, and burn rate metrics. CloudWatch can retrieve exclusion windows on behalf of you.	March 13, 2025
AWSServiceRoleForObservabilityAdmin – New service-linked role	CloudWatch added this new service-linked role and corresponding managed policy, AWSObservabilityAdminServiceRolePolicy, to support resource and telemetry config discovery for Amazon Organizations.	November 26, 2024
AWSServiceRoleForCloudWatchApplicationSignals – Update to permissions of service-linked role policy	CloudWatch add more log groups to the scope of the `logs:StartQuery` and `logs:GetQueryResults` permissions granted by this role.	April 24, 2024
AWSServiceRoleForCloudWatchApplicationSignals – New service-linked role	CloudWatch added this new service-linked role to allow CloudWatch Application	November 9, 2023

Change	Description	Date
	Signals to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data from applications that you have enabled for CloudWatch Application Signals.	
AWSServiceRoleForCloudWatchMetrics_DbPerfInsights – New service-linked role	CloudWatch added this new service-linked role to allow CloudWatch to fetch Performance Insights metrics for alarming and snapshotting. An IAM policy is attached to this role, and the policy grants permission to CloudWatch to fetch Performance Insights metrics on your behalf.	September 13, 2023
AWSServiceRoleForCloudWatchAlarms_ActionSSMIncidents – New service-linked role	CloudWatch added a new service-linked role to allow CloudWatch to create incidents in Amazon Systems Manager Incident Manager.	April 26, 2021
CloudWatch started tracking changes	CloudWatch started tracking changes for its service-linked roles.	April 26, 2021

Using service-linked roles for CloudWatch RUM

CloudWatch RUM uses a Amazon Identity and Access Management (IAM) service-linked role. A service-linked role is a unique type of IAM role that is linked directly to RUM. The service-linked role is predefined by RUM and includes all the permissions that the service requires to call other Amazon services on your behalf.

RUM defines the permissions of the service-linked role, and unless defined otherwise, only RUM can assume the role. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete the role only after first deleting its related resources. This restriction protects your RUM resources because you can't inadvertently remove permissions to access the resources.

For information about other services that support service-linked roles, see Amazon services that work with IAM and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

Service-linked role permissions for RUM

RUM uses the service-linked role named **AWSServiceRoleForCloudWatchRUM** – this role allows RUM to send Amazon X-Ray trace data into your account, for app monitors that you enable X-Ray tracing for.

The **AWSServiceRoleForCloudWatchRUM** service-linked role trusts the X-Ray service to assume the role. X-Ray sends the trace data to your account.

The **AWSServiceRoleForCloudWatchRUM** service-linked role has an IAM policy attached named **AmazonCloudWatchRUMServiceRolePolicy**. This policy grants permission to CloudWatch RUM to publish monitoring data to other relevant Amazon services. It includes permissions that allow RUM to complete the following actions:

- `xray:PutTraceSegments`
- `cloudwatch:PutMetricData`

The complete contents of **AmazonCloudWatchRUMServiceRolePolicy** are as follows.

```
{
 "Version": "2012-10-17",
```

```
  "Statement": [
   {
    "Effect": "Allow",
    "Action": [
     "xray:PutTraceSegments"
    ],
    "Resource": [
     "*"
    ]
   },
   {
    "Effect": "Allow",
    "Action": "cloudwatch:PutMetricData",
    "Resource": "*",
    "Condition": {
     "StringLike": {
      "cloudwatch:namespace": [
       "RUM/CustomMetrics/*",
       "AWS/RUM"
      ]
     }
    }
   }
  ]
 }
```

Creating a service-linked role for RUM

You do not need to manually create the service-linked role for CloudWatch RUM. The first time that you create an app monitor with X-Ray tracing enabled, or update an app monitor to use X-Ray tracing, RUM creates **AWSServiceRoleForCloudWatchRUM** for you.

For more information, see Creating a Service-Linked Role in the *IAM User Guide*.

Editing a service-linked role for RUM

CloudWatch RUM does not allow you to edit the **AWSServiceRoleForCloudWatchRUM** role. After you create these roles, you cannot change their names because various entities might reference these roles. However, you can edit the description of these roles using IAM.

Editing a service-linked role description (IAM console)

You can use the IAM console to edit the description of a service-linked role.

To edit the description of a service-linked role (console)

1. In the navigation pane of the IAM console, choose **Roles**.
2. Choose the name of the role to modify.
3. To the far right of **Role description**, choose **Edit**.
4. Type a new description in the box, and choose **Save**.

Editing a service-linked role description (Amazon CLI)

You can use IAM commands from the Amazon Command Line Interface to edit the description of a service-linked role.

To change the description of a service-linked role (Amazon CLI)

1. (Optional) To view the current description for a role, use the following commands:

   ```
   $ aws iam get-role --role-name role-name
   ```

   Use the role name, not the ARN, to refer to roles with the Amazon CLI commands. For example, if a role has the following ARN: `arn:aws-cn:iam::123456789012:role/myrole`, you refer to the role as **`myrole`**.
2. To update a service-linked role's description, use the following command:

   ```
   $ aws iam update-role-description --role-name role-name --description description
   ```

Editing a service-linked role description (IAM API)

You can use the IAM API to edit the description of a service-linked role.

To change the description of a service-linked role (API)

1. (Optional) To view the current description for a role, use the following command:

   GetRole
2. To update a role's description, use the following command:

   UpdateRoleDescription

Deleting a service-linked role for RUM

If you no longer have app monitors with X-Ray enabled, we recommend that you delete the **AWSServiceRoleForCloudWatchRUM** role.

That way you don't have an unused entity that is not actively monitored or maintained. However, you must clean up your service-linked role before you can delete it.

Cleaning up a service-linked role

Before you can use IAM to delete a service-linked role, you must first confirm that the role has no active sessions and remove any resources used by the role.

To check whether the service-linked role has an active session in the IAM console

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Roles**. Choose the name (not the check box) of the **AWSServiceRoleForCloudWatchRUM** role.
3. On the **Summary** page for the selected role, choose **Access Advisor** and review the recent activity for the service-linked role.

> **Note**
>
> If you are unsure whether RUM is using the **AWSServiceRoleForCloudWatchRUM** role, try to delete the role. If the service is using the role, then the deletion fails and you can view the Regions where the role is being used. If the role is being used, then you must wait for the session to end before you can delete the role. You cannot revoke the session for a service-linked role.

Deleting a service-linked role (IAM console)

You can use the IAM console to delete a service-linked role.

To delete a service-linked role (console)

1. Open the IAM console at https://console.amazonaws.cn/iam/.
2. In the navigation pane, choose **Roles**. Select the check box next to the name of the role you want to delete, not the name or row itself.

3. For **Role actions**, choose **Delete role**.
4. In the confirmation dialog box, review the service last accessed data, which shows when each of the selected roles last accessed an Amazon service. This helps you to confirm whether the role is currently active. To proceed, choose **Yes, Delete**.
5. Watch the IAM console notifications to monitor the progress of the service-linked role deletion. Because the IAM service-linked role deletion is asynchronous, the deletion task can succeed or fail after you submit the role for deletion. If the task fails, choose **View details** or **View Resources** from the notifications to learn why the deletion failed. If the deletion fails because there are resources in the service that are being used by the role, then the reason for the failure includes a list of resources.

Deleting a service-linked role (Amazon CLI)

You can use IAM commands from the Amazon Command Line Interface to delete a service-linked role.

To delete a service-linked role (Amazon CLI)

1. Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `deletion-task-id` from the response to check the status of the deletion task. Type the following command to submit a service-linked role deletion request:

```
$ aws iam delete-service-linked-role --role-name service-linked-role-name
```

2. Type the following command to check the status of the deletion task:

```
$ aws iam get-service-linked-role-deletion-status --deletion-task-id deletion-task-id
```

The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

Deleting a service-linked role (IAM API)

You can use the IAM API to delete a service-linked role.

To delete a service-linked role (API)

1. To submit a deletion request for a service-linked role, call DeleteServiceLinkedRole. In the request, specify the role name that you want to delete.

   Because a service-linked role cannot be deleted if it is being used or has associated resources, you must submit a deletion request. That request can be denied if these conditions are not met. You must capture the `DeletionTaskId` from the response to check the status of the deletion task.

2. To check the status of the deletion, call GetServiceLinkedRoleDeletionStatus. In the request, specify the `DeletionTaskId`.

   The status of the deletion task can be `NOT_STARTED`, `IN_PROGRESS`, `SUCCEEDED`, or `FAILED`. If the deletion fails, the call returns the reason that it failed so that you can troubleshoot.

Supported Regions for CloudWatch RUM service-linked roles

CloudWatch RUM supports using service-linked roles in all of the Amazon Regions where the service is available. For more information, see CloudWatch RUM service endpoints.

Using service-linked roles for CloudWatch Application Insights

CloudWatch Application Insights uses Amazon Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to CloudWatch Application Insights. Service-linked roles are predefined by CloudWatch Application Insights and include all of the permissions that the service requires to call other Amazon services on your behalf.

A service-linked role makes setting up CloudWatch Application Insights easier because you don't have to manually add the necessary permissions. CloudWatch Application Insights defines the permissions of its service-linked roles, and unless defined otherwise, only CloudWatch Application Insights can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see Amazon Services That Work with IAM and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** link to view the service-linked role documentation for that service.

Service-linked role permissions for CloudWatch Application Insights

CloudWatch Application Insights uses the service-linked role named **AWSServiceRoleForApplicationInsights**. Application Insights uses this role to perform operations such as analyzing the resource groups of the customer, creating CloudFormation stacks to create alarms on metrics, and configuring the CloudWatch Agent on EC2 instances. This service-linked role has an IAM policy attached to it named `CloudwatchApplicationInsightsServiceLinkedRolePolicy`. For updates to this policy, see Application Insights updates to Amazon managed policies.

The role permissions policy allows CloudWatch Application Insights to complete the following actions on resources.

```
{

        "route53resolver:GetResolverEndpoint",
        "route53resolver:GetFirewallRuleGroupAssociation"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}
```

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the *IAM User Guide*.

Creating a service-linked role for CloudWatch Application Insights

You don't need to manually create a service-linked role. When you create a new Application Insights application in the Amazon Web Services Management Console, CloudWatch Application Insights creates the service-linked role for you.

If you delete this service-linked role, and then want to create it again, you can use the same process to recreate the role in your account. When you create a new Application Insights application, CloudWatch Application Insights creates the service-linked role for you again.

Editing a service-linked role for CloudWatch Application Insights

CloudWatch Application Insights does not allow you to edit the AWSServiceRoleForApplicationInsights service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the *IAM User Guide*.

Deleting a service-linked role for CloudWatch Application Insights

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you avoid having an unused entity that is not actively monitored or maintained. However, you must delete all applications in Application Insights before you can manually delete the role.

> **Note**
>
> If the CloudWatch Application Insights service is using the role when you try to delete the resources, the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete CloudWatch Application Insights resources used by the AWSServiceRoleForApplicationInsights

- Delete all of your CloudWatch Application Insights applications. For more information, see "Deleting Your Application(s)" in the CloudWatch Application Insights User Guide.

To manually delete the service-linked role using IAM

Use the IAM console, the Amazon CLI, or the Amazon API to delete the AWSServiceRoleForApplicationInsights service-linked role. For more information, see Deleting a Service-Linked Role in the *IAM User Guide*.

Supported Regions for CloudWatch Application Insights service-linked roles

CloudWatch Application Insights supports using service-linked roles in all of the Amazon Regions where the service is available. For more information, see CloudWatch Application Insights Regions and Endpoints.

Amazon managed policies for Amazon CloudWatch Application Insights

An Amazon managed policy is a standalone policy that is created and administered by Amazon. Amazon managed policies are designed to provide permissions for many common use cases so that you can start assigning permissions to users, groups, and roles.

Keep in mind that Amazon managed policies might not grant least-privilege permissions for your specific use cases because they're available for all Amazon customers to use. We recommend that you reduce permissions further by defining customer managed policies that are specific to your use cases.

You cannot change the permissions defined in Amazon managed policies. If Amazon updates the permissions defined in an Amazon managed policy, the update affects all principal identities (users, groups, and roles) that the policy is attached to. Amazon is most likely to update an Amazon managed policy when a new Amazon Web Services service is launched or new API operations become available for existing services.

For more information, see Amazon managed policies in the *IAM User Guide*.

Amazon managed policy: CloudWatchApplicationInsightsFullAccess

You can attach the `CloudWatchApplicationInsightsFullAccess` policy to your IAM identities.

This policy grants administrative permissions that allow full access to Application Insights functionality.

Permissions details

This policy includes the following permissions.

- `applicationinsights` – Allows full access to Application Insights functionality.
- `iam` – Allows Application Insights to create the service-linked role, AWSServiceRoleForApplicationInsights. This is required so that Application Insights can perform operations such as analyze the resource groups of a customer, create CloudFormation stacks to create alarms on metrics, and configure the CloudWatch Agent on EC2 instances. For more information, see Using service-linked roles for CloudWatch Application Insights.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "applicationinsights:*",
      "Resource": "*"
    },
    {

          "iam:AWSServiceName": "application-insights.amazonaws.com"
        }
      }
    }
  ]
}
```

Amazon managed policy: CloudWatchApplicationInsightsReadOnlyAccess

You can attach the `CloudWatchApplicationInsightsReadOnlyAccess` policy to your IAM identities.

This policy grants administrative permissions that allow read-only access to all Application Insights functionality.

Permissions details

This policy includes the following permissions.

- `applicationinsights` – Allows read-only access to Application Insights functionality.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "applicationinsights:Describe*",
                "applicationinsights:List*"
            ],
            "Resource": "*"
        }
    ]
}
```

Amazon managed policy: CloudwatchApplicationInsightsServiceLinkedRolePolicy

You can't attach CloudwatchApplicationInsightsServiceLinkedRolePolicy to your IAM entities. This policy is attached to a service-linked role that allows Application Insights to monitor customer resources. For more information, see Using service-linked roles for CloudWatch Application Insights.

Application Insights updates to Amazon managed policies

View details about updates to Amazon managed policies for Application Insights since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Application Insights Document history page.

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added a new permission. The policy change allows Amazon CloudWatch Application Insights to enable and disable termination protection on CloudFormation stacks to manage SSM resources used to install and configure CloudWatch agents.	July 25, 2024
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to list CloudFormation stacks. These permissions are required for Amazon CloudWatch Application Insights to analyze and monitor Amazon resources nested in the CloudFormation stack.	April 24, 2023
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to get list of Amazon VPC and Route 53 resources. These permissions are required for Amazon CloudWatch Application Insights to automatically set up best practice network	January 23, 2023

Change	Description	Date
	monitoring with Amazon CloudWatch.	
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to get SSM command invocation results. These permissions are required for Amazon CloudWatch Application Insights to automatically detect and monitor workloads running on Amazon EC2 instances.	December 19, 2022
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe Amazon VPC and Route 53 resources. These permissions are required for Amazon CloudWatch Application Insights to read customer Amazon VPC and Route 53 resource configurations, and to help customers automatically set up best practice network monitoring with Amazon CloudWatch.	December 19, 2022

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe EFS resources. These permissions are required for Amazon CloudWatch Application Insights to read Amazon EFS customer resource configurations, and to help customers automatically set up best practices for EFS monitoring with CloudWatch.	October 3, 2022
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe the EFS file system. These permissions are required for Amazon CloudWatch Application Insights to create account-based applications by querying all of the supported resources in an account.	October 3, 2022

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to retrieve information about FSx resources. These permissions are required for Amazon CloudWatch Application Insights to monitor workloads by retrieving sufficient information about the underlying FSx volumes.	September 12, 2022
Amazon managed policy: CloudWatchApplicationInsightsFullAccess – Update to an existing policy	Application Insights added a new permission to describe log groups. This permissions is required for Amazon CloudWatch Application Insights to ensure that the correct permissions for monitoring log groups are in an account when creating a new application.	January 24, 2022

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to create and delete CloudWatch Log Subscription Filters. These permissions are required for Amazon CloudWatch Application Insights to create Subscription Filters to facilitate log monitoring of resources within configured applications.	January 24, 2022
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe target groups and target health for Elastic Load Balancers. These permissions are required for Amazon CloudWatch Application Insights to create account-based applications by querying all of the supported resources in an account.	November 4, 2021

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to run the `AmazonCloudWatch-ManageAgent` SSM document on Amazon EC2 instances. This permissions is required for Amazon CloudWatch Application Insights to clean up CloudWatch agent configuration files created by Application Insights.	September 30, 2021

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to support account-based application monitoring to onboard and monitor all supported resources in your account. These permissions are required for Amazon CloudWatch Application Insights to query, tag resources, and create groups for these resources. Application Insights added new permissions to support monitoring of SNS topics. These permissions are required for Amazon CloudWatch Application Insights to gather metadata from SNS resources to configure monitoring for SNS topics.	September 15, 2021

Change	Description	Date
Amazon managed policy: CloudWatchApplicationInsightsFullAccess – Update to an existing policy	Application Insights added new permissions to describe and list supported resources. These permissions are required for Amazon CloudWatch Application Insights to create account-based applications by querying all of the supported resources in an account.	September 15, 2021
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe FSx resources. These permissions are required for Amazon CloudWatch Application Insights to read customer FSx resource configurations, and to help customers automatically set up best practice FSx monitoring with CloudWatch.	August 31, 2021

Change	Description	Date
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to describe and list ECS and EKS service resources. This permission is required for Amazon CloudWatch Application Insights to read customer container resources configuration, and to help customers automatically set up best practice container monitoring with CloudWatch.	May 18, 2021
CloudwatchApplicationInsightsServiceLinkedRolePolicy – Update to an existing policy	Application Insights added new permissions to allow OpsCenter to tag OpsItems using the `ssm:AddTagsToResource` action on resources with the `opsitem` resource type. This permission is required by OpsCenter. Amazon CloudWatch Application Insights creates OpsItems so that the customer can resolve problems using Amazon SSM OpsCenter.	April 13, 2021
Application Insights started tracking changes	Application Insights started tracking changes for its Amazon managed policies.	April 13, 2021

Amazon CloudWatch permissions reference

The following table lists each CloudWatch API operation and the corresponding actions for which you can grant permissions to perform the action. You specify the actions in the policy's `Action` field, and you specify a wildcard character (*) as the resource value in the policy's `Resource` field.

You can use Amazon-wide condition keys in your CloudWatch policies to express conditions. For a complete list of Amazon-wide keys, see Amazon Global and IAM Condition Context Keys in the *IAM User Guide*.

> **Note**
>
> To specify an action, use the `cloudwatch:` prefix followed by the API operation name. For example: `cloudwatch:GetMetricData`, `cloudwatch:ListMetrics`, or `cloudwatch:*` (for all CloudWatch actions).

Topics

CloudWatch API operations and required permissions for actions

CloudWatch API operations	Required permissions (API actions)
DeleteAlarms	`cloudwatch:DeleteAlarms` Required to delete an alarm.
DeleteDashboards	`cloudwatch:DeleteDashboards`

CloudWatch API operations	Required permissions (API actions)
	Required to delete a dashboard.
[DeleteMetricStream](https://docs.aws.amazon.com/AmazonCloudWatch/latest/APIReference/API_DeleteMetricStream.html)	`cloudwatch:DeleteMetricStream` Required to delete a metric stream.
DescribeAlarmHistory	`cloudwatch:DescribeAlarmHistory` Required to view alarm history. To retrieve information about composite alarms, your `cloudwatch:DescribeAlarmHistory` permission must have a * scope. You can't return information about composite alarms if your `cloudwatch:DescribeAlarmHistory` permission has a narrower scope.
DescribeAlarms	`cloudwatch:DescribeAlarms` Required to retrieve information about alarms. To retrieve information about composite alarms, your `cloudwatch:DescribeAlarms` permission must have a * scope. You can't return information about composite alarms if your `cloudwatch:DescribeAlarms` permission has a narrower scope.
DescribeAlarmsForMetric	`cloudwatch:DescribeAlarmsForMetric` Required to view alarms for a metric.

CloudWatch API operations	Required permissions (API actions)
DisableAlarmActions	`cloudwatch:DisableAlarmActions` Required to disable an alarm action.
EnableAlarmActions	`cloudwatch:EnableAlarmActions` Required to enable an alarm action.
GetDashboard	`cloudwatch:GetDashboard` Required to display data about existing dashboards.
GetMetricData	`cloudwatch:GetMetricData` Required to graph metric data in the CloudWatch console, to retrieve large batches of metric data, and perform metric math on that data.
GetMetricStatistics	`cloudwatch:GetMetricStatistics` Required to view graphs in other parts of the CloudWatch console and in dashboard widgets.
GetMetricStream	`cloudwatch:GetMetricStream` Required to view information about a metric stream.

CloudWatch API operations	Required permissions (API actions)
[GetMetricWidgetImage](#)	`cloudwatch:GetMetricWidgetImage` Required to retrieve a snapshot graph of one or more CloudWatch metrics as a bitmap image.
[ListDashboards](#)	`cloudwatch:ListDashboards` Required to view the list of CloudWatch dashboards in your account.
ListEntitiesForMetric (CloudWatch console-only permission)	`cloudwatch:ListEntitiesForMetric` Required to find the entities associated with a metric. Required to explore related telemetry within the CloudWatch console.
[ListMetrics](#)	`cloudwatch:ListMetrics` Required to view or search metric names within the CloudWatch console and in the CLI. Required to select metrics on dashboard widgets.
[ListMetricStreams](#)	`cloudwatch:ListMetricStreams` Required to view or search the list of metric streams in the account.

CloudWatch API operations	Required permissions (API actions)
PutCompositeAlarm	`cloudwatch:PutCompositeAlarm` Required to create a composite alarm. To create a composite alarm, your `cloudwatch:PutCompositeAlarm` permission must have a * scope. You can't return information about composite alarms if your `cloudwatch:PutCompositeAlarm` permission has a narrower scope.
PutDashboard	`cloudwatch:PutDashboard` Required to create a dashboard or update an existing dashboard.
PutMetricAlarm	`cloudwatch:PutMetricAlarm` Required to create or update an alarm.
PutMetricData	`cloudwatch:PutMetricData` Required to create metrics.
PutMetricStream	`cloudwatch:PutMetricStream` Required to create a metric stream.
SetAlarmState	`cloudwatch:SetAlarmState` Required to manually set an alarm's state.

CloudWatch API operations	Required permissions (API actions)
StartMetricStreams	`cloudwatch:StartMetricStreams` Required to start the flow of metrics in a metric stream.
StopMetricStreams	`cloudwatch:StopMetricStreams` Required to temporarily stop the flow of metrics in a metric stream.
TagResource	`cloudwatch:TagResource` Required to add or update tags on CloudWatch resources such as alarms and Contributor Insights rules.
UntagResource	`cloudwatch:UntagResource` Required to remove tags from CloudWatch resources .

CloudWatch Application Signals API operations and required permissions for actions

CloudWatch Application Signals API operations	Required permissions (API actions)
BatchGetServiceLevelObjectiveBudgetReport	`application-signals:BatchGetServiceLevelObjectiveBudgetReport`

CloudWatch Application Signals API operations	Required permissions (API actions)
	Required to retrieve service level objective budget reports.
[CreateServiceLevelObjective](#)	`application-signals:CreateServiceLevelObjective` Required to create a service level objective (SLO).
[DeleteServiceLevelObjective](#)	`application-signals:DeleteServiceLevelObjective` Required to delete a service level objective (SLO).
[GetService](#)	`application-signals:GetService` Required to retrieve information about a service discovered by Application Signals.
[GetServiceLevelObjective](#)	`application-signals:GetServiceLevelObjective` Required to retrieve information about a service level objective (SLO).
ListObservedEntities	`application-signals:ListObservedEntities` Grants permission to list entities that are associated with other entities.

CloudWatch Application Signals API operations	Required permissions (API actions)
ListServiceDependencies	`application-signals:ListServiceDependencies` Required to retrieve a list of service dependencies of a service that you specify. This service and the dependencies were discovered by Application Signals.
ListServiceDependents	`application-signals:ListServiceDependents` Required to retrieve a list of dependents that invoked a service that you specify. This service and the dependents were discovered by Application Signals.
ListServiceLevelObjectives	`application-signals:ListServiceLevelObjectives` Required to retrieve a list of service level objectives (SLOs) in the account.
ListServiceOperations	`application-signals:ListServiceOperations` Required to retrieve a list of service operations of a service that you specify. This service and the dependencies were discovered by Application Signals.

CloudWatch Application Signals API operations	Required permissions (API actions)
ListServices	`application-signals:ListServices` Required to retrieve a list of services discovered by Application Signals.
ListTagsForResource	`application-signals:ListTagsForResource` Required to retrieve a list of the tags associated with a resource.
StartDiscovery	`application-signals:StartDiscovery` Required to be able to enable Application Signals in the account and create the required service-linked role.
TagResource	`application-signals:TagResource` Required to be able to add tags to resources.
UntagResource	`application-signals:UntagResource` Required to be able to remove tags from resources.

CloudWatch Application Signals API operations	Required permissions (API actions)
UpdateServiceLevelObjective	`application-signals:UpdateServiceLevelObjective` Required to update an existing service level objective

CloudWatch Contributor Insights API operations and required permissions for actions

Important

When you grant a user the `cloudwatch:PutInsightRule` permission, by default that user can create a rule that evaluates any log group in CloudWatch Logs. You can add IAM policy conditions that limit these permissions for a user to include and exclude specific log groups. For more information, see Using condition keys to limit Contributor Insights users' access to log groups.

CloudWatch Contributor Insights API operations	Required permissions (API actions)
DeleteInsightRules	`cloudwatch:DeleteInsightRules` Required to delete Contributor Insights rules.
DescribeInsightRules	`cloudwatch:DescribeInsightRules` Required to view the Contributor Insights rules in your account.
EnableInsightRules	`cloudwatch:EnableInsightRules`

CloudWatch Contributor Insights API operations	Required permissions (API actions)
	Required to enable Contributor Insights rules.
[GetInsightRuleReport]()	`cloudwatch:GetInsightRuleReport` Required to retrieve time series data and other statistics collectd by Contributor Insights rules.
[PutInsightRule]()	`cloudwatch:PutInsightRule` Required to create Contributor Insights rules. See the **Important** note at the beginning of this table.

CloudWatch Events API operations and required permissions for actions

CloudWatch Events API operations	Required permissions (API actions)
[DeleteRule]()	`events:DeleteRule` Required to delete a rule.
[DescribeRule]()	`events:DescribeRule` Required to list the details about a rule.
[DisableRule]()	`events:DisableRule` Required to disable a rule.
[EnableRule]()	`events:EnableRule`

CloudWatch Events API operations	Required permissions (API actions)
	Required to enable a rule.
ListRuleNamesByTarget	`events:ListRuleNamesByTarget` Required to list rules associated with a target.
ListRules	`events:ListRules` Required to list all rules in your account.
ListTargetsByRule	`events:ListTargetsByRule` Required to list all targets associated with a rule.
PutEvents	`events:PutEvents` Required to add custom events that can be matched to rules.
PutRule	`events:PutRule` Required to create or update a rule.
PutTargets	`events:PutTargets` Required to add targets to a rule.
RemoveTargets	`events:RemoveTargets` Required to remove a target from a rule.

CloudWatch Events API operations	Required permissions (API actions)
TestEventPattern	`events:TestEventPattern` Required to test an event pattern against a given event.

CloudWatch Logs API operations and required permissions for actions

> **Note**
>
> CloudWatch Logs permissions can be found in the CloudWatch Logs user guide.

Amazon EC2 API operations and required permissions for actions

Amazon EC2 API operations	Required permissions (API actions)
DescribeInstanceStatus	`ec2:DescribeInstanceStatus` Required to view EC2 instance status details.
DescribeInstances	`ec2:DescribeInstances` Required to view EC2 instance details.
RebootInstances	`ec2:RebootInstances` Required to reboot an EC2 instance.
StopInstances	`ec2:StopInstances` Required to stop an EC2 instance.
TerminateInstances	

Amazon EC2 API operations	Required permissions (API actions)
	`ec2:TerminateInstances` Required to terminate an EC2 instance.

Amazon EC2 Auto Scaling API operations and required permissions for actions

Amazon EC2 Auto Scaling API operations	Required permissions (API actions)
Scaling	`autoscaling:Scaling` Required to scale an Auto Scaling group.
Trigger	`autoscaling:Trigger` Required to trigger an Auto Scaling action.

Compliance validation for Amazon CloudWatch

To learn whether an Amazon Web Services service is within the scope of specific compliance programs, see Amazon Web Services services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see Amazon Web Services Compliance Programs.

You can download third-party audit reports using Amazon Artifact. For more information, see Downloading Reports in Amazon Artifact.

Your compliance responsibility when using Amazon Web Services services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. Amazon provides the following resources to help with compliance:

- Security & Compliance – These solution implementation guides discuss architectural considerations and provide steps for deploying security and compliance features.
- Amazon Compliance Resources – This collection of workbooks and guides might apply to your industry and location.

- Evaluating Resources with Rules in the *Amazon Config Developer Guide* – The Amazon Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.
- Amazon Security Hub – This Amazon Web Services service provides a comprehensive view of your security state within Amazon. Security Hub uses security controls to evaluate your Amazon resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.
- Amazon GuardDuty – This Amazon Web Services service detects potential threats to your Amazon Web Services accounts, workloads, containers, and data by monitoring your environment for suspicious and malicious activities. GuardDuty can help you address various compliance requirements, like PCI DSS, by meeting intrusion detection requirements mandated by certain compliance frameworks.

Resilience in Amazon CloudWatch

The Amazon global infrastructure is built around Amazon Regions and Availability Zones. Regions provide multiple physically separated and isolated Availability Zones, which are connected through low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

For more information about Amazon Regions and Availability Zones, see Amazon Global Infrastructure.

Infrastructure security in Amazon CloudWatch

As a managed service, Amazon CloudWatch is protected by Amazon global network security. For information about Amazon security services and how Amazon protects infrastructure, see Amazon Cloud Security. To design your Amazon environment using the best practices for infrastructure security, see Infrastructure Protection in *Security Pillar Amazon Well‐Architected Framework*.

You use Amazon published API calls to access CloudWatch through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.

- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the Amazon Security Token Service (Amazon STS) to generate temporary security credentials to sign requests.

Network isolation

A virtual private cloud (VPC) is a virtual network in your own logically isolated area in the Amazon Web Services Cloud. A subnet is a range of IP addresses in a VPC. You can deploy a variety of Amazon resources in the subnets of your VPCs. For example, you can deploy Amazon EC2 instances, EMR clusters, and DynamoDB tables in subnets. For more information, see the Amazon VPC User Guide.

To enable CloudWatch to communicate with resources in a VPC without going through the public internet, use Amazon PrivateLink. For more information, see Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints.

A private subnet is a subnet with no default route to the public internet. Deploying an Amazon resource in a private subnet does not prevent Amazon CloudWatch from collecting built-in metrics from the resource.

If you need to publish custom metrics from an Amazon resource in a private subnet, you can do so using a proxy server. The proxy server forwards those HTTPS requests to the public API endpoints for CloudWatch.

Amazon Security Hub

Monitor your usage of CloudWatch as it relates to security best practices by using Amazon Security Hub. Security Hub uses *security controls* to evaluate resource configurations and *security standards* to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate CloudWatch resources, see Amazon CloudWatch controls in the Amazon Security Hub User Guide.

Using CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring with interface VPC endpoints

If you use Amazon Virtual Private Cloud (Amazon VPC) to host your Amazon resources, you can establish a private connection between your VPC, CloudWatch, CloudWatch Synthetics, and CloudWatch Network Monitoring features. You can use these connections to enable these services to communicate with resources in your VPC without going through the public internet.

Amazon VPC is an Amazon service that you can use to launch Amazon resources in a virtual network that you define. With a VPC, you have control over your network settings, such the IP address range, subnets, route tables, and network gateways. To connect your VPC to CloudWatch services, you define an *interface VPC endpoint* for your VPC. The endpoint provides reliable, scalable connectivity to CloudWatch and supported CloudWatch services without requiring an internet gateway, network address translation (NAT) instance, or VPN connection. For more information, see What is Amazon VPC in the *Amazon VPC User Guide*.

Interface VPC endpoints are powered by Amazon PrivateLink, an Amazon technology that enables private communication between Amazon services using an elastic network interface with private IP addresses. For more information, see the following blog post: New – Amazon PrivateLink for Amazon Services

The following steps are for users of Amazon VPC. For more information, see Getting Started in the *Amazon VPC User Guide*.

CloudWatch VPC endpoints

CloudWatch currently supports VPC endpoints in the following Amazon Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Osaka)
- Asia Pacific (Seoul)

- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- Middle East (UAE)
- South America (São Paulo)
- Amazon GovCloud (US-East)
- Amazon GovCloud (US-West)

Creating a VPC endpoint for CloudWatch

To start using CloudWatch with your VPC, create an interface VPC endpoint for CloudWatch. The service name to choose is `com.amazonaws.region.monitoring`. For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

You do not need to change the settings for CloudWatch. CloudWatch calls other Amazon services using either public endpoints or private interface VPC endpoints, whichever are in use. For example, if you create an interface VPC endpoint for CloudWatch, and you already have metrics flowing to CloudWatch from resources located on your VPC, these metrics begin flowing through the interface VPC endpoint by default.

Controlling access to your CloudWatch VPC endpoint

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. If you don't attach a policy when you create an endpoint, Amazon VPC attaches a default policy for you that allows full access to the service. An endpoint policy doesn't override or replace user policies or service-specific policies. It's a separate policy for controlling access from the endpoint to the specified service.

Endpoint policies must be written in JSON format.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

The following is an example of an endpoint policy for CloudWatch. This policy allows users connecting to CloudWatch through the VPC to send metric data to CloudWatch and prevents them from performing other CloudWatch actions.

```
{
  "Statement": [
    {
      "Sid": "PutOnly",
      "Principal": "*",
      "Action": [
        "cloudwatch:PutMetricData"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}
```

To edit the VPC endpoint policy for CloudWatch

1. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. If you have not already created the endpoint for CloudWatch, choose **Create endpoint**. Select **com.amazonaws.*region*.monitoring**, and then choose **Create endpoint**.
4. Select the **com.amazonaws.*region*.monitoring** endpoint, and then choose the **Policy** tab.
5. Choose **Edit policy**, and then make your changes.

CloudWatch Synthetics VPC endpoint

CloudWatch Synthetics currently supports VPC endpoints in the following Amazon Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)

- Asia Pacific (Hong Kong)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Paris)
- South America (São Paulo)

Creating a VPC endpoint for CloudWatch Synthetics

To start using CloudWatch Synthetics with your VPC, create an interface VPC endpoint for CloudWatch Synthetics. The service name to choose is `com.amazonaws.region.synthetics`. For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

You do not need to change the settings for CloudWatch Synthetics. CloudWatch Synthetics communicates with other Amazon services using either public endpoints or private interface VPC endpoints, whichever are in use. For example, if you create an interface VPC endpoint for CloudWatch Synthetics, and you already have an interface endpoint for Amazon S3, CloudWatch Synthetics begins communicating with Amazon S3 through the interface VPC endpoint by default.

Controlling access to your CloudWatch Synthetics VPC endpoint

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. If you don't attach a policy when you create an endpoint, we attach a default policy for you that allows full access to the service. An endpoint policy doesn't override or replace user policies or service-specific policies. It's a separate policy for controlling access from the endpoint to the specified service.

Endpoint policies affect canaries that are managed privately by VPC. They are not needed for canaries that run on private subnets.

Endpoint policies must be written in JSON format.

For more information, see [Controlling access to services with VPC endpoints]() in the *Amazon VPC User Guide*.

The following is an example of an endpoint policy for CloudWatch Synthetics. This policy enables users connecting to CloudWatch Synthetics through the VPC to view information about canaries and their runs, but not to create, modify, or delete canaries.

```
{
    "Statement": [
        {
            "Action": [
                "synthetics:DescribeCanaries",
                "synthetics:GetCanaryRuns"
            ],
            "Effect": "Allow",
            "Resource": "*",
            "Principal": "*"
        }
    ]
}
```

To edit the VPC endpoint policy for CloudWatch Synthetics

1. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. If you have not already created the endpoint for CloudWatch Synthetics, choose **Create endpoint**. Select **com.amazonaws.*region*.synthetics** and then choose **Create endpoint**.
4. Select the **com.amazonaws.*region*.synthetics** endpoint, and then choose the **Policy** tab.
5. Choose **Edit policy**, and then make your changes.

CloudWatch Network Monitoring feature VPC endpoints

CloudWatch Network Monitoring includes the following features: Network Flow Monitor, Internet Monitor, and Network Synthetic Monitor. These features each support VPC endpoints in the Amazon Regions where the Network Monitoring feature is supported.

To see a list of supported Regions for each Network Monitoring feature, see the following topics:

- **Network Flow Monitor:** Supported Amazon Web Services Regions for Network Flow Monitor
- **Internet Monitor:** Supported Amazon Web Services Regions for Internet Monitor
- **Network Synthetic Monitor:** Supported Amazon Web Services Regions for Network Synthetic Monitor

Creating a VPC endpoint for a CloudWatch Network Monitoring feature

To start using CloudWatch Network Monitoring features with your VPC, create an interface VPC endpoint for the feature that you want to use. For Network Monitoring, the following service names are available:

- `com.amazonaws.region.networkflowmonitor`
- `com.amazonaws.region.networkflowmonitorreports`
- `com.amazonaws.region.internetmonitor`
- `com.amazonaws.region.internetmonitor-fips`
- `com.amazonaws.region.networkmonitor`

For more information, see Creating an interface endpoint in the *Amazon VPC User Guide*.

You don't need to change the settings for Network Monitoring services. Network Monitoring services communicate with other Amazon services using either public endpoints or private interface VPC endpoints, whichever are being used. For example, if you create an interface VPC endpoint for a Network Monitoring service, and you already have metrics flowing to the service from resources located on your VPC, the metrics begin flowing through the interface VPC endpoint by default.

Controlling access to your CloudWatch Network Monitoring feature VPC endpoints

A VPC endpoint policy is an IAM resource policy that you attach to an endpoint when you create or modify the endpoint. An endpoint policy doesn't override or replace user policies or service-specific policies. It's a separate policy for controlling access from the endpoint to the specified service.

If you don't attach a policy when you create an endpoint, Amazon VPC attaches a default policy for you that allows full access and does not restrict access to a specific service. For additional security, you can attach a policy to the endpoint to specifically limit access to the feature. For example, for

Internet Monitor, you could allow full access to just Internet Monitor by attaching the Amazon managed policy that enables full access to the feature, CloudWatchInternetMonitorFullAccess. Or, you can further limit permissions to just specific actions for the endpoint.

For more information, see Controlling access to services with VPC endpoints in the *Amazon VPC User Guide*.

The following is an example of an endpoint policy that you could create for Network Flow Monitor to limit actions for the endpoint. This policy allows requests to Network Flow Monitor through the VPC to use only the `Publish` action, which enables requests to publish metrics to Network Flow Monitor backend ingestion.

```
{
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": "*",
            "Action": "networkflowmonitor:Publish",
            "Resource": "*"
        }
    ]
}
```

If you want to use a specific VPC endpoint policy with an interface VPC endpoint for a Network Monitoring feature, use steps similar to the following example for adding a policy for Network Flow Monitor.

To edit a VPC endpoint policy for Network Flow Monitor

1. Open the Amazon VPC console at https://console.amazonaws.cn/vpc/.
2. In the navigation pane, choose **Endpoints**.
3. If you have not already created the endpoint for Internet Monitor, choose **Create endpoint**.
4. Select **com.amazonaws.*region*.networkflowmonitor**, and then choose **Create endpoint**.
5. Select the **com.amazonaws.*region*.networkflowmonitor** endpoint, and then choose the **Policy** tab.
6. Choose **Edit policy**, and then make your changes.

Security considerations for Synthetics canaries

The following sections explain security issues that you should consider when creating and running canaries in Synthetics.

Use secure connections

Because canary code and the results from canary test runs can contain sensitive information, do not have your canary connect to endpoints over unencrypted connections. Always use encrypted connections, such as those that begin with `https://`.

Canary naming considerations

The Amazon Resource Name (ARN) of a canary is included in the user-agent header as a part of outbound calls made from the Puppeteer-driven Chromium browser that is included as a part of the CloudWatch Synthetics wrapper library. This helps identify CloudWatch Synthetics canary traffic and relate it back to the canaries that are making calls.

The canary ARN includes the canary name. Choose canary names that do not reveal proprietary information.

Additionally, be sure to point your canaries only at websites and endpoints that you control.

Secrets and sensitive information in canary code

If you pass your canary code directly into the canary using a zip file, the contents of the script can be seen in Amazon CloudTrail logs.

If you have sensitive information or secrets (such as access keys or database credentials) in a canary script, we strongly recommend that you store the script as a versioned object in Amazon S3 and pass the Amazon S3 location into the canary, instead of passing the canary code by a zip file.

If you do use a zip file to pass the canary script, we strongly recommend that you don't include secrets or sensitive information in your canary source code. For more information about how to use Amazon Secrets Manager to help keep your secrets safe, see [What is Amazon Secrets Manager?](https://docs.aws.amazon.com/secretsmanager/latest/userguide/intro.html).

Permissions considerations

We recommend that you restrict access to resources that are created or used by CloudWatch Synthetics. Use tight permissions on the Amazon S3 buckets where canaries store test run results and other artifacts, such as logs and screenshots.

Similarly, keep tight permissions on the locations where your canary source code is stored, so that no user accidentally or maliciously deletes the Lambda layers or Lambda functions used for the canary.

To help make sure you run the canary code you intend, you can use object versioning on the Amazon S3 bucket where your canary code is stored. Then when you specify this code to run as a canary, you can include the object `versionId` as part of the path, as in the following examples.

```
https://bucket.s3.amazonaws.com/path/object.zip?versionId=version-id
https://s3.amazonaws.com/bucket/path/object.zip?versionId=version-id
https://bucket.s3-region.amazonaws.com/path/object.zip?versionId=version-id
```

Stack traces and exception messages

By default, CloudWatch Synthetics canaries capture any exception thrown by your canary script, no matter whether the script is custom or is from a blueprint. CloudWatch Synthetics logs both the exception message and the stack trace to three locations:

- Back into the CloudWatch Synthetics service to speed up debugging when you describe test runs
- Into CloudWatch Logs according to the configuration that your Lambda functions are created with
- Into the Synthetics log file, which is a plaintext file that is uploaded to the Amazon S3 location specified by the value you set for the `resultsLocation` of the canary

If you want to send and store less information, you can capture exceptions before they return to the CloudWatch Synthetics wrapper library.

You can also have request URLs in your errors. CloudWatch Synthetics scans for any URLs in the error thrown by your script and redacts restricted URL parameters from them based on the **restrictedUrlParameters** configuration. If you are logging error messages in your script, you can use getSanitizedErrorMessage to redact URLs before logging.

Scope your IAM roles narrowly

We recommend that you do not configure your canary to visit potentially malicious URLs or endpoints. Pointing your Canary to untrusted or unknown websites or endpoints could expose your Lambda function code to malicious user’s scripts. Assuming a malicious website can break out of

Chromium, it could have access to your Lambda code in a similar way to if you connected to it using an internet browser.

Run your Lambda function with an IAM execution role that has scoped-down permissions. This way, if your Lambda function is compromised by a malicious script, it is limited in the actions it can take when running as your canary's Amazon account.

When you use the CloudWatch console to create a canary, it is created with a scoped-down IAM execution role.

Sensitive data redaction

CloudWatch Synthetics captures URLs, status code, failure reason (if any), and headers and bodies of requests and responses. This enables a canary user to understand, monitor, and debug canaries.

The configurations described in the following sections can be set at any point in canary execution. You can also choose to apply different configurations to different synthetics steps.

Request URLs

By default, CloudWatch Synthetics logs request URLs, status codes, and the status reason for each URL in canary logs. Request URLs can also appear in canary execution reports, HAR files, and so on. Your request URL might contain sensitive query parameters, such as access tokens or passwords. You can redact sensitive information from being logged by CloudWatch Synthetics.

To redact sensitive information, set the configuration property **restrictedUrlParameters**. For more information, see SyntheticsConfiguration class. This causes CloudWatch Synthetics to redact URL parameters, including path and query parameter values, based on **restrictedUrlParameters** before logging. If you are logging URLs in your script, you can use getSanitizedUrl(url, stepConfig = null) to redact URLs before logging. For more information, see SyntheticsLogHelper class.

Headers

By default, CloudWatch Synthetics doesn't log request/response headers. For UI canaries, this is the default behavior for canaries using runtime version `syn-nodejs-puppeteer-3.2` and later.

If your headers don't contain sensitive information, you can enable headers in HAR file and HTTP reports by setting the **includeRequestHeaders** and **includeResponseHeaders** properties to `true`. You can enable all headers but choose to restrict values of sensitive header keys. For example, you can choose to only redact `Authorization` headers from artifacts produced by canaries.

Request and response body

By default, CloudWatch Synthetics doesn't log the request/response body in canary logs or reports. This information is particularly useful for API canaries. Synthetics captures all HTTP requests and can show headers, request and response bodies. For more information, see executeHttpStep(stepName, requestOptions, [callback], [stepConfig]). You can choose to enable request/response body by setting the **includeRequestBody** and **includeResponseBody** properties to `true`.

Logging Amazon CloudWatch API and console operations with Amazon CloudTrail

Amazon CloudWatch, CloudWatch Synthetics, CloudWatch RUM, Amazon Q Developer operational investigations, Network Flow Monitor, and Internet Monitor are integrated with Amazon CloudTrail, a service that provides a record of actions taken by a user, role, or an Amazon service. CloudTrail captures API calls made by or on behalf of your Amazon account. The captured calls include calls from the CloudWatch console and code calls to CloudWatch API operations. Using the information collected by CloudTrail, you can determine the request that was made to CloudWatch, the IP address from which the request was made, when it was made, and additional details.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made on behalf of an IAM Identity Center user.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another Amazon Web Services service.

CloudTrail is active in your Amazon Web Services account when you create the account and you automatically have access to the CloudTrail **Event history**. The CloudTrail **Event history** provides a viewable, searchable, downloadable, and immutable record of the past 90 days of recorded management events in an Amazon Web Services Region. For more information, see Working with CloudTrail Event history in the *Amazon CloudTrail User Guide*. There are no CloudTrail charges for viewing the **Event history**.

For an ongoing record of events in your Amazon Web Services account past 90 days, create a trail or a CloudTrail Lake event data store.

CloudTrail trails

A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. All trails created using the Amazon Web Services Management Console are multi-Region. You can create a single-Region or a multi-Region trail by using the Amazon CLI. Creating a multi-Region trail is recommended because you capture activity in all Amazon Web Services Regions in your account. If you create a single-Region trail, you can view only the events logged in the trail's Amazon Web Services

Region. For more information about trails, see Creating a trail for your Amazon Web Services account and Creating a trail for an organization in the *Amazon CloudTrail User Guide*.

You can deliver one copy of your ongoing management events to your Amazon S3 bucket at no charge from CloudTrail by creating a trail, however, there are Amazon S3 storage charges. For more information about CloudTrail pricing, see Amazon CloudTrail Pricing. For information about Amazon S3 pricing, see Amazon S3 Pricing.

CloudTrail Lake event data stores

CloudTrail Lake lets you run SQL-based queries on your events. CloudTrail Lake converts existing events in row-based JSON format to Apache ORC format. ORC is a columnar storage format that is optimized for fast retrieval of data. Events are aggregated into *event data stores*, which are immutable collections of events based on criteria that you select by applying advanced event selectors. The selectors that you apply to an event data store control which events persist and are available for you to query. For more information about CloudTrail Lake, see Working with Amazon CloudTrail Lake in the *Amazon CloudTrail User Guide*.

CloudTrail Lake event data stores and queries incur costs. When you create an event data store, you choose the pricing option you want to use for the event data store. The pricing option determines the cost for ingesting and storing events, and the default and maximum retention period for the event data store. For more information about CloudTrail pricing, see Amazon CloudTrail Pricing.

> **Note**
>
> For information about CloudWatch Logs API calls that are logged in CloudTrail, see CloudWatch Logs information in CloudTrail.

CloudWatch information in CloudTrail

CloudWatch supports logging the following actions as events in CloudTrail log files:

- DeleteAlarms
- DeleteAnomalyDetector
- DeleteDashboards
- DescribeAlarmHistory
- DescribeAlarms
- DescribeAlarmsForMetric
- DescribeAnomalyDetectors
- DisableAlarmActions
- EnableAlarmActions
- GetDashboard
- ListDashboards
- PutAnomalyDetector
- PutDashboard
- PutMetricAlarm
- SetAlarmState
- TagResource
- UntagResource

Example: CloudWatch log file entries

The following example shows a CloudTrail log entry that demonstrates the `PutMetricAlarm` action.

```
{
    "Records": [{
        "eventVersion": "1.01",
        "userIdentity": {
            "type": "Root",
            "principalId": "EX_PRINCIPAL_ID",
            "arn": "arn:aws:iam::123456789012:root",
            "accountId": "123456789012",
            "accessKeyId": "EXAMPLE_KEY_ID"
        },
        "eventTime": "2014-03-23T21:50:34Z",
        "eventSource": "monitoring.amazonaws.com",
        "eventName": "PutMetricAlarm",
        "awsRegion": "us-east-1",
        "sourceIPAddress": "127.0.0.1",
        "userAgent": "aws-sdk-ruby2/2.0.0.rc4 ruby/1.9.3 x86_64-linux Seahorse/0.1.0",
        "requestParameters": {
            "threshold": 50.0,
            "period": 60,
            "metricName": "CloudTrail Test",
            "evaluationPeriods": 3,
            "comparisonOperator": "GreaterThanThreshold",
            "namespace": "AWS/CloudWatch",
            "alarmName": "CloudTrail Test Alarm",
            "statistic": "Sum"
        },
        "responseElements": null,
        "requestID": "29184022-b2d5-11e3-a63d-9b463e6d0ff0",

         "apiVersion":"2015-10-07",
         "recipientAccountId":"123456789012"
}
```

The following log file entry shows that a user called the CloudWatch Logs `CreateExportTask` action.

```
{
        "eventVersion": "1.03",
        "userIdentity": {
            "type": "IAMUser",
            "principalId": "EX_PRINCIPAL_ID",
            "arn": "arn:aws:iam::123456789012:user/someuser",
            "accountId": "123456789012",
            "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
```

```
            "userName": "someuser"
        },
        "eventTime": "2016-02-08T06:35:14Z",
        "eventSource": "logs.amazonaws.com",
        "eventName": "CreateExportTask",
        "awsRegion": "us-east-1",
        "sourceIPAddress": "127.0.0.1",
        "userAgent": "aws-sdk-ruby2/2.0.0.rc4 ruby/1.9.3 x86_64-linux Seahorse/0.1.0",
        "requestParameters": {
            "destination": "yourdestination",
            "logGroupName": "yourloggroup",
            "to": 123456789012,
            "from": 0,
            "taskName": "yourtask"
        },
        "responseElements": {
            "taskId": "15e5e534-9548-44ab-a221-64d9d2b27b9b"
        },
        "requestID": "1cd74c1c-ce2e-12e6-99a9-8dbb26bd06c9",
        "eventID": "fd072859-bd7c-4865-9e76-8e364e89307c",
        "eventType": "AwsApiCall",
        "apiVersion": "20140328",
        "recipientAccountId": "123456789012"
}
```

CloudWatch data events in CloudTrail

CloudTrail can capture API activities related to the CloudWatch data plane operations GetMetricData and GetMetricWidgetImage.

Data events, also known as data plane operations, give you insight into the resource operations performed on or within a resource. Data events are often high-volume activities.

By default, CloudTrail doesn’t log data events. The CloudTrail **Event history** doesn't record data events.

Additional charges apply for data events. For more information about CloudTrail pricing, see Amazon CloudTrail Pricing.

You can log data events for the CloudWatch resource types by using the CloudTrail console, Amazon CLI, or CloudTrail API operations. For more information about how to log data events, see

Logging data events with the Amazon Web Services Management Console and Logging data events with the Amazon Command Line Interface in the *Amazon CloudTrail User Guide*.

Data plane events can be filtered by resource type. Because there are additional costs for using data events in CloudTrail, filtering by resource allows you to have more control over what you log and pay for.

Using the information that CloudTrail collects, you can identify a specific request to the CloudWatch GetMetricData or GetMetricWidgetImage APIs, the IP address of the requester, the requester's identity, and the date and time of the request. Logging the **GetMetricData** and **GetMetricWidgetImage** APIs using CloudTrail helps you enable operational and risk auditing, governance, and compliance of your Amazon account.

Note

When you view the **GetMetricData** events in CloudTrail, you might see more calls than the calls that you initiated. This is because CloudWatch logs events to CloudTrail for **GetMetricData** actions that are initiated by internal components. For example, you'll see **GetMetricData** calls initiated by CloudWatch dashboards to refresh widget data, and **GetMetricData** calls initiated by a monitoring account to retrieve data from a source account, in cross-account observability. These internally-initiated calls don't incur CloudWatch charges, but they do count toward the number of events logged in CloudTrail, and CloudTrail charges according to the number of events logged.

The following is an example of a CloudTrail event for a **GetMetricData** operation.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "AIDA2NYTR2EPCTNY7AF3L",
        "arn": "arn:aws:iam::111122223333:user/admin",
        "accountId": "111122223333",
        "accessKeyId": "EXAMPLE1234567890",
        "userName": "admin"
    },
    "eventTime": "2024-05-08T16:20:34Z",
    "eventSource": "monitoring.amazonaws.com",
    "eventName": "GetMetricData",
```

```
    "awsRegion": "us-east-1",
    "sourceIPAddress": "99.45.3.7",
    "userAgent": "aws-cli/2.13.23 Python/3.11.5 Darwin/23.4.0 exe/x86_64 prompt/off
 command/cloudwatch.get-metric-data",
    "requestParameters": {
        "metricDataQueries": [{
                "id": "e1",
                "expression": "m1 / m2",
                "label": "ErrorRate"
            },
            {
                "id": "m1",
                "metricStat": {
                    "metric": {
                        "namespace": "CWAgent",
                        "metricName": "disk_used_percent",
                        "dimensions": [{
                            "name": "LoadBalancerName",
                            "value": "EXAMPLE4623a5cb6a7384c5229"
                        }]
                    },
                    "period": 300,
                    "stat": "Sum",
                    "unit": "Count"
                },
                "returnData": false
            },
            {
                "id": "m2",
                "metricStat": {
                    "metric": {
                        "namespace": "CWAgent",
                        "metricName": "disk_used_percent",
                        "dimensions": [{
                            "name": "LoadBalancerName",
                            "value": "EXAMPLE4623a5cb6a7384c5229"
                        }]
                    },
                    "period": 300,
                    "stat": "Sum"
                },
                "returnData": true
            }
        ],
```

```
        "startTime": "Apr 19, 2024, 4:00:00 AM",
        "endTime": "May 8, 2024, 4:30:00 AM"
    },
    "responseElements": null,

Query generation information in CloudTrail

CloudTrail logging for Query generator console events is also supported. Query generator is currently supported for CloudWatch Metric Insights and CloudWatch Logs Insights. In these CloudTrail events, the `eventSource` is `monitoring.amazonaws.com`.

The following example shows a CloudTrail log entry that demonstrates the **GenerateQuery** action in CloudWatch Metrics Insights.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::123456789012:assumed-role/role_name",
        "accountId": "123456789012",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
```

```
                "arn": "arn:aws:iam::111222333444:role/Administrator",
                "accountId": "123456789012",
                "userName": "SAMPLE_NAME"
            },
            "attributes": {
                "creationDate": "2020-04-08T21:43:24Z",
                "mfaAuthenticated": "false"
            }
        }
    },
    "eventTime": "2020-04-08T23:06:30Z",

Amazon Q Developer operational investigations events in CloudTrail

Amazon Q Developer operational investigations supports logging the following actions as events in CloudTrail log files.

- CreateInvestigation
- GetInvestigation
- UpdateInvestigation
- DeleteInvestigation
- ListInvestigations
- CreateInvestigationGroup
- GetInvestigationGroup
- UpdateInvestigationGroup
- DeleteInvestigationGroup
- ListInvestigationsGroup
- PutInvestigationGroupPolicy
- DeleteInvestigationGroupPolicy
- ListTagsForResource
- GetInvestigationGroupPolicy
- TagResource
- UntagResource
- CreateInvestigationEvent
- GetInvestigationEvent
- UpdateInvestigationEvent
- ListInvestigationEvents
- CreateInvestigationResource
- GetInvestigationResource

Example: Amazon Q Developer operational investigations log file entries

The following example shows a Amazon Q Developer operational investigations log entry that demonstrates the `CreateInvestigationGroup` action.

```
{
 "eventVersion": "1.09",
 "userIdentity": {
  "type": "AssumedRole",
  "principalId": "EX_PRINCIPAL_ID",
  "arn": "arn:aws:iam::123456789012:assumed-role/role_name",
  "accountId": "123456789012",
  "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
  "sessionContext": {
   "sessionIssuer": {
    "type": "Role",
    "principalId": "EX_PRINCIPAL_ID",
    "arn": "arn:aws:iam::123456789012:role/role_name",
    "accountId": "123456789012",
    "userName": "SAMPLE_NAME"
   },
   "attributes": {
    "creationDate": "2024-10-30T18:42:05Z",
    "mfaAuthenticated": "false"
   }
  }
 },
 "eventTime": "2024-10-30T18:48:26Z",

Network Flow Monitor in CloudTrail

Network Flow Monitor supports logging the following actions as events in CloudTrail log files.

- CreateMonitor
- GetMonitor
- DeleteMonitor
- ListMonitors
- UpdateMonitor

- CreateScope
- GetScope
- ListScopes
- DeleteScope
- UpdateScope

Example: Network Flow Monitor log file entry

The following example shows a Network Flow Monitor CloudTrail log file entry that demonstrates the `CreateMonitor` action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::000000000000:assumed-role/role_name",
        "accountId": "123456789012",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::000000000000:role/Admin",
                "accountId": "123456789012",

```

Network Flow Monitor data plane events in CloudTrail

CloudTrail can capture API activities related to the CloudWatch-NetworkFlowMonitor data plane operations.

Data events, also known as data plane operations, give you insight into the resource operations performed on or within a resource. Data events are often high-volume activities.

To enable logging of Network Flow Monitor data events in CloudTrail files, you'll need to enable the logging of data plane API activity in CloudTrail. See Logging data events for trails for more information.

Data plane events can be filtered by resource type. Because there are additional costs for using data events in CloudTrail, filtering by resource allows you to have more control over what you log and pay for.

Using the information that CloudTrail collects, you can identify a specific request to the CloudWatch-NetworkFlowMonitor data plane APIs, the IP address of the requester, the requester's identity, and the date and time of the request. Logging the data plane APIs using CloudTrail can help you with operational and risk auditing, governance, and compliance of your Amazon account.

The following are data plane APIs in Network Flow Monitor.

- StartQueryWorkloadInsightsTopContributors
- StopQueryWorkloadInsightsTop Contributors
- GetQueryStatusWorkloadInsightsTopContributors
- GetQueryResultsWorkloadInsightsTopContributors
- StartQueryWorkloadInsightsTopContributorsData
- StopQueryWorkloadInsightsTopContributorsData
- GetQueryStatusWorkloadInsightsTopContributorsData
- GetQueryResultsWorkloadInsightsTopContributorsData
- StartQueryMonitorsTopContributors
- StopQueryMonitorsTopContributors
- GetQueryStatusMonitorsTopContributors
- GetQueryResultsMonitorsTopContributors

The following example shows a CloudTrail log entry that demonstrates the GetQueryResultsMonitorsTopContributors action.

```
{
  "eventVersion": "1.09",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "EX_PRINCIPAL_ID",
    "arn": "arn:aws:iam::000000000000:assumed-role/role_name",

Internet Monitor in CloudTrail

Internet Monitor supports logging the following actions as events in CloudTrail log files.

- CreateMonitor
- DeleteMonitor
- GetHealthEvent
- GetMonitor
- GetQueryResults
- GetQueryStatus
- ListHealthEvents
- ListMonitors
- ListTagsForResource
- StartQuery
- StopQuery
- UpdateMonitor

Example: Internet Monitor log file entries

The following example shows a CloudTrail Internet Monitor log entry that demonstrates the `ListMonitors` action.

```
{
        "eventVersion": "1.08",
        "userIdentity": {
            "type": "AssumedRole",
            "principalId": "EX_PRINCIPAL_ID",
            "arn": "arn:aws:iam::000000000000:assumed-role/role_name",
            "accountId":"123456789012",
            "accessKeyId":"AKIAIOSFODNN7EXAMPLE",
            "sessionContext": {
                "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::000000000000:role/Admin",
                "accountId":"123456789012",
                "userName": "SAMPLE_NAME"
                },
                "webIdFederationData": {},
                "attributes": {
                    "creationDate": "2022-10-11T17:25:41Z",
                    "mfaAuthenticated": "false"
                }
            }
        },
        "eventTime": "2022-10-11T17:30:18Z",
        "eventSource": "internetmonitor.amazonaws.com",
        "eventName": "ListMonitors",
        "awsRegion": "us-east-2",
        "sourceIPAddress": "192.0.2.0",
        "userAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_7)",
        "requestParameters": null,

CloudWatch Synthetics information in CloudTrail

CloudWatch Synthetics supports logging the following actions as events in CloudTrail log files:

- CreateCanary
- DeleteCanary
- DescribeCanaries
- DescribeCanariesLastRun
- DescribeRuntimeVersions
- GetCanary
- GetCanaryRuns
- ListTagsForResource
- StartCanary
- StopCanary
- TagResource
- UntagResource
- UpdateCanary

Example: CloudWatch Synthetics log file entries

The following example shows a CloudTrail Synthetics log entry that demonstrates the `DescribeCanaries` action.

```
{
    "eventVersion": "1.05",
    "userIdentity": {
```

```
        "type": "AssumedRole",
        "principalId": "EX_PRINCIPAL_ID",
        "arn": "arn:aws:iam::123456789012:assumed-role/role_name",
        "accountId":"123456789012",
        "accessKeyId":"AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EX_PRINCIPAL_ID",
                "arn": "arn:aws:iam::111222333444:role/Administrator",
                "accountId":"123456789012",
                "userName": "SAMPLE_NAME"
            },
            "webIdFederationData": {},
            "attributes": {
                "mfaAuthenticated": "false",
                "creationDate": "2020-04-08T21:43:24Z"
            }
        }
    },
    "eventTime": "2020-04-08T23:06:47Z",

CloudWatch RUM information in CloudTrail

CloudWatch RUM supports logging the following actions as events in CloudTrail log files:

- BatchCreateRumMetricDefinitions
- BatchDeleteRumMetricDefinitions
- BatchGetRumMetricDefinitions
- CreateAppMonitor
- DeleteAppMonitor
- DeleteRumMetricsDestination
- GetAppMonitor
- GetAppMonitorData
- ListAppMonitors
- ListRumMetricsDestinations
- ListTagsForResource
- PutRumMetricsDestination
- TagResource
- UntagResource
- UpdateAppMonitor
- UpdateRumMetricDefinition

Example: CloudWatch RUM log file entries

This section contains example CloudTrail entries for some CloudWatch RUM APIs.

The following example shows a CloudTrail log entry that demonstrates the CreateAppMonitor action.

```
{
    "eventVersion": "1.09",
    "userIdentity": {
        "type": "AssumedRole",
        "principalId": "EXAMPLE_PRINCIPAL_ID",
        "arn": "arn:aws:sts::777777777777:assumed-role/EXAMPLE",
        "accountId": "777777777777",
        "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
        "sessionContext": {
            "sessionIssuer": {
                "type": "Role",
                "principalId": "EXAMPLE_PRINCIPAL_ID",
                "arn": "arn:aws:iam::777777777777:role/EXAMPLE",
                "accountId": "777777777777",
                "userName": "USERNAME_EXAMPLE"
            },
            "attributes": {
                "creationDate": "2024-07-23T16:48:47Z",
                "mfaAuthenticated": "false"
            }
        }
    },
    "eventTime": "2024-07-23T18:02:57Z",
    "eventSource": "rum.amazonaws.com",

CloudWatch RUM data plane events in CloudTrail

CloudTrail can capture API activities related to the CloudWatch RUM data plane operation PutRumEvents.

Data events, also known as data plane operations, give you insight into the resource operations performed on or within a resource. Data events are often high-volume activities.

To enable logging of the **PutRumEvents** data events in CloudTrail files, you'll need to enable the logging of data plane API activity in CloudTrail. See Logging data events for trails for more information.

Data plane events can be filtered by resource type. Because there are additional costs for using data events in CloudTrail, filtering by resource allows you to have more control over what you log and pay for.

Using the information that CloudTrail collects, you can identify a specific request to the CloudWatch RUM **PutRumEvents** API, the IP address of the requester, the requester's identity, and the date and time of the request. Logging the **PutRumEvents** API using CloudTrail helps you enable operational and risk auditing, governance, and compliance of your Amazon account.

The following example shows a CloudTrail log entry that demonstrates the PutRumEvents action.

```

Tagging your Amazon CloudWatch resources

A *tag* is a custom attribute label that you or Amazon assigns to an Amazon resource.

Tags help you do the following:

- Identify and organize your Amazon resources. Many Amazon services support tagging. You can assign the same tag to resources from different services to indicate the resources are related. For example, you can assign the tag that you assigned to a CloudWatch rule to an EC2 instance.

Tags have two parts:

- A *tag key* (for example, `CostCenter`, `Environment`, or `Project`). Tag keys are case sensitive.
- An optional field known as a *tag value* (for example, `111122223333` or `Production`). Omitting the tag value is the same as using an empty string. Like tag keys, tag values are case sensitive.

The following sections provide more information about tags for CloudWatch.

Supported resources in CloudWatch

The following resources in CloudWatch support tagging:

- Alarms – You can tag alarms using the tag-resource Amazon CLI command and the TagResource API. You can also view and manage your alarm tags using the *Alarms* details page in the CloudWatch console.
- Canaries – You can tag canaries using the CloudWatch console. For more information, see Creating a canary.
- Contributor Insights rules – You can tag Contributor Insights rules when you create them by using the put-insight-rule Amazon CLI command and the PutInsightRule API. You can add tags to existing rules by using the tag-resource Amazon CLI command and the TagResource API.
- Metric streams – You can tag metric streams when you create them by using the put-metric-stream Amazon CLI command and the PutMetricStream API. You can add tags to existing metric streams by using the tag-resource Amazon CLI command and the TagResource API.

For information about adding and managing tags, see Managing tags.

Managing tags

Tags consist of the `Key` and `Value` properties on a resource. You can use the CloudWatch console, the Amazon CLI, or the CloudWatch API to add, edit, or delete the values for these properties. For information about working with tags, see the following:

- TagResource, UntagResource, and ListTagsForResource in the *Amazon CloudWatch API Reference*
- tag-resource, untag-resource, and list-tags-for-resource in the *Amazon CloudWatch CLI Reference*
- Working with Tag Editor in the *Resource Groups User Guide*

Tag naming and usage conventions

The following basic naming and usage conventions apply to using tags with CloudWatch resources:

- Each resource can have a maximum of 50 tags.
- For each resource, each tag key must be unique, and each tag key can have only one value.
- The maximum tag key length is 128 Unicode characters in UTF-8.
- The maximum tag value length is 256 Unicode characters in UTF-8.
- Allowed characters are letters, numbers, spaces representable in UTF-8, and the following characters: ***. : + = @ _ / -*** (hyphen).
- Tag keys and values are case sensitive. As a best practice, decide on a strategy for capitalizing tags and consistently implement that strategy across all resource types. For example, decide whether to use `Costcenter`, `costcenter`, or `CostCenter` and use the same convention for all tags. Avoid using similar tags with inconsistent case treatment.
- The `aws:` prefix is prohibited for tags because it's reserved for Amazon use. You can't edit or delete tag keys or values with this prefix. Tags with this prefix don't count against your tags per resource limit.

Grafana integration

You can use Grafana version 6.5.0 and later to contextually advance through the CloudWatch console and query a dynamic list of metrics by using wildcards. This can help you monitor metrics for Amazon resources, such as Amazon Elastic Compute Cloud instances or containers. When new instances are created as part of an Auto Scaling event, they appear in the graph automatically. You don't need to track the new instance IDs. Prebuilt dashboards help simplify the getting started experience for monitoring Amazon EC2, Amazon Elastic Block Store, and Amazon Lambda resources.

You can use Grafana version 7.0 and later to perform CloudWatch Logs Insights queries on log groups in CloudWatch Logs. You can visualize your query results in bar, line, and stacked graphs and in a table format. For more information about CloudWatch Logs Insights, see Analyzing Log Data with CloudWatch Logs Insights.

For more information about how to get started, see Using Amazon CloudWatch in Grafana in the Grafana Labs documentation.

CloudWatch service quotas

You can use the table in this section to learn about alarms, alarm email notifications, and API requests in Amazon CloudWatch.

> **Note**
>
> For some Amazon services including CloudWatch, you can use the CloudWatch usage metrics to visualize your current service usage on CloudWatch graphs and dashboards. You can use a CloudWatch metric math function to display the service quotas for those resources on your graphs. You can also configure alarms that alert you when your usage approaches a service quota. For more information, see Visualizing your service quotas and setting alarms.

Resource	Default quota
Alarm actions	5/alarm. This quota can't be changed.
Alarm evaluation period	This is calculated by multiplying the alarm period by the number of evaluation periods used. The maximum value is seven days for alarms with a period of at least one hour (3600 seconds). The maximum is one day for alarms with a shorter period, and the maximum is one day for alarms using the custom Lambda data source. This quota can't be changed.
Alarms	10/month/customer for free. Additional alarms incur charges. No limit on the total number of alarms per account. Alarms based on metric math expressions can have up to 10 metrics. 200 Metrics Insights alarms per Region. You can request a quota increase.

Resource	Default quota
Anomaly detection models	500 per Region, per account.
API requests	1,000,000/month/customer for free.
Application Signals API requests	The following APIs have a quota of 10 transactions per second (TPS) and per Region. You can request a quota increase. • BatchGetServiceLevelObjectiveBudgetReport • GetService • ListServiceDependencies • ListServiceDependents • ListServiceOperations • ListServices The following APIs have a quota of 5 transactions per second (TPS) and per Region. You can request a quota increase. • CreateServiceLevelObjective • DeleteServiceLevelObjective • GetServiceLevelObjective • ListServiceLevelObjectives • ListTagsForResource • StartDiscovery • TagResource • UntagResource • UpdateServiceLevelObjective

Resource	Default quota
SLOs	Maximum number of SLOs supported per Region per account: **250** Maximum number of SLOs supported per Service: **100** You can request a quota increase.
Canaries	200 per Region per account. You can request a quota increase.
Contributor Insights API requests	The following APIs have a quota of 20 transactions per second (TPS) and per Region. • DescribeInsightRules The quota can't be changed. • GetInsightRuleReport You can request a quota increase. The following APIs have a quota of 5 TPS per Region. This quota can't be changed. • DeleteInsightRules • PutInsightRule The following APIs have a quota of 1 TPS per Region. This quota can't be changed. • DisableInsightRules • EnableInsightRules

Resource	Default quota
Contributor Insights rules	100 rules per Region per account. You can request a quota increase.
Custom metrics	No quota.
Dashboards	Up to 500 widgets per dashboard. Up to 500 metrics per dashboard widget. Up to 2500 metrics per dashboard, across all widgets. These quotas include all metrics retrieved for use in metric math functions, even if those metrics are not displayed on the graph. These quotas can't be changed.
DescribeAlarms	9 transactions per second (TPS) per Region. The maximum number of operation requests you can make per second without being throttled. You can request a quota increase.
DescribeAlarmHistory	20 transactions per second (TPS) per Region. The maximum number of operation requests you can make per second without being throttled. This quota can't be changed.
DeleteAlarms request DisableAlarmActions request EnableAlarmActions request SetAlarmState request	3 TPS per Region for each of these operations. The maximum number of operation requests you can make per second without being throttled. These quotas can't be changed.

Resource	Default quota
DescribeAlarmsForMetric request	9 TPS per Region. The maximum number of operation requests you can make per second without being throttled. This quota can't be changed.
DeleteDashboards request GetDashboard request ListDashboards request PutDashboard request	10 TPS per Region for each of these operations. The maximum number of operation requests you can make per second without being throttled. These quotas can't be changed.
PutAnomalyDetector DescribeAnomalyDetectors	10 TPS per Region. The maximum number of operation requests you can make per second without being throttled.
DeleteAnomalyDetector	5 TPS per Region. The maximum number of operation requests you can make per second without being throttled.
Dimensions	30/metric. This quota can't be changed.

Resource	Default quota
GetMetricData	10 TPS per Region for operations that include Metrics Insights queries. For operations that do not include Metrics Insights queries, the quota is 50 TPS per Region. This is the maximum number of operation requests you can make per second without being throttled. You can request a quota increase. For `GetMetricData` operations that include a Metrics Insights query, the quota is 4,300,000 Datapoints Per Second (DPS) for the most recent 3 hours. This is calculated against the total number of data points scanned by the query (which can include no more than 10,000 metrics.) 180,000 Datapoints Per Second (DPS) if the `StartTime` used in the API request is less than or equal to three hours from current time. 396,000 DPS if the `StartTime` is more than three hours from current time. This is the maximum number of datapoints you can request per second using one or more API calls without being throttled. This quota can't be changed. The DPS is calculated based on estimated data points, not actual data points. The data point estimate is calculated using the requested time range, period, and retention period. This means that if the actual data points in the requested metrics are sparse or empty, throttling still occurs if the estimated data points exceed the quota. The DPS quota is per-Region.

Resource	Default quota
GetMetricData	A single `GetMetricData` call can include the following: • As many as 500 `MetricDataQuery` structures. • As many as 100 `SERVICE_QUOTA()` functions. • As many as 100 `SEARCH()` functions. • As many as 5 `LAMBDA()` functions. These quotas can't be changed.
GetMetricStatistics	400 TPS per Region. The maximum number of operation requests you can make per second without being throttled. You can request a quota increase.
GetMetricWidgetImage	Up to 500 metrics per image. This quota can't be changed. 20 TPS per Region. The maximum number of operation requests you can make per second without being throttled. You can request a quota increase.
ListMetrics	25 TPS per Region. The maximum number of operation requests you can make per second without being throttled. You can request a quota increase.
Metric data values	The value of a metric data point must be within the range of -2^360 to 2^360. Special values (for example, NaN, +Infinity, -Infinity) are not supported. This quota can't be changed.

Resource	Default quota
MetricDatum items	1000/PutMetricData request. A MetricDatum object can contain a single value or a StatisticSet object represent ing many values. This quota can't be changed.
Metrics	10/month/customer for free.
Metrics Insights queries	A single query can process no more than 10,000 metrics. This means that if the **SELECT**, **FROM**, and **WHERE** clauses would match more than 10,000 metrics, only the first 10,000 of these metrics that are found will be processed by the query. A single query can return no more than 500 time series. You can query only the most recent three hours of data
Metrics Insights query generator requests	As many as five concurrent natural-language generated requests.
Observability Access Manager (OAM) API request rates.	1 TPS per Region for PutSinkPolicy. 10 TPS per Region for each other CloudWatch OAM API. These quotas reflect the maximum number of operation requests you can make per second without being throttled. These quotas can't be changed.
OAM source account links	Each source account can be linked to as many as 5 monitoring accounts This quota can't be changed.
OAM sinks	1 sink per Region per account This quota can't be changed.

Resource	Default quota
PutCompositeAlarm request	3 TPS per Region. The maximum number of operation requests you can make per second without being throttled. You can request a quota increase.
PutPutDashboard payload size	The payload of `PutDashboard` requests can be up to 1 MB. This quota can't be changed.
PutMetricAlarm request	3 TPS per Region. The maximum number of operation requests you can make per second without being throttled. You can request a quota increase.
PutMetricData request	1MB for HTTP POST requests. PutMetricData can handle 500 transactions per second (TPS), which is the maximum number of operation requests that you can make per second without being throttled. `PutMetricData` can handle 1,000 metrics per request. You can request a quota increase.
Amazon Q Developer operational investigations investigations	You can have as many as 20 active investigations. Only two of these investigations at a time can have active analysis currently happening.
Amazon SNS email notifications	1,000/month/customer for free.
Synthetics Groups	20 per account. This quota can't be changed.

Resource	Default quota
TagResource	20 TPS per Region. The maximum number of operation requests you can make per second without being throttled. This quota can't be changed.
UntagResource	20 TPS per Region. The maximum number of operation requests you can make per second without being throttled. This quota can't be changed.

Document history

The following table describes important changes for each release of the *Amazon CloudWatch User Guide*, beginning in June 2018. To receive notifications about updates to this documentation, you can subscribe to an RSS feed.

Change	Description	Date
CloudWatch Network Monitoring releases multiple account support for Network Flow Monitor	Network Flow Monitor, a feature of CloudWatch Network Monitoring, now supports monitoring network performance metrics for network flows for resources in multiple accounts. For more information, see Initialize Network Flow Monitor for multi-account monitoring.	May 6, 2025
AmazonCloudWatchRUMReadOnlyAccess updated	The `rum:GetResourcePolicy` permission was added so that CloudWatch RUM can view the resource policy attached to the RUM application monitor.	April 28, 2025
CloudWatch Synthetics deprecates five runtime metrics on October 1, 2025	CloudWatch Synthetics metrics `syn-nodejs-puppeteer-7.0` , `syn-nodejs-puppeteer-6.2` , `syn-nodejs-puppeteer-5.2` , `syn-python-selenium-3.0` , and `syn-python-selenium-2.1` will be deprecated on October 1, 2025.	April 4, 2025

Updated CloudWatchApplicationSignalsServiceRolePolicy policy	CloudWatch updated the policy to exclude time windows from impacting the SLO attainment rate, error budget, and burn rate metrics. CloudWatch can retrieve exclusion windows on behalf of you. For more information, see CloudWatchApplicationSignalsServiceRolePolicy.	March 13, 2025
Time window exclusions	SLOs adds support for time window exclusions which is a block of time with a defined start and end date. This time period is excluded from the SLO's performance metrics and you can schedule one-time or recurring time exclusions windows. For more information, see Service level objectives (SLOs).	March 13, 2025
New AIOpsReadOnlyAccess policy	CloudWatch added the **AIOpsReadOnlyAccess** policy, which grants read-only permissions for Amazon AI Operations and other related services.	December 3, 2024

New AIOpsOperatorAccess policy	CloudWatch added the **AIOpsOperatorAccess** policy, which grants users access to Amazon AI Operations actions, and to additional Amazon actions that are necessary for accessing investigation events.	December 3, 2024
New AIOpsConsoleAdminPolicy policy	CloudWatch added the **AIOpsConsoleAdminPolicy** policy, which grants users full administrative access for managing Amazon Q investigations, including the management of trusted identity propagation, and the management of IAM Identity Center and organizational access.	December 3, 2024
New AIOpsAssistantPolicy policy	CloudWatch added the **AIOpsAssistantBasicAccess** policy, which you can assign to the Amazon AI Operations assistant to enable the assistant to have basic functionality.	December 3, 2024

Amazon Q Developer operational investigations feature in Preview	CloudWatch released a Preview of Amazon Q Developer operational investigations. This feature is a generative AI-powered assistant that can help you respond to incidents in your system. It uses generativ e AI to scan your system's telemetry and quickly surface suggestions that might be related to your issue, to help you troubleshoot operational issues faster.	December 3, 2024
CloudWatchFullAccessV2 and CloudWatchFullAccess policies updated	CloudWatch updated both **CloudWatchFullAccessV2** and **CloudWatchFullAcce ss**. Permissions for Amazon OpenSearch Service were added to to enable CloudWatch Logs integration with OpenSearch Service for some features.	December 1, 2024
Telemetry config feature generally available	CloudWatch added the telemetry config feature to discover and understan d the state of telemetry configuration for your Amazon resources.	November 26, 2024
New AWSServiceRoleForO bservabilityAdmin service-l inked role	CloudWatch added the new AWSServiceRoleForObservabil ityAdmin service-linked role and AWSObservabilityAd minServiceRolePolicy policy.	November 26, 2024

CloudWatch supports exploring related telemetry	CloudWatch supports exploring related telemetry data across interconnected resources.	November 22, 2024
Updated CloudWatchSyntheticsFullAccess IAM policy	CloudWatch updated the **CloudWatchSyntheticsFullAccess** policy to grant CloudWatch Synthetics access to get Amazon Lambda functions, and perform actions on logs available in CloudWatch Logs. Additionally, Lambda layer version actions apply to all CloudWatch Synthetics layer ARNs.	November 21, 2024
New CloudWatch Synthetics support for Node.js with the Playwright runtime	CloudWatch Synthetics adds support for Node.js canary scripts that use the Playwright runtime.	November 21, 2024
CloudWatchReadOnlyAccess policy updated	The scope of the policy was changed to include the `xray:List *`, `xray:StartTraceRetrieval` , and `xray:CancelTraceRetrieval` permissions. This change allows CloudWatch to access new X-Ray read APIs. For more infomration, see CloudWatchReadOnlyAccess.	November 21, 2024

CloudWatch Transaction Search is generally available	CloudWatch releases Transacti on Search, a search and analytics experience. Transacti on Search provides visibilit y into application transacti on issues. Explore interacti ons between application components to establish a root cause. Understand your application transactions and their impact on customers . Search transactions using terms like customer name or order. For more information, see CloudWatch Transaction Search.	November 21, 2024
Application Signals supports Lambda functions	You can now enable Applicati on Signals for Lambda functions.	November 21, 2024
OpenTelemetry	You can use OpenTelemetry to directly send traces to an OpenTelemetry Protocol (OTLP) endpoint, and get out-of-the box application performance monitoring experiences in CloudWatch Application Signals.	November 20, 2024
Application Signals collects runtime metrics	Application Signals now collects OpenTelemetry-compatible runtime metrics from your Java and Python applications.	November 19, 2024

Application Signals collects runtime metrics	Application Signals now collects OpenTelemetry-compatible runtime metrics from your Java and Python applications.	November 19, 2024
Internet traffic monitoring for VPCs in Amazon Local Zones	Internet Monitor now supports internet traffic monitoring for VPCs deployed in Amazon Local Zones	November 18, 2024
Application Signals support for Node.js applications is generally available	CloudWatch supports enabling Node.js applications for Application Signals.	November 15, 2024
New CloudWatchInternet MonitorReadOnlyAccess IAM policy	CloudWatch added a **CloudWatchInternet MonitorReadOnlyAcc ess** policy, to grant read-only access to actions and resources available in the CloudWatch console for Internet Monitor.	November 14, 2024
CloudWatch added observabi lity solutions	CloudWatch observability solutions offer a catalog of readily available configura tions to help you quickly implement monitoring for various Amazon services and common workloads, such as Java Virtual Machines (JVM), Apache Kafka, Apache Tomcat, and NGINX.	November 13, 2024

CloudWatch added burn rate monitoring for Application Signals SLOs	CloudWatch added burn rate monitoring to Application Signals SLOs. A burn rate is a metric that indicates how fast the service is consuming the error budget, relative to the attainment goal of the SLO.	November 13, 2024
New Internet Monitor latency reduction suggestions through Route 53 routing updates	Amazon CloudWatch Internet Monitor now provides actionable suggestions to help you optimize your Route 53 IP-based routing configurations. Easily identify the optimal Amazon Web Services Regions for routing your end user traffic, and then configure your Route 53 IP-based routing based on the recommendations.	November 1, 2024
New CloudWatchInternet MonitorFullAccess IAM policy	CloudWatch added a **CloudWatchInternet MonitorFullAccess** policy, to grant full access to actions and resources available in the CloudWatch console for Internet Monitor.	October 23, 2024
End of support notice	End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.	October 17, 2024

End of support notice	End of support notice: On October 16, 2025, Amazon will discontinue support for CloudWatch Evidently. After October 16, 2025, you will no longer be able to access the Evidently console or Evidently resources.	October 17, 2024
New CloudWatchLambdaApplicationSignalsExecutionRolePolicy IAM policy	CloudWatch added a new policy named **CloudWatchLambdaApplicationSignalsExecutionRolePolicy**. This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.	October 16, 2024
New CloudWatchLambdaApplicationSignalsExecutionRolePolicy IAM policy	CloudWatch added a new policy named **CloudWatchLambdaApplicationSignalsExecutionRolePolicy**. This policy is used when CloudWatch Application Signals is enabled for Lambda workloads. It enables write access to X-Ray and the log group used by CloudWatch Application Signals.	October 16, 2024

CloudWatchSyntheticsFullAccess policy updated	Permissions were added to the **CloudWatchSyntheticsFullAccess** IAM policy. The `lambda:ListTags` , `lambda:TagResource` , and `lambda:UntagResource` permissions were added so that when you apply or change tags on a canary, you can choose to have Synthetics also apply those same tags or changes to the Lambda function that the canary uses.	October 11, 2024
Application Signals supports request-based SLOs	Application Signals adds support for request-based service level objects (SLOs). For more information, see Service level objectives (SLOs).	September 6, 2024
Internet Monitor refreshed dashboard and latency improvement suggestions	Amazon CloudWatch Internet Monitor has launched an updated console experience, including new features for visualizing configuration changes that can help you reduce latency for your application.	August 12, 2024
Application Signals previewing support for .NET applications	CloudWatch Application Signals has added support for .NET applications, with ADOT Instrumentation for .NET on supported platforms. This feature is in preview release.	August 5, 2024

New CloudWatch Applicati on Insights service linked role permission added	Allows CloudWatch Applicati on Insights to enable and disable termination protectio n on Amazon CloudFormation stacks.	July 25, 2024
CloudWatch Metrics Insights support for natural language query generation is generally available.	CloudWatch Metrics Insights supports natural language query to generate and update queries. For more informati on, see Use natural language to generate and update CloudWatch Metric Insights queries.	June 10, 2024
CloudWatch Application Signals is generally available	CloudWatch Application Signals is now generally available. Use Application Signals to instrument your applications on Amazon so that you can monitor current application health, create service level objectives (SLOs), and track long-term applicati on performance against your business objectives. For more information, see Application Signals.	June 10, 2024
New CloudWatchApplicat ionSignalsReadOnlyAccess IAM policy	CloudWatch added a **CloudWatchApplicat ionSignalsReadOnlyAccess** policy to add read only actions and resources available in the CloudWatc h console for Application Signals.	June 7, 2024

New CloudWatchApplicationSignalsFullAccess policy	CloudWatch added a **CloudWatchApplicationSignalsFullAccess** policy to add actions and resources available in the CloudWatch console for Application Signals.	June 7, 2024
CloudTrail now captures API activities related to CloudWatch data plane operations.	CloudTrail now logs events in CloudTrail for **GetMetricData** and **GetMetricWidgetImage** API activities.	June 6, 2024
CloudWatch Application Signals service map supports canary, RUM clients and Amazon service dependency groupings.	The Application Signals preview release has added default groupings in the service map for canaries, RUM clients, and Amazon service dependencies of the same type. This change reduces the number of icons in the service map default view to make it easier to view and navigate.	May 21, 2024

CloudWatchReadOnlyAccess policy updated	CloudWatch changed the scope of a permission in **CloudWatchReadOnlyAccess**. The scope of the policy added the `application-signals:BatchGet*` , `application-signals:Get*` , and `application-signals:List*` actions so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services. CloudWatch also added an `iam:GetRole` action so that users can check if Application Signals is set up.	May 17, 2024
CloudWatchFullAccessV2 policy updated	CloudWatch changed the scope of a permission in **CloudWatchFullAccessV2**. The scope of the policy added the `application-signals:*` so that users can use CloudWatch Application Signals to view, investigate, and diagnose issues with the health of their services.	May 17, 2024
Lambda Insights supports Amazon GovCloud (US-East) and Amazon GovCloud (US-West)	CloudWatch Lambda Insights has added support for the Amazon GovCloud (US-East) and Amazon GovCloud (US-West) Regions.	April 29, 2024

CloudWatch cross-account observability supports resource filters	You can now create filters to specify which metric namespaces and log groups are shared from the source account to the monitoring account, when you create the link between the accounts.	April 26, 2024
CloudWatch Application Signals updates	The Application Signals preview release has added three features. Applicati on Signals now supports Python applications. It offers a simpler enablement process for applications on Amazon EKS architectures. And it includes new configurations that you can use to manage the cardinality of metrics that are collected.	April 26, 2024
CloudWatch Container Insights with enhanced observability for Amazon EKS can collect Amazon Elastic Fabric Adapter (EFA) metrics	You can now use CloudWatc h Container Insights with enhanced observability for Amazon EKS collect Amazon Elastic Fabric Adapter (EFA) metrics from Amazon EKS clusters.	April 23, 2024

Updated IAM policy	CloudWatch updated the **CloudWatchApplicationSignalsServiceRolePolicy** policy. The scoping of the `logs:StartQuery` and `logs:GetQueryResults` permissions in this policy was changed to add `arn:aws:logs:*:*:log-group:/aws/appsignals/*:*` and `"arn:aws:logs:*:*:log-group:/aws/application-signals/data:*"` to enable Application Signals on more architecures. This policy is attached to the **AWSServiceRoleForCloudWatchApplicationSignals** service-linked role.	April 18, 2024
Internet Monitor provides a global internet weather map to authenticated Amazon customers	Amazon CloudWatch Internet Monitor now displays a global internet weather map that is available in the console to all authenticated Amazon customers. To view the map, in the Amazon CloudWatch console, navigate to Internet Monitor.	April 16, 2024

CloudWatch Container Insights with enhanced observability for Amazon EKS can collect Amazon Neuron metrics	You can now use CloudWatch Container Insights with enhanced observability for Amazon EKS collect Amazon Neuron metrics from Amazon EKS clusters.	April 16, 2024
CloudWatch Application Signals adds a **Service overview** tab and more metrics to aid in diagnostics	A new **Service overview** tab displays an overview of your service, including number of operations, dependencies, synthetics, and client pages. The tab shows key metrics for your entire service, and top operations and dependencies. You can also now view X-Ray traces that are correlated with issues including faults, errors, and latency problems.	April 16, 2024
CloudWatch Container Insights with enhanced observability for Amazon EKS adds support for Windows	You can now use CloudWatch Container Insights with enhanced observability for Amazon EKS collect metrics from Windows worker nodes on Amazon EKS clusters.	April 10, 2024
CloudWatchApplicationSignalsServiceRolePolicy IAM policy updated	CloudWatch changed the scope of a permission in **CloudWatchApplicationSignalsServiceRolePolicy**. The scope of the `cloudwatch:GetMetricData` permission was changed to * so that Application Signals can retrieve metrics from sources in linked accounts.	April 8, 2024

Amazon CloudWatch Internet Monitor now supports cross-account observability	You can now use Internet Monitor cross-account observability to monitor your applications that span multiple Amazon Web Services accounts within a single Amazon Web Services Region.	March 29, 2024
New service linked role and IAM policy for CloudWatch Network Monitor	CloudWatch added a new service-linked role, called **AWSServiceRoleForNetworkMonitor**. CloudWatch added this new service-linked role to allow you to create monitors to fetch network metrics between source subnets and destination IP addresses. The new **CloudWatchNetworkMonitorServiceRolePolicy** IAM policy is attached to this role, and the policy grants permission to CloudWatch to fetch network metrics on your behalf.	December 22, 2023
CloudWatch releases Amazon CloudWatch Network Monitor	CloudWatch released a new feature, Amazon CloudWatch Network Monitor. This is a new active network monitoring service that identifies if a network issues exists within the Amazon network or your own company network.	December 22, 2023

CloudWatchReadOnlyAccess policy updated	CloudWatch added existing read-only permissions for CloudWatch Synthetics, X-Ray, and CloudWatch RUM and new read-only permissions for CloudWatch Application Signals to**CloudWatchReadOnlyAccess** so that users with this policy can triage and diagnose service health issues as reported by CloudWatch Application Signals. The `cloudwatch:GenerateQuery` permission was added so that users with this policy can generate a CloudWatch Metrics Insights query string from a natural language prompt.	December 5, 2023
CloudWatchFullAccessV2 policy updated	CloudWatch added existing permissions to **CloudWatchFullAccessV2** for CloudWatch Synthetics, X-Ray, and CloudWatch RUM, and added new permissions for CloudWatch Application Signals so that users with this policy can fully manage Application Signals to triage and diagnose issues with service health.	December 5, 2023

New service-linked role and new IAM policy	CloudWatch added a new service-linked role, called **AWSServiceRoleForCloudWatchApplicationSignals**. CloudWatch added this new service-linked role to allow CloudWatch Application Signals to collect CloudWatch Logs data, X-Ray trace data, CloudWatch metrics data, and tagging data from applications that you have enabled for CloudWatch Application Signals. The new **CloudWatchApplicationSignalsServiceRolePolicy** IAM policy is attached to this role, and the policy grants permission to CloudWatch Application Signals to collect monitoring and tagging data from other relevant Amazon services.	November 30, 2023

CloudWatch launches Preview release of Application Signals	CloudWatch Application Signals is in Preview. Use Application Signals to instrument your applications on Amazon so that you can monitor current application health, create service level objectives (SLOs), and track long-term application performance against your business objectives. For more information, see Application Signals.	November 30, 2023
CloudWatch adds support for querying other data sources	You can use CloudWatch to query, visualize, and create alarms for metrics from other data sources For more information, see Querying metrics from other data sources.	November 26, 2023
CloudWatch Metrics Insights supports natural language query generation	CloudWatch Metrics Insights supports natural language query to generate and update queries. For more information, see Use natural language to generate and update CloudWatch Metric Insights queries.	November 26, 2023

CloudWatch releases Container Insights with enhanced observability for Amazon EKS	CloudWatch released a new version of Container Insights. This version supports enhanced observability for Amazon EKS clusters and can collect more detailed metrics from clusters running Amazon EKS. After installat ion, it automatically collects detailed infrastructure telemetry and container logs for your Amazon EKS clusters. You can then use curated, immediately usable dashboards to drill down into application and infrastructure telemetry.	November 6, 2023
CloudWatch metric streams adds quick partner setup	CloudWatch metric streams now provides a quick partner setup option, which you can use to quickly set up a metric stream to some third-party providers.	October 17, 2023
CloudWatch releases alarm recommendations	CloudWatch Synthetics now provides alarm recommend ations for metrics from other Amazon services. These recommendations can help you identify the metrics that you should set alarms for to follow best practices for monitoring these services.	October 16, 2023

CloudWatch Synthetics releases runtime syn-nodejs-puppeteer-6.0	CloudWatch Synthetics released runtime `syn-nodejs-puppeteer-6.0` .	September 26, 2023
Adds Amazon CloudWatch Application Insights support for cross-account applications	You can now share CloudWatch Application Insights applications across account boundaries.	September 26, 2023
New service-linked role and new IAM policy	CloudWatch added a new service-linked role, called **AWSServiceRoleForCloudWatchMetrics_DbPerfInsights**. CloudWatch added this new service-linked role to allow CloudWatch to fetch Performance Insights metrics for alarming, anomaly detection, and snapshotting. The new **AWSServiceRoleForCloudWatchMetrics_DbPerfInsightsServiceRolePolicy** IAM policy is attached to this role, and the policy grants permission to CloudWatch to fetch Performance Insights metrics on your behalf.	September 20, 2023

Adds new metric math function	CloudWatch added a new metric math function, `DB_PERF_INSIGHTS` , that you can use to fetch Performance Insights metrics from Amazon database services for alarming, anomaly detection, and snapshotting.	September 20, 2023
CloudWatchReadOnlyAccess policy updated	CloudWatch added the `application-autoscaling:DescribeScalingPolicies` permission to **CloudWatchReadOnlyAccess** so that users with this policy can access information about Application Auto Scaling policies.	September 14, 2023
CloudWatch agent added support for AL2023	The CloudWatch agent supports AL2023.	August 8, 2023
New managed IAM policy, CloudWatchFullAccessV2	CloudWatch added a new policy **CloudWatchFullAccessV2**. This policy grants full access to CloudWatch actions and resources while better scoping the permissions granted to other services such as Amazon SNS and Amazon EC2 Auto Scaling.	August 1, 2023

Updated service linked role for Amazon CloudWatch Internet Monitor – update to an existing policy	Adds new permissions, `elasticloadbalancing:DescribeLoadBalancers` and `ec2:DescribeNetworkInterfaces`, to the service linked role for Internet Monitor, to support monitoring traffic for specific Network Load Balancer resources.	July 25, 2023
Added support for Network Load Balancer resources in Amazon CloudWatch Internet Monitor	Adds support for creating a monitor in Internet Monitor with specific Network Load Balancer resources, to provide more granular levels of observability for your application.	July 25, 2023
Dashboard variables feature	CloudWatch released *dashboard variables*, which you can use to create flexible dashboards that can quickly display different contents depending on how you set one input field within the dashboard. For example, you can create a dashboard that can quickly switch between different Lambda functions or Amazon EC2 instance IDs, or one that can switch to different Amazon Regions. For more information, see Create flexible dashboards with dashboard variables.	June 28, 2023

Internet Monitor now supports customizing the threshold for health events	Internet Monitor added the ability to customize the threshold for when a global performance score or availability score triggers a heath event. For more information, see Tracking real-time performance and availability in Amazon CloudWatch Internet Monitor.	June 26, 2023
Internet Monitor now supports all commercial Regions	Internet Monitor added seven new Amazon Web Services Regions and now supports all commercial Regions.	June 19, 2023
New Lambda Insights extension versions	CloudWatch added the 1.0.229.0 version of the Lambda Insights extension for both x86-64 platforms and ARM64 platforms. For more information, see Available versions of the Lambda Insights extension.	June 12, 2023
CloudWatchReadOnlyAccess policy updated	CloudWatch added permissions to **CloudWatchReadOnlyAccess**. The `logs:StartLiveTail` and `logs:StopLiveTail` permissions were added so that users with this policy can use the console to start and stop CloudWatch Logs live tail sessions. For more information, see Use live tail to view logs in near real time.	June 6, 2023

CloudWatch RUM adds support for custom metrics	You can use CloudWatch RUM app monitors to create custom metrics and send them to CloudWatch and CloudWatch Evidently. This feature includes an update to the **AmazonCloudWatchRUMServiceRolePolicy** managed IAM policy. In that policy, a condition key was changed so that CloudWatch RUM can send custom metrics to custom metric namespaces.	February 9, 2023
New and updated managed polices for CloudWatch	To support CloudWatch cross-account observability, the `CloudWatchFullAccess` and `CloudWatchReadOnlyAccess` policies have been updated, and the following new managed policies have been added: `CloudWatchCrossAccountSharingConfiguration` , `OAMFullAccess` , and `OAMReadOnlyAccess` . For more information, see CloudWatch updates to Amazon managed policies.	February 7, 2023
CloudWatch Application Insights service-linked role policy updates — update to an existing policy.	CloudWatch Application Insights updated an existing Amazon service-linked role policy.	December 19, 2022

Amazon CloudWatch Application Insights support for containerized applications and microservices from the Container Insights console.	You can display CloudWatch Application Insights detected problems for Amazon ECS and Amazon EKS on your Container Insights dashboard.	November 17, 2021
Amazon CloudWatch Application Insights monitoring for SAP HANA databases.	You can monitor SAP HANA databases with Application Insights.	November 15, 2021
Amazon CloudWatch Application Insights support for monitoring all resources in an account.	You can onboard and monitor all resources in an account.	September 15, 2021
Amazon CloudWatch Application Insights support for Amazon FSx.	You can monitor metrics retrieved from Amazon FSx.	August 31, 2021
SDK Metrics is no longer supported.	CloudWatch SDK Metrics is no longer supported.	August 25, 2021
Amazon CloudWatch Application Insights support for setting up container monitoring.	You can monitor containers using best practices with Amazon CloudWatch Application Insights.	May 18, 2021
Metric streams is generally available	You can use metric streams to continually stream CloudWatch metrics to a destination of your choice. For more information, see Metric streams in the *Amazon CloudWatch User Guide*.	March 31, 2021

Amazon CloudWatch Application Insights monitoring for Oracle databases on Amazon RDS and Amazon EC2.	You can monitor metrics and logs retrieved from Oracle with Amazon CloudWatch Application Insights.	January 16, 2021
Lambda Insights is generally available	CloudWatch Lambda Insights is a monitoring and troubleshooting solution for serverless applications running on Amazon Lambda. For more information, see Using Lambda Insights in the *Amazon CloudWatch User Guide*.	December 3, 2020
Amazon CloudWatch Application Insights monitoring for Prometheus JMX exporter metrics.	You can monitor metrics retrieved from Prometheus JMX exporter with Amazon CloudWatch Application Insights.	November 20, 2020
CloudWatch Synthetics releases new runtime version	CloudWatch Synthetics has released a new runtime version. For more information, see Canary Runtime Versions in the *Amazon CloudWatch User Guide*.	September 11, 2020
Amazon CloudWatch Application Insights monitoring for Postgre SQL on Amazon RDS and Amazon EC2.	You can monitor applications built with PostgreSQL running on Amazon RDS or Amazon EC2.	September 11, 2020

CloudWatch supports dashboard sharing	You can now share CloudWatch dashboards with people outside of your organization and Amazon account. For more information, see Sharing CloudWatch Dashboards in the *Amazon CloudWatch User Guide*.	September 10, 2020
Set up monitors for .NET applications using SQL Server on the backend with CloudWatch Application Insights	You can use the documentation tutorial to help you to set up monitors for .NET applications using SQL Server on the backend with CloudWatch Application Insights.	August 19, 2020
Amazon CloudFormation support for Amazon CloudWatch Application Insights applications.	You can add CloudWatch Application Insights monitoring, including key metrics and telemetry, to your application, database, and web server, directly from Amazon CloudFormation templates.	July 30, 2020
Amazon CloudWatch Application Insights monitoring for Aurora for MySQL database clusters.	You can monitor Aurora for MySQL database clusters (RDS Aurora) with Amazon CloudWatch Application Insights.	July 2, 2020

CloudWatch Contributor Insights general availability	CloudWatch Contributor Insights is now generally available. It enables you to analyze log data and create time series that display contributor data. You can see metrics about the top-N contributors, the total number of unique contributors, and their usage. For more information, see Using Contributor Insights to Analyze High-Cardinality Data in the *Amazon CloudWatch User Guide*.	April 2, 2020
CloudWatch Synthetics public preview	CloudWatch Synthetics is now in public preview. It enables you to create canaries to monitor your endpoints and APIs. For more information, see Using Canaries in the *Amazon CloudWatch User Guide*.	November 25, 2019

CloudWatch Contributor Insights public preview	CloudWatch Contributor Insights is now in public preview. It enables you to analyze log data and create time series that display contributor data. You can see metrics about the top-N contributors, the total number of unique contributors, and their usage. For more information, see Using Contributor Insights to Analyze High-Cardinality Data in the *Amazon CloudWatch User Guide*.	November 25, 2019
CloudWatch launches ServiceLens feature	ServiceLens ehances the observability of your services and applications by enabling you to integrate traces, metrics, logs, and alarms into one place. ServiceLens integrates CloudWatch with Amazon X-Ray to provide an end-to-end view of your application.	November 21, 2019

Use CloudWatch to proactively manage your Amazon service quotas	You can use CloudWatch to proactively manage your Amazon service quotas. CloudWatch usage metrics provide visibility into your account's usage of resources and API operations. For more information, see Service Quotas Integration and Usage Metrics in the *Amazon CloudWatch User Guide*.	November 19, 2019
CloudWatch sends events when alarms change state	CloudWatch now sends an event to Amazon EventBridge when any CloudWatch alarm changes state. For more information, see Alarm Events and EventBridge in the *Amazon CloudWatch User Guide*.	October 8, 2019
Container Insights	CloudWatch Container Insights is now generally available. It enables you to collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. For more information, see Using Container Insights in the *Amazon CloudWatch User Guide*.	August 30, 2019

Updates for Container Insights preview metrics on Amazon EKS and Kubernetes	The Container Insights on Amazon EKS and Kubernetes public preview has been updated. InstanceId is now included as a dimension to the cluster EC2 instances . This allows alarms that have been created on these metrics to trigger the following EC2 actions: Stop, Terminate, Reboot, or Recover. Additionally, pod and service metrics are now reported by Kubernetes namespace to simplify the monitoring and alarming on metrics by namespace.	August 19, 2019
Updates for Amazon Systems Manager OpsCenter integration	Updates on how CloudWatch Application Insights integrates with Systems Manager OpsCenter.	August 7, 2019
CloudWatch usage metrics	CloudWatch usage metrics help you track the usage of your CloudWatch resources and stay within your service limits. For more information, see https://docs.amazonaws.cn/AmazonCloudWatch/latest/monitoring/CloudWatch-Usage-Metrics.html.	August 6, 2019

CloudWatch Container Insights public preview	CloudWatch Container Insights is now in public preview. It enables you to collect, aggregate, and summarize metrics and logs from your containerized applications and microserv ices. For more information, see Using Container Insights in the *Amazon CloudWatch User Guide*.	July 9, 2019
CloudWatch Anomaly Detection public preview	CloudWatch anomaly detection is now in public preview. CloudWatch applies machine-learning algorithm s to a metric's past data to create a model of the metric's expected values. You can use this model for visualiza tion and for setting alarms. For more information, see Using CloudWatch Anomaly Detection in the *Amazon CloudWatch User Guide*.	July 9, 2019
CloudWatch Application Insights for .NET and SQL Server	CloudWatch Application Insights for .NET and SQL Server facilitates observabi lity for .NET and SQL Server applications. It can help you set up the best monitors for your application resources to continuously analyze data for signs of problems with your applications.	June 21, 2019

CloudWatch agent section re-organized	The CloudWatch agent documentation has been rewritten to improve clarity, especially for customers using the command line to install and configure the agent. For more information, see Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the *Amazon CloudWatch User Guide*.	March 28, 2019
SEARCH function added to metric math expressions	You can now use a SEARCH function in metric math expressions. This enables you to create dashboards that update automatically as new resources are created that match the search query. For more information, see Using Search Expressions in Graphs in the *Amazon CloudWatch User Guide*.	March 21, 2019
Amazon SDK Metrics for Enterprise Support	SDK Metrics helps you assess the health of your Amazon services and diagnose latency caused by reaching your account usage limits or by a service outage. For more information, see Monitor Applications Using Amazon SDK Metrics in the *Amazon CloudWatch User Guide*.	December 11, 2018

Alarms on math expressions	CloudWatch supports creating alarms based on metric math expressions. For more information, see Alarms on Math Expressions in the *Amazon CloudWatch User Guide*.	November 20, 2018
New CloudWatch console home page	Amazon has created a new home page in the CloudWatch console, which automatically displays key metrics and alarms for all the Amazon services you are using. For more information, see Getting Started with Amazon CloudWatch in the *Amazon CloudWatch User Guide*.	November 19, 2018
Amazon CloudFormation templates for the CloudWatch Agent	Amazon has uploaded Amazon CloudFormation templates that you can use to install and update the CloudWatch agent. For more information, see Install the CloudWatch Agent on New Instances Using Amazon CloudFormation in the *Amazon CloudWatch User Guide*.	November 9, 2018

Enhancements to the CloudWatch Agent	The CloudWatch agent has been updated to work with both the StatsD and collectd protocols. It also has improved cross-account support. For more informati on, see Retrieve Custom Metrics with StatsD, Retrieve Custom Metrics with collectd, and Sending Metrics and Logs to a Different Amazon Account in the *Amazon CloudWatch User Guide*.	September 28, 2018
Support for Amazon VPC endpoints	You can now establish a private connection between your VPC and CloudWatc h. For more information, see Using CloudWatch with Interface VPC Endpoints in the *Amazon CloudWatch User Guide*.	June 28, 2018

The following table describes important changes to the *Amazon CloudWatch User Guide* before June 2018.

Change	Description	Release date
Metric math	You can now perform math expressions on CloudWatch metrics, producing new time series that you can add to graphs on your dashboard. For more information, see Using math expressions with CloudWatch metrics.	April 4, 2018
"M out of N" alarms	You can now configure an alarm to trigger based on "M out of N" datapoints in any alarm evaluatio	December 8, 2017

Change	Description	Release date
	n interval. For more information, see Evaluating an alarm.	
CloudWatch agent	A new unified CloudWatch agent was released. You can use the unified multi-platform agent to collect custom both system metrics and log files from Amazon EC2 instances and on-premises servers. The new agent supports both Windows and Linux and enables customization of metrics collected, including sub-resource metrics such as per-CPU core. For more information, see Collect metrics, logs, and traces with the CloudWatch agent.	September 7, 2017
NAT gateway metrics	Added metrics for Amazon VPC NAT gateway.	September 7, 2017
High-resolution metrics	You can now optionally set up custom metrics as high-resolution metrics, with a granularity of as low as one second. For more information, see High-resolution metrics.	July 26, 2017
Dashboard APIs	You can now create, modify, and delete dashboards using APIs and the Amazon CLI. For more information, see Creating a customized CloudWatch dashboard.	July 6, 2017
Amazon Direct Connect metrics	Added metrics for Amazon Direct Connect.	June 29, 2017
Amazon VPC VPN metrics	Added metrics for Amazon VPC VPN.	May 15, 2017
AppStream 2.0 metrics	Added metrics for AppStream 2.0.	March 8, 2017

Change	Description	Release date
CloudWatch console color picker	You can now choose the color for each metric on your dashboard widgets. For more information, see Editing a graph on a CloudWatch dashboard .	February 27, 2017
Alarms on dashboards	Alarms can now be added to dashboards. For more information, see Adding an alarm to a CloudWatch dashboard.	February 15, 2017
Added metrics for Amazon Polly	Added metrics for Amazon Polly.	December 1, 2016
Added metrics for Amazon Managed Service for Apache Flink	Added metrics for Amazon Managed Service for Apache Flink.	December 1, 2016
Added support for percentile statistics	You can specify any percentile, using up to two decimal places (for example, p95.45). For more information, see Percentiles.	November 17, 2016
Added metrics for Amazon Simple Email Service	Added metrics for Amazon Simple Email Service.	November 2, 2016
Updated metrics retention	Amazon CloudWatch now retains metrics data for 15 months instead of 14 days.	November 1, 2016
Updated metrics console interface	The CloudWatch console is updated with improvements to existing functionality and new functionality.	November 1, 2016
Added metrics for Amazon Elastic Transcoder	Added metrics for Amazon Elastic Transcoder.	September 20, 2016

Change	Description	Release date
Added metrics for Amazon API Gateway	Added metrics for Amazon API Gateway.	September 9, 2016
Added metrics for Amazon Key Management Service	Added metrics for Amazon Key Management Service.	September 9, 2016
Added metrics for the new Application Load Balancers supported by Elastic Load Balancing	Added metrics for Application Load Balancers.	August 11, 2016
Added new NetworkPa cketsIn and NetworkPa cketsOut metrics for Amazon EC2	Added new NetworkPacketsIn and NetworkPa cketsOut metrics for Amazon EC2.	March 23, 2016
Added new metrics for Amazon EC2 Spot fleet	Added new metrics for Amazon EC2 Spot fleet.	March 21, 2016
Added new CloudWatch Logs metrics	Added new CloudWatch Logs metrics.	March 10, 2016

Change	Description	Release date
Added Amazon OpenSearch Service and Amazon WAF metrics and dimensions	Added Amazon OpenSearch Service and Amazon WAF metrics and dimensions.	October 14, 2015
Added support for CloudWatch dashboards	Dashboards are customizable home pages in the CloudWatch console that you can use to monitor your resources in a single view, even those that are spread out across different Regions. For more information, see Using Amazon CloudWatch dashboards.	October 8, 2015
Added Amazon Lambda metrics and dimensions	Added Amazon Lambda metrics and dimensions.	September 4, 2015
Added Amazon Elastic Container Service metrics and dimensions	Added Amazon Elastic Container Service metrics and dimensions.	August 17, 2015
Added Amazon Simple Storage Service metrics and dimensions	Added Amazon Simple Storage Service metrics and dimensions.	July 26, 2015
New feature: Reboot alarm action	Added the reboot alarm action and new IAM role for use with alarm actions. For more information, see Create alarms to stop, terminate, reboot, or recover an EC2 instance.	July 23, 2015

Change	Description	Release date
Added Amazon WorkSpaces metrics and dimensions	Added Amazon WorkSpaces metrics and dimensions.	April 30, 2015
Added Amazon Machine Learning metrics and dimensions	Added Amazon Machine Learning metrics and dimensions.	April 9, 2015

Change	Description	Release date
Updated guide to use the new Amazon Command Line Interface (Amazon CLI)	The Amazon CLI is a cross-service CLI with a simplified installation, unified configuration, and consistent command line syntax. The Amazon CLI is supported on Linux/Unix, Windows, and Mac. The CLI examples in this guide have been updated to use the new Amazon CLI. For information about how to install and configure the new Amazon CLI, see Getting Set Up with the Amazon CLI Interface in the *Amazon Command Line Interface User Guide*.	February 21, 2014
Added Amazon Redshift and Amazon OpsWorks metrics and dimensions	Added Amazon Redshift and Amazon OpsWorks metrics and dimensions.	July 16, 2013
Added Amazon Route 53 metrics and dimensions	Added Amazon Route 53 metrics and dimensions.	June 26, 2013
New feature: Amazon CloudWatch Alarm Actions	Added a new section to document Amazon CloudWatch alarm actions, which you can use to stop or terminate an Amazon Elastic Compute Cloud instance. For more information, see Create alarms to stop, terminate, reboot, or recover an EC2 instance.	January 8, 2013
Updated EBS metrics	Updated the EBS metrics to include two new metrics for Provisioned IOPS volumes.	November 20, 2012

Change	Description	Release date
New billing alerts	You can now monitor your Amazon charges using Amazon CloudWatch metrics and create alarms to notify you when you have exceeded the specified threshold. For more information, see Create a billing alarm to monitor your estimated Amazon charges.	May 10, 2012
New metrics	You can now access six new Elastic Load Balancing metrics that provide counts of various HTTP response codes.	October 19, 2011
New feature	You can now access metrics from Amazon EMR.	June 30, 2011
New feature	You can now access metrics from Amazon Simple Notification Service and Amazon Simple Queue Service.	July 14, 2011
New Feature	Added information about using the `PutMetricData` API to publish custom metrics. For more information, see Publish custom metrics.	May 10, 2011
Updated metrics retention	Amazon CloudWatch now retains the history of an alarm for two weeks rather than six weeks. With this change, the retention period for alarms matches the retention period for metrics data.	April 7, 2011
New feature	Added ability to send Amazon Simple Notificat ion Service or Auto Scaling notifications when a metric has crossed a threshold. For more information, see Alarms.	December 2, 2010
New feature	A number of CloudWatch actions now include the MaxRecords and NextToken parameters, which enable you to control pages of results to display.	December 2, 2010

Change	Description	Release date
New feature	This service now integrates with Amazon Identity and Access Management (IAM).	December 2, 2010
